There is, however, an easy method of distinguishing doublets, which is only to behold them betwixt the eye and light, in such a position, that the light may pass through the upper part and corners of the stone; when it will easily be perceived that there is no colour in the body of the stone.

DOUBLETS, a game on dice within tables; the men, which are only 15, being placed thus: Upon the sice, cinque, and quatre points, there stand three men a-piece; and upon the trey, duce, and ace, only two. He that throws highest hath the benefit of throwing first, and what he throws he lays down, and so doth the other; what the one throws, and hath not, the other lays down for him, but on his own account; and thus they do till all the men are down, and then they bear. He that is down first, bears first; and will doubtless win the game, if the other throws not doublets to overtake him: which he is sure to do, since he advances or bears as many as the doublets make, viz. eight for two fours.

DOUBLING, in the military art, is the putting two ranks or files of soldiers into one. Thus, when the word of command is *double your ranks*, the second, fourth, and six ranks march into the first, third, and fifth, so that the six ranks are reduced to three, and the intervals between the ranks become double what they were before.

Doubling, among hunters, who say that a hare doubles, when she keeps in plain fields, and winds about to deceive the hounds.

Doubling, in the manege, a term applied to a horse, who is said to double his reins, when he leaps several times together, to throw his rider; thus it is said, *the ramingue doubles his reins, and makes pontlevis.*

Doubling, in *Navigation*, the art of sailing round, or passing beyond, a cape or promontory, so as that the cape or point of land separates the ship from her former situation, or lies between her and any distant observer.

Doubling Upon, in *Naval Tactics*, the act of enclosing any part of a hostile fleet between two fires, or of cannonading it on both sides.

It is usually performed by the van or rear of that fleet which is superior in number, taking the advantage of the wind, or of its situation, and taking or veering round the van or rear of the enemy, who can scarcely avoid being thrown into general confusion.

DOUBLON, or **Dubloon**, a Spanish and Portuguese coin, being the double of a Pistole.

DOUBS, the name of a river of France, which has its source in the mountains of Jura, and falls into the Saone; and also the name of a department which is nearly surrounded by that river.

DOUBTING, the act of withholding our assent from any proposition, on suspicion that we are not thoroughly apprised of the merits thereof, or from not being able peremptorily to decide between the reasons for and against it. Doubting is distinguished by the schoolmen into two kinds, *dubitatio sterilis*, and *dubitatio efficax*. The former is that where no determination ensues: in this manner the Sceptics and Academics doubt, who withhold their assent from every thing. See Sceptics, &c. The latter is followed by judgment, which distinguishes truth from falsehood: such is the doubting of the Peripatetics and Cartesians. The last in particular perpetually inculcate the deceitfulness of our senses, and tell us that we are to doubt of every one of their reports, till they have been examined and confirmed by reason. On the other hand, the Epicureans teach, that our senses always tell truth; and that, if you go ever so little from them, you come within the province of doubting. See Cartesians, Epicureans, &c.

Doubting, in *Rhetoric*, a figure wherein the orator appears some time fluctuating, and undetermined what to do or say. Tacitus furnishes us with an instance of doubting, almost to a degree of distraction, in those words of Tiberius written to the senate: *Quid scribam*, P. S. *aut quomodo scribam, aut quid omnino non scribam hoc tempore, dii me deæque pejus perdant quam perire quotidie sentio, si scio.*

DOUCETS, or **Doulcets**, among sportsmen, denote the testes of a deer or stag.

DOUCINE, in *Architecture*, a moulding concave above and convex below, serving commonly as a cymatium to a delicate corniche. It is likewise called Gula.

DOVE. See Columba, Ornithology *Index*.

Dove-Tailing, in carpentry, is the manner of fastening boards together by letting one piece into another in the form of the tail of a dove. The dove-tail is the strongest of the assemblages or joinings; because the tenon, or piece of wood which is put into the other, goes widening to the extreme, so that it cannot be drawn out again, by reason the extreme or tip is bigger than the hole.

DOVER, a borough and port town of England, in the county of Kent, situated in E. Long. 0. 25. N. Lat. 51. 10. It sends two members to parliament, styled *barons of the Cinque ports*, whereof Dover is the chief. The number of voters is about 1600. It contained 14,845 inhabitants in 1801, and 19,128 in 1811.

By the Romans this town was named *Dubris*, and by the Saxons *Dofra*, probably from the British word *Dour*, which signifies water. The convenience of its situation drew the attention of the Roman governors, who ruled here while they possessed this part of the island; and there still remain indubitable testimonies of their care and respect for this important place. For the defence of the town, the Romans, or, according to some, Arviragus, a British king, their confederate, by cutting out walls with infinite labour in the solid rock, constructed a stony fortress; and, as its venerable remains still prove, erected also a light-house, for the benefit of navigation. The Saxons, Danes, and Normans, had a very high opinion of this place; and when the barons invited over the young prince, afterwards Louis VIII. of France, his father Philip Augustus conceived a bad opinion of the expedition, because the castle and port of Dover were held for King John, though a great part of the kingdom had submitted to Louis. In its most flourishing state, the fortress was impregnable, and the town a very opulent emporium. It had 21 wards, each of which furnished a ship for the public service, 10 gates, 7 parish-churches, many religious houses, hospitals, and other public edifices. The decay of the town was brought on by that of the harbour. To recover this, Henry VIII. spent no less than 63,000l. in constructing piers; and 5000l. in building a castle between this and Folkstone, called *Sandgate*, where the shore was flat, and the landing easy. Notwithstanding all this expence, however, it was again choked up in the reign of Queen Elizabeth, by whom it was again cleared at a vast expence, so that ships of some hundred tons could enter it. After that time it again declined, notwithstanding of many efforts for its relief, and great assistance from time to time given by parliament for this purpose. At present the harbour is capable of receiving vessels of 400 or 500 tons; and as the packets to France and Flanders are stationed here in time of peace, it is still a place of some consequence, and the people are active and industrious.

Dover Straits, the narrow channel between Dover and Calais, which separates our island from the opposite continent. Britain is supposed by many to have been once peninsulated, the present straits occupying the site of the isthmus which joined it to Gaul. "No certain cause (says Mr Pennant*) can be given for the mighty convulsion which tore us from this continent; whether it was rent by an earthquake, or whether it was worn through by the continual dashing of the waters, no Pythagoras is left to solve the *fortuna locorum :*

Vidi ego, quod fuerat quondam solidissima tellus
Esse fretum.

But it is most probable, that the great philosopher alluded to the partial destruction of the *Atlantica insula*, mentioned by Plato as a distant tradition in his days. It was effected by an earthquake and a deluge, which might have rent asunder the narrow isthmus in question, and left Britain, large as it seems at present, the mere wreck of its original size. The Scilly isles, the Hebrides, Orkneys, Shetlands, and perhaps the Feroe islands, may possibly be no more than fragments of the once far-extended region. I have no quarrel about the word *island*. The little isthmus, compared to the whole, might have been a junction never attended to in the limited navigations of very early times. The peninsula had never been wholly explored, and it passed with the ancients for a genuine island. The correspondency of strata on part of the opposite shores of Britain and France, leaves no room to doubt but that they were once united. The chalky cliffs of Blancnez between Calais and Boulogne, and those to the westward of Dover, exactly tally: the last are vast and continued; the former short, and the termination of the immense bed. Between Boulogne and Folkstone (about six miles from the latter) is another memorial of the junction of the two countries; a narrow submarine hill, called the *Rip-raps*, about a quarter of a mile broad, and ten miles long, extending eastwards towards the Goodwin sands. Its materials are boulderstones, adventitious to many strata. The depth of water on it, in very low ebbs during spring tides, is only fourteen feet. The fishermen from Folkstone have often touched it with a fifteen feet oar; so that it is justly the dread of navigators. Many a tall ship has perished on it, and sunk instantly into twenty-one fathoms water. In July 1782, the Belleisle of sixty-four guns struck, and lay on it during three hours; but, by starting her beer and water, got clear off.

"These celebrated straits are only twenty-one miles wide in the narrowest part. From the pier at Dover to that at Calais is twenty-four. It is conjectured, that their breadth lessens, and that they are two miles narrower than they were in ancient times. An accurate observer of fifty years remarks to me, that the increased height of water, from a decrease of breadth, has been apparent even in that space. The depth of the channel at a medium in highest spring tides is about twenty-five fathoms. The bottom either coarse sand or rugged scars, which have for ages unknown resisted the attrition of the currents. From the straits both eastward and westward is a gradual increase of depth through the channel to a hundred fathoms, till soundings are totally lost or unattended to. The spring tides in the straits rise on an average twenty-four feet, the neap tides fifteen. The tide flows from the German sea, passes the straits, and meets, with a great rippling, the western tide from the ocean between Fairleigh near Hastings and Boulogne; a proof that, if the separation of the land was effected by the seas, it must have been by the overpowering weight of those of the north."

DOVER, a town of Delaware in North America. It is the chief town of the county of Kent in the Delaware state, and is the seat of government. It stands on Jones's creek, a few miles from the Delaware river, and consists of about 100 houses, principally of brick. Four streets intersect each other at right angles, in the centre

---

* *Arctic Zoology*, vol. I. Introd. p. ii.

over,
uglas.

centre of the town, whose incidencies form a spacious parade, on the east side of which is an elegant state-house of brick. The town has a lively appearance, and drives on a considerable trade with Philadelphia. Wheat is the principal article of export. The landing is five or six miles from the town of Dover.

DOUGLAS, Lord. See (*History of*) SCOTLAND.

Douglas, *Gavin*, bishop of Dunkeld in Scotland, was the third son of Archibald earl of Angus, and born in the year 1474. Where he was educated, is not known; but it is certain that he studied theology: a study, however, which did not estrange him from the muses; for he employed himself at intervals in translating into beautiful verse the poem of Ovid *de Remedio Amoris.* The advantages of foreign travel, and the conversation of the most learned men in France and Germany, to whom his merit produced the readiest access, completed his education. With his superior recommendations and worth, it was impossible he could remain unnoticed. His first preferment was to be provost of the collegiate church of St Giles in Edinburgh; a place at that time of great dignity and revenue. In the year 1514, the queen mother, then regent of Scotland, appointed Douglas abbot of Aberbrothock, and soon after archbishop of St Andrew's; but the queen's power not being sufficient to establish him in the possession of that dignity, he relinquished his claim in favour of his competitor Foreman, who was supported by the pope. In 1515, he was by the queen appointed bishop of Dunkeld; and that appointment was soon after confirmed by his holiness Leo X. Nevertheless it was some time before he could obtain peaceable possession of his see. The duke of Albany, who in this year was declared regent, opposed him because he was supported by the queen; and, in order to deprive him of his bishopric, accused him of acting contrary to law in receiving bulls from Rome. On this accusation he was committed to the castle of Edinburgh, where he continued in confinement above a year; but the regent and the queen being at last reconciled, he obtained his liberty, and was consecrated bishop of Dunkeld. In 1517, he attended the duke of Albany to France; but returned soon after to Scotland. In 1521, the disputes between the earls of Arran and Angus having thrown the kingdom into violent commotion, our prelate retired to England, where he became intimately acquainted with Polydore Virgil the historian. He died in London of the plague in 1522; and was buried in the Savoy. He wrote, 1. The Palace of Honour: a most ingenious poem under the similitude of a vision; in which he paints the vanity and inconstancy of all worldly glory. It abounds with incidents, and a very rich vein of poetry. The palace of happiness, in the picture of Cebes, seems to be the groundwork of it. 2. *Aureæ Narrationes:* a performance now lost; in which, it is said, he explained, in a most agreeable manner, the mythology of the poetical fictions of the ancients. 3. *Comœdiæ aliquot sacræ:* None of which are now to be found. 4. Thirteen Bukes of Eneades, of the famose poet Virgil, translatet out of Latin verses into Scottish metre, every buke having its particular prologe. Imprinted at London 1553, in 4to; and reprinted at Edinburgh 1710, in folio. The last is the most esteemed of all his works. He undertook it at the desire of Lord Henry Sinclair, a munificent patron of arts in those times: and he completed it in 18 months; a circumstance which his admirers are too fond of repeating to his advantage. David Hume of Godscroft, an author of uncommon merit, and an admirable judge of poetry, gives the following testimony in his favour. "He wrote (says he) in his native tongue divers things; but his chiefest work is his translation of Virgil, yet extant, in verse: in which he ties himself so strictly as is possible; and yet it is so well expressed, that whosoever will essay to do the like will find it a hard piece of work to go through with it. In his prologues before every book, where he hath his liberty, he showeth a natural and ample vein of poetry, so pure, pleasant, and judicious, that I believe there is none that hath written before or since but cometh short of him." It has been said, that he compiled an historical treatise *De Rebus Scoticis;* but no remain of it hath descended to the present times.

Douglas,
Douw.

Douglas, the principal town of the isle of Man, and which has lately increased both in trade and buildings. The harbour, for ships of a tolerable burden, is the safest in the island, and is much improved by a fine mole that has been built. Population 2631. W. Long. 3. 25. N. Lat. 54. 7.

DOUW, Gerhard, a celebrated painter, was born at Leyden in 1613; and received his first instructions in drawing and design from Bartholomew Dolendo an engraver, and also from Peter Kouwhoorn a painter on glass; but at the age of fifteen he became a disciple of Rembrandt. In that famous school he continued for three years; and then found himself qualified to study nature, the most unerring director.

From Rembrandt he learned the true principles of colouring, and obtained a complete knowledge of the chiaro-scuro: but to that knowledge he added a delicacy of pencil, and a patience in working up his colours to the highest degree of neatness, superior to any other master. He therefore was more pleased with those pictures of Rembrandt which were painted in his youth than those by which he was distinguished in his more advanced age; because the first seemed finished with more care and attention, the latter with more boldness, freedom, and negligence, which was quite opposite to the taste of Douw. But although his manner appears so different from that of his master, yet it was to Rembrandt alone that he owed all that excellence in colouring by which he triumphed over all the artists of his own country.

His pictures are usually of a small size, with figures so exquisitely touched, so transparent, so wonderfully delicate, as to excite astonishment as well as pleasure. He designed every object after nature, and with an exactness so singular, that each object appears as perfect as nature itself, in respect to colour, freshness and force. His general manner of painting portraits, was by the aid of a concave mirror, and sometimes by looking at the object through a frame with many exact squares of fine silk. But the latter custom is disused, as the eye of a good artist seems a more competent rule, though the use of the former is still practised by painters in miniature.

It is almost incredible what vast sums have been given and are given at this day for the pictures of Douw, even in his own country; as also in Italy and every polite part of Europe: for he was exceedingly curious in finishing them, and patiently assiduous beyond example. Of that patience Sandrart gives a strong proof in a circumstance which he mentions relative to this artist. He says, that having once, in company with Bamboccio, visited Gerhard Douw, they could not forbear to admire the prodigious neatness of a picture which he was then painting, in which they took particular notice of a broom; and expressing their surprise at the excessive neatness of the finishing that minute object, Douw told them he should spend three days more in working on that broom before he should account it entirely complete. In a family picture of Mrs Spiering, the same author observes, that the lady sat five days for the finishing one of her hands that leaned on an arm chair. For that reason not many would sit to him for their portraits; and he therefore indulged himself mostly in works of fancy, in which he could introduce objects of still life, and employ as much time on them as suited his own inclination. Houbraken testifies, that his great patron Mr Spiering allowed him a thousand guilders a-year, and paid beside whatever he demanded for his pictures, and purchased some of them for their weight in silver; but Sandrart, with more probability, assures us, that the thousand guilders a-year were paid to Gerhard, on no other consideration than that the artist should give his benefactor the option of every picture he painted, for which he was immediately to receive the utmost of his demand. This great master died in 1674, aged 61.

Douw appears incontestably to be the most wonderful in his finishing of all the Flemish masters. Every thing that came from his pencil is precious, and his colouring hath exactly the true and the lovely tints of nature; nor do his colours appear tortured, nor is their vigour lessened by his patient pencil; for whatever pains he may have taken, there is no look of labour or stiffness; and his pictures are remarkable, not only for retaining their original lustre, but for having the same beautiful effect at a proper distance as they have when brought to the nearest view.

At Turin are several pictures by Gerhard Douw, wonderfully beautiful; especially one, of a doctor attending a sick woman, and surveying an urinal. The execution of that painting is astonishingly fine, and although the shadows appear a little too dark, the whole has an inexpressible effect. In the gallery at Florence there is a night-piece by candle light, which is exquisitely finished; and in the same apartment, a mountebank attended by a number of figures, which it seems impossible either sufficiently to commend or to describe.

DOULEIA, (Δουλεια), among the Athenians, a kind of punishment by which the criminal was reduced into the condition of a slave. It was never inflicted upon any but the *ατιμοι*, *sojourners* and *freed servants*.

To DOUSE, in sea language, is to lower suddenly, or slacken; and it is applied to a sail in a squall of wind, an extended hawser, &c.

DOWAGER, *Dotisca* (*q. d.* a widow endowed, or that has a jointure), a title, or addition, applied to the widows of princes, dukes, earls, and persons of high rank only.

Queen Dowager, is the widow of the king, and as such enjoys most of the privileges belonging to her as queen consort: but it is not high treason to violate her chastity or conspire her death, because the succession is not endangered thereby; but no man can marry her without special license from the king, on pain of forfeiting his lands and goods. See Queen.

DOWER, (*Dotarium*, *Doarium*, or *Dos*), a portion of lands or tenements which a widow enjoys for term of life from her husband, in case she survives him; and which, at her death, descends to their children. But she must have been the wife of the party at the time of his decease; or not divorced *à vinculo matrimonii*: nor, if she has eloped from her husband, and lives with an adulterer, shall she be entitled to dower, unless her husband be voluntarily reconciled to her. The widows of traitors are also barred of their dower by 5 and 6 Edw. VI. cap. 11. but not the widows of felons. An alien cannot be endowed, unless she be queen consort. And if a woman levies a fine with her husband, or if a common recovery be had with the husband and wife of the husband's lands, she is barred of her dower.—A widow, clear of these impediments, is by law entitled to be endowed of all lands and tenements, of which her husband was seised in fee-simple or fee-tail at any time during the coverture; and of which any issue she might have had might by possibility have been heir. See Jointure.

DOWN, a county of Ireland in the province of Ulster; bounded on the east and south by St George's channel; on the west by the county of Armagh; and on the north by the county of Antrim. It lies opposite to the isle of Man, Cumberland, and Westmoreland; and the north part of it fronts the Mull of Galloway in Scotland, and is about 44 miles from it.—It is about 44 miles in length and 30 in breadth, and contains about 558,000 English acres. The county of Down contains 60 parishes, and in 1813 the population amounted to 204,500 souls.

This county is rough and full of hills; but the air is temperate and healthy. The soil naturally produces wood, unless constantly kept open and ploughed; and the low grounds degenerate into bogs and moss, where the drains are neglected. But by the industry of the inhabitants it produces good crops of corn, particularly oats; and, where marl is found, barley. This last is exported from Killogh to Dublin. The staple commodity of this county is the linen manufacture. See Down, Supplement.

Down, or *Down-Patrick*, a town of Ireland, in the county of Down, is one of the most ancient in that kingdom. It is a market town and a bishopric, said to be erected in the fifth century by St Patrick, but is now united to the see of Connor. Within 200 paces of the town, on the ascent of a hill, are the ruins of an old cathedral, remarkable for the tomb of St Patrick the founder, in which they say the bodies of St Bridget and St Columb are also laid. The town, which is seated on the south corner of Lough Coin, now called the *lake of Strangford*, is adorned with several handsome public buildings. Among the hills, and in many islands, are flights of swans and other water fowl; and the lough abounds with salmon, mullets,

lets, and other sea fish. About a mile from this town is St Patrick's well, which many people frequent to drink at some seasons of the year, and others to perform a penance enjoined them by the Popish priests.—The linen manufacture is carried on here, as it is in several places in this county. The population is about 5000. W. Long. 5. 50. N. Lat. 54. 23.

Down, the fine feathers from the breasts of several birds, particularly of the duck kind.—That of the eider duck is the most valuable. These birds pluck it from their breasts and line their nests with it. We are told that the quantity of down found in one nest more than filled the crown of a hat, yet weighed no more than three quarters of an ounce. Br. Zool.—Three pounds of this down may be compressed into a space scarce bigger than one's fist; yet it is afterwards so dilatable as to fill a quilt five feet square. Salern. Orn. p. 416.—That found in the nests is most valued, and termed *live down*; it is infinitely more elastic than that plucked from the dead bird, which is little esteemed in Iceland. The best sort is sold at 45 fish per pound when cleansed, and at 16 when not cleansed. There are generally exported every year, on the company's account, fifteen hundred or two thousand pounds of both sorts, exclusively of what is privately exported by foreigners. In 1750 the Iceland company sold as much in quantity of this article as amounted to three thousand seven hundred and forty-five banco dollars, besides what was sent directly to Gluckstadt.—*Von Troil*, p. 146.

Down, or hair of plants. See Hair.

DOWNETON, a borough town of Wiltshire, five miles south of Salisbury. It contained 2624 inhabitants in 1811, and sends two members to parliament.

DOWNHAM, a market town of Norfolk, 10 miles south of Lynn, famous for its good butter; there being 1000, and sometimes 2000, firkins bought here every Monday, and sent up the river Ouse to Cambridge, and thence to London. Population 1771 in 1811.

DOWNS, a bank or elevation of sand, which the sea gathers and forms along its shores; and which serves it as a barrier. The word is formed from the French *dune*, of the Celtic *dum*, a "mountain." Charles de Visch, in his *Compend. Chronolog. Exord. et Progress. Abbat. Clariss. B. Mariæ, de Dunis*, says, *Vallem reperit arenarum collibus (quos incolæ* Duynen *vocant) undique cinctam.*

Downs is particularly used for a famous road for ships, along the eastern coast of the county of Kent, from Dover to the North Foreland; where both the outward and homeward bound ships frequently make some stay; and squadrons of men of war rendezvous in time of war.

It affords excellent anchorage; and is defended by the castles of Deal, Dover, and Sandwich.

DOWRY, the money or fortune which the wife brings her husband in marriage; it is otherwise called *maritagium*, marriage goods, and differs from dower. See Dower.

DOXOLOGY, a hymn used in praise of the Almighty, distinguished by the title of *greater* and *lesser*.

The lesser doxology was anciently only a single sentence, without response, running in these words, *Glory be to the Father, and to the Son, and to the Holy Ghost, world without end, Amen.* Part of the latter clause, *As it was in the beginning, is now, and ever shall be*, was inserted some time after the first composition. Some read this ancient hymn, *Glory be to the Father, and to the Son with the Holy Ghost.* Others, *Glory be to the Father in or by the Son, and by the Holy Ghost.* This difference of expression occasioned no dispute in the church, till the rise of the Arian heresy; but when the followers of Arius began to make use of the latter as a distinguishing character of their party, it was entirely laid aside by the Catholics, and the use of it was enough to bring any one under suspicion of heterodoxy.

The doxology was used at the close of every solemn office. The western church repeated it at the end of every psalm, and the eastern church at the end of the last psalm. Many of their prayers were also concluded with it, particularly the solemn thanksgiving or consecration prayer at the eucharist. It was also the ordinary conclusion of their sermons.

The greater doxology, or angelic hymn, was likewise of great note in the ancient church. It began with these words, which the angels sung at our Saviour's birth, *Glory be to God on high*, &c. It was chiefly used in communion service, and in men's private devotions. Both the doxologies have a place in the church of England, the former being repeated after every psalm, and the latter used in the communion service.

DRABA, a genus of plants belonging to the tetradynamia class; and in the natural method ranking under the 39th order, *Siliquosæ*. See Botany *Index*.

DRABLER, in the sea-language, a small sail in a ship, which is the same to a bonnet as a bonnet is to a course, and is only used when the course and bonnet are too shoal to clothe the mast. See Bonnet and Course.

DRABLING, in *Angling*, is a method of catching barbels. Take a strong line of six yards; which, before you fasten it to your rod, must be put through a piece of lead, that if the fish bite, it may slip to and fro, and that the water may something move it on the ground; bait with a lob worm well secured, and so by its motion the barbel will be enticed into the danger without suspicion. The best places are in running water near piles, or under wooden bridges, supported with oaks floated and slimy.

DRABS, in the salt works, a kind of wooden boxes for holding the salt when taken out of the boiling pan; the bottoms of which are made shelving or inclining forwards, that the briny moisture of the salt may drain off.

DRAC, an imaginary being, much dreaded by the country people in many parts of France. The dracs are supposed to be malicious or at least tricksome demons; but, which is very rare, if one of them happens to take a fancy to a man or woman, they are sure to be the better for it. They are still said to lay gold cups and rings on the surface over pits and rivers, as baits to draw women and children in; though their usual dwelling is some old empty house, whence they make excursions in human form, visible or invisible as best suits their purpose. The country folks shudder at the very name of the drac. Some are positive that they have

seen

seen him; for happy indeed is that village in which there is not a house execrated as the lurking place of this tremendous drac.

DRACÆNA, Dragon-tree; a genus of plants belonging to the hexandria class. See Botany *Index*.

DRACHM, a Grecian coin, of the value of sevenpence three farthings. Drachm is also a weight used by our physicians; containing just sixty grains, or three scruples, or the eighth part of an ounce.

DRACO, a celebrated lawgiver of Athens. When he exercised the office of archon, he made a code of laws for the use of his citizens, which, on account of their severity, were said to be written in letters of blood. By them idleness was punished with as much severity as murder, and death was denounced against the one as well as the other. Such a code of rigorous laws gave occasion to a certain Athenian to ask of the legislator, why he was so severe in his punishments? and Draco gave for answer, that as the smallest transgression had appeared to him deserving death, he could not find any punishment more rigorous for more atrocious crimes. These laws were at first enforced, but they were often neglected on account of their extreme severity; and Solon totally abolished them, except that one which punished a murderer with death. The popularity of Draco was uncommon, but the gratitude of his admirers proved fatal to him. When once he appeared on the theatre, he was received with repeated applause; and the people, according to the custom of the Athenians, showed their respect to their lawgiver by throwing garments upon him. This was done in such profusion, that Draco was soon hid under them, and smothered by the too great veneration of his citizens. He lived about 624 years before the Christian era.

Draco, the *Dragon*, a genus of reptiles belonging to the class of amphibia. See Erpetology *Index*.

Draco Volans, in *Meteorology*, a fiery exhalation, frequent in marshy and cold countries.

It is most common in summer; and though principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders: it appearance being that of an oblong, sometimes roundish, fiery body, with a long tail. It is entirely harmless, frequently sticking to the hands and clothes of people without injuring them in the least.

Draco, in *Astronomy*, a constellation of the northern hemisphere; whose stars, according to Ptolemy, are 81: according to Tycho, 32; according to Hevelius, 40; according to Bayer, 33; and according to Mr Flamstead, 80. See Astronomy, N° 406.

DRACOCEPHALUM, Dragon's Head; a genus of plants belonging to the didynamia class. See Botany *Index*.

DRACONARIUS, in antiquity, Dragon-bearer. Several nations, as the Persians, Parthians, Scythians, &c. bore dragons on their standards; whence the standards themselves were called *dracones*, "dragons." The Romans borrowed the same custom from the Parthians; or, as Casaubon has it, from the Daci; or, as Codin, from the Assyrians.

The Roman dracones were figures of dragons painted in red on the flags, as appears from Ammianus Marcellinus: but among the Persians and Parthians they were, like the Roman eagle, figures in full relievo; so that the Romans were frequently deceived, and took them for real dragons.

The soldier who bore the dragon or standard was called by the Romans *draconarius;* and by the Greeks δϱακοναϱιος and δϱακοντειοφοϱος; for the emperors carried the custom with them to Constantinople.

DRACONTIC month, the time of the revolution of the moon from her ascending node, called *caput draconis*, to her return thither.

DRACONTIUM, Dragons; a genus of plants belonging to the gynandria class; and in the natural method ranking under the first order, *Palmæ*. See Botany *Index*.

DRACUNCULI, in *Medicine*, a peculiar eruption, which was supposed to be worms in the muscular parts of the arms and legs, called *Guinea worms*. These worms were removed by the point of a needle; and to prevent their forming again, the usual custom is to wash the parts with wine and vinegar, with alum, nitre, or common salt, or with a strong lixivium of oak ashes, and afterwards anoint them with an ointment of the common kind used for scorbutic eruptions, with a small mixture of quicksilver.

DRACUNCULUS. See Arum, Botany *Index*.

DRAFF, a name given in some places to the wash given to hogs, and the grain given to cows.

DRAG, in building. A door is said to *drag* when in opening or shutting it hangs or grates upon the floor.

Drag, in sea language, is a machine consisting of a sharp, square, iron ring, encircled with a net, and commonly used to take the wheel off from the platform or bottom of the decks.

DRAGOMAN, or Drogman, a term of general use through the east for an interpreter, whose office is to facilitate commerce between the orientals and occidentals. These are kept by the ambassadors of Christian nations residing at the Porte for this purpose.

The word is formed from the Arabic *targeman* or *targiman*, of the verb *taragem*, "he has interpreted." From *dragoman* the Italians formed *dragomano* and, with a nearer relation to its Arabic etymology, *turcimanno;* whence the French and our *trucheman*, as well as *dragoman* and *drogman*.

DRAGON, in *Astronomy*. See Draco.

Dragon's Head and Tail (*caput et cauda draconis*), are the nodes of the planets; or the two points wherein the ecliptic is intersected by the orbits of the planets and particularly that of the moon; making with it angles of five degrees and eighteen minutes. One of these points looks northward; the moon beginning then to have north latitude, and the other southward, where she commences south. Thus her deviation from the ecliptic seems (according to the fancy of some) to make a figure like that of a dragon, whose belly is where she has the greatest latitude; the intersection representing the head and tail, from which resemblance the denomination arises.

But note, that these points abide not always in one place, but have a motion of their own in the zodiac, and retrograde-wise, 3 minutes 11 seconds per day; completing their circle in 18 years 225 days; so that the

the moon can be but twice in the ecliptic during her monthly period, but at all other times she will have a latitude or declination from the ecliptic.

It is about these points of intersection that all eclipses happen. They are usually denoted by these characters, ☊ dragon's head, ☋ dragon's tail.

Dragon, in *Zoology*. See Draco.

Dragon's-Blood, a gummi-resinous substance brought from the East Indies, either in oval drops wrapped up in flag leaves, or in large masses composed of smaller tears. It is said to be obtained from the palmijuncus draco, the calamus rotang, the dracæna draco, the pterocarpus draco, and several other vegetables.

The writers on the materia medica in general give the preference to the former, though the others are not unfrequently of equal goodness. The fine dragon's blood of either sort breaks smooth, free from any visible impurities, of a dark red colour, which changes upon being powdered into an elegant bright crimson. Several artificial compositions, coloured with the true dragon's blood, or Brazil wood, are sometimes sold in the room of this commodity. Some of these dissolve like gums in water; others crackle in the fire without proving inflammable; whilst the genuine sanguis draconis readily melts and catches flame, and is not acted on by watery liquors. It totally dissolves in pure spirit, and tinges a large quantity of the menstruum of a deep red colour. It is likewise soluble in expressed oils, and gives them a red hue, less beautiful than that communicated by anchusa. This drug in substance has no sensible smell or taste; when dissolved, it discovers some degree of warmth and pungency. It is usually, but without foundation, looked upon as a gentle astringent; and sometimes directed as such in extemporaneous prescription against seminal gleets, the fluor albus, and other fluxes. In these cases, it is supposed to produce the general effects of resinous bodies, lightly incrassating the fluids, and somewhat strengthening the solids. But in the present practice it is very little used either externally or internally.

A solution of dragon's blood in spirit of wine is used for staining marble, to which it gives a red tinge, which penetrates more or less deeply according to the heat of the marble during the time of application. But as it spreads at the same time that it sinks deep, for fine designs the marble should be cold. M. Dufay says, that by adding pitch to this solution the colour may be rendered deeper.

Dragon Fish, or *Dragonet*. See Callionymus, Ichthyology *Index*.

Dragon Fly. See Libellula, Entomology *Index*.

Dragon Shell, in *Natural History*, a name given by some to a species of concamerated patella or limpet. This has a top very much bent; and is of an ash colour on the outside, but of an elegant and bright flesh-colour within. This has been found sticking on the back of a tortoise, as the common limpets do on the sides of rocks; and some have been found affixed to large shells of the pinna marina brought from the East Indies at different times.

Dragons. See Dracontium, Botany *Index*.

DRAGONET, or *Dragon Fish*. See Callionymus, Ichthyology *Index*.

DRAGONNE'E, in *Heraldry*. A lion dragonée is where the upper half resembles a lion, the other half going off like the hinder part of a dragon. The same may be said of any other beast as well as a lion.

DRAGOON, in military affairs, a musqueteer mounted on horseback, who sometimes fights or marches on foot, as occasion requires.

Menage derives the word *dragoon* from the Latin *draconarius*, which in Vegetius is used to signify *soldier*. But it is more probably derived from the German *tragen* or *dragen*, which signifies *to carry*; as being infantry carried on horseback.

Dragoons are divided into brigades as the cavalry; and each regiment into troops; each troop having a captain, lieutenant, cornet, quarter-master, two serjeants, three corporals, and two drums. Some regiments have hautboys. They are very useful on any expedition that requires despatch; for they can keep pace with the cavalry, and do the duty of infantry; they encamp generally on the wings of the army, or at the passes leading to the camp; and sometimes they are brought to cover the general's quarters: they march in the front and rear of the army.

The first regiment of dragoons raised in England was in 1681, and called the regiment of dragoons of North Britain. In battle or attacks they generally fight sword in hand after the first fire. Their arms are, a sword, firelock, and bayonet. In the French service, when the dragoons march on foot, their officers bear the pike and the serjeants the halbert, neither of which are used in the English service.

DRAGOONING, one of the methods used by Papists for converting refractory heretics, and bringing them within the pale of the true church.

The following method of dragooning the French Protestants, after the revocation of the edict of Nantz, under Louis XIV. is taken from a French work translated in 1686.

"The troopers, soldiers, and dragoons, went into the Protestants houses, where they marred and defaced their household stuff, broke their looking glasses, and other utensils and ornaments, let their wine run about their cellars, and threw about their corn and spoiled it. And as to those things which they could not destroy in this manner, such as furniture of beds, linen, wearing apparel, plate, &c. they carried them to the market place, and sold them to the Jesuits and other Roman Catholics. By these means the Protestants in Montaubon alone were, in four or five days, stripped of above a million of money. But this was not the worst.

"They turned the dining rooms of gentlemen into stables for their horses; and treated the owners of the houses where they quartered with the highest indignity and cruelty, lashing them about from one to another, day and night, without intermission, not suffering them to eat or drink; and when they began to sink under the fatigue and pains they had undergone, they laid them on a bed, and when they thought them somewhat recovered, made them rise, and repeated the same tortures. When they saw the blood and sweat run down their faces and other parts of their bodies, they sluiced them with water, and putting over their heads kettle drums, turned upside down, they made a continual din upon them till these unhappy creatures lost their senses. When one party of these tormentors

mentors were weary, they were relieved by another, who practised the same cruelties with fresh vigour.

" At Negreplisse, a town near Montaubon, they hung up Isaac Favin, a Protestant citizen of that place, by his armpits, and tormented him a whole night by pinching and tearing off his flesh with pincers. They made a great fire round a boy of about 12 years old, who with his hands and eyes lifted up to heaven cried out "My God, help me!" And when they found the youth resolved to die rather than renounce his religion, they snatched him from the fire just as he was on the point of being burnt.

" In several places the soldiers applied red-hot irons to the hands and feet of men and breasts of women. At Nantz they hung up several women and maids by their feet, and others by their armpits, and thus exposed them to public view stark naked. They bound to posts mothers that gave suck, and let their sucking infants lie languishing in their sight for several days and nights, crying, mourning, and gasping for life. Some they bound before a great fire, and being half roasted, let them go: a punishment worse than death. Amidst a thousand hideous cries and a thousand blasphemies, they hung up men and women by the hair, and some by their feet, on hooks in chimneys, and smoked them with wisps of wet hay till they were suffocated. They tied some under the arms with ropes, and plunged them again and again into wells; they bound others like criminals, put them to the torture, and with a funnel filled them with wine till the fumes of it took away their reason, when they made them say, they consented to be Catholics. They stripped them naked, and after a thousand indignities, stuck them with pins and needles from head to foot. They cut and slashed them with knives; and sometimes with red-hot pincers took hold of them by the nose and other parts of the body, and dragged them about the rooms till they made them promise to be Catholics, or till the cries of these miserable wretches, calling upon God for help, forced them to let them go. They beat them with staves, and thus bruised, and with broken bones, dragged them to church, where their forced presence was taken for an abjuration. In some places they tied fathers and husbands to their bed-posts, and before their eyes ravished their wives and daughters with impunity. They blew up men and women with bellows till they burst them. If any to escape these barbarities endeavoured to save themselves by flight, they pursued them into the fields and woods, where they shot at them like wild beasts, and prohibited them from departing the kingdom (a cruelty never practised by Nero or Dioclesian) upon pain of confiscation of effects, the galleys, the lash, and perpetual imprisonment; insomuch that the prisons of the seaport towns were crammed with men, women, and children, who endeavoured to save themselves by flight from their dreadful persecution. With these scenes of desolation and horror, the Popish clergy feasted their eyes, and made them only a matter of laughter and sport.

" Though my heart aches (says the writer of the piece from which we are transcribing) whilst I am relating these barbarities, yet for a perpetual memorial of the infernal cruelty practised by these monsters I beg the reader's patience to lay before him two other instances, which, if he hath a heart like mine, he will not be able to read without watering these sheets with his tears.

" The first is of a young woman, who being brought before the council, upon refusing to abjure her religion, was ordered to prison. There they shaved her head, singed off the hair from other parts of her body; and having stripped her stark naked, led her through the streets of the city, where many a blow was given her, and stones flung at her; then they set her up to the neck in a tub full of water, where, after she had been for a while, they took her out, and put on her a shift dipt in wine, which, as it dried and stuck to her sore and bruised body, they snatched off again, and then had another ready dipt in wine to clap on her. This they repeated six times, thereby making her body exceeding raw and sore. When all these cruelties could not shake her constancy, they fastened her by her feet in a kind of gibbet, and let her hang in that posture, with her head downward, till she expired.

" The other is of a man in whose house were quartered some of these missionary dragoons. One day, having drank plentifully of his wine, and broken their glasses at every health, they filled the floor with the fragments, and by often walking over them reduced them to very small pieces. This done, in the insolence of their mirth, they resolved on a dance, and told their Protestant host that he must be one of their company; but as he would not be of their religion, he must dance quite barefoot; and thus barefoot they drove him about the room, treading on the sharp points of the broken glasses. When he was no longer able to stand, they laid him on a bed, and, in a short time, stripped him stark naked, and rolled him from one end of the room to the other, till every part of his body was full of the fragments of glass. After this they dragged him to his bed, and having sent for a surgeon, obliged him to cut out the pieces of glass with his instruments, thereby putting him to the most exquisite and horrible pains that can possibly be conceived.

" These, fellow Protestants, were the methods used by the most Christian king's apostolic dragoons to convert his heretical subjects to the Roman Catholic faith! These, and many other of the like nature, were the torments to which Louis XIV. delivered them over to bring them to his own church! and as Popery is unchangeably the same, these are the tortures prepared for you, if ever that religion should be permitted to become settled amongst you; the consideration of which made Luther say of it, what every man that knows any thing of Christianity must agree with him in, 'If you had no other reason to go out of the Roman church, this alone would suffice, that you see and hear, how contrary to the law of God, they shed innocent blood. This single circumstance shall, God willing, ever separate me from the Papacy. And if I was now subject to it, and could blame nothing in any of their doctrines; yet for this crime of cruelty, I would fly from her communion, as from a den of thieves and murderers."

DRAGS, in the sea language, are whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats, when towed, or whatever else that after this

this manner may hinder the ship's way when she sails, are called *drags*.

DRAIN, a cut or ditch for carrying off water from the soil, to improve it for the purposes of agriculture. In the fen countries of England drains are 20, 30, and sometimes 40 feet wide, carried through the marshy ground to some river or other place capable of discharging the water which they carry out of the fen lands.

DRAINING. For the different methods, see AGRICULTURE *Index*.

DRAKE, the male of the duck kind. See ANAS, ORNITHOLOGY *Index*.

DRAKE, *Sir Francis*, a celebrated English admiral, was the son of Edmund Drake a sailor, and born near Tavistock in Devonshire, in the year 1545. He was brought up at the expence, and under the care of, Sir John Hawkins, who was his kinsman; and, at the age of 18, was purser of a ship trading to Biscay. At 20, he made a voyage to Guinea; and, at 22, had the honour to be made captain of the Judith. In that capacity he was in the harbour of St John de Ulloa, in the gulf of Mexico, where he behaved most gallantly in the glorious actions under Sir John Hawkins, and returned with him to England with great reputation, though not worth a groat. Upon this he projected a design against the Spaniards in the West Indies; which he no sooner published, than he had volunteers enough ready to accompany him. In 1570, he made his first expedition with two ships; and the next year with only one, in which he returned safe, if not with such advantages, as he expected. He made another expedition in 1572, wherein he did the Spaniards some mischief, and gained considerable booties. In these expeditions he was much assisted by a nation of Indians, who then were, and have been ever since, engaged in perpetual wars with the Spaniards. The prince of these people was named *Pedro*; to whom Drake presented a fine cutlass from his side, which he saw the Indian greatly admired. Pedro, in return, gave him four large wedges of gold; which Drake threw into the common stock, saying, That he thought it but just that such as bore the charge of so uncertain a voyage on his credit, should share the utmost advantage that voyage produced. Then, embarking his men with all the wealth he had obtained, which was very considerable, he bore away for England, where he arrived in August 1573.

His success in this expedition, joined to his honourable behaviour towards his owners, gained him high reputation; and the use he made of his riches, a still greater. For, fitting out three stout frigates at his own expence, he sailed with them to Ireland; where, under Walter earl of Essex, the father of the famous unfortunate earl, he served as a volunteer, and did many glorious actions. After the death of his noble patron, he, returned to England; where Sir Christopher Hatton introduced him to her majesty, and procured him countenance and protection at court. By this means he acquired a capacity of undertaking that grand expedition which will render his name immortal. The first thing he proposed was a voyage into the South seas through the straits of Magellan; which was what hitherto no Englishman had ever attempted. This project was well received at court: the queen furnished him with means; and his own fame quickly drew together a sufficient force. The fleet with which he sailed on this extraordinary undertaking, consisted only of five vessels, small when compared with modern ships, and no more than 164 able men. He sailed on the 13th of December 1577; on the 25th fell in with the coast of Barbary, and on the 29th with Cape Verd. On the 18th of March he passed the equinoctial, made the coast of Brazil on the 5th of April, and entered the river de la Plata, where he lost the company of two of his ships; but meeting them again, and taking out their provisions, he turned them adrift. On the 29th of May he entered the port of St Julian's, where he continued two months for the sake of laying in provisions; on the 20th of August he entered the straits of Magellan, and on the 25th of September passed them, having then only his own ship. On the 25th of November he came to Macao, which he had appointed for a place of rendezvous in case his ships separated; but Captain Winter his vice admiral having repassed the straits, was returned to England. Thence he continued his voyage along the coast of Chili and Peru, taking all opportunities of seizing Spanish ships, and attacking them on shore, till his men were sated with plunder; and then, coasting America to the height of 48 degrees, he endeavoured to find a passage that way back into our seas, but could not. However he landed, and called the country *New Albion*, taking possession of it in the name and for the use of Queen Elizabeth; and having careened his ship, set sail from thence on the 29th September 1579, for the Moluccas. He is supposed to have chosen this passage round, partly to avoid being attacked by the Spaniards at a disadvantage, and partly from the lateness of the season, whence dangerous storms and hurricanes were apprehended. On the 13th of October he fell in with certain islands inhabited by the most barbarous people he had met with in all his voyage: on the 4th of November he had sight of the Moluccas; and, coming to Ternate, was extremely well received by the king thereof, who appears from the most authentic relations of this voyage to have been a wise and politic prince. On the 10th of December he made Celebes; where his ship unfortunately ran upon a rock, the 9th of January following; from which, beyond all expectation, and in a manner miraculously, they got off, and continued their course. On the 16th of March he arrived at Java Major; and from thence he intended to have directed his course to Malacca; but found himself obliged to alter his purpose, and to think of returning home. On the 25th of March 1580, he put this design in execution; and on the 15th of June he doubled the Cape of Good Hope, having then on board 57 men, and but three casks of water. On the 12th of July he passed the line, reached the coast of Guinea on the 16th, and there watered. On the 11th of September he made the island of Tercera; and on the 3d of November entered the harbour of Plymouth. This voyage round the world was performed in two years and about ten months. Shortly after his arrival, the queen going to Deptford went on board his ship; where, after dinner, she conferred on him the order of knighthood, and declared her absolute approbation of all he had done. She likewise gave directions for the preservation of his ship, that it might remain a monument of his own and his

Drake.

country's glory. This celebrated ship, which had been contemplated many years at Deptford, at length decaying, it was broke up, and a chair, made out of the planks, was presented to the university of Oxford; upon which the famous Abraham Cowley made the following verses:

> To this great ship, which round the world has run,
> And match'd in race the chariot of the sun:
> This Pythagorean ship (for it may claim
> Without presumption, so deserv'd a name,
> By knowledge once, and transformation now)
> In her new shape this sacred port allow.
> Drake and his ship could not have wished, from fate,
> A happier station, or more blest estate:
> For lo! a seat of endless rest is given,
> To her in Oxford, and to him in heaven.
>
> Works, Vol. II.

In the year 1585, he sailed with a fleet to the West Indies, and took the cities of St Jago, St Domingo, Carthagena, and St Augustine. In 1587, he went to Lisbon with a fleet of 30 sail; and having intelligence of a great fleet assembled in the bay of Cadiz, which was to have made part of the armada, he with great courage entered that port, and burnt there upwards of 10,000 tons of shipping: which he afterwards merrily called *burning the king of Spain's beard*. In 1588, when the armada from Spain was approaching our coasts, Sir Francis Drake was appointed vice-admiral under Charles Lord Howard of Effingham, high admiral of England, where fortune favoured him as remarkably as ever: for he made prize of a very large galleon, commanded by Don Pedro de Valdez, who was reputed the projector of this invasion. This affair happened in the following manner: On the 22d of July, Sir Francis observing a great Spanish ship floating at a distance from both fleets, sent his pinnace to summon the commander to yield. Valdez replied, with much Spanish solemnity, that they were 450 strong; that he himself was Don Pedro, and stood much upon his honour; and thereupon propounded several conditions, upon which he was willing to yield. But the vice-admiral replied, that he had no leisnre to parley; but if he thought fit instantly to yield, he might; if not, he should soon find that Drake was no coward. Pedro, hearing the name of Drake, immediately yielded, and with 46 of his attendants came on board Drake's ship. This Don Pedro remained about two years Sir Francis Drake's prisoner in England; and when he was released, paid him for his own and his captain's liberties a ransom of 3500l. Drake's soldiers were well recompensed with the plunder of this ship; for they found in it 55,000 ducats of gold, which were divided among them.

A little before this formidable Spanish armament put to sea, the ambassador of his Catholic majesty had the confidence to propound to Queen Elizabeth, in Latin verse, the terms upon which she might hope for peace; which, with an English translation by Dr Fuller, we will insert in this place, because Drake's expedition to the West Indies makes a part of this message. The verses are these:

> *Te veto ne pergas bello defendere Belgas;*
> *Quæ Dracus eripuit nunc restituantur oportet:*
> *Quas pater evertit jubeo te condere cellas:*
> *Religio Papæ fac restituantur ad unguem.*

Drake, Drakenborch.

> These to you are our commands,
> Send no help to th' Netherlands:
> Of the treasure took by Drake,
> Restitution you must make:
> And those abbeys build anew,
> Which your father overthrew:
> If for any peace you hope,
> In all points restore the pope.

The queen's extempore return:

> *Ad Græcas, bone rex, fiant mandata kalendas.*

> Worthy king, know this yonr will
> At Latter Lammas we'll fulfil.

In the year 1559, Sir Francis Drake commanded as admiral the fleet sent to restore Don Antonio king of Portugal, the command of the land forces being given to Sir John Norris: but they were hardly got to sea, before the commanders differed, and so the attempt proved abortive. The war with Spain continuing, a more effectual expedition was undertaken by Sir John Hawkins and Sir Francis Drake, against thier settlements in the West Indies, than had hitherto been made during the whole course of it: but the commanders here again not agreeing about the plan, this also did not turn out so successfully as was expected. All difficulties, before these two last expeditions, had given way to the skill and fortune of Sir Francis Drake; which probably was the reason why he did not bear these disappointments so well as he otherwise would have done. A strong sense of them is supposed to have thrown him into a melancholy, which occasioned a bloody flux; and of this he died on board his own ship, near the town of Nombre de Dios in the West Indies, on the 28th of January 1595-6. His death was lamented by the whole nation, and particularly by his countrymen; who had great reason to love him from the circumstance of his private life, as well as to esteem him in his public character. He was elected burgess for the town of Bossiny, alias Tintagal, in the county of Cornwall, in the 27th parliament of Queen Elizabeth; and for Plymouth in Devonshire, in the 35th of the same reign. This town had very particular obligations to him: for, in the year 1587, he undertook to bring water into it, through the want of which, till then, it had been grievously distressed; and he performed it by conducting thither a stream from springs at eight miles distance, that is to say, in a straight line: for in the manner he brought it, the course of it runs upwards of 20 miles.

DRAKENBORCH, Arnold, doctor of laws. This celebrated literary character was a native of Utrecht, and was born on the 1st of January 1684, and in which city he was afterwards professor of rhetoric and history. Grævius and Burmann taught him the belles lettres, and Cornelius Van Eck was his preceptor while he devoted his attention to the law. He succeeded Professor Burmann in the year 1716, and terminated his mortal career in 1748, in the 64th year of his age. He was an author of very considerable eminence, as the following publications sufficiently evince. His dissertation entitled, *Disputatio Philolog. Hist.*

Hist. de præfectis urbis, in 4to, proves him to have been an able philologist, and gave flattering indications of future eminence. Its intrinsic merit caused it to be reprinted at Frankfort-on-the-Oder, in 1750, by Professor Uhl, accompanied with a life of its learned author. His next work, entitled *Disputatio de officio præfectorum prætorio*, was published in the year 1707; and ten years after his *C. Silii Italici Punicorum*, in 17 books, to render which perfect and complete, nothing was omitted by this great man; many historical subjects being engraved for the purpose of elucidating the text, to which his own copious and learned annotations most powerfully contributed. His splendid edition of Livy, with a life of that eminent historian, will render his name immortal. It is entitled *T. Livii Patavini historiarum ab urbe condita libri, qui supersunt, omnes.* Lugd. Batav. 1738 and 1746; 7 tom. The preface to this work is very long, and replete with erudition, giving a particular account of all the literary characters who have at different periods commented on the works of Livy. He took the edition of Gronovius for his model, as being in his estimation the most correct; but he made many important alterations on the authority of manuscripts which it is probable Gronovius had either never seen, or not taken the pains to consult. Upon the whole, this edition of Livy is at once the most elaborate, interesting, and instructive, ever given to the world, since into it he has introduced the criticisms of Duchier, Gronovius, Perizonius, and Sigonius; in addition to his own, which are certainly fraught with much literature and deep discernment.

DRAMA, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind. The principal species of the drama are two, comedy and tragedy. See the subject fully considered in a historical view of the ancient and modern drama, in the article DRAMA, SUPPLEMENT.

DRAMATIC, an epithet given to pieces written for the stage. See POETRY.

DRAN, HENRY FRANCIS LE, a French surgeon of distinguished eminence, was born in the year 1685. His father followed the same profession at Paris, and was highly celebrated for his treatment of cancers. Dran had much experience as well as abilities, although his anatomical knowledge was rather circumscribed, and his acquaintance with books was far from being extensive. In 1730, he published in 8vo a valuable work, entitled *Parallele des differentes Manières de tirer la Pierre hors de la Vessie.* In this work he takes a comparative view of the different modes of performing the hazardous operation of lithotomy, preferring the lateral method which was practised by Cheselden. In the year 1731, he published his *Observations de Chirurgie, avec des Reflections*, in 2 vols 12mo, which is justly considered as a valuable performance for men who are employed in the practice of surgery. In 1757, appeared his *Traité ou Reflections tirées de la Pratique sur les Playes d' Armes à Feu*; in which he gives the results of his own practice while in the army, with efficacious methods for the cure of gun-shot wounds. Gataker translated into English his *Traité des Operations de Chirurgie*, to which many interesting observations were added by Cheselden. In 1763, were published his *Consultations sur la plupart des Maladies qui sont du Ressort de la Chirurgie*; the plan of which is admirably calculated for the instruction of young practitioners. As at least one evidence of the merit of Dran's works, translations of them have been made into various languages. If his judgment was penetrating, he was equally famed for his successful operations. He died at Paris in the year 1770, in the 85th year of his age.

DRANK, among farmers, a term used to denote wild oats, which never fail to infest worn-out lands; so that, when ploughed lands run to these weeds and thistles, the farmer knows it is high time to fallow them, or else to sow them with hay seed, and make pasture of them.

DRAPERY, in *Sculpture* and *Painting*, signifies the representation of the clothing of human figures, and also hangings, tapestry, curtains, and most other things that are not carnations or landscapes. See PAINTING, CRAYON, DRAWING, and MINIATURE.

DRASTIC, in *Physic*, an epithet bestowed on such medicines as are of present efficacy, and potent in operation; and is commonly applied to emetics and cathartics.

DRAVE, a large navigable river, which, taking its rise in the archbishopric of Saltzburgh, in Germany, runs south-east through Stiria; and continuing its course, divides Hungary from Sclavonia, and falls into the Danube at Esseck.

DRAUGHT, in *Medicine*. See POTION.

DRAUGHT, in trade, called also *cloff* or *clouch*, is a small allowance on weighable goods, made by the king to the importer, or by the seller to the buyer, that the weight may hold out when the goods are weighed again.

The king allows 1℔ draught for goods weighing no less than 1 cwt. 2℔ for goods weighing between 1 and 2 cwt. 3℔ for goods weighing between 2 and 3 cwt. 4℔ from 3 to 10 cwt. 7℔ from 10 to 18 cwt. 9℔ from 18 to 30 or upwards.

DRAUGHT is also used sometimes for a bill of exchange, and commonly for an order for the payment of any sum of money due, &c. Then the person who gives the order, is said to draw upon the other.

DRAUGHT, or, as it is pronounced, *Draft*, in *Architecture*, the figure of an intended building described on paper; wherein are laid down, by scale and compass, the several divisions and partitions of the apartments, rooms, doors, passages, conveniences, &c, in their due proportion.

It is usual, and exceedingly convenient, before a building is begun to be raised, to have draughts of the ichnography, or ground-plot of each floor or story: as also of the form and fashion of each front, with the windows, doors, ornaments, &c. in an orthography, or upright. Sometimes the several fronts, &c. are taken, and represented in the same draught, to show the effect of the whole building: this is called a *scenography*, or *perspective*.

DRAUGHT, the depth of a body of water necessary to float a ship: hence a ship is said to draw so many feet of water, when she is borne up by a column of water of that particular depth. Thus, if it requires a body of water whose depth is equal to 12 feet, to float or buoy up a ship on its surface, she is said to draw 12 feet water; and that this draught may be more readily known, the feet are marked on the stem and stern post, regularly from the keel upwards.

Draught-Hooks, are large hooks of iron, fixed on the cheeks of a cannon carriage, two on each side, one near the trunnion-hole, and the other at the train, distinguished by the name of *fore* and *hind draught hooks.* Large guns have draught hooks near the middle transom, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forewards, by men with strong ropes, called *draught-ropes*, fixed to these hooks.

Draught-Horse, in farming, a sort of coarse-made horse, destined for the service of a cart or plough.

DRAWBACK, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandises, that have paid duty on importation.

The oaths of the merchants importing and exporting are required to obtain the drawback on foreign goods, affirming the truth of the officers certificate on the entry, and the due payment of the duties: and these may be made by the agent or husband of any corporation or company; or by the known servant of any merchant usually employed in making his entries, and paying his customs. In regard to foreign goods entered outward, if less quantity or value be fraudulently shipped out than what is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no drawback to be allowed for the same. Foreign goods exported by certificate in order to obtain the drawback, not shipped or exported, or relanded in Great Britain, unless in case of distress to save them from perishing, are to lose the benefit of the drawback, and are forfeited, or their value, with the vessel, horses, carriages, &c. employed in the relanding thereof; and the persons employed in the relanding them, or by whose privity they are relanded, or into whose hands they shall knowingly come, are to forfeit double the amount of the drawback. Officers of the customs conniving at, or assisting in any fraud relating to certificate goods, besides other penalties, are to forfeit their office, and suffer six months imprisonment without bail or mainprise; as are also masters, or persons belonging to the ships employed therein. Bonds given for the exportation of certificate goods to Ireland must not be delivered up, nor drawback allowed for any goods, till a certificate under the hands and seals of the collector or comptroller, &c. of the customs be produced, testifying the landing.

Draw-Bridge, a bridge made after the manner of a float, to draw up or let down, as occasions serve, before the gate of a town or castle. See Bridge.

A draw-bridge may be made after several different ways; but the most common are made with plyers, twice the length of the gate, and a foot in diameter. The inner square is traversed with a cross, which serves for a counterpoise; and the chains which hang from the extremities of the plyers to lift up or let down the bridge are of iron or brass.

In navigable rivers it is sometimes necessary to make the middle arch of bridges with two moveable platforms, to be raised occasionally, in order to let the masts and rigging of ships pass through. This kind of draw-bridge is represented in Plate CLXVIII. where AB is the width of the middle arch; AL and BL, the two piers that support the draw-bridge NO, one of the platforms of which is raised, and the other let down, having the beam PQ for its plyer. To NO are suspended two moveable braces EH, EH; which resting on the support E, press against the bracket M, and thereby strengthen the draw-bridge. These braces are conducted to the rest by means of the weight S, pulling the chain SLF.

Draw-Net, a kind of net for taking the larger sort of wildfowl, which ought to be made of the best sort of packthread, with wide meshes; they should be about two fathoms deep and six long, verged on each side with a very strong cord, and stretched at each end on long poles. It should be spread smooth and flat upon the ground; and strewed over with grass, sedge, or the like, to hide it from the fowl: and the sportsman is to place himself in some shelter of grass, fern, or some such thing.

DRAWING, in general, denotes the action of pulling out, or hauling along; thus we read of tooth-drawing, wire-drawing, &c.

DRAWING,

THE art of representing the appearances of objects upon a plane surface, by means of lines, shades, and shadows, formed with certain materials adapted to the purpose.

§ 1. *Of the proper Materials for Drawing, and the manner of using them.*

The first thing necessary for a beginner is to furnish himself with proper materials, such as black lead pencils, crayons of black, white, or red chalk, crow-quill pens, a rule and compasses, camels hair pencils, and Indian ink. He must accustom himself to hold the pencil farther from the point than one does a pen in writing; which will give him a better command of it, and contribute to render the strokes more free and bold. The use of the pencil is to draw the first sketches or outlines of the piece, as any stroke or line that is amiss may in this be more easily rubbed out than in any other thing; and when he has made the sketch as correct as he can with the pencil, he may then draw carefully the best outline he has got, with his crow-quill pen and ink (A); after which he may discharge the pencil lines, by rubbing the piece gently with the crumb of stale bread or Indian rubber. Having thus got the outline clear, his next work is to shade the piece properly, either by drawing fine strokes with his pen where it requires to be shaded, or by washing it with his pencil and the Indian ink. As to his rule and compasses, they are never, or very rarely to be used, except in measuring the proportions of figures after he has drawn them, to prove whether they are right or not; or in houses, fortifications, and other pieces of architecture.

§ 2. *Of Drawing Lines, Squares, Circles, and other regular and irregular Figures.*

Having got all these implements in readiness, the first practice must be to draw straight and curve lines, with ease and freedom, upwards and downwards, sidewise to the right or left, or in any direction whatsoever. He must also learn to draw, by command of hand, squares, circles, ovals, and other geometrical figures: for, as the alphabet, or a knowledge of the letters, is an introduction to grammar; so is geometry to drawing. The practice of drawing these simple figures till he is master of them, will enable him to imitate, with greater ease and accuraey, many things both in nature and art. And here it is proper to admonish him, never to be in a hurry: but to make himself perfectly master of one figure before he proceeds to another: the advantage, and even necessity, of this, will appear as he proceeds. Two observations more may be added: 1. That he accustom himself to draw all his figures very large, which is the only way of acquiring a free bold manner of designing. 2. That he practise drawing till he has gained a tolerable mastery of his pencil, before he attempts to shadow any figure or object of any kind whatever.

§ 3. *Of Drawing Eyes, Ears, Legs, Arms, Hands, Feet, &c.*

As to the drawing of eyes and ears, legs and arms, the learner will have very little more to do than to copy carefully the examples given in Plate CLXXVII. and CLXXVIII. taken from Sebastian le Clerc's drawing book. But the actions and postures of the hands are so many and various, that no certain rules can be giving for drawing them, that will universally hold good. Yet as the hands and feet are difficult members to draw, it is very necessary, and well worth while, to bestow some time and pains about them, carefully imitating their various postures and actions, so as not only to avoid all lameness and imperfection, but also to give them life and spirit. To arrive at this, great eare, study, and practice, are requisite; particularly in imitating the best prints or drawings that can be got of hands and feet (some good examples of which are given in Plate CLXXVIII.); for, as to the mechanical rules of drawing them by lines and measures, they are not only perplexed and difficult, but also contrary to the practice of the best masters. One general rule, however, may be given (which is universally to be observed in all subjects), and that is, Not to finish perfectly at first any single part, but to sketch out faintly, and with light strokes of the pencil, the shape and proportion of the whole hand, with the action and turn of it; and after considering carefully whether this first sketch be perfect, and altering it wherever it is amiss, you may then proceed to the bending of the joints, the knuckles, the veins, and other small particulars, which, when the learner has got the whole shape and proportion of the hand or foot, will not only be more easily but also more perfectly designed.

§ 4. *Of Drawing Faces.*

The head is usually divided into four equal parts, (1.) From the crown of the head to the top of the forehead. (2.) From the top of the forehead to the eyebrows. (3.) From the eyebrows to the bottom of the nose. (4.) From thence to the bottom of the chin. But this proportion is not constant; those features in different men being often very different as to length and shape. In a well-proportioned face, however, they are nearly right. To direct the learner therefore in forming a perfect face, his first business is to draw an oval, or rather the form of an egg; in the middle of which, from the top to the bottom, draw a perpendicular line. Through the centre or middle of this line draw a diameter line, directly across from one side to the other of your oval. On these two lines all the features of your face are to be placed as follows: Divide your perpendicular line into four equal parts; the first must be allotted to the hair of the head; the second is from the top of the forehead to the top of the nose between the eyebrows; the third is from thence to the bottom of the nose; and the fourth includes the lips and chin. Your diameter line, or the breadth of the face, is always supposed to be the length of five eyes; you must therefore divide it into five equal parts, and place the eyes upon it so as to leave exactly the length of one eye betwixt them. This is to be understood only of a full front face, Plate CLXXVII. fig. *a*; for if it turn to either side, then the distances are to be lessened on that side which turns from you, less or more in proportion to its turning (fig. *b b b*). The top of the ear is to rise parallel to the eyebrows, at the end of the diameter line; and the bottom of it must be equal to the bottom of the nose. The nostrils ought not to come out farther than the corner of the eye in any face; and the middle of the mouth must always be placed upon the perpendicular line.

§ 5. *Of Drawing Human Figures.*

When the learner is tolerably perfect in drawing faces, heads, hands, and feet, he may next attempt to draw the human figure at length. In order to which, let him first sketch the head; then draw a perpendicular

---

(A) The ink made use of for this purpose must not be common but Indian ink; which is much softer than the other, and does not run: by mixing it with water, it may be made to any degree of strength, and used in a pen like common ink.

lar line from the bottom of the head seven times its length (for the length of the head is about one-eighth part of the length of the figure).

The best proportioned figures of the ancients are 7$\frac{3}{4}$ heads in height. If, therefore, the figure stands upright, (as fig. *a*, Plate CLXXIX.) draw a perpendicular line from the top of the head to the heel, which must be divided into two equal parts. The bottom of the belly is exactly the centre. Divide the lower part into two equal parts again, the middle of which is the middle of the knee. For the upper part of the figure, the matter must be varied. Take off with your compasses the length of the face (which is three parts in four of the length of the head; from the throat pit to the pit of the stomach is one face, from thence to the navel is another, and from thence to the lower rim of the belly is a third. The line must be divided into seven equal parts. Against the end of the first division, place the breasts; the second comes down to the navel; the third to the privities; the fourth to the middle of the thigh; the fifth to the lower part of the knee; the sixth to the lower part of the calf; and the seventh to the bottom of the heel, the heel of the bearing leg being always exactly under the pit of the throat. But as the essence of all drawing consists in making at first a good sketch, the learner must in this particular be very careful and accurate; he ought to draw no one part perfect or exact till he see whether the whole draught be good; and when he has altered that to his mind, he may then finish one part after another as perfectly as he can.

There are some who, having a statue to copy, begin with the head, which they finish, and then proceed in the same manner to the other parts of the body, finishing as they go: but this method generally succeeds ill; for if the head be made in the least too big or too little, the consequence is a disproportion between all the parts, occasioned by their not having sketched the whole proportionably at first. Let the learner remember, therefore, in whatever he intends to draw, first to sketch its several parts, measuring the distances and proportions between each with his finger or pencil, without using the compasses; and then judge of them by the eye, which by degrees will be able to judge of truth and proportion, and will become his best and principal guide. And let him observe, as a general rule, always to begin with the right side of the piece he is copying: for by that means he will always have what he has done before his eyes; and the rest will follow more naturally, and with greater ease; whereas if he begin with the left side, his hand and arm will cover what he does first, and deprive him of the sight of it; by which means he will not be able to proceed with so much ease, pleasure, or certainty.

As to the order and manner of proceeding in drawing the human body, he must first sketch the head; then the shoulders in the exact breadth; then draw the trunk of the body, beginning with the armpits (leaving the arms till afterwards), and so draw down to the hips on both sides; and be sure he observe the exact breadth of the waist. When he has done this, let him then draw that leg which the body stands upon; and afterwards the other which stands loose; then the arms; and last of all the hands.

He must take notice also of the bowings and bendings that are in the body; making the part which is opposite to that which bends correspond to it in bending with it. For instance: If one side of the body bend in, the other must stand out answerable to it; if the back bend in, the belly must stick out; if the knee bend out, the ham must fall in; and so of any other joint of the body. Finally, he must endeavour to form all parts of the figure with truth, and in just proportion; not one arm or one leg bigger or less than the other; not broad Herculean shoulders, with a thin and slender waist; nor raw and bony arms, with thick and gouty legs: but let there be a kind of harmonious agreement amongst the members, and a beautiful symmetry throughout the whole figure.

Proportions and Measures of the Human Body. The centre or middle part, between the two extremes of the head and feet of a new born child, is in the navel, but that of an adult is in the os pubis; and the practice of dividing the measures of children into four, five, or six parts, whereof the head is one, is made use of by painters and sculptors.

A child of two years old has about five heads in its whole length, but one of four or five years old has near six; about the fifteenth or sixteenth year, seven heads are the proportion or measure, and the centre inclines to the upper part of the pubis. Hence it appears, as the growth of the body advances, there is a gradual approach to the proportion of an adult of near eight heads in the whole length, of which, as mentioned above, the head makes one.

Agreeable to these principles, the following Table is constructed, exhibiting the proportions of the parts of a man and of a woman, as they were fixed by the ancients, and measured by M. Audran from the Apollo Pythius (Plate CLXXX.) in the garden of the Vatican at Rome, and the Venus Aphrodites (Plate CLXXXI.) belonging to the family of the Medicis. Supposing the figures to stand upright and duly poised on both legs, the whole height of the former is divided into 31$\frac{1}{2}$ parts, being 7 heads 3 parts and 6 minutes; and that of the latter into 31 parts, being 7 heads and 3 parts.

LENGTH of the HEAD and TRUNK of the BODY.	*Apollo.*			*Venus.*

The other most admired antique statues differ a little from these proportions, the Laocoon measuring 7 h. 2 p. 3 m. the Hercules 7 h. 3 p. 7 m. the Pyramus 7 h. 2 p. the Antinous 7 h. 2 p. the Grecian shepherdess 7 h. 3 p. 6 m. and the Mirmillo 8 h. But all their other proportions are allowed to be harmonious and agreeable to the characters of the figures they represent.

The most remarkable differences of the symmetry or proportions of a man and of a woman to be observed from the Table are: First, The shoulders of a man are broader, measuring two heads, and the haunches narrower, measuring 1 h. 1 p. 5 m. whereas the shoulders of a woman measure only 1 h. 3 p. 8 m. and the haunches measure 1 h. 2 p. 3 m. The sternum or breast-bone of a man is longer, measuring 3 p. 8 m. and the sternum of the woman only 3 p. 3 m. On the contrary, the pelvis of a man is less, measuring from the top to bottom only 4 p. whereas the pelvis of a woman measures from the top to the bottom 4 p. 3 m.

It is a leading principle, in which every person conversant in designing has agreed, that without a perfect knowledge of the proportions, nothing can be produced but monstrous and extravagant figures; and it is also universally admitted, that the ancient Greek and Roman sculptors attained the highest success in producing the most perfect models.

The greatest of the modern artists who have examined their figures with attention admit, that several of the ancient sculptors in some degree have excelled nature, they never having found any man so perfect in all his parts as some of their figures are. Their opportunities indeed were great; Greece abounded with beauties; and Rome being mistress of the world, every thing that was curious and beautiful was brought to it from all parts. Their motives were also powerful; religion, glory, and interest. They considered it as a kind of religious worship to give the figures of their gods so much nobleness and beauty as to be able to attract the love and veneration of the people. Their own glory was also concerned, particular honours being bestowed on those who succeeded; and for their fortune they had no further care to take when they once arrived at a certain degree of merit.

Attitudes and Action of the Muscles. If a strong person is to be represented in a vigorous action, such as Hercules, &c. after a suitable proportion to such a figure and the action is designed, the parts or limbs employed in the chiefest force of the action ought to be considered. If the figure is standing, the foot must be placed in a right line, or perpendicular to the trunk or bulk of the body, where the centre of gravity may be placed *in æquilibrio*. This centre is determined by the heel: or, if the figure is upon tiptoe, then the ball of the great toe is in the centre. The muscles of the leg which supports the body ought to be swelled, and their tendons drawn more to extension than those of the other leg, which is only placed so as to receive the weight of the body towards that way to which the action inclines it. For example, suppose Hercules with a club striking at any thing before him towards the left side: Then let his right leg be placed so as to receive the whole weight of the body, and the left loosely touching the ground with his toes. Here the external muscles of the right leg ought to be expressed very strong; but those of the left scarcely appearing more than if it were in some sedentary posture, except in the present case. The foot being extended, the muscles which compose the calf of the leg are in action and appear very strong; though it is not meant that *all* the muscles of the right leg, which supports the weight of of the body, ought to be expressed very strong or equally swelled, but those most tumefied which are chiefly concerned in the action or posture that the leg is then in. For example, if the leg or tibia is extended, then the extending muscles placed on the thigh are most swelled: if it is bended, then the bending muscles and their tendons appear most. The like may be observed of the whole body in general when it is put into vigorous action. The Laocoon formerly in the Vatican garden at Rome, now in the Louvre at Paris, furnishes an example of this muscular appearance through the whole; but in the Antinous, Apollo, also in the Louvre, and other figures of the ancients, in postures where no considerable actions are designed, we see their muscles expressed but faintly, or scarcely appearing.

The clavicles or collar-bones, and muscles in general, do not appear in women as in men; nor will any action in which a woman uses her utmost strength occasion such swellings or risings of the muscles to appear as they do in men, since the great quantity of fat placed under the skin of women so clothes their muscles, &c. as to prevent any such appearance.

Effects of the Exertion of the Muscles. The following are the most obvious effects of the exertion of several of the muscles; of those, to wit, which chiefly demand the attention of an artist.

If either of the mastoid muscles (Plate CLXXXII. 1. 1.) act, the head is turned to the contrary side, and the muscle which performs that action appears very plain under the skin.

If the arms are lifted up, the deltoid muscles placed on the shoulders, which perform that action, swell, and make the extremities of the spines of the shoulder-blades (Plate CLXXXIII. 3. 3.), called the tops of the shoulders, appear indented or hollow.

The shoulder-blades following the elevation of the arms, their bases (Plate CLXXXIII. 4. 4.) incline at that time obliquely downward.

If the arms are drawn down, put forwards, or pulled backwards, the shoulder-blades necessarily vary their positions accordingly. All these particulars are to be learned by consulting the life only; when being well acquainted with what then appears in every action, the artist will be able to form an adequate idea how it ought to be expressed. These circumstances are little known; hence seldom attended to in designing.

When the cubit or fore-arm is bended, the biceps (Plate CLXXXII. 5. 5.) has its belly very much raised, as appears in the left arm. The like may be observed of the triceps (Plate CLXXXIII. 6. 6.) when the arm is extended as observed in the right arm.

The straight muscles of the abdomen (Plate CLXXXII. 7. 7.) appear very strong when rising from a decumbent posture.

The parts of the great serratus muscle (ib. 8. 8.) which are received in the teeth or beginnings of the oblique descending muscle immediately below, are very much swelled when the shoulder on the same side is brought forwards; that serratus muscle then being in action in drawing the scapular forwards.

The long extending muscles of the trunk (Plate CLXXXIII. 9. 9.) act alternately in walking, after this manner: If the right leg bears the weight of the body, and the left is in translation as on tiptoe, the last-mentioned muscles of the back on the left side may be observed to be tumefied on the other side about the region of the loins, and so on the other side.

The trochanters, or outward and uppermost heads of the thigh-bones (Plate CLXXXIII. 10. 10.), vary in their positions in such a manner as no precise observation can explain their several appearances; but the study after the life ought to be carefully attended to.

If the thigh is extended, as when the whole weight of the body rests on that side, the gluteus or buttock muscle (Plate CLXXXIII. 11. 11.) makes a very different appearance from what offers at another time; but if the thigh is drawn backwards, that muscle appears still more and more tumefied.

When the whole leg is drawn upwards forwards, and at the same time the foot is inclined inwards, the upper part of the sartorius muscle (Plate CLXXXII. 12. 12.) appears rising very strong; in other positions of the thigh, that muscle makes a furrowing appearance in its whole progress.

If a man is upon tiptoe, the extending muscles of the leg placed on the fore part of the thigh (Plate CLXXXII. 13. 13. 13.), and those of the foot that compose the calf of the leg (Plate CLXXXIII. 14. 14.) appear very strong, and the long peronæus (Plate CLXXXII. 15.) makes a considerable indentation or furrowing at that time in its progress on the outside of the leg.

Many other remarks might here be offered: but a due attention to nature will soon discover them.

§ 6. *Of Light and Shade.*

After the learner has made himself in some measure perfect in drawing outlines, his next endeavour must be to shade them properly. It is this which gives an appearance of substance, shape, distance, and distinction, to whatever body he endeavours to represent, whether animate or inanimate. The best rule for doing this is, to consider from what point, and in what direction, the light falls upon the objects which he is delineating, and to let all his lights and shades be placed according to that direction throughout the whole work. That part of the object must be lightest which hath the light most directly opposite to it; if the light falls sideways on the picture, he must make that side which is opposite to it lightest, and that side which is farthest from it darkest. If he is drawing the figure of a man, and the light be placed above the head, then the top of the head must be made lightest, the shoulders next lightest, and the lower parts darker by degrees. That part of the object, whether in naked figures or drapery, or buildings, that stands farthest out, must be made the lightest, because it comes nearest to the light; and the light loseth so much of its brightness, by how much any part of the body bends inward, because those parts that stick out hinder the lustre and full brightness of the light from striking on those parts that fall in. Titian used to say, that he knew no better rule for the distribution of lights and shadows than his observations drawn from a bunch of grapes. Satins and silks, and all other shining stuffs, have certain glancing reflections, exceeding bright where the light falls strongest. The like is seen in armour, brass pots, or any other glittering metal, where you see a sudden brightness in the middle or centre of the light, which

which discovers the shining nature of such things. Observe also, that a strong light requires a strong shade, a fainter light a fainter shade; and that an equal balance be preserved throughout the piece between the lights and shades. Those parts which must appear round require but one stroke in shading, and that sometimes but very faint; such parts as should appear steep or hollow, require two strokes across each other, or sometimes three, which is sufficient for the deepest shade. Care must be also taken to make the outlines faint and small in such parts as receive the light; but where the shades fall, the outline must be strong and bold. The learner must begin his shadings from the top, and proceed downward, and use his utmost endeavours both by practice and observation to learn how to vary the shadings properly; for in this consists a great deal of the beauty and elegance of drawing. Another thing to be observed is, that as the human sight is weakened by distances, so objects must seem more or less confused or clear according to the places they hold in the piece: Those that are very distant,—weak, faint, and confused; those that are near and on the foremost ground,—clear, strong, and accurately finished.

§ 7. *Of Drapery.*

In the art of clothing the figures, or casting the drapery properly and elegantly upon them, many things are to be observed. 1. The eye must never be in doubt of its object; but the shape and proportion of the part or limb, which the drapery is supposed to cover, must appear; at least so far as art and probability will permit: and this is so material a consideration, that many artists draw first the naked figure, and afterwards put the draperies upon it. 2. The drapery must not sit too close to the parts of the body: but let it seem to flow round, and as it were to embrace them; yet so as that the figure may be easy, and have a free motion. 3. The draperies which cover those parts that are exposed to great light must not be so deeply shaded as to seem to pierce them; nor should those members be crossed by folds that are too strong, lest by the too great darkness of the shades the members look as if they were broken. 4. The great folds must be drawn first, and then stroked into lesser ones: and great care must be taken that they do not cross one another improperly. 5. Folds in general should be large, and as few as possible. However, they must be greater or less according to the quantity and quality of the stuffs of which the drapery is supposed to be made. The quality of the person is also to be considered in the drapery. If they are magistrates, their draperies ought to be large and ample: if country clowns or slaves, they ought to be coarse and short; if ladies or nymphs, light and soft. 6. Suit the garments to the body, and make them bend with it, according as it stands in or out, straight or crooked; or as it bends one way or another; and the closer the garment sits to the body, the narrower and smaller must be the folds. 7. Folds well imagined give much spirit to any kind of action; because their motion implies a motion in the acting member, which seems to draw them forcibly, and makes them more or less stirring as the action is more or less violent. 8. An artful complication of folds in a circular manner greatly helps the effect of foreshortenings. 9. All folds consist of two shades, and no more; which you may turn with the garment at pleasure, shadowing the inner side deeper, and the outer more faintly. 10. The shades in silk and fine linen are very thick and small, requiring little folds and a light shadow. 11. Observe the motion of the air or wind, in order to draw the loose apparel all flying one way; and draw that part of the garment that adheres closest to the body before you draw the looser part that flies off from it; lest, by drawing the loose part of the garment first, you should mistake the position of the figure, and place it awry. 12. Rich ornaments, when judiciously and sparingly used, may sometimes contribute to the beauty of draperies. But such ornaments are far below the dignity of angels or heavenly figures; the grandeur of whose draperies ought rather to consist in the boldness and nobleness of the folds, than in the quality of the stuff or the glitter of ornaments. 13. Light and flying draperies are proper only to figures in great motion, or in the wind: but when in a calm place, and free from violent action, their draperies should be large and flowing; that by their contrast and the fall of the folds, they may appear with grace and dignity. Thus much for draperies; an example or two of which are given in Plate CLXXIX. But see farther the articles CRAYON and PAINTING.

§ 8. *On the Passions.*

The passions, says M. le Brun, are motions of the soul, either upon her pursuing what she judges to be for her good, or shunning what she thinks hurtful to her; and commonly, whatever causes emotion or passion in the soul, creates also some action in the body. It is therefore necessary for a painter to know which are the different actions in the body that express the several passions of the soul, and how to delineate them.

M. le Brun has been extremely happy in expressing many of the passions, and the learner cannot study any thing better than the examples which he has left us of them. However, as M. de Piles justly observes, it is absurd as well as impossible to pretend to give such particular demonstrations of them as to fix their expression to certain strokes, which the painter should be obliged to make use of as essential and invariable rules. This (says he) would be depriving the art of that excellent variety of expression which has no other principle than diversity of imagination, the number of which is infinite. The same passion may be finely expressed several ways, each yielding more or less pleasure in proportion to the painter's understanding and the spectator's discernment.

Though every part of the face contributes towards expressing the sentiments of the heart, yet the eyebrow, according to M. le Brun, is the principal seat of expression, and where the passions best make themselves known. It is certain, says he, that the pupil of the eye, by its fire and motion, very well shows the agitation of the soul, but then it does not express the kind or nature of such an agitation; whereas the motion of the eyebrow differs according as the passions change their nature. To express a simple passion, the motion is simple; to express a mixed passion, the motion is compound: if the passion be gentle, the motion is gentle; and if it be violent, the motion is so too. We may observe farther, says he, that there are two

two kinds of elevation in the eyebrows. One, in which the eyebrows rise up in the middle; this elevation expresses agreeable sensations, and it is to be observed that then the mouth rises at the corners: Another, in which the eyebrows rise up at the ends, and fall in the middle; this motion denotes bodily pain, and then the mouth falls at the corners. In laughter, all the parts agree; for the eyebrows, which fall toward the middle of the forehead, make the nose, the mouth, and the eyes, follow the same motion. In weeping, the motions are compound and contrary; for the eyebrows fall toward the nose and over the eyes, and the mouth rises that way. It is to be observed also, that the mouth is the part of the face which more particularly expresses the emotions of the heart: for when the heart complains, the mouth falls at the corners; when it is at ease, the corners of the mouth are elevated; and when it has an aversion, the mouth shoots forward, and rises in the middle.

"The head (says M. de Piles) contributes more to the expression of the passions than all the other parts of the body put together. Those separately can only show some few passions, but the head expresses them all. Some, however, are more particularly expressed by it than others: as humility, by hanging it down; arrogance, by lifting it up; languishment, by inclining it to one side; and obstinacy, when with a stiff and resolute air it stands upright, fixed, and stiff between the two shoulders. The head also best shows our supplications, threats, mildness, pride, love, hatred, joy, and grief. The whole face, and every feature, contributes something: especially the eyes; which, as Cicero says, are the windows of the soul. The passions they more particularly discover are, pleasure, languishing, scorn, severity, mildness, admiration, and anger; to which one might add joy and grief, if they did not proceed more particularly from the eyebrows and mouth; but when those two passions fall in also with the language of the eyes, the harmony will be wonderful. But though the passions of the soul are more visible in the lines and features of the face, they often require the assistance also of the other parts of the body. Without the hands, for instance, all action is weak and imperfect; their motions, which are almost infinite, create numberless expressions: it is by them that we *desire, hope, promise, call, send back;* they are the instruments of *threatening, prayer, horror,* and *praise;* by them we *approve, condemn, refuse, admit, fear, ask;* express our *joy* and *grief,* our *doubts, regrets, pain,* and *admiration.* In a word, it may be said, as they are the language of the dumb, that they contribute not a little to speak a language common to all nations, which is the language of painting. But to say how these parts must be disposed for expressing the various passions, is impossible; nor can any exact rules be given for it, both because the task would be infinite, and because every one must be guided in this by his own genius and the particular turn of his own studies." See the article PASSIONS, and the Plate there referred to.

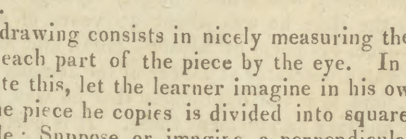
§ 9. *Of drawing Flowers, Fruits, Birds, Beasts,* &c.

The learner may proceed now to make some attempts at drawing flowers, fruits, birds, beasts, and the like; not only as it will be a more pleasing employment, but as it is an easier task, than the drawing of hands and feet, and other parts of the human body, which require not only more care, but greater exactness and nicer judgment. Very few rules or instructions are requisite upon this head: the best thing the learner can do is, to furnish himself with good prints or drawings by way of examples, and with great care and exactness to copy them. If it is the figure of a beast, begin with the forehead, and draw the nose, the upper and under jaw, and stop at the throat. Then go to the top of the head, and form the ears, neck, back, and continue the line till you have given the full shape of the buttock. Then form the breast, and mark out the legs and feet, and all the smaller parts. And, last of all, finish it with the proper shadows. It is not amiss, by way of ornament, to give a small sketch of landscape; and let it be suitable and natural to the place or country of the beast you draw. Much the same may be said with regard to birds. Of these, as well as beasts and other objects, the learner will find many examples among the plates given in this work.

§ 10. *Of drawing Landscapes, Buildings,* &c.

Of all the parts of drawing, this is the most useful and necessary, and it is what every man may have occasion for at one time or another. To be able, on the spot, to take the sketch of a fine building, or a beautiful prospect; of any curious production of art, or uncommon appearance in nature; is not only a very desirable accomplishment, but a very agreeable amusement. Rocks, mountains, fields, woods, rivers, cataracts, cities, towns, castles, houses, fortifications, ruins, or whatsoever else may present itself to view on our journeys or travels in our own or foreign countries, may be thus brought home, and preserved for our future use either in business or conversation. On this part, therefore, more than ordinary pains should be bestowed.

All drawing consists in nicely measuring the distances of each part of the piece by the eye. In order to facilitate this, let the learner imagine in his own mind, that the piece he copies is divided into squares. For example: Suppose or imagine a perpendicular and a horizontal line crossing each other in the centre of the picture you are drawing from; then suppose also two such lines crossing your own copy. Observe in the original, what parts of the design those lines intersect, and let them fall on the same parts of the supposed lines in the copy: We say, the supposed lines; because though engravers, and others who copy with great exactness, divide both the copy and original into many squares, as below; yet this is a method not to be recommended, as it will be apt to deceive the learner, who will fancy himself a tolerable proficient, till he comes to draw after nature, where these helps are not to be had, when he will find himself miserably defective and utterly at a loss.



If he is to draw a landscape from nature, let him take his station on a rising ground, where he will have a large horizon; and mark his tablet into three divisions, downwards from the top to the bottom; and divide in his own mind the landscape he is to take, into three divisions also. Then let him turn his face directly opposite to the midst of the horizon, keeping his body fixed, and draw what is directly before his eyes upon the middle division of the tablet; then turn his head, but not his body, to the left hand, and delineate what he views there, joining it properly to what he had done before; and, lastly, do the same by what is to be seen upon his right hand, laying down every thing exactly both with respect to distance and proportion. One example is given on Plate CLXXIX.

The best artists, in drawing their landscapes, make them shoot away one part lower than another. Those who make their landscapes mount up higher and higher, as if they stood at the bottom of a hill to take the prospect, commit a great error: the best way is to get upon a rising ground, make the nearest objects in the piece the highest, and those that are farther off to shoot away lower and lower till they come almost level with the line of the horizon, lessening every thing proportionably to its distance, and observing also to make the objects fainter and less distinct the farther they are removed from the eye. He must make all his lights and shades fall one way, and let every thing have its proper motion: as trees shaken by the wind, the small boughs bending more, and the large ones less: water agitated by the wind, and dashing against ships or boats, or falling from a precipice upon rocks and stones, and spirting up again into the air, and sprinkling all about: clouds also in the air; now gathered with the winds; now violently condensed into hail, rain, and the like: Always remembering, that whatever motions are caused by the wind must be made all to move the same way, because the wind can blow but one way at once.

Finally, It must be observed, that in order to attain any considerable proficiency in drawing, a knowledge of PERSPECTIVE is absolutely necessary: see that article.

Dray, Drayton.

DRAY, a kind of cart used by brewers for carrying barrels of beer or ale; also a sledge drawn without wheels.

DRAY, among sportsmen, denotes squirrel nests built in the tops of trees.

DRAYTON, MICHAEL, an eminent English poet, was born in 1563, of an ancient family in Warwickshire. His propensity to poetry was extremely strong, even from his infancy; and we find the most of his principal poems published, and himself highly distinguished as a poet, by the time he was about 30 years of age.—It appears from his poem of Moses's Birth and Miracles, that he was a spectator at Dover of the famous Spanish armada, and it is not improbable that he was engaged in some military employment there. It is certain, that not only for his merit as a writer but his valuable qualities as a man, he was held in high estimation, and strongly patronized by several personages of consequence; particularly by Sir Henry Goodere, Sir Walter Aston, and the countess of Bedford; to the first of whom he owns himself indebted for great part of his education, and by the second he was for many years supported.

His poems are very numerous; and so elegant, that his manner has been copied by many modern writers of eminence since. Among these the most celebrated one is the Poly-Albion, a chorographical description of England, with its commodities, antiquities, and curiosities, in metre of 12 syllables; which he dedicated to Prince Henry, by whose encouragement it was written: and whatever may be thought of the poetry, his descriptions are allowed to be exact. He was styled *poet laureat* in his time: which, as Ben Johnson was then in that office, is to be understood in a loose sense of approbation as an excellent poet; and was bestowed on others as well as Drayton, without being confined strictly to the office known by that appellation. He died in 1631; and was buried in Westminster abbey among the poets, where his bust is to be seen, with an epitaph penned by Ben Johnson.

Drayton, Dreams

DREAMS, are all those thoughts which people feel passing through their minds, and those imaginary transactions in which they often fancy themselves engaged, when in the state of sleep.

Scarce any part of nature is less open to our observation than the human mind in this state. The dreamer himself cannot well observe the manner in which dreams arise or disappear to him. When he awakes, he cannot recollect the circumstances of his dreams with sufficient accuracy. Were we to watch over him with the most vigilant attention, we could not perceive with certainty what emotions are excited in his mind, or what thoughts pass through it, during his sleep. But though we could ascertain these phenomena, many other difficulties would still remain. What parts of a human being are active, what dormant, when he dreams? Why does not he always dream while asleep? Or why dreams he at all? Do any circumstances in our constitution, situation, and peculiar character, determine the nature of our dreams?

We may lay before our readers such facts as have been ascertained concerning dreaming, and the most plausible conjectures that have been offered to explain those particulars, about which we can only conjecture, or have at least hitherto obtained nothing more certain than conjecture.

1. In dreaming, we are not conscious of being asleep. This is well known from a thousand circumstances. When awake, we often recollect our dreams; and we remember on such occasions, that while those dreams were passing through our minds, it never occurred to us that we were separated by sleep from the active world. We are often observed to act and talk in dreaming as if we were busily engaged in the intercourse of social life.

2. In dreaming, we do not consider ourselves as witnessing

witnessing or bearing a part in a fictitious scene: we seem not to be in a similar situation with the actors in a dramatic performance, or the spectators before whom they exhibit, but engaged in the business of real life. All the varieties of thought that pass through our minds when awake may also occur in dreams; all the images which imagination presents in the former state, she is also able to call up in the latter; all the same emotions may be excited, and we are often actuated by equal violence of passion; none of the transactions in which we are capable of engaging while awake is impossible in dreams: in short, our range of action and observation is equally wide in the one state as in the other; and while dreaming, we are not sensible of any distinction between our dreams and the events and transactions in which we are actually concerned in our intercourse with the world.

3. It is said that all men are not liable to dream. Dr Beattie, in a very pleasing essay on this subject, relates, that he knew a gentleman who never dreamed except when his health was in a disordered state; and Locke mentions that a certain person of his acquaintance was almost a stranger to dreaming till the 26th year of his age; and then began to dream in consequence of having a fever. These instances, however, are too few, and we have not been able to obtain more; and, besides, it does not appear that those persons had always attended, with the care of a philosopher making an experiment, to the circumstances of their sleep. They might dream, but not recollect their dreams on awaking; and they might both dream and recollect their dreams immediately upon awaking, yet afterwards suffer the remembrance of them to slip out of their memory. We do not advance this, therefore, as a certain fact concerning dreaming; we are rather inclined to think it a mistake.

But though it appears to be by no means certain that any of the human race are through the whole of life absolute strangers to dreaming; yet it is well known that all men are not equally liable to dream. The same person dreams more or less at different times; and as one person may be more exposed than another to those circumstances which promote this exercise of fancy, one person may therefore dream more than another. The same diversity will naturally take place in this as in other accidents to which mankind are in general liable.

4. Though in dreams imagination appears to be free from all restraint, and indulges in the most wanton freaks; yet it is generally agreed, that the imaginary transactions of the dreamer bear always some relation to his particular character in the world, his habits of action, and the circumstances of his life. The lover, we are told, dreams of his mistress; the miser of his money; the philosopher renews his researches in sleep often with the same pain and fatigue as when awake; and even the merchant, at times, returns to balance his books, and computes the profits of an adventure, when slumbering on his pillow. And not only do the more general circumstances of a person's life influence his dreams; his passions and habits are nearly the same when asleep as when awake. A person whose habits of life are virtuous, does not in his dreams plunge into a series of crimes; nor are the vicious reformed when they pass into this imaginary world. The choleric man finds himself offended by slight provocations as well in his dreams as in his ordinary intercourse with the world, and a mild temper continues pacific in sleep.

5. The character of a person's dreams is influenced by his circumstances when awake in a still more unaccountable manner. Certain dreams usually arise in the mind after a person has been in certain situations. Dr Beattie relates, that he once, after riding 30 miles in a high wind, passed a part of the succeeding night in dreams beyond description terrible. The state of a person's health, and the manner in which the vital functions are carried on, have a considerable influence in determining the character of dreams. After too full a meal, or after eating of an unusual sort of food, a person is very apt to be harassed with dreams.

6. In dreaming, the mind for the most part carries on no intercourse through the senses with surrounding objects. Touch a person gently who is asleep, he feels not the impression. You may awake him by a smart blow; but when the stroke is not sufficiently violent to awake him, he remains insensible of it. We speak softly beside a person asleep without fearing that he overhear us. His eyelids are shut; and even though light should fall upon the eyeball, yet still his powers of vision are not wakened to active exertion, unless the light be so strong as to rouse him from sleep. He is insensible both to sweet and to disagreeable smells. It is not easy to try whether his organs of taste retain their activity, without awakening him; yet from analogy it may be presumed that these too are inactive. With respect to the circumstances here enumerated, it is indifferent whether a person be dreaming or buried in deep sleep.

Yet there is one remarkable fact concerning dreaming, which may seem to contradict what has been here asserted. In dreams we are liable not only to speak aloud in consequence of the suggestions of imagination, but even to get up, and walk about and engage in little enterprises, without awaking. Now, as we are in this instance so active it seems that we cannot be then insensible of the presence of surrounding objects. The sleepwalker is really sensible in a certain degree of the presence of the objects around him; but he does not attend to them with all their circumstances, nor do they excite in him the same emotions as if he were awake. He feels no terror on the brink of a precipice; and in consequence of being free from fear, he is also without danger in such a situation unless suddenly awaked. This is one of the most inexplicable phenomena of dreaming.

There is also another fact not quite consonant with what has been above mentioned. It is said, that in sleep a person will continue to hear the noise of a cataract in the neighbourhood, or regular strokes with a hammer, or any similar sound sufficiently loud, and continued uninterruptedly from before the time of his falling asleep. We know not whether he awakes on the sudden cessation of the noise. The fact is asserted on sufficient evidence: it is curious. Even when awake, if very deeply intent on any piece of study, or closely occupied in business, the sound of a clock striking in the neighbourhood, or the beating of a drum, will escape us unnoticed; and it is therefore the more surprising that we should thus continue sensible to sounds when asleep.

7. Not only do a person's general character, habits of life, and state of health, influence his dreams; but those concerns in which he has been most deeply interested during the preceding day, and the views which have arisen most frequently to his imagination, very often afford the subjects of his dreams. When I look forward with anxious expectation towards any future event, I am likely to dream either of the disappointment or the gratification of my wishes. Have I been engaged through the day, either in business or amusements which I have found exceedingly agreeable, or in a way in which I have been extremely unhappy; either my happiness or my misery is likely to be renewed in my dreams.

8. Though dreams have been regarded among almost all nations through the world, at least in some periods of their history, as prophetic of future events; yet it does not appear that this popular opinion has been established on good grounds. Christianity, indeed, teaches us to believe, that the Supreme Being may, and actually does, operate on our minds, and influence at times the determinations of our will, without making us sensible of the restraint to which we are thus subjected. And, in the same manner, no doubt, the suggestions which arise to us in dreams, may be produced. The imaginary transactions in which we are then engaged, may be such as are actually to occupy us in life; the strange and seemingly incoherent appearances which are then presented to the mind's eye, may allude to some events which are to befal ourselves or others. It is, therefore, by no means impossible, or inconsistent with the general analogy of nature, that dreams should have a respect to futurity. We have no reason to regard the dreams which are related in the Holy Scriptures to have been prophetic of future events, as not inspired by Heaven, or to laugh at the idea of a prophetic dream as absurd or ridiculous.

Yet it would be too much to allow to dreams all that importance which has been ascribed to them by the priesthood among heathen nations, or by the vulgar among ourselves. We know how easily ignorance imposes on itself, and what arts imposture adopts to impose upon others. We cannot trace any certain connexion between our dreams and those events to which the simplicity of the vulgar pretends that they refer. And we cannot, therefore, if disposed to confine our belief to certain or probable truths, join with the vulgar in believing them really referable to futurity.

9. It appears that the brutes are also capable of dreaming. The dog is often observed to start suddenly up in his sleep, in a manner which cannot be accounted for in any other way than by supposing that he is roused by some impulse received in a dream. The same thing is observable of others of the inferior animals. That they should dream, is not an idea inconsistent with what we know of their economy and manners in general. We may, therefore, consider it as a pretty certain truth, that many, if not all, of the lower species are liable to dream as well as human beings.

It appears, then, that in dreaming we are not conscious of being asleep; that to a person dreaming, his dreams seem realities; that though it be uncertain whether mankind are all liable to dreams, yet it is well known that they are not all *equally* liable to dream: that the nature of a person's dreams depends in some measure on his habits of action, and on the circumstances of his life: that the state of the health too, and the manner in which the vital functions are carried on, have a powerful influence in determining the character of a person's dreams: that in sleep and in dreaming, the senses are either absolutely inactive, or nearly so: that such concerns as we have been very deeply interested in during the preceding day, are very likely to return upon our minds in dreams in the hours of rest: that dreams may be rendered prophetic of future events; and therefore, wherever we have such evidence of their having been prophetic as we would accept on any other occasion, we cannot reasonably reject the fact on account of its absurdity; but that they do not appear to have been actually such, in those instances in which the superstition of nations, ignorant of true religion, has represented them as referring to futurity, nor in those instances in which they are viewed in the same light by the vulgar among ourselves; and, lastly, that dreaming is not a phenomenon peculiar to human nature, but common to mankind with the brutes.

We know of no other facts that have been fully ascertained concerning *dreaming*. But we are by no means sufficiently acquainted with this important phenomenon in the history of mind. We cannot tell by what laws of our constitution we are thus liable to be so frequently engaged in imaginary transactions, nor what are the particular means by which the delusion is accomplished. The delusion is indeed remarkably strong. One will sometimes have a book presented to him in a dream, and fancy that he reads; and actually enter into the nature of the imaginary composition before him, and even remember, after he awakes, what he knows that he only fancied himself reading (A). Can this be delusion? If delusion, how or for what purposes is it produced? The mind, it would appear, does not, in sleep, become inactive like the body; or at least is not always inactive while we are asleep. When we do not dream, the mind must either be inactive, or the connexion between the mind and the body must be considered as in some manner suspended: and, when we dream, the mind, though it probably acts in concert with the body, yet does not act in the same manner as when we are awake. It seems to be clouded or bewildered, in consequence of being deprived for a time of the service of the senses. Imagination becomes more active and more capricious: and all the other powers, especially judgment and memory, become disordered and irregular in their operation.

Various theories have been proposed to explain what appears here most inexplicable. The ingenious Mr Baxter,

---

(A) The writer of this article has been told by a respectable old gentleman of his acquaintance, since dead, that he had frequently dreams of this nature. The fact may therefore be considered as unquestionable.

Baxter, in his Treatise on the Immateriality of the Human Soul, endeavours to prove that dreams are produced by the agency of some spiritual beings, who either amuse or employ themselves seriously in engaging mankind in all those imaginary transactions with which they are employed in dreaming. This theory, however, is far from being plausible. It leads us entirely beyond the limits of our knowledge. It requires us to believe without evidence. It is unsupported by any analogy. It creates difficulties still more inexplicable than those which it has been proposed to remove. Till it appear that our dreams cannot possibly be produced without the interference of other spiritual agents, possessing such influence over our minds as to deceive us with fancied joys, and involve us in imaginary afflictions, we cannot reasonably refer them to such a cause. Besides, from the facts which have been stated as well known concerning dreams, it appears that their nature depends both on the state of the human body and on that of the mind. But were they owing to the agency of other spiritual beings, how could they be influenced by the state of the body? Those must be a *curious* set of spiritual beings who depend in such a manner on the state of our corporeal frame. Better not to allow them existence at all, than to place them in such a dependence.

Wolfius, and after him M. Formey, have supposed, that dreams never arise in the mind, except in consequence of some of the organs of sensation having been previously excited. Either the ear or the eye, or the organs of touching, tasting, or smelling, communicate information, somehow, in a tacit, secret manner; and thus partly rouse its faculties from the lethargy in which they are buried in sleep, and engage them in a series of confused and imperfect exertions. But what passes in dreams is so very different from all that we do when awake, that it is impossible for the dreamer himself to distinguish, whether his powers of sensation *perform* any part on the occasion. It is not necessary that imagination be always excited by sensation. Fancy, even when we are awake, often wanders from the present scene. *Absence of mind* is incident to the studious: the poet and the mathematician many times forget where they are. We cannot discover from any thing that a person in dreaming displays to the observation of others, that his organs of sensation take a part in the imaginary transactions in which he is employed. In those instances, indeed, in which persons asleep are said to hear sounds; the sounds which they hear are said also to influence, in some manner, the nature of their dreams. But such instances are singular. Since then it appears that the person who dreams is himself incapable of distinguishing either during his dreams, or by recollection when awake, whether any new impressions are communicated to him in that state by his organs of sensation; that even by watching over him, and comparing our observations of his circumstances and emotions, in his dreams, with what he recollects of them after awaking, we cannot, except in one or two singular instances, ascertain this fact; and that the mind is not incapable of acting while the organs of sensation are at rest, and on many occasions refuses to listen to the information which they convey; we may, without hesitation, conclude, that the theory of Wolfius and Formey has been too hastily and incautiously advanced.

Other physiologists tell us, that the mind, when we dream, is in a state of *delirium*. Sleep, they say, is attended with what is called a *collapse* of the brain; during which either the whole or a part of the nerves of which it consists, are in a state in which they cannot carry on the usual intercourse between the mind and the organs of sensation. When the whole of the brain is in this state, we become entirely unconscious of existence, and the mind sinks into inactivity: when only a part of the brain is *collapsed*, as they term it, we are then neither asleep nor awake, but in a sort of delirium between the two. This theory, like the last mentioned, supposes the mind incapable of acting without the help of sensation: it supposes that we know the nature of a state of which we cannot ascertain the phenomena: it also contradicts a known fact, in representing dreams as confused images of things around us, not fanciful combinations of things not existing together in nature or in human life. We must treat it likewise, therefore, as a baseless fabric.

In the last edition of this work, a theory somewhat different from any of the foregoing was advanced in this subject. It was observed, that the nervous fluid, which is allowed to be secreted from the blood by the brain, appears to be likewise absorbed from the blood by the extremities of the nerves. It was farther advanced, that as this fluid was to be considered as the principle of sensibility; therefore, in all cases in which a sufficient supply of it was not absorbed from the blood by the extremities of the nerves, the parts of the body to which those nerves belonged, must be, in some degree, deprived of sensation. From these positions it was inferred, that as long as impressions of external objects continue to communicate a certain motion from the sentient extremities of the nerves to the brain,—so long we continue awake; and that, when there is a deficiency of this vital fluid in the extremities of the nerves, or when from any other cause it ceases to communicate to the brain the peculiar motion alluded to, we must naturally fall asleep, and become insensible of our existence. It followed of consequence, that, in sleep, the nervous fluid between the extreme parts of the nerves and the brain must either be at rest, or be deficient, or be prevented by some means from passing into the brain: and it was concluded, that whenever irregular motions of this fluid were occasioned by an internal cause, *dreaming* was produced. In this manner it appeared that we might be deceived with regard to the operation of any of the senses;—so as to fancy that we saw objects not actually before us,—to hear imaginary sounds,—to taste,—to feel, and to smell in imagination. The instances of visions which will sometimes arise, and as it were swim before us when awake, though our eyes be shut, *tinnitus aurium*, which is often a symptom in nervous diseases, and the strange feelings in the case of the amputated limb, were produced in proof of this theory, and applied so as to confirm it.

We are still of opinion, that this theory is more plausible, and goes farther toward explaining the nature of *dreaming*, and the manner in which *dreams* are produced, than any other with which we are acquainted. But it must be confessed, upon a review, that even in it there is too much supposition. The nature of the nervous fluid is but imperfectly known, and even its existence not very fully ascertained. The nature of the connexion by which the soul and body are united, seems to be almost beyond our comprehension. And till we can apply experiment and observation in a better manner to this branch of physiology, it must undoubtedly remain unknown. To something mysterious in the nature of that connexion, the delusion produced in dreams is in all probability owing.

Amid this uncertainty with respect to the manner in which the powers of mind and body perform their functions in dreaming, it is pleasing to find that we can, however, apply to useful purposes the imperfect knowledge which we have been able to acquire concerning this series of phenomena. Our dreams are affected by the state of our health, by the manner in which we have passed the preceding day, by our general habits of life, by the hopes which we most fondly indulge, and the fears which prevail most over our fortitude when we are awake. From recollecting our dreams, therefore, we may learn to correct many improprieties in our conduct; to refrain from bodily exercises, or from meats and drinks that have unfavourable effects on our constitution; to resist, in due time, evil habits that are stealing upon us; and to guard against hopes and fears which detach us from our proper concerns, and unfit us for the duties of life. Instead of thinking what our dreams may forebode, we may with much better reason reflect by what they have been occasioned, and look back to those circumstances in our past life to which they are owing. The sleep of innocence and health is sound and refreshing; their dreams delightful and pleasing. A distempered body, and a polluted or perturbed mind, are haunted in sleep with frightful, impure, and unpleasing dreams.

Some very beautiful fables have been written both by ancients and moderns in the form of dreams. The *Somnium Scipionis* is one of the finest of Cicero's compositions. He who shall carefully peruse this piece, with Macrobius's commentary upon it, will acquire from them considerable knowledge of ancient philosophy. In the periodical publications, which have diffused so much elegant and useful knowledge through Britain, the Tatlers, Spectators, Guardians, &c. we find a number of excellent dreams. Addison excelled in this way of writing. The public are now less partial to this species of composition than they formerly were.

Dr Beattie, in his valuable essay on the subject of dreaming, quotes a very fine one from the Tatler, and gives it due praise.

DREDGING, a process for removing mud and other deposited matters from the beds of rivers, canals, &c. See SUPPLEMENT.

DRELINCOURT, CHARLES, minister of the reformed church at Paris, was born at Sedan in 1593, where his father enjoyed a considerable post. He had all the qualifications that compose a respectable clergyman; and though he defended the Protestant cause against the Romish religion, was much esteemed even among the Catholics. He is best known in England by his Consolations against the Fears of Death, which work was translated, and is often printed. He married the daughter of a rich merchant at Paris, by whom he had 16 children. His third son, professor of physic at Leyden, was physician to the prince and princess of Orange before their accession to the crown of England. Bayle has given him a high character. Mr Drelincourt died in 1660.

DRENCH, among farriers, a physical potion for horses. The ingredients for this purpose are to be beat coarsely, and either mingled with a decoction or with wine. Then let all infuse about a quarter of an hour, and give it to the horse with a horn after he has been tied up two hours to the rack.

DREPANE, the ancient name of Corcyra, from the curvity of its figure, resembling a sickle.

DREPANE, (*Drepanum*) in *Ancient Geography*, a town of Bithynia, situated between the Sinus Astacenus and the Bosphorus Thracius; called *Helenopolis* by Constantine, in honour of his mother. (Nicephorus Callistus).

DREPANUM, in *Ancient Geography*, the promontory Rhium in Achaia; so called because bent in the manner of a sickle. Another *Drepanum* on the Arabic gulf, on the side of Egypt. A third on the north side of Crete, situated between Cydonia and the Sinus Amphimallus. A fourth on the west side of Cyprus. A fifth, a promontory of Cyrenaica, on the Mediterranean.

DREPANUM, *-i;* or *Drepana, -orum;* a town and port on the west side of Sicily, and to the west of Mount Eryx; *Drepanitani* the people. Now *Trepano*, a city and port town on the westmost point of Sicily. E. Long. 12. 8. N. Lat. 38. 0.

DRESDEN, the capital city of the electorate of Saxony in Germany. It is seated on the river Elbe, which divides it into two parts. One part is called *Old Dresden*, and the other the *New Town*, in the German language *New Stadt*. They are joined together by a stone bridge, supported by 19 piers, and 630 paces in length. As this bridge was too narrow for the crowds of people that were continually passing and repassing, King Augustus in 1730, caused two walks for foot passengers to be built, one on each side, in a very wonderful manner; the one for those that go into the city, and the other for those that return back. These are bordered with iron pallisadoes of curious workmanship. This noble bridge was much injured by the French in 1813. Dresden is surrounded by fortifications; and was said to contain 45,000 inhabitants in 1811.

All the buildings of this city are constructed with square freestone, and are almost all of the same height. They have stone from the neighbourhood of Pirna, about ten miles from this city, which is readily brought down the Elbe. In general the houses are high and strong; the streets wide, straight, well paved, clean, and well illuminated in the night; and there are large squares, disposed in such a manner, that Dresden may pass for one of the handsomest cities in the world. The king's palace is a magnificent structure, and abounds in many valuable curiosities both of nature and art. The collection of pictures is reckoned one of the finest that exists, and is valued at 500,000l.

Above 700 men are here constantly employed in the porcelain manufacture, the annual expence of which is estimated at no more than 80,000 crowns; and the manufacture yields to the king 200,000 crowns yearly, besides

besides the magnificent presents which he occasionally makes, and the large quantity reserved for the use of his household.

The other most considerable article of trade is silver, of which the mines near Friburg produce every 15 days near the value of 20,000 dollars. The metal is brought into the city in ingots, where it is immediately coined and delivered to the proprietors.

The court of Dresden is one of the most remarkable in Europe for splendour and profusion. Six thousand five hundred ducats are yearly allowed for comfits and similar articles, which is near twice as much as the king of Prussia allows for the whole expence of his table. The revenues of the king of Saxony are estimated at about 900,000l.; which arise from the taxes on lands, and a capitation on all males as soon as they commence an apprenticeship or begin to work. People of a higher rank are taxed according to their class, and are liable to be called to account if they assume not an exterior appearance correspondent to the extent of their fortune. Every foreigner pays capitation after residing six months in the country. The Jews are taxed at 50, their wives at 30, and their children at 20 dollars. There is also an excise on all eatables and liquors; and 10 per cent. is levied out of the incomes of the people.

Though this city lies in a low situation, yet it hath agreeable prospects. It is supplied with a prodigious quantity of provisions, not only out of the neighbourhood, but from Bohemia, which are brought every market day, which is once a-week. E. Long. 13. 34. N. Lat. 51. 12.

DRESSING of Hemp and Flax. See *Flax-Dressing.*

Dressing of Meats, the preparing them for food by means of culinary fire.

The design of dressing is to loosen the compages or texture of the flesh, and dispose it for dissolution and digestion in the stomach. Flesh not being a proper food without dressing, is alleged as an argument that man was not intended by nature for a carnivorous animal.

The usual operations are roasting, boiling, and stewing.—In roasting, it is observed, meat will bear a much greater and longer heat than either in boiling or stewing; and in boiling, greater and longer than in stewing. The reason is, that roasting being performed in the open air, as the parts begin externally to warm, they extend and dilate, and so gradually let out part of the rarefied included air, by which means the internal succussions, on which the dissolution depends, are much weakened and abated. Boiling being performed in water, the pressure is greater, and consequently the succussions to lift up the weight are proportionably strong, by which means the coction is hastened; and even in this way there are great differences; for the greater the weight of water, the sooner is the business done.

In stewing, though the heat be infinitely short of what is employed in the other ways, the operation is much more quick, because performed in a close vessel, and full; by which means the succussions are oftener repeated, and more strongly reverberated. Hence the force of Papin's digester; and hence an illustration of the operation of digestion.

Boiling, Dr Cheyne observes, draws more of the rank strong juices from meat, and leaves it less nutritive, more diluted, lighter, and easier of digestion: roasting, on the other hand, leaves it fuller of the strong nutritive juices, harder to digest, and needing more dilution. Strong, grown, and adult animal food, therefore, should be boiled, and the younger and tenderer roasted.

Dressing, in *Surgery*, the treatment of a wound, or any disordered part. The apparatus of dressing consists of dossils, tents, plasters, compresses, bandages, bands, ligatures, and strings. See Surgery *Index*.

DREVET, Peter, the Younger, an eminent French engraver, was a member of the royal academy of painting and sculpture; and died at Paris in 1739, at 42 years of age. His portraits are neat and elegant, but laboured to the last degree. He particularly excels in representing lace, silk, fur, velvet, and other ornamental parts of dress. His father was excellent in the same art, and had instructed, but was surpassed by the son. The younger Drevet did not confine himself to portraits. We have several historical prints by him, which in point of neatness and exquisite workmanship are scarcely to be equalled. His most esteemed and best historical print is very valuable; but the first impressions of it are rarely to be met with: it is The Presentation of Christ in the Temple; a very large plate, lengthwise, from Louis de Bologna. The following deserve also to be particularized: The Meeting of Abraham's Servant with Rebecca at the Well; a large upright plate, from Ant. Coypel: and Abraham, with his son Isaac on the Altar, the same, from the same, date 1707; the first impressions of which are before the work upon the right thigh of Isaac was altered, the curved lines from the button almost down to the knee being in those impressions arched downwards, but in posterior ones arched upwards. Among his portraits, the two following are justly held in the highest estimation: M. Bossuet, bishop of Meaux; a whole length figure standing, a middling sized upright plate, from Rigaud: and Samuel Bernard; a whole length figure sitting in a chair, a large upright plate. The first impressions of the last are, before the words *Conseiller d'Etat* were inserted upon the plate.

DREUX, a town in the Isle of France, remarkable for its antiquities; and for the battle which was fought in December 1562 between the Papists and the Protestants, in which the latter were defeated. Some think it took its name from the priests of Gaul, called the *Druids*, in the times of Paganism. It consists of two parishes, St Stephen's, and Notre Dame, called the *great church*, which is pretty well built. It is seated on the river Blaise, at the foot of a mountain, on which is a ruined castle. Population 5450. E. Long. 1. 27. N. Lat. 48. 44.

DRIEPER, or Dnieper, a river of Russia, which rises in the forest of Volkonski, near the source of the Volga, about 100 miles from Smolensko. It passes by Smolensko and Mohilef, separates the Ukraine from Poland, flows by Kiof, and falls into the Black sea between Otzakof and Kinburn. By the acquisition of the province of Mohilef, its whole course is now included within the Russian territories. It begins to be navigable at a little distance above Smolensko, though in some seasons of the year it is so shallow near the town, that the goods must be transported upon rafts and small flat-bottomed boats.

DRIFT, in *Navigation*, the angle which the line of a ship's motion makes with the nearest meridian, when she drives with her side to the wind and waves, and is not governed by the power of the helm: it also implies the distance which the ship drives on that line.

A ship's way is only called *drift* in a storm; and then when it blows so vehemently as to prevent her from carrying any sail, or at least restrains her to such a portion of sail as may be necessary to keep her sufficiently inclined to one side, that she may not be dismasted by her violent labouring produced by the turbulence of the sea.

Drift, in mining, a passage cut out under the earth betwixt shaft and shaft, or turn and turn; or a passage or way wrought under the earth to the end of a meer of ground, or part of a meer.

Drift-Sail, a sail used under water, veered out right a-head by sheets, as other sails are. It serves to keep the ship's head right upon the sea in a storm, and to hinder her from driving too fast in a current.

DRILL, in *Mechanics*, a small instrument for making such holes as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners.

Drill, or *Drill-Box*, a name given to an instrument for sowing land in the new method of horsehoeing husbandry. See Agriculture *Index*.

Drill-Sowing, a method of sowing grain or seed of any kind, so that it may all be at a proper depth in the earth, which is necessary to its producing healthful and vigorous plants. For this purpose a variety of drill ploughs have been invented and recommended. See Agriculture *Index*.

DRILLING is popularly used for exercising soldiers. The word is derived from the French *drille*, which signifies a *raw soldier*.

DRIMYS, a genus of plants changed by Murray, in the 14th edit. of *Syst. Veget.* to Wintera; which see in Botany *Index*.

DRINK, a part of our ordinary food in a liquid form. See Dietetics, Supplement.

The general use of drink is to supply fluid; facilitate solution; in consequence of that, to expede the evacuation of the stomach, and promote the progress of the aliment through the intestines: for, by the contraction of the longitudinal fibres of the stomach, the pylorus is drawn up, and nothing but fluid can pass; which, by its bulk, makes a hurried progress through the intestines, and so determines a greater excretion by stool, as less then can be absorbed by the lacteals. Hence a large quantity of common water has been found purgative; and, *cæteris paribus*, that aliment which is accompanied with the largest proportion of drink, makes the largest evacuation by stool. Here a question has risen, about where the feculent part of the aliment is first remarkably collected. It is commonly thought to be in the great guts: but undoubtedly it often begins in the lower part of the ileum, especially when the drink is in a small proportion, and when the progress of the aliment is slow; for when the contents of the guts are very fluid, they are quickly pushed on, and reach the great guts before they deposite any feculency. Another effect of drink is, to facilitate the mixture of the lymph, refluent from every part of the system, with the chyle. In the blood-vessels, where all must be kept fluid in order to proper mixture, drink increases the fluidity, and gives tension, by its bulk, without concomitant acrimony or too much elasticity, and so strength and oscillatory motion: hence drink contributes to sanguification, as sometimes food gives too dense a nutriment to be acted upon by the solids; and hence also we can see how drink promotes the secretions. These are the effects of drink in general; but what has been said must be taken with some limitations; for the more liquid the food, it is sooner evacuated, and less nourishment is extracted. Hence drink is, in some degree, opposed to nourishment; and so, *cæteris paribus*, those who use least drink are most nourished.

All the effects of drink above mentioned are produced by simple water; and it may be said, that other liquors are fit to drink in proportion to the water they contain. Water, when used as drink, is often impregnated with vegetable and farinaceous substances; but, as drinks, these impregnations are of little consequence: they add, indeed, a little nourishment; but this is not to be regarded in a healthy state. Sometimes we impregnate water with the *fructus acido-dulces*; and then, indeed, it acquires other qualities, of considerable use in the animal economy. All drinks, however, may be reduced to two heads: first, pure water, or where the additional substances give no additional virtue; secondly, the *fermentatæ*. Of the first we have already spoken; and the latter have not only the qualities of the first, but also qualities peculiar to themselves.

Fermented liquors are more or less poignant to the taste, and better calculated to quench thirst. Thirst may be owing to various causes: First, To defect of fluid in the system, which occasions a scanty secretion in the mouth, fauces, and stomach; the dryness of the mouth and fauces will also in this case be increased, by their continual exposure to the perpetual flux and reflux of the evaporating air. Secondly, Thirst depends on a large proportion of solid viscid food. Thirdly, On an alkalescent aliment, especially if it has attained any thing of the putrefactive taint. Fourthly, On the heat of the system; but this seems to operate in the same manner as the first cause, giving a sense of dryness from its dissipation of the fluids. The fermented liquors are peculiarly adapted for obviating all these causes; stimulating the mouth, fauces, and stomach, to throw out the saliva and gastric liquor by their poignancy; by their acescency they are fitted to destroy alkalescent acrimony, to quench thirst from that cause; by their fluidity they dilute viscid food; though here, indeed, they answer no better than common water. In two ways they promote the evacuation by stool, and progress through the intestines: first, by their fluidity and bulk; secondly, by their acescency, which, uniting with the bile, forms the peculiar stimulus formerly mentioned. Carried into the blood-vessels, in so far as they retain any of the saline nature, they stimulate the excretories, and promote urine and sweat; correcting thus alkalescency, not only by mixture, but dissipation of the degenerated fluids.

Many physicians, in treating of fermented liquors, have

have only mentioned these qualities, rejecting their nutritious virtue, which certainly ought to be taken in; though by expediting the evacuation by stool they make less of the nutritious parts of the aliment to be taken up, and by stimulating the excretories make these nutritious parts to be for a shorter time in the system. All these and many more effects arise from fermented liquors. Their acescency sometimes promotes the disease of acescency, by increasing that of vegetables, acting as a ferment, and so producing flatulency, purging, cholera, &c.: so that, with vegetable aliment, as little drink is necessary, the most innocent is pure water; and it is only with animal food that fermented liquors are necessary. In warmer climates, *fermentatæ* would seem necessary to obviate alkalescency and heat. But it should be considered, that though fermented liquors contain an acid, yet they also contain alcohol; which, though it adds stimulus to the stomach, yet is extremely hurtful in the warmer climates, and wherever alkalescency prevails in the system. Nature in these climates has given men an appetite for water impregnated with acid fruits, *e.g.* sherbet: but the use of this needs caution, as in these countries they are apt to shun animal food, using too much of the vegetable, and often thus causing dangerous refrigerations, choleras, diarrhœas, &c.

Of varieties of fermented liquors. We shall only mention here the chief heads on which these varieties depend. First, They are owing to the quality of the subject, as more or less viscid; and to its capacity also of undergoing an active fermentation, although perhaps the more viscid be more nutritious. Hence the difference between ales and wines; by the first meaning fermented liquors from *farinacea*, by the second from the fruits of plants. It depends, secondly, On the acerbity, acidity, nature, and maturation, of the fruit. Thirdly, The variety depends on the conduct of the fermentation. In general, fermentation is progressive, being at first active and rapid, detaching the fixed air or *gas sylvestre*, at the same time acquiring more acid than before. These qualities of flatulency and acidity remain for some time: but as the fermentation goes on, the liquor becomes more perfect, no air is detached and alcohol is produced; so that fermented liquors differ according to the progress of the fermentation, and have different effects on the system. When fermentation is stopped before it comes to maturity, though naturally it proceeds in this way, yet by addition of new ferment it may be again renewed with a turbid intestine motion.

DRIVERS, among sportsmen, a machine for driving pheasant powts, consisting of good strong osier wands, such as the basketmakers use; these are to be set in a handle, and twisted or bound with small osiers in two or three places. With this instrument the sportsman drives whole eyes of young powts into his nets. See the next article.

DRIVING, among sportsmen, a method of taking pheasant powts. It is thus: The sportsman finds out the haunts of these birds; and having fixed his nets there, he calls them together by a pheasant call, imitating the voice of the dam; after this he makes a noise with his driver, which will make them run a little way forward in a cluster; and this he is to repeat till he has made sure of them, which an expert sportsman never fails to do, by driving them into his nets.

DRIVING, in *Metallurgy*, is said of silver, when, in the operation of refining, the lead being burnt away, the remaining copper rises upon its surface in red fiery bubbles.

DRIVING, in the sea language, is said of a ship, when an anchor being let fall will not hold her fast, nor prevent her sailing away with the wind or tide. The best help in this case is to let fall more anchors, or to veer out more cable; for the more cable she has out, the safer she rides. When a ship is a-hull or a-try, they say she drives to leeward.

DROGHEDA, by the English called *Tredah*, a town of Ireland, in the province of Leinster and county of Lowth, and situated on the bay of the same name, in W. Long. 6. 17. N. Lat. 53. 45. It was formerly very remarkable for its situation and strength. In consequence of this it was much distinguished by the old English monarchs. Edward II. granted it a market and fair; and to these were added other great privileges in succeeding ages, particularly the right of coinage. It was bravely defended against the rebels in 1641. After the cessation of arms, it was taken by the duke of Ormond and the earl of Inchiquin: but was retaken by Cromwell in 1649. At this time it suffered so much, that for a long time after it remained almost in ruins. The buildings were exceedingly shattered; and the town being taken by storm, not only the garrison, but the inhabitants, men, women, and children, were mostly put to the sword. By degrees, however, it recovered, and is at present a large place, with 15,000 inhabitants. It is a town and county; and sends one member to the imperial parliament. It has a great share of inland trade, and an advantageous commerce with England.

Drogheda is perhaps one of the strongest instances that can be mentioned of the inestimable benefit of a river in any degree navigable; for though the Boyne is not capable of carrying vessels of a greater size than barges or pretty large boats, yet the conveniency that this affords of conveying coals by water carriage through a great extent of country, produced an intercourse between this place and Whitehaven in Cumberland, to which the revival of its commerce has been in a great measure owing.

DROITWITCH, a town of Worcestershire in England, noted for excellent white salt made from the salt springs in its neighbourhood. It sends two members to parliament. Population 2079. W. Long. 2. 16. N. Lat. 52. 20.

DROMEDARY. See CAMELUS, MAMMALIA *Index*.

DROME, a department of France, on the east side of the Rhone. It contained 253,000 inhabitants in 1815, including 34,000 Protestants. It is hilly, and abounds in wood. Wine is a staple produce, and it imports corn. Valence is the chief town.

DROMORE, a town of Ireland, in the county of Down. It is a very ancient town, and the seat of a bishopric. The see was founded by St Colman in the 6th century. It was refounded by King James I. who, by his charters (now preserved in the Rolls office) granted it very great and uncommon privileges. Among other marks of royal favour, he distinguishes the bishops of this see by the style of "A. B. by Divine Providence bishop of Dromore:" whereas all other bishops in Ireland, except those of Meath and Kildare, are styled, "by Divine Permission." This see, although the least in its extent, is so complete and perfect in its endowment and jurisdiction, that it need not envy the greatest and most opulent.

DRONE, a kind of large bees which make their appearance in hives about the month of May, but never work nor prepare any honey: and are at last all killed by the rest. Under the article BEE, N° 20. *et seq.* we have given an account of the experiments of Messrs Debraw and Schirach concerning these animals: but in a Treatise upon Bees and their Management by Mr Bonner near Berwick on Tweed, who has made the management of bees his study for a great number of years, this author dissents from the opinions of the above-mentioned gentlemen for the following reasons, which we shall give in his own words. Having mentioned the opinions of Mr Debraw concerning the little drones mentioned in the article above mentioned, he proceeds thus:

"1. Can it be thought that the prying eyes of multitudes in many generations should have escaped seeing those little drones (they being, according to his account, vastly numerous) thrust their posterior parts into the cells? Yet none ever saw them do it except himself; while many have seen the queen do it, though but a single bee.

"2. It is well known the queen is very long behind the wings, wise nature having made her so, in order that she might thrust her posterior part into the cells, and yet her wings scarcely touch them, nor receive the least injury. If these imaginary little drones had to thrust their posterior parts into the cells in the same manner as the queen, certainly their wings would have been made in the same manner short, and their posterior parts long and taper, which is not the case. Whereas were a bee of any kind (the queen excepted) to thrust its hinder part into a common cell, its wings or coats would come over its head, and be antic-like, and injure both them and its body. Besides, I scarcely think they could get into the common cells that way at any rate for want of room.

"3. Mr Debraw grants, that without a queen or eggs bees will not begin to work, as well knowing they cannot propagate their species without her; and yet he says, those bees which wanted little drones began to work, and the queen laid eggs, and all went forward, till they were not impregnated, and then they gave over work, and deserted the hive. Certainly those sagacious creatures would have been as sensible that they wanted drones at the very first, when they were put into the hive, and that they could not do without them, as they are sensible when they want a queen, and that it is needless to begin work without her; and it might be added that two different kinds of drones in one hive does not appear to be probable, or serve any end.

"But I shall narrate some of my own experiments on that head, which will put it, I hope, beyond dispute: On September 1st, I had a hive breeding fast; I took out all her bees (among which were only four large drones, which I killed), and I put them in a hive that had nothing in her but empty combs: I waited ten days, when, by looking between the combs, I saw her have new sealed up maggots in her cells. I then took all her bees out, and shook them into a tub full of water, and recovered them gradually; and when recovering, I pressed every one of them, in order to see if I could find any of those little drones, but could not find one; but all and every one of them had stings: they were in number 3000. After which I searched the hive I took them out of, and cut out all her combs that had eggs in them, and found they had new laid eggs, four days old eggs, and maggots in them. I then recovered the queen and all her bees, and put in the same hive again, which had not an egg in her now, and waited other twenty days, and saw her in fine days working very well; a sure indication she was breeding again. I then turned her up, and cut out one of her brood combs, and saw in it new laid eggs, four days old eggs, and maggots and some young almost fit for emerging out of their cells.

"The very same day I made a further experiment: I had a hive which I saw had some brood combs in her, but she had not had a large drone for four weeks before in her; she had not above 500 bees in her, which favoured me, because few in number. I took the hive into a close place in my house, in order that not a single bee should escape me; I then took all the bees out of her, and immersed them in water; and when recovering, I pressed every one of them, and each bee had a sting, as in the former experiment.

"I think the above experiments may satisfy any judicious person, that there is no such thing in being as little drones, unless in Mr Debraw's brain. And if Mr Debraw, who can find 57 in a small swarm of bees, will send me the odd seven, I will send him one of my best hives for them, and he will scarcely think he is ill paid. I add, I never saw a hive in spring, however few bees in her, but she bred some, if she had a queen, though to be sure few in proportion to her bees.

"By this time the reader will be very ready, no doubt, to ask me the use of the drones. I beg to be excused on that head, as I have not the least idea of their use in a hive; they do not fecundate the qneen, for she can lay and breed too though she never see them. Their heat does not appear to me to be necessary for hatching the young, as they are mostly hatched before any are bred in a hive; and when drones are in the hive, the weather is so warm, and so many common bees in it, that they appear to have rather too much heat, by their lying out of the hives often.

"I have many times had good hives with few or no drones in them all the year; and Keys is quite wrong when he says a top swarm will not do without drones in her; for I am positive to the contrary, as in the summer 1785 I took off four swarms of mine own in one day with not a single drone in any of them, and they all throve well, and bred drones in themselves about four weeks after.

"Although I cannot say what use the drones are of to a hive (unless it be to help away with a great deal of her honey, which they are very good at), yet the best hives have them soonest in the year, they generally appearing in such about the latter end of May, and the bees put a period to their lives about Lammas, at which time I give them all the assistance I can. The way they kill them is thus: They pull and bite them with their teeth, and sting them also. I have seen great havock made of them in one day, as appeared by their lying dead before the door of the hive. But their most effectual way of killing them is their banishing them from the honeycombs; upon which the drones betake themselves to the under edges of the hives in great numbers, and to the board the hive stands on; and sometimes, though rare, I have even seen them come to the outside of the hive, and cluster there about the bulk of a man's hand. When they are banished thus, they are very dull and lifeless: and I have lifted up a hive from the board, and there they would have been sitting close on it, with scarcely three or four common bees among them; and I have trod to death 40 or more at a time.

"We may now take a view of the disadvantages attending the old, and also Mr Debraw's principles on bees, were they true; and next see how a hive of bees may be preserved from coming to ruin, according to my sentiments on them.

"1. The old principles on bees say, that without a queen or royal cell be in a hive, it will come to ruin.

"2. Mr Debraw's principles say, that without little drones be in a hive it will come to ruin.

"3. I say, if a hive have only new laid eggs in her (which may be easily got the greatest part of the year, in case she have none of her own) and common bees, she will find herself a queen, and so thrive.

"According to the old principle, it is easily seen that, in case a hive lose her queen, when there is no royal cell in her, and no queen can be got to put to her (neither of which can be expected but in June and July), she is entirely ruined.

"According to the Frenchman's scheme, there must be drones in a hive at all times of the year to fecundate the eggs, otherwise the hive is useless. Supposing his sentiments to be true (which, however, can by no means be admitted, seeing there is no such thing as little drones), how perplexed would the owner be to know when there were little drones in the hive! When he wanted to make an artificial swarm, he might bring off a queen and common bees with her; but how should he come to know whether there were any, or a sufficient quantity, of little drones among them, as they cannot be distinguished from the commons but by immersion and pressure, which would be intolerably troublesome, and next to killing the bees, and not at all practicable? All that could be done would be to hope the best, that there were little drones in her at any time of the year.

"I say, if a queen die in a hive, and that hive have some new-laid eggs in her, or some put to her, in case she have none of her own, she will nourish up some of these eggs to be a queen to herself: and also by taking out a queen and some commons out of a hive (without a single drone, large or small), and putting them in an empty hive, will make a swarm, and the old hive will breed herself a queen again, if she have eggs in her."

Drone-Fly, a two-winged insect, extremely like the common drone bee, whence also the name.

DROPS, in *Meteorology*, small spherical bodies which the particles of fluids spontaneously form themselves into when let fall from any height. The spherical figure, the Newtonian philosophers demonstrate to be the effect of corpuscular attraction; for considering that the attractive force of one single particle of a fluid is equally exerted to an equal distance, it must follow that other fluid particles are on every side drawn to it, and will therefore take their places at an equal distance from it, and consequently form a round superfices. See the articles ATTRACTION, FLUID, and RAIN.

DROPS, in *Medicine*, a liquid remedy, the dose of which is estimated by a certain number of drops.

English DROPS, (*Guttæ Anglicanæ*,) a name given to a chemical preparation esteemed of great virtue against vapours and lethargic affections, and purchased at 5000l. by King Charles II. from the inventor Dr Goddard. The medicine appeared to be only a spirit drawn by the retort from raw silk, and afterwards rectified with oil of cinnamon, or any other essential oil; and was in reality no better than the common sal volatile oleosum, or any of the volatile spirits impregnated with an essential oil, except that it was less disagreeable than any of them to the taste.

DROPSY, in *Medicine*, an unnatural collection of water in any part of the body. See MEDICINE *Index*.

DROPWORT. See FILIPENDULA, BOTANY *Index*.

*Water-*DROPWORT. See OENANTHE, BOTANY *Index*.

DROSERA, ROS SOLIS, or *Sun-Dew*. See BOTANY *Index*.

DROWNING, signifies the extinction of life by a total immersion in water.

In some respects, there seems to be a great similarity between the death occasioned by immersion in water, and that by strangulation, suffocation by fixed air, apoplexies, epilepsies, sudden faintings, violent shocks of electricity, or even violent falls and bruises. Physicians, however, are not agreed with regard to the nature of the injury done to the animal system in any or all of these accidents. It is indeed certain, that in all the cases above mentioned, particularly in drowning, there is very often such a suspension of the vital powers as to us hath the appearance of a total extinction of them; while yet they may be again set in motion, and the person restored to life, after a much longer submersion than hath been generally thought capable of producing absolute death. It were to be wished, however, that, as it is now universally allowed, that drowning is only a suspension of the action of the vital powers, physicians could as unanimously determine the means by which these powers are suspended; because on a knowledge of these means, the methods to be used for recovering drowned persons must certainly depend.

Dr de Haen, who has written a treatise on this subject, ascribes this diversity of opinion among the physicians to their being so ready to draw general conclusions from a few experiments. Some, having never found water in the lungs, have thought that it never was there; and others, from its presence, have drawn a contrary conclusion. Some have ascribed the death which happens in cases of drowning to that species of apoplexy which arises from a great fulness of the stomach. But this opinion our author rejects, because in 13 dogs which he had drowned and afterwards dissected, no signs of such a fulness appeared. Another reason is drawn from the want of the common marks

Drowning.

of apoplexy on the dissection of the brain, and from the actual presence of water in the lungs. He is of opinion, that the death of drowned persons happens in consequence of water getting into the lungs, and stopping the blood in the arteries. He then discusses the question how far the blowing of air into the lungs is useful in recovering drowned people. If their death is to be ascribed to the water entering the lungs, this practice, he observes, must be hurtful, as it will increase the pressure on the blood-vessels, or may even force the water into them; which, on the authority of Lewis's experiments, he alleges is possible. But, in spite of this reasoning, he asserts, that from experience it has been found useful. He allows, that the practice of suspending drowned people by the feet must be hurtful, by determining the blood too much to the head; but he observes, that remedies in some respects hurtful may be used when the advantages derived from them preponderate; and is of opinion, that the practice above mentioned may be used by agitating the viscera against each other, and thus renewing their motions. Cutting the larynx in order to admit air more freely to the lungs, he reckons to be of little or no use; but acknowledges, however, that it may sometimes prove beneficial on account of the irritation occasioned by the operation.

Dr Cullen, in his Letter to Lord Cathcart concerning the recovery of persons drowned and seemingly dead, tells us, that "From the dissection of drowned men, and other animals, it is known, that very often the water does not enter into the cavity of the lungs, nor even into the stomach, in any quantity to do hurt to the system; and, in general, it is known, that, in most cases, no hurt is done to the organization of the vital parts. It is therefore probable, that the death which ensues, or seems to ensue, in drowned persons, is owing to the stopping of respiration, and to the ceasing, in consequence, of the circulation of the blood, whereby the body loses its heat, and, with that, the activity of the vital principle."

In the Phil. Trans. vol. lxvi. Mr Hunter gives the following theory. The loss of motion in drowning seems to arise from the loss of respiration; and the immediate effect this has upon the other vital motions of the animal, at least this privation of breathing, appears to be the first cause of the heart's motion ceasing. It is most probable, therefore, Mr Hunter observes, that the restoration of breathing is all that is necessary to restore the heart's motion; for if a sufficiency of life still remains to produce that effect, we may suppose every part equally ready to move the very instant in which the action of the heart takes place, their actions depending so much upon it. What makes it very probable, that the principal effect depends upon throwing air into the lungs, is, that children in the birth, when too much time has been spent after the loss of that life which is peculiar to the fœtus, lose altogether the disposition for the new life. In such cases there is a total suspension of the actions of life; the child remains to all appearance dead; and would die, if air was not thrown into its lungs, and the first principle of action by that means restored. To put this in a clearer light, Mr Hunter gives the result of some experiments made on a dog in 1755.—A pair of double bellows were provided, which were so constructed, that by one action air was thrown into the lungs, and by the other the air was sucked out which had been thrown in by the former, without mixing them together. The muzzle of these bellows was fixed into the trachea of a dog, and by working them he was kept perfectly alive. While this artificial breathing was going on, the sternum was taken off, so that the heart and lungs were exposed to view. The heart then continued to act as before, only the frequency of its action was greatly increased. Mr Hunter then stopped the motion of the bellows; and observed that the contraction of the heart became gradually weaker and less frequent, till it left off moving altogether; but by renewing the operation, the motion of the heart also revived, and soon became as strong and frequent as before. This process was repeated upon the same dog ten times; sometimes stopping for five, eight, or ten minutes. Mr Hunter observed, that every time he left off working the bellows, the heart became extremely turgid with blood, and the blood in the left side became as dark as that in the right, which was not the case when the bellows were working. These situations of the animal, he observes, seem to be exactly similar to drowning.

Dr Edmund Goodwyn, in a treatise lately published on this subject, has endeavoured to ascertain the effects of submersion upon living animals in a more accurate manner than had hitherto been done. His first care was to determine the symptoms which took place before death; and to observe these, he procured a large glass bell in which the animals were to be immersed. Having inverted, and filled this with water, he put into it several cats, dogs, rabbits, and smaller animals, confining them among the water till they were apparently dead. In these experiments he observed, that immediately after submersion the pulse became weak and frequent; there was an apparent anxiety about the breast, and struggling to relieve it. In these struggles the animal rose to the top of the water, throwing out a quantity of air from the lungs. After this the anxiety increases, the pulse becomes weaker, and the struggles more violent; he rises again to the surface, throws out more air from the lungs, and in his efforts to inspire, a quantity of water commonly passes into the mouth. The skin about the face and lips then becomes blue, the pulse ceases, the sphincters are relaxed, and the animal falls down without sense or motion. On dissecting the bodies of drowned animals, our author met with the following appearances: 1. The external surface of the brain was darker, but the vessels of it were not more turgid than usual, nor was there any appearance of extravasation. 2. The pulmonary arteries and veins were filled with black blood, and the lungs themselves contained some frothy liquor. 3. Notwithstanding these symptoms, the right auricle and ventricle were still contracting and dilating; the left sinus venosus and auricle moving feebly, but the left ventricle at rest. 4. The right and left auricles of the heart, the right ventricle, and the left sinus venosus, were filled with black blood; but the last ventricle only half filled with the same, and a quantity of the same black blood was also contained in the smaller branches of the arteries proceeding from the left ventricle.

This investigation was followed by a most careful and

Drowning.

and ingenious inquiry concerning the causes of the symptoms already related. To find out whether or not the entrance of water into the lungs was the cause, or whether water really entered the lungs in these cases or not, he drowned several animals among ink; and by inspecting their bodies, found, that though water really did enter, it was in such small quantity that it could not be supposed capable of producing such violent effects. To ascertain this, however, more exactly than could be done by the ink, he drowned other animals in quicksilver; which, by reason of its not being miscible with the animal fluids, could be more accurately collected. By these it appeared that no more than five drachms of the fluid in which a cat was immersed entered her lungs in the time of drowning; and to determine whether or not this could be the occasion of the animal's death, he made the following experiment: Having confined a cat in an erect posture, he made a small opening in the trachea, by cutting one of the cartilaginous rings; and through this opening he introduced two ounces of water into the lungs. The only consequences were a difficulty of breathing and weak pulse; but these soon abated, and it lived several hours afterwards without any apparent inconvenience. On strangling it he found two ounces and a half of water in the lungs. On repeating the experiment with other fluids, he found the difficulty of breathing and alteration in the pulse somewhat greater; but in these instances also they abated in a few hours: and when the animals were strangled, the lungs were found to contain four ounces of fluid.

From all these experiments Dr Goodwyn draws the following conclusions: 1. "A small quantity of fluid usually passes into the lungs in drowning. 2. This water enters the lungs during the efforts to inspire; and mixing with the pulmonary mucus, occasions the frothy appearance mentioned by authors. 3. The whole of this fluid in the lungs is not sufficient to produce the changes that take place in drowning. And hence it follows, that the water produces all the changes that take place in drowning *indirectly*, by excluding the atmospheric air from the lungs." This naturally leads to an investigation of the uses of respiration, and the effects of the air upon the blood and lungs in that action, which our author traces with great accuracy and very convincing experiments. He begins with attempting to determine the quantity of air drawn in at each inspiration, with the proportional quantity left after expiration. The experiments by which he endeavoured to ascertain these quantities seem to be more uncertain than the others, as indeed there are not data sufficient for them. From such as he had an opportunity of making, however, the following conclusions were deduced: 1. "The lungs contain 109 cubic inches of air after a complete expiration; and this quantity receives an additional quantity of 14 cubic inches during each inspiration. 2. The dilatation of the lungs after expiration is to their dilatation after inspiration as 109 to 123. 3. The blood circulates through the pulmonary vessels in all the degrees of natural respiration. 4. The circulation through them, after respiration, is sufficiently free to keep up the health of the system."

The last part of our author's inquiry, viz. concerning the chemical changes produced in the air by respiration, and the effects of the air upon the blood itself falls naturally to be considered under the article RESPIRATION: so that here we shall only observe in general, that his experiments evidently show that the disease produced by drowning arises entirely from the exclusion of the atmospheric air or its dephlogisticated part; for which reason he recommends inflating the lungs with that kind of air in preference to any other.

Drowning.

From these different views of this matter, physicians have differed considerably in their account of the methods to be followed in attempting the recovery of drowned persons. De Haen recommends agitation of all kinds; every kind of stimulus applied to the mouth, nose, and rectum; bleeding; heat, both by warm clothes and warm water; blowing air into the trachea; stimulants, such as blisters, warm ashes, &c. applied to the head, ankles, thighs, pit of the stomach, and other parts.

Doctor Cullen's observations on this subject are as follow.—"With respect to the particular means to be employed for the recovery of drowned persons, it is to be observed, in the first place, That such as were recommended and practised, upon a supposition that the suffocation was occasioned by the quantity of water taken into the body, and therefore to be evacuated again, were very unhappily advised. The hanging up of persons by the heels, or setting them upon the crown of the head, or rolling the body upon a cask, were generally practised, upon a supposition altogether false; or upon the supposition, of a case which, if real, is apprehended to be irrecoverable. At the same time, these practices were always attended with the danger of bursting some vessels in the brain or lungs, and of rendering thereby some cases incurable that were not so from the drowning alone. All such practices, therefore, are now very properly disapproved of and forbidden.

"In those cases in which the body has not been long in the water, and in which therefore the natural heat is not entirely extinguished, nor the irritability of the moving fibres very greatly impaired, it is possible that a good deal of agitation of the body may be the only means necessary to restore the action of the vital organs; but in other cases, where the heat and irritability have ceased to a greater degree, it is to me very doubtful if much agitation can be safe, and if any degree of it can be useful, till the heat and irritability are in some measure restored. In all cases, any violent concussion cannot be safe, and, I believe, is never necessary. It may be proper here to observe also, that in transporting the body from the place where it is taken out of the water, to the place where it may be necessary for applying the proper means of its recovery, all postures exposing to any improper compression, as that of the body's being carried over a man's shoulder, are to be avoided. The body is to be kept stretched out, with the head and upper parts a little raised; and care is to be taken to avoid the neck's being bent much forward. In this manner, laid upon one side, and upon some straw in a cart, it may be most properly conveyed; and the agitation which a pretty brisk motion of the cart may occasion, will, in most cases, do no harm.

"From the account I have given above of the causes,

ses, or of the appearances, of death in drowned persons, it is evident, that the first step to be taken for their recovery is to restore the heat of the body, which is absolutely necessary to the activity of the moving fibres. For this purpose, the body, as soon as possible, is to be stripped of its wet clothes, to be well dried, and to be wrapped up in dry, and (if possible) warm, coverings: and it is to be wished, in all cases, as soon as the report of a person's being drowned is heard, that blankets should be immediately carried to the water side; so that as soon as the body is got out of the water, the change of covering just now mentioned may be instantly made; or, if the body has been naked when drowned, that it may be immediately dried and defended against the cold of the air. Besides covering the body with blankets, it will be further of advantage, if it can be done without loss of time, to cover the drowned body with a warm shirt or waistcoat immediately taken from a living person.

"When, at the time of a person's being drowned, it happens that the sun shines out very hot, I think there can be no better means of recovering the heat, than by exposing the naked body, in every part, to the heat of the sun; while, at the same time, all other means necessary or useful for the recovery of life are also employed.

"When the heat of the sun cannot be employed, the body should be immediately transported to the nearest house that can be got convenient for the purpose: the fittest will be one that has got a tolerably large chamber, in which a fire is ready, or can be made; and if possible, the house should afford another chamber, in which also a fire can be provided.

"When the drowned body is brought into such house, and care is at the same time taken that no more people are admitted than are absolutely necessary to the service of the drowned person, every endeavour must be immediately employed for recovering the heat of the body, and that by different measures, as circumstances shall direct.

"If, in the neighbourhood of the place, there be any brewery, distillery, dyery, or fabric which gives an opportunity of immediately obtaining a quantity of warm water and a convenient vessel, there is nothing more proper than immersing the body in a warm bath. Even where a sufficient quantity of warm water cannot be had at once, the bath may be still practised, if the accident has happened in or very near a town or village, where a great many fires may be at once employed in heating small quantities of water; for in this way the necessary quantity may be soon obtained. To encourage this practice, it is to be observed, that one part of boiling water is more than sufficient to give the necessary heat to two parts of spring or sea water, as it is not proper to apply the bath at first very warm, nor even of the ordinary heat of the human body, but somewhat under it; and, by the addition of warm water, to bring it gradually to a heat very little above it.

"If the drowned body be of no great bulk, it may be conveniently warmed by a person's lying down in bed with it, and taking it near to their naked body, changing the position of it frequently, and at the same time chafing and rubbing with warm cloths the parts which are not immediately applied to their warm body.

"If none of these measures can be conveniently practised, the body is to be laid upon a bed before a moderate fire, and frequently turned, to expose the different parts of it; and thus, by the heat of the fire gradually employed, and by rubbing the body well with coarse towels, or other cloths well warmed, pains are to be taken for restoring its heat. This will be promoted by warm cloths applied and frequently renewed under the hams and armpits; and by hot bricks, or bottles of warm water, laid to the feet.

"In the practice of rubbing, it has been proposed to moisten the cloths applied with camphorated spirits, or other such stimulating substances; but I think this must prove an impediment to the rubbing; and I would not recommend any practice of this kind, except, perhaps, the application of the vinous spirits of sal ammoniac to the wrists and ankles only.

"For recovering the heat of the body, it has been proposed to cover it all over with warm grains, ashes, sand, or salt; and where these, sufficiently warm, are ready at hand, they may be employed; but it is very seldom they can be obtained, and the application might often interfere with other measures that may be necessary. All therefore that I can propose with respect to the use of these, is to observe, that bags of warm and dry salt may be amongst the most convenient applications to the feet and hands of drowned persons; and the quantity necessary for this purpose may be got pretty quickly by heating the salt in a frying pan over a common fire.

"While these measures are taking for recovering the heat, means are at the same time to be employed for restoring the action of the moving fibres. It is well known, that the intestines are the parts of the body which, both from their internal situation and peculiar constitution, retain the longest their irritability; and therefore, that, in drowned persons, stimulants applied may have more effect upon the intestines than upon other parts. The action, therefore, of the intestines is to be supported or renewed as soon as possible; as the restoring and supporting the action of such a considerable portion of moving fibres as those of the intestines, must contribute greatly to restore the activity of the whole system.

"For exciting the action of the intestines, the most proper mean is, the application of their ordinary stimulus of dilatation; and this is most effectually applied, by forcing a quantity of the air into them by the fundament. Even the throwing in cold air has been found useful: but it will certainly be better if heated air can be employed; and further, if that air can be impregnated with something which, by its acrimony also may be powerful in stimulating the intestines.

"From all these considerations, the smoke of burning tobacco has been most commonly applied, and has upon many occasions proved very effectual. This will be most properly thrown in by a particular apparatus, which, for other purposes as well as this, should be in the hands of every surgeon; or at least should, at the public expence, be at hand in every part of the country where drownings are likely to happen. With regard to the use of it, I have to observe, that till the

the tobacco is kindled in a considerable quantity, a great deal of cold air is blown through the box and tube; and as that, as hinted above, is not so proper, care should be taken to have the tobacco very well kindled, and to blow through it very gently, till the heated smoke only passes through. If upon certain occasions, the apparatus referred to should not be at hand, the measure however may be executed by a common tobacco pipe, in the following manner: A common glyster pipe, that has a bag mounted upon it, is to be introduced into the fundament, and the mouth of the bag is to be applied round the small end of a tobacco pipe. In the bowl of this, tobacco is to be kindled; and, either by a playing card made into a tube and applied round the mouth of the bowl, or by applying upon this the bowl of another pipe that is empty, and blowing through it, the smoke may be thus forced into the intestines, and, in a little time, in a considerable quantity.

"If none of these means for throwing in the smoke can be employed, it may be useful to inject warm water to the quantity of three or four English pints. This may be done by a common glyster bag and pipe, but better by a large syringe; and it may be useful to dissolve in the water some common salt, in the proportion of half an ounce to an English pint; and also to add to it some wine or brandy.

"While these measures for recovering the heat of the body and activity of the moving fibres are employed, and especially after they have been employed for some time, pains are to be taken to complete and finish the business, by restoring the action of the lungs and heart.

"On this subject, I am obliged to my learned and ingenious colleague Dr Monro, who has made some experiments for ascertaining the best manner of inflating the lungs of drowned persons. By these experiments he finds it may be more conveniently done by blowing into one of the nostrils, than by blowing into the mouth. For blowing into the nostril, it is necessary to be provided with a wooden pipe, fitted at one extremity for filling the nostril, and at the other for being blown into by a person's mouth, or for receiving the pipe of a pair of bellows, to be employed for the same purpose. Dr Monro finds, that a person of ordinary strength can blow into such a pipe, with a sufficient force to inflate the lungs to a considerable degree; and thinks the warm air from the lungs of a living person will be most conveniently employed at first; but when it is not soon effectual in restoring the respiration of the drowned person, and that a longer continuance of the inflation is necessary, it may be proper to employ a pair of bellows, large enough at once to contain the quantity of air necessary to inflate the lungs to a due degree.

"Whether the blowing in is done by a person's mouth, or by bellows, Dr Monro observes, that the air is ready to pass by the gullet into the stomach; but that this may be prevented, by pressing the lower part of the larynx backwards upon the gullet. To persons of a little knowledge in anatomy, it is to be observed, that the pressure should be only upon the cricoid cartilage, by which the gullet may be straitened, while the passage through the larynx is not interrupted.

"When, by blowing thus into the nostrils, it can be perceived, by the raising of the chest or belly, that the lungs are filled with air, the blowing in should cease; and by pressing the breast and belly, the air received into the lungs should be again expelled; then the blowing and expulsion should be again repeated; and thus the practice is to be continued, so as to imitate, as exactly as possible, the alternate motions of natural respiration.

"It is hardly necessary to observe, that when the blowing into the nostril is practised, the other nostril and the mouth should be accurately closed.

"If it should happen, that in this practice the air does not seem to pass readily into the lungs, Dr Monro informs me it is very practicable to introduce directly into the glottis and trachea a crooked tube, such as the catheter used for a male adult. For this he offers the following directions: The surgeon should place himself on the right side of the patient; and, introducing the fore finger of his left hand at the right corner of the patient's mouth, he should push the point of it behind the epiglottis; and using this as a directory, he may enter the catheter, which he holds in his right hand, at the left corner of the patient's mouth, till the end of it is passed beyond the point of his fore finger; and it is then to be let fall, rather than pushed into the glottis; and through this tube, by a proper syringe applied to it, air may be with certainty blown into the lungs. I observe, that some such measure had been proposed by Mons. le Cat in France; but I have not learned that it has ever been put in practice, and I am afraid it may be attended with several difficulties, and must be left to the discretion of surgeons who may be properly provided and instructed for this purpose.

"For throwing air with more certainty into the lungs, it has been proposed to open the windpipe in the same manner as is done in the operation which the surgeons call *bronchotomy*, and by this opening to blow into the lungs; and when the blowing into the nostril does not seem to succeed, and a skilful operator is at hand, I allow that the measure may be tried; but I can hardly suppose that it will be of any advantage when the blowing in by the nostril has entirely failed.

"It is to be hoped, that by blowing into the lungs one way or other, even a quantity of water which had been taken into the lungs may be again washed out; and the same seems to be the only effectual means of washing out that frothy matter which is found to fill the lungs of drowned persons, and which proves, if I mistake not, the most common cause of their mortal suffocation. This practice, therefore, is to be immediately entered upon, and very assiduously continued for an hour or two together.

"I have now mentioned the measures chiefly to be pursued and depended upon for the recovery of drowned persons; but must still mention some others that may prove considerable helps to it.

"One of these is, the opening the jugular veins, to relieve the congestion which almost constantly occurs in the veins of the head, and is probably a frequent cause of the death of drowned persons. For relieving this congestion, the drawing some blood from the jugulars, very early, may certainly be of service; and it will be particularly indicated by the livid and purple colour of the face. It may even be repeated, according to the effect it seems to have in taking off that suffusion; but when the drowned person is in some measure recovered, and some motion of the blood is restored, it will be proper to be very cautious in making this evacuation, and at least to take care not to push it so as to weaken too much the recovering, but still weak, powers of life.

"Another measure for recovering the activity of the vital principle, is the application of certain stimulants to the more sensible parts of the body, such as holding the quicklime spirit of sal ammoniac to the nose, or putting a little of it upon a rag into the nostrils. It has been usual to pour some liquids into the mouth; but it is dangerous to pour in a quantity of liquid, till it appear that the power of swallowing is in some measure restored.

"When a surgeon is at hand, and is provided with proper apparatus, a crooked pipe may be introduced into the gullet; and by this a gill or two of warm wine may be poured down into the stomach, and probably with advantage. But when no such apparatus is at hand or surgeon to employ it, and the power of swallowing is still doubtful, the trial of pouring liquids into the mouth should be made by a small quantity of warm water alone; and when, from such trial, the power of swallowing shall appear to be recovered, it may then be allowable to favour the further recovery of the person, by pouring in some wine or brandy.—In short, till some marks of the recovery of swallowing and respiration appear, it will not be safe to apply any stimulants to the mouth; excepting that of a few drops of some acrid substance to the tongue, and which are not of bulk enough to slide back upon the glottis: I can think of no stimulant more conveniently and safely to be applied to the mouth and nostrils, than a moderate quantity of tobacco smoke blown into them.

"Though I do not imagine that drowned persons are ever hurt by the quantity of water taken into their stomach, yet, as a stimulus applied to the stomach, and particularly as the action of vomiting proves a stimulus to the whole system, I can have no objection to the French practice of throwing in an emetic as soon as any swallowing is restored. For this purpose, I would successively throw in some tea-spoonfuls of the ipecacuanha wine; and when it does not interfere with other necessary measures, the fauces may be gently irritated by an oiled feather thrust into them.

"With regard to the stimulants, I must conclude with observing, That when a body has lain but for a short time in the water, and that therefore its heat and irritability are but little impaired, the application of stimulants alone has been often found effectual for the recovery: but on the contrary, when the body has lain long in the water, and the heat of it is very much extinguished, the application of any other stimulants than that of tobacco smoke to the intestines can be of very little service; and the application of others ought never to interfere with the measures for recovering heat and the motion of respiration.

"With respect to the whole of these practices, I expect, from the principles upon which they are in general recommended, it will be understood that they are not to be soon discontinued, though their effects do not immediately appear. It is obvious, that, in many cases, it may be long before the heat of the body, and the activity of the vital principle, can be restored, although in a longer time it may very possibly be accomplished. In fact, it has often happened, that though means employed for one hour have not succeeded, the same continued for two or more hours, have at length had the wished-for effects. It should therefore be a constant rule, in this business, that the proper means should be employed for several hours together; unless it happen that, while no symptoms of returning life appear, the symptoms of death shall, at the same time, go on constantly increasing.

"In the whole of the above I have kept in view chiefly the case of drowned persons; but it will be obvious, that many of the measures proposed will be equally proper and applicable in other cases of suffocation; as those from strangling, the damps of mines, the fumes of charcoal, &c.; and a little attention to the difference of circumstances will lead to the measures most proper to be employed."

Mr Hunter, in the before-mentioned paper, differs pretty considerably from De Haen and Dr Cullen. He observes, that when assistance is soon called after immersion, blowing air into the lungs will in some cases effect a recovery; but when any considerable time has been lost, he advises stimulant medicines, such as the vapour of volatile alkali, to be mixed with the air; which may easily be done, by holding spirits of hartshorn in a cup under the receiver of the bellows. And, as applications of this kind to the olfactory nerves tend greatly to rouse the living principle, and put the muscles of respiration into action, it may probably, therefore, be most proper to have air impregnated in that manner thrown in by the nose. To prevent the stomach and intestines from being too much distended by the air so injected, the larynx is directed to be gently pressed against the œsophagus and spine.

While this business is going on, an assistant should prepare bed clothes, carefully brought to a proper degree of heat. Heat our author considers as congenial with the living principle; increasing the necessity of action, it increases action: cold, on the other hand, lessens the necessity, and of course the action is diminished: to a due degree of heat, therefore, the living principle, he thinks, owes its vigour. From experiments, he says, it appears to be a law in animal bodies, that the degree of heat should bear a proportion to the quantity of life; as life is weakened, this proportion requires great accuracy, while greater powers of life allow it greater latitudes.

After these and several other observations on the same subject, our author proceeds to more particular directions for the management of drowned people.

If bed clothes are put over the person, so as scarce to touch him, steams of volatile alkali, or of warm balsams, may be thrown in, so as to come in contact with many parts of the body. And it might probably be advantageous, Mr Hunter observes, to have steams of the same kind conveyed into the stomach. This, we are told, may be done by a hollow bougie and a syringe: but the operation should be very speedily performed,

formed, as the instrument, by continuing long in the mouth, might produce sickness, which our author says he would always wish to avoid.

Some of the warm stimulating substances, such as juice of horseradish, peppermint water, and spirits of hartshorn, are directed to be thrown into the stomach in a fluid state, as also to be injected by the anus. Motion possibly may be of service; it may at least be tried: but as it hath less effect than any other of the usually prescribed stimuli, it is directed to be the last part of the process.

The same care in the operator, in regulating the proportion of every one of these means, is here directed, as was formerly given for the application of heat. For every one of them, our author observes, may possibly have the same property of destroying entirely the feeble action which they have excited, if administered in too great a quantity: instead, therefore, of increasing and hastening the operations on the first signs of returning life being observed, as is usually done, he desires they may be lessened; and advises their increase to be afterwards proportioned, as nearly as possible, to the quantity of powers as they arise.

When the heart begins to move, the application of air to the lungs should be lessened, that, when the muscles of respiration begin to act, a good deal may be left for them to do.

Mr Hunter absolutely forbids bloodletting in all such cases; for as it not only weakens the animal principle, but lessons life itself, it must consequently, he observes, lessen both the powers and dispositions to action. For the same reason, he is against introducing any thing into the stomach that might produce sickness or vomiting; and, on the same principle, he says, we should avoid throwing tobacco fumes, or any other such articles, up by the anus, as might tend to an evacuation that way.

The following is a description of instruments recommended for such operations by our author.

First, A pair of bellows, so contrived, with two separate cavities, that, by opening them when applied to the nostrils or mouth of a patient, one cavity will be filled with common air, and the other with air sucked out from the lungs, and by shutting them again, the common air will be thrown into the lungs, and that sucked out of the lungs discharged into the room. The pipe of these should be flexible; in length a foot, or a foot and a half; and, at least, three eighths of an inch in width. By this the artificial breathing may be continued, while the other operations, the application of the stimuli to the stomach excepted, are going on, which could not be conveniently done, if the muzzle of the bellows were introduced into the nose. The end next the nose should be double, and applied to both nostrils. Secondly, A syringe, with a hollow bougie, or flexible catheter, of sufficient length to go into the stomach, and convey any stimulating matter into it, without affecting the lungs. Thirdly, A pair of small bellows, such as are commonly used in throwing fumes of tobacco up by the anus.

Notwithstanding the differences in theory, however, between the physicians above mentioned, it is certain, that within these few years great numbers of drowned people have been restored to life by a proper use of the remedies we have enumerated, and societies for the recovery of drowned persons have been instituted in different places. The first society of this kind was instituted in Holland, where from the great abundance of canals and inland seas, the inhabitants are particularly exposed to accidents by water. In a very few years 150 persons were saved from death by this society; and many of these had continued upwards of an hour without any signs of life, after they had been taken out of the water. The society was instituted at Amsterdam in 1767: and, by an advertisement, informed the inhabitants of the United Provinces of the methods proper to be used on such occasions; offering rewards at the same time to those who should, with or without success, use those methods for recovering persons drowned and seemingly dead. The laudable and humane example of the Dutch, was followed in the year 1768 by the magistrates of health in Milan and Venice; afterwards by the magistrates of Hamburg in the year 1771, by those of Paris in the year 1772, and by the magistrates of London in 1774.

The following directions are given for the recovery of drowned persons by the society at London.

I. As soon as the patient is taken out of the water, the wet clothes, if the person is not naked at the time of the accident, should be taken off with all possible expedition on the spot (unless some convenient house be very near), and a great coat or two, or some blankets if convenient, should be wrapped round the body.

II. The patient is to be thus carefully conveyed in the arms of three or four men, or on a bier, to the nearest public or other house, where a good fire, if in the winter season, and a warm bed, can be made ready for its reception. As the body is conveying to this place, a great attention is to be paid to the position of the head; it must be kept supported in a natural and easy posture, not suffered to hang down.

III. In cold or moist weather, the patient is to be laid on a mattress or bed before the fire, but not too near, or in a moderately heated room; in warm and sultry weather, on a bed only. The body is then to be wrapped as expeditiously as possible with a blanket, and thoroughly dried with warm coarse cloths or flannels.

IV. In summer or sultry weather too much air cannot be admitted. For this reason it will be necessary to set open the windows and doors, as cool refreshing air is of the greatest importance in the process of resuscitation.

V. Not more than six persons are to be present to apply the proper means; a greater number will be useless, and may retard, or totally prevent, the restoration of life, by rendering the air of the apartment unwholesome. It will be necessary, therefore, to request the absence of those who attend merely from motives of curiosity.

VI. It will be proper for one of the assistants, with a pair of bellows of the common size, applying the pipe a little way up one nostril, to blow with some force, in order to introduce air into the lungs: at the same time the other nostril and the mouth are to be closed by another assistant, whilst a third person gently presses the chest with his hands, after the lungs are observed to be inflated. By pursuing this process, the noxious and stagnant vapours will be expelled, and natural breathing imitated. If the pipe of the bellows be too large,

the

the air may be blown in at the mouth, the nostrils at the same time being closed, so that it may not escape that way: but the lungs are more easily filled, and natural breathing better imitated, by blowing up the nostril.

VII. Let the body be gently rubbed with common salt, or with flannels, sprinkled with spirits, as rum or geneva (A). A warming pan heated (the body being surrounded with flannel) may be lightly moved up and down the back. Fomentations of hot brandy are to be applied to the pit of the stomach, loins, &c. and often renewed. Bottles filled with hot water, heated tiles covered with flannel, or hot bricks, may be efficaciously applied to the soles of the feet, palms of the hands, and other parts of the body. The temples may be rubbed with spirits of hartshorn, and the nostrils now and then tickled with a feather; and snuff, or *eau de luce*, should be occasionally applied.

VIII. Tobacco fumes should be thrown up the fundament: if a fumigator be not at hand, the common pipe may answer the purpose. The operation should be frequently performed, as it is of importance; for the good effects of this process have been experienced in a variety of instances of suspended animation. But should the application of tobacco smoke in this way not be immediately convenient, or other impediments arise, clysters of this herb, or other acrid infusions with salt, &c. may be thrown up with advantage.

IX. When these means have been employed a considerable time without success, and any brewhouse or warm bath can be readily obtained, the body should be carefully conveyed to such a place, and remain in the bath, or surrounded with warm grains, for three or four hours.

If a child has been drowned, its body should be wiped perfectly dry, and immediately placed in bed between two healthy persons. The salutary effects of the natural vital warmth, conveyed in this manner, have been proved in a variety of successful cases.

X. While the various methods of treatment are employed, the body is to be well shaken every ten minutes, in order to render the process of animation more certainly successful; and children, in particular, are to be much agitated, by taking hold of their legs and arms, frequently and for a continuance of time. In various instances agitation has forwarded the recovery of boys who have been drowned, and continued for a considerable time apparently dead.

XI. If there be any signs of returning life, such as sighing, gasping, or convulsive motions, a spoonful of any warm liquid may be administered; and if the act of swallowing is returned, then a cordial of warm brandy or wine may be given in small quantities, and frequently repeated.

XII. Electricity may be tried by the judicious and skilful, as its application neither prevents nor retards the various modes of recovery already recommended; but on the other hand, will most probably tend to render the other means employed more certainly and more expeditiously efficacious. This stimulus bids fair to prove an important auxiliary in cases of suspended animation; and therefore deserves the serious regard and attention of the faculty.

The methods which have been fully described, are to be employed with vigour for three hours or upwards, although no favourable circumstances should arise; for it is a vulgar and dangerous opinion to suppose that persons are irrecoverable, because life does not soon make its appearance; an opinion that has consigned to the grave an immense number of the seemingly dead, who might have been restored to life by resolution and perseverance.

Bleeding is never to be employed in such cases, unless by the direction of one of the medical assistants, or some other gentleman of the faculty who has paid attention to the resuscitating art.

DRUG, a general term for goods of the druggist and grocery kinds, especially those used in medicine and dyeing. See MATERIA MEDICA, PHARMACY, and DYEING.

DRUGGET, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded, but usually plain. Those that have the woof of wool, and the warp of thread, are called *threaded druggets*; and those wrought with the shuttle on a loom of four marches, as the serges of Moui, Beauvois, and other like stuffs corded, are called *corded druggets*. As to the plain, they are wrought on a loom of two marches, with the shuttle, in the same manner as cloth, camblets, and other like stuffs not corded.

DRUIDÆ, or DROIUM, in *Ancient Geography*, a very ancient town, the principal place of the Druides or Druidæ in Gaul, as they are called (Cæsar, Cicero). Now *Dreux* in the Orleannois. Here they met every year in a consecrated grove, according to Cæsar. The town was also called *Durocâses*. W. Long. 1. 21. N. Lat. 48. 45.

DRUIDS, DRUIDES, or DRUIDÆ, the priests or ministers of religion among the ancient Celtæ or Gauls, Britons, and Germans.

Some authors derive the word from the Hebrew דרושים *derussim*, or *drussim*, which they translate *contemplatores*. Picard, Celtopæd. lib. ii. p. 58. believes the druids to have been thus called from *Druis*, or *Dryius*, their leader, the fourth or fifth king of the Gauls, and father of Saron or Naumes. Pliny, Salmasius, Vigenere, &c. derive the name from δρυς, *oak*; on account of their inhabiting, or at least frequenting, and teaching in forests; or perhaps because, as Pliny says, they never sacrificed but under the oak. But it is hard to imagine how the druids should come to speak Greek. Menage derived the word from the old British *drus*, "dæmon, magician." Borel, from the Saxon *dry*, "magician;" or rather from the old British *dru*, or *derw*, "oak," whence he takes δρυς to be derived; which is the most probable supposition. Gorop. Becanus, lib. i. takes *druis* to be an old Celtic and German word, formed from *trowis* or *truwis*, "a doctor of the

out of
t Druids.

The druids were the first and most distinguished order among the Gauls and Britons; they were chosen out of the best families; and the honours of their birth, joined with those of their function, procured them the highest veneration among the people. They were versed in astrology, geometry, natural philosophy, politics, and geography; they were the interpreters of religion, and the judges of all affairs indifferently. Whoever refused obedience to them was declared impious and accursed. We know but little as to their peculiar doctrines; only that they believed the immortality of the soul, and, as is generally also supposed, the metempsychosis; though a late author makes it appear highly probable they did not believe this last, at least not in the sense of the Pythagoreans.

The chief settlement of the druids in Britain was in the isle of Anglesey, the ancient *Mona*, which they might choose for this purpose, as it is well stored with spacious groves of their favourite oak. They were divided into several classes or branches, viz. the *vacerri*, *bardi*, *eubages*, *symnothii* or *semnothei*, and *saronidæ*. The *vacerri* are held to have been the priests; the *bardi*, the poets; the *eubages*, the augurs; and the *saronidæ*, the civil judges and instructors of youth. As to the *semnothei*, who are said to have been immediately devoted to the service of religion, it is probable they were the same with the *vacerri*. Strabo, however, (lib. iv. p. 147.) and Picard after him in his Celtopædia, do not comprehend all these different orders under the denomination of druids, as species under their genus, or parts under the whole; but make them quite different conditions or orders. Strabo, in effect, only distinguishes three kinds; *bardi*, *vates*, and *druids*. The *bardi* were the poets; the *vates*, ȣατεις, (apparently the same with the *vacerri*), were the priests and naturalists; and the *druids*, beside the study of nature, applied themselves likewise to morality.

Diogenes Laertius assures us, in his prologue, that the druids were the same among the ancient Britons with the sophi or philosophers among the Greeks; the magi among the Persians; the gymnosophists among the Indians; and the Chaldeans among the Assyrians.

Their garments were remarkably long; and, when employed in religious ceremonies, they always wore a white surplice. They generally carried a wand in their hands; and wore a kind of ornament enchased in gold about their necks, called the *druid's egg*. Their necks were likewise decorated with gold chains, and their hands and arms with bracelets: they wore their hair very short, and their beards remarkably long.

The druids had one chief, or arch-druid, in every nation, who acted as high priest, or *pontifex maximus*. He had absolute authority over the rest; and commanded, decreed, punished, &c. at pleasure. At his death he was succeeded by the most considerable among his survivors; and, if there were several pretenders, the matter was ended by an election, or else put to the decision of arms.

The druids, we have observed, were in the highest esteem. They presided at sacrifices, and other ceremonies; and had the direction of every thing relating to religion. The British and Gaulish youth flocked to them in crowds to be instructed by them. The children of the nobility, Mela tells us, they retired with into caves, or the most desolate parts of forests, and kept them there sometimes for twenty years under their discipline. Besides the immortality and metempsychosis, they were here instructed in the motion of the heavens, and the course of the stars; the magnitude of the heavens and the earth; the nature of things; the power and wisdom of the gods, &c. They preserved the memory and actions of great men in their verses, which they never allowed to be wrote down, but made their pupils get them by heart. In their common course of learning, they are said to have taught them twenty-four thousand such verses. By this means their doctrines appeared more mysterious by being unknown to all but themselves; and having no books to recur to, they were the more careful to fix them in their memory.

Druids.

They worshipped the Supreme Being under the name of *Esus*, or *Hesus*, and the symbol of the oak; and had no other temple than a wood or a grove, where all their religious rites were performed. Nor was any person admitted to enter that sacred recess, unless he carried with him a chain, in token of his absolute dependence on the Deity. Indeed, their whole religion originally consisted in acknowledging, that the Supreme Being, who made his abode in these sacred groves, governed the universe; and that every creature ought to obey his laws, and pay him divine homage.

They considered the oak as the emblem, or rather the peculiar residence, of the Almighty; and accordingly chaplets of it were worn both by the druids and people in their religious ceremonies, the altars were strewed with its leaves, and encircled with its branches. The fruit of it, especially the misletoe, was thought to contain a divine virtue, and to be the peculiar gift of heaven. It was therefore sought for on the sixth day of the moon with the greatest earnestness and anxiety; and when found was hailed with such raptures of joy, as almost exceeds imagination to conceive. As soon as the druids were informed of this fortunate discovery, they prepared every thing ready for the sacrifice under the oak, to which they fastened two white bulls by the horns; then the arch-druid, attended by a prodigious number of people, ascended the tree, dressed in white; and with a consecrated golden knife, or pruning-hook, cropped the misletoe, which he received in his sagum or robe, amidst the rapturous exclamations of the people. Having secured this sacred plant, he descended the tree; the bulls were sacrificed; and the Deity invoked to bless his own gift, and render it efficacious in those distempers in which it should be administered.

The consecrated groves, in which they performed their religious rites, were fenced round with stones, to prevent any person's entering between the trees, except through the passages left open for that purpose, and which were guarded by some inferior druids, to prevent any stranger from intruding into their mysteries. These groves were of different forms; some quite circular, others oblong, and more or less capacious as the votaries in the districts to which they belonged were more or less numerous. The area in the centre of the grove was encompassed with several rows of large oaks set very close together. Within this large circle were several smaller ones surrounded with large stones; and near the centre of these smaller circles were stones of a prodigious size and convenient height, on which the victims were slain and offered. Each of these being a kind of altar, was surrounded with another row of stones, the use of which cannot now be known, unless they were intended as cinctures to keep the people at a convenient distance from the officiating priest.

Suetonius, in his life of Claudius, assures us the druids sacrificed men; and Mercury is said to be the god to whom they offered these victims. Diod. Siculus, lib. vi. observes it was only upon extraordinary occasions they made such offerings; as, to consult what measures to take, to learn what should befal them, &c. by the fall of the victim, the tearing of his members, and the manner of his blood gushing out. Augustus condemned the custom, and Tiberius and Claudius punished and abolished it.

We learn from Cæsar, that the druids were the judges and arbiters of all differences and disputes, both public and private: they took cognizance of murders, inheritances, boundaries, and limits; and decreed rewards and punishments. Such as disobeyed their decisions they excommunicated, which was their principal punishment; the criminal being hereby excluded from all public assemblies, and avoided by all the world; so that nobody durst speak to him for fear of being polluted. Strabo observes, they had sometimes interest and authority enough to stop armies upon the point of engaging, and accommodate their differences.

2
Their opinions and philosophy whence derived.

It hath been disputed, whether the druids were themselves the inventors of their opinions and systems of religion and philosophy, or received them from others. Some have imagined, that the colony of Phocians which left Greece and built Marseilles in Gaul about the 57th Olympiad, imported the first principles of learning and philosophy, and communicated them to the Gauls and other nations in the west of Europe. It appears, indeed, that this famous colony contributed not a little to the improvement of that part of Gaul where it settled, and to the civilization of its inhabitants. "The Greek colony of Marseilles (says Justin) civilized the Gauls, and taught them to live under laws; to build cities and enclose them with walls; to cultivate the vine and olive; and, in a word, made so great a change both in the face of the country and the manners of its inhabitants, that Gaul seemed to be translated into Greece, rather than a few Greeks transplanted into Gaul." But though we may allow that the druids of Gaul and Britain borrowed some hints and embellishments of their philosophy from this Greek colony, and perhaps from other quarters, we have reason to believe that the substance of it was their own. Others have suggested, that the druids derived their philosophy from Pythagoras, who published his doctrines at Crotona in Italy; where he lived in the highest reputation for his virtue, wisdom, and learning, above 20 years. This conjecture is very much confirmed by this remarkable expression of Ammianus Marcellinus, "That the druids were formed into fraternities, as the authority of Pythagoras decreed." It hath been also observed, that the philosophy of the druids bore a much greater resemblance to that of Pythagoras than to that of any of the other sages of antiquity. But it seems probable, that Ammianus meant no more by the above expression than to illustrate the nature of the druidical fraternities, by comparing them to those of the Pythagoreans, which were well known to the Romans; and the resemblance between the Pythagorean and druidical philosophy may perhaps be best accounted for, by supposing, that Pythagoras learned and adopted some of the opinions of the druids, as well as imparted to them some of his discoveries. It is well known, that this philosopher, animated by the most ardent love of knowledge, travelled into many countries in pursuit of it, and got himself admitted into every society that was famous for its learning. It is therefore highly probable in itself, as well as directly asserted by several authors, that Pythagoras heard the druids of Gaul, and was initiated into their philosophy.

3
More particular account of the learning of the druids.

From the concurring testimonies of several authors, it appears that physiology, or natural philosophy, was the favourite study of the druids of Gaul and Britain. Cicero tells us, that he was personally acquainted with one of the Gaulish druids, Divitiacus the Æduan, a man of quality in his country, who professed to have a thorough knowledge of the laws of nature, or that science which the Greeks call *physics* or *physiology*. According to Diodorus Siculus, Strabo, Cæsar, Mela, Ammianus Marcellinus, and others, they entered into many disquisitions and disputations in their schools, concerning the form and magnitude of the universe in general, and of this earth in particular, and even concerning the most sublime and hidden secrets of nature. On these and the like subjects they formed a variety of systems and hypotheses; which they delivered to their disciples in verse, that they might the more easily retain them in their memories, since they were not allowed to commit them to writing. Strabo hath preserved one of the physiological opinions of the druids concerning the universe; viz. that it was never to be entirely destroyed or annihilated; but was to undergo a succession of great changes and revolutions, which were to be produced sometimes by the power and predominancy of water, and sometimes by that of fire. This opinion, he intimates, was not peculiar to them, but was entertained also by the philosophers of other nations; and Cicero speaks of it as a truth universally acknowledged and undeniable. "It is impossible for us (says he) to attain a glory that is eternal, or even of very long duration, on account of these deluges and conflagrations of the earth which must necessarily happen at certain periods." This opinion, which was entertained by the most ancient philosophers of many different and very distant nations, was probably neither the result of rational inquiry in all these nations, nor communicated from one of them to others; but descended to them all from their common ancestors of the family of Noah by tradition, but corrupted and misunderstood through length of time. The agreement of the druids with the philosophers of so many other nations in this opinion about the alternate dissolution and renovation of the world, gives us reason to believe, that they agreed with them also in their opinion of its origin from two distinct principles; the one intelligent and omnipotent, which

4
Physics, o natural philosophy

which was God; the other inanimate and inactive, which was matter. We are told, by Cæsar, that they had many disquisitions about the power of God; and, no doubt, amongst other particulars, about his creating power. But whether they believed with some that matter was eternal, or with others that it was created; and in what manner they endeavoured to account for the disposition of it into the present form of the universe, we are entirely ignorant, though they certainly had their speculations on these subjects. We are only informed, that they did not express their sentiments on these and like heads in a plain and natural, but in a dark, figurative, and enigmatical manner. This might incline us to suspect, that Pythagoras had borrowed from them his doctrine about numbers, to whose mystical energy he ascribes the formation of all things; for nothing can be more dark and enigmatical than that doctrine. The druids disputed likewise about the magnitude and form of the world in general, and of the earth in particular, of which things they pretended to have a perfect knowledge. We know not what their opinions were about the dimensions of the universe or of the earth, but we have several reasons to make us imagine that they believed both to be of a spherical form. This is visibly the shape and form of the sun, moon and stars, the most conspicuous parts of the universe; from whence it was natural and easy to infer, that this was the form of the world and of the earth. Accordingly this seems to have been the opinion of the philosophers of all nations; and the circle was the favourite figure of the druids, as appears from the form both of their houses and places of worship. Besides these general speculations about the origin, dissolution, magnitude, and form of the world and of the earth, the druids engaged in particular inquiries into the natures and properties of the different kind of substances. But all their discoveries in this most useful and extensive branch of natural philosophy, whatever they were, are entirely lost.

Astronomy.

Astronomy also appears to have been one of the chief studies of the druids of Gaul and Britain. "The druids (says Cæsar) have many disquisitions concerning the heavenly bodies and their motions, in which they instruct their disciples." Mela, speaking of the same philosophers, observes, "That they profess to have great knowledge of the motions of the heavens and of the stars." Some knowledge of this science indeed was not only necessary for measuring time in general, marking the duration of the different seasons, regulating the operations of the husbandman, directing the course of the mariner, and for many other persons in civil life; but it was especially necessary for fixing the times and regular returns of their religious solemnities, of which the druids had the sole direction. Some of these solemnities were monthly, and others annual. It was therefore necessary for them to know, with some tolerable degree of exactness, the number of days in which the sun and moon performed their revolutions, that these solemnities might be observed at their proper seasons. This was the more necessary, as some of these solemnities were attended by persons from different and very distant countries, who were all to meet at one place on one day; who must have had some rule to discover the annual return of that day.

6
Their method of computing time.

The most perceptible division of time by the two great luminaries is into day and night; the former occasioned by the presence of the sun above the horizon, the latter by his absence, which is in some measure supplied by the moon and stars. The druids computed their time by nights, and not by days; a custom which they had received from their most remote ancestors by tradition, and in which they were confirmed by their measuring their time very much by the moon, the mistress and queen of night. As the changes in the aspect of that luminary are most conspicuous, they engaged the attention of the most ancient astronomers of all countries, and particularly of the druids, who regulated all their great solemnities, both sacred and civil, by the age and aspect of the moon. "When no unexpected accident prevents it, they assemble upon stated days, either at the time of the new or full moon; for they believe these to be the most auspicious times for transacting all affairs of importance." Their most august ceremony of cutting the misletoe from the oak by the arch-druid, was always performed on the sixth day of the moon. Nay, they even regulated their military operations very much by this luminary, and avoided, as much as possible, to engage in battle while the moon was on the wane. As the attention of the druids was so much fixed on this planet, it could not be very long before they discovered that she passed through all her various aspects in about thirty days; and by degrees, and more accurate observations, they would find, that the real time of her performing an entire revolution was very nearly 29½ days. This furnished them with the division of their time into months, or revolutions of the moon; of which we know with certainty they were possessed. But this period, though of great use, was evidently too short for many purposes, and particularly for measuring the seasons; which they could not fail to perceive depended on the influences of the sun. By continued observation they discovered, that about 12 revolutions of the moon included all the variety of seasons, which begun again, and revolved every 12 months. This suggested to them that larger division of time called a year, consisting of 12 lunations, or 354 days, which was the most ancient measure of the year in almost all nations. That this was for some time at least the form of the druidical year, is both probable in itself, and from the following expression of Pliny: "That they began both their months and years, not from the change, but from the sixth day of the moon." This is even a demonstration that their years consisted of a certain number of lunar revolutions, as they always commenced on the same day of the moon. But as this year of 12 lunar months falls 11 days and nearly one-fourth of a day short of a real revolution of the sun, this error would soon be perceived, and call for reformation; though we are not informed of the particular manner in which it was rectified. Various arguments might be collected to make it very probable that the Britons were acquainted with a year exact enough for every purpose of life, when they were first invaded by the Romans; but it will be sufficient to mention one, which is taken from the time and circumstances of that invasion. The learned Dr Halley hath demonstrated that Cæsar arrived in Britain, in his first year's expedition, on the 26th day of August:

gust: and Cæsar himself informs us, that at his arrival the harvest was finished, except in one field, which by some means or other was more backward than the rest of the country. This is a proof that the British husbandmen knew and used the most proper seasons for ploughing, sowing, and reaping. The druids, as we are told by Pliny, had also a cycle or period of 30 years, which they called an age, and which commenced likewise on the sixth day of the moon: but that author hath not acquainted us on what principle this cycle was formed, nor to what purpose it was applied. We can hardly suppose that this was the cycle of the sun, which consists of 28 years, and regulates the dominical letters. It is more probable, that while the druids made use of the year of 12 lunar months, and had not invented a method of adjusting it to the real revolution of the sun, they observed that the beginning of this year had passed through all the seasons, and returned to the point from whence it set out, in a course of about 33 years; which they might therefore call an age. Others may perhaps be of opinion, that this 30 years cycle of the druids is the same with the great year of the Pythagoreans, or a revolution of Saturn. Some have imagined that the druids were also acquainted with the cycle of 19 years, which is commonly called the cycle of the moon. But the evidence of this depends entirely on the truth of that supposition, that the Hyperborean island, which is described by Diodorus Siculus, was Britain, or some of the British isles. Among many other surprising things, that author says, concerning the Hyperborean island, "That its inhabitants believed that Apollo descended into their island at the end of every 19 years; in which period of time the sun and moon, having performed their various revolutions, return to the same point, and begin to repeat the same revolutions. This is called by the Greeks the great year, or the cycle of Meton."

7
Their knowledge of the stars.

We are told both by Cæsar and Mela, that the druids studied the stars as well as the sun and moon; and that they professed to know, and taught their disciples, many things concerning the motions of these heavenly bodies. From these testimonies we may conclude that the druids were acquainted with the planets, distinguished them from the fixed stars, and carefully observed their motions and revolutions. If this discovery was the result of their own observations, it would be gradual, and it would be a long time before they found out all the planets. They might perhaps have received some assistance and information from Pythagoras, or from some other quarter. But whether this discovery of the planets was their own, or communicated to them by others, it is highly probable that they were acquainted with the precise number of these wandering stars. Dio Cassius says, that the custom of giving the name of one of the planets to each of the seven days of the week was an invention of the Egyptians, and from them was gradually communicated to all the other nations of the world; and that in his time this custom was so firmly established, not only among the Romans, but among all the rest of mankind, that in every country it appeared to be a native institution. The knowledge of the planets, and perhaps the custom of giving their names to the days of the week, was brought out of Egypt into Italy by Pythagoras, more than 500 years before the beginning of the Christian era; and from thence it could not be very long before it reached Gaul and Britain. But though we have little or no reason to doubt that the druids knew the number and observed the motion of the planets, yet it may be questioned whether they had discovered the times in which they performed their several revolutions. Some of these stars, as Jupiter and Saturn, take so great a number of years in revolving, that it required a very extraordinary degree of patience and attention to discover the precise periods of their revolutions. If we could be certain that the island in which the ancients imagined Saturn lay asleep, was one of the British isles, as Plutarch intimates it was, we might be inclined to think that the British druids were not ignorant of the length of the period in which the planet Saturn performs a revolution. For that same author, in another treatise, tells us, "That the inhabitants of that island kept every thirtieth year a solemn festival in honour of Saturn, when his star entered into the sign of Taurus."

If we could depend upon the above testimony of Plutarch, we should have one positive proof that the druids of the British isles were acquainted with the constellations, and even with the signs of the zodiac; and that they measured the revolutions of the sun and planets, by observing the length of time between their departure from and return to one of these signs. But we have no direct evidence of this remaining in history.

The druids of Gaul and Britain, as well as the ancient philosophers of other countries, had a general plan or system of the universe, and of the disposition and arrangement of its various parts, in which they instructed their disciples. This is both probable in itself, and is plainly intimated by several authors of the greatest authority. But we cannot be certain whether this druidical system of the world was of their own invention, or was borrowed from others. If it was borrowed, it was most probably from the Pythagoreans, to whom they were the nearest neighbours; and with whom they had the greatest intercourse.

It hath been imagined, that the druids had instruments of some kind or other, which answered the same purposes with our telescopes, in making observations on the heavenly bodies. The only foundation of this very improbable conjecture is an expression of Diodorus Siculus, in his description of the famous Hyperborean island. "They say further, that the moon is seen from that island, as if she was but at a little distance from the earth, and having hills or mountains like ours on her surface." But no such inference can be reasonably drawn from this expression, which in reality merits little more regard than what Strabo reports was said of some of the inhabitants of Spain: "That they heard the hissing noise of the sun every evening when he fell into the western ocean."

The application of the druids to the study of philosophy and astronomy amounts almost to a demonstration that they applied also to the study of arithmetic and geometry. For some knowledge of both these sciences is indispensably necessary to the physiologist and astronomer, as well as of great and daily use in the common affairs of life.

If we were certain that **Abaris**, the famous Hyperborean philosopher, the friend and scholar of Pythagoras, Druids.

thagoras, was really a British druid, as some have imagined, we should be able to produce direct historical evidence of their arithmetical knowledge. For Iamblicus, in the life of Pythagoras, says, "that he taught Abaris to find out all truth by the science of arithmetic." It may be thought improbable that the druids had made any considerable progress in arithmetic, as this may seem to be impossible by the mere strength of memory without the assistance of figures and of written rules. But it is very difficult to ascertain what may be done by memory alone, when it hath been long exercised in this way. We have had an example in our own age, of a person * who could perform some of the most tedious and difficult operations in arithmetic by the mere strength of his memory. The want of written rules could be no great disadvantage to the druids, as the precepts of this, as well as of the other sciences, were couched in verse, which would be easily got by heart and long remembered. Though the druids were unacquainted with the Arabic characters, which are now in use, we have no reason to suppose that they were destitute of marks or characters of some other kind, which, in some measure, answered the same purposes, both in making and recording their calculations. In particular, we have reason to think, that they made use of the letters of the Greek alphabet for both these purposes. This seems to be plainly intimated by Cæsar in the following expression concerning the druids of Gaul: "In almost all other public transactions and private accounts or computations, they make use of the Greek letters." This is further confirmed by what the same author says of the Helvetii; a people of the same origin, language, and manners, with the Gauls and Britons. "Tables were found in the camp of the Helvetii written in Greek letters, containing an account of all the men capable of bearing arms, who had left their native country, and also separate accounts of the boys, old men, and women." There is historical evidence of the druids being also well acquainted with geometry. "When any disputes arise (says Cæsar) about their inheritances, or any controversies about the limits of their fields, they are entirely referred to the decision of their druids." But besides the knowledge of mensuration which this implies, both Cæsar and Mela plainly intimate that the druids were conversant in the most sublime speculations of geometry; "in measuring the magnitude of the earth, and even of the world."

Ski n mecha cs.

There are still many monuments remaining in Britain and the adjacent isles, which cannot so reasonably be ascribed to any as to the ancient Britons, and which give us cause to think, that they had made great progress in this useful part of learning, and could apply the mechanical powers so as to produce very astonishing effects. As these monuments appear to have been designed for religious purposes, we may be certain that they were erected under the direction of the druids. How many obelisks or pillars, of one rough unpolished stone each, are still to be seen in Britain and its isles! Some of these pillars are both very thick and lofty, erected on the summits of barrows and of mountains; and some of them (as at Stonehenge) have ponderous blocks of stone raised aloft, and resting on the tops of the upright pillars. We can hardly suppose that it was possible to cut these prodigious masses of stone (some of them above 40 tons in weight) without wedges, or to raise them out of the quarry without levers. But it certainly required still greater knowledge of the mechanical powers, and of the method of applying them, to transport those huge stones from the quarry to the places of their destination; to erect the perpendicular pillars, and to elevate the imposts to the tops of these pillars. If that prodigious stone in the parish of Constantine, Cornwall, was really removed by art from its original place, and fixed where it now stands (as one of our most learned and diligent antiquaries thinks it was *). it is a demonstration, that the druids could perform the most astonishing feats by their skill in mechanics. That the British druids were acquainted with the principles and use of the balance, we have good reason to believe, not only from the great antiquity of that discovery in other parts of the world, but also from some druidical monuments which are still remaining in this island. These monuments are called *Logan Stones*, or rocking stones; and each of them consists of one prodigious block of stone, resting upon an upright stone or rock, and so equally balanced, that a very small force, sometimes even that of a child, can move it up and down, though hardly any force is sufficient to remove it from its station. Some of these stones may have fallen into this position by accident, but others of them evidently appear to have been placed in it by art. That the ancient Britons understood the construction and use of wheels, the great number of their war-chariots and other wheel-carriages is a sufficient proof; and that they knew how to combine them together and with the other mechanical powers, so as to form machines capable of raising and transporting very heavy weights, we have good reason to believe. In a word, if the British druids were wholly ignorant of the principles and use of any of the mechanical powers, it was most probably of the screw, though even of this we cannot be certain.

10 Medicine.

In Germany and in the northern nations of Europe, the healing art was chiefly committed to the old women of every state; but in Gaul and Britain it was entrusted to the druids, who were the physicians as well as the priests of these countries. Pliny says expressly, "That Tiberius Cæsar destroyed the druids of the Gauls, who were the poets and physicians of that nation;" and he might have added of the Britons. The people of Gaul and Britain were probably induced to devolve the care of their health on the druids, and to apply to these priests for the cure of their diseases, not only by the high esteem they had of their wisdom and learning, but also by the opinion which they entertained, that a very intimate connection subsisted between the arts of healing and the rites of religion, and that the former were most effectual when they were accompanied by the latter. It appears indeed to have been the prevailing opinion of all the nations of antiquity, that all internal diseases proceeded immediately from the anger of the gods; and that the only way of obtaining relief from these diseases was by applying to their priests to appease their anger by religious rites and sacrifices. This was evidently the opinion and practice of the Gauls and Britons, who in some dangerous cases sacrificed one man as the most effectual means of curing

---

* *Dr Borlase's Antiq. Cornwall*, p. 174, 175.

another. "They are much addicted (says Cæsar) to superstition; and for this cause, those who are afflicted with a dangerous disease sacrifice a man, or promise that they will sacrifice one for their recovery. For this purpose they make use of the ministry of the druids; because they have declared, that the anger of the immortal gods cannot be appeased, so as to spare the life of one man, but by the life of another." This way of thinking gave rise also to that great number of magical rites and incantations with which the medical practices of the druids, and indeed of all the physicians of antiquity, were attended. "Nobody doubts (says Pliny) that magic derived its origin from medicine, and that, by its flattering but delusive promises, it came to be esteemed the most sublime and sacred part of the art of healing."

11 Botany. That the druids made great use of herbs for medicinal purposes, we have sufficient evidence. They not only had a most superstitious veneration for the misletoe of the oak, on a religious account, but they also entertained a very high opinion of its medical virtues, and esteemed it a kind of panacea or remedy for all diseases. "They call it (says Pliny) by a name which in their language signifies *All-heal*, because they have an opinion that it cureth all diseases. They believed it to be in particular a specific against barrenness, and a sovereign antidote against the fatal effects of poisons of all kinds. It was esteemed also an excellent emollient and discutient for softening and discussing hard tumours; good for drying up scrophulous sores; for curing ulcers and wounds; and (provided it was not suffered to touch the earth after it was cut) it was thought to be a very efficacious medicine in the epilepsy or falling sickness. It hath been thought useful in this last calamitous disease by some modern physicians. The pompous ceremonies with which the misletoe was gathered by the druids have been already described. The selago, a kind of hedge hyssop resembling savin, was another plant much admired by the druids of Gaul and Britain for its supposed medicinal virtues, particularly in all diseases of the eyes. But its efficacy, according to them, depended very much upon its being gathered exactly in the following manner: The person who gathered it was to be clothed in a white robe; to have his feet bare, and washed in pure water; to offer a sacrifice of bread and wine before he proceeded to cut it; which he was to do with his right hand covered with the skirt of his garment, and with a hook of some more precious metal than iron. When it was cut, it was to be received into, and kept in a new and very clean cloth. When it was gathered exactly according to this whimsical ritual, they affirmed that it was not only an excellent medicine, but also a powerful charm and preservative from misfortunes and unhappy accidents of all kinds. They entertained a high opinion also of the herb samolus or marshwort, for its sanative qualities; and gave many directions for the gathering it no less fanciful than those above mentioned. The person who was to perform that office was to do it fasting, and with his left hand; he was on no account to look behind him, nor to turn his face from the herbs he was gathering. It would be tedious to relate the extravagant notions they entertained of the many virtues of the vervain, and to recount the ridiculous mummeries which they practised in gathering and preparing it, both for the purposes of divination and physic. These things may be seen in Plin. Hist. Nat. l. 25. c. 9. from whence we have received all these anecdotes of the botany of the druids. It is easy to see that his information was very imperfect; and that, like many of the other Greek and Roman writers, he designedly represents the philosophers of Gaul and Britain in an unfavourable light. The herb which was called *Britannica* by the ancients, which some think was the great water-dock, and others the cochlearia or scurvy-grass, was probably much used in this island for medicinal purposes; as it derived its name from hence, and was from hence exported to Rome and other parts. Though these few imperfect hints are all that we can now collect of the botany of the British druids, yet we have some reason to think that they were not contemptible botanists. Their circumstances were peculiarly favourable for the acquisition of this kind of knowledge. For as they spent most of their time in the recesses of mountains, groves, and woods, the spontaneous vegetable productions of the earth constantly presented themselves to their view, and courted their attention.

The opinions which, it is said, the druids of Gaul and Britain entertained of their anguinum or serpents egg, both as a charm and as a medicine, are romantic and extravagant in a very high degree. This extraordinary egg was formed, as they pretended, by a great number of serpents, interwoven and twined together; and when it was formed, it was raised up in the air by the hissing of these serpents, and was to be catched in a clean white cloth before it fell to the ground. The person who catched it was obliged to mount a swift horse, and to ride away at full speed to escape from the serpents, who pursued him with great rage, until they were stopped by some river. The way of making trial of the genuineness of the egg was no less extraordinary. It was to be enchased in gold, and thrown into a river, and if it was genuine it would swim against the stream. "I have seen (says Pliny) that egg; it is about the bigness of a moderate apple, its shell is a cartilaginous incrustation, full of little cavities, such as are on the legs of the polypus; it is the insignia or badge of distinction of the druids." The virtues which they ascribed to this egg were many and wonderful. It was particularly efficacious to render those who carried it about with them superior to their adversaries in all disputes, and to procure them the favour and friendship of great men. Some have thought that this whole affair of the serpents egg was a mere fraud, contrived by the druids, to excite the admiration and pick the pockets of credulous people, who purchased these wonder-working eggs from them at a high price. Others have imagined that this story of the anguinum (of which there is an ancient monument in the cathedral at Paris) was an emblematical representation of the doctrine of the druids concerning the creation of the world. The serpents, say they, represent the Divine wisdom forming the universe, and the egg is the emblem of the world formed by that wisdom. It may be added, that the virtue ascribed to the anguinum, of giving those who possessed it a superiority over others, and endearing them to great men, may perhaps be intended to represent the natural effects of learning and philosophy. But in so doubtful a matter every one is at full liberty to form what judgment he thinks proper.

12 toric. As the influence and authority of the druids in their country, depended very much upon the reputation of their superior wisdom and learning, they wisely applied to the study of those sciences which most directly contributed to the support and advancement of that reputation. In this number, besides those already mentioned, we may justly reckon rhetoric, which was diligently studied and taught by the druids of Gaul and Britain; who to the charms of their eloquence were indebted for much of the admiration and authority which they enjoyed. They had indeed many calls and opportunities to display their eloquence, and to discover its great power and efficacy; as when they were teaching their pupils in their schools; when they discoursed in public to the people on religious and moral subjects; when they pleaded causes in the courts of justice; and when they harangued in the great councils of the nation, and at the heads of armies ready to engage in battle, sometimes with a view to inflame their courage, and at other times with a design to allay their fury, and dispose them to make peace. Though this last was certainly a difficult task among fierce and warlike nations, yet such was the authority and eloquence of the druids, that they frequently succeeded in it. "They pay a great regard (says Diodorus Siculus) to their exhortations, not only in the affairs of peace, but even of war, and these are respected both by their friends and enemies. They sometimes step in between two hostile armies, who are standing with their swords drawn and their spears extended, ready to engage; and by their eloquence, as by an irresistible enchantment, they prevent the effusion of blood, and prevail upon them to sheath their swords. So great are the charms of eloquence and the power of wisdom even amongst the most fierce barbarians. The British kings and chieftains, who were educated by the druids, were famous for their eloquence. This is evident from the many noble speeches which are ascribed to them by the Greek and Roman writers. For though these speeches may not be genuine, yet they are a proof that it was a well known fact, that these princes were accustomed to make harangues on these and the like occasions. This we are expressly told by Tacitus:—"The British chieftains, before a battle, fly from rank to rank, and address their men with animating speeches, tending to inflame their courage, increase their hopes, and dispel their fears." These harangues were called, in the ancient language of Britain, *Brosnichty Kah*, which is literally translated by Tacitus, *Incitamenta Belli*, "incentives to war." The genuine posterity of the ancient Britons long retained their taste for eloquence, and their high esteem for those who excelled in that art. "Orators (says Mr Martin) were in high esteem, both in these islands (the Æbudæ) and the continent, until within these forty years. They sat always among the nobles or chiefs of families in the streah or circle. Their houses and little villages were sanctuaries, as well as churches, and they took place before doctors of physic. The orators, after the druids were extinct, were brought in to preserve the genealogy of families, and to repeat the same at every succession of a chief; and upon the occasion of marriages and births, they made epithalamiums and panegyrics, which the poet or bard pronounced. The orators, by the force of their eloquence, had a powerful ascendant over the greatest men in their time. For if any orator did but ask the habit, arms, horse, or any other thing belonging to the greatest man in these islands, it was readily granted him; sometimes out of respect, and sometimes for fear of being exclaimed against by a satire, which in those days was reckoned a great dishonour."

13 Magic and divination. If the British druids, considering the times in which they lived, had made no contemptible proficiency in several parts of real and useful learning, it cannot be denied that they were also great pretenders to superior knowledge in certain vain fallacious sciences, by which they excited the admiration, and took advantage of the ignorance and credulity of mankind. These were the sciences (if they may be so called) of magic and divination; by which they pretended to work a kind of miracles, and exhibit astonishing appearances in nature; to penetrate into the counsels of heaven; to foretel future events, and to discover the success or miscarriage of public or private undertakings. Their own countrymen not only believed that the Druids of Gaul and Britain were possessed of these powers, but they were celebrated on this account by the philosophers of Greece and Rome. "In Britain (says Pliny) the magic arts are cultivated with such astonishing success, and so many ceremonies, at this day, that the Britons seem to be capable of instructing even the Persians themselves in these arts. They pretend to discover the designs and purposes of the gods. The Eubates or Vates in particular investigate and display the most sublime secrets of nature; and, by auspices and sacrifices, they foretel future events." They were so famous for the supposed veracity of their predictions, that they were not only consulted on all important occasions by their own princes and great men, but even sometimes by the Roman emperors. Nor is it very difficult to account for all this. The druids finding that the reputation of their magical and prophetical powers contributed not a little to the advancement of their wealth and influence, they endeavoured, no doubt, to strengthen and establish it by all their art and cunning. Their knowledge of natural philosophy and mechanics enabled them to execute such works, and to exhibit such appearances, or to make the world believe that they did exhibit them, as were sufficient to gain them the character of great magicians. The truth is, that nothing is more easy than to acquire this character in a dark age, and among an unenlightened people. When the minds of men are haunted with dreams of charms and enchantments, they are apt to fancy that the most common occurrences in nature are the effects of magical arts. The following strange story, which we meet with in Plutarch's Treatise of the Cessation of Oracles, was probably occasioned by something of this kind. "There are many islands which lie scattered about the isle of Britain after the manner of our Sporades. They are generally unpeopled, and some of them are called the *Islands of the Heroes*. One Demetrius was sent by the emperor (perhaps Claudius) to discover those parts. He arrived at one of these islands (supposed by some to be Anglesey, but more probably one of the Æbudæ) next adjoining to the isle of Britain before mentioned, which

which was inhabited by a few Britons, who were esteemed sacred and inviolable by their countrymen. Immediately after his arrival the air grew black and troubled, and strange apparitions were seen; the winds arose to a tempest, and fiery spouts and whirlwinds appeared dancing towards the earth." This was probably no more than a storm of wind, accompanied with rain, and lightning; a thing neither unnatural nor uncommon: but Demetrius and his companions having heard that the British druids, by whom this isle was chiefly inhabited, were great magicians, they imagined that it was raised by them; and fancied that they saw many strange and unnatural sights. The druids did not think proper to undeceive them; for when they inquired at them about the cause of this storm, they told them it was occasioned by the death of one of those invisible beings or genii who frequented their isle. A wonderful and artful tale, very well calculated to increase the superstitious terrors of Demetrius and his crew; and to determine them to abandon this enchanted isle, with a resolution never to return. Stonehenge, and several other works of the druids, were believed to have been executed by the arts of magic and enchantment, for many ages after the destruction of their whole order; nor is it improbable that they persuaded the vulgar in their own times to entertain the same opinion of these works, by concealing from them the real arts by which they are performed. The natural and acquired sagacity of the druids, their long experience, and great concern in the conduct of affairs, enabled them to form very probable conjectures about the event of enterprises. These conjectures they pronounced as oracles, when they were consulted; and they pretended to derive them from the inspection of the entrails of victims, the observation of the flight and feeding of certain birds, and many other mummeries. By these, and the like arts, they obtained and preserved the reputation of prophetic foresight among an ignorant and credulous people. But these pretensions of the druids to magic and divination, which contributed so much to the advancement of their fame and fortune in their own times, have brought very heavy reproaches upon their memory, and have made some learned moderns declare that they ought to be expunged out of the catalogue of philosophers, and esteemed no better than mere cheats and jugglers. This censure is evidently too severe, and might have been pronounced with equal justice upon all the ancient philosophers of Egypt, Assyria, Persia, Greece, and Rome; who were great pretenders to magic and divination, as well as our druids. "I know of no nation in the world (says Cicero) either so polite and learned, or so savage and barbarous, as not to believe that future events are presignified to us, and may by some men be discovered and foretold." The only conclusion therefore that can be fairly drawn, from the successful pretensions of the British druids to the arts of magic and divination, is this—That they had more knowledge than their countrymen and contemporaries; but had not so much virtue as to resist the temptation of imposing upon their ignorance to their own advantage.

DRUM, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or slackened at pleasure by the means of small cords or sliding knots. It is beat upon with sticks. Drums are sometimes made of brass, but most commonly they are of wood.—The drum is by Le Clerc said to have been an oriental invention, and to have been brought by the Arabians, or perhaps rather the Moors, into Spain.

Kettle DRUMS, are two sorts of large basons of copper or brass, rounded in the bottom, and covered with vellum or goat skin, which is kept fast by a circle of iron round the body of the drum, with a number of screws to screw up and down. They are much used among the horse; as also in operas, oratorios, concerts, &c.

DRUM, or *Drummer*, he that beats the drum; of whom each company of foot has one, and sometimes two. Every regiment has a drum major, who has the command over the other drums. They are distinguished from the soldiers by clothes of a different fashion: their post, when a battalion is drawn up, is on the flanks, and on a march it is betwixt the divisions.

DRUM *of the Ear*, the same with the *tympanum*. See ANATOMY *Index*.

DRUMMOND, WILLIAM, a Scottish poet, was born in 1585, and was the son of Sir John Drummond, who for ten or twelve years was usher and afterwards knight of the black rod to James VI. His family became first distinguished by the marriage of Robert III. whose queen was sister to William Drummond of Carnock their ancestor; as appears by the patent of that king and James I. the one calling him "our brother," the other "our uncle."

Drummond was educated at Edinburgh, where he took the degree of A. M. In 1606 he was sent by his father to study civil law at Bourges in France: but having no taste for the profession of a lawyer, he returned to Scotland, and retired to his agreeable seat at Hawthornden; where he applied himself with great assiduity to classical learning and poetry, and presented to the world several fine productions. Here he wrote, after a dangerous fit of sickness, his Cypress Grove, a piece of excellent prose; and about the same time his Flowers of Sion in verse. But an accident befel him, which obliged him to quit his retirement; and that was the death of an amiable lady to whom he was just going to be married. This affected him so deeply, that he went to Paris and Rome, between which two places he resided eight years. He travelled also through Germany, France, and Italy: where he visited universities; conversed with learned men; and made a choice collection of the ancient Greek and of the modern Spanish, French, and Italian books. He then returned to his native country; and some time thereafter married Margaret Logan, a grand-daughter of Sir Robert Logan. Upon the appearance of a civil war, he retired again; and in his retirement is supposed to have written his history of the Five James's, successively kings of Scotland, which was not published till after his death. Having been grafted as it were on the royal family of Scotland, and upheld by them, he was steadily attached to Charles I.; but does not appear ever to have armed for him. As he had always been a laborious student, and had applied himself equally to history and politics as to classical learning, his services were better rendered by occasional publications, in which

Drummond.

which he several times distinguished himself. In a piece called *Irene*, he harangues the king, nobility, and clergy, about their mutual mistakes, fears, and jealousies; and lays before them the consequences of a civil war, from indisputable arguments and the histories of past times. The great marquis of Montrose wrote a letter to him, desiring him to print this Irene, as the best means to quiet the minds of a distracted people: he likewise sent him a protection, dated August 1645, immediately after the battle of Kilsyth, with a letter, in which he commends Mr Drummond's learning and loyalty. Mr Drummond wrote other things also with the same view of promoting peace and union, of calming the disturbed minds of the people, of reasoning the better sort into moderation, and checking the growing evils which would be the consequence of their obstinacy. But his efforts were fruitless; and his attachment to the king and his cause was so strong, that when he heard of the sentence being executed on him, he was overwhelmed with grief, and lifted his head no more. He died in the year 1649, leaving behind him several children: the eldest of whom, William, was knighted by Charles II. He had a great intimacy and correspondence with the two famous English poets, Michael Drayton and Ben Johnson; the latter of whom, at the age of 45, travelled from London on foot to visit him at Hawthornden. An edition of his works, with his life prefixed, was printed in folio at Edinburgh, 1711.

Among all the writers at the beginning of the 17th century, who flourished after the death of Shakespeare, an ingenious critic * observes, there is not one whom a general reader of the English poetry of that age will regard with so much and so deserved attention as William Drummond. In a survey of his poetry, two considerations must be had, viz. the nation of which he was, and the time when he wrote. Yet will these be found not offered to extenuate faults, but to increase admiration. His thoughts are often, nay generally, bold and highly poetical: he follows nature, and his verses are delicately harmonious. As his poems are not easily met with, and have perhaps by many readers never been heard of, a few extracts may be excused.

On the death of Henry prince of Wales in 1612, Drummond wrote an elegy, entitled Tears on the Death of Moeliades; a name which that prince had used in all his challenges of martial sport, as the anagram of *Miles a Deo*. In this poem are lines, according to Denham's terms, as strong, as deep, as gentle, and as full, as any of his or Waller's. The poet laments the fate of the prince, that he died not in some glorious cause of war: "Against the Turk (says he) thou hadst ended thy life and the Christian war together:"

> Or, as brave Bourbon, thou hadst made old Rome,
> Queen of the world, thy triumph and thy tombe.

Of the lamentation of the river Forth:

> And as she rushed her Cyclades among,
> She seem'd to plain that Heav'n had done her wrong.

Further:

> Tagus did court his love with golden streams,
> Rhine with her towns, fair Seine with all she claims:
> But ah, poor lovers! death did them betray;
> And unsuspected, made their hopes his prey.

And concludes:

> The virgins to thy tomb will garlands bear
> Of flowers, and with each flower let fall a tear.
> Moeliades sweet courtly nymphs deplore,
> From Thulé to Hydaspes' pearly shore.

Perhaps there are no lines of Pope of which the easy flow may be more justly admired than of those in his third pastoral;

> Not bubbling fountains to the thirsty swain,
> Not balmy sleep to lab'rers faint with pain,
> Not showers to larks, or sunshine to the bee,
> Are half so charming as thy sight to me.

When King James I. after his accession to the English throne, returned to Scotland in 1617, his arrival was celebrated by every effort of poetical congratulation. Upon this occasion Drummond composed a panegyric entitled The Wandering Muses, or the River Forth feasting; in which are found four lines apparently imitated by Pope in the above passage, and which do not in point of harmony fall much short of that imitation. He says,

> To virgins, flow'rs; to sun-burnt earth, the rain;
> To mariners, fair winds amidst the main;
> Cool shades, to pilgrims whom hot glances burn;
> Are not so pleasing as thy blest return.

Of these two poems of Drummond, it is observable, that the first was written in 1612, the last in 1617. The earliest piece of Waller is that to the king on his navy in 1625. The piece in which Sir John Denham's greatest force lies, Cooper's Hill, was not written till 1640. The harmony of Drummond, therefore, at a time when those who are usually called the first introducers of a smooth and polished versification had not yet begun to write, is an honour to him that should never be forgotten. Nor is his excellence half enough praised or acknowledged.

Drummond and Petrarch had this in common, that each lamented, first the cruelty, and then the loss of his mistress; so that their sonnets are alike naturally divided into two parts, those before and those after their several mistresses deaths. It may justly be doubted, that among all the sonneteers in the English language any one is to be preferred to Drummond. He has shown in some of those compositions nearly the spirit of Petrarch himself. Of each period one is here inserted; the first, before the death of his mistress:

> Ah me, and am I now the man, whose muse
> In happier times was wont to laugh at love,
> In those who suffered that blind boy abuse
> The noble gifts were giv'n them from above!
> What metamorphose strange is this I prove?
> Myself I scarce now find myself to be;
> And think no fable Circe's tyrannie,
> And all the tales are told of changed Jove.
> Virtue hath taught, with her philosophy
> My mind into a better course to move.
> Reason may chide her full, and oft reprove
> Affection's power; but what is that to me,
> Who ever think, and never think on aught
> But that bright cherubim which thralls my thought!

* Cursory Remarks on some of the English Poets, 8vo 1789.

Drummond, Drunkenness.

From Part II. after her death, (Sonnet I.)

Of mortal glory, O soon darken'd ray!
O winged joys of man, more swift than wind!
O fond desires which in our fancies stray!
O traitorous hope which do our judgments blind!

Lo, in a flash that light is gone away,
Which dazzle did each eye, delight each mind;
And with that sun from whence it came combin'd,
Now makes more radiant heaven's eternal day.

Let Beauty now bedew her cheeks with tears;
Let widow'd Music only roar and groan;
Poor Virtue, get thee wings and mount the spheres,
For dwelling place on earth for thee is none:
Death hath thy temple raz'd, Love's empire soil'd,
The world of honour, worth, and sweetness spoil'd.

The seventh sonnet of the first part has much resemblance to Sir Henry Wotton's elegant little poem on the queen of Bohemia, "Ye meaner beauties," &c. Among Drummond's Flowers of Sion, the poem which begins "Amidst the azure clear—of Jordan's sacred streams," eminently distinguishes him, whether he be considered as a philosopher or a poet.

DRUNKENNESS, a well-known disorder in the brain, occasioned by drinking too freely of spirituous liquors. Drunkenness appears in different shapes in different constitutions: some it makes gay, some sullen, and some furious. The mischief of drunkenness consists in the following bad effects: 1. It betrays most constitutions either into extravagancies of anger, or sins of lewdness. 2. It disqualifies men for the duties of their station, both by the temporary disorder of their faculties, and at length by a constant incapacity and stupefaction. 3. It is attended with expences, which can often be ill spared. 4. It is sure to occasion uneasiness to the family of the drunkard. 5. It shortens life. To these consequences of drunkenness must be added the peculiar danger and mischief of the example. "Drunkenness (Mr Paley observes) is a social festive vice. The drinker collects his circle; the circle naturally spreads; of those who are drawn within it, many become the corrupters and centres of sets and circles of their own; every one countenancing, and perhaps emulating, the rest, till a whole neighbourhood be infected from the contagion of a single example. With this observation upon the spreading quality of drunkenness, may be connected a remark which belongs to the several evil effects above recited. The consequences of a vice, like the symptoms of a disease, though they be all enumerated in the description, seldom all meet in the same subject. In the instance under consideration, the age and temperature of one drunkard may have little to fear from inflammations of lust or anger; the fortune of a second may not be injured by the expence: a third may have no family to be disquieted by his irregularities; and a fourth may possess a constitution fortified against the poison of strong liquors. But if, as we always ought to do, we comprehend within the consequences of our conduct the mischief and tendency of the example, the above circumstances, however fortunate for the individual, will be found to vary the guilt of his intemperance less, probably, than he supposes. Although the waste of time and money may be of small importance to you, it may be of the utmost to some one or other whom your society corrupts. Repeated or long-continued excesses, which hurt not your health, may be fatal to your companion. Although you have neither wife nor child, nor parent, to lament your absence from home, or expect your return to it with terror; other families, whose husbands and fathers have been invited to share in your ebriety, or encouraged to imitate it, may justly lay their misery or ruin at your door. This will hold good, whether the person seduced be seduced immediately by you, or the vice be propagated from you to him through several intermediate examples."

Drunkenness.

The ancient Lacedæmonians used to make their slaves frequently drunk, to give their children an aversion and horror for the same. The Indians hold drunkenness a species of madness; and in their language, the same term (*ramgam*), that signifies "drunkard," signifies also "a phrenetic."

Drunkenness is repeatedly forbidden by St Paul: "Be not drunk with wine, wherein is excess." "Let us walk honestly as in the day, not in rioting and drunkenness: "Be not deceived: neither fornicators, nor drunkards, nor revilers, nor extortioners, shall inherit the kingdom of God," Eph. vi. 18. Rom. xiii. 13. 1 Cor. vi. 9, 10. The same apostle likewise condemns drunkenness, as peculiarly inconsistent with the Christian profession: "They that be drunken, are drunken in the night; but let us, who are of the day, be sober." 1 Thess. v. 7, 8.

Drunkenness, by our laws, is looked upon as an aggravation rather than an excuse for any criminal behaviour. A drunkard, says Sir Edward Coke, who is *voluntarius dæmon*, hath no privilege thereby: but what hurt or ill soever he doth, his drunkenness doth aggravate it: *nam omne crimen ebrietas et incendit et detergit*. It hath been observed that the real use of strong liquors, and the abuse of them by drinking to excess, depend much upon the temperature of the climate in which we live. The same indulgence which may be necessary to make the blood move in Norway, would make an Italian mad. A German, therefore, says the president Montesquieu, drinks through custom founded upon constitutional necessity; a Spaniard drinks through choice, or out of the mere wantonness of luxury; and drunkenness, he adds, ought to be more severely punished where it makes men mischievous and mad, as in Spain and Italy, than where it only renders them stupid and heavy, as in Germany, and more northern countries. And accordingly, in the warmer climate of Greece, a law of Pittacus enacted, "that he who committed a crime when drunk should receive a double punishment;" one for the crime itself, and the other for the ebriety which prompted him to commit it. The Roman law indeed made great allowances for this vice: *per vinum delapsis capitalis pœna remittitur*. But the law of England, considering how easy it is to counterfeit this excuse, and how weak an excuse it is (though real), will not suffer any man thus to privilege one crime by another.

For the offence of drunkenness a man may be punished in the ecclesiastical court, as well as by justices of peace by statute. And by 4 Jac. I. c. 5. and 21 Jac. I. c. 7. if any person shall be convicted of drunkenness by the view of a justice, oath of one witness,

ness, &c. he shall forfeit 5s. for the first offence, to be levied by distress, and sale of his goods; and for want of a distress shall sit in the stocks six hours: and for the second offence, he is to be bound with two sureties in 10l. each, to be of good behaviour, or to be committed. And he who is guilty of any crime through his own voluntary drunkenness, shall be punished for it as if he had been sober. It has been held that drunkenness is a sufficient cause to remove a magistrate; and the prosecution for this offence by the statute of 4 Jac. I. c. 5. was to be, and still may be, before justices of peace in their sessions by way of indictment, &c. Equity will not relieve against a bond, &c. given by a man when drunk, unless the drunkenness is occasioned through the management or contrivance of him to whom the bond is given.

The appetite for intoxicating liquors appears to be almost always acquired. One proof of which is, that it is apt to return only at particular times and places; as after dinner, in the evening, on the market day, at the market town, in such a company, at such a tavern. And this may be the reason, that if a habit of drunkenness be ever overcome, it is upon some change of place, situation, company, or profession. A man sunk deep in a habit of drunkenness, will upon such occasions as these, when he finds himself loosened from the associations which held him fast, sometimes make a plunge, and get out. In a matter of such great importance, it is well worth while, where it is tolerably convenient, to change our habitation and society, for the sake of the experiment.

Habits of drunkenness commonly take their rise either from a fondness for, or connexion with, some company, or some companion, already addicted to this practice; which affords an almost irresistible invitation to take a share in the indulgencies which those about us are enjoying with so much apparent relish and delight; or from want of regular employment, which is sure to let in many superfluous cravings and customs, and often this amongst the rest; or, lastly, from grief or fatigue, both which strongly solicit that relief which inebriating liquors administer for the present, and furnish a specious excuse for complying with the inclination. But the habit, when once set in, is continued by different motives from those to which it owes its origin. Persons addicted to excessive drinking suffer, in the intervals of sobriety, and near the return of their accustomed indulgence, a faintness and oppression about the *præcordia* which it exceeds the ordinary patience of human nature to endure. This is usually relieved for a short time by a repetition of the same excess: and to this relief, as to the removal of every long-continued pain, they who have once experienced it are urged almost beyond the power of resistance. This is not all; as the liquor loses its stimulus, the dose must be increased, to reach the same pitch of elevation or ease; which increase proportionably accelerates the progress of all the maladies that drunkenness brings on. Whoever reflects, therefore, upon the violence of the craving in advanced stages of the habit, and the fatal termination to which the gratification of it leads, will, the moment he perceives the least tendency in himself of a growing inclination to intemperance, collect his resolution to this point; or (what perhaps he will find his best security) arm himself with some peremptory rule, as to the times and quantity of his indulgencies.

DRUPA, or **Druppa**, in *Botany*, a species of *pericarpium* or seed-vessel, which is succulent or pulpy, has no valve or external opening like the capsule and pod, and contains within its substance a stone or nut. The cherry, plum, peach, apricot, and all other stone fruits are of this kind.

The term, which is of great antiquity, is synonymous to Tournefort's *fructus mollis ossiculo*, "soft fruit with a stone;" and to the *prunus* of other botanists.

The stone or nut, which in this species of fruit is surrounded by the soft pulpy flesh, is a kind of ligneous or woody cup, which contains a single kernel or seed.

This definition, however, will not apply to every seed-vessel denominated *drupa* in the *Genera Plantarum.* The almond is a *drupa*, so is the seed-vessel of the elm tree and the genus *rumphia*, though far from being pulpy or succulent; the first and third are of a substance like leather, the second like parchment. The same may be said of the walnut, pistachia nut, *guettarda*, *quisqualis*, jack-in-a-box, and some others.

Again, the seeds of the elm, *schrebera*, *flagellaria*, and the mango tree, are not cantained in a stone. The seed-vessel of burr reed is dry, shaped like a top, and contains two angular stones.

This species of fruit, or more properly seed-vessel, is commonly roundish, and when seated below the calyx or receptacle of the flower, is furnished, like the apple, at the end opposite to the footstalk, with a small umbilicus or cavity, which is produced by the swelling of the fruit before the falling off of the flower-cup.

DRUSES, or **Druzes**, a remarkable nation in Palestine, inhabiting the environs of Mount Lebanon, of whose origin and history we have the following detail by M. Volney.

Twenty-three years after the death of Mahomet, the disputes between Ali his son-in-law and Moaouia governor of Syria, occasioned the first schism in the empire of the Arabs, and the two sects subsist to this day: but, in reality, this difference related only to power; and the Mahometans, however divided in opinion respecting the rightful successor of the prophet, were agreed with respect to their dogmas. It was not until the following century that the perusal of Greek books introduced among the Arabs a spirit of discussion and controversy, to which till then they were utter strangers. The consequence was, as might be expected, by reasoning on matters not susceptible of demonstration, and guided by the abstract principles of an unintelligible logic, they divided into a multitude of sects and opinions. At this period, too, the civil power lost its authority; and religion, which from that derives the means of preserving its unity, shared the same fate, and the Mahometans now experienced what had before befallen the Christians. The nations which had received the religion of Mahomet, mixed with it their former absurd notions; and the errors which had anciently prevailed over Asia again made their appearance, though altered in their forms. The metempsychosis, the doctrine of a good and evil principle, and the renovation after six thousand years, as it had been taught by Zoroaster, were again revived among the Mahometans. In this political and religious confusion every

every enthusiast became an apostle, and every apostle the head of a sect. No less than sixty of these were reckoned, remarkable for the numbers of their followers, all differing in some points of faith, and all disavowing heresy and error. Such was the state of these countries when, at the commencement of the 11th century, Egypt became the theatre of one of the most extravagant scenes of enthusiasm and absurdity ever recorded in history. The following account is extracted from the western writers.

In the year of the Hegira 386 (A. D. 996), the third caliph of the race of the Fatimites, called *Hakem-b'amr-ellah*, succeeded to the throne of Egypt at the age of 11 years. He was one of the most extraordinary princes of whom history has preserved the memory. He caused the first caliphs, the companions of Mahomet, to be cursed in the mosques, and afterwards revoked the anathema: He compelled the Jews and Christians to abjure their religion, and then permitted them to resume it. He prohibited the making slippers for women, to prevent them from coming out of their houses. He burnt one half of the city of Cairo for his diversion, while his soldiers pillaged the other. Not contented with these extravagant actions, he forbade the pilgrimage to Mecca, fasting, and the five prayers; and at length carried his madness so far as to desire to pass for God himself. He ordered a register of those who acknowledged him to be so, and the number amounted to sixteen thousand. This impious pretension was supported by a false prophet, who came from Persia into Egypt; which impostor, named *Mohammed ben-Ismael*, taught that it was not necessary to fast or pray, to practise circumcision, to make the pilgrimage to Mecca, or observe festivals; that the prohibition of pork and wine was absurd; and that marriage between brothers and sisters, fathers and children, was lawful. To ingratiate himself with Hakem, he maintained that this caliph was God himself incarnate; and instead of his name *Hakem-b'amr-ellah*, which signifies *governor by the order of God*, he called him *Hakem b'amr-eh, governing by his own order.* Unluckily for the prophet, his new god had not the power to protect him from the fury of his enemies, who slew him in a tumult almost in the arms of the caliph, who was himself massacred soon after on Mount Mokattam, where he, as he said, had held conversation with angels.

The death of these two chiefs did not stop the progres of their opinions; a disciple of Mohammed-ben-Ismael, named *Hamzu-ben-Ahmud*, propagated them with an indefatigable zeal in Egypt, in Palestine, and along the coast of Syria, as far as Sidon and Berytus. His proselytes being persecuted by the sect in power, they took refuge in the mountains of Lebanon, where they were better able to defend themselves; at least it is certain, that, shortly after this era, we find them established there, and forming an independent society.

The difference of their opinions disposes them to be enemies; but the urgent interest of their common safety forces them to allow mutual toleration, and they have always appeared united, and have jointly opposed, at different times, the Crusaders, the sultans of Aleppo, the Mamelukes, and the Ottomans. The conquest of Syria by the latter made no change in their situation. Selim I. on his return from Egypt, meditating no less than the conquest of Europe, disdained to waste his time before the rocks of Lebanon. Soliman II. his successor, incessantly engaged in important wars, either with the knights of Rhodes, the Persians, the kingdom of Yemen, the Hungarians, the Germans, or the emperor Charles V. had no time to think of the Druses. Emboldened by this inattention, and not content with their independence, they frequently descended from their mountains, to pillage the Turks. The pachas in vain attempted to repel their inroads; their troops were invariably routed or repulsed. And it was not till the year 1588 that Amurath III. wearied with the complaints made to him, resolved, at all events, to reduce these rebels, and had the good fortune to succeed. His general Ibrahim Pacha marched from Cairo, and attacked the Druses and Maronites with so much address and vigour as to force them into their strong holds, the mountains. Dissension took place among their chiefs, of which he availed himself to exact a contribution of upward of one million of piastres, and to impose a tribute which has continued to the present time.

It appears that this expedition was the epoch of a considerable change in the constitution of the Druses. Till then they had lived in a sort of anarchy, under the command of different sheiks or lords. The nation was likewise divided into two factions, such as is to be found in all the Arab tribes, and which are distinguished into the party Kaisi and the party Yamani. To simplify the administration, Ibrahim permitted them only one chief, who should be responsible for the tribute, and execute the office of civil magistrate; and this governor, from the nature of his situation, acquiring great authority, became almost the king of the republic; but as he was always chosen from among the Druses, a consequence followed which the Turks had not foreseen, and which was nearly fatal to their power. For the chief thus chosen, having at his disposal the whole strength of the nation, was able to give it unanimity and energy, and it naturally turned against the Turks; since the Druses, by becoming their subjects, had not ceased to be their enemies. They took care, however, that their attacks should be indirect, so as to save appearances, and only engaged in secret hostilities, more dangerous, perhaps, than open war.

About this time, that is, the beginning of the 17th century, the power of the Druses attained its greatest height; which it owed to the talents and ambition of the celebrated Faker-el-din, commonly called *Fakardin.* No sooner was this prince advanced to be the chief of that people, than he turned his whole attention to humble the Ottoman power, and aggrandise himself at its expence. In this enterprise he displayed an address seldom seen among the Turks. He first gained the confidence of the Porte, by every demonstration of loyalty and fidelity; and as the Arabs at that time infested the plain of Balbec and the countries of Sour and Acre, he made war upon them, freed the inhabitants from their depredations, and thus rendered them desirous of living under his government.

The city of Bairout was situated advantageously for his designs, as it opened a communication with foreign countries, and among others, with the Venetians, the natural enemies of the Turks. Faker-el-din availed himself of the misconduct of the aga, expelled ed him, seized on the city, and even had the art to make a merit of this act of hostility with the Divan, by paying a more considerable tribute. He proceeded in the same manner at Saide, Balbec, and Sour; and at length, about the year 1613, saw himself master of all the country as far as Adjaloun and Safad. The pachas of Tripoli and Damascus could not see these encroachments with indifference; sometimes they opposed him with open force, though ineffectually, and sometimes endeavoured to ruin him at the Porte by secret insinuations; but the emir, who maintained there his spies and defenders, defeated every attempt.

At length, however, the Divan began to be alarmed at the progress of the Druses, and made preparations for an expedition capable of crushing them. Whether from policy or fear, Faker-el-din did not think proper to wait this storm. He had formed connexions in Italy, on which he built great hopes, and determined to go in person to solicit the succours they had promised him; persuaded that his presence would increase the zeal of his friends, while his absence might appease the resentment of his enemies. He therefore embarked at Bairout; and after resigning the administration to his son Ali, repaired to the court of the Medici at Florence. The arrival of an Oriental prince in Italy did not fail to attract the public attention. Inquiry was made into his nation, and the origin of the Druses became a popular topic of research. Their history and religion were found to be so little known, as to leave it a matter of doubt whether they should be classed with the Mahometans or Christians. The Crusades were called to mind; and it was soon suggested, that a people who had taken refuge in the mountains, and were enemies to the natives, could be no other than the offspring of the Crusaders.

This idle conceit was too favourable to Faker-el-din for him to endeavour to disprove it: he was artful enough, on the contrary, to pretend he was related to the house of Loraine; and the missionaries and merchants, who promised themselves a new opening for conversion and commerce, encouraged his pretensions. When an opinion is in vogue, every one discovers new proofs of its certainty. The learned in etymology, struck with the resemblance of the names, insisted, that Druses and Dreux, must be the same word; and on this foundation formed the system of a pretended colony of French Crusaders, who, under the conduct of a Comte de Dreux, had formed a settlement in Lebanon. This hypothesis, however, was completely overthrown by the remark, that the name of the Druses is to be found in the itinerary of Benjamin of Tudela, who travelled before the time of the Crusades. Indeed the futility of it ought to have been sufficiently apparent at first, from the single consideration, that had they been descended from any nation of the Franks, they must have retained at least the traces of some European language; for a people, retired into a separate district, and living distinct from the natives of the country, do not lose their language. That of the Druses, however, is very pure Arabic, without a single word of European origin. The real derivation of the name of this people has been long in our possession, without our knowing it. It originates from the founder of the sect of Mohammed-ben-Ismael, who was surnamed *El-Dorzi*, and not *El-Darari*, as it is usually printed: the confusion of these two words, so different in our writing, arises from the figure of the two Arabic letters *r* and *z*, which have only this difference, that the *z* has a point over it, frequently omitted or effaced in the manuscripts.

After a stay of nine years in Italy, Faker-el-din returned to resume the government of his country. During his absence, his son Ali had repulsed the Turks, appeased discontents, and maintained affairs in tolerable good order. Nothing remained for the emir, but to employ the knowledge he could not but have acquired, in perfecting the internal administration of government, and promoting the welfare of the nation; but instead of the useful and valuable arts, he wholly abandoned himself to the frivolous and expensive, for which he had imbibed a passion while in Italy. He built numerous villas, constructed baths, and planted gardens: he even presumed, without respect to the prejudices of his country, to employ the ornaments of painting and sculpture, notwithstanding these are prohibited by the Koran.

The consequences of this conduct soon manifested themselves: the Druses, who paid the same tribute as in time of war, became dissatisfied. The Yamani faction were roused; the people murmured at the expences of the prince; and the luxury he displayed renewed the jealousy of the pachas. They attempted to levy greater tribute: hostilities again commenced, and Faker-el-din repulsed the forces of the pachas; who took occasion, from this resistance, to render him suspected by the sultan himself. Amurath III. incensed that one of his subjects should dare to enter into a competition with him, resolved on his destruction; and the pacha of Damascus received orders to march, with all his forces, against Bairout, the usual residence of Faker-el-din; while 40 galleys invested it by sea, and cut off all communication.

The emir, who depended on his good fortune and succours from Italy, determined at first to brave the storm. His son Ali, who commanded at Safad, was ordered to oppose the progress of the Turkish army: and in fact he bravely resisted them, notwithstanding the great disparity of his forces; but after two engagements, in which he had the advantage, being slain in a third attack, the face of affairs was greatly changed, and every thing went to ruin. Faker-el-din, terrified at the loss of his troops, afflicted at the death of his son, and enfeebled by age and a voluptuous life, lost both courage and presence of mind. He no longer saw any resource but in a peace, which he sent his second son to solicit of the Turkish admiral, whom he attempted to seduce by presents; but the admiral detaining both the presents and envoy, declared he would have the prince himself. Faker-el-din, intimidated, took to flight, and was pursued by the Turks, now masters of the country. He took refuge on the steep eminence of Niha, where they besieged him ineffectually for a whole year, when they left him at liberty; but shortly after, the companions of his adversity, wearied with their sufferings, betrayed and delivered him up to the Turks. Faker-el-din, though in the hands of his enemies, conceived hopes of pardon, and suffered himself to be carried to Constantinople;

where Amurath, pleased to behold at his feet a prince so celebrated, at first treated him with the benevolence which arises from the pride of superiority; but soon returning to his former jealousies, yielded to the instigations of his courtiers, and, in one of his violent fits of passion, ordered him to be strangled, about the year 1631.

After the death of Faker-el-din, the posterity of that prince still continued in possession of the government, though at the pleasure, and as vassals of the Turks. This family failing in the male line at the beginning of the last century, the authority devolved, by the election of the shaiks, on the house of Shelah, in which it still continues. The only emir of that house, whose name deserves to be preserved, is the emir Melhem, who reigned from 1740 to 1759; in which interval he retrieved the losses of the Druses, and restored them to that consequence which they had lost by the defeat of Faker-el-din. Towards the end of his life, about the year 1754, Melhem, wearied with the cares of government, abdicated his authority, to live in religious retirement, after the manner of the Okkals; but the troubles that succeeded occasioned him once more to resume the reins of government, which he held till 1759, when he died, universally regretted.

He left three sons, minors; the eldest of whom ought, according to the custom of the country, to have succeeded him; but being only 11 years of age, the authority devolved on his uncle Mansour, agreeably to a law very general in Asia, which wills the people to be governed by a sovereign who has arrived at years of maturity. The young prince was but little fitted to maintain his pretensions; but a Maronite, named Sad-el-Kouri, to whom Melhem had intrusted his education, took this upon himself. Aspiring to see his pupil a powerful prince, that he might himself become a powerful visir, he made every exertion to advance his fortune. He first retired with him to Djebail, in the Kesraouan, where the emir Yousef possessed large domains, and there undertook to conciliate the Maronites, by embracing every opportunity to serve both individuals and the nation. The great revenues of his pupil, and the moderation of his expenditure, amply furnished him with the means. The farm of the Kesraouan was divided between several shaiks, with whom the Porte was not very well satisfied. Sad treated for the whole with the pacha of Tripoli, and got himself appointed sole receiver. The Motoualis of the valley of Balbec had for some years before made several encroachments on Lebanon, and the Maronites began to be alarmed at the near approach of these intolerant Mahometans. Sad purchased of the pacha of Damascus a permission to make war upon them; and in 1763 drove them out of the conntry. The Druses were at that time divided into two factions: Sad united his interest with those who opposed Mansour, and secretly prepared the plot which was to raise the nephew on the ruin of the uncle.

At this period the Arab Daher, who had made himself master of Galilee, and fixed his residence at Acre, disquieted the Porte by his progress and pretensions; to oppose him, the Divan had just united the pachalics of Damascus, Saide, and Tripoli, in the hands of Osman and his children; and it was evident that an open war was not very remote. Mansour, who dreaded the Turks too much to resist them, made use of the policy usual on such occasions, pretending a zeal for their service, while he secretly favoured their enemy. This was a sufficient motive for Sad to pursue measures directly opposite. He supported the Turks against the faction of Mansour, and manœuvred with so much good fortune or address as to depose that emir in 1770, and place Yousef in his government.

In the following year Ali Bey declared war, and attacked Damascus. Yousef, called on by the Turks, took part in the quarrel, but without being able to draw the Druses from their mountains to enter into the army of the Ottomans. Besides their natural repugnance, at all times, to make war out of their country, they were on this occasion too much divided at home to quit their habitations, and they had reason to congratulate themselves on the event. The battle of Damascus ensued; and the Turks, as we have already seen, were completely routed. The pacha of Saide escaping from this defeat, and not thinking himself in safety in that town, sought an asylum even in the house of the emir Yousef. The moment was unfavourable; but the face of affairs soon changed by the flight of Mohammed Bey. The emir, concluding that Ali Bey was dead, and not imagining that Daher was powerful enough singly to maintain the quarrel, declared openly against him. Saide was threatened with a siege, and he detached 1500 men of his faction to its defence; while himself in person, prevailing on the Druses and Maronites to follow him, made an incursion with 25,000 peasants into the valley of Bekaa; and in the absence of the Motoualis, who had joined the army of Daher, laid the whole country waste with fire and sword from Balbec to Tyre.

While the Druses, proud of this exploit, were marching in disorder towards the latter city, 500 Motoualis, informed of what had happened, flew from Acre, inflamed with rage and despair, and fell with such impetuosity on their army as to give them a complete overthrow. Such was the surprise and confusion of the Druses, that, imagining themselves attacked by Daher himself, and betrayed by their companions, they turned their swords on each other as they fled. The steep declivities of Djezin, and the pine woods which were in the route of the fugitives, were strewed with dead, but few of whom perished by the hands of the Motoualis.

The emir Yousef, ashamed of this defeat, escaped to Dair-el-Kamar, and shortly after attempted to take revenge; but being again defeated in the plain between Saide and Sour (Tyre), he was constrained to resign to his uncle Mansonr the ring, which among the Druses is the symbol of command. In 1773 he was restored by a new revolution; but he could not support his power but at the expence of a civil war. In order, therefore, to prevent Bairout falling into the hands of the adverse faction, he requested the assistance of the Turks, and demanded of the pacha of Damascus a man of sufficient abilities to defend that city. The choice fell on an adventurer, who from his subsequent fortune, merits to be made known.

This man, named Ahmad, was a native of Bosnia, and

and spoke the Sclavonian as his mother tongue, as the Ragusan captains, with whom he conversed in preference to those of every other nation, assert. It is said, that flying from his country at the age of 16, to escape the consequences of an attempt to violate his sister-in-law, he repaired to Constantinople, where, destitute of the means of procuring subsistence, he sold himself to the slave merchants to be conveyed to Egypt; and, on his arrival at Cairo, was purchased by Ali Bey, who placed him among his Mamelukes.

Ahmad was not long in distinguishing himself by his courage and address. His patron employed him on several occasions in dangerous *coups de main*, such as the assassination of such beys and cachefs as he suspected; of which commissions he acquitted himself so well as to acquire the name of *Djezzar*, which signifies *Cut-throat.* With this claim to his friendship, he enjoyed the favour of Ali until it was disturbed by an accident.

This jealous bey having proscribed one of his benefactors called Saleh Bey, commanded Djezzar to cut off his head. Either from humanity or some secret friendship for the devoted victim, Djezzar hesitated, and even remonstrated among the order. But learning the next day that Mohammed Bey had executed the commission, and that Ali had spoken of him not very favourably, he thought himself a lost man, and, to avoid the fate of Saleh Bey, escaped unobserved, and reached Constantinople. He there solicited employment suitable to his former rank; but meeting, as is usual in capitals, with a great number of rivals, he pursued another plan, and went to seek his fortune in Syria as a private soldier. Chance conducted him among the Druses, where he was hospitably entertained, even in the house of the kiaya of the emir Yousef. From thence he repaired to Damascus, where he soon obtained the title of *Aga*, with a command of five pair of colours, that is to say, of 50 men; and he was thus situated when fortune destined him to the government of Bairout.

Djezzar was no sooner established there than he took possession of it for the Turks. Yousef was confounded at this proceeding. He demanded justice at Damascus; but finding his complaints treated with contempt, entered into a treaty with Daher, and concluded an offensive and defensive alliance with him at Ras-el-aen, near to Sour. No sooner was Daher united with the Druses than he laid siege to Bairout by land, whilst two Russian frigates, whose service was purchased by 600 purses, cannonaded it by sea. Djezzar was compelled to submit to force, and, after a vigorous resistance, gave up the city, and surrendered himself prisoner. Shaik Daher, charmed with his courage, and flattered with the preference he had given him in the surrender, conducted him to Acre, and showed him every mark of kindness. He even ventured to trust him with a small expedition into Palestine; but Djezzar, on approaching Jerusalem, went over to the Turks, and returned to Damascus.

The war of Mohammed Bey breaking out, Djezzar offered his service to the captain pacha, and gained his confidence. He accompanied him to the siege of Acre; and that admiral having destroyed Daher, and finding no person more proper than Djezzar to accomplish the designs of the Porte in that country, named him pacha of Saide.

Being now, in consequence of this revolution, superior lord to the emir Yousef, Djezzar is mindful of injuries in proportion as he has reason to accuse himself of ingratitude. By a conduct truly Turkish, feigning alternately gratitude and resentment, he is alternately on terms of dispute and reconciliation, with him, continually exacting money as the price of peace, or an indemnity for war. His artifices have succeeded so well, that within the space of five years he has extorted from the emir four millions of French money (above 160,000l.); a sum the more astonishing, as the farm of the country of the Druses did not then amount to 100,000 livres (4000l.).

In 1784, he made war on him, deposed him, and bestowed the government on the emir of the country of Hasbeya, named Ismael. Yousef, having once more purchased his favour, returned towards the end of the same year to Dair-el-Kamar, and even courted his confidence so far as to wait on him at Acre, from whence nobody expected him to return; but Djezzar is too cunning to shed blood while there are any hopes of getting money: he released the prince, and sent him back with every mark of friendship. Since that period the Porte has named him pacha of Damascus, while he also retained the sovereignty of the pachalic of Acre, and of the country of the Druses.

As to the religion of the Druses: What has been already said of the opinions of Mohammed-ben-Ismael may be regarded as the substance of it. They practise neither circumcision, nor prayers, nor fasting; they observe neither festivals nor prohibitions. They drink wine, eat pork, and allow marriage between brothers and sisters, though not between fathers and children. From this we may conclude, with reason, that the Druses have no religion; yet one class of them must be excepted, whose religious customs are very peculiar. Those who compose it are to the rest of the nation what the initiated are to the profane; they assume the name of *Okkals*, which means spiritualists, and bestow on the vulgar the epithet of *Djahel*, or ignorant: they have various degrees of initiation, the highest orders of which require celibacy. These are distinguishable by the white turban they affect to wear, as a symbol of their purity; and so proud are they of this supposed purity, that they think themselves sullied by even touching a profane person. If you eat out of their plate, or drink out of their cup, they break them; and hence the custom, so general in this country, of using vases with a sort of cock, which may be drank out of without touching them with the lips. All their practices are enveloped in mysteries: their oratories always stand alone, and are constantly situated on eminences: in these they hold their secret assemblies, to which women are admitted. It is pretended they perform ceremonies there in presence of a small statue resembling an ox or a calf; whence some have pretended to prove that they are descended from the Samaritans. But besides that the fact is not well ascertained, the worship of the ox may be deduced from other sources.

They have one or two books which they conceal with the greatest care; but chance has deceived their jealousy; for in a civil war which happened some years ago, the emir Yousef, who is *Djahel* or ignorant, found one among the pillage of one of their oratories. M. Volney was assured, by persons who had read it, that it contains only a mystic jargon, the obscurity of which doubtless renders it valuable to adepts. Hakem B'amr-ellah is there spoken of, by whom they mean God incarnated in the person of the caliph. It likewise treats of another life, of a place of punishment, and a place of happiness where the Okkals shall of course be most distinguished. Several degrees of perfection are mentioned, to which they arrive by successive trials. In other respects, these sectaries have all the insolence and all the fears of superstition: they are not communicative, because they are weak; but it is probable that, were they powerful, they would be promulgators and intolerant.

The rest of the Druses, strangers to this spirit, are wholly indifferent about religious matters. The Christians who live in their country pretend that several of them believe in the metempsychosis; that others worship the sun, moon, and stars: all which is possible; for, as among the Ansaria, every one, left to his own fancy, follows the opinion that pleases him most; and these opinions are those which present themselves most naturally to unenlightened minds. When among the Turks, they affect the exterior of Mahometans, frequent the mosques, and perform their ablutions and prayers. Among the Maronites, they accompany them to church, and, like them, make use of holy water. Many of them, importuned by the missionaries, suffer themselves to be baptized; and if solicited by the Turks, receive circumcision, and conclude by dying neither Christians nor Mahometans; but they are not so indifferent in matters of civil policy.

The Druses may be divided into two classes; the common people; and the people of eminence and property, distinguished by the title of shaiks and emirs, or descendants of princes. The greater part are cultivators, either as farmers or proprietors; every man lives on his inheritance, improving his mulberry trees and vineyards: in some districts they grow tobacco, cotton, and some grain; but the quantity of these is inconsiderable. It appears that at first all the lands were, as formerly in Europe, in the hands of a small number of families. But to render them productive, the great proprietors were forced to sell part of them, and let leases; which subdivision is become the chief source of the power of the state, by multiplying the number of persons interested in the public weal: there still exist, however, some traces of the original inequality, which even at this day produces pernicious effects. The great property possessed by some families gives them too much influence in all the measures of the nation; and their private interests have too great weight in every public transaction. Their history, for some years back, affords sufficient proofs of this; since all the civil or foreign wars in which they have been engaged have originated in the ambition and personal views of some of the principal families, such as the Lesbeks, the Djambelats, the Ismaels of Solyma, &c. The shaiks of these houses, who alone possess one-tenth part of the country, procured creatures by their money, and at last involved all the Druses in their dissensions. It must be owned, however, that possibly to this conflict between contending parties the whole nation owes the good fortune of never having been enslaved by its chief.

This chief, called *Hakem* or governor, also *Emir* or prince, is a sort of king or general, who unites in his own person the civil and military powers. His dignity is sometimes transmitted from father to son, sometimes from one brother to another; and the succession is determined rather by force than any certain laws. Females can in no case pretend to this inheritance. They are already excluded from succession in civil affairs, and consequently can still less expect it in political: in general, the Asiatic governments are too turbulent, and their administration renders military talents too necessary, to admit of the sovereignty of women. Among the Druses the male line of any family being extinguished, the government devolves to him who is in possession of the greatest number of suffrages and resources. But the first step is to obtain the approbation of the Turks, of whom he becomes the vassal and tributary. It even happens, that, not unfrequently to assert their supremacy, they name the Hakem, contrary to the wishes of the nation, as in the case of Ismael Hasbeya, raised to that dignity by Djezzar; but this constraint lasts no longer than it is maintained by that violence which gave it birth. The office of the governor is to watch over the good order of the state, and to prevent the emirs, shaiks, and villages, from making war on each other: in case of disobedience, he may employ force. He is also at the head of the civil power, and names the cadis, only always reserving to himself the power of life and death. He collects the tribute, from which he annually pays to the pacha a stated sum. This tribute varies in proportion as the nation renders itself more or less formidable: at the beginning of this century, it amounted to 160 purses, 8330l.; but Melhem forced the Turks to reduce it to 60. In 1784 Emir Yousef paid 80 and promised 90. This tribute, which is called *Miri*, is imposed on the mulberry trees, vineyards, cotton, and grain. All sown land pays in proportion to its extent; every foot of mulberries is taxed at three medins, or three sols nine deniers (not quite twopence). A hundred feet of vineyard pays a piastre or 40 medins; and fresh measurements are often made to preserve a just proportion. The shaiks and emirs have no exemption in this respect; and it may be truly said they contribute to the public stock in proportion to their fortune. The collection is made almost without expence. Each man pays his contingent at Dair-el-Kamar, if he pleases, or to the collectors of the prince, who make a circuit round the country after the crop of silks. The surplus of this tribute is for the prince; so that it is his interest to reduce the demands of the Turks, as it would be likewise to augment the impost: but this measure requires the sanction of the shaiks, who have the privilege of opposing it. Their consent is necessary, likewise, for peace and war. In these cases, the emir must convoke general assemblies, and lay before them the state of his affairs. There every shaik, and every peasant who has any reputation for courage or understanding, is entitled to give his suffrage; so that this government may be considered as a well-proportioned mixture of monarchy, aristocracy, and democracy. Every thing depends on circumstances: if the governor be a man of ability, he is absolute; if ruses.

Druses.

if weak, a cipher. This proceeds from the want of fixed laws; a want common to all Asia, and the radical cause of all the disorders in the governments of the Asiatic nations.

Neither the chief nor the individual emirs maintain troops; they have only persons attached to the domestic service of their houses, and a few black slaves. When the nation makes war, every man, whether shaik or peasant, able to bear arms, is called upon to march. He takes with him a little bag of flour, a musket, some bullets, a small quantity of powder, made in his village, and repairs to the rendezvous appointed by the governor. If it be a civil war, as sometimes happens, the servants, the farmers, and their friends, take up arms for their patron, or the chief of their family, and repair to his standard. In such cases, the parties irritated frequently seem on the point of proceeding to the last extremities; but they seldom have recourse to acts of violence, or attempt the death of each other; mediators always interpose, and the quarrel is appeased the more readily, as each patron is obliged to provide his followers with provisions and ammunition. This system, which produces happy effects in civil troubles, is attended with great inconvenience in foreign wars, as sufficiently appeared in that of 1784. Djezzar, who knew that the whole army lived at the expence of the emir Yousef, aimed at nothing but delay, and the Druses, who were not displeased at being fed for doing nothing, prolonged the operations; but the emir, wearied of paying, concluded a treaty, the terms of which were not a little rigorous for him, and eventually for the whole nation, since nothing is more certain than that the interests of a prince and his subjects are always inseparable.

"The ceremonies to which I have been a witness on these occasions (says M. Volney), bear a striking resemblance to the customs of ancient times. When the emir and the shaiks had determined on war at Dair-el-Kamar, cryers in the evening ascended the summits of the mountain; and there began to cry with a loud voice: 'To war, to war; take your guns, take your pistols: noble shaiks, mount your horses; arm yourselves with the lance and sabre; rendezvous to-morrow at Dair-el-Kamar. Zeal of God! zeal of combats!' This summons, heard from the neighbouring villages, was repeated there; and as the whole country is nothing but a chain of lofty mountains and deep valleys, the proclamation passed in a few hours to the frontiers. These voices, from the stillness of the night, the long resounding echoes, and the nature of the subject, had something awful and terrible in their effect. Three days after 15,000 armed men rendezvouzed at Dair-el-Kamar, and operations might have been immediately commenced.

"We may easily imagine that troops of this kind no way resemble our European soldiers; they have neither uniforms, nor discipline, nor order. They are a crowd of peasants with short coats, naked legs, and muskets in their hands; differing from the Turks and Mamelukes in that they are all foot; the shaiks and emirs alone having horses, which are of little use from the rugged nature of the country. War there can only be a war of posts. The Druses never risk themselves in the plain; and with reason: for they would be unable to stand the shock of cavalry, having no bayonets to their muskets. The whole art consists in climbing rocks, creeping among the bushes and blocks of stone; from whence their fire is the more dangerous, as they are covered, fire at their ease, and by hunting and military sports have acquired the habit of hitting a mark with great dexterity. They are accustomed to sudden inroads, attacks by night, ambuscades, and all those *coups de main* which require to fall suddenly on, and come to close fight with the enemy. Ardent in improving their success, easily dispirited, and prompt to resume their courage; daring even to temerity, and sometimes ferocious, they possess above all two qualities essential to the excellency of any troops; they strictly obey their leaders, and are endowed with a temperance and vigour of health at this day unknown to most civilized nations. In the campaign of 1784, they passed three months in the open air without tents or any other covering than a sheep skin; yet were there not more deaths or maladies than if they had remained in their houses. Their provisions consisted, as at other times, of small loaves baked on the ashes or on a brick, raw onions, cheese, olives, fruits, and a little wine. The table of the chiefs was almost as frugal; and we may affirm, that they subsisted 100 days on what the same number of Englishmen or Frenchmen would not have lived ten. They have no knowledge of the science of fortification, the management of artillery, or encampments, nor, in a word, any thing which constitutes the art of war. But had they among them a few persons versed in military science, they would readily acquire its principles, and become a formidable soldiery. This would be the more easily effected, as their mulberry plantations and vineyards do not occupy them all the year, and they could afford much time for military exercises."

By the last estimates, according to M. Volney's information, the number of men able to bear arms was 40,000, which supposes a total population of 120,000; no addition is to be made to this calculation, since there are no Druses in the cities or on the coast. As the whole country contains only 100 square leagues, there results for every league 1090 persons; which is equal to the population of our richest provinces. To render this more remarkable, it must be observed, that the soil is not fertile, that a great many eminences remain uncultivated, that they do not grow corn enough to support themselves three months in the year, that they have no manufactures, and that all their exportations are confined to silks and cottons, the balance of which exceeds very little the importation of corn from the Hauran, the oils of Palestine, and the rice and coffee they procure from Bairout. Whence arises then such a number of inhabitants within so small a space? "I can discover no other cause (says our author), than that ray of liberty which glimmers in this country. Unlike the Turks, every man lives in a perfect security of his life and property. The peasant is not richer than in other countries; but he is free. 'He fears not,' as I have often heard them say, 'that the Aga, the Kaimmakam, or the Pacha, should send their Djendis to pillage his house, carry off his family, or give him the bastinado.' Such oppressions are unknown among these mountains. Security, therefore, has been the original cause of population, from that inherent desire which all men have to multiply themselves wherever they find an easy subsistence. The frugality of the

the nation, which is content with little, has been a secondary, and not less powerful reason; and a third is the emigration of a number of Christian families, who daily desert the Turkish provinces to settle in Mount Lebanon, where they are received with open arms by the Maronites from similarity of religion, and by the Druses from principles of toleration, and a conviction how much it is the interest of every country to multiply the number of its cultivators, consumers, and allies.

"The comparison which the Druses often have an opportunity of making between their situation and that of other subjects of the Turkish government, has given them an advantageous opinion of their superiority, which, by a natural effect, has an influence on their personal character. Exempt from the violence and insults of despotism, they consider themselves as more perfect than their neighbours, because they have the good fortune not to be equally debased. Hence they acquire a character more elevated, energetic, and active; in short, a genuine republican spirit. They are considered throughout the Levant as restless, enterprising, hardy, and brave even to temerity. Only 300 of them have been seen to enter Damascus in open day, and spread around them terror and carnage. No people are more nice than they with respect to the point of honour: any offence of that kind, or open insult, is instantly punished by blows of the kanjur or the musket; while among the inhabitants of the towns it only excites injurious retorts. This delicacy has occasioned in their manners and discourse a reserve, or, if you will, a politeness, which one is astonished to discover among peasants. It is carried even to dissimulation and falsehood, especially among the chiefs, whose greater interests demand greater attentions. Circumspection is necessary to all, from the formidable consequences of that retaliation of which I have spoken. These customs may appear barbarous to us; but they have the merit of supplying the deficiency of regular justice, which is necessarily tedious and uncertain in these disorderly and almost anarchical governments.

"The Druses have another point of honour, that of hospitality. Whoever presents himself at their door in the quality of a suppliant or passenger, is sure of being entertained with lodging and food in the most generous and unaffected manner. M. Volney often saw the lowest peasants give the last morsel of bread they had in their houses to the hungry traveller; and when it was observed to them that they wanted prudence, their answer was, 'God is liberal and great, and all men are brethren.' There are, therefore, no inns in their country any more than in the rest of Turkey. When they have once contracted with their guest the sacred engagement of bread and salt, no subsequent event can make them violate it. Various instances of this are related, which do honour to their character. A few years ago, an aga of the janissaries having been engaged in a rebellion, fled from Damascus and retired among the Druses. The pacha was informed of this, and demanded him of the emir, threatening to make war on him in case of refusal. The emir demanded him of the shaik Talhouk, who had received him; but the indignant shaik replied, 'When have you known the Druses deliver up their guests? Tell the emir, that as long as Talhouk shall preserve his beard, not a hair of the head of his suppliant shall fall!' The emir threatened him with force; Talhouk armed his family. The emir, dreading a revolt, adopted a method practised as juridical in that country. He declared to the shaik, that he would cut down 50 mulberry trees a-day until he should give up the aga. He proceeded as far as a thousand, and Talhouk still remained inflexible. At length the other shaiks, enraged, took up the quarrel; and the commotion was about to become general, when the aga, reproaching himself with being the cause of so much mischief, made his escape without the knowledge even of Talhouk.

"The Druids have also the prejudices of the Bedouins respecting birth; like them, they pay great respect to the antiquity of families; but this produces no essential inconveniences. The nobility of the emirs and shaiks does not exempt them from paying tribute in proportion to their revenues. It confers on them no prerogatives, either in the attainment of landed property or public employments. In this country, no more than in all Turkey, are they acquainted with game laws, or glebes, or signorial or ecclesiastical tithes, franc fiefs or alienation fines: every thing is held in freehold: Every man, after paying his miri and his rent, is master of his property. In short, by a particular privilege, the Druses pay no fine for their succession; nor does the emir, like the sultan, arrogate to himself original and universal property: there exists, nevertheless, in the law of inheritance, an imperfection which produces disagreeable effects. Fathers have, as in the Roman law, the power of preferring such of their children as they think proper; hence it has happened in several families of the shaiks, that the whole property has centered in the same person, who has perverted it to the purpose of intriguing and caballing, while his relations remain, as they will express it, *princes of olives and cheese*; that is to say, poor as peasants.

"In consequence of their prejudices, the Druses do not choose to make alliances out of their own families. They invariably prefer their relation, though poor, to a rich stranger; and poor peasants have been known to refuse their daughters to merchants of Saide and Bairout, who possessed from twelve to fifteen thousand piastres. They observe also, to a certain degree, the custom of the Hebrews, which directed that a brother should espouse his brother's widow; but this is not peculiar to them, for they retain that, as well as several other customs of that ancient people, in common with other inhabitants of Syria and all the Arab tribes.

"In short, the proper and distinctive character of the Druses is a sort of republican spirit, which gives them more energy than any other subjects of the Turkish government; and an indifference for religion, which forms a striking contrast with the zeal of the Mahometans and Christians. In other respects, their private life, their customs and prejudices, are the same with other orientals. They may marry several wives, and repudiate them when they choose; but, except by the emir and a few men of eminence, that is rarely practised. Occupied with their rural labours, they experience neither artificial wants, nor those inordinate passions which are produced by the idleness of the inhabitants of cities and towns. The veil, worn by by their women, is of itself a preservative against those desires which are the occasion of so many evils in society. No man knows the face of any other woman than his wife, his mother, his sister, and sisters-in-law. Every man lives in the bosom of his own family, and goes little abroad. The women, those even of the shaiks, make the bread, roast the coffee, wash the linen, cook the victuals, and perform all domestic offices. The men cultivate their lands and vineyards, and dig canals for watering them. In the evening they sometimes assemble in the court, the area, or house of the chief of the village or family. There, seated in a circle, with legs crossed, pipes in their mouths, and poniards at their belts, they discourse of their various labours, the scarcity or plenty of their harvests, peace or war, the conduct of the emir, or the amount of the taxes; they relate past transactions, discuss present interests, and form conjectures on the future. Their children, tired with play, come frequently to listen; and a stranger is surprised to hear them, at ten or twelve years old, recounting, with a serious air, why Djezzar declared war against the emir Yousef, how many purses it cost that prince, what augmentation there will be of the miri, how many muskets there were in the camp, and who had the best mare. This is their only education. They are neither taught to read the psalms as among the Maronites, nor the Koran like the Mahometans; hardly do the shaiks know how to write a letter. But if their minds be destitute of useful or agreeable information, at least it is not preoccupied by false and hurtful ideas; and, without doubt, such natural ignorance is well worth all our artificial folly. This advantage results from it, that their understandings being nearly on a level, the inequality of conditions is less perceptible. For, in fact, we do not perceive among the Druses that great distance which, in most other societies, degrades the inferior, without contributing to the advantage of the great. All, whether shaiks or peasants, treat each other with that rational familiarity, which is equally remote from rudeness and servility. The grand emir himself is not a different man from the rest: he is a good country gentleman, who does not disdain admitting to his table the meanest farmer. In a word, their manners are those of ancient times, and of that rustic life which marks the origin of every nation; and prove, that the people among whom they are still found are as yet only in the infancy of the social state."

DRUSIUS, John, a Protestant writer of great learning, born at Oudenarde in Flanders in 1555. He was designed for the study of divinity; but his father being outlawed, and deprived of his estate, they both retired to England, where the son became professor of the oriental languages at Oxford: but upon the pacification of Ghent, they returned to their own country, where Drusius was also appointed professor of the oriental languages. From thence he returned to Friesland, where he was admitted Hebrew professor in the university of Franeker; the functions of which he discharged with great honour till his death in 1616. His works show him to have been well skilled in Hebrew; and the states-general employed him in 1600 to write notes on the most difficult passages in the Old Testament, with a pension of 400 florins a-year: but being frequently disturbed in this undertaking, it was not published till after his death. He held a vast correspondence with the learned; for besides letters in Hebrew, Greek, and other languages, there were found 2300 Latin letters among his papers. He had a son John, who died in England at 21, and was a prodigy for his early acquisition of learning.

DRYADES, in the heathen theology, a sort of deities, or nymphs, which the ancients thought inhabited groves and woods. They differed from the Hamadryades; these latter being attached to some particular tree, with which they were born, and with which they died; whereas the Dryades were goddesses of trees and woods in general. See HAMADRYADES.

DRYANDER, Jonas, an eminent Swedish naturalist. See SUPPLEMENT.

DRYAS, in *Botany*, a genus of plants belonging to the icosandria class; and in the natural method ranking under the 35th order, *Senticosæ*. See BOTANY *Index*.

DRYDEN, John, one of the most eminent English poets of the 17th century, descended of a genteel family in Huntingdonshire, was born in that county at Oldwincle 1631, and educated at Westminster school under Dr Bushby. From thence he was removed to Cambridge in 1650, being elected scholar of Trinity college, of which he appears, by his *Epithalamia Cantabrigiens.* 4to, 1662, to have been afterwards a fellow. Yet in his earlier days he gave no extraordinary indication of genius: for even the year before he quitted the university, he wrote a poem on the death of Lord Hastings, which was by no means a presage of that amazing perfection in poetical powers which he afterwards possessed.

On the death of Oliver Cromwell he wrote some heroic stanzas to his memory; but on the Restoration, being desirous of ingratiating himself with the new court, he wrote first a poem entitled *Astræa Redux*, and afterwards a panegyric to the king on his coronation. In 1662, he addressed a poem to the lord chancellor Hyde, presented on New Year's day; and in the same year a satire on the Dutch. In 1668 appeared his *Annus Mirabilis*, which was a historical poem in celebration of the duke of York's victory over the Dutch. These pieces at length obtained him the favour of the crown; and Sir William Davenant dying the same year, Mr Dryden was appointed to succeed him as poet laureat. About this time also his inclination to write for the stage seems first to have shown itself. For besides his concern with Sir William Davenant in the alteration of Shakespeare's Tempest, in 1669 he produced his Wild Gallants, a comedy. This met with very indifferent success; yet the author, not being discouraged by its failure, soon published his Indian Emperor. This finding a more favourable reception, encouraged him to proceed; and that with such rapidity, that in the key to the duke of Buckingham's Rehearsal he is recorded to have engaged himself by contract for the writing of four plays per year; and, indeed, in the years 1679 and 1680 he appears to have fulfilled that contract. To this unhappy necessity that our author lay under, are to be attributed all those irregularities, those bombastic flights, and sometimes even puerile exuberances, for which he has been so severely criticised; and which, in the unavoidable hurry in which he wrote, it was impossible he should find time either for lopping away or correcting.

In 1675, the earl of Rochester, whose envious and malevolent disposition would not permit him to see growing merit meet with its due reward, and was therefore sincerely chagrined at the very just applause with which Mr Dryden's dramatic pieces had been received, was determined if possible to shake his interest at court; and succeeded so far as to recommend Mr Crowne, an author by no means of equal merit, and at that time of an obscure reputation, to write a mask for the court, which certainly belonged to Mr Dryden's office as poet laureat.—Nor was this the only attack, nor indeed the most potent one, that Mr Dryden's justly acquired fame drew on him. For, some years before, the duke of Buckingham, a man of not much better character than Lord Rochester, had most severely ridiculed several of our author's plays in his admired piece called the *Rehearsal.* But though the intrinsic wit which runs through that performance cannot even to this hour fail of exciting our laughter, yet at the same time it ought not to be the standard on which we should fix Mr Dryden's poetical reputation, if we consider, that the pieces there ridiculed are not any of those looked on as the *chef d'œuvres* of this author; that the very passages burlesqued are frequently, in their original places, much less ridiculous than when thus detached, like a rotten limb, from the body of the work; and exposed to view with additional distortions, and divested of that connexion with the other parts, which, while preserved, gave it not only symmetry but beauty; and, lastly, that the various inimitable beauties, which the critic has sunk in oblivion, are infinitely more numerous than the deformities which he has thus industriously brought forth to our more immediate inspection.

Mr Dryden, however, did not suffer these attacks to pass with impunity; for in 1679 there came out an Essay on Satire, said to be written jointly by that gentleman and the earl of Mulgrave, containing some very severe reflections on the earl of Rochester and the duchess of Portsmouth, who, it is not improbable, might be a joint instrument in the above-mentioned affront shown to Mr Dryden; and in 1681 he published his Absalom and Achitophel, in which the well-known character of Zimri, drawn for the duke of Buckingham, is certainly severe enough to repay all the ridicule thrown on him by that nobleman in the character of Bayes.—The resentment shown by the different peers was very different. Lord Rochester, who was a coward as well as a man of the most depraved morals, basely hired three ruffians to cudgel Dryden in a coffeehouse: but the duke of Buckingham, as we are told, in a more open manner, took the task upon himself: and at the same time presented him with a purse containing no very trifling sum of money: telling him, that he gave him the beating as a punishment for his impudence, but bestowed the gold on him as a reward for his wit.

In 1680 was published a translation of Ovid's Epistles in English verse by several hands, two of which, together with the preface, were by Mr Dryden: and in 1682 came out his *Religio Laici*, designed as a defence of revealed religion, against Deists, Papists, &c. Soon after the accession of King James II. our author changed his religion for that of the church of Rome, and wrote two pieces in vindication of the Romish tenets; viz. A Defence of the Papers written by the late king, found in his strong box; and the celebrated poem, afterwards answered by Lord Halifax, entitled, The Hind and the Panther.—By this extraordinary step he not only engaged himself in controversy, and incurred much censure and ridicule from his contemporary wits: but on the completion of the Revolution, being, on account of his newly-chosen religion, disqualified from bearing any office under the government, he was stripped of the laurel, which, to his still greater mortification, was bestowed on Richard Flecknoe, a man to whom he had a most settled aversion. This circumstance occasioned his writing the very severe poem called *Mac Flecknoe.*

Mr Dryden's circumstances had never been affluent; but being now deprived of this little support, he found himself reduced to the necessity of writing for mere bread. We consequently find him from this period engaged in works of labour as well as genius, viz. in translating the works of others, and to this necessity perhaps our nation stands indebted for some of the best translations extant. In the year he lost the laurel, he published the life of St Francis Xavier from the French. In 1693 came out a translation of Juvenal and Persius; in the first of which he had a considerable hand, and of the latter the entire execution. In 1695 was published his prose version of Fresnoy's Art of Painting; and the year 1697 gave the world that translation of Virgil's works entire, which still does, and perhaps ever will, stand foremost among the attempts made on that author. The petite pieces of this eminent writer, such as prologues, epilogues, epitaphs, elegies, songs, &c. are too numerous to specify here, and too much dispersed to direct the reader to. The greatest part of them, however, are to be found in a collection of miscellanies in 6 vols. 12mo. His last work is what is called his *Fables*, which consists of many of the most interesting stories in Homer, Ovid, Boccace, and Chaucer, translated or modernized in the most elegant and poetical manner; together with some original pieces, among which is that amazing ode on St Cecilia's day, which, though written in the very decline of the author's life, and at a period when old age and distress conspired as it were to damp his poetic ardour, and clip the wings of fancy, yet possesses so much of both, as would be sufficient to have rendered him immortal had he never written a single line besides.

Dryden married the lady Elizabeth Howard, sister to the earl of Berkshire, who survived him eight years; though for the last four of them she was a lunatic, having been deprived of her senses by a nervous fever.—By this lady he had three sons; Charles, John, and Henry. Of the eldest of these there is a circumstance related by Charles Wilson, Esq. in his life of Congreve, which seems so well attested, and is itself of so very extraordinary a nature, that we cannot avoid giving it a place here. Dryden, with all his understanding, was weak enough to be fond of judicial astrology, and used to calculate the nativity of his children. When his lady was in labour with his son Charles, he being told it was decent to withdraw, laid his watch on the table, begging one of the ladies then present, in a most solemn manner, to take exact notice of the very

very minute that the child was born; which she did, and acquainted him with it. About a week after, when his lady was pretty well recovered, Mr Dryden took occasion to tell her that he had been calculating the child's nativity; and observed with grief, that he was born in an evil hour; for Jupiter, Venns, and the Sun, were all under the earth, and the lord of his ascendant afflicted with a hateful square of Mars and Saturn. "If he lives to arrive at the 8th year," says he, "he will go near to die a violent death on his very birthday; but if he should escape, as I see but small hopes, he will in the 23d year be under the very same evil direction; and if he should escape that also, the 33d or 34th year is, I fear"—. Here he was interrupted by the immoderate grief of his lady, who could no longer hear calamity prophesied to befal her son. The time at last came, and August was the inauspicious month in which young Dryden was to enter into the eighth year of his age. The court being in progress, and Mr Dryden at leisure, he was invited to the country seat of the earl of Berkshire, his brother-in-law, to keep the long vacation with him at Charlton in Wilts; his lady was invited to her uncle Mordaunt's to pass the remainder of the summer. When they came to divide the children, Lady Elizabeth would have him take John, and suffer her to take Charles: but Mr Dryden was too absolute, and they parted in anger; he took Charles with him, and she was obliged to be content with John. When the fatal day came, the anxiety of the lady's spirits occasioned such an agitation, as threw her into a violent fever, and her life was despaired of, till a letter came from Mr Dryden, reproving her for her womanish credulity, and assuring her that her child was well; which recovered her spirits, and in six weeks after she received an ecclaircissement of the whole affair. Mr Dryden, either through fear of being reckoned superstitious, or thinking it a science beneath his study, was extremely cautious of letting any one know that he was a dealer in astrology; therefore could not excuse his absence, on his son's anniversary, from a general hunting match which Lord Berkshire had made, to which all the adjacent gentlemen were invited. When he went out, he took care to set the boy a double exercise in the Latin tongue, which he taught his children himself, with a strict charge not to stir out of the room till his return; well knowing the task he had set him would take up longer time. Charles was performing his duty, in obedience to his father; but, as ill fate would have it, the stag made towards the house; and the noise alarming the servants, they hastened out to see the sport. One of them took young Dryden by the hand, and led him out to see it also; when, just as they came to the gate, the stag being at bay with the dogs, made a bold push, and leaped over the court wall, which was very low, and very old; and the dogs following, threw down a part of the wall 10 yards in length, under which Charles Dryden lay buried. He was immediately dug out; and after six weeks languishing in a dangerous way, he recovered, So far Dryden's prediction was fulfiled. In the 23d year of his age, Charles fell from the top of an old tower belonging to the Vatican at Rome, occasioned by a swimming in the head with which he was seized, the heat of the day being excessive. He again recovered, but was ever after in a languishing sickly state. In the 33d year of his age, being returned to England, he was unhappily drowned at Windsor. He had with another gentleman swam twice over the Thames; but returning a third time, it was supposed he was taken with the cramp, because he called out for help, though too late. Thus the father's calculation proved but too prophetical.

At last, after a long life, harassed with the most laborious of all fatigues, viz. that of the mind, and continually made anxious by distress and difficulty, our author departed this life on the first of May 1701.—The day after Mr Dryden's death, the dean of Westminster sent word to Mr Dryden's widow, that he would make a present of the ground and all other abbey fees for the funeral: and Lord Halifax likewise sent to the lady Elizabeth, and to Mr Charles Dryden, offering to defray the expences of our poet's funeral, and afterwards to bestow 500l. on a monument in the abbey; which generous offer was accepted. Accordingly, on Sunday following, the company being assembled, the corpse was put into a velvet herse, attended by 18 mourning coaches. When they were just ready to move, Lord Jeffreys, son of Lord Chancellor Jeffreys, a name dedicated to infamy, with some of his rakish companions, riding by, asked whose funeral it was; and being told it was Mr Dryden's, he protested he should not be buried in that private manner; that he would himself, with the lady Elizabeth's leave, have the honour of the interment, and would bestow 1000l. on a monument in the abbey for him. This put a stop to their procession: and the lord Jeffreys, with several of the gentlemen who had alighted from their coaches, went up stairs to the lady, who was sick in bed. His lordship repeated the purport of what he had said below; but the lady Elizabeth refusing her consent, he fell on his knees, vowing never to rise till his request was granted. The lady under a sudden surprise fainted away: and Lord Jeffreys, pretending to have obtained her consent, ordered the body to be carried to Mr Russel's an undertaker in Cheapside, and to be left there till further orders. In the mean time the abbey was lighted up, the ground opened, the choir attending, and the bishop waiting some hours to no purpose for the corpse. The next day Mr Charles Dryden waited on the lord Halifax and the bishop; and endeavoured to excuse his mother, by relating the truth. Three days after, the undertaker having received no orders, waited on the lord Jeffreys; who pretended that it was a drunken frolic, that he remembered nothing of the matter, and he might do what he pleased with the body. Upon this the undertaker waited upon the lady Elizabeth, who desired a day's respite, which was granted. Mr Charles Dryden immediately wrote to the lord Jeffreys. who returned for answer, that he knew nothing of the matter, and would be troubled no more about it. Mr Dryden, hereupon applied again to Lord Halifax and the bishop of Rochester, who absolutely refused to do any thing in the affair.

In this distress, Dr Garth, who had been Mr Dryden's intimate friend, sent for the corpse to the college of physicians, and proposed a subscription; which succeeding, about three weeks after Mr Dryden's decease, Dr Garth pronounced a fine Latin oration over the body, which was conveyed from the college, attended by a numerous train of coaches, to Westminster abbey, but in very great disorder. At last the corpse arrived at the abbey, which was all unlighted. No organ played, no anthem sung: only two of the singing boys preceded the corpse, who sung an ode of Horace, with each a small candle in their hand. When the funeral was over, Mr Charles Dryden sent a challenge to Lord Jeffreys: who refusing to answer it, he sent several others, and went often himself; but could neither get a letter delivered, nor admittance to speak to him: which so incensed him, that finding his lordship refused to answer him like a gentleman, he resolved to watch an opportunity, and brave him to fight, though with all the rules of honour; which his lordship hearing, quitted the town, and Mr Charles never had an opportunity to meet him, though he sought it to his death with the utmost application.

Mr Dryden had no monument erected to him for several years; to which Mr Pope alludes in his epitaph intended for Mr Row, in this line,

> Beneath a rude and nameless stone he lies.

In a note upon which we are informed that the tomb of Mr Dryden was erected upon this hint by Sheffield duke of Buckingham, to which was originally intended this epitaph:

> This *Sheffield* rais'd—The sacred dust below
> Was *Dryden* once; the rest, who does not know?

Which was since changed into the plain inscription now upon it, viz.

J. DRYDEN,
Natus Aug. 9. 1631.
Mortuus Maii 1. 1701.
Johannes Sheffield, dux Buckinghamiensis, fecit.

Mr Dryden's character has been very differently drawn by different hands, some of which have exalted it to the highest degree of commendation, and others debased it by the severest censure.—The latter, however, we must charge to that strong spirit of party which prevailed during great part of Dryden's time, and ought therefore to be taken with great allowances. Were we indeed to form a judgment of the author from some of his dramatic writings, we should perhaps be apt to conclude him a man of the most licentious morals; many of his comedies containing a great share of looseness, even extending to obscenity: But if we consider, that, as the poet tells us,

> Those who live to please, must please to live;

if we then look back to the scandalous license of the age he lived in, the indigence which at times he underwent, and the necessity he consequently lay under of complying with the public taste, however depraved; we shall not refuse our pardon to the compelled writer, nor our credit to his contemporaries, who have assured us there was nothing remarkably vicious in his character.

From some parts of his history he appears unsteady, and to have too readily temporized with the several revolutions in church and state. This however might in some measure have been owing to that natural timidity and diffidence in his disposition, which almost all the writers seem to agree in his possessing. Congreve, whose authority cannot be suspected, has given us such an account of him, as makes him appear no less amiable in his private character as a man, than he was illustrious in his public one as a poet. In the former light, according to that gentleman, he was humane, compassionate, forgiving, and sincerely friendly: of an extensive reading, a tenacious memory, and a ready communication: gentle in the correction of the writings of others, and patient under the reprehension of his own deficiencies: easy of access himself, but slow and diffident in his advances to others; and of all men the most modest and the most easy to be discountenanced in his approaches either to his superiors or his equals. As to his writings, he is perhaps the happiest in the harmony of his numbers, of any poet who ever lived either before or since his time, not even Mr Pope himself excepted. His imagination is ever warm, his images noble, his descriptions beautiful, and his sentiments just and becoming. In his prose he is poetical without bombast, concise without pedantry, and clear without prolixity. His dramatic have, perhaps, the least merit of all his writings. Yet there are many of them which are truly excellent; though he himself tells us that he never wrote any thing in that way to please himself but his *All for Love*. This last, indeed, and his *Spanish Friar*, may be reckoned two of the best plays in our language.

DRYPIS, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 22d order, *Caryophyllei*. See BOTANY *Index*.

DRY-ROT, a destructive disease in timber. See SUPPLEMENT.

DUBLIN, the metropolis of Ireland, the second city in his majesty's dominions, and esteemed the fifth for magnitude in Europe, is situated in the province of Leinster, in the county of Dublin, at the bottom of a large bay. The river Liffey, which here falls into the ocean, divides the town into two nearly equal parts. Formerly the city of Dublin was confined to the south side of the river. It was a place of great antiquity. Ptolemy, who flourished in the reign of Antoninus Pius, about the year 140, says, it was anciently called *Aschcled*. In 155, Alpinus, whose daughter Auliana was drowned in the Liffey, changed the name from *Aschcled* to *Auliana*. It was afterwards named *Dublana*, and Ptolemy calls it *Eblana*. *Dublana*, whence comes *Dublinum* and *Dublin*, is evidently derived from *Dub-leana*, "the place of the black harbour or lake," or rather "the lake of the sea," the bay of Dublin being frequently so called. This city has had a variety of names. The Irish call it *Drum-choll-coil*, "the brow of a hazel wood;" and in 181, Eogan king of Munster being on a royal tour, paid a visit to this place, which was then called *Atha Cliath Dubh-Line*, "the passage of the ford of hurdles over the black pool:" the harbour of Dublin was likewise known by the name of *Lean-Cliath*, or *Leam-Cliath*, from *Lean* or *Leam*, "a harbour;" and from *Cliath* or *Cliabb*, which literally signifies "a hurdle or any thing made of wicker work;" it also signified certain wears formed with hurdles, and placed in rivers and bays by the ancient Irish for the purpose of taking fish: whence any river, or bay, wherein these wears were fixed had the name of *Cliath* or *Cliab*, annexed to it, to signify the establishment of a fishery. Dublin, therefore, being originally built on or near one of these harbours, Dublin.

harbours, was anciently called *Baly-lean-Cliath*, that is, "the town on the fishing harbour." It is described at the present day in the Irish language by the appellations of *Ath-Cliath*, "the ford of hurdles," and *Bally-ath-Cliath*, "the town of the ford of hurdles," the inhabitants having formerly had access to the river by hurdles laid on the low marshy grounds adjoining the water: and this name was also extended to the north side of the river, from a temporary bridge of hurdles thrown over the Anna Liffey, a corruption of *Auin Louiffa*, or "the swift river," so termed from the rapidity of the mountain floods. This side was enlarged by Mac Turkill the Danish prince, who, notwithstanding, fixed his habitation on the south side, and abandoned the northern town; which, from the original country of the invaders, was called *Eastmantown*, since corrupted to *Oxmantown*. King Edgar, in the preface to his charter dated 964, mentions Ireland with its most noble city (*nobilissima civitas*) of *Dublin*. By the Fingalians it is called *Divelin*, and by the Welch *Dinas Dulin*, or *the city of Dulin*.

In 448, Alpin Mac Eachard, king of Dublin, and all his subjects, were converted to Christianity by St Patrick.

In the year 498, the Ostmen or Danes having entered the Liffey with a fleet of 60 sail, made themselves masters of Dublin and the adjacent country, and soon after environed the city with walls. About 1170 Dermot Mac Murrough, king of Leinster, having quarrelled with the other princes of the kingdom, a confederacy was formed against him by Roderick O'Conor, monarch of Ireland. Dermot applied to Henry II. king of England, who sent over a number of English adventurers, by whose assistance he was reinstated in his dominions; and in the year 1171, the descendants of the Danes still continuing to hold possession of Dublin, it was besieged and taken by a powerful party of the English under Raymond le Gros. Mac Turkill the Danish king escaped to his shipping: he returned, however, soon after with a strong fleet to recover the city, but was killed in the attempt, and in him ended the race of easterling princes in Ireland.

In 1172, Henry II. landed at Waterford, and obtained from Richard Earl Strongbow (who married the daughter of Dermot Mac Murrough, and by compact was his successor) a surrender of the city of Dublin, where he built a pavilion of wicker work near St Andrew's church, then situated where Castlemarket lately stood, and there entertained several Irish princes, who voluntarily submitted to him on condition of being governed by the same laws as the people of England. Henry also held a parliament here. In 1173 he granted his first charter to Dublin, and by divers privileges encouraged a colony from Bristol to settle here.

In 1210, upwards of 20 Irish princes swore allegiance to King John at Dublin; engaging to establish the English laws and customs in the kingdom; and in the same year courts of judicature were instituted. In 1216, magna charta was granted to the Irish by Henry III. an entry of which was made in the red book of the exchequer at Dublin. In 1217, the city was granted to the citizens in fee-farm at 200 marks per annum; and in 1227 the above monarch ordained that the charter granted by King John should be kept inviolably. In 1404, the statutes of Kilkenny and Dublin were confirmed in a parliament held at this city under the earl of Ormond. The charter of the city of Dublin was renewed in 1609 by James I.

Dublin.

The civil government of the city was anciently under the management of a provost and bailiffs; in 1308, John le Decer was appointed the first provost, and Richard de St Olave and John Stakebold bailiffs. In 1409, the title of the chief magistrate was changed to that of mayor, when Thomas Cusack was appointed to the office, Richard Bove and Thomas Shortall being bailiffs; the office of bailiffs was changed to sheriffs in 1547. In 1660, Charles II. gave a collar of SS. and a company of foot guards to the mayor; and in 1665, this monarch conferred the title of lord mayor on the chief magistrate, to whom he also granted 500l. per annum in lieu of the foot company. Sir Daniel Bellingham was the first lord mayor of Dublin; Charles Lovet and John Quelsh were sheriffs the same year. In 1672, Arthur earl of Essex introduced new rules for the better government of the city; and in 1683 the Tholsel was built for the purpose of the magistrates meeting to hold their courts, assemblies, &c.

In the 10th century, after the fortifications of Dublin were repaired by the Ostmen, the walls of the city, including those of the castle, did not occupy more than an Irish mile; they extended from Winetavern gate to Audeon's arch, and were continued from thence to where Newgate formerly stood; and from a plan published by John Speed in 1610, it appears that they were continued to Ormond's gate, or, as it has been since called, *Wormwood gate*; from thence to the old bridge, and along the banks of the river to a very large portal called *Newman's tower*, nearly in the present site of the south entrance of Essex bridge; and from Newman's tower in an angular direction to Dame's gate, at the west end of Dame's street. From the gate at the south-west angle of the castle the wall ran to Nicholas gate, and was continued from thence to Newgate. The principal streets without the walls were, on the west, New row, Francis street, Thomas street, and James's street; on the south were Patrick street, Bride street, and Ship street; and on the east, Dame street, George's lane, and Stephen street. That space of ground now occupied by Crane lane, Temple bar, Fleet street, Lazar's hill, or as it is now called *South Townsend street*, Crampton, Aston's, George's, and Sir John Rogerson's quays, &c. was then overflowed by the Liffey. On the north side of the river there were only Church street, Mary's lane, Hammond lane, and Pill lane, then built but on one side as far as Mary's abbey, which terminated the extent of that part of the town to the eastward; Grange Gorman, Stoney-batter, now called *Manor street*, and Glassmanogue, were then villages at some distance from the city; and at the latter the sheriffs have held their courts in times of the plague, as being remote from the stage of infection. In 1664, the inhabitants being numbered amounted to 2565 men and 2986 women, Protestants; and 1202 men and 1406 women, Roman Catholics; making in the whole 8159.

By comparing this account of the ancient state and boundaries of the metropolis with the following description of its present extent, population, and magnificence, an idea will be readily formed of the amazing increase and improvement it has experienced within the course of a century.

Dublin is seated in view of the sea on the east, and a fine country which swells into gently-rising eminences on the north and west, while it towers boldly up in lofty mountains that bound the horizon on the south. The city itself cannot be seen to full advantage on entering the harbour: but the approach to it from thence exhibits a fine prospect of the country for improvement and cultivation, interspersed with numerous villas, that have a most agreeable effect to enliven this delightful scene, which, beginning at the water's edge, is continued all over the coast to the northward of the bay as far as the eye can reach, and is finely contrasted by a distant view of the Wicklow mountains to the south, where the conical hills, called the *Sugar Loaves*, contribute not a little, by the singularity of their appearance, to embellish the landscape, so extensive and picturesque as not to be equalled by any natural scenery in Europe, but the entrance of the bay of Naples, to which it bears a very striking resemblance.

The form of Dublin is nearly square, a figure that includes the largest area proportioned to its circumference. From the royal hospital at Kilmainham, at the western extremity of the town, to the east end of Townsend street, the length is two miles and a half, and its greatest breadth is computed to be of the same extent: hence the city is about 10 miles in circumference. Its increase within the last thirty years has been amazing. It contains 16,458 houses, and 187,939 inhabitants.

Dublin, with respect to its streets, bears a near resemblance to London. Some of the old streets were formerly narrow: but this defect is now in a great measure remedied by an act of parliament, passed in 1774, for opening the public avenues, taking down sign posts, palisades, pent-houses, &c. new paving the streets, and flagging the foot passages: and, in 1785, another act passed for the better paving, cleansing, and lighting the city. Still greater improvements have been made in the essential points of paving, lighting, and cleansing, since 1806. Those necessary improvements contribute exceedingly to the beauty and convenience of the metropolis: the new streets are wide and commodious, the houses lofty, uniform, and elegant; nor are several of the old streets totally deficient in these respects; Sackville street, or the Mall, which, though built many years ago, has been included in the number of our new streets by the late geographers (a self-evident proof that these writers had not even seen the city), is a noble avenue, with a gravel walk in the centre, enclosed by a wall of about three feet high; this walk is 36 feet and a half broad, and the distance between it and the palisades fronting the houses, on either side, is 42 feet and a half. The new customhouse, a building universally admired for its beauty, has rendered this a most desirable situation for wholesale merchants, not only on account of its proximity to that building, but its great depth in the rear. Some years ago, it was esteemed one of the finest public avenues in Europe: many of the new streets, however, in this city are now much superior to it in the magnificence and uniformity of the houses. Among these, on the north side of the river, in the same quarter with Sackville street, are Gardiner's row, North Great George's street, Cranby row, Cavendish row, and Palace row; the last three form a superb square, having the garden of the lying-in hospital in the centre: the old wall that encompassed the garden has been taken down: there is now a full view of this delightful spot surrounded with iron palisades, and upwards of 100 globes with double burners disposed at equal distances, which added to the globes from the surrounding houses, have a most brilliant effect. This square, which for its size, is not perhaps to be equalled, has received the name of Rutland square, in compliment to his grace the duke of Rutland, who contributed munificently towards the improvements in the enclosure of the new garden, and the erecting an elegant edifice for a ball and supper rooms, situated to the east of the hospital. In Sackville street is Nelson's pillar, a fluted column 130 feet high.

Among the new streets and buildings on the south side of the river, those wherein persons of distinction reside, lie chiefly to the eastward of the college and Stephen's green; which last, though it does not rank with the new buildings, possesses much grandeur and elegance, being one of the largest squares in Europe: it is an English mile in circumference, surrounded by a gravel walk planted on each side with trees; within this walk is a smooth level meadow, having in the centre an equestrian statue of the late king: there are several fine edifices, though almost all differing in the style of their architecture; this variety, however, is esteemed by many rather a beauty than a defect: but, besides the other streets and buildings in this quarter, there is a new square nearly as extensive as Stephen's green, called *Merion square;* it was laid out some years ago by the late Lord Fitzwilliam: the houses on the north side are uniform and lofty; most of them being carried up with hewn stone to the first story, gives the whole an air of strength, beauty, and magnificence. At the south-west angle of Stephen's green, a new street has been also opened, called *Harcourt street*, in which are several elegant structures that merit notice, particularly the town residence of the right honourable Lord Earlsford. A variety of other public buildings have been erected since the union. The Dublin penitentiary, begun in 1813, cost 40,000l.; the Richmond lunatic asylum, finished in 1815, cost 28,000l.; and the post-office, begun in 1815, and which was estimated to cost 50,000l.

The principal entrance to the walks of Stephen's green is on the west side opposite the end of York-street (which may properly be classed among the new streets), as all the old houses have been pulled down and modern buildings erected in their room. Those parts of the city inhabited by merchants and traders begin to wear a new face; and amongst this number the new buildings of Dame street on the south side, exhibit an extensive, uniform, and beautiful range of houses all of an equal height; the shop doors and windows are formed by arches, exactly similar in their construction and ornaments, which are simply elegant. When the other side of this street shall be rebuilt, it may be justly pronounced one of the first trading streets in Europe; and Parliament street, which was built some years ago, is now nearly equal to any trading street in London.

The river Liffey, being banked in through the whole length of the town, exhibits spacious and beautiful quays, where vessels below the bridges load and unload before the merchants doors and warehouses: it is navigable as far as a bridge near the west end of the custom-house. This bridge, which is a very elegant structure, was built since the year 1790. Essex bridge was first built in 1681, and took its name from the unfortunate earl of Essex, then viceroy of Ireland. It was taken down in 1753, and rebuilt in an elegant form, after the model of Westminster bridge, but much better proportioned, and on a more secure foundation. It has five arches, the buttresses between which support semicircular niches that project from the parapet; there are balustrades between these niches, and continued to the ends of the bridge, which is commodiously flagged for foot passengers; the whole constructed with hewn stone in a very fine taste. There are five bridges besides the two already mentioned; three of which have nothing to recommend them, further than the antiquity of the Old bridge, which was erected in this city at a very early period, when it had the name of *Dublin Bridge;* it was rebuilt in 1428, since which time it received its present title. Bloody bridge, built in 1671, was originally constructed with wood, and derives its present harsh appellation from an attempt to break it down, wherein four persons were killed. Ormond bridge was built in 1684, during the Ormond administration. Arran bridge, now called *Queen's bridge*, was erected in the same year; but, being destroyed by the floods in 1763, was rebuilt of hewn stone, and finished in 1768. It consists of three arches, with flagged foot passages, stone balustrades and ornamental decorations, in a handsome light style, which has been much admired. Richmond bridge, which was begun in 1813, was opened to the public in 1816. It is 52 feet broad, and 220 long, and cost 25,800l. Between this bridge and Essex bridge, an iron bridge for foot passengers was opened in 1816. It is 140 feet long, 12 feet broad, and cost 3000l. The foundation of Whitworth bridge was laid in 1816, in place of the one formerly known under the names of the Old bridge, Dublin bridge, and Ormond bridge, which was carried away in 1802.

This city has 2 cathedrals, 19 parish churches, several chapels of ease, 26 Roman Catholic chapels, 6 meeting houses for Presbyterians, 1 for Anabaptists, 4 for Methodists, 2 for Quakers, a church for French Calvinists, a Danish and a Dutch church, and a Jewish synagogue.

Christ church, or the Holy Trinity, built in 1038 by Donat bishop of Dublin, to whom Sitricus the son of Amlave king of the Ostmen of Dublin granted the site for that purpose, stands on the summit of the rising ground at the head of Winetavern street. It is a venerable Gothic pile; and its present appearance evinces its antiquity. St Patrick's cathedral, first built by Archbishop Comyn in 1190, and decorated by Archbishop Minot in 1370 with a steeple, on which a lofty spire was erected in 1750, is also a fine Gothic structure; it stands on the east side of Patrick's street; the monuments here are more numerous than in Christ church; and the steeple is the highest in the city.

St Werburgh's church was originally built in a very early age. In 1301, when a great part of the city was consumed by an accidental fire, this church suffered in the conflagration: it was burnt a second time in 1754, and repaired in its present beautiful form in 1759. The front and steeple are admired for their elegance, lightness, and symmetry: the spire is a fine octagon supported by eight pillars; and a gilt ball terminates the whole, being 160 feet from the ground. Catherine's church, first built in 1105, and re-edified in its present form in 1769, is situated on the south side of Thomas's street. St Thomas's church is the latest foundation of the kind in this city, having been begun in the year 1758, and finished and consecrated in 1762. It is situated on the west side of Marlborough street, opposite Gloucester street, to which it forms an elegant termination. The other churches in this city are; on the north side of the river, Mary's, Michan's, and Paul's; on the south side, James's, Luke's, Kevin's, Peter's, Bride's, Nicholas within, Audeon's, Michael's, Mark's, Anne's, John's, and Andrew's: this last is called also the *Round church*, from its form being exactly circular: most, if not all the others were built in an early age: many, however, have been since re-edified, and assumed a more modern form; some of these are not totally devoid of elegance, particularly Anne's. St John's in Fishamble street was rebuilt in 1773, and has now a handsome front of hewn stone decorated with columns supporting a pediment. Besides these churches, Dublin is adorned with several other public buildings; the most remarkable of which are the following: The castle, the residence of the chief governor, built in 1213 by Henry de Londres, was formerly moated and flanked with towers; but the ditch has been long since filled up, and the old buildings razed, the chapel and wardrobe tower excepted, which still remain: Birmingham tower was rebuilt in 1777, and is now called *Harcourt tower*. The castle at present consists of two courts, the principal of which is an oblong square formed by four ranges of building: within a few years, in the middle of the south range, a handsome edifice called *Bedford tower* has been erected; the front is decorated with a small arcade of three arches, over which is a colonnade supporting a pediment, from whence rises an octagon steeple crowned with a small cupola and gilt ball in a light pleasing style. This tower, which fronts the entrance to the viceroy's apartments, is connected with the buildings on each side by two fine gates; over that on the right hand is a statue of Fortitude; and over the left gate, which is the grand portal to the upper court, is the statue of Justice. In the lower court are the treasury and other offices, with military stores, an arsenal and armory for 40,000 men, and a barrack in which a captain's detachment of infantry are stationed. Between this barrack and the arsenal is the castle garden; opposite to which, at the rear of the lord lieutenant's apartments, is a range of building called the *Garden front*, erected about the year 1740, finished in mountain stone, ornamented by semicolumns of the Ionic order, and the windows embellished with cornices and architraves, in a fine taste. The hall room is now titled *St Patrick's Hall*. The viceroy's body guard consists of a captain, two subalterns, and sixty private men, with a subaltern's guard of horse. The parliament

ment house, a most superb structure, is situated on the north side of College green; it was begun in 1729, finished in 10 years, and cost 40,000l. It is built with Portland stone, and the front formed by a grand portico of Ionic columns in the most finished style of architectural elegance: the internal parts correspond with its outward magnificence; and the manner in which the inside is lighted is universally admired. The house of commons is an octagon, covered with a dome supported by columns of the Ionic order, that rise from an amphitheatrical gallery balustraded with iron scroll-work; this room is admirably well adapted to its purpose. The house of lords is an oblong room, spacious and lofty, and ornamented in a superb manner; it is also judiciously adapted for the reception of the august assembly which formerly met there; among other decorations are two very fine pieces of tapestry, representing the battle of the Boyne and siege of Derry. Since the union of Ireland with Great Britain, this building being no longer necessary as a place of meeting for the Irish legislative body, has been converted into apartments for the national bank.

The college founded by Queen Elizabeth in 1591 is situated at the east end of College green. It is a most beautiful structure, consisting of two spacious squares, the first of which contains the refectory, the old hall and chapel, and the new theatre for lectures and examinations; the front of this last building is finely decorated with Corinthian columns supporting a pediment; and over the front of the old hall, on the east side of this square, a handsome steeple rises crowned with a cupola. In the other square, which consists partly of brick buildings for the students, there is a superb library, extending through its whole length on the south side: behind this square there is a fine park. The west side of the first square, which is built with Portland stone, forms the grand front, upwards of 300 feet in length, ornamented with Corinthian pillars and other decorations in a very fine taste. At a small distance to the south side of this front is an elegant edifice in which the provost resides. The printing office is a neat handsome structure on the north side of the park; and opposite to it is the anatomy house, in which are to be seen the celebrated wax models of the human figure, executed at Paris by M. Douane, purchased by the right honourable the earl of Shelburne, and presented to this university. The college of Dublin is an university in itself, consisting of a provost, vice provost, 7 senior and 15 junior fellows, and 17 scholars of the house; the number of students in 1817 was 1230: it has also professors in divinity, common and civil law, physic, Greek, modern languages, mathematics, oriental tongues, history and oratory, modern history, natural philosophy, anatomy and surgery, chemistry and botany. To accommodate the increasing number of students at the university, it has been found necessary to erect a new and extensive range of apartments, on the south side of the New Square, which had not before been completed. This wing forms a new front to the college, 270 feet in length.

The Royal Exchange, situated on Cork hill, was begun in 1769, and opened for business in 1779; the expence, amounting to 40,000l. being defrayed by lottery schemes, conducted by the merchants of Dublin with an integrity that did them honour. The building is nearly a square, having three fronts of Portland stone in the Corinthian order, and crowned in the midst with a fine dome, which is supported on the inside by 12 Composite fluted pillars that form a circular walk in the centre of the ambulatory: above these pillars are 12 circular windows, and the ceiling of the dome, which is ornamented with stucco, in the mosaic style, has also a large window in the middle that illuminates most of the building. Opposite the north entrance, in the circular walk, is a statue of his late majesty George III. in a Roman military habit; it is executed in bronze by Van Nost, and elevated on a white marble pedestal. In a niche on the staircase leading to the coffee room is a white marble statue of the late Dr Charles Lucas, executed by Smith. The north front, which commands a fine view of Parliament street and Essex bridge, is embellished by a range of six columns and their correspondent pilasters, supporting a grand pediment with a balustrade on each side: a flight of stone steps leads from the street to the entrance, which is by three fine iron-railed gates: the west front varies but little from the north, except in the want of a pediment, and having only three steps ascending to the entrance, the ground on that side being nearly on a level; this front is opposite the east end of Castle street, near the principal entrance to the castle.

The hospital for lying-in women, founded by Dr Bartholomew Mosse, and opened in 1757, stands on the north side of Great-Britain street. The building is extremely light and elegant; a beautiful steeple rises in the centre, and the wings are formed by simicircular colonnades on each side. Adjoining the east colonnade is the Rotunda, where balls and assemblies are held, and concerts performed, for the benefit of the charity: close to it are erected the grand suit of apartments before mentioned. The garden at the rear of the hospital is laid out in a good taste.

The Blue-coat hospital was founded on the west side of Queen street by Charles II. in 1670, for educating the children of reduced freemen of the city: but the original building being greatly decayed, was taken down, and the new Blue-coat hospital, situated in Oxmantown green, was begun in 1773. The front is enriched by four Ionic columns, supporting a pediment in the centre, over which the steeple rises, embellished with Corinthian and Composite columns in an admired taste. Connected with the front by circular walls ornamented with balustrades and niches, are the school on one side and the church on the other: these form two well-proportioned wings; they are of a similar construction; and each is crowned with a small steeple or turret, corresponding with the rest in uniform harmony and beauty.

The Barracks, the foundation of which was laid in 1704, are esteemed the largest and most commodious in Europe. They consist of four squares, situated at the west end of the town, on the north side of the river. The royal square in the centre, with the horse barrack and the little square on each side, form a spacious and extensive front to the south: the palatine, now called the new square, is opposite to Oxmantown green; it has been lately rebuilt with hewn stone in a very elegant manner.

The royal hospital at Kilmainham for the support of invalids of the Irish army was founded by King Charles II. on a plan similar to that of Chelsea in England. The building was completed in 1683, and cost upwards of 23,500l. It is situated at the west end of the town, on a rising ground near the south side of the river, from whence there is an easy ascent to it through several rows of tall trees. This edifice is of a quadrangular form, enclosing a specious area handsomely laid out in grass plots and gravelled walks: an arcade is carried along the lower story in each square to the entrance of the hall and chapel, which are both curiously decorated; in the former are several whole-length portraits of royal personages and other distinguished characters.

Dr Stevens's Hospital, the foundation of which was laid in 1720, is a neat quadrangular building, pleasantly situated on the banks of the river near the west end of James's street, from whence a gravelled walk leads by a gentle descent to the entrance of the hospital, and is continued from thence to the water's edge.

The Linen Hall, at the north end of Linen Hall street, which was opened at the public expence in 1728, for the reception of linen cloths brought to the Dublin market, is a handsome building, lately enlarged with treble its number of former rooms, which furnish a new proof of commercial prosperity.

The New Prison in Green street, the first stone of which was laid in 1773, is a large quadrangular structure, designed and executed under the direction of the late Mr Cooley. The east front consists of a centre break of mountain stone rusticated and crowned by a pediment, with a plain façade of black limestone on each side; and at the external angles of the building are four round towers.

There are many other public edifices in this city and its environs which merit particular notice. The Hospital for Lunatics in West Bow lane, founded by Dean Swift, and opened in 1757; the Hibernian school in the Phœnix Park, and the Marine School on Sir John Rogerson's Quay, the first for educating the poor children of soldiers, and the other for bringing up to the sea service the sons of deceased or disabled seamen; the Hospital for Incurables in South Townsend street; Mercer's Hospital in Stephen street; the Meath Hospital on the Coombe; and Simpson's Hospital in Great-Britain street, the last of which was established for the reception of blind and gouty men; are all handsome edifices constructed of hewn stone in the modern style.

To these public buildings may be added St Nicholas's Hospital in Francis street; the Infirmary for sick and wounded soldiers of the army, and the Foundling Hospital in James's street; the Magdalen Asylum in Leeson street; and the House of Industry in Channel row; the halls for corporations (particularly the Weavers Hall on the Coombe, over the entrance of which is a statue of his late majesty George II.); the Tholsel; the old Four Courts; the old Customhouse; and several others. The Charitable Infirmary, which was first opened in 1728 and rebuilt in 1741, stood on the Inn's Quay, but has lately been pulled down, together with most of the houses on that quay, where the new courts of justice are to be erected; and the benefits of this humane institution are now dispensed to the public at a house taken for that purpose in Jervis street.

Dublin.

The new courts of justice, on the north side of the river, form a principal ornament to the metropolis, and are from a design of Mr Gandon's, as well as the new customhouse on the north wall. The front of the latter extends 375 feet, enriched with arcades and columns of the Doric order, crowned with an entablature: the centre has a portico finished with a pediment, in which is a bas relief of emblematical figures alluding to commerce: over the pediment is an attic story; and a magnificent dome finishes the centre, whereon is a pedestal supporting a statue of Commerce; the key stones over the entrances and in the centre of the pavilions are decorated with emblematical heads representing the produce of the principal rivers of Ireland: the south or front to the river, with the arms of Ireland over each pavilion, is of Portland stone: the whole, being formed of large and striking parts, adds much to the picturesque scene of the river, and will remain a lasting monument of reputation to the several artists employed in this superb building.

The playhouses, considered as public buildings, have nothing to recommend them to notice. One only, viz. the old house, now the theatre-royal, in Smock-alley, is kept open by Mr Daly; who, in consequence of a bill passed in the Irish parliament for the regulation of the stage, enjoys the exclusive privilege of managing and directing the theatrical exhibitions in this metropolis. The playhouse in Crow street, which formerly possessed the distinction of theatre-royal, has been shut up these several years past.

But a minute description of every public edifice would occupy more room than this publication admits, not to mention the several private houses justly admired for their elegance. Among these are,

Leinster House, the town residence of his grace the duke of Leinster. The entrance to this princely mansion is from Kildare street, through a grand gateway of rustic stone work, into a spacious court which forms a segment of a circle before the principal front. The inside of this magnificent structure is equal to its exterior appearance; the hall is lofty and noble; and the apartments, which are decorated and furnished in a splendid taste, are enriched with several very valuable paintings. The garden front, plain yet bold, possesses a pleasing simplicity; the garden is spacious and elegant, with a beautiful lawn in the centre. The whole of this building is inferior to few private edifices in the British dominions.

The earl of Charlemont's house is finely situated in the middle of Palace row, on an eminence exactly fronting the centre of the garden at the rear of the lying-in hospital. The front is built with hewn stone brought from Arklow, superior to that of Portland. The inside of this house is superb and convenient: the hall ceiling is supported by columns; some of the apartments are decorated with a select but choice collection of paintings of the best masters; among which are one of Rembrandt's finest pictures, representing Judas repenting and casting the silver pieces on the ground; a portrait of Cæsar Borgia, by Titian; and the Lady's Last Stake by Hogarth, &c. &c. The library is esteemed one of the finest apartments in Dublin, and contains a very valuable collection of the best authors. At one end of it is an antichamber, with a fine statue in white marble of the Venus de Medicis, by Wilton; and

Dublin.

and at the other end are two small rooms, one a cabinet of pictures and antiquities, the other of medals: it is situated at the rear of the house, and connected with it by a corridore, in which are some handsome statues and Egyptian curiosities.

Dublin, which is the seat of government and of the chief courts of justice, has received many charters and ample privileges from the kings of England since the reign of Henry II. who introduced the English laws into this kingdom. Richard II. erected it into a marquisate in favour of Robert de Vere earl of Oxford, whom he also created duke of Ireland. It is an archiepiscopal see, and returns with the university and the county six members to parliament. The civil government of Dublin is executed by a lord mayor, recorder, two sheriffs, twenty-four aldermen, and a common council formed of representatives from the twenty-five corporations. Every third year the lord mayor, in conformity with an old charter, perambulates the bounds of the city and its liberties; and formerly the freemen of the several corporations, armed and mounted on horseback, were accustomed to attend the chief magistrate on this occasion, which was titled riding the franchises: but as this custom was productive of idleness, intoxication, and riots, among the lower orders of the people, it has been of late years very properly laid aside. Besides the silk, woollen, and worsted manufactures carried on in that quarter of the suburbs called the Earl of Meath's Liberty, and which have been considerably improved within these few years, other branches of useful manufactures are establishing in different parts of the metropolis; and though the trade of Dublin has heretofore consisted chiefly in the importation of foreign commodities, yet, now that the restrictions on their woollens and most of their other goods are removed, it is hoped the daily enlargement of their export trade will cause a proportionable increase of national opulence.

Dublin would have had a commodious station for shipping, were it not that the harbour is choked up with two banks of sand, called the *North and South Bulls*, which prevent vessels of large burden from coming over the bar. This, however, is in some measure remedied by a prodigious work of stone, and piles of wood extending some miles into the bay on the south side, at the end of which there is a lighthouse, beautifully constructed, after a design of the late Mr Smith's. But the port of Dublin is capable of much greater improvement; particularly by turning the course of the river Dodder, building a mole from the north wall to Ringsend, and clearing the harbour so as to form a grand bason on the south side for the reception of vessels of all burthens. This work is to be immediately carried into execution, and will no doubt meet every possible encouragement, from that spirit for promoting the national welfare which now prevails throughout this kingdom, and is remarkably conspicuous in the capital, where, among others, are the following public institutions.

The Board of Trustees for promoting the linen and hempen manufactures, established by act of parliament. The Dublin Society, incorporated by charter in the year 1749, for improving husbandry and other useful arts. The Royal College of Physicians, established in the year 1679 for promoting medical knowledge. The Royal College of Surgeons, instituted in the year 1785. The Royal Irish Academy, for the advancement of science, polite literature, and antiquities, incorporated by letters patent the 28th of January 1786: His majesty is patron, and the chief governor for the time being his visitor. The Hibernian Society, for maintaining, educating, and apprenticing, the orphans and children of soldiers in Ireland. The Hibernian Marine Society, for maintaining, educating, and apprenticing, the orphans and children of decayed seamen in his majesty's navy and the merchants service; also incorporated by royal charter.

But among these public institutions, that of the Bank of Ireland must not be omitted: it was established by act of parliament in 1783; and by facilitating the circulation of specie, gives life and vigour to manufactures and commerce. It is conducted under the management of a governor, deputy-governor, and fifteen directors, chosen annually from among the subscribers; with this restriction, that five new directors at least must be chosen every year. This bank is kept in the late parliament house of Ireland. There are four other great banks in the city under the following firms, viz. Right Honourable David La Touche and Co. and Sir William Glendowe Newcomen, Bart. and Co. both in Castle street; John Dawson Coats, Esq. Thomas street; and John Finlay and Co. Upper Ormond quay. The houses in which the first three are kept are structures worthy of notice, particularly that of Sir William Glendowe Newcomen's, which has been rebuilt with hewn stone, in a good taste, after a design of the late Mr Ivory's.

To these public institutions may be added the General Post Office of Ireland, established by act of parliament in 1784, previous to which time the post office of this kingdom was only considered a branch of the English one. The building erected for this purpose was begun in 1815. It is 223 feet in front and 150 in depth, and consists of three stories. In the centre is a grand portico 80 feet in length, consisting of a pediment supported by six pillars, and surmounted by three beautiful statues. There are two postmasters-general, a secretary, treasurer, accountant-general, resident surveyor, and comptroller. There is also a penny-post under the direction of the same officers, established for the conveyance of letters to all parts throughout the city and its environs.

Dublin is remarkably well supplied with flesh, fowl, and fish, the latter in much greater perfection than any other capital in Europe. It is supplied with coals chiefly from Cumberland and Scotland; and water is conveyed to the city on the north side from the river Liffey, by machines curiously constructed for the purpose, at an outlet called *Island bridge;* the south side is supplied with that necessary article from a fine reservoir or bason, surrounded with a wall and a handsome grass walk enclosed on each side by a thick-set hedge and trees planted at equal distances. From one end of it there is a view of the canal for the convenience of inland water carriage, now completed as far as Monastereven, between which and the canal harbour in James's street, passage boats ply daily; they are well appointed and accommodated with all necessary refreshments. At a small distance from the bason there is a bridge of a single arch thrown over the canal, the elegance and architecture of which are much admired: the sides of the canal for some miles into the

the country are planted with elm trees, which renders its banks in fair weather a delightful place of exercise for the citizens; who also resort for recreation to his majesty's Phœnix park, a fine extensive inclosure at the west end of the town, and on the side of the river opposite to the canal, diversified with woodland, champaign, and rising ground, and well stocked with deer. It is seven miles in circuit; and besides the Hibernian school, is adorned with the viceroy's beautiful villa and some handsome lodges belonging to the rangers: in this park are also a magazine for powder and a battery that commands the city. In 1747, a fluted pillar 30 feet high, with a phœnix on the top, was erected in the centre of a ring in this park by the celebrated earl of Chesterfield when lord lieutenant of Ireland.

The circular road which surrounds the city, beginning on one side of the river, at the east end of the town, and terminating on the opposite shore, is carried through the park. This road forms a very agreeable ride, and is much frequented. It is the boundary of the jurisdiction of the new police, instituted for the better preservation of the peace and good order of the city and the personal security of its inhabitants. This institution, established by act of parliament, is under the direction of a chief commissioner, assistant commissioners, and divisional justices, who are all aldermen of the city; which is therefore properly termed *the district of the metropolis*, and divided into four wards. The police guard consists of horsemen and foot, well armed, and in regular uniform: they are taught military discipline, and stationed at night time in the several watchhouses; from whence parties are constantly patrolling the streets, and centinels are placed at different stands. This institution is found by experience to be a much more effectual prevention of robberies, riots, and nocturnal outrages, than the parish watches; and to this security which the well-disposed working manufacturers enjoy, may in a great measure be attributed that increasing spirit of industry and peaceable behaviour now so prevalent among this useful class of the community. See the recent improvements of Dublin more particularly described in the article Dublin, in the Supplement.

Dublin, a county of Ireland. See Supplement.

DUBOS, John Baptist, a learned and ingenious French author, born at Beauvais in 1670. He finished his studies at Paris, and at length was intrusted with the management of several important affairs in Italy, England, and Holland. At his return to Paris, he had a prebendary given him; afterwards he had a pension of two thousand livres, and the abbey of Notre Dame at Ressons, near Beauvais. He died at Paris, when perpetual secretary of the French academy, on the 23d of March 1742. His principal works are, 1. Critical Reflections on Poetry and Painting, in three volumes duodecimo. 2. A Critical History of the French Monarchy in Gaul, two volumes 4to.

DUBRIS, in *Ancient Geography*, a town of Britain; now *Dover*, from *Dovoria* of the lower age. A port town in Kent, opposite to Calais.

DUCAL, in general, something belonging to a duke. See Duke.

The letters patent granted by the senate of Venice are called *ducal:* so also are the letters wrote, in the name of the senate, to foreign princes. The denomination of ducal is derived hence; that, at the beginning of such patents, the name of the duke or doge is wrote in capitals, thus, *N— Dei Gratia Dux Venetiorum*, &c. The date of ducals is usually in Latin, but the body is in Italian. A courier was despatched with a ducal to the emperor, returning him thanks for renewing the treaty of alliance in 1716, against the Turks, with the republic of Venice.

DUCAS, a learned Greek, who wrote a history of what passed under the last emperors of Constantinople, till the ruin of that city. This work, which is esteemed, was printed at the Louvre in 1649, with the Latin translation and notes of Boillaud.

DUCAT, a foreign coin, either of gold or silver, struck in the dominions of a duke; being about the same value with a Spanish piece of eight, or a French crown; or four shillings and sixpence sterling when of silver, and twice as much when of gold. See Coin.

The origin of ducats is referred to one Longinus, governor of Italy; who revolting against the emperor Justin the Younger, made himself duke of Ravenna, and called himself *Exarcha*, i. e. *without lord or ruler;* and to show his independence, struck pieces of money of very pure gold in his own name, and with his own stamp, which were called *ducati*, ducats; as Procopius relates the story.

After him, the first who struck ducats were the Venetians, who called them *Zecchini* or *sequins*, from Zecca, the place where they first were struck. This was about the year 1280, in the time of John Danduli; but we have pretty good evidence, that Roger king of Sicily had coined ducats as early as 1240. And Du Cange scruples not to affirm, that the first ducats were struck in the duchy of Apulia in Calabria. The chief gold ducats now current are, the single and double ducats of Venice, Florence, Genoa, Germany, Hungary, Poland, Sweden, Denmark, Flanders, Holland, and Zurich. The heaviest of them weighs 5 pennyweights 17 grains, and the lightest 5 pennyweights 10 grains; which is to be understood of the double ducats, and of the single in proportion.

The Spaniards have no ducats of gold; but, in lieu thereof, they make use of the silver one; which, with them, is no real species, but only a money of account like our pound. It is equivalent to 11 rials. See Rial. The silver ducats of Florence serve there for crowns.

DUCATOON, a silver coin, struck chiefly in Italy; particularly at Milan, Venice, Florence, Genoa, Lucca, Mantua, and Parma; though there are also Dutch and Flemish ducatoons. They are all nearly on the same footing; and being a little both finer and heavier than the piece of eight, are valued at twopence or threepence more; viz. at about four shillings and eightpence sterling.

There is also a gold ducatoon struck and current chiefly in Holland: it is equivalent to twenty florins, on the footing of one shilling and elevenpence halfpenny the florin.

DUCENARIUS, in antiquity, an officer in the Roman army, who had the command of 2000 men.

The emperors had also ducenarii among their procurators or intendants, called *procuratores ducenarii.* Some say, that these were such whose salary was two hundred sesterces; as in the games of the circus, horses hired for two hundred sesterces were called *ducenarii*. Others hold, that ducenarii were those who levied the two hundredth penny, the officers appointed to inspect the raising of that tribute. In the inscriptions at Palmyra, the word *ducenarius*, in Greek δȣκεναριος, occurs very often.

DUCENTESIMA, in antiquity, a tax of the two hundredth penny, exacted by the Romans.

DUCHAL, James, D. D. a late pious and learned dissenting minister, was born in Ireland, and finished his studies at the university of Glasgow; which afterwards, from a regard to his merit, conferred on him the degree of doctor of divinity. He resided 10 or 11 years at Cambridge, as the pastor of a small congregation there; where he enjoyed his beloved retirement, the advantage of books and of learned conversation, which he improved with the greatest diligence. On Mr Abernethy's removal from Antrim, he succeeded him there; and on that gentleman's death, he succeeded him as minister of a dissenting meeting-house in Wood-street, Dublin. In this situation he continued till his death, which happened on the 4th of May 1761, when he had completed his 64th year. He published a volume of excellent discourses on the presumptive arguments in favour of the Christian religion, and many occasional tracts; and after his death was published a number of his sermons, in three volumes 8vo.

DUCHY, in *Geography*, an appellation given to the dominions of a duke.

Duchy Court, a court where all matters belonging to the duchy or county palatine of Lancaster are decided by decree of the chancellor of that court.

The origin of this court was in Henry IV's time, who obtained the crown by the deposition of Richard II. and having the duchy of Lancaster by descent, in right of his mother, became seized thereof as king, not as duke: So that all the liberties, franchises, and jurisdictions of the said county passed from the king by his great seal, and not by livery or attornment, as the earldom of March, and other possessions, which descended to him by other ancestors than the king's did. Henry IV. by authority of parliament severed the possessions, liberties, &c. of the said duchy from the crown; but Edward IV. restored them to their former nature.

The officers belonging to this court are, a chancellor, attorney general, receiver general, clerk of the court, and messenger; beside the assistants, as an attorney in the exchequer, another in chancery, and four counsellers.

DUCK. See Anas, Ornithology *Index*.

This fowl is furnished with a peculiar structure of vessels about the heart, which enables it to live a considerable time under water, as is necessary for it in diving. This made Mr Boyle think it a more proper subject for experiments with the air-pump, than any other bird. A full-grown duck, being put into the receiver of an air-pump, of which she filled one-third part, and the air exhausted, the creature seemed to bear it better for the first moments than a hen or other such fowl: but after about a minute, she showed great signs of uneasiness, and in less than two minutes her head fell down, and she appeared dying, till revived by the admission of the air. Thus, whatever facility of diving this and other water fowl may have, it does not appear that they can subsist, without air for respiration, any longer than other animals. A young callow duck was afterwards tried in the same manner, and with the same success, being reduced very near death in less than two minutes. But it is observable, that both birds swelled very much in pumping out the air, so that they appeared greatly larger to the spectators, especially about the crop. It not being intended that any water-fowl should live in an exceeding rarefied air, but only be able to continue occasionally some time under water, Nature, though she has provided them with the means of this, hath done nothing for them in regard to the other.

The strongest instance of these creatures being calculated to live almost in any situation, we have in the accounts of the blind ducks in the Zirchnitzer lake in Carniola. It is supposed that this lake communicates with another lake under ground in the mountain Savornic, and fills or empties itself according to the fulness or emptiness of that lake; the water of the upper lake running off, and that in vast quantities, by holes in the bottom. The ducks which are here always in great numbers, are often carried down along with the water, and forced into the subterraneous lake to which it retires. In this unnatural habitation many of these creatures undoubtedly perish, but some remain alive. These become blind, and lose all their feathers; and in the next filling of the lake, both they and vast numbers of fish are thrown up with the water. At this time they are fat, but make a strange appearance in their naked state, and are easily caught, by reason of their want of sight. In about a fortnight they recover their sight and feathers: and are then of the size of a common wild duck, but of a black colour, with a white spot on their forehead. When opened, on being taken at their first coming up in their blind state, their stomachs are found full of small fishes, and somewhat resembling weeds. From this it seems that they cannot be absolutely blind: but that the degree of light to which they have been accustomed in their subterraneous habitation, is sufficient to enable them to procure food for themselves: and their blindness, on coming again to open day light, is no other than that of a man who has been long in the dark, on having in an instant a large blaze of candles set under his eyes.

Duck, *Stephen*, originally a thrasher in a barn, was born about the beginning of the 18th century. By his poetical talents, he first attracted the notice of some gentlemen at Oxford; and being recommended to Queen Caroline, he, under her patronage, took orders, and was preferred to the living of Byfleet in Surry. His abilities were, however, much more conspicuous in his primitive station than in his advancement: though, it is said, he was not disliked as a preacher. Falling at length into a low-spirited melancholy way, probably owing to his change of life and cessation from his usual labour, he in a fit of lunacy flung himself into the Thames, in 1756.

DUCKING, plunging in water, a diversion anciently practised among the Goths by way of exercise; but among the Celtæ, Franks, and ancient Germans, it was a sort of punishment for persons of scandalous lives.—At Marseilles and Bourbon their men and women

men of scandalous life are condemned to the cale, as they call it; that is, to be shut up naked to the shift in an iron cage fastened to the yard of a shallop, and ducked several times in the river. The same has been done at Thoulouse to blasphemers.

Ducking, a sort of marine punishment, inflicted by the French, on those who have been convicted of desertion, blasphemy, or exciting sedition. It is performed as follows: The criminal is placed astride of a short thick batten, fastened at the end of a rope, which passes through a block hanging at one of the yard-arms. Thus fixed, he is hoisted suddenly up to the yard, and the rope being slackened at once, he is plunged into the sea. This chastisement is repeated several times conformable to the purport of the sentence pronounced against the culprit, who has at that time several cannon shot fastened to his feet during the punishment; which is rendered public by the firing of a gun, to advertise the other ships of the fleet thereof, that their crews may become spectators.

Ducking is also a penalty which veteran sailors pretend to inflict on those who, for the first time, pass the tropic of Cancer, the equator, or the straits of Gibraltar, in consequence of their refusal or incapacity to pay the usual fine levied on this occasion.

Ducking-Stool. See Castigatory.

DUCKUP, at sea, is a term used by the steersman, when the main-sail, fore-sail, or sprit-sail, hinders his seeing to steer by a land-mark: upon which he calls out, *Duck up the clew-lines of these sails;* that is, haul the sails out of the way.

DUCLOS, Charles Pineau, a French miscellaneous writer. See Supplement.

DUCT, in general, denotes any tube or canal. It is a term much used by anatomists.

DUCTILITY, in *Physics*, a property possessed by certain solid bodies, which consists in their yielding to percussion or pressure, and in receiving different forms without breaking.

Some bodies are ductile both when they are hot and when they are cold, and in all circumstances. Such are metals, particularly gold and silver. Other bodies are ductile only when heated to a sufficient degree; such as wax and other substances of that kind, and glass. Other bodies, particularly some kinds of iron, called by the workmen *red short*, brass, and some other metallic mixtures, are ductile only when cold, and brittle when hot. The degrees of heat requisite to produce ductility in bodies of the first kind, vary according to their different natures. In general, the heat of the body must be such as is sufficient to reduce it to a middle state, betwixt solidity and perfect fusion. As wax, for instance, is fusible with a very small heat, it may be rendered ductile by a still smaller one; and glass, which requires a most violent heat for its perfect fusion, cannot acquire its greatest ductility until it is made perfectly red hot, and almost ready to fuse. Lastly, Some bodies are made ductile by the absorption of a fluid. Such are certain earths, particularly clay. When these earths have absorbed a sufficient quantity of water to bring them into a middle state betwixt solidity and fluidity, that is, to the consistence of a considerable firm paste, they have then acquired their greatest ductility. Water has precisely the same effect upon them in this respect that fire has upon the bodies above mentioned.

DUDLEY, Edmund, an eminent lawyer and able statesman in the reign of Henry VII.; who with Sir Richard Empson, another lawyer of the same complexion, assisted in filling that rapacious monarch's coffers by arbitrary prosecutions of the people on old penal statutes. They were beheaded on the accession of Henry VIII. to pacify the clamours of the people for justice.

Dudley, *John*, duke of Northumberland, son of the above, a statesman; memorable in the English history for his unsuccessful attempt to place the crown on the head of his daughter-in-law, Lady Jane Grey, who fell a victim to his ambition; was born in 1502, and beheaded in 1553. See (*History of*) England. Ambrose his eldest son was a brave general and able statesman under Queen Elizabeth; and received the appellation of *the good earl of Warwick*. Henry, the duke's second son, was killed at the siege of St Quintin. Robert, the third son, a man of bad character, was created earl of Leicester; and was one of Queen Elizabeth's favourites. His fourth son was the unfortunate Lord Guildford Dudley, whose only crime was his being the husband of Lady Jane Grey, for which he was beheaded in 1554.

Dudley, *Sir Robert*, as he was called in England, and, as he was styled abroad, *earl of Warwick and duke of Northumberland*, was the son of Robert above mentioned, by the lady Douglas Sheffield; and was born at Sheen in Surrey in 1573, where he was carefully concealed, to prevent the queen's knowledge of the earl's engagement with his mother. He studied at Oxford; when his father dying, left him the bulk of his estate. He was at this time one of the finest gentleman in England: and having a particular turn to navigation, fitted out a small squadron at his own expence, with which he sailed to the river Oroonoque, and took and destroyed nine sail of Spanish ships. In 1595, he attended the earl of Essex, and the lord high admiral of England, in their expedition against the Spaniards; when, for his gallant behaviour at the taking of Cadiz, he received the honour of knighthood. He now endeavoured to prove the legitimacy of his birth, in order to be entitled to his hereditary honours. But being overpowered by the interest of the countess dowager of Leicester, he applied for a license to travel; and being well received at the court of Florence, resolved to continue there, notwithstanding his receiving a letter of recal; on which his whole estate was seized by King James I. and vested in the crown. He discovered at the court of Cosmo II. great duke of Tuscany, those great abilities for which he had been admired in England, and was at length made chamberlain to his serene highness's consort. He there contrived several methods of improving shipping; introduced new manufactures; and by other services obtained so high a reputation, that at the desire of the archduchess, the emperor Ferdinand, in 1620, created him a duke of the holy Roman empire. He afterwards drained a vast tract of morass between Pisa and the sea; and raised Leghorn, which was then a mean, pitiful place, into a large and beautiful town, improving the haven by a mole, which rendered it both safe and

and commodious; and having engaged his highness to declare it a free port, he by his influence and correspondence, drew many English merchants to settle and set up houses there, which was of very great service to his native country, as well as to the Spaniards. He was also the patron of learned men, and held a high place himself in the republic of letters. His most celebrated work is his *Del Arcano del Mare*, in two volumes folio.

DUEL, a single combat, at a time and place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes and Franks, that none were excused from it but women, sick people, cripples, and such as were under 21 years of age or above 60. Even ecclesiastics, priests, and monks, were obliged to find champions to fight in their stead. The punishment of the vanquished was either death, by hanging or beheading; or mutilation of members, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil ones for the maintenance of rights to estates, and the like? in latter times, however, before they were entirely abolished, they were restrained to these four cases. 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must by common fame be supposed guilty. And, 4. The matter not capable of proof by witnesses.

DUEL, at present, is used for single combat on some private quarrel; and must be premeditated, otherwise it is called a *rencounter*. If a person is killed in a duel, both the principals and seconds are guilty, whether the seconds engage or not. (See the article MURDER). It is also a very high offence to challenge a person either by word or letter, or to be the messenger of a challenge. (See LAW *Index*.)

The general practice of duelling, in this last sense, took its rise in the year 1527, at the breaking up of a treaty between the emperor Charles V. and Francis I. The former desired Francis's herald to acquaint his sovereign, that he would henceforth consider him not only as a base violator of public faith, but as a stranger to the honour and integrity becoming a gentleman. Francis, too high-spirited to bear such an imputation, had recourse to an uncommon expedient to vindicate his character. He instantly sent back the herald with a cartel of defiance, in which he gave the emperor the lie in form, challenged him to single combat, requiring him to name the time and place of the encounter, and the weapons with which he chose to fight. Charles, as he was not inferior to his rival in spirit or bravery, readily accepted the challenge; but after several messages concerning the arrangement of all the circumstances relative to the combat, accompanied with mutual reproaches bordering on the most indecent scurrility, all thoughts of this duel, more becoming the heroes of romance than the two greatest monarchs of their age, were entirely laid aside.

The example of two personages so illustrious, drew such general attention, and carried with it so much authority, that it had considerable influence in introducing an important change in manners all over Europe. Duels, as has already been observed, had been long permitted by the laws of all the European nations; and, forming a part of their jurisprudence, were authorized by the magistrate on many occasions, as the most proper method of terminating questions with regard to property, or of deciding in those which regarded crimes. But single combats being considered as solemn appeals to the omniscience and justice of the Supreme Being, they were allowed only in public causes, according to the prescription of law, and carried on in a judicial form †. Men accustomed to this manner of decision in courts of justice, were naturally led to apply it to personal and private quarrels. Duels, which at first could be appointed by the civil judge alone, were fought without the interposition of his authority, and in cases to which the laws did not extend. The transactions between Charles and Francis strongly countenanced this practice. Upon every affront or injury which seemed to touch his honour, a gentleman thought himself entitled to draw his sword, and to call on his adversary to make reparation. Such an opinion, introduced among men of fierce courage, of high spirit, and of rude manners, where offence was often given, and revenge was always prompt, produced most fatal consequences. Much of the best blood in Christendom was shed; many useful lives were lost; and, at some periods, war itself had hardly been more destructive than these contests of honour. So powerful, however, is the dominion of fashion, that neither the terror of penal laws, nor reverence for religion, have been able entirely to abolish a practice unknown among the ancients, and not justifiable by any principle of reason: though at the same time we must ascribe to it, in some degree, that extraordinary gentleness and complaisance of modern manners, and that respectful attention of one man to another, which at present render the social intercourses of life far more agreeable and decent than among the most civilized nations of antiquity.

† See the article *Battel*.

Public opinion is not easily controlled by civil institutions; for which reason it may be questioned whether any regulations can be contrived of sufficient force to suppress or change the rule of honour which stigmatizes all scruples about duelling with the reproach of cowardice.

The inadequate redress which the law of the land affords for those injuries which chiefly affect a man in his sensibility and reputation, tempts many to redress themselves. Prosecutions for such offences, by the trifling damages that are recovered, serve only to make the sufferer more ridiculous.—This ought to be remedied.

For the army, where the point of honour is cultivated with exquisite attention and refinement, there might be established a court of honour, with a power of awarding those submissions and acknowledgements which it is generally the object of a challenge to obtain; and it might grow into a fashion with persons of rank of all professions to refer their quarrels to the same tribunal.

Duelling, as the law now stands, can seldom be overtaken by legal punishment. The challenge, appointment, and other previous circumstances, which indicate the intention with which the combatants meet, being suppressed,

suppressed, nothing appears to a court of justice but the actual rencounter; and if a person be slain when actually fighting with his adversary, the law deems his death nothing more than manslaughter.

DUERO, or DOURO, a large river, which, rising in Old Castile in Spain, runs from east to west, crosses the province of Leon, and after dividing Portugal from Spain, falls into the Atlantic ocean near Oporto.

DUGDALE, SIR WILLIAM, an eminent English historian, antiquarian, and herald, born in Warwickshire in 1605. He was introduced into the herald's office by Sir Christopher Hatton; and ascended gradually through all the degrees, until he became Garter principal king at arms. His chief work is the *Monasticon Anglicanum*, in three vols. folio; containing the charters and descriptions of all the English monasteries, adorned with engravings: in the former part of which work he was assisted by Mr Roger Dodsworth. Nor are his antiquities of Warwickshire less esteemed. He wrote likewise, among other things of less note, the History of St Paul's Cathedral; a History of Embanking and Draining; a Baronage of England; and completed the second volume of Sir Henry Spelman's Councils, with a second part of his Glossary. He died in 1686. His son, Sir John, was Norroy king at arms, and published a Catalogue of English Nobility. His daughter Elizabeth married the famous Elias Ashmole.

DUHAMEL, HENRY LEWIS, a French writer on natural history, &c. See SUPPLEMENT.

DUILLIA LEX, was enacted by M. Duillius, a tribune, in the year of Rome 304. It made it a capital crime to leave the Roman people without its tribunes, or to create any new magistrate without a sufficient cause. Another in 392, to regulate what interest ought to be paid for money lent.

DUILLIUS NEPOS, C. a Roman consul, the first who obtained a victory over the naval power of Carthage in the year of Rome 492. He took fifty of the enemy's ships, and was honoured with a naval triumph, the first that ever appeared at Rome. The senate rewarded his valour by permitting him to have music playing and torches lighted at the public expence every day while he was at supper. There were some medals struck in commemoration of his victory; and there exists a column at Rome which was erected on the occasion.

DUKE, (*Dux*), a sovereign prince, without the title or quality of king. Such are the dukes of Lorrain, of Holstein, of Savoy, of Parma, &c. The word is borrowed from the modern Greeks, who call *doucas* what the Latins call *dux*.

There are also two sovereigns who bear the title of *grand duke*: as the grand duke of Tuscany, and the grand duke of Muscovy, now called the *czar* or emperor of Russia. The title of *great duke* belongs to the apparent heir of Russia; and the title of *archduke* is given to all the sons of the house of Austria, as that of *archduchess* to all the daughters.

DUKE, (*Dux*), is also a title of honour or nobility, the next below princes.

The dukedom or dignity of duke is a Roman dignity, denominated *à ducendo*, "leading" or "commanding." Accordingly, the first dukes, *duces*, were the *ductores exercituum*, "commanders of armies." Under the later emperors, the governors of provinces in war time were entitled *duces*. In after times the same denomination was also given to the governors of provinces in time of peace. The first governor under the name of *duke* was a duke of the Marchia Rhætica, or Grisons, whereof mention is made in Cassiodorus; and there were afterwards thirteen dukes in the eastern empire, and twelve in the western. The Goths and Vandals, upon their overrunning the provinces of the western empire, abolished the Roman dignities wherever they settled. But the Franks, &c. to please the Gauls, who had long been used to that form of government, made it a point of politics not to change any thing therein: and accordingly they divided all Gaul into duchies and counties; and gave the names sometimes of dukes, and sometimes of counts, *comites*, to the governors thereof.

In England, during the Saxon times, Camden observes, the officers and commanders of armies were called dukes, *duces*, after the ancient Roman manner, without any addition. After the Conqueror came in, the title lay dormant till the reign of Edward III. who created his son Edward, called the *Black Prince*, first duke of Cornwall; which hath ever since been the peculiar inheritance of the king's eldest son during the life of his father; so that he is *dux natus, non creatus*. After whom there were more made, in such a manner as that their titles descended to their posterity. They were created with much solemnity, *per cincturam gladii, cappæque, et circuli aurei in capite impositionem*. However, in the reign of Queen Elizabeth, A. D. 1572, the whole order became utterly extinct; but it was revived about 50 years afterwards by her successor, in the person of George Villiers duke of Buckingham.

Though the French retained the names and forms of the ducal government, yet under their second race of kings there were scarce any such thing as dukes: but all the great lords were called *counts*, *peers*, or *barons*; excepting, however, the dukes of Burgundy and Aquitain; and the duke of France, which was a dignity Hugh Capet himself held, corresponding to the modern dignity of maire de palais, or the king's lieutenant. By the weakness of the kings, the dukes or governors sometimes made themselves sovereigns of the provinces trusted to their administration. This change happened chiefly about the time of Hugh Capet; when the great lords began to dismember the kingdom, so that that prince found more competitors among them than subjects. It was even with a great deal of difficulty they could be brought to own him their superior, or to hold of him by faith and homage. By degrees, what with force, and what by marriages, these provinces, both duchies and counties, which had been rent from the crown, were again united to it. But the title *duke* was no longer given to the governors of provinces. From that time duke became a mere title of dignity, annexed to a person and his heirs male, without giving him any domain, territory, or jurisdiction over the place whereof he was duke. All the advantages thereof now consist in the name, and the precedence it gives.

The dukes of our days retain nothing of their ancient splendour but the coronet on their escutcheon, which is the only mark of their departed sovereignty. They are created by patent, cincture of the sword, mantle of state, imposition of a cap and coronet of gold on the head, and a verge or rod of gold in their hand.

The eldest sons of dukes are by the courtesy of England styled *marquises*, though they are usually distinguished by their father's second title, whether it be that of marquis or earl: and the younger sons *lords*, with the addition of their Christian name, as Lord James, Lord Thomas, &c. and they take place of viscounts, though not so privileged by the laws of the land.

A duke has the title of *grace;* and being writ to, he is styled, in the herald's language, *most high, potent, and noble prince.* Dukes of the blood royal are styled *most high, most mighty, and illustrious princes.*

DUKE, among Hebrew grammarians, is an appellation given to a species of accents answering to our comma. See ACCENT.

DUKE-Duke, a quality given in Spain to a grandee of the house of Sylva, on account of his having several duchies from the uniting of two considerable houses in his person. Don Roderigo de Sylva, eldest son of Don Ruy Gomez de Sylva, and heir of his duchies and principalities, having married the eldest daughter of the duke de l'Infantado, the duke de Pastrana, who is descended therefrom, added to his other great titles that of duke-duke, to distinguish himself from the other dukes; some whereof may enjoy several duchies, but none so considerable ones.

DULCIFYING, in *Chemistry*, is the sweetening any matter impregnated with salts, by frequently washing it in pure water.

DULL, in the manege. The marks of a dull horse, called by the French *marques de ladre*, are white spots round the eye and on the tip of the nose, upon any general colour whatsoever. Though the vulgar take these spots for signs of stupidity, it is certain they are great marks of the goodness of a horse; and the horses that have them are very sensible and quick upon the spur.

DULLART, HEIMAN, a Dutch painter and poet. He was a pupil to Rembrandt, for whose works the few he left are often mistaken. He died in 1684.

DUMARSAIS, CESAR CHESNAU, a French writer on Grammar. See SUPPLEMENT.

DUMBARTON. See DUNBARTON.

DUMBNESS, the privation of the faculty of speech. The most general, or rather the sole cause of dumbness, is the want of the sense of hearing. The use of language is originally acquired by imitating articulate sounds. From this source of intelligence, deaf people are entirely excluded: they cannot acquire articulate sounds by the ear: unless, therefore, articulation be communicated to them by some other medium, these unhappy people must for ever be deprived of the use of language; and as language is the principal source of knowledge, whoever has the misfortune to want the sense of hearing, must remain in a state little superior to that of the brute creation. Deafness has in all ages been considered as such a total obstruction to speech or written language, that an attempt to teach the deaf to speak or read has been uniformly regarded as impracticable, till Dr Wallis and some others have of late shown, that although deaf people cannot learn to speak or read by the direction of the ear, there are other sources of imitation, by which the same effect may be produced. The organs of hearing and of speech have little or no connexion. Persons deprived of the former generally possess the latter in such perfection, that nothing further is necessary, in order to make them articulate, than to teach them how to use these organs. This indeed is no easy task; but experience shows that it is practicable. Mr THOMAS BRAIDWOOD, late of Edinburgh, was perhaps the first who ever brought this surprising art to any degree of perfection. He began with a single pupil in 1764; and since that period has taught great numbers of people born deaf to speak distinctly; to read, to write, to understand figures, the principles of religion and morality, &c. At the time we first conversed with him, being a few years after the commencement of his practice, he had a considerable number of deaf pupils, some of them above 20 years of age, all making a rapid and amazing progress in those useful branches of education.

Mr Braidwood's principal difficulty, after he had discovered this art, was to make people believe in the practicability of it. He advertised in the public papers; he exhibited his pupils to many noblemen and gentlemen: still he found the generality of mankind unwilling to believe him. A remarkable instance of this incredulity occurred some years ago. A gentleman in England sent a deaf girl of his to Mr Braidwood's care. A year or two afterwards, Mr Braidwood wrote to the father, that his daughter could speak, read, and write distinctly. The father returned an answer, begging Mr Braidwood's excuse, as he could not believe it: however, he desired a friend of his, who was occasionally going to Edinburgh, to call at Mr Braidwood, and inquire into the truth of what he had wrote him: he did so; conversed with Mr Braidwood, saw the young lady, heard her read, speak, and answer any question he put to her. On his return, he told the father the surprising progress his child had made; but still the father thought the whole an imposition; the girl herself wrote to her father, but he looked upon the letter as a forgery. About this time the father died; and the mother sent an uncle and cousin of the deaf lady's from Shrewsbury, in order to be satisfied of the truth. When they arrived, Mr Braidwood told the girl her uncle and cousin were in the parlour; and desired her to go and ask them how they did, and how her mother and other friends did. The friends were astonished, and could hardly credit their own ears and eyes.

When we conversed with Mr Braidwood concerning the nature and method of teaching this wonderful art, he seemed to be very desirous of communicating and transmitting his discovery to posterity; but observed, and from the nature of the thing we believe it to be true, that he could not communicate it so fully in writing as to enable any other person to teach it. The first thing in the method is, to teach the pupil to pronounce the simple sounds of the vowels and consonants. We have even seen him performing this operation; but are unable to give a clear idea of it. He pronounces the sound of *a* slowly, pointing out the figure of the letter at the same time; makes his pupil observe the motion of his mouth and throat; he then puts his finger into the pupil's mouth, depresses or elevates the tongue, and makes him keep the parts in that position; then he lays hold of the outside of the windpipe, and gives it some kind of squeeze, which it is impossible to describe:

scribe: all the while he is pronouncing *a*, the pupil is anxiously imitating him, but at first seems not to understand what he would have him to do. In this manner he proceeds, till the pupil has learned to pronounce the sounds of the letters. He goes on in the same manner to join a vowel and a consonant, till at length the pupil is enabled both to speak and read.

That his pupils were taught not only the mere *pronunciation*, but also to understand the *meaning* of what they read, was easily ascertained by a conversation with any of them. Of this Mr Pennant gives a remarkable instance in a young lady of about 13 years of age, who had been some time under the care of Mr Braidwood. "She readily apprehended (says he) all I said, and returned me answers with the utmost facility. She read; she wrote well. Her reading was not by rote. She could clothe the same thoughts in a new set of words, and never vary from the original sense. I have forgot the book she took up, or the sentences she made a new version of: but the effect was as follows.

"*Original passage.* Lord Bacon has divided the whole of human knowledge into history, poetry, and philosophy; which are referred to the three powers of the mind,—memory, imagination, and reason.

"*Version.* A nobleman has parted the total or all of man's study or understanding into, An account of the life, manners, religion or customs of any people or country; verse or metre; moral or natural knowledge: which are pointed to the three faculties of the soul or spirit; the faculty of remembering what is past, thought or conception, and right judgment."

Mr Braidwood's success since he went to settle in London is universally known. Several other persons have since attempted the same art with various degrees of ability. But a new and different method, equally laborious and successful we understand, is practised by the abbé de l'Epee of Berlin. We are informed* that he begins his instructions not by endeavouring to form the organs of speech to articulate sounds, but by communicating ideas to the mind by means of signs and characters: to effect this, he writes the names of things; and, by a regular system of signs, establishes a connection between these words and the ideas to be excited by them. After he has thus furnished his pupils with ideas, and a medium of communication, he teaches them to articulate and pronounce, and renders them not only grammarians but logicians. In this manner he has enabled one of his pupils to deliver a Latin oration in public, and another to defend a thesis against the objections of one of his fellow pupils in a scholastic disputation; in which the arguments of each were communicated to each other, but whether by signs or in writing is not said; for it does not appear that the abbé teaches his pupils to discern what is spoken, by observing the motion of the organs of speech, which those instructed by Messrs Braidwoods are able to do with astonishing readiness.

There is perhaps no word, says the abbé, more difficult to explain by signs than the verb *croire*, "to believe." To do this, he writes the verb with its significations in the following manner:

Je crois {
Je dis oui par l' esprit, Je pense qui oui.
Je dis oui par le coeur, J'aime à penser que oui.
Je dis oui par la bouche.
Je ne vois pas des yeux.

After teaching these four significations, which he does by as many signs, he connects them with the verb, and adds other signs, to express the number, person, tense, and mood, in which it is used. If to the four signs, corresponding with the lines above mentioned, be added that of a substantive, the pupil will write the word *foi* "faith;" but, if a sign, indicating a participle used substantively, be adjoined, he will express *la croyance*, "belief;" to make him write *croyable*, "credible," the four signs of the verb must be accompanied with one that indicates an adjective terminating in *able*; all these signs are rapidly made, and immediately comprehended.

M. Linguet, a member of the Royal Academy, having asserted that persons thus instructed could be considered as little more than automata, the abbé invited him to be present at his lessons, and expressed his astonishment that M. Linguet should be so prejudiced in favour of the medium by which he had received the first rudiments of knowledge, as to conclude that they could not be imparted by any other; desiring him, at the same time to reflect, that the connexion between ideas, and the articulate sounds by which they are excited in the mind, is not less arbitrary than that between these ideas and the written characters which are made to represent them to the eye. M. Linguet complied with the invitation; and the abbé having desired him to fix on some abstract term which he would by signs communicate to his pupils, he chose the word *unintelligibility*: which, to his astonishment, was almost instantly written by one of them. The abbé informed him, that to communicate this word he had used five signs, which, though scarcely perceivable to him, were immediately and distinctly apprehended by his scholars: the first of the signs indicated an internal action; the second represented the act of a mind that reads internally, or, in other words, comprehends what is proposed to it; a third signified that such a disposition is possible; those, taken together, form the word *intelligible*: a fourth sign transforms the adjective into the substantive; and a fifth, expressing negation, completes the word required. M. Linguet afterwards proposed this question, *What do you understand by metaphysical ideas?* which being committed to writing, a young lady immediately answered on paper in the following terms: "I understand the ideas of things which are independent of our senses, which are beyond the reach of our senses, which make no impression on our senses, which cannot be perceived by our senses." On reading this, we cannot help exclaiming with the poet, *Labor omnia vincit improbus!* a maxim by none more forcibly illustrated than by the abbé de l'Epee.

Periodical DUMBNESS. In the Ephemerides of the Curious, we have an account of a periodical dumbness, which had continued for more than 15 years, and had not gone off at the time the account was wrote. The person was son to an innkeeper at Jesing in the duchy of Wirtemberg in Germany. He was one night taken so ill after supper, that he could neither stand nor sit. He continued, for about an hour, oppressed with sickness to such a degree as to be in danger of suffocation. At the expiration of this time he grew better; but, during three months, he was much dejected, melancholy, and, at times, fearful. He was then suddenly struck

---

* Nov. Me de 'Acemie Roy, &c. de Berlin, 78 (Mo Rev. vol. xx. 6)

struck dumb, and became unable to pronounce the least word, or form the least sound, though he could speak very articulately before. The loss of speech was at first instantaneous, and continued only a few minutes; but the duration of it began to lengthen every day; so that it soon amounted to half an hour, two hours, three hours, and at last to 23 hours, yet without any order. At last the return of speech kept so constant and regular an order, that, for 14 years together, he could not speak except from noon, during the space of one entire hour, to the precise moment of one o'clock. Every time he lost his speech, he felt something rise from his stomach to his throat. Excepting this loss of speech, he was afflicted with no other disorder of any animal function. Both his internal and external senses continued sound: he heard always perfectly well, and answered the questions proposed to him by gestures or writing. All suspicion of deceit was removed by his keeping exactly the same hour, though he had no access to any instruments by which time can be measured.

DUMFERMLINE, a royal borough of Scotland, situated in the county of Fife, 15 miles north-west of Edinburgh. W. Long. 30. 20. N. Lat. 56. 15. Here was formerly a magnificent abbey and palace of the kings of Scotland, in which the princess Elizabeth, daughter of King James VI. and mother of the princess Sophia, from whom the present royal family are descended, was born. In the inn of this town, it is said, is the marriage-bed of James VI. and his queen: it is still entire, and used by strangers who lodge here. This place is noted for a manufactory of figured linen cloth called diaper. The town gave title of earl to a baronet of the Seton family, which was forfeited in the year 1690.

DUMFRIES, a county in the south of Scotland, comprehending the shire of Nithsdale, the stewarty of Annandale, and the lordship of Eskdale, extends in length from north-west to south-east about 60 miles, and is about 30 miles in breadth where broadest. It is bounded on the south-west by Galloway and part of Kyle; on the north-east by the counties of Roxburgh, Selkirk, and Peebles; on the north-west by Clydesdale; and on the south-east by Solway frith and the marches between Scotland and England. A great part of the county is mountainous and overspread with heath, well stocked with game of all kinds: but the valleys, through which the Esk, the Annan, the Nith, and other small rivers run, are extremely pleasant; and some of them well cultivated, and very fertile, and produce oats, barley, and wheat in abundance, both for maintaining the inhabitants and for exportation; while the mountainous parts afford pasture for innumerable flocks of sheep and herds of black cattle, many thousands of which are annually exported to England. In the valleys are several natural woods, and some extensive plantations of different kinds of timber. In the division called *Nithsdale*, are the rich lead mines of Wanlockhead, the coal mines of Sanquhar and Cairnburn, the inexhaustible lime quarries of Closeburn and Barjarg, and freestone in almost every parish. Annandale has the rich lime quarries of Kellhead and Comlongan, with plenty of freestone near the towns of Annan and Lochmaben: and in the lower part of Eskdale are limestone and some coal.

The following is a view of the population of this county, with the number of souls in each parish, taken at two different periods, and extracted from the Statistical History of Scotland.

Parishes.	Population in 1755.	Population in 1790—1798.

See Dumfries-shire, Supplement.

Dumfries, the capital of the above mentioned county, a handsome town, situated on a ridge or rising ground on the north-east side of the river Nith, about 10 miles above where it falls into Solway frith, in N. Lat. 55. 8. 30. Long. W. of Greenwich Observatory, 3. 56. Its ancient name, it is said by some of the Scotch historians, was *Cotiac*; but on what authority we cannot tell. Its present name appears to have been derived partly from its situation, and partly from the monastery of Gray Friars that formerly stood near the head

head of the street called the *Friar vennal*, the kitchen of which is all that now remains; being only a corruption of *Drum friars*, or "the eminence of the friary:" and accordingly, till within these 40 or 50 years, it was always spelt *Drumfries*, and not *Dumfries*, as it is now for the sake of greater softness. Besides the pleasantness of its situation on the side of a beautiful winding river, it is surrounded on all sides with one of the finest and best cultivated sheets of dale country that one can anywhere meet with, and the prospect from it terminated, at the distance of a few miles, by a continued chain of hills, forming altogether one of the grandest natural amphitheatres perhaps in Britain. There was anciently a strong castle at the south end of the town belonging to the Cummings, lords of Badenoch, of which there are now no remains. Another castle was afterwards built at the north-west end, which was taken down about a century ago. On the north-east side of it, at some little distance, are the ruins of a chapel built by King Robert Bruce, and endowed for a number of priests to say mass for the repose of the soul of Sir Christopher Seaton his brother-in-law, who was taken prisoner by Edward I. at Loch Urr, and hanged at this place. It is now only employed as a burying place for suicides. It is not certain at what period Dumfries was erected into a royal borough; but it must have been before the middle of the eleventh century, as a grave-stone was discovered some time ago bearing the date of 1079, and mentioning the person buried under it to have been a merchant and burgess of the town; and that it was a place of consequence in the beginning of the fourteenth century, is evident from this circumstance, that Edward II. called the estates of Scotland to meet there in the year 1307. In the above-mentioned monastery too, King Robert Bruce killed his rival Cumming lord of Badenoch, with the assistance of James Lindsay and Roger Kirkpatrick, on the 5th of February 1305. As to the present state of the town, the houses are well built and commodious, the streets spacious, open, and neatly paved. It has two very elegant churches, an Episcopal chapel with a fine little organ, besides four meeting houses belonging to different descriptions of sectaries; a tolbooth; a council chamber; a trades hall; a meal market; a strong prison; a correction house; a large hospital; an infirmary, with apartments for insane patients; a narrow bridge of nine arches over the river, said to have been built by one of the three daughters and co-heiresses of Alan Lord Galloway, and a handsome new bridge built in 1795. A large village, called the *Bridge-end*, stands on the opposite side, and is within the stewarty of Kircudbright. The assizes for the county, and for the shire of Galloway and stewarty of Kircudbright, are held in the town twice a-year. It is also the place for holding the sheriff and commissary courts, the quarter-sessions of the peace, and the courts of the commissioners of supply. It is governed by a provost, three bailies, a dean of guild, and a town council, composed of merchants and the convener and deacons of the incorporated trades, of which there are seven, viz. square-men, smiths, weavers, tailors, shoemakers, skinners, and butchers. The trades got from King James VI in one of his journeys to England, a small silver tube, like a pistol barrel, called the *silver gun*, with his royal license to shoot for it every year. At that festival they all appear in arms, and march out of the town under their respective colours, to some convenient place, where they shoot at a mark; and the person that hits or shoots nearest to it, returns to town, marching at the convener's right hand, with the silver gun tied to his hat with ribbons; after which they conclude the day with a social entertainment. The town has a weekly market on Wednesday, with two annual fairs, the first on the Wednesday on or next after the 13th of February, and the other on the Wednesday on or next after the 25th of September. But though well situated for fuel at a cheap rate, it has only two manufactures, one for stockings and the other for cottons; but the latter only in its infancy. Its foreign trade for many years has only consisted in timber, iron, and other articles for home consumption. It gives the title of earl to the chief of the family of Crichton: and is the seat of a presbytery and provincial synod. A handsome monument to the memory of Robert Burns, the Ayrshire poet, was erected in the church-yard in 1817. The town contained 9262 inhabitants in 1811.

DUMONT, Francis, a Frenchman, compiler of a general collection of treaties of commerce, alliance, and peace, between the powers of Europe. This collection, with Barbeyrac's, containing the treaties B. C. makes 16 vols. folio, very useful for historical writers. Dumont retired to Holland in 1720. The time of his death is uncertain.

DUMOSÆ (from *dumus*, "a bush"), an order of plants in the *Fragmenta methodi naturalis* of Linnæus, containing the following genera, viz. *Viburnum*, *Tinus*, *Opulus*, *Sambucus*, *Rondeletia*, *Bellonia*, *Cassine*, *Ilex*, *Tomax*, &c.

DUN, or Burgh, the name of an ancient species of buildings, of a circular form, common in the Orkney and Shetland islands, the Hebrides, and northern parts of Scotland. The latter term points out the founders, who at the same time bestowed on them their natal name of *borg*, "a defence or castle," a Sueo-Gothic word; and the Highlanders universally apply to these places the Celtic name *dun*, signifying a hill defended by a tower, which plainly points out their use. They are confined to the countries once subject to the crown of Norway. With few exceptions, they are built within sight of the sea, and one or more within sight of the other; so that on a signal by fire, by flag, or by trumpet, they could give notice of approaching danger, and yield a mutual succour. In the Shetland and Orkney islands, they are most frequently called *wart* or *ward hills*, which shows that they were garrisoned. They had their wardmadher, or watchman, a sort of centinel, who stood on the top, and challenged all who came in sight. The gackman was an officer of the same kind, who not only was on the watch against surprise, but was to give notice if he saw any ships in distress. He was allowed a large horn of generous liquor, which he had always by him, to keep up his spirits. Along the Orkney and Shetland shores, they almost form a chain; and by that means not only kept the natives in subjection, but were situated commodiously for covering the landing of their countrymen, who were perpetually roving on piratical expeditions. These towers were even made use of as state prisons; for we learn from Torfæus, that after Sueno had surprised Paul, count of Caithness, he carried him into Sutherland, and confined him there in a Norwegian tower. Out of our own kingdom, no buildings similar to these are to be found, except in Scandinavia. On the mountain Swalberg in Norway is one; the Stir-biskop, at Upsal in Sweden, is another; and Umseborg, in the same kingdom, is a third.

These towers vary in their inner structure; but externally are universally the same; yet some have an addition of strength on the outside. The burgh of Culswick in Shetland, notwithstanding it is built on the top of a hill, is surrounded with a dry ditch 13 feet broad; that of Snaburgh in Unst, has both a wet and a dry ditch; the first cut, with great labour, through the live rock. The burgh of Moura is surrounded by a wall, now reduced to a heap of stones, and the inside is cylindrical, not taper, as is usual with others. The burgh of Hogscter, upon an isle in a loch of the same name, has also its addition of a wall; a peculiarity in a causeway, to join it to the main land, and a singular internal structure. Numbers of little burghs, with single cells, are scattered about these islands, in the neighbourhood of the greater; and which probably were built by the poorer sort of people, in order to enjoy their protection. A multitude of places in these islands have the addition of burgh to their names, notwithstanding there is not a vestige of a tower near them; the materials having long since been carried away, and applied to various uses.

DUNBAR, a royal borough of Scotland, in the shire of East Lothian, once remarkable for a strong castle, the key of Scotland from the east, and which gave shelter to Edward II. of England in his flight from Bannockburn, but of which scarce a vestige now remains. Here are still preserved some of the Scottish pikes, six ells long, and formed both for offence and defence. This town has now a tolerable trade in the fisheries, and is remarkable for making good malt. Dunbar contained 3965 inhabitants in 1811.

DUNBARTON, the county town of Lennox or Dunbartonshire, in Scotland, situated in W. Long. 4. 32. N. Lat. 56. 30. is a royal borough, and one of the most ancient towns of Scotland. It is said to have been once the capital of a kingdom of the Britons, established in the vale of the Clyde, and to have been one of the seats of Fingal, called in the poems of Ossian, the *tower of Balclutha*. Alcluid was indeed the name of this ancient capital of the Strathclydenses; but whether it was situated on the site of the present town, or confined within the precincts of the castle, cannot be exactly ascertained. Dunbarton is built upon the eastern bank of the Leven, which almost encircles it. The greater part of the buildings are old, and the principal street has an air of decayed grandeur. It was erected into a royal borough by Alexander II. in the year 1221, and declared to be free of all imposts and borough taxes; but notwithstanding this material advantage, and the excellent harbour it possesses, it is by no means in a flourishing state. There are here considerable glass-houses, which employ about 300 hands; and some idea may be conceived of the extent of this manufacture, from the amount of the duties to government, which, in the five years preceding 1818, averaged 97,300l. per annum. This place is exceedingly well adapted for manufactures, both on account of its situation on the Clyde, and from its being well supplied with fuel at a cheap rate. The parish is nearly circular, having a diameter of about two miles and a half: the surface is flat, and the soil fertile, but shallow, inclining to gravel. The Clyde washes it on the south, and the Leven on the west, both of which contain excellent trout and salmon. The population of the town in 1811 was 2970, of the parish 3121. The castle of Dunbarton lies at a small distance from the town, on the point of land formed by the junction of the Clyde and Leven; it is situated on the top of a rock, which presents a picturesque object: the rock divides about the middle, and forms two summits: the sides are craggy, and the buildings upon it, though not of themselves beautiful, have a good effect, and, as Mr Gilpin observes, "serve to give it an air of consequence." The fortress is entered by a gate at the bottom; and within the rampart, which defends the entrance, is the guard-house, and lodgings for the officers; from hence the ascent is by a long flight of stone steps to the part where the rock divides: here is a strong battery, barracks for the garrison, and a reservoir always filled with water; above these, on the lower summit, are several batteries, which command a most extensive range. According to Pennant, the Britons, in very early times, made this rock a fortress, it being usual for them, after the departure of the Romans, to retire to the tops of craggy inaccessible mountains, to forests, and to rocks on the sides of rivers, or the shores of the sea. Boethius, however, asserts, that it was possessed by the Caledonians long before the Britons, and that it resisted all the efforts of Agricola to reduce it. The venerable Bede informs us, that it was the strongest fortification in the kingdom in his time, and deemed almost impenetrable; it was reduced by famine in the year 756, by Egbert king of Northumberland, and taken by escalade in the year 1551. The rock seems to have been anciently a volcano: the sides are composed of rude basaltic columns, of which huge masses have been broken off, and fallen to the bottom, by the injuries of time. Many parts of the rock are strongly magnetic, causing the compass to vary at a considerable distance: this circumstance was long since noticed by Buchanan, (Scot. Hist. lib. xx. lect. 28.). As the castle of Dunbarton commands the navigation of the Clyde, and is the key of the western Highlands, the fortifications are generally kept in repair. It is garrisoned by a governor, lieutenant-governor, a fort-major, subaltern officers, and a company of invalids. The government is said to be worth 700l. per annum.

DUNBARTONSHIRE, or, as it was anciently called, the shire of *Lennox*, extends in length about 40 miles, and in breadth about 23. It is bounded on the north by Argyleshire; on the east by the counties of Perth and Stirling; on the south by the river Clyde, and part of Lanarkshire; and on the west by an arm of the sea, called *Loch Long*. The greater part of the county is covered with heathy hills which are now assuming a more luxuriant appearance, since the introduction of sheep. Many of the mountains are elevated to a great height, Benlomond measuring 3158 feet above the level of the sea. The ridge of which Benlomond is a part, is the beginning of that extensive ridge which crosses the country from this place to the east coast at Aberdeen, called the *Grampians*. The lower grounds, which lie on the banks of Loch Lomond, the river Clyde and the Leven, are not so fertile as the corresponding parts of some of the neighbouring counties; notwithstanding which, it is agreeably diversified, and well inhabited. The banks of the Leven, in particular, are covered with numerous bleachfields, printfields, and cotton-works, giving employment to thousands; while the villages erected for the accommodation of the workmen, the hamlets, and elegant seats, cannot fail to impress the mind with high ideas of the wealth, the industry, the public spirit, and the happiness of the inhabitants. Agriculture in this county was formerly rather neglected; but the public spirit has of late been roused to this most useful and important occupation; and the county of Dunbarton, which is capable of much improvement, is fast advancing in agricultural progress. The county contains altogether 230 square miles, or 147,200 acres. The farmers here, indeed, possess numerous advantages: being near a sea-port town, where every article bears the highest price, they find a ready market for their corn; and the numerous inhabitants in the immediate neighbourhood require supplies of other necessaries from the farmer. Upwards of 12,000 acres are covered with natural wood, and there are many fine lakes or lochs, of which Loch Lomond is the chief. Dunbartonshire contains one royal borough, Dunbarton, several thriving manufacturing villages; and is divided into 12 parishes, containing in all 24,189 inhabitants in 1811.

Population of this County at two different periods, from Statist. Hist. of Scotland.

See Dunbartonshire, Supplement.

DUNCANNON, a fort in the county of Wexford, and province of Leinster, in Ireland, seated on the river Ross. It commands the river, insomuch that no ship can pass to Waterford or Ross without its permission. Here are barracks for three companies of foot. W. Long. 6. 30. N. Lat. 52. 10.

DUNCARDS, Dunkers, or *Tunkers*. See Tunkers.

DUNCOMBE, William, younger, son of John Duncombe, Esq. of Stocks in Hertfordshire, in 1722 published a translation of Racine's Athaliah; which was well received by the public, and has gone through three editions. In 1724 he was editor of the works of Mr Needler; in 1755, of the poems of his deceased brother-in-law Mr Hughes, 2 vols 12mo; in 1737, of the miscellanies of his younger brother Mr Jabez Hughes, for the benefit of his widow, in one volume 8vo; and in 1745, of the works of the Rev. Mr Samuel Say, in one volume 4to. In 1726 he married the only sister of John Hughes, Esq. whom he long survived. In 1734 his tragedy of Lucius Junius Brutus was acted at Drury Lane theatre. It was published in 1735, and again in 1747. The works of Horace, in English verse, by several hands, were published by him in two vols 8vo, with notes, &c. in 1757. A second edition, in 4 vols 12mo, with many imitations, was published in 1762. In 1763 he collected and republished "Seven sermons by Archbishop Herring, on public occasions, with a biographical preface." He died Feb. 26. 1769, aged 80.

DUNDALK, a town of Ireland, in the county of Louth, about 48 miles from Dublin. It is a large, ancient, and thriving town, with a wide street, near a mile long, and a very fine market-house, near the entrance from Dublin. In the reign of Edward II. it was a royal city, and the last we read of where a monarch of all Ireland was actually crowned and resided. It was formerly very strong, and had many towers and small castles in it. The bay has good moorings at all times, in four to upwards of eight fathoms water, with very good land-marks, either for bringing up to, or making the harbour; and in crossing the bar at high water, or ordinary neap tides, there is from 15 to 18 feet water. The only cambric manufacture in Ireland is in this town. The population is about 15,000.

DUNDAS, Henry, *Viscount Melville*, an eminent British statesman. See Supplement.

DUNDEE, a borough town of Scotland, in the shire of Forfar or Angus, is seated on the north side of the river Tay, about 12 measured miles from its mouth, 40 measured miles north of Edinburgh, and 22 east from Perth, in W. Long. 2. 48. N. Lat. 56. 26. Its situation for commerce is very advantageous. Trading vessels of the largest burden can get into the harbour; and on the quay there are three very convenient and handsome warehouses built in 1756, as well as good room for shipbuilding, which is carried on to a large extent. The houses are built of stone, generally three or four stories high. The market-place or high street in the middle of the town is a very spacious oblong square, 360 feet long and 100 feet broad; from whence branch out the four principal streets, which with a number of lesser ones are all paved in the best manner. On the south side of the market-place stands the townhouse, an elegant structure, with a very handsome front, piazzas below, and a neat spire over it 140 feet high. This building was finished in the year 1734, and contains the guildhall, the court-room, a very neat mason lodge, the bank, vaulted repositories for the records, and the common prison, which is in the upper story, and does honour to the taste and humanity of the magistrates, under whose auspices it was constructed, being well aired commodious rooms, at the same time very strong and secure. Each prison is

20 feet by 12, and 7½ feet high, well arched above and below.

The meal market and shambles, which were formerly on the high street, and esteemed a nuisance, were removed some years ago; and in the place of the shambles there is now erected by the incorporated trades, on the east end of the above large square, a grand building, with a large and elegant cupola: in the ground flat of which is a very neat coffee room, and several merchant shops; and in the upper stories public rooms for each trade, and a common hall occasionally used as a theatre. This hall is 50 feet long, 30 feet broad, and 25 feet high; having its front to the square decorated with Ionic columns.

The opulence of the corporations, nine in number, may be inferred from this, that they had, along with the kirk session, but very lately finished a most elegant church when they set about building the hall. This church, which is called *St Andrew's Church*, stands on a rising ground a little north from the Cowgate street; and has an elegant spire 130 feet high, with a peal of bells much admired. There is a neat entry to the church by a broad gravel walk, with grass plots on each side; and the whole policies around it are laid out with excellent taste, and in a superb style, as complete and well executed as any in Scotland.

Dundee, beside St Andrew's church, has four other churches, and five ministers on the legal establishment. The old church, in which were originally four places of worship, when entire, had been a very magnificent building, with a large square Gothic tower or steeple 186 feet high, on the west end of the church. This building was in the form of a cross, erected by David earl of Huntingdon, brother to William I. of Scotland (surnamed the Lion), and was dedicated to the virgin Mary. This he did on his return from the third crusade (in which with 500 of his countrymen he had accompanied Richard I. of England) anno 1189, in gratitude for his deliverance from several imminent dangers, and particularly from shipwreck, by which he had nearly perished when in sight of this town. At the same time he changed the name of the town from *Allectum* to *Dei Donum*, whence its present name is thought by many to be derived; while others maintain that its name was *Duntay*, or "the hill of Tay." The word *Allectum* in the Gaelic signifies "beautiful," and harmonizes very well with the Scripture sense of the hill of God. The word *Duntay* has the very same signification, "the Hill of God;" and both agree with the delightful situation of Dundee, and unite in giving it with propriety the name of *Bonny Dundee.* The hill rises on the north of the town to a great height, and is called *The Law of Dundee; law* being a Saxon word for a round hill such as it is. On its top there is evidently the remains of a camp, said to have been first erected by Edward I. of England, and lastly repaired by General Monk. Where the meal market stood is now erected an elegant Episcopal meeting-house; with handsome shops below.

Dundee had an old castle which was demolished by the famous Scots governor Sir William Wallace, who was educated in this town. The castle had proved very useful to Edward I. when he put a garrison into it to awe the inhabitants; but Wallace getting possession, ordered it to be destroyed, lest it should again fall into the hands of the English. This treatment so exasperated Edward, that, taking the town by storm, he set fire to the churches; and a number of the inhabitants having taken sanctuary there with their most valuable effects, were all burnt along with them. At that time he burnt also a great part of the town. The desolation he brought on the church has continued ever since, till the year 1787, when a noble edifice began to be built on the site of the one that was burnt down, and is now finishing; in which the ancient Gothic of the outside is excellently united with internal modern architecture, making one of the largest and neatest churches in the kingdom, and again completing the superb superstructure as erected at first by the earl of Huntingdon.

This town suffered greatly last century during the troubles of Charles II. and the usurpation of Oliver Cromwell; being sometimes under the command of one party, and at others in the mercy of another. In 1645 the marquis of Montrose took it by storm; and in 1651, under the command of its provost Major General Lumsden, it vigorously opposed General Monk, who carried it by storm the 1st of September, and put all in arms to the sword. And so great were the riches of Dundee, all the neighbouring gentlemen having retired to it with their best effects as a place of safety, that every private soldier in General Monk's army had near 60l. sterling to his share of the plunder; there being above 60 merchant vessels in the harbour at that time, and the like number of vessels sailed for England loaded with the spoils of the unfortunate inhabitants. By these and other invasions, the whole ancient records of the town were destroyed, except a deed of Queen Mary, signed by herself, conferring the present burying ground; and some charters of the Charles's, confirming the ancient rights and privileges as disponed by the Alexanders and other kings of Scotland. This burying-ground is the only place in Scotland we know of called *The Hoff*, a Dutch word bearing all the senses of the English word *court*, having been formerly the burying-ground of one of the many religious houses that were in this town previous to the Reformation.

Dundee at present has 154 vessels belonging to the port, of about 16,000 tons burden, which employ 1300 seamen. Of these vessels 8 are employed in the Greenland fishery, 11 in the London trade, and the rest in the Baltic and country trade. Between 1814 and 1818 the bonding system was extended to Dundee by various acts of parliament. The magistrates have been lately and still are at great expence in enlarging and fitting up the harbour, so as to render it of easy access, safe, and commodious; and have now made the passage over the Tay, where there is a great resort, so convenient, that travellers with their horses can get over at any time of tide, and a sufficient number of good boats properly manned are always ready. The river Tay opposite Dundee is about three miles broad; and being sheltered by high lands on both sides is a safe road for ships of the greatest burden: the piers are extensive, broad, and well adapted for the purposes of loading and discharging vessels; and when the harbour is completed on the plan they are presently engaged in, there will not be one superior to it in Scotland.

To enable the town to repair the damage done by Cromwell's ndee.

Cromwell's army, and also their harbour and other public works, Charles II. granted them a small impost of one-sixth of a penny sterling, for 25 years, on the pint of ale brewed or brought into the town for sale; which grant has been frequently renewed by subsequent parliaments; and the fund arising therefrom is most properly bestowed by the magistrates in improving the town, and making it more convenient and healthy. For these purposes, several new streets have been made, the old ones have been widened, and a large convenient one at a considerable expence, carried down from the market place to join a fine walk, shaded very neatly with trees, that leads to the shore. This new street makes the acces easy and commodious, which was formerly much confined and steep.

Till the year 1745, the town had only draw wells; but since that period it is most amply supplied from a large fine fountain of excellent water, conveyed through the town in lead pipes, and discharged by good wells at proper distance. These, with a fine well in the town's meadows, and a stream of water that runs through the ward and the meadows (two large beautiful greens on the north of the town), make it as well watered as any town in Scotland; and these greens, just at hand, serve all the inhabitants most commodiously for the necessary labours of washing and bleaching.

The number of inhabitants in Dundee has increased amazingly since 1780. There was then an accurate list of them taken, when they amounted to near 16,000; but by the census of 1801, the number was 26,084; and by the census of 1811, it was 29,616. Beside the established churches, there are three Episcopal meeting-houses, two of Seceders, one of Methodists, two of Independents, one Berean, and two Anabaptists. One of the Independents is of the Glassite denomination. Mr John Glass, from whom they take that name, resided here; and his principles, though spread far and wide, have always had the most extensive influence in Dundee.

The trade in the town has increased amazingly of late. Its staple is undoubtedly the linen manufacture: for which in summer 1788, they imported from the Baltic 32 cargoes of flax, hemp, &c. (near 3000 tons), besides several quantities from London, Leith, and other places; and on an average the brown linen stamped for the two preceding seasons at the stamp office here amounted to above four millions of yards, in value about 115,000l. sterling. But the annual average value of the cloth stamped in Dundee for 1815, 1816, and 1817, was above 300,000l. The flax is wrought up into coarse linens, chiefly osnaburgs, sheetings, soldiers shirtings, &c. which is sold partly bleached (several fine large bleachfields being well employed in the neighbourhood) and partly brown. These linens are sent principally to London, Glasgow, and Liverpool, and from thence exported. Seven or eight vessels are constantly employed in the trade between Dundee and London, one of which sails every ten or twelve days. The making sailcloth has been long established here, and is carried on to a good extent; and rope-works have succeeded well. The Dundee coloured threads have been long justly esteemed, and give bread to a great number of people; indeed it was here that coloured threads first made a figure among the articles of trade in Scotland. Their sugar-house, a large undertaking, and tan works, are of established reputation. There has been lately erected a large glass-work at a great expence, and a plumbery and foundery are also now carried on to advantage. No doubt the trade of the place has been greatly promoted by the Bank; which is carried forward on the surest and most steady footing, and has always managed the business of the town and neighbourhood in such a way as to keep any other establishment of that kind from taking place. Of late the cotton manufactory has been introduced; a number of jennies being employed in spinning, and several looms in weaving it. A spirit for literature and education has greatly prevailed of late years in Dundee: for beside the public grammar school, which has an able rector and two good masters; the public English and writing school, where are three very proper masters; there is also lately established, and much encouraged, an academy for mathematics, French, Italian, and the polite arts, with masters suitable for the different branches, and a large apparatus for natural philosophy.

Dundee
||
Dunkeld.

The salmon fishing in Tay is of much consequence; and the town is generally well supplied with fish of various kinds, though like every other article of living much raised in price of late years. Their other markets are also well supplied. An excellent nursery at the west end of the town has been much encouraged; and its neighbourhood is now adorned with many neat and elegant villas, showing the wealth and taste of the inhabitants.

Dundee is the birthplace of the celebrated and learned Hector Boethius, whose History of Scotland has been long in much reputation with many. Dundee, with Perth, Forfar, St Andrew's, and Cupar, returns one member to the British parliament.

DUNFERMLINE. See DUMFERMLINE.

DUNG, in *Husbandry*. See AGRICULTURE *Index*.

DUNG-*Bird*. See UPUPA, ORNITHOLOGY *Index*.

DUNG-*Meers*, in *Husbandry*, places where soils and dungs are mixed and digested together. These consist of pits, prepared at the bottom with stone and clay, that they may hold water, or the moisture of the dung: and ought to be so situated, that the sinks and drips of the houses and barns may run into them. Into these pits they cast refuse, fodder, litter, dung, weeds, &c. where they lie and rot together, till the farmer have occasion for them.

DUNG-*Worms*, a species of fly worms, of a short and somewhat flat body, found in great plenty among cowdung in the months of September and October.

DUNGANNON, the chief town of the county of Tyrone, in the province of Ulster in Ireland. It is seated on a hill, and is a place of some strength.

DUNGARVON, a town of Ireland, in the county of Waterford. It stands on a bay of the same name, has a commodious harbour for ships, and is a walled town, with a castle. W. Long. 7. 55. N. Lat. 51. 57.

DUNIPACE. See CARRON.

DUNKELD, a town of Scotland, in the shire of Perth, seated on the north side of the river Tay, in a situation truly romantic, among very high and almost inaccessible crags, part naked and part wooded.

wooded. It is the chief market town of the Highlands, and has been greatly improved with buildings by the dukes of Athol.

The place is of great antiquity. It was the capital of ancient Caledonia. About the dawn of Christianity, a Pictish king made it the seat of religion, by erecting a monastery of Culdees there; which King David I. in 1130 converted into a cathedral, and it ranked as the first in Scotland. The entire shell of the cathedral still remains, the east end serving for a kirk, on the north side of which is the burial place of the dukes of Athol. The style of architecture is simple and elegant, the pillars round. The monument of one of its bishops remains on the south aisle of the nave, as also that of Alexander Stuart earl of Buchan, third son of Robert II. called for his cruelty *The Wolf of Badenoch*, who died in 1394. The tower at the west end, with a singular crack down one of its sides, adds to the picturesque appearance which the whole makes among the venerable pines at the end of the duke's garden. His Grace's seat is a modern building, and not large, with pleasant walks and plantations, and a fine cascade on the water of Bran, which in its way from the western hills forms an astonishing fall of 150 feet, called the *Rumbling Brig*, from a narrow bridge made by the fall of two rocks across the stream. The pencil of Rosa never formed a more horrid scene. The stream has a second fall, which, without seeing the other, would be deemed capital. Sir James Galloway, master of requests to James VI. and Charles I. was created Lord Dunkeld 1645, whose grandson James was attainted at the Revolution, and dying at the beginning of this century, the title became extinct. Population 1360 in 1811.

DUNKERS, DUNCARDS, or *Tunkers*. See TUNKERS.

DUNKIRK, a maritime town of the French Netherlands, situated in E. Long. 2. 28. N. Lat. 51. 10. and is the most easterly harbour on the side of France which is next to Great Britain.—It was originally a mean hamlet, consisting only of a few fishermen's huts: but a church being built there, it was from that, and from its situation, which is a sandy eminence, called *Dunkirk; dun* signifying, in the old Gallic language, a hill; and *kirk* being the old Flemish name for church.

About the year 960, Baldwin earl of Flanders, thinking the situation convenient, enlarged it into a kind of town, and surrounded it with a wall. In the year 1322, Robert of Flanders, who held it as an appendage, built a castle for its defence; which was afterwards demolished by the revolters of Flanders. Robert of Bar erected a fortification round it, the remains of which are visible on the side next the harbour. The emperor Charles V. who held it as part of Flanders, built another castle to defend the harbour; but this was also demolished soon afterwards. In 1588, the French, under Marshal de Thermes, took Dunkirk by storm, and almost ruined the place; the Spaniards recovered it again in about a fortnight, and put all the French to the sword.

During a peace procured for the Dunkirkers by Philip II. of Spain, they rebuilt their town with greater splendour than before, and the inhabitants for a long time subsisted by privateers fitted out against the Dutch; and at length, growing rich by these hostilities, they fortified their town and harbour, and fitted out no less than 15 ships of war at their own charge.

In 1634, the Dunkirkers agreed with the inhabitants of Bergues to dig a canal, at their joint expence, for a communication between the two towns; which was some time afterwards effected. By this time Dunkirk was become the best harbour the Spaniards possessed in Flanders, which induced many foreigners to settle there; and it being necessary to enlarge the town for their accommodation, a new fortified wall was built at a considerable distance from the former. In 1646, it was besieged and taken by the prince of Condé. In 1652 it was retaken by the archduke Leopold, then governor of the Netherlands. France entering into a treaty with England in 1655, the Dunkirkers, with views of pecuniary advantage, fitted out privateers against both these powers: the consequence of which was, that the French, assisted by Cromwell, attacked and took it; and it was put into the hands of the English, in consequence of a treaty between them and the French. To the English it was even then of very great importance; for during the war in which it was taken, the Dunkirkers had made prizes of no less than 250 of their ships, many of which were of great value. They therefore improved the fortifications, and built a citadel; yet they kept it only four years; for in 1662, two years after the Restoration, Charles II. sold this valuable acquisition to France, for the paltry sum of 500,000l. In consequence of this sale, the town was taken possession of for the French king Louis XIV. by the count d'Estrades, on the 29th of November 1662. Louis having acquainted the celebrated engineer Monsieur Vauban, that he intended to make Dunkirk one of the strongest places in Europe, Vauban drew up a plan with that view, which was gradually executed. An arsenal was erected, large enough to contain all the stores necessary for fitting out and maintaining a large fleet of men of war; the fortifications on the land side were constructed in a manner that was thought to render them impregnable; and, towards the sea, the entrance of the harbour being properly formed, it was fortified by the jetties, and the two forts called *Green Fort* and the *Fort of Good Hope* at their extremities; the famous risbank was also erected on the side of the jetties, and Fort Galliard on the other, to secure the town. These works were all completed in 1683; and in 1685, the whole circumference of the bason was faced with masonry, and the keys completely formed: at the same time care was taken to build at the entrance of this bason a sluice, almost 45 feet wide, that the ships within might be constantly afloat. In 1689, the fort called the *Cornichon*, and some other works, were completed. But though 30 years had been now employed in improving the fortifications of Dunkirk, it was not yet in the state in which Louis intended to put it; and therefore, in 1701, he caused a new risbank to be built, called *Fort Blanc*.

At the treaty of Utrecht, it having been made appear, that the privateers of Dunkirk had, during the war then closing, taken from the English no less than 1614 prizes valued at 1,334,375l. sterling, it was stipulated, that the fortifications of the city and port

port of Dunkirk should be entirely demolished, and the harbour filled up, so as never to be a harbour again.

The treaty of which this demolition of Dunkirk was an article, was signed on the 28th of April 1713; but the demolition did not take place till the September following, when the queen deputed Colonel Armstrong and Colonel Clayton to oversee the execution of the treaty as far as concerned the works and harbour of Dunkirk. Under the inspection of these gentlemen, the places of arms were broken down, the ditches filled up, and the demi-lunes, bastions, and covered way, totally destroyed; the citadel was razed, and the harbour and bason filled up; the jetties were also levelled with the strand, and all the forts which defended the entrance into the harbour were demolished. A large dam, or bar, was also built across the mouth of the harbour between the jetties and the town, by which all communication between the harbour and the canal, which formed its entrance, was entirely cut off. The sluices were also broken up, and the materials of them broken to pieces.

But this was no sooner done, than Louis XIV. ordered 30,000 men to work incessantly upon a new canal, the canal of Mardick, which in a short time they accomplished; by which the harbour was rendered almost as commodious as ever; but in 1717 this likewise was rendered unserviceable. In the year 1720, during a great storm, the sea broke up the bar or dam, and restored to the Dunkirkers the use of the harbour in a very considerable degree. In the year 1740, when Great Britain was engaged in a war with Spain, Louis XV. set about improving the advantage which Dunkirk had derived from the storm in 1720, by restoring the works, and repairing the harbour; and soon afterwards he espoused the cause of Spain, and became a principal in the war against us. But at the peace of Aix-la-Chapelle in 1748, it was stipulated, that all the works towards the sea should be destroyed a second time; yet, before the declaration of the American war, the place was in a good state of defence towards the sea. At the peace in 1783 Britain was not in a condition to insist on so obnoxious a stipulation, and its harbour has since been unmolested. The check which the British troops received here in 1793, was the commencement of a series of disasters.

DUNNING John, *Lord Ashburton*, an eminent English lawyer. See Supplement.

DUNSE, a market town of Scotland, in the shire of Mers, situated in W. Long. 2. 15. N. Lat. 55. 42. It is situated on a rising ground in the middle of the shire, and has a weekly market for cattle. It is by some reputed the birthplace of the famous John Duns Scotus. A mile south of the town is a well of mineral water, of great use as a deobstruent and antiscorbutic, first discovered in 1747 by Dr Thomas Simpson who practised there. Population 3082 in 1811.

DUNS SCOTUS, *John*, a Franciscan friar, commonly called *Doctor Subtilis*, was born in the year 1274; but whether in England, Scotland, or Ireland, hath long been a matter of dispute among the learned of each nation. Dempster, Mackenzie, and other Scottish writers, assert positively that he was born at Dunse, a town in Scotland, about 15 miles from Berwick; and, to secure him more effectually, Mackenzie makes him descended from the Dunses in the Mers. Maccaghwell, an Irish author, who wrote the life of this Scotus, proves him to have been born at Down in the province of Ulster in Ireland: but Leland, Bale, Camden, and Pits, assure us, that he was born at Dunstone in the parish of Emildune, near Alnwick in Northumberland; and this opinion is rendered probable by the following conclusion of his manuscript works in the library of Merton college in Oxford.—"Here end the writings of that subtile doctor of the university of Paris, John Duns, who was born in a certain village, in the parish of Emildune, called *Dunston*, in the county of Northumberland." We are told, that when a boy, he became accidentally known to two Franciscan friars; who, finding him to be a youth of very extraordinary capacity, took him to their convent at Newcastle, and afterwards persuaded him to become one of their fraternity. From thence he was sent to Oxford, where he was made fellow of Merton college, and professor of divinity; and Mackenzie says, that not less than 30,000 students came to Oxford to hear his lectures. His fame was now become so universal, that the general of his order commanded him to go to Paris, that the students of that university might also profit from his lectures. He went to Paris in the year 1304, where he was honoured first with the degree of bachelor, then of doctor of divinity, and in 1307 was appointed regent of the divinity schools: during his residence here, the famous controversy about the *Immaculate conception of the virgin Mary* arose. Albertus Magnus maintained that she was born in original sin. Scotus advanced 200 arguments in support of the contrary opinion, and convinced the university of Paris that she was really conceived immaculate. This important nonsense, however, continued to be disputed till the year 1496, after the council of Basil, when the university of Paris made a decree, that no student, who did not believe the *immaculate conception*, should be admitted to a degree. Our author had not been above a year at Paris, when the same general of the Franciscans ordered him to remove to Cologne; where he was received with great pomp and ceremony by the magistrates and nobles of that city, and where he died of an apoplexy soon after his arrival, in the year 1308, in the 34th year of his age. Some writers have reported, that Scotus was buried in an epileptic fit; and that, upon removing his bones, he appeared to have turned himself in his coffin. This *Doctor Subtilis* was doubtless one of the first wranglers of his time, admirably well versed in scholastic divinity, and a most indefatigable scribbler; but the misfortune is, that all his huge volumes do not contain a single page worth the perusal of a rational being. He was the author of a new sect of schoolmen called *Scotists;* who opposed the opinions of the Thomists, so called from St Thomas Aquinas. The reader will find a more particular account of Scotus in the Franciscan Martyrology, published at Paris in 1638. He was a most voluminous writer; his works making 12 vols folio, as published at Lyons by Luke Wadding, 1639.

DUNSTABLE, a town in Bedfordshire, with a market on Wednesdays. It is seated on a chalky hill; and has ponds in the streets, which are never dry though only supplied with rain-water. It is remarkable for several good inns, it being a great thoroughfare on the northern

Dunstable
‖
Dunstan.

northern road. It consists of four streets, intersecting each other at right angles; and in the centre stood one of those beautiful crosses of Queen Eleanor, which was destroyed in the time of the civil wars. Population 1616 in 1811. W. Long. 0. 29. N. Lat. 51. 50.

DUNSTAFFNAGE. See LORNE.

DUNSTAN, a famous saint, and archbishop of Canterbury: of whom the monkish historians give us the following account. He was descended from a noble family in Wessex, and educated in the abbey of Glastonbury. Here he studied so hard, that it threw him into a violent fever, which brought him to the very point of death. When the whole family were standing about his bed, dissolved in tears, and expecting every moment to see him expire, an angel came from heaven in a dreadful storm, and gave him a medicine which restored him to perfect health in a moment. Dunstan immediately started from his bed, and ran with all his speed towards the church to return thanks for his recovery; but the devil met him by the way, surrounded by a great multitude of black dogs, and endeavoured to obstruct his passage. This would have frightened some boys; but it had no such effect upon Dunstan; who pronouncing a sacred name, and brandishing his stick, put the devil and all his dogs to flight. The church doors being shut, an angel took him in his arms, conveyed him through an opening in the roof, and set him softly down on the floor, where he performed his devotions. After his recovery, he pursued his studies with the greatest ardour, and soon became a perfect master in philosophy, divinity, music, painting, writing, sculpture, working in gold, silver, brass, and iron, &c. When he was still very young he entered into holy orders, and was introduced by his uncle Athelm archbishop of Canterbury to King Athelstan; who, charmed with his person and accomplishments, retained him in his court, and employed him in many great affairs. At leisure hours he used to entertain the king and his courtiers with playing on his harp, or some other musical instrument; and now and then he wrought a miracle, which gained him great admiration. His old enemy the devil was much offended at this, and prompted some envious courtiers to persuade the king that his favourite was a magician, which that prince too readily believed. Dunstan discovering by the king's countenance that he had lost his favour, and resolving to resign rather than be turned out, retired from court to another uncle, who was bishop of Winchester. This good prelate prevailed upon his nephew to forsake the world and become a monk; after which he retired to a little cell, built against the church wall of Glastonbury. Here he slept, studied, prayed, meditated, and sometimes amused himself with forging several useful things in brass and iron. One evening, as he was working very busily at his forge, the devil, putting on the appearance of a man, thrust his head in at the window of his cell, and asked him to make something or other for him. Dunstan was so intent upon his work that he made no answer; on which the devil began to swear and talk obscenely, which betrayed the lurking fiend. The holy blacksmith, putting up a secret ejaculation, pulled his tongs, which were red hot, out of the fire, seized the devil with them by the nose, and squeezed him with all his strength; which made his infernal majesty roar and scold at such a rate, that he awakened and terrified all the people for many miles around. Thus far the legend.

Dunstan

Ridiculous as were these fictions, they served, in those times of ignorance, to procure Dunstan a reputation which has been confirmed by the authority of several succeeding historians. It appears that this extraordinary person was called to court by King Edmund, A. D. 941; who bestowed upon him the rich abbey of Glastonbury, which for his sake he honoured with many peculiar privileges. He enjoyed a very high degree of the favour of this prince during his short reign of six years; but he stood much higher in the favour of his brother and successor King Edred, to whom he was confessor, chief confidant, and prime minister. He employed all his influence during this period of court favour in promoting the interest of the monks of the Benedictine order, to which he belonged, and of which he was a most active and zealous patron. Having the treasures of these two princes, especially of the last, very much at his command, he lavished them away in building and endowing monasteries for these monks, because almost all the old monasteries were in the possession of secular canons. Not contented with this, he persuaded Edred (who was a bigotted valetudinary) to bestow such immense treasures on the churches and monasteries by his last will, that the crown was stripped of its most valuable possessions, and left in a state of indigence. This conduct of Dunstan, while he was in power, rendered him very odious to Edwi, who succeeded his uncle Edred A. D. 955; and his rude behaviour to himself, and his beloved queen Elgiva, raised the resentment of that prince so high, that he deprived him of all his preferments, and drove him into exile *. The banishment of Dunstan, the great patron, or (as Malmsbury calls him) the prince of monks, was a severe blow to that order, who were expelled from several monasteries; which were made the impure stables (according to the same author) of the married clergy. But their sufferings were not of long continuance. For Edgar the younger brother of Edwi, having raised a successful rebellion against his unhappy brother, and usurped all his dominions on the north side of the river Thames, recalled Dunstan, and gave him the bishopric of Worcester, A. D. 957. From this moment he was the chief confidant and prime minister of King Edgar, who became sole monarch of England A. D. 959, by the death of his elder brother Edwi. In the following year Dunstan was raised to be archbishop of Canterbury; and being thus possessed of the primacy, and assured of the royal support and assistance, he prepared to execute the grand design which he had long meditated, of compelling the secular canons to put away their wives and become monks; or of driving them out, and introducing Benedictine monks in their room. With this view he procured the promotion of Oswald to the see of Worcester, and of Ethelwald to that of Winchester; two prelates who were monks themselves, and animated with the most ardent zeal for the advancement of their order. And these three great champions of the order found means, by their arts and intrigues, in the course of a few years, to fill no fewer than 48 monasteries with Benedictines. But on the death of Edgar in 975 they received a check. The

sufferings

---

*See
land, N

sufferings of the persecuted canons had excited much compassion; and many of the nobility, who had been overawed by the power and zeal of the late king, now espoused their cause and promoted their restoration. Elferc duke of Mercia drove the monks by force out of all the monasteries in that extensive province, and brought back the canons, with their wives and children; while Elfwin duke of East Anglia, and Brithnot duke of Essex, raised their troops to protect the monks in these countries. To allay these commotions, several councils were held: in which Dunstan was so hard pushed by the secular canons and their friends, that he was obliged to practise some of his holy stratagems; and finally, by dint of miracles, overcame all opposition *.

St Dunstan died A. D. 988, in the 64th year of his age, having held the bishopric of London, together with the archbishopric of Canterbury, about 27 years. As this prelate was the great restorer and promoter of the monastic institutions, the grateful monks, who were almost the only historians of those dark ages, have loaded him with the most extravagant praises, and represented him as the greatest wonder-worker and highest favourite of heaven that ever lived. To say nothing of his many conflicts with the devil, in which he often belaboured that enemy of mankind most severely, the following short story, which is told with great exultation by his biographer Osbern, will give the reader some idea of the astonishing impiety and impudence of those monks, and of the no less astonishing blindness and credulity of those unhappy times. "The most admirable, the most inestimable Father Dunstan (says that author), whose perfections exceeded all human imagination, was admitted to behold the mother of God and his own mother in eternal glory; for before his death he was carried up into heaven, to be present at the nuptials of his own mother with the Eternal King, which were celebrated by the angels with the most sweet and joyous songs. When the angels reproached him for his silence on this great occasion, so honourable to his mother, he excused himself on account of his being unacquainted with those sweet and heavenly strains; but being a little instructed by the angels, he broke out into this melodious song, O King and Ruler of nations," &c. It is unnecessary to make any comment on this most shocking story.

The violent and too successful zeal of Dunstan and his associates, in promoting the building and endowing so great a number of houses for the entertainment of useless monks and nuns, was very fatal to their country: for by this means a spirit of irrational unmanly superstition was diffused amongst the people, which debased their minds, and diverted them from nobler pursuits; and a very great proportion of the lands of England being put into hands who contributed nothing to its defence, rendered it an easy prey, first to the insulting Danes, and afterwards to the victorious Normans.

DUNUM, a Celtic term, denoting a hill or eminence, and which often concurs to form the names of towns, to signify their high situation, places of strength or citadels; hills or eminences being adapted to such structures. See DUN.

DUNUM (Ptolemy), a town of Ireland; now thought to be *Down* or *Down-Patrick*, in the county of Down. W. Long. 5. 57. N. Lat. 54. 23.

DUO, in *Music*, a song or composition, to be performed on two parts only; one sung, the other played on an instrument, or by two voices.

DUO is also when two voices sing different parts, as accompanied with a third, which is a thorough bass. It is seldom that unisons and octaves are used in duos, except at the beginning and end.

DUODECIMA, in *Music*, is the twelfth or the fifth doubled.

DUODENUM. See ANATOMY *Index*.

DUPIN, LEWIS ELLIS, a learned doctor of the Sorbonne, and one of the greatest critics of his time, especially in ecclesiastical matters, was born at Paris in 1657. When he published the first volume of his *Bibliotheque Universelle des Auteurs Ecclesiastiques*, in 1686, the liberty with which he treated some ecclesiastical writers gave such offence, that M. de Harlay, archbishop of Paris, obliged Dupin to retract many propositions, and suppressed the work. He was nevertheless suffered to continue it, by altering the title from *Bibliotheque Universelle* to *Bibliotheque Nouvelle*. This great undertaking, continued in several successive volumes, though sufficient to occupy the life of an ordinary man, did not hinder M. Dupin from obliging the world with several other works. He was a man of prodigious reading; and had an easy happy way of writing, with an uncommon talent at analyzing the works of an author; which makes his Ecclesiastical Bibliotheque so valuable. M. Dupin was professor of philosophy in the royal college: but was banished some time from the chair to Chatelherault, on account of the famous *Cas de Conscience*; but was restored, and died in 1719.

DUPLE, among mathematicians, denotes the ratio of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

Sub-DUPLE Ratio, is just the reverse of the former, or as 1 to 2. Such is 4 to 8, or 6 to 12.

DUPLICATE, among lawyers, denotes a copy of any deed, writing, or account. It is also used for the second letters-patent, granted by the lord chancellor in a case wherein he had before done the same. Also a second letter written and sent to the same party and purpose as a former, for fear of the first's miscarrying, is called a *Duplicate*.

DUPLICATE Proportion or *Ratio*. See RATIO.

DUPLICATION, in general, signifies the doubling of any thing, or multiplying of it by 2: also the folding of any thing back again on itself.

DUPLICATURE, among anatomists, a term used to denote the folds of any membrane or vessel: thus we say, the *duplicatures of the intestines*, *peritonæum*, &c.

DUPONDIUS, in antiquity, a weight of two pounds, or money of the value of two asses. See AS.

As the as at first weighed just a pondo or libra, the dupondius then weighed two; and hence the name.

And though the weight of the as was afterwards diminished, and of consequence that of the dupondius also, yet they still retained the denomination. See POUND and LIBRA.

DUPPA, BRIAN, a learned English bishop, born in 1589

---

* S Eng- an N°64.

1589 at Lewisham in Kent, of which place his father was then vicar. In 1634, he was instituted chancellor of the church at Sarum, and soon after made chaplain to Charles I. He was appointed tutor to Charles prince of Wales, and his brother James duke of York; was made bishop of Chichester; and in 1641 translated to Salisbury, though the confusions that followed deprived him of all benefit from his promotion. Charles I. held him in high esteem, and he is said to have assisted the king in composing the *Eikon Basilike*. On the Restoration he was made bishop of Winchester, and lord high almoner; but died in 1662.

DUPUIS, Charles Francis, an eminent French writer. See Supplement.

DURANDUS, William, born at Puimoission in Provence, in the 13th century, was one of the most knowing lawyers of his time. Pope Martin made him one of his nuncios, and then bishop of Mende and Languedoc. His *Speculum Juris* gave him the name of *Speculator*; his second piece was *Rationale divinorum officiorum*, containing eight books. He wrote several others.

DURANTA, in *Botany*, a genus of plants, belonging to the didynamia class, and in the natural method ranking under the 40th order, *Personatæ*. See Botany *Index*.

DURATION, an idea we get by attending to the fleeting and perpetual perishing parts of succession. See Metaphysics.

Duration, as marked by certain periods and measures, is what we most properly call *time*. See Time.

Duration of Action, according to Aristotle, is confined to a natural day in tragedy; but the epopea, according to the same critic, has no fixed time. See Poetry.

DURER, Albert, descended of an Hungarian family, and born at Nuremberg in 1471, was one of the best engravers and painters of his age. He was at the same time a man of letters and a philosopher; and he was an intimate friend of Erasmus, who revised some of the pieces which he published. He was a man of business also, and for many years the leading magistrate of Nuremberg. Though not the inventor, he was one of the first improvers of the art of engraving; and he bethought himself of working also in wood, for expedition, having an inexhaustible fund of designs. In many of those prints which he executed on copper, the engraving is elegant to a great degree. His *Hell-Scene* particularly, which was engraved in the year 1513, is as highly finished a print as ever was engraved, and as happily executed. In his wooden prints too we are surprised to see so much meaning in so early a master; the heads so well marked, and every part so well executed.—This artist seems to have understood the principles of design. His composition, too, is often pleasing; and his drawing generally good. But he knows very little of the management of light; and still less of grace: and yet his ideas are purer and more elegant than we could have supposed from the awkward archetypes which his country and education afforded. In a word, he was certainly a man of very extensive genius; and, as Vasari remarks, would have been an extraordinary artist, if he had had an Italian instead of a German education. His prints are very numerous. They were much admired in his own lifetime, and eagerly bought up; which put his wife, who was a teasing woman, upon urging him to spend more time upon engraving than he was inclined to do. He was rich; and chose rather to practice his art as an amusement than as a business. He died in the year 1527.

DURESSE, Hardship, in *Law*, is where a person is kept in prison or restrained of his liberty, contrary to order of law; or is threatened to be killed, maimed, or beaten. In which case, if a person so in prison, or in fear of such threats, make any specialty or obligation, by reason of such imprisonment or threats, such deed is void in law; and in an action brought on such specialty, the party may plead, that it was brought by duresse.

D'URFEY, Thomas, an eminent English satirist and songster, whose name, though as well known as that of any writer extant, yet there are very few particulars of his life to be collected. He was born in Devonshire; but when, where, or of what family, are all uncertain. He was bred to the law, which he forsook for the more agreeable employment of writing plays and songs; and the latter he had so happy a talent both of writing and singing, that he received many favours from persons of quality on that account. Even crowned heads did not disdain his company. The writer of the Guardian, N° 67. tells us, he remembered to have seen Charles II. leaning on Tom D'Urfey's shoulder more than once, humming over a song with him. This indeed was not extraordinary in so merry a monarch; but even the phlegmatic King William could relax his muscles on hearing him sing. He was certainly by all accounts a cheerful, honest, good-natured man; but as this character does not include prudence, D'Urfey grew poor as he grew old: and prevailing on the managers of the playhouse to act his comedy of the *Plotting Sisters* for his benefit, Mr Addison wrote the above-mentioned paper in the Guardian, with another, N° 82. representing him in a good-humoured light, to procure him a full house. He died very old, in 1723.

DURHAM, Bishopric of, one of the counties of England. Before the arrival of the Romans it was included in the British principality of the Brigantes, and after their arrival made part of the province of Maxima Cæsariensis. During the Heptarchy it made part of the kingdom of Northumberland, the 5th established, which began in 547, and ended in 827, having been governed by 31 kings. It was not mentioned by Alfred in his division of counties, being at that time considered as a part of Yorkshire. At present it is included in the northern circuit, in the province of York; and is a diocese and principality under the government of its own bishop, being a county palatine, the second in rank, and the richest in England. It is bounded on the north by Northumberland, on the south by Yorkshire, on the east by the North sea, and on the west by Cumberland. It is 39 miles long, 35 broad, and 107 in circumference; containing 410,000 square acres, or 758 square miles; with 177,625 inhabitants (1811), 80 parishes, 21 vicarages, one city (Durham), and 9 market towns, viz. Stockton, Sunderland, Barnard-Castle, Darlington, Stanhope, Hartlepool, Auckland, Staindrop, and Marwood; besides 223 villages. It is divided ham. divided into 4 wards, sends 4 members to parliament, pays three portions of the land tax, and provides 400 of the national militia. It has 21 parks, 4 castles, and 20 bridges, with the rivers Tees, Tine, Were, Tame, Lune, Darwent, Gauntless, Skern, &c. and the Lune and Teesdale forests. Its principal products are lead, coals, iron, corn, mustard, salt, glass, fine ale, with excellent butter and salmon. The soil is various; the south is rich, but the western parts rocky and moorish.

Durham, as already observed, is a county palatine, governed by the bishop, who had formerly great prerogatives. He had power to create barons, appoint judges, convoke parliaments, raise taxes, and coin money. The courts of justice were kept in his name; and he granted pardons for trespasses, alienations, rapes, murders, and felonies of every denomination. He erected corporations, granted markets and fairs, created officers by patent, was lord admiral of the seas and waters within the county palatine: great part of the lands were held of the see *in capite*. In a word, he exercised all the power and jurisdiction of a sovereign prince. How and at what period these prerogatives were obtained, it is not easy to determine. Malmsbury says, the lands were granted by King Alfred, who likewise made the church a sanctuary for criminals. This see was anciently called the *patrimony of St Cuthbert*, who had been bishop of Lindisfarne or Holy Island near Berwick. His bones being transferred to Durham, were long esteemed as precious relics; and the people of the county considered themselves as Halwerk men, exempted from all other but holy work, that is, the defence of St Cuthbert's body. Certain it is, they pretended to hold their lands by this tenure; and refused to serve out of the county either for the king or bishop: but King Edward I. broke through these privileges, and curtailed the prerogatives of the bishops, which were still further abridged by Henry VIII. Nevertheless, the bishop is still earl of Sadberg, a place in this county which he holds by barony. He is sheriff paramount, and appoints his own deputy, who makes up his audit to him, instead of accounting to the exchequer. He has all the forfeitures upon outlawries: and he and his temporal chancellor act as justices of the peace for the county palatine, which comprehends Creke in Yorkshire, Bedlington, Northam, and Holy Island, in Northumberland; the inhabitants of these places having the benefit of the courts at Durham. The judges of assize, and all the officers of the court, have still their ancient salaries from the bishop; and he constitutes the standing officers by his letters patent. He has the power of presiding in person in any of the courts of judicature. Even when judgment of blood is given, this prelate may sit in court in his purple robes, though the canons forbid any clergyman to be present in such cases: hence the old saying, *Solum Dunelmense stola jus dicet et ense.* It was not till the reign of Charles II. that the bishopric sent representatives to parliament.

Durham.

Durham, the capital of the above-mentioned county, is situated in W. Long. 1. 14. N. Lat. 54. 50. It stands on a hill almost surrounded by the river Were; and is considerable for its extent and the number of its inhabitants, as well as for being the see or seat of the bishop, who is lord paramount. It stands about 280 miles north from London; being remarkable for the salubrity of its air, and the abundance and cheapness of its provisions. These circumstances have induced a great deal of good company to take up their residence at Durham, which is still further animated by the presence and court of the bishop and his clergy. The town is said to have been built about 70 years before the Roman conquest, on occasion of bringing hither the body of St Cuthbert. It was first incorporated by King Richard I. but Queen Elizabeth extended its privileges. At length, in the year 1684, it obtained a charter; in consequence of which, it is now governed by a mayor, 12 aldermen, 12 common council men, with a recorder and inferior officers. These can hold a court leet and court baron within the city; but under the style of the bishop, who, as count palatine, appoints a judge, steward, sheriffs, and other inferior magistrates. The mayor and aldermen also keep a *pie pouldres* court at their fairs, and pay a yearly toll to the bishop. They have a weekly market on Saturday, and three annual fairs. Durham is about half a mile in length, and has been by some compared to the figure of a crab, the market place exhibiting the body, and the claws being represented by the streets, which bend according to the course of the river, which almost surrounds one part of the city. They are, moreover, dark and narrow; and some of them steep and dangerous to wheel carriages. The number of inhabitants in 1811 was 6763. The houses are in general strong built, but neither light nor elegant. The most remarkable edifices are the cathedral, with six other churches, three standing in the city, and as many in the suburbs; the college; the castle, or bishop's palace; the tolbooth near St Nicholas's church; the cross and conduit in the market place; with two bridges over the Were. The cathedral was begun by Bishop Carilepho in the 11th century. It is a large, magnificent, Gothic structure, 411 feet long, and 80 in breadth, having a cross aisle in the middle 170 feet in length, and two smaller aisles at each end. On the south side is a fine cloister; on the east, the old library, the chapter house and part of the deanery; on the west, the dormitory, under which is the treasury and chantry; and on the west side is the new library, an elegant building begun by Dean Sudbury about 70 years ago, on the spot where stood the old refectory of the convent. The middle tower of the cathedral is 212 feet high. The whole building is arched and supported by huge pillars. Several of the windows are curiously painted; and there is a handsome screen at the entrance into the choir. Sixteen bishops are interred in the chapter-house, which is 75 feet long, and 33 broad, arched overhead, with a magnificent seat at the upper end for the instalment of the bishops. The consistory is kept in the chapel of the west aisle called *Galilee*, which was built by Bishop Pubsey, and had formerly 16 altars for women, as they were not allowed to advance farther than the line of marble by the side of the font; here likewise are deposited the bones of the venerable Bede, whose eulogium is written on an old parchment scroll that hangs over his tomb. The long cross aisle at the extremity of the church was formerly distinguished by nine altars, four to the north, and four to the south, and the most magnificent in the middle dedicated to the patron St Cuthbert,

Durham.

bert, whose rich shrine was in this quarter, formerly much frequented by pilgrims. The church is possessed of some old records relating to the affairs of Scotland, the kings of which were great benefactors to this cathedral. The ornaments here used for administering the divine offices, are said to be richer than those of any other cathedral in England. Before the Reformation, it was distinguished by the name *Ecclesia sanctæ Mariæ et sancti Cuthberti;* but it obtained the appellation of *Ecclesia cathedralis Christi et beatæ Mariæ*, in the reign of Henry VIII. who endowed the deanery with 12 prebendaries, 12 minor canons, a deacon, subdeacon, 16 lay singing men, a schoolmaster and usher, a master of the choir, a divinity reader, eight almsmen, 18 scholars, 10 choristers, two vergers, two porters, two cooks, two butlers, and two sacristans. On the south side of the cathedral is the college; a spacious court formed by the houses of the prebendaries, who are richly endowed and extremely well lodged. Above the college gate, at the east end, is the exchequer; and at the west, a large hall for entertaining strangers, with the granary and other offices of the convent. The college school, with the master's house, stands on the north side of the cathedral. Between the churchyard and castle is an open area called the *palace green;* at the west end of which stands the shire hall, where the assizes and sessions are held for the county. Close by is the library built by Bishop Cosin; together with the exchequer raised by Bishop Nevil, in which are kept the offices belonging to the county palatine court. There is an hospital on the east, endowed by Bishop Cosin, and at each end of it are two schools founded by Bishop Langley. On the north, is the castle built by William the Conqueror, and afterwards converted into the bishop's palace, the outward gate of which is at present the county gaol.

The city consists of three manors; the bishop's manor, containing the city liberties and the bailey, held of him by the service of castle guard; the manor of the dean and chapter, consisting of the Elvet's cross-gate, South-gate street; and the manor of Gilligate, formerly belonging to the dissolved hospital of Kepyar in this neighbourhood, but granted by Edward VI. to John Cockburn, lord of Ormistoun, and late in the possession of John Tempest, Esq.

The bishopric of Durham is deemed the richest bishopric in the kingdom; and the prebends are frequently styled the Golden Prebends of Durham. The diocese contains the whole counties of Durham and Northumberland, except the jurisdiction of Hexham in the latter. It hath also one parish in the county of Cumberland: making in the whole 135 parishes, whereof 87 are impropriate. The see is valued in the king's books at 2821l. 1s. 5$\frac{1}{4}$d. but is said to be worth about ten times that sum annually. The clergy's tenths amount to 385l. 5s. 6$\frac{1}{2}$d. It has two archdeacons, viz. of Durham and Northumberland. This see hath given to the church of Rome eight saints and one cardinal; and to the English nation one lord chief justice, five lord chancellors, three lord treasurers, one principal secretary of state, one chancellor to the university of Oxford, and two masters of the rolls.

In the neighbourhood of this city is Nevil's cross, famous for the battle fought in the year 1346, against David II. king of Scotland, who was defeated and taken prisoner.

Durham ‖ Dury.

DURIO, a genus of plants belonging to the polyadelphia class. See BOTANY *Index.*

DURNIUM, or DURNOVARIA, a town of the Durotriges in Britain; now *Dorchester*, the capital of Dorsetshire, on the Frome.

DUROBRIVÆ, in *Ancient Geography*, a town of the Catyeuchlani in Britain. Now in ruins, which lie on the Nen, between Caster and Dornford, in Northamptonshire, on the borders of Huntingdon.

DUROBRIVÆ, or *Durocobrivæ*, a town of the Trinobantes, in Britain; whose ruins are situated between Flamstead and Redburn, in Hertfordshire.

DUROBRIVES, 25 miles to the west of Durovernum, or Canterbury; from which it appears to be Rochester town: confirmed by the charter of foundation of the church, in which it is called *Durobrevis.*

DUROCASES, DUROCASSIUM, DUROCASSÆ, and DUROCASSES, a town of the Carnutes in Gallia Celtica; now Dreux. See DRUIDÆ.

DUROCORNOVIUM, in *Ancient Geography*, a town of Britain; now *Cirencester* in Gloucestershire (Camden), called *Corinium* by Ptolemy.

DUROCORTORUM, or DURICORTORA, a town of the Rhemi in Belgica; now *Rheims* in Champagne. E. Long. 4. 8. N. Lat. 49. 20.

DUROIA, in *Botany;* a genus of plants belonging to the hexandria class of plants. See BOTANY *Index.*

DUROLENUM, a town of the Cantii in Britain; now *Lenham*, in Kent (Camden); *Charing* (Talbot.)

DUROLITUM, a town of the Trinobantes; now *Leiton*, on the Ley, in Essex (Camden).

DUROTRIGES, an ancient British nation, seated in that part of the country which is now called *Dorsetshire.* Their name is derived from the two British words *Dur*, "water," and *Trigo*, "to dwell;" and it is no less evident that they got their name from the situation of their country, which lies along the sea coast. It is not very certain whether the Durotriges formed an independent state, under a prince of their own, or were united with their neighbours the Danmonii; as they were reduced by Vespasian under the dominion of the Romans, at the same time, and with the same ease, and never revolted. The peaceable disposition of the inhabitants was probably the reason that the Romans had so few towns, forts, and garrisons, in this pleasant country. Dorchester, its present capital, seems to have been a Roman city of some consideration, though our antiquaries are not agreed about its Roman name. It is most probable, that it was the Durnovaria in the 12th Iter of Antoninus. Many Roman coins have been found at Dorchester; the military way, called *Jeening-street*, passed through it; and some vestiges of the ancient stone wall with which it was surrounded, and of the amphitheatre with which it was adorned, are still visible. The country of the Durotriges was included in the Roman province called *Flavia Cæsariensis*, and governed by the president of that province, as long as the Romans kept any footing in these parts.

DURY, JOHN, a Scots divine, who travelled much, and laboured with great zeal to reunite the Lutherans with

with the Calvinists. His discouragements in this scheme started another still more impracticable; and this was to reunite all Christians by means of a new explication of the Apocalypse, which he published at Frankfort in 1677. He enjoyed then a comfortable retreat in the country of Hesse; but the time of his death is unknown: his letter to Peter du Moulin concerning the state of the churches of England, Scotland, and Ireland, was printed at London in 1658, by the care of du Moulin, and is esteemed to be curious.

DUSKY BAY, a bay of the island of New Zealand in the Southern Pacific ocean. It is in S. Lat. 45. 47. and in E. Long. 166. 18.

DUSSAULX, JOHN, a French writer of the last century. See SUPPLEMENT.

DUSSELDORF, a city of Germany, and capital of the duchy of Berg. It is situated at the conflux of the river Dussel with the Rhine, in E. Long. 6. 25. N. Lat. 51. 12. It was formerly the residence of the elector palatine. Carlstadt, or the new town, is divided into six regular quarters which open into an extensive square; and forms a beautiful addition to the old city. Dusseldorf was taken by the French in 1795. The fortifications were demolished after the peace in 1801. In 1806 it became the residence of the grand duke of Berg; but in 1815 it was made over, with the rest of the duchy, to Prussia. It contains, including the garrison, 18,000 inhabitants.

DUTENS, LOUIS, a French miscellaneous writer. See SUPPLEMENT.

DUTCHY. See DUCHY.

DUTY, in general, denotes any thing that one is obliged to perform.

DUTY, in a moral sense. See *MORAL Philosophy*.

DUTY, in polity and commerce, signifies the impost laid on merchandises, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp duties, &c. See CUSTOMS, EXCISE, &c.

The principles on which all duties and customs should be laid on foreign merchandises which are imported into these kingdoms, are such as tend to cement a mutual friendship and traffic between one nation and another; and therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries; they should be so laid as to make the exports of this nation at least equal to our imports from those nations wherewith we trade, to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exportations to such countries. These are the national principles on which all our treaties of commerce with other countries ought to be grounded.

DUTY, in the military art, is the exercise of those functions that belong to a soldier: with this distinction, that mounting guard and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy is called going on service.

DUUMVIRATE, the office or dignity of the duumviri. See the next article.

The duumvirate lasted till the year of Rome 388, when it was changed into a decemvirate.

DUUMVIRI, in Roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

DUUMVIRI Capitales were the judges in criminal causes: from their sentence it was lawful to appeal to the people, who only had the power of condemning a citizen to death. These judges were taken from the body of the decuriones; they had great power and authority, were members of the public council, and had two lictors to walk before them.

DUUMVIRI Municipales, were two magistrates in some cities of the empire, answering to what the consuls were at Rome: they were chosen out of the body of the decuriones; their office lasted commonly five years, upon which account they were frequently termed *quinquinales magistratus*. Their jurisdiction was of great extent: they had officers who walked before them, carrying a small switch in their hands; and some of them assumed the privilege of having lictors, carrying axes, and the fasces or bundles of rods, before them.

DUUMVIRI Navales, were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duty of their office consisted in giving orders for the fitting of ships, and giving their commissions to the marine officers, &c.

DUUMVIRI Sacrorum, were magistrates created by Tarquinius Superbus, for the performance of the sacrifices, and keeping of the sibyls books. They were chosen from among the patricians, and held their office for life; they were exempted from serving in the wars, and from the offices imposed on the other citizens, and without them the oracles of the sibyls could not be consulted.

DUYVELAND, or DIVELAND, one of the islands of Zealand, in the United Provinces, lying eastward of Schonen, from which it is only separated by a narrow channel.

DWAL, in *Heraldry*, the herb nightshade, used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

DWARF, in general an appellation given to things greatly inferior in size to that which is usual in their several kinds: thus there are dwarfs of the human species, dwarf dogs, dwarf trees, &c.

The Romans were passionately fond of dwarfs, whom they called *nani* or *nanæ*, insomuch that they often used artificial methods to prevent the growth of boys designed for dwarfs, by enclosing them in boxes, or by the use of tight bandages. Augustus's niece, Julia, was extremely fond of a dwarf called *Sonopas*, who was only two feet and a handbreadth high. We have many other accounts of human dwarfs, but most of them deformed in some way or other besides the smallness of their size. Many relations also concerning dwarfs we must necessarily look upon to be fabulous, as well as those concerning giants. The following history, however, which we have reason to look upon as authentic, is too remarkable not to be acceptable to the generality of our readers.

Dwarf.

Jeffery Hudson, the famous English dwarf, was born at Oakham, in Rutlandshire, in 1619; and about the age of seven or eight, being then but 18 inches high, was retained in the service of the duke of Buckingham, who resided at Burleigh on the Hill. Soon after the marriage of Charles I. the king and queen being entertained at Burleigh, little Jeffery was served up to table in a cold pie, and presented by the duchess to the queen, who kept him as her dwarf. From 7 years of age till 30, he never grew taller; but after 30, he shot up to three feet nine inches, and there fixed. Jeffery became a considerable part of the entertainment of the court. Sir William Davenant wrote a poem called *Jeffreidos*, on a battle between him and a turkey cock; and in 1638, was published a very small book, called the *New Year's Gift*, presented at court by the lady Parvula to the lord Minimus (commonly called *Little Jeffery*) her majesty's servant, &c. written by Microphilus, with a little print of Jeffery prefixed. Before this period, Jeffery was employed on a negotiation of great importance: he was sent to France to fetch a midwife for the queen; and on his return with this gentlewoman, and her majesty's dancing master, and many rich presents to the queen from her mother Mary de Medicis, he was taken by the Dunkirkers. Jeffery, thus made of consequence, grew to think himself really so. He had borne with little temper the teasing of the courtiers and domestics, and had many squabbles with the king's gigantic porter. At last, being provoked by Mr Crofts, a young gentleman of family, a challenge ensued; and Mr Crofts coming to the rendezvous armed only with a squirt, the little creature was so enraged, that a real duel ensued; and the appointment being on horseback with pistols, to put them more on a level, Jeffery, with the first fire, shot his antagonist dead. This happened in France, whither he had attended his mistress in the troubles. He was again taken prisoner by a Turkish rover, and sold into Barbary. He probably did not remain long in slavery; for at the beginning of the civil war, he was made a captain in the royal army; and in 1644 attended the queen to France, where he remained till the Restoration. At last, upon suspicion of his being privy to the popish plot, he was taken up in 1682, and confined in the Gatehouse, Westminster, where he ended his life, in the 63d year of his age.

In the memoirs of the Royal Academy of Sciences, a relation is given by the count de Tressau, of a dwarf called *Bebe* kept by the late Stanislaus, king of Poland, and who died in 1764, at the age of 23, when he measured only 32 inches. At the time of his birth, he measured only between eight and nine inches. Diminutive as were his dimensions, his reasoning faculties were not less scanty; appearing indeed not to have been superior to those of a well-taught pointer; but that the size and strength of the intellectual powers are not affected by the diminutiveness or tenuity of the corporeal organs, is evident from a still more striking instance of littleness, given us by the same nobleman, in the person of Monsieur Borulawski, a Polish gentleman, whom he saw at Luneville, who has since been at Paris, and who at the age of 22 measured only 28 inches. This miniature of a man, considering him only as to his bodily dimensions, appears a giant with regard to his mental powers and attainments. He is described by the count as possessing all the graces of wit, united with a sound judgment and an excellent memory; so that we may with justice say of M. Borulawski, in the words of Seneca, and nearly in the order in which he has used them, "*Posse ingenium fortissimum ac beatissimum sub quolibet corpusculo latere.*" Epist. 66.

Dwarf, Dwina.

Count Borulawski was the son of a Polish nobleman attached to the fortunes of King Stanislaus, who lost his property in consequence of that attachment, and who had six children, three dwarfs, and three well grown. What is singular enough, they were born alternately, a big one and a little one, though both parents were of the common size. The little count's youngest sister was much less than him, but died at the age of 23. The count continued to grow till he was about 30, and has at present attained his 51st year, and the height of three feet two inches. He never experienced any sickness, but lived in a polite and affluent manner under the patronage of a lady, a friend of the family, till love at the age of 41 intruded into his little peaceful bosom, and involved him in matrimony, care, and perplexity. The lady he chose was of his own country, but of French extraction, and the middle size. They have three children, all girls, and none of them likely to be dwarfs. To provide for a family now became an object big with difficulty, requiring all the exertion of his powers (which could promise but little) and his talents, of which music alone afforded any view of profit. He plays extremely well upon the guitar; and by having concerts in several of the principal cities in Germany, he raised temporary supplies. At Vienna he was persuaded to turn his thoughts to England, where it was believed the public curiosity might in a little time benefit him sufficiently to enable him to live independent in so cheap a country as Poland. He was furnished by very respectable friends with recommendations to several of the most distinguished characters in this kingdom, as the duchess of Devonshire, Rutland, &c. &c. whose kind patronage he is not backward to acknowledge. He was advised to let himself be seen as a curiosity, and the price of admission was fixed at a guinea. The number of his visitors, of course, was not very great. After a pretty long stay in London he went to Bath and Bristol; visited Dublin and some other parts of Ireland; whence he returned by way of Liverpool, Manchester, and Birmingham, to London. He also visited Edinburgh and some other towns of Scotland. In every place he acquired a number of friends. In reality, the ease and politeness of his manners and address please no less, than the diminutive, yet elegant, proportions of his figure astonish those who visit him. His person is pleasing and graceful, and his look manly and noble. He speaks French fluently, and English tolerably. He is remarkably lively and cheerful, though fitted for the most serious and rational conversation. Such is this wonderful little man—an object of curiosity really worthy the attention of the philosopher, the man of taste, and the anatomist. His life has been published, written by himself.

DWINA, the name of two large rivers; one of which rises in Lithuania, and, dividing Livonia from Courland, falls into the Baltic sea a little below Riga; the other gives name to the province of Dwina in Russia.

It runs from south to north, and discharges itself into the White sea a little below Archangel.

DYCK. See VANDYCK.

DYE, in *Architecture*, any square body, as the trunk or notched part of a pedestal: or it is the middle of the pedestal, or that part included between the base and the corniche; so called because it is often made in the form of a cube or dye. See ARCHITECTURE, N° 61.

DYER, a person who professes the art of dyeing all manner of colours. See DYEING.

DYER, *Sir James*, an eminent English lawyer, chief judge of the court of common pleas in the reign of Queen Elizabeth. He died in 1581: and about 20 years after was published his large collection of Reports, which have been highly esteemed for their succinctness and solidity. He also left other writings behind him relative to his profession.

DYER, *John*, the son of Robert Dyer, Esq. a Welsh solicitor of great capacity, was born in 1700. He passed through Westminster school under the care of Dr Freind, and was then called home to be instructed in his father's profession. His genius, however, led him a different way; for besides his early taste for poetry, having a passion no less strong for the arts of design, he determined to make painting his profession. With this view, having studied a while under his master, he became, as he tells his friend, an itinerant painter, and wandered about South Wales, and the parts adjacent; and about 1727 printed Grongar Hill. Being probably unsatisfied with his own proficiency, he made the tour of Italy; where, besides the usual study of the remains of antiquity, and the works of the great masters, he frequently spent whole days in the country about Rome and Florence, sketching those picturesque prospects with facility and spirit. Images from hence naturally transferred themselves into his poetical compositions: the principal beauties of The Ruins of Rome are perhaps of this kind; and the various landscapes in The Fleece have been particularly admired. On his return to England, he published The Ruins of Rome, 1740; but soon found that he could not relish a town life, nor submit to the assiduity required in his profession. As his turn of mind was rather serious, and his conduct and behaviour always irreproachable, he was advised by his friends to enter into holy orders; and it is presumed, though his education had not been regular, that he found no difficulty in obtaining them. He was ordained by the bishop of Lincoln, and had a law degree conferred on him.

About the same time he married a lady of Coleshill named Ensor; "whose grandmother (says he) was a Shakespeare, descended from a brother of every body's Shakespeare." His ecclesiastical provision was a long time but slender. His first patron, Mr Harper, gave him, in 1741, Calthorp in Leicestershire, of 80l. a-year, on which he lived ten years; and in April 1751 exchanged it for Belchford in Lincolnshire, of 75l. which was given him by Lord-chancellor Hardwicke, on the recommendation of a friend to virtue and the muses. His condition now began to mend. In 1752, Sir John Heathcote gave him Coningsby, of 140l. a-year; and in 1756, when he was LL. B. without any solicitation of his own, obtained for him from the chancellor Kirby-on-Bane, of 110l. In 1757, he published The Fleece, his greatest poetical work; of which Dr Johnson relates this ludicrous story. Dodsley the bookseller was one day mentioning it to a critical visitor, with more expectation of success than the other could easily admit. In the conversation the author's age was asked: and being represented as advanced in life, "He will (said the critic) be buried in woollen." He did not indeed long outlive that publication, nor long enjoy the increase of his preferments; for a consumptive disorder, with which he had long struggled, carried him off at length in 1758.

Mr Dyer's character as a writer has been fixed by three poems, Grongar Hill, The Ruins of Rome, and The Fleece; wherein a poetical imagination perfectly original, a natural simplicity connected with and often productive of the true sublime, and the warmest sentiments of benevolence and virtue, have been universally observed and admired. These pieces were put out separately in his lifetime: but after his death they were collected and published in one volume 8vo, 1761; with a short account of himself prefixed.

DYER's-Weed. See RESEDA, BOTANY and DYEING Index.

DYEING.

Definition.

1. DYEING is the art of communicating a permanent colour to any substance; but it is generally employed in a more limited sense, and is applied to the art of giving colours to wool, silk, cotton or flax, or to thread or cloth fabricated of these substances. To this more limited sense we propose to confine it in the following treatise; and for the dyeing or staining of other substances, as paper, wood, hone, leather, marble, the reader is referred to these articles.

Origin of arts.

2. Among the arts of life there are some which are essential to man even in the earliest period of his history; while others derive their origin from chance, and owe their improvement and perfection to the progress of refinement and luxury. Those arts which are connected with the means of providing food or shelter are necessary even in the rudest state of man, and are practised with more or less dexterity and success according to the abundance or scantiness of the supply with which he is furnished, and the varieties of climate which he inhabits. But those arts which have been distinguished by the name of *fine arts* can only flourish and arrive at a high degree of perfection in the more luxurious ages of refined society. To this account of the origin and progress of the arts among mankind, the art of dyeing forms a remarkable exception. Totally unconnected with the means of providing food to satisfy the urgent calls of hunger, of preparing raiment to secure the body from cold, or of procuring shelter from the storm, this art might at first sight be considered as one of those which exclusively

Origin.

belong to an age of luxury. But the history of mankind assigns to its origin a very different period. The art of dyeing seems to be almost co-eval with man. In the rudest state of his existence, his simple and scanty clothing is frequently coloured; and even the naked savage, while he is yet a houseless wanderer in the woods, has discovered the means of staining his body with different colours. And yet the art of dyeing in no respect contributes to relieve the real and primary wants of man. It renders not his raiment warmer, and it serves not to make his lodging more comfortable.

Of dyeing.

3. Whence then is the origin of this art? It depends not like others on the necessities of man, and it exists long before he is acquainted with refinement and luxury. It must therefore be traced to a different source.

We see that the desire of distinction is one of the most active principles in the human mind. This principle operates equally in the breast of the savage in the midst of his naked companions, and in that of the sage and the soldier in polished society. Man rarely rests satisfied with the solid, but frequently less obvious pre-eminence, which superior strength, genius, or learning, confers. The proofs of this superiority can be but seldom exhibited; they are often not generally understood or acknowledged, and therefore cannot always be fairly estimated. He who possesses any of those talents which give him a superiority to others, naturally wishes to be distinguished by certain marks by which he may more uniformly and more directly excite admiration and command respect. He seeks, therefore, for some adventitious circumstances, which may be regarded as a kind of symbolical representation of power and greatness; and as they are constantly present to the senses, they make a deep impression, and keep alive those feelings of admiration which are so gratifying to the vain and ambitious. Dress and its ornaments have been usually employed as external marks of distinction. Hence it is, that the chief or the warrior among rude nations is clothed with a finer and more beautiful skin; his head is decorated with flowers or feathers; or the leaves of the oak, or the laurel, simply adorn his brow. And in the progress of civilization and refinement, the diadem of gold, and the robe of purple or of scarlet, supplant these simpler decorations as characteristics of dignity and power. To increase still more the beauty and variety of those substances which are employed as clothing or as the ornaments of dress, the aid of colours has been called in; and accordingly we find that coloured clothing has been held in high estimation in all ages. This principle, therefore, the desire of distinction, seems to be the natural origin of the art of dyeing. Nature, however, furnishes the model, and may be regarded as the antetype of the art, in the gay plumage with which she has clothed the feathered tribes, and in the splendid colours and infinite variety of shades which are exhibited in her vegetable productions.

History.

4. But without indulging farther in these speculations, which are to be considered as subjects of curious investigation, rather than as topics of practical utility, let us now take a short view of the history and progress of this art.

and progress;

We have endeavoured to shew that the beauty of brilliant colours is one of the means of attracting attention, and of acquiring distinction, which mankind in every period of society have employed. Even before the use of clothing has been introduced, the rude inhabitants of savage nations applied them first to their skins. This practice existed among the Britons in the time of Cæsar; and the women of Gaul about the same period stained themselves of a brown olive colour. At this day, it is still the practice of many of the savage tribes of America, as well as of the natives of the South sea islands. But when mankind had made some progress in arts and civilization, and had begun to wear clothing, the colours which they admired were afterwards communicated to their garments. The art of dyeing, therefore, though in a rude and imperfect state, is indisputably of great antiqnity; and indeed considering its nature and origin, this might have been expected.

in India;

5. India, the nursery of the arts and sciences, which were afterwards improved and brought to perfection among other nations, seems to have given birth to the art of dyeing; and it would appear that the knowledge of dyeing cotton had advanced as far in the time of Alexander the Great as at the present time, so stationary have the arts become in that country. The beautiful colours of the Indian linens would naturally lead to the supposition that the art had reached a very high degree of perfection; but it is known that the Indian processes are so tedious, complicated and imperfect, that they would be totally impracticable in any other country.

among the Greeks,

6. It was not till the time of Alexander the Great that the art of dyeing cotton and linen, which had gradually spread from the east to the west, was known in Europe. The Greeks, however, as appears from many passages in the Iliad and Odyssey, were acquainted with the art of dyeing purple in the time of Homer. And it is supposed that they derived their knowledge of it from the Phenicians, a people who were very early celebrated for the art of dyeing. But their art seems to have been confined to wool; silk, indeed, was at that time unknown, and linen was usually worn white.

the Jews

7. Dyeing and coloured stuffs are frequently mentioned in the sacred writings. It would appear that the art had made considerable progress in the time of the patriarchs, from what is mentioned in the book of Genesis. The dyed stuffs which are described in the book of Exodus were purchased by the Jews from the Phenicians.

the Egyptians.

8. The Egyptians, according to Pliny, practised a kind of topical dyeing or calico-printing, which from his general description seems to have been similar to that which was found many ages after to exist in different parts of India, and was from thence introduced into the different countries of Europe. He says, the Egyptians began by painting on white cloths, which were no doubt of linen or cotton, with certain drugs which were themselves colourless, but possessed the property of absorbing colouring substances. These cloths were afterwards immersed in a heated dyeing liquor which was of one uniform colour, and although they were formerly colourless, yet when they were taken out, they were found to be dyed of different colours, according to the different qualities of the substances which had been applied to their different parts; and these colours could not afterwards be discharged by

by washing†. This art was probably borrowed from the natives of India.

he Tyrian urple.

9. The Tyrian purple, so celebrated among the ancients, was probably from the name discovered at Tyre, and perhaps contributed not a little to the opulence of that city. The liquor which was employed in dyeing the purple was extracted from two kinds of shell-fish, one of which, the larger, was called the *purple*, and the other was a species of whelk. Each of these species was subdivided into different varieties, and were otherwise distinguished, according to the places where they were found, and as they yielded more or less of a beautiful colour. It is in a vessel in the throat of the fish that the colouring liquor is found.

epara- n of the uor.

Each fish only afforded a single drop. When a certain quantity of the liquor had been obtained, it was mixed with a proportion of common salt, macerated together for three days, and five times the quantity of water was added. The mixture being kept in a moderate heat, the animal parts which happened to be mixed with it, separated and rose to the surface. At the end of ten days, when these operations were finished, a piece of white wool was immersed, by which means they ascertained whether the liquor had acquired the proper shade.

the ff.

Various processes were followed to prepare the stuff to receive the dye. By some it was immersed in lime water, and by others it was prepared with a kind of *fucus*, which acted as a mordant to give it a more fixed colour. Alkanet was used by some for the same purpose.

The liquor of the whelk did not alone yield a durable colour. The liquor from the other shell-fish served to increase its brightness; and thus two operations were in use to communicate this colour. A first dye was given by the liquor of the purple, and a second by that of the whelk; from which it was called by Pliny *purpura dibapha*, or purple twice dipped.

ma- cy.

10. Some kinds of purple have been found to possess great durability. Plutarch, in his life of Alexander the Great, mentions that the Greeks discovered in the treasury of the king of Persia a great quantity of purple which was 190 years old, and still retained all its beauty.

h price.

11. The small quantity of liquor which could be obtained from each shell-fish, and the tedious process in its preparation and application to the stuffs, raised the price of purple so high, that in the time of Augustus a pound of wool of the Tyrian purple dye, could not be purchased for one thousand denarii, equal to about 36l. sterling.

n by t Ro- ms.

12. The purple, which has been almost everywhere a mark of distinction attached to high birth and dignity, was worn by those who held the first offices in Rome. The emperors at last reserved to themselves the right of wearing it, and prohibited all others from using it on pain of death.

S used in eing.

13. The substances which have been discovered and used in dyeing by the moderns, and the superiority which they have obtained in many colours, have superseded the use of the purple of the ancients. The shell-fish from which the liquor is extracted, is supposed to be now as abundant as ever. Similar shell-fish have been found near Nicoya, a small Spanish town in South America, and they are at present used for dyeing cotton on the coasts of Guaiaquil and Guatimala.

The shell-fish found on the coasts of England

14. In the year 1683, Mr Cole of Bristol discovered, on the coast of England, the shell-fish which yields the purple liquor. The liquor was contained in a white vein, lying transversely in a little furrow or cleft, next to the head of the fish. He found by experiment, that letters or marks, made with this white liquor, appeared when first exposed to the air of a green colour. When exposed to the sun, it became of a deeper green, afterwards of a purplish red, and by the continued action of the sun's rays, of a deep purple red. Mr Cole sent some of the first linen marked with this liquor to Dr Plot, one of the secretaries of the Royal Society, in the year 1684. It was soon after shown to King Charles II. who greatly admired it, and desired that some of the shell-fish might be collected, and brought to town, that he might have an opportunity of seeing the liquor applied, and the successive changes of colour through which it passed.

and of France.

A species of this shell-fish was also found by Plumier at the Antilles; and Reaumur made a number of experiments on whelks, which were collected on the coast of Poitou. Duhamel found the same shell-fish in great abundance on the coast of Provence. The experiments of these philosophers on this liquor afforded the same result as those of Mr Cole. They observed that, although at first white, it becomes by the action of light, of a yellowish green, then deepens to a kind of blue, which is afterwards changed to a red. In less than five minutes, the latter is converted into a fine deep purple, having all the characters of the purple of the ancients.

Eudocia Macrembolitissa, daughter of the emperor Constantine VIII. who lived in the 11th century, while the knowledge and practice of dyeing that colour for the use and at the expence of the Greek emperors still subsisted, has given a minute account of the mode of catching the shell-fish which produced the purple. Of this operation she herself, it would appear, was an eyewitness. As it was applied at that time, it did not acquire its full lustre and perfection of colour, till it had been exposed to the action of the sun's rays.

Purple liquor found in snails.

15. A liquor which yields the same colour, and has otherwise similar properties, is found in different parts of the world. Abundance of purple snails, it is said, are found in the islands opposite to Batavia. They are boiled and eaten by the Chinese, who polish the shells, and pick out of the middle of the snail a purple-coloured substance, which they use in colouring and making red ink. Dr Peysonnel describes what he calls the naked snail, which is found in the seas of the Antilles, and affords a liquor of a beautiful purple colour. This liquor is thrown out by the animal when it is disturbed, in the same way as the cuttle-fish discharges the ink. The liquor of the snail is naturally of a purple colour, without the application of light *. Two shell-fishes, which yield a similar colouring liquor, are described by Dr Brown in his history of Jamaica. The one, he says, is frequent in the American seas, and emits on being touched a considerable quantity of viscid purple liquor, which thickens and colours water. The other is called the *purple ocean shell*, and yields a beautiful purple liquor, which seems to resemble the former. But investigations concern-

---

† *Plin.* lib.

* *Phil. Trans.* vol. i.

ing the nature and application of the purple dye from shell-fish are now to be considered merely as subjects of curiosity; because the colours which are obtained by the processes of the moderns are more beautiful, and far less expensive.

The arts lost.

16. In the 5th century, during the irruption of the northern barbarians, the arts, which had been encouraged and protected by the Romans, were lost amidst the devastations of the western empire. A few, indeed. were preserved in Italy, but they were in a state of decay; and otherwise no traces remained of knowledge, industry, or humanity. A manuscript of the 8th century is quoted by Muratori, which contains a description of some dyes, principally for skins, as well as some processes connected with other arts; but from the barbarous Latin in which it is written, no distinct notion can be formed of the nature of these processes. The arts met with a better fate in the East, where they were protected and encouraged. So late as the 12th century, articles of luxury were procured by some of the great from eastern countries.

Are revived in Italy.

17. During the time of the crusades, Venice and other cities of Italy became rich and powerful, first by supplying with provisions the Europeans who engaged in these frantic and destructive expeditions, and afterwards by establishing an intercourse with the Grecian empire. By these means the arts, which had been preserved among the Greeks, were established in Italy. In the year 1338, the city of Florence contained 200 manufacturers, who are said to have produced from 70,000 to 80,000 pieces of cloth. In the year 1300, archil was accidentally discovered by a Florentine merchant. Observing that urine produced a fine colour on certain species of moss, he made experiments, and from these learned the mode of preparing this substance. The discovery was long kept secret. His posterity, a branch of which it is said still exists, have retained the appellation of *Rucellai*, from the Spanish word which signifies that kind of moss.

Dyeing revived in Italy.

18. The arts, after being revived in Italy, continued for a long time to be cultivated and improved with increasing success. Along with these, the art of dyeing made considerable progress. The first collection of the processes employed in this art appeared at Venice in the year 1429. It was entitled *Mariegola del' arte de i tentori*. To render this description more useful and extensive, a person of the name of Giovanni Ventura Rosetti, travelled through different parts of Italy, and the neighbouring countries, where the arts had begun to flourish, that he might acquire a knowledge of the processes which were employed by different dyers. These were collected and published in 1548, under the title of *Plictho*. This treatise has been by some considered as the leading step towards the perfection which the art of dyeing has attained; for it is the first in which the different processes are collected. No mention is made either of cochineal or of indigo; so that it would appear, these dyes were either not known, or not employed in Italy previous to the time in which it was written.

19. Italy, but especially Venice, for a long time almost exclusively possessed the art of dyeing, and this seems to have contributed greatly to the prosperity of the manufactures and commerce which the Italian states long enjoyed. By degrees it was introduced into France, Holland, and Britain. The process for dyeing the true scarlet had been communicated to a person of the name of Gobelin. who established a manufactory near Paris, which still bears his name. At the time, this was considered so rash an enterprise, that it received the name of *Gobelin's folly*; but such was his success, and such was the ignorance of the times, that it was supposed he derived his knowledge of the processes he employed, from the devil!

Is introduced into France, &c.

20. The discovery of America brought the knowledge of the cochineal insect into Europe. The Spaniards observing that the Mexicans employed it in painting their houses, and in dyeing cotton, transmitted an account of the beauty of that colour to their government, whose attention was afterwards directed to encourage and promote the increase of this valuable insect from which it is obtained. The discovery of cochineal was soon followed by that of the process for dyeing scarlet, by means of a solution of tin. For this discovery we are indebted to a German chemist of the name of Kuster, or Kufler, who carried the secret to London in the year 1643. Gluck or Kloeck, a Flemish painter, having obtained possession of this secret, communicated it to Gobelin, and afterwards the knowledge of it spread throughout all Europe. The use of indigo, which was a great acquisition to the art of dyeing, was more slowly established than that of cochineal. In the reign of Queen Elizabeth, the use of this substance, as well as of logwood, was strictly prohibited in England, and, if found in any manufactory, was ordered to be burned. This, as must appear at the present time, very strange prohibition, was not withdrawn till the reign of Charles II. It met with the same fate in Saxony. In the edict in which the use of it is forbidden, it is said to be a corrosive colour, and called *food for the devil!!*

Indigo firs used.

21. In France also, some prejudice was entertained against it, and although it was not entirely prohibited, the use of it was limited to a certain proportion. The reason on which this prejudice was founded, on a narrow view of the principles of political economy, might even in the present day be admitted as specious, if not satisfactory. It was held out by those who dyed blue, and were accustomed to use pastil and woad, that the introduction of indigo would supersede the use of these substances; and it was represented that their consumption would be destroyed, and the encouragement for the productions of the country diminished.

Dyeing e- couraged in Franc

22. Previous to the administration of the celebrated Colbert, the industry and arts of France long remained in a state of languor and decay. By the wise measures which were adopted by this minister, she soon rose to distinction among the nations of Europe, and in a short time saw her commerce and manufactures greatly extended. He invited the most skilful artists, encouraged and rewarded their talents, and thus established many arts and manufactures. Among these, the art of dyeing received its share of attention. In the year 1672, he published a table of instructions for dyeing, which, although it contains many useless and improper restrictions, is on many accounts worthy of attention, and particularly the reasons which he has given for considering it as an object of consequence. As a proof of this, we may refer to the following extract.

tract from the instructions: "If, it is said, the manufactories of silk, wool, and thread, are to be reckoned among those which most contribute to the support of commerce; dyeing, which gives them that striking variety of colour, by which they resemble what is most beautiful in nature, may be considered as the soul of them, without which a body could scarcely exist.

"Wool and silk, the natural colour of which rather indicates the rudeness of former ages, than the genius and improvement of the present, would be in no great request, if the art of dyeing did not furnish attractions which recommend them, even to the most barbarous nations. All visible objects are distinguished and recommended by colours; but for the purposes of commerce, it is not only necessary that they should be beautiful, but that they should be good, and that their duration should equal that of the materials which they adorn."

stric-
ns.

23. But notwithstanding these just and liberal views, and many useful regulations, which were published for instruction in the art of dyeing, the restrictions imposed upon it, as we have already observed, were from mistaken views improper and injurious, because in this, as in every other art, these restraints infallibly operate as checks on industry and improvement. The effects of these prohibitions, however, were moderated by the facility with which they might be eluded, and by the rewards bestowed on those whose experiments promoted the progress of the art, and whose discoveries being afterwards published, served to modify the existing regulations. The effects of these prohibitions, too, were in a great measure obviated, by the judicious appointment of men of science, to whom the superintendence of arts and manufactures was entrusted. By their prudent exertions, and by the still more efficacious means of the diffusion of knowledge, this art, as well as others, has been encouraged and improved.

24. The French government continued to direct its attention to promote the plan which was thus begun by Colbert, and many eminent chemists have been employed to superintend and improve the processes of the art of dyeing. Dufay, Hellot, Macquer, and Berthollet, have been successively charged with the care of this department; and to their labours and exertions we are indebted for many valuable acquisitions which have been made in the art of dyeing, during the 18th century. Dufay was the first who entertained just views of the nature of colouring matters, and the powers by which they adhere. In the examination of certain processes he discovered great sagacity, and established the surest means which the state of knowledge at the time afforded, to ascertain the durability of a colour. Under his direction a new table of instructions, which superseded that of Colbert, was published in 1737. Hellot, who succeeded him, published in 1740 a methodical description of the processes for dyeing wool; and this treatise may be considered, even at the present day, as one of the best systems on the subject. Macquer in 1763 published a treatise on dyeing silk, in which he has given an accurate description of the processes, has discovered the combinations of the colouring principle of Prussian blue, and has endeavoured to make an application of it to the art of dyeing. Macquer died in 1784, and was succeeded in that department by the celebrated Berthollet, to whom was intrusted the superintendence of the arts connected with chemistry, and particularly that of dyeing. To his being placed in this department, we are probably indebted for the excellent work which he has published on this subject, and for different memoirs which have appeared in different periodical works. To these we must acknowledge ourselves greatly indebted for much of the information, both of the theory and practice of this art, which we propose to lay before our readers in the following treatise. He has endeavoured, he observes, to bring into one point of view the processes of industry, and the operations of nature; to take his situation between the philosopher and the artist. To the first he has shown, where it is that the phenomena of the art of dyeing and those of nature meet, and what are the principles which their discoveries have established. When these comprehensive views, we may add, are completed, the art of dyeing may be considered as perfect.

State of, in Britain.

25. The art of dyeing has been long successfully practised in Britain, although little has been done towards the investigation of the theory on which it depends. At an early period of the Royal Society, it attracted the attention of some of its members; but nothing was published on the subject. Many years afterwards, some useful observations on dyeing were published by Dr Lewis, but these were limited to a very few processes. The only work with which the British dyers were acquainted, till within these few years, was a translation of the treatise of Hellot, mentioned above.

Improved by chemistry.

26. But since the progress of chemical science has opened so wide a field of investigation; and since all the essential processes in the art of dyeing are to be considered as purely chemical, the attention of philosophers has been greatly occupied with its investigation and improvement. By their experiments and observations a great deal of new information has been accumulated, and much new light has been thrown upon the art.

Authors on dyeing.

27. The only treatise which has appeared in Sweden on this subject, is that of Scheffer, accompanied with notes by the celebrated Bergman. In Germany, experiments in different processes of dyeing have been published by Beckmann, Poerner, Vogler, and Francheville. The authors of the different treatises in France on this subject, which have greatly contributed to the improvement of the art, are D'Ambourney, D'Apligny, Haussmann, Chaptal, and Berthollet, whose works we have already mentioned. In Britain, two very valuable essays by Delaval and Henry have appeared: and to these we may add, the excellent treatise on the Philosophy of Permanent Colours, by Dr Bancroft.

In the following treatise, we propose to give a pretty full view, both of the theory and practice of dyeing, This subject naturally divides itself into two parts. In the first, we shall treat of dyeing in general, or of those departments of physical science, the knowledge and application of which may be considered as constituting the theory of the art. In the second part, we shall take a view of the different processes which are employed in communicating colours to different stuffs, or, in general terms, the practice of dyeing.

PART I. OF DYEING IN GENERAL.

Of Colours, &c.

UNDER this head we propose to take a general view of what may be regarded as the theory of dyeing; and investigate those principles of physical science which are immediately connected with the art, and by the application of which the phenomena of the art can only be accounted for, or satisfactorily explained. With this view we shall treat the subjects which come under this part in the four following chapters. In the *first*, we shall consider the nature of colours and colouring matters; in the *second*, we shall treat of the nature and operations of mordants; the *third* will include an account of the properties of the substances to which colours are communicated; and, in the *fourth*, we shall add some general observations on the operations of dyeing.

CHAP. I. *Of Colours and Colouring Matters.*

28. THE physical theory of light and vision properly belongs to optics; and the changes produced by the action of light on different substances are detailed under chemistry. In this place, therefore, we shall only make a few observations on the nature of light and colours, which are more immediately connected with the subject under consideration. For our knowledge of light and vision we are indebted to Sir Isaac Newton. It was first demonstrated by that sagacious philosopher, that the light of the sun is composed of seven rays which have different powers of refrangibility. The colours of these seven rays are red, orange, yellow, green, blue, indigo, violet. When these rays are separated by the prism, as they run gradually into each other, according to their different degrees of refrangibility, they produce every various shade of colour. The violet ray is the most refracted, the indigo next, and so on to the red, which is the least refracted of all the rays. The same rays of light also differ in their degrees of reflexibility. All known colours, and their different shades, are produced by mixing together the different rays. Thus, for instance, by mixing together red and yellow, an orange colour is obtained; yellow and blue give a green colour; and blue and red, according to their different proportions, produce a violet, purple, &c. and thus, as Sir Isaac Newton has observed, the variety of colours depends on the composition of light; for if the sun's light consisted but of one sort of rays, there would be but one colour.

Nature of light.

29. Colours in an object, the same philosopher farther observes, are nothing but a disposition to reflect this or that sort of rays more copiously than the rest; in the rays there are nothing but their dispositions to propagate this or that motion into the *sensorium*; and in the *sensorium* they are sensations of those motions under the forms of colours. In their power of reflecting light, bodies, it is well known, differ greatly from each other. Some bodies reflect it in such quantities, that the eye cannot bear it. Such, for instance, are metallic substances highly polished. Others again, as dark coloured or black substances, reflect it very feebly. It is found in general, that the quantity of light reflected from a body depends greatly on the smoothness of its surface. On this account bodies which have the smoothest surface, or are most highly polished, are the brightest: that is, they reflect the greatest quantity of light. But there is also a very great difference among bodies, in the nature or quality of the rays of light which they have the power of reflecting. When all the rays of light are equally reflected by any body, that body is said to be white; but when a very few rays only are reflected from a body, that body is said to be black, because the greater number of the rays being absorbed by the body, the few that are reflected make a very faint impression on the organ of vision. A body which has the power of reflecting the red rays only, is said to be red; a body which reflects the blue rays, is said to be blue; the body reflecting only the yellow rays, is yellow: but when any two of these rays are reflected in combination with each other, a different colour is produced; as for instance, the red and the yellow rays afford an orange colour; and, as we have already observed, the various shades of colour exhibited by different bodies, depend on the different combinations of rays reflected from their surface. Thus it appears, that colour in bodies is to be ascribed to their disposition of absorbing certain rays, and reflecting the rest. In opaque bodies, it is owing to their disposition to absorb some rays, and to reflect the rest. In transparent bodies, it is owing to their disposition to absorb certain rays, and to transmit the rest.

Nature of colours.

Of Colours, &c.

Cause of colours investigated.

30. Newton has demonstrated, that transparent bodies reflect the rays of one colour, and transmit those of another, according to the difference of their thickness or density. He observes that transparent substances, such as glass, water, air, &c. when made very thin by being blown into bubbles, or otherwise formed into plates, exhibit various colours, according to their various thinness; although at a greater thickness they appear very clear and colourless. His method of conducting these experiments was the following. He took two object-glasses, the one a plano-convex for a 14 feet telescope, and the other a large, double convex, for one of about 50 feet; and upon this laying the other with its plain side downwards, he pressed them slowly together, to make the colours successively emerge in the middle of the circles, and then slowly lifted the upper glass from the lower, to make them successively vanish again, in the same place. The colour which, by pressing the glasses together, emerged last in the middle of the other colours, would, upon its first appearance, look like a circle of a colour almost uniform from the circumference to the centre; and by compressing the glasses still more, grow continually broader, until a new colour emerged in its centre, and thereby it became a ring, encompassing that new colour; and by compressing the glasses still more, the diameter of this ring would increase, until another new colour emerged in the centre of the last, and so on, until a third, a fourth, a fifth, and other following new colours successively emerged there, and became

came rings, encompassing the innermost colour, the last of which was the black spot. And on the contrary, by lifting up the upper glass from the lower, the diameter of the rings would decrease, and the breadth of their orbit increase, until their colours reached successively to the centre, and then, as they were of considerable breadth, he could more easily discern their species than before. By proceeding in this manner, he produced 25 different-coloured, circular rings, which he divided into seven orders, because the same colour was always repeated. They are reckoned from the central colour, which was always black, in the following order:

1. Blue, white, yellow, and red.
2. Violet, blue, green, yellow, red.
3. Purple, blue, green, yellow, red.
4. Green, red.
5. Greenish blue, and red.
6. Greenish blue, and pale red.
7. Greenish blue, and reddish white.

But in the three last orders the colours were very indistinct, and terminated in perfect whiteness.

31. These colours were occasioned by the thin films of air which were included between the two glasses. For he found, he observes, by looking through the two object-glasses, that the interjacent air exhibited rings of different colours, as well by transmitting light, as by reflecting it. The film of air varies in thickness from the centre of the glasses to the circumference. In the centre where the film is thinnest the colour is black; and the other colours from the centre to the circumference are produced in their order by the gradual increase of the thickness of the film.

32. These experiments were repeated on films of water and also of glass; and it was found that the thickness of the films in these cases, reflecting any particular colour, was diminished, and this diminution appeared to be proportional to the density of the reflecting film. As there is no method of measuring the distance between the two glasses where the black spot appears, it is impossible to ascertain the absolute thickness of the films; but it certainly does not exceed the 1000th part of an inch. Newton, however, endeavoured by a mathematical investigation to measure the relative thickness of air, water, and glass, at which the several orders of colour appear. The following table exhibits the relative thickness of air which produced the coloured circles.

1. Black	1	green	$25\frac{1}{5}$
blue	$2\frac{2}{5}$	yellow	$27\frac{1}{7}$
white	$5\frac{1}{4}$	red	31
yellow	$7\frac{1}{9}$	4. Green	35
red	$8\frac{1}{2}$	red	$40\frac{1}{3}$
2. Violet	$11\frac{1}{6}$	5. Green-blue	46
blue	14	red	$52\frac{1}{2}$
green	$15\frac{1}{8}$	6. Green-blue	$58\frac{3}{4}$
yellow	$16\frac{2}{7}$	red	65
red	$18\frac{1}{3}$	7. Green-blue	71
3. Purple	21	reddish-white	77
blue	$21\frac{2}{3}$		

Newton's

33. The conclusion which Newton drew from these experiments was, that the power or disposition of the particles of bodies to reflect or transmit particular rays depended on the size and density of these particles; and proceeding on this theory he attempted to measure the size, or at least the thickness, of the particles of bodies, from the colours which they reflected or transmitted.

Supported by Delaval.

34. This subject was still farther investigated by Mr Delaval. In the year 1765, he published, in the Philosophical Transactions, an account of his "Experiments and Observations on the agreement between the specific gravities of the several metals, and their colours, when united to glass, as well as of their other preparations." In this paper, Mr Delaval treats of the difference of density, and of the colours produced by that cause; and yet he considers colours as arising from a difference of the size of the colouring particles. For since the particles of a coloured substance being separated they are removed to a greater distance from each other, and thus occupy a greater space, that substance must undergo a diminution of its specific gravity, while at the same time the size of its particles is smaller. According to Sir Isaac Newton, the refractive and reflective powers of bodies are nearly proportional to their densities, and the least refrangible rays require the greatest power to reflect them. From this, Mr Delaval supposed, that denser substances, by their greater reflective power, ought in similar circumstances to reflect the less refrangible rays; and that substances of less density should reflect rays proportionably more refrangible, and therefore appear of several colours in the order of their density. The densest bodies, he supposes, are the red; the next in density are the orange; the next are the yellow; and so, according to the order of the refrangibility of the different rays. Mr Delaval some time after extended his researches to animal and vegetable substances, and endeavoured to establish the theory of Newton by a great number of experiments, an account of which he published in an essay entitled, an Experimental Inquiry into the cause of the Permanent Colours of Opaque Bodies †.

35. According to the theory of Newton, with the exception of combustible bodies, which follow a different law, colour depends solely upon the size of the integrant particles of bodies, in which the density is the same; and upon the size and density of all bodies taken together. But the evidence for the truth of this theory can only be derived from experiment. Newton adduced but a small number of experiments in support of it. The experiments of Mr Delaval were more numerous and more varied; but they were made long before the important facts in chemical science, which have completely changed the views and opinions of philosophers, with regard to the nature and action of the constituent principles of bodies, were discovered; so that it is now universally acknowledged that they proceeded on a false hypothesis. It was supposed that alkalies enlarge, and that acids diminish, the size of the particles of bodies on which they act, without inducing any other change. This opinion, in the present state of chemical knowledge, will not readily find a place.

Is imperfect.

36. But if this theory were true, every change in the size of the integrant particles of bodies would occasion a different colour in these particles; and in all these changes, if they correspond with the theory, the

---

† *Manchester Mem.* ii. 131.

the colour produced must be precisely that colour which is the result of a diminution or increase of size.

Inconsistent with the facts.

37. But there is no such coincidence with the facts. The magnitude of the integrant particles of bodies cannot be ascertained; and there is no method by which the increase or diminution of the particles in the changes which they undergo can be measured; but the addition or abstraction of matter to particles can in many cases be distinctly determined. In the change which takes place on gold by the process of oxidation, that is, by combining with oxygen, an integrant particle of the oxide is larger than the integrant particle of gold in the metallic state; for it has united with one particle at least of oxygen. But if the theory were true, there should be a difference of colour between the oxide and the gold, which is not the case, for they are both yellow. In the amalgam of silver, a compound of silver and mercury, the colour is white, which is the colour of both metals; and yet an integrant particle of the compound must be larger than an integrant particle of either the mercury or the silver.

The same colours reflected in different orders.

38. But the same colour, it may be said, is reflected in the different orders of colours, in which the particles are of very different sizes. This circumstance, as Dr Bancroft* justly observes, proves incontestably, that although thickness or size of the particles may be one, it cannot be the only cause of the repeated variation of colour. It follows, therefore, that there must be some other cause. But besides, the most common colour remaining after an increase of the size of the integrant particles of bodies is white: and yet this colour does not appear in any of the orders except the first; its permanency, therefore, cannot be accounted for in any way which is at all compatible with this theory.

Colours of metals independent of density.

39. And in the changes of colour which are observed to follow the increase or diminution of the sizes of the particles of bodies, the order of these changes is not such as will correspond with the theory. It is obvious that the colours of metallic substances do not depend on their density. The colour of platina, the densest body known, is not red, as it should be according to the theory, but white; in this respect resembling tin, one of the metals which has the least density, and little more than one-third that of the former.

40. The size of the particles of the green oxide of iron must be increased when they enter into combination with the prussic acid. But the colour of the compound is white; and, according to the theory, it should be accompanied with a diminution of the size of the particles, which is not the case. The colour of indigo is naturally green. The addition of oxygen, which must increase the size of the particles, converts it to a blue colour. This, then, is another case incompatible with the Newtonian theory; and from these facts it must appear, that this theory is deficient in accounting for the reflection or transmission of particular rays, and the absorption of the rest. It is not sufficient for the explanation of the causes of colour. The smallness and the density of particles are not the only circumstances which ought to be taken into the account, in explaining the cause of colour in bodies. It appears, from Newton's own experiments, that we must have recourse to the chemical properties of bodies, which have a considerable influence on their colour. It cannot be supposed, that a force which acts powerfully in refracting the rays, will not also have great influence in their reflection.

Chemical changes affect the colour.

Affinity o bodies fo certain rays the cause of colour.

41. Numerous facts tend to prove that bodies have a particular affinity for the rays of light; and indeed it is entirely upon these affinities that the phenomena of light depend. Coloured bodies have a certain affinity for some of the rays of light. Those rays for which any body has a strong affinity, are absorbed by it, and retained; while the other rays, for which it has no affinity, are either reflected or transmitted, according to the nature of the body, as it may be opaque or transparent, and according to the direction of the incident ray. A red body, for instance, reflects only the red rays, because it has an affinity for all the other rays, excepting the red. It therefore absorbs them, if it be an opaque body, or transmits them if it be transparent. A green body absorbs all the rays excepting the green; a black body has a strong affinity for all the rays, and therefore they are all absorbed; while a white body, which has little affinity for any of the rays, if it be opaque, reflects, or if transparent, transmits them all.

Changes colour owing to differenc in size, & of the pa ticles,

42. The differences which exist between the particles of bodies, may be conceived to be differences in size, density, and figure; and changes in these circumstances may account for all the varieties of affinity. If then affinity depends upon these circumstances, and if the colour of bodies is to be ascribed to the affinity between their particles and the different rays of light, the cause of the colour of bodies, it seems obvious, is capable of being accounted for from the size, density, and figure of their particles. It cannot be accounted for, according to the theories of Newton and Delaval, solely on the variations in size and density.

and to n combinations.

43. If then the colour of bodies depends upon their affinity for light, and every body have some colour in consequence of the absorption of particular rays which it retains, and the reflection or transmission of all the rest, it is obvious, that it must continue of its first colour without suffering any change, till it is either saturated with the particular rays which it absorbs, or till the particles of the body have undergone some change by decomposition or combination with new substances. As many substances have been long exposed to the action of light without their colours being changed, there is no certain evidence that the changes in the colours of bodies are to be ascribed to the first cause. The light which is absorbed either escapes unchanged or under some unknown form. But the action of the second cause which has been mentioned, may be traced in almost all cases where alterations of the colours of bodies have been observed. We may take as an example of this change of colour the green oxide of iron, which readily combines with oxygen, and is converted into the red oxide. The latter oxide, in combination with the gallic acid, assumes a black colour, and with prussic acid a blue colour. In these cases, where there is a change in the composition of the body, accompanied with a change of colour, the cause of this change is obvious; because every change in the composition of a body produces some change in the affinity, and therefore in the size, density, and figure of the particles; and it is not improbable in all of these circumstances together. But if the affinity of any body

---

* *Phil. of Perm. Col.* 7.

dy for other substances has undergone a change, it is natural to suppose that its affinity for light is also in some degree altered. This, however, although it happens in many instances, is not constant and uniform; because it may happen, that the changes in the size, density, or figure of the particles of the body, are such as to render it capable of combining with, or reflecting, the same rays of light as before it suffered any chemical change. Thus it must appear, that in most cases, the permanency of the colours of bodies will depend greatly on the permanency of their composition, and on the force of the affinities which they have for other bodies, to whose action they may be exposed.

oured tters do reflect ht.

44. In the ingenious experiments of Mr Delaval, which we have already alluded to, he has shown that coloured matters do not reflect any light. "Reflective media, (he observes), act indiscriminately on all the different rays. It does not appear from the optical phenomena which have hitherto been observed, that nature affords any kind of matter endowed with a power of reflecting one sort of rays more copiously than the other sorts; consequently no reflective substances are capable of separating the differently refrangible rays, and thereby producing colours. There are several experiments and observations in Sir Isaac Newton's optics, from which it might have been inferred, that coloured light is not reflected from coloured matter, but from white or colourless matter only. Although that great philosopher supposes that all coloured bodies reflect the rays of their own colours more copiously than the rest, yet he observes that they do not reflect the light of their own colours so copiously as white bodies do. If red-lead, for instance, and white paper, be placed in the red light of the coloured spectrum, made in a dark chamber by the refraction of a prism, the paper will appear more lucid than the red-lead, and therefore reflects the red-making rays more copiously than red-lead doth *.

"If it be supposed that the red particles of the minium reflect the red rays more strongly than the rest, what reason can be assigned why minium should not exhibit the red rays as vividly as white paper, which acts indifferently on all the rays? But if it be considered that in opaque coloured bodies, the rays which are reflected from white reflective matter pass back through the transparent coloured media with which the reflective matter is covered, it will evidently appear why the coloured light reflected from white paper is more copious and bright than that which is exhibited by red-lead.

"A considerable part of the incident light is lost in passing through transparent coloured media; therefore the light reflected immediately from the white paper, must be more copious and lucid than that which has undergone a diminution in its passage to and from the reflective particles of the opaque coloured body, through the transparent coloured medium.

"When a small portion of colouring matter is mixed with a colourless medium, the mass appears tinged with colour; but when a great quantity of colouring matter is added, the mass exhibits no colour, but appears black; therefore, to attribute to colouring matter a reflective power, is to advance an inexplicable and contradictory proposition; for it is asserting that in proportion as more reflective colouring matter is opposed to the incident light, less colour is reflected; and that when the quantity of colouring matter is very great, no colour at all is reflected, but blackness is thereby produced."

Proved.

45. "From these arguments it might have been shewn, that the reflective power does not exist in colouring matter, but in opaque white substances only. Nevertheless, in this disquisition, I have not entirely relied on arguments drawn from a few known and obvious appearances, but have endeavoured, by numerous experiments, to ascertain the cause of the colours of natural as well as artificial bodies, and the manner in which they are produced.

46. "M. Euler observed, that the colours of bodies are not produced by reflection. He supposes that the coloured rays are emitted by the colorific particles. This hypothesis, however, is not agreeable to experiment; for as the colouring matter acts upon light by transmission only, it is evident that bodies do not appear coloured, either by reflecting or emitting the rays. I have not attended to any other hypotheses which are unsupported by experiments. Sir Isaac Newton, and I believe all later philosophers, except M. Euler, have attributed to colouring matter a reflective power; and the artists whose works depend upon the preparation and use of colouring materials, seem in general to have adopted the same theory. As an instance of this agreement, I have cited, from M. Hellot, one of the most skilful and intelligent authors who have treated of the art of dyeing, a passage which comprises his opinion respecting the action of the tinging particles on the rays of light (A). All the other writers on the same subject, appear to agree in that established opinion; but they seem rather to have yielded to the authority of Sir Isaac Newton and other theorists, than to have appealed to the operations of their own art, from which the real cause and origin of colours is obviously deducible †."

47. The art of dyeing consists principally in covering white substances, from which light is strongly reflected, with transparent coloured media, which, according to their several colours, transmit more or less copiously the several rays reflected from the white substances.

---

* tics, bo i. pa ii. pr 5.

† *Manch. Mem.* ii. p. 131.

(A) The passage from Hellot is the following. "At present we only know of two plants which afford a blue colour after their preparation. The one is the *isatis* or *glastum*, otherwise called *pastel* or *woad*. In the preparation of these plants, the fermentation is continued till the putrefactive process of all the parts of the plant, the root excepted, has been induced; consequently there takes place a separation of all their principles, with a new combination and arrangement of these same principles, from which results an assemblage of particles greatly divided, which being applied to any substance, reflect the light in a very different manner from what they did when those particles were combined with the other parts of the plant, previous to fermentation." *Art de la Teinture des Laines*, p. 117.

stances. The transparent coloured media themselves reflect no light; and it is evident that, if they yielded their colours by reflecting instead of transmitting the rays, the whiteness or colour of the ground on which they are applied would not anywise alter or affect the colours which they exhibit. Such an erroneous conception of the principles of the art cannot fail greatly to obstruct its progress and improvement. All colouring matter is black when viewed by incident light, and all substances inclined to blackness, in proportion as they are copiously stored with tinging particles.

Coloured matters appear black by incident light.

48. As a farther illustration of this subject, we shall make another extract from the same author. "For the purpose," he observes, "of procuring masses made up of colouring particles, I reduced several transparent coloured liquors to a solid consistence by evaporation. When a gentle heat is employed in this operation, the colouring matter, which is thus concentrated, remains unimpaired, and capable of again imparting its colour unaltered, to other liquors. In this state the colouring particles reflect no colour; and as no light is transmitted through them, they are black. Among the liquors which I evaporated, were the tinctures and infusions of the colouring particles of red, purple, blue, and yellow flowers; of logwood, Brazil-wood, fustic, turmeric, red sanders, alkanet, sap-green, kermes, and other transparent coloured liquors, which are capable of being reduced to a solid consistence, without undergoing such changes during their evaporation, as to render them opaque.

Shewn by experiment.

Effect of colours on white bodies.

49. "White paper and linen may be tinged by dipping them in the infusions of flowers of different colours; and by spreading upon those white grounds the expressed juices of such flowers, their colours may be communicated to the paper and the linen. These means of tinging are somewhat similar to the application of vegetable dyes to linen, and of transparent water colours to paper, many of which consist of the colouring matter of plants, such as indigo, litmus, gamboge, &c.

50. "The consideration of these white substances affords much insight into the manner in which the natural colours of vegetables are produced. When the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, display that whiteness which is their distinguishing character. White paper and linen are formed of such fibrous vegetable matter, which is bleached by dissolving and detaching the heterogeneous coloured particles. When these are dyed or painted with vegetable colours, it is evident that they do not differ, in their manner of acting on the rays of light, from natural vegetable bodies, both yielding their colours, by transmitting through the transparent coloured matter the light which is reflected from the white ground; for it appears, that no reflective power resides in any of their component parts, except in their white matter only *."

51. Thus then it appears, that the colouring particles with which stuffs are dyed, being transparent, the reflected light must proceed entirely from the fibres of the cloth or stuff which are covered with the transparent colouring matter. If the stuff be already of a black colour, no other colour can be communicated to it; because it has not the power of reflecting any colour, and therefore it cannot transmit any. And if the stuff were of a red, blue, or yellow colour, it could not be dyed of any other colour excepting black; because the red, blue, or yellow rays only being reflected, no other rays could be transmitted. But these observations will strictly apply only when the whole of the surface of the cloth is of one uniform colour. They point out also the importance of the cloth being of a pure white colour before it is dyed, especially when it is to be dyed any bright colour; for then the rays are copiously reflected; so that any colour may be given by combining with it any colouring matter which has the power of transmitting only particular rays.

Stuffs to dyed sho be pure white.

Colouring matter a plied to stuffs sho be minu divided.

52. As it is by the force of affinity that the colouring matter enters into combination with the stuffs which are dyed, that this chemical action be complete, it is necessary that the matter be in a state of minute division. No permanent colour could be produced by merely covering the surface of the fibres of the stuffs with the colouring substance; for unless it adhere so strongly that it cannot be separated by mechanical action, or by means of any of the processes to which dyed stuffs must be subjected, it must appear to be of little value, and the object in view is not obtained. To allow the chemical action to take place between the colouring matter and the stuffs, the former is dissolved in some liquid, for which it has a weaker attraction than for the stuffs; so that when they are immersed in the solution, the colouring matter, in consequence of the stronger attraction which it has for the stuffs than for the solvent, combines with them, and thus they are dyed; and the facility with which this combination takes place, must obviously depend on the affinity between the colouring matter and the liquid holding it in solution, and the affinity between the cloth and the colouring matter. When these two affinities balance each other, no change takes place; but when the affinity between the stuff and the colouring matter prevails, the combination is effected, and the process proceeds more or less rapidly according to the force of this affinity.

Coloure bodies c pounds.

53. Coloured bodies are compounds; and several substances enter into their composition. In all coloured bodies some of the component parts have a strong affinity for oxygen, which they attract from the atmosphere. The permanency of a colour consists in its power of resisting the action of all substances to which it is exposed. This power varies greatly according to the nature of the colour and the kind of stuff. The durability of the same colours on animal and vegetable matters is very different. But before the colour of a body can be permanent, all its component parts must be combined together by such strong affinities, that the substances which come in contact with them shall not be able to unite with any of these parts, and thus form a new compound. Should such a decomposition take place, the colour of the body cannot be permanent; and if the decomposition be suddenly effected, the colour is immediately destroyed. If the new combination proceeds slowly, the decay of the colour is also slow and gradual.

The con bination oxygen produce change colour.

54. The combination of oxygen with some of the component parts of a coloured body, is one of the principal causes of the change of colours. The action of

---

* Ibid.

Colours, &c.

of oxygen on bodies is greatly promoted in particular circumstances. With the assistance of heat, almost all coloured bodies are decomposed by means of oxygen. At the temperature of 448°, wheat flour is deprived of its white colour, becomes first brown, and then changes to black. The oxygen enters into combination with the hydrogen, one of the component parts of the vegetable matter, and in this state it is driven off. The action of light produces effects similar to those of heat. A decomposition of the colouring matter takes place by means of the light to which the body is exposed; and one of its component parts combines with oxygen. The effects of light on the colour of wood have been long observed. Wood kept in the dark retains its natural appearance; but when it is exposed to the light it becomes yellow, brown, or of some other shade. This effect is found to be subject to considerable variations in different kinds of wood, and bears some proportion to the intensity of the light. If the solution of the green part of vegetables in alcohol, which is of a fine green colour, be exposed to the light of the sun, it very soon assumes an olive hue, and in the course of a few minutes it is entirely deprived of its colour. When the light is weak the change proceeds more slowly; and if it be kept in the dark no change whatever takes place; at least it requires a great length of time. Light seems to favour the tendency to decomposition in many bodies, by producing combinations of some of their constituent principles, as when water is formed by the union of oxygen and hydrogen, or carbonic acid by the union of carbone and oxygen. Some bodies even are deprived of the whole or part of their oxygen by the action of light. Oxymuriatic acid exposed to the light, becomes common muriatic acid by losing its oxygen; and the nitrate of silver becomes black by a partial decomposition and loss of its oxygen.

55. Such then seem to be the most general causes, the action of which produces changes in the colour of coloured bodies. It is either by the decomposition of the substances, in consequence of new compounds formed by the combination of some of the constituent parts; by some of these parts combining with oxygen; or by the addition or abstraction of oxygen. And to such changes colouring matters must be subjected from their compound nature; since they are most generally derived from animal or vegetable substances. The selection of such substances as resist the action of these causes, must therefore be an object of the greatest importance in the art of dyeing. A colour too which is sufficiently permanent ought to be such as will resist the action of acids, alkalies, soap, and other substances to which dyed cloth may be exposed.

M od of
pr ng the
pe anen-
cy a co-
lou

56. There is a great difference in colours with regard to their power of resisting the action of air and light; and as it is in this that their permanency chiefly consists, independent of their lustre, it becomes an object of great importance, to be able to ascertain by easy tests the durability or goodness of any colour. In France, where the art of dyeing was more under the regulation of government than in other countries, and a distinction was established by law between dyers of durable and fading colours, the means of ascertaining the permanency of colours became of still greater consequence. For the dyer of fading colours was subject to punishment if he produced colours which were too permanent; so rigorous and capricious were the laws which regulated these matters. The observations of M. Dufay on this subject laid the foundation of the regulations which were made to ascertain this point. For this purpose he made experiments by dyeing wool of all colours, with all kinds of colouring matters; and setting entirely aside the prejudices of the dyers, he collected most of the substances which he supposed might be employed in the art, and tried a great number of them, investigating their good or bad qualities with great care.

Of Colours, &c.

Dufay's.

57. His first experiments were made on woollen yarn; but finding afterwards that pieces of white cloth were more suitable to the purpose, he employed them. And that he might distinguish between permanent and fading colours, he exposed to the action of the sun and air for the space of twelve days, patterns of all colours which he had dyed with known substances. In this time durable colours were little injured, but those which were of a fading nature were almost entirely obliterated. But as the action of the sun might be less intense in cloudy weather, and thus the test would be less severe when that happened than during twelve days of bright sunshine; to obviate this inconvenience and uncertainty, he selected one of the worst colours, that is, one on which the sun had the greatest effect in the same time. This colour served as a standard in his experiments; and whenever he exposed stuffs to the air to prove the colour, he exposed a piece of this stuff along with them. He did not calculate by the number of days, but by the change on the colour of the standard stuff. For he kept the pattern exposed to the air till it had lost as much as the standard would have done by the action of the sun during twelve days in summer. He found from these experiments that it required four or five days longer in winter than in summer to produce the same effect.

58. But by this method of exposure to the air he had another object in view. This was to discover the proper proof for each colour. By the application of this proof a stuff is tried whether its colour be permanent or not. The pattern for instance is boiled with alum, tartar, soap, vinegar, &c. and by the effect of these substances its quality is ascertained. But from the component parts of the substances employed being then unknown, and the imperfect state of chemical science, these proofs must appear now to have been extremely precarious and insufficient. Some which were applied, from their natural effects, destroyed good colours, and produced no effect whatever on bad colours.

59. As the method he employed may suggest the means of discovering others founded on more correct principles and more accurate knowledge of the substances whose action is investigated, we shall mention the ingenious process which he followed. Having observed the effects of air and light on each colour, whether it were a good or bad colour; he tried the same stuff with different proofs, and stopped as soon as he discovered one which produced the same effects as the air. He then noted the weight of the ingredients, the quantity of water, and the length of time; and thus he was certain of producing on a colour an effect similar to that which the air would have produced, on the

supposition that it was dyed in the same way with his, as was the case in France where all the processes were then regulated by law. In this way he was enabled to ascertain the qualities of any colour, by making an analysis of the ingredients of which it was composed. By means of the proofs which were invented by this ingenious chemist, as much of a colour which was not of a durable nature, could be discharged in a few minutes, as would be lost by the action of the air and light in twelve or fifteen days. But as general rules framed for such trials are liable to many exceptions, from different unavoidable causes, their application in many cases may be considered as too severe. For instance, light colours require less active proofs than those which are of a deeper dye, and are more loaded with colouring matter; in the latter case, a considerable proportion of colouring substance may be carried off without much visible change on the colour; but in the former, by means of the same active test, the colour would be entirely obliterated. Every variety of shade, therefore, would have required a separate proof. The sun and the air must always be considered as the true test; and those colours which undergo no change in a certain time by this exposure, may be considered permanent colours, although they may be greatly changed by the application of proofs. Scarlet, which is dyed with cochineal alone, assumes a purple colour when tried by means of alum: but if scarlet be exposed to the sun, it loses some of its brightness, and becomes of a deeper shade; but this shade is different from that which is produced by alum. In certain cases then the same effect is not to be expected from the action of proofs and that of air and light.

Hellot's.

60. An experiment by Hellot is added as a farther illustration of a colour resisting the effects of exposure to the air, and yet being destroyed by the action of other substances. Brazil wood, he mentions, like other woods loaded with colour, produces a fading dye. With this he prepared a red, much finer than madder reds, and as bright as those made with kermes. This red was exposed to the air for the two last months of the year 1740, in which much rain fell, and for the two first of 1741; and notwithstanding the rain and bad weather, it was so far from losing, that it gained body. Yet this red, so durable in the air, is incapable of resisting the trial by tartar. Colours then may be reckoned sufficiently durable when they resist the effects of the air, although they are decomposed or destroyed by means of powerful chemical agents. From these observations, it is therefore obvious, that the only sure mode of ascertaining the permanency of colours, is by exposing the dyed stuffs for a certain length of time to the action of light and air.

Berthollet's.

61. Berthollet[*] proposes to employ the oxygenated muriatic acid as a quick and easy method of ascertaining the degree of durability which a colour may possess; because it acts like the air itself. When a trial is to be made on any piece of stuff, all that is necessary is to put a pattern of it into the acid, along with one of a stuff which is known to have been dyed properly. The relative power of resisting its action, which appears in the two patterns, becomes the test or measure of the quality of the colour. This liquor having a very powerful action on the colouring particles, must be employed in a very diluted state. In the use of this proof, it is attended with the advantage of exhibiting nearly the shades and changes through which a stuff must pass when it comes to be acted on by the air. Still, however, the same philosopher adds, the oxygenated muriatic acid is not to be considered as an infallible test; entire confidence can only be placed in the results obtained by the action of the air and light.

Test for silk.

62. To prove the colours of silk, it has been thought sufficient to expose them to heat in acetous acid or lemon juice; and those colours which stand this test are considered as permanent. When the colours have been obtained from the woods or archil alone, they are reddened by means of a vegetable acid; but if the solution of tin has been used to dye with these substances, the colour which has been prepared in an acid liquor suffers no change from vegetable acids. Thus the colour which is the least expensive in the preparation may be reckoned good by the test, although it will prove the least permanent. For silk, therefore, the oxygenated muriatic acid should be employed; but more especially exposure to the air.

For dye-stuffs.

63. It must appear an object of much importance to the dyer to be able to estimate the relative qualities of colouring substances of the same kind. The oxygenated muriatic acid may also be employed as a test for this purpose. By its use we may ascertain the proportional quantity of colouring matter in those substances, the nature of whose colouring particles is the same; as, for instance, when different parcels of indigo are to be compared together. In this case no foreign affinity can interrupt the action of the acid. And even if it should happen, that any considerable difference exists in the nature of colouring particles supposed to be the same, the action of this acid, it is probable, would still be a measure of their comparative goodness. If then it is proposed to compare together two or more colouring substances of the same nature, and to ascertain the relative quantity and quality of the colouring particles in each, all that is necessary is to compare the quantity of the same oxygenated muriatic acid which is required to produce the same degree of change in equal weights of each. For the qualities of these substances, or the quantities of colouring particles they contain, are directly proportional to the quantities of liquor required to produce the same effect on each. In conducting this experiment it is scarcely necessary to observe, that the colouring matter of each substance should be dissolved in a proper liquor, and that all the circumstances attending the comparison should be as nearly as possible the same.

Indigo.

64. If different kinds of indigo are to be compared together, let an equal weight of each be carefully powdered and introduced into separate matrasses with eight times their weight of concentrated sulphuric acid, and let them remain for 24 hours in a heat of from 100° to 120° Fahrenheit. Each solution is then to be diluted with water, and filtered. What remains on the filter is to be collected, ground in a glass mortar, and again digested with a little more sulphuric acid. These last solutions are then to be diluted with equal quantities of water, filtered and added to its corresponding liquor. As much oxygenated muriatic acid is then to be added to each solution as will discharge the colour, or bring them to a shade of yellow:

---

[*] *Elem. of Dyeing*, i. 180.

low: Thus the qualities of the different kinds of indigo may be ascertained by the quantity of oxygenated muriatic acid which is required to discharge their colour.

65. The process is more simple to compare the qualities of those colouring matters which are soluble in water. To equal bulks of the decoction, containing the same weight of each substance, the oxygenated muriatic acid is added till they are all brought to the same shade; and the quality of the substance is proportionate to the quantity of acid required.

Chap. II. *Of Mordants.*

66. The term mordant, derived from the French word *mordre*, to bite or corrode, is applied to those substances which are employed in dyeing, to facilitate or modify the combination of the colouring particles with the stuff. This name was given to these substances, from a supposed mechanical action which they produced on the substance to which the colour was communicated; and as no equivalent word has yet been proposed, the original is retained in the English language.

portance nor- ts.

67. The knowledge of this class of substances is not less important in the art of dyeing than that of colouring matters themselves, because on their action depend the variety, brightness, and durability of colours. The action of mordants is undoubtedly owing to chemical changes, so that more extensive observation and a complete knowledge of their effects, must greatly contribute to the improvement and perfection of the art of dyeing. It is by a new series of attractions which are introduced by their action, that the colouring particles are combined with the stuff, and the qualities and degrees of the colours are affected.

68. A mordant is not always to be considered as a simple agent; for, of the different ingredients which enter into its composition, new combinations are sometimes formed, so that the substances which are immediately employed, are not the direct agents in effecting the changes, but the new compounds which are produced.

e of ication

69. Mordants are applied in different ways, according to their nature, according to the nature of the colouring matter, and that of the stuff to be dyed. Sometimes they are mixed with the colouring particles, and sometimes the stuffs to which the colour is to be communicated, are impregnated with them; and sometimes both these processes are combined. In some of the more complicated operations of dyeing, substances are successively applied to stuffs in which the action of the last only produces the effect. In such cases, there is a gradual progress of combination; but it is only by the effect of the last compound which is formed, that the colour is evolved.

rated.

70. The effects of mordants are well illustrated in many of the processes which are followed in the art of printing linen; and for the illustration of these effects, we shall extract from Berthollet a short account of some of these processes. For linens to which it is proposed to give different shades of red, the mordant employed is prepared by dissolving in eight pounds of hot water, three pounds of alum, and one pound of acetate of lead, or sugar of lead. To this solution two ounces of potash, and afterwards two ounces of powdered chalk, are to be added. Our chemical readers will readily perceive, that the first change which takes place, is the decomposition of the alum, by means of the acetate of lead. The oxide of lead combines with the acid of the alum, and forms an insoluble salt, which is precipitated. The alumina which constitutes the base of the alum, unites with the acetous acid, and forms an acetate of alumina. The chalk and potash, according to Berthollet, serve to saturate the excess of acid; but it seems more probable that the addition of these substances is found necessary, on account of new decompositions which are effected by their action. Several advantages arise from the formation of the acetate of alumina, in the future changes which are to be effected. The alumina, or earthy basis of this salt, is retained in combination with the acid, by a much weaker affinity than when combined with sulphuric acid in the state of alum. Its affinity being thus weakened, it is more easily decomposed, and unites more readily with the stuff and colouring particles. Another advantage not less important is, that the effect of the acetous acid on the colouring matter being less powerful than the sulphuric acid, the acid liquor which remains after the separation of the alumina, does not produce such hurtful effects. And besides, as the acetate of alumina does not crystallize, the mordant which is thickened with starch or gum, to prepare it for being applied to the block on which the design is engraved, retains the same uniform consistence, which would not be the case if it contained alum, the latter being disposed to crystallize.

71. Let us now trace the different steps of the operation in printing a piece of cloth. When it has been impregnated with the mordant, in the manner determined by the design, it is immersed into a madder bath. Thus the whole of the cloth is coloured; but the colours are deeper on those parts to which the mordant has been communicated; because in those parts the colouring particles of the madder have entered into combination with the alumina and the stuff, forming a triple compound. The acetous acid separated from its earthy basis remains in the bath.

72. The effect of external agents on the colouring particles in this state of combination is much less considerable than when they are in a separate state, or only combined with the stuff, without the intermediate action of another substance. It is on this property that the subsequent operations depend. Having been immersed in the madder bath, the cloth is afterwards boiled with bran, and exposed to the open air by spreading it out on the grass; and the ultimate repetition of these operations is continued till the ground is whitened. The colouring particles of the madder which have not come in contact with the alumina are completely changed by entering into new combinations; while those which have united with it remain unaltered in consequence of the stronger affinity, so that those parts of the cloth which have been impregnated with the mordant, retain the colour and exhibit the design.

73. The decomposition of the colouring particles by boiling the stuff with bran, and exposure to the air, seems to be effected in a manner similar to the destruction of the colouring matter of flax, and is to be ac-

counted for in the same way. In the process of bleaching, indeed, alkaline substances are employed. But for the purpose of discharging the superfluous colouring-matter from printed cloths, bran is preferred as a substitute; because part of the colouring-matter, even when fixed by alumina, would be destroyed by the stronger action of alkalies; but as the action of the bran is much weaker, it affects only the colouring particles which have not come in contact with the alumina, and which by the action of the air are disposed to undergo a more easy solution.

74. Let us take another example with a different mordant. If, instead of alum, a solution of iron, as the acetate of iron, be employed, similar phenomena are exhibited. The solution of iron is decomposed by the particles of colouring-matter, and a triple compound is thus formed of the colouring-matter, the oxide of iron, and the stuff. But when this mordant is employed, a great variety of shades from brown to a deep black are obtained by the use of madder; and by a combination of alum and iron, the colours produced are of a mixed nature, inclining on the one hand to red, and to black on the other. And if another substance, as dyers weed, be substituted for the madder, other colours are obtained. Indeed the great variety of shades which are communicated to printed stuffs are derived from the colouring matter of madder, dyers weed, and indigo, fixed by alumina or the oxide of iron as mordants.

75. The different substances which enter into the composition of a mordant remain in combination till a new action is induced by the application of another substance. Thus, the affinity of the stuff for one of their constituent parts produces a decomposition and new combinations. But even this effect is sometimes incomplete, or does not at all take place without the action of another affinity, namely, that of the colouring particles. We have an example of this in the mixture of alum and tartar, which is one of the most common mordants in the dyeing of wool.

76. The following experiments were made by Berthollet, to ascertain the effects of these substances as mordants. He dissolved equal weights of alum and of tartar; and he found that the solubility of the tartar was increased by the mixture. By evaporation and a second crystallization, the two salts were separated, so that no decomposition had taken place. Half an ounce of alum and one ounce of wool were boiled together for an hour, a precipitate was formed, which being carefully washed, was found to consist of filaments of wool incrusted with earth. To this sulphuric acid was added, and the solution being evaporated to dryness, crystals of alum were obtained, with the separation of some particles of carbonaceous matter. The liquid in which the wool had been boiled being evaporated, yielded only a few grains of alum; what remained would not crystallize. This being redissolved and precipitated by means of an alkali, the alumina which was thrown down was of a slate colour, became black when placed on red-hot coals, and emitted alkaline vapours. In this experiment it appears that the alum was decomposed by the wool, and part of the alumina had combined with its most detached filaments which were least retained by the force of aggregation; that part of its animal substance had been dissolved and precipitated by the alkali from the triple compound.

77. The same experiment was repeated with half an ounce of alum and two drams of tartar; but no precipitation followed. A small portion of the tartar, and some irregular crystals of alum, were obtained by crystallization: the remainder refused to crystallize; but being diluted with water, precipitated by potash, and evaporated, it yielded a salt which burned like tartar. The wool which was boiled with the alum had a harsh feel; but the other retained all its softness. The first, after being subjected to the process of maddering, had a duller and lighter tint; but the colour of the latter was fuller and brighter.

78. In the first of these experiments the wool had effected a decomposition of the alum, had united with part of the alumina; and even part of the alum which retained its alumina had dissolved some portion of the animal matter. In the second experiment it appears, that the tartar and alum, between which there seems to exist a balance of affinities, can only act on each other by the intermediate action of the wool. The principal use of the tartar seems to be to moderate the action of the alum on the wool, by which it is injured. In the aluming of silk and thread, whose action on alum is less powerful than that of wool, tartar is not found requisite.

79. Whatever be the mode adopted in aluming, or whatever be the chemical changes which are produced, its final effect is the union of the alumina with the stuff. At first this combination has probably been incomplete, and a partial separation only of the acids has taken place; but it is perfected after the cloth has been boiled with the madder, as appeared in the case of printed stuffs *.

Substances used as mordants.

80. The principal substances which are employed for the purposes of mordants in the process of dyeing, are earths, metallic oxides, and some astringent matters. Alumina, which is now one of the most important, and in most general use, was very early employed as a mordant. This earth, as has been proved by direct experiment, and which is still farther confirmed by daily practice and observation, is useful in the art of dyeing, in consequence of the affinity which exists between it, the stuffs to be dyed, and the colouring matter. The affinity of alumina for animal matters, as wool and silk, as much stronger than that for vegetable productions, as cotton and linen; and hence the difference in the facility of fixing the colours on these different substances, and in their durability.

Alum.

81. When alumina is employed as a mordant, it is always in a state of combination, either in that of alum, which is the sulphate of alumina and potash, or united with the acetous acid, forming the acetate of alumina. Alum was employed at a very early period as a mordant. It was used by the ancients as it was found native, and therefore far from being in a state of purity. But as the nature of the constituent parts of alum was long unknown, its use in dyeing, as well as that of mordants in general, can only be ranked among the discoveries of modern chemistry. Alumina is also employed for a similar purpose, in combination with the acetous acid. This combination of alumina seems to have been first introduced about the beginning of the 18th century, and its introduction, like other valuable improvements,

---

* Elem. o Dyeing, i. 34.

improvements, was owing to accident. It was first employed by the calico-printers; but at what time, or by whom it was first used, is not exactly known. In one of the earliest recipes for preparing the mixtures employed as mordants in calico-printing, which Dr Bancroft, in his investigation of this subject, informs us he examined, the substances directed to be used are alum, sal ammoniac, saltpetre, red orpiment, and kelp; and these were to be mixed with water. In another, which he observes probably followed this, these ingredients were to be dissolved in vinegar. Sugar-of-lead was afterwards added in small quantity, and among a great variety of other substances which were employed at different times, litharge and white-lead came into use. In cases where vinegar was employed as the solvent, after different decompositions had taken place, a portion of acetate of alumina was formed, and the use of it was found to be followed with good effects. The quantity of sugar-of-lead, from observing the advantages derived from it, was gradually increased, and the employment of many of the other substances which were found by experience to be useless, was omitted. As the introduction of acetate of alumina was at first owing to chance, and as the changes and decompositions which took place in its formation were entirely unknown, it is not to be wondered at that the discovery or invention of this substance as a mordant, should not be distinctly ascertained.

82. The usual method of preparing the acetate of alumina is by pouring acetate of lead into a solution of alum. Both the salts are decomposed, by an exchange of their constituent parts. The sulphuric acid and the lead having a stronger affinity than the sulphuric acid and the alumina, combine together, and fall to the bottom in the form of an insoluble powder. The alumina at the same time enters into combination with the acetous acid, and remains dissolved in the liquid. But the application and effects of this substance in dyeing have been fully illustrated in treating of mordants in general.

83. Lime is the only earth, besides alumina, which is employed in dyeing. The affinity of lime for cloth is sufficiently strong; it is, however, found to answer the purpose of a mordant less perfectly than alumina, on account of the colour, which is not so good. It is employed, either in the state of lime water, or in that of sulphate of lime dissolved in water.

84. Metallic oxides have a strong affinity for animal substances. They have also so great an attraction for many colouring matters, that they separate from the acids with which they are combined, and are precipitated in combination with the colouring matters. In consequence of these different affinities, metallic oxides are of great importance in dyeing, and hence they were early applied in that art, and are now extensively used. But besides the affinity of these oxides for the colouring particles, and for animal substances, their solutions in acids possess properties by which they are more or less fit to be employed as mordants. Thus, those oxides which easily part with their acids, such as that of tin, are capable of entering into combination with animal substances, without the aid of colouring particles. All that is necessary is to impregnate the wool or the silk with a solution of tin. Some metallic substances yield only in combination, a white and colourless basis; but there are others which, by means of their own colour, produce modifications on the peculiar colour of the colouring particles. But the effects of many metallic oxides are extremely different, according to the proportion of oxygen with which they are combined; and this proportion is variable.

Of Mordants.

85. The affinity of metallic oxides for vegetable matters is considerably weaker than that which they have for animal substances. Metallic solutions, therefore, are found not to answer so well as mordants for colours in dyeing cotton or linen. Iron, indeed, is an exception, the oxide of which, it is well known, has a strong affinity for vegetable substances. Iron moulds on cotton or linen are owing to a combination of the oxide of iron with the vegetable matter.

86. Although almost all metallic oxides have an affinity for animal and vegetable matters, and might therefore be employed as mordants, yet two only, either because they are found to answer the purpose better, or because they are cheaper, are used to any extent. These are the oxides of tin and of iron.

Oxide of tin.

87. The use of the oxide of tin seems to have been first discovered by a German chemist of the name of Kuster or Kuffler. Observing the effects of a solution of tin in nitric acid, in giving a more vivid colour to stuffs dyed with cochineal, he was led to the discovery of the method of producing what has since been denominated *cochineal scarlet*. This discovery has been ascribed by others to Drebel, a Dutch chemist: and Macquer, who is of this opinion, supposes that the first solutions of tin were made with nitro-muriatic acid; but Dr Bancroft thinks that there is good reason to believe, that nitric acid only was used for some years for this purpose. According to Mr Delaval, the use of tin in dyeing was known to the ancients; and he supposes that the tin which the Phœnicians carried from Britain, was employed in this way, because he thinks that it is necessary to the production of red colours, whether from animal or vegetable matter. Dr Bancroft, however, has proved, that this opinion is founded in mistake.

88. About the year 1543, Kuster brought his secret to London, and it appears that it was first employed for this purpose at Bow. Hence the scarlet colour thus produced was denominated in this country the *Bow dye*. It seems too, that this mode of dyeing scarlet was very early introduced into Holland. A Frenchman of the name of Gobelins, received an account of the process from a Flemish painter called Kloeck, to whom it had been communicated by Kuster himself, and established it in France. Hence the Bow dye of England was known in other parts of Europe under the names of Dutch scarlet, scarlet of the Gobelins.

89. We have mentioned above, that the effects of metallic oxides as mordants in dyeing, depend on the different proportions of oxygen with which they may be combined. Thus, there are two oxides of tin containing different proportions of oxygen; the one contains 30 parts of oxygen in the 100, and the other contains 40. The oxide having the smaller proportion of oxygen, being exposed to the air, combines with a new portion of oxygen, and is soon converted into the oxide with the greater proportion, or the white oxide. It is this

this last which is the mordant, for if the other were applied to the stuff, it would soon be converted into the white oxide, by combining with an additional portion of oxygen.

90. Tin was first used as a mordant dissolved in nitric acid; but this preparation was found not to answer well, because the nitric acid readily converted the tin to the state of white oxide, in which state it is incapable of dissolving it. A precipitation of the tin took place, to prevent which, different substances were added, as common salt, or sal ammoniac; and thus a nitro-muriatic acid was produced, by which means the white oxide of tin was held in solution. It appears, however, that it was a considerable time before this method came into general use. Hellot, in an account of the process employed in his time for dyeing scarlet at Carcassonne, mentions that the tin was dissolved only in diluted nitric acid, adding that a Mr Baron was the first in that city who employed nitro-muriatic acid for the solution of tin, to prevent the precipitation of the oxide.

Preparation.

91. The ordinary solution of tin is made with that species of nitric acid called single aquafortis, and as it is usually prepared, it is found capable of dissolving about $\frac{1}{8}$ part of its weight of granulated tin. To each pound of aquafortis from one to two ounces of sea salt, or, what is deemed preferable by some, of sal ammoniac, are added. The acid is commonly diluted with a little water. The solutions which are made most slowly, and with the least separation of vapours, are found to succeed best. Two ounces of granulated tin are usually allowed for each pound of aquafortis; and the metal should be added at different times to moderate the rapidity of the solution. The water added to the acid should be weighed or measured, that a solution of the same strength may be always obtained. Eighteen or 20 pounds of this solution (B) are required to give a full cochineal scarlet to 100 pounds of woollen cloth.

92. But in the dyeing of scarlet, according to the ordinary process, a quantity of tartar is dissolved in the water, along with the nitromuriate of tin; and if the tartar be employed in sufficient quantity, the mordant is not to be considered as a nitromuriate of tin, but a tartrate or combination of tin with tartaric acid, in consequence of the decomposition which takes place, when these substances are brought to act on each other; for the nitromuriatic acid enters into combination with the potash or the tartar, while the acid of the tartar forms a compound with the oxide of tin.

93. It has been proposed by Haussman to employ the acetate of tin as a mordant for cotton and linen, instead of the nitromuriate. The acetate of tin is prepared by mixing together acetate of lead and nitromuriate of tin; and as the affinity between metallic oxides and vegetable substances is less powerful than the affinity between these oxides and animal matters, this mordant has been found preferable for cotton and linen stuffs; for the affinity of the oxide of tin for the acetous acid being weaker than for the nitromuriatic acid, it is more easily decomposed.

94. Dr Bancroft * tried the solution of tin in sulphuric acid, but found that it would not answer, on account of its destructive action on the cochineal colour; but he found afterwards, that, by the use of muriatic acid combined with $\frac{1}{4}$ its weight of sulphuric acid, good effects were obtained. The proportions which he employed were about 14 ounces of tin in a mixture of two pounds of sulphuric acid of the ordinary strength, with about 3 pounds of muriatic acid. This preparation may be made in the cold; but the solution is very rapidly promoted with a sand heat. The solution of tin made in these proportions, Dr Bancroft observes, is perfectly transparent and colourless; and in the space of three years, during which time he kept a solution of it, no precipitation had taken place. It produces, he adds, full twice as much effect as the dyer's *spirit*, or nitromuriatic solution of tin, and at less than one-third of the expence.

Oxide of iron.

95. Iron exists in two states of combination with oxygen. In the state of green oxide it contains the smaller proportion of oxygen, and in that of red oxide the greater proportion. In the last state it can only be employed as a mordant in dyeing; for if it be applied in the state of green oxide, in consequence of its strong affinity for oxygen, it attracts it from the atmosphere, and is soon converted into red oxide. The difficulty of removing iron spots or mould from cotton or linen shows with what force of affinity the red oxide of iron adheres to cloth. Iron is employed as a mordant in two states of combination, either in that of sulphate or acetate of iron. The sulphate of iron is generally employed for wool. The stuff is immersed in the solution of the salt in water. In this state it may be also used for cotton; but it is more commonly preferred in the state of acetate of iron. This is the combination of iron with the acetous acid, and it is usually prepared by dissolving iron in vinegar or sour beer; and the longer it is retained in the solution, it is found to act more powerfully as a mordant, because it is then in a state of more complete oxidation.

96. Some other saline bodies are also employed as mordants, to facilitate the combination of the colouring matter with the cloth, or to produce greater variety of shades of colour. Among these substances may be mentioned common salt, sal ammoniac, acetate of lead, sulphate and acetate of copper, sulphate of zinc.

Animal and vegetable matters.

97. Besides the mordants obtained from the class of salts, vegetable and animal substances also serve a similar purpose. In the process for dyeing the Turkey red, which will be afterwards described, the cotton stuffs should be impregnated with an animal substance, as oil; and the astringent principle is often employed as a medium of combination between colouring particles and stuffs. Tan, or the astringent principle, having a strong affinity for cloth, is found extremely useful as a mordant. It is commonly prepared by infusing nut-galls in water. The cloth is immersed in this solution, and allowed to remain till it is sufficiently impregnated with the tan. Sumach, which is the shoots of the *Rhus coriaria* Lin. a shrub which grows in the southern parts of

Mor- nts.

of Europe, is often used and prepared in the same way as the nut galls.

ts of ants e co- ou

98. Mordants have a very considerable effect on the colour; and, by varying the mordant, very different colours, and a great variety of shades, may be obtained from the same colouring matter. Some mordants themselves may be considered as communicating a colour without the addition of any colouring substance; and although, when the latter is added, a new set of affinities is brought into action, yet there is little doubt that the mordant also has a considerable share in fixing the shades of colour. Let us take an example in dyeing with cochineal. When the aluminous mordant is employed, the colour produced is crimson; but when the oxide of iron is substituted for the alumina, the colour obtained is black. The effect is obviously produced by a change in the action of the affinities between the colouring matter and the mordant, and the colouring matter and light. In the use of mordants, therefore, it is necessary to attend to their combined effects with the colouring matter employed, and to be able to communicate particular colours to stuffs with any degree of certainty, to know the amount of that effect.

99. Even in the mode of applying mordants, the variety of shades may be greatly multiplied. Different effects, for instance, are produced by previously impregnating the stuff with the mordant, or by mixing it with the bath. Different effects also arise from using heat, or, as the stuff is more or less rapidly dried; and this must appear to be the case, if we consider the different affinities which are in action, and the change on the action of these affinities in these different circumstances, as well as in others which can scarcely be appreciated. The combination of these substances which have an affinity for the stuff, and the decompositions which are the result of that combination, are greatly facilitated by the evaporation of the water or other liquid which held these substances in solution; because by its affinity, which is opposed to the action of the affinity between these substances and the stuff, the affinity of the latter produces a more limited effect. But in dyeing, the process should proceed slowly, that the substances may not be separated before their mutual affinities have begun to operate.

100. Considerable differences must be observed in the mode of employing the mordant, as the force of affinity between the stuff and the colouring matter is greater or less. When this affinity is strong, the mordant and the colouring substance may be mixed together; the compound thus formed, immediately enters into combination with the stuff. But if the affinity between the stuff and the colouring particles be weak, the compound formed of the latter and the mordant may separate, and a precipitation take place, before it can be attached to the stuff; and hence it is in these cases, that the mordant which is to serve as the medium of union between the stuff and the colouring matter, must be combined with the former, before the application of the latter. It is from these differences that different processes must be followed in fixing colouring matters on animal and vegetable productions; as for instance, in dyeing wool or silk black, or with cochineal.

Of Substances to be coloured.

101. In estimating the effects of mordants, and in judging of the most advantageous manner of applying them, it is necessary to attend to the combinations which may be formed, either by the action of the ingredients of which they are composed, or, by that of the colouring matter and the stuff. It is necessary also, to take into consideration the circumstances which may tend to bring about these combinations with more or less rapidity, or that may render them more or less perfect. The action which the liquor in which the stuff is immersed may have, either on its colour or texture, must also be considered; and to be able accurately to judge of the extent of this action, we must know the proportions of the principles of which the mordant is composed; which of these principles remains in an uncambined state in the liquor, and the proportion or quantity which is thus separated.

Chap. III. *Of the Nature and Properties of the Substances to which Colours are communicated in the Processes of Dyeing.*

102. In the more limited sense to which we have here restricted the art of dyeing, the substances to which colours are usually communicated by means of this art, are wool, silk, cotton, flax, and hemp. Of these, the two first are animal substances, and the three latter are derived from the vegetable kingdom. These two classes of bodies present striking differences, not only in structure, but also in their composition and chemical properties.

Difference between animal and vegetable matters.

103. Animal substances are distinguished from those which have a vegetable origin, by the nature of their constituent parts. The former contain a large proportion of azote, which exists sparingly in the latter. Hydrogen, or the base of hydrogen gas or inflammable air, is found in greater abundance in animal matters, than in vegetable productions. In the distillation of animal and vegetable substances, the difference of their constituent parts is not less remarkable. The former afford a large proportion of ammonia, or volatile alkali; the latter yield very little, and sometimes give out an acid substance. Animal matters afford much oil, while vegetable substances sometimes do not afford it in any perceptible quantity. From the nature of their component parts, animal substances produce a bright flame in burning; and their combustion is accompanied with a penetrating odour, which is owing to the formation and emission of ammonia and oil. Animal matters run rapidly into the putrefactive process, while vegetable substances more slowly undergo the changes which are induced by the vinous or acetous fermentation.

104. The constituent principles of animal substances have a stronger tendency than those which enter into the composition of vegetable matters, to assume the elastic form. On this account the cohesive force existing between the particles of the former is inferior to that of the particles of the latter. Hence animal matters are more disposed to combine with other substances, more liable to be destroyed by different agents, and to enter into combination with colouring particles. Thus, animal substances are destroyed by the caustic fixed alkalies, and they are decomposed by the nitric and sulphuric

phuric acids. The action of acids and alkalies on silk is less powerful than upon wool, and it is less disposed to combine with the particles of colouring matter. In this respect it bears some resemblance to vegetable substances; but on vegetable matters, the action of alkalies and acids is less powerful than on animal substances; and the action of acids is more feeble on cotton than on flax or hemp. It is even decomposed with considerable difficulty by means of nitric acid.

In the four following sections, we shall consider the peculiarities of these substances at greater length.

SECT. I. *Of Wool.*

Structure.

105. Wool, which is well known as the covering of sheep, derives its value from the length and fineness of its filaments. The filaments of wool are considerably elastic, for they may be drawn out beyond their usual length, and when the force is removed, they recover it again. The surface of the filaments of wool or hair is not perfectly smooth; for although no roughness or inequality can be discovered by the microscope, yet they seem to be formed of small laminæ placed over each other in a slanting direction, from the root of the filament towards its point, resembling the arrangement of the scales of a fish, which cover each other from the head of the animal to its tail; or perhaps they consist of zones placed over each other, as is observed in the horns of animals. This peculiarity of structure of the filaments of hair and wool is proved by a simple experiment. If a hair be laid hold of by the root in one hand, and drawn between the fingers of the other hand, from the root towards the point, scarcely any friction or resistance is perceived, and no noise is heard; but if it be grasped by the point, and passed in the same manner between the fingers from the point towards the root, a resistance is felt, and a tremulous motion is perceptible to the touch, while the ear is sensible to a slight noise. Thus it appears, that the texture of the surface of hair or wool is not the same from the root towards the point, as it is from the point towards the root. This is farther confirmed by another experiment. If a hair be held between the thumb and forefinger, and they are rubbed against each other in the longitudinal direction of the hair, it acquires a progressive motion towards the root. This effect depends not on the nature of the skin of the finger, or on its texture, for if the hair be turned, and the point placed where the root formerly was, the motion is reversed, that is, it will still be towards the root.

Felting.

106. On this peculiarity of structure, which was observed by M. Monge, depend the processes of felting and fulling, to which hair and wool are subjected, for different purposes. In the process of felting, the flocculi of wool are struck with the string of the bow, by which the filaments are separately detached, and dispersed in the air. These filaments fall back on each other in all directions on the table, and when a layer of a certain thickness is formed, they are covered with a cloth, on which the workman presses with his hands in all parts. By this pressure the filaments of wool are brought nearer to each other; the points of contact are multiplied; the progressive motion towards the root is produced by the agitation; the filaments entangle each other; and the laminæ of each filament, taking hold of those of the other filaments, which are in an opposite direction, the whole is retained in the state of close contexture.

Fulling

107. Connected with this operation is that of fulling. The roughness on the surface of the filaments of wool, and their tendency to acquire a progressive motion towards the root, produces considerable inconvenience in the operations of spinning and weaving. These inconveniences are obviated by covering the filaments with a coat of oil, which fills up the cavities, and renders the asperities less sensible. When these operations are finished, the stuff must be freed from the oil, which would prevent it from taking the colour with which it is to be dyed. For this purpose it is taken to the fulling-mill, where it is beaten with large beetles, in a trough of water, through which clay has been diffused. The clay unites with the oil, which being thus rendered soluble in the water, is carried off by fresh portions of water, conveyed to it by proper apparatus. In this way the stuff is scoured; but this is not the sole object of the operation. By the alternate pressure of the beetles, an effect similar to that of the hands in the operation of felting, is produced. The filaments composing a thread of warp or woof, acquire a progressive motion, are entangled with the filaments of the adjoining threads; those of the latter into the next, and so on, till the whole threads are felted together. The stuff is now contracted in all its dimensions, and participating both of the nature of cloth and of felt, may be cut without being subjected to ravel; and when employed to make a garment, requires no hemming. In a common woollen stocking web, after this operation, the stitches, when one happens to slip, are now no longer subject to run, and the threads of the warp and woof being less distinct from each other, the whole stuff is thickened, and forms a warmer clothing.

Importa of wool.

108. The various manufactures of which wool constitutes the basis, are justly regarded among the most important to man in civilized society. Accordingly, the production of fine wool, and the causes which retard or improve the breed of sheep from which it is obtained, have greatly occupied the attention of economists and philosophers in our own, as well as in other countries. The wool of different breeds of sheep, in different countries, it is well known, possesses very different qualities, both with regard to the fineness of the filament, and the colour. Some is of a white, or yellow, and some of a reddish, and black colour. Excepting the wool of the breed of sheep in Andalusia, the Spanish wool was formerly all of a brownish black colour. This was preferred by the native Spaniards; and even at this day, the dress of some religious orders in Roman Catholic countries, consists of cloth manufactured from this wool, and retaining its natural colour. But for the purposes of dyeing, white wool is now always preferred, because it is found susceptible of receiving better and more durable colours.

Scourin

109. Wool is naturally covered with a kind of grease or oil, which is found to preserve it from insects or moths, and on this account this greasy matter is not removed, or the wool is not scoured, till it is to be dyed or

Of Sub-
ances to
colour-
ed.

or spun (c). The process for scouring wool is the following. It is put for about a quarter of an hour into a kettle, with a sufficient quantity of water, to which a fourth part of putrid urine has been added. It is then heated to such a degree as the hand can bear, occasionally stirred, and after being taken out, is allowed to drain. It is then put into a basket, and exposed to a stream of running water, and moved about till the grease is so completely separated, that it no longer renders the water turbid. After being drained, it is sometimes found to lose by this operation above one-fifth of its weight. It is almost unnecessary to observe, that the more carefully and completely this process is performed, the better the wool is fitted to receive the colouring matter. Our chemical readers will readily perceive the nature of the changes which are effected in this process of scouring. The ammonia, or volatile alkali, which exists in the urine, combines with the oil of the wool, and forms a soap, which being soluble in water, is dissolved, and carried off.

ing.

110. Wool is either dyed in the fleece, or after it is spun into threads, or when it has been manufactured into cloth. For the purpose of forming cloths of mixed colours, it is dyed before it is spun; for the purposes of tapestry, it is dyed in the state of thread; but most commonly it is subjected to this process after it has been manufactured into cloth. In these different states, the quantity of colouring matter which is taken up is very different. The proportion is largest when it is dyed in the fleece, because then the filaments being more separated, a greater surface is exposed to the action of the colouring particles. For a similar reason the quantity of colouring matter taken up is greater when in the state of thread or yarn, than when it is formed into cloth. But cloths themselves must vary greatly in this respect, according to their different qualities. Their different degrees of fineness, or closeness of texture, will produce considerable variations; and besides, the difference in the quantity and dimensions of the substances to be dyed, the different qualities of the ingredients employed in the process, and the different circumstances in which it is performed, should be a caution against trusting to precise quantities, regulated by weight or measure, which are recommended according to general rules. According to the fineness of the texture of the wool, and the nature of the colouring matter employed, it is found to be more or less penetrated with this matter. The coarse wool from the thighs and tails of some sheep, receives colours with difficulty, and the finest cloth is never completely penetrated with the scarlet dye. The interior of the cloth appears always, when cut, of a lighter shade, and sometimes even white.

SECT. II. *Of Silk.*

Ori

111. Silk, which forms the basis of one of the richest and most splendid parts of dress, among the wealthy and luxurious, in civilized society, is the production of different species of insects. The *phalæna bombyx*, or silk-worm, which is a native of China, attracted the attention of mankind in that country, from the earliest ages. The honour of having first collected and prepared silk from the cocoons or balls in which it is wound up by the insect, during its metamorphosis, is ascribed by the Chinese historians, to the wife of an emperor. The *phalæna atlas*, Lin. which is also a native of China, is said to form larger cocoons, and to yield a stronger silk. The silk-worm was first carried from China to Hindostan, and afterwards to Persia. Silk seems not to have been known to the Greeks or Romans till the time of Augustus. Its nature and origin were little understood, and for many ages it was so scarce, that it could only be purchased at a price which was equal to its weight in gold. The emperor Aurelian, it is said, from a principle of economy, resisted the urgent solicitations of his empress, who wished to have a silken robe, alleging the extravagance of the expence. About the middle of the sixth century, two monks returned from India to Constantinople, and brought with them a considerable number of silk-worms, with instructions for managing and breeding them, as well as for collecting, preparing, and manufacturing the silk. Establishments were thus formed at Corinth, Athens, and other parts of Greece. The crusades, which greatly contributed to the diffusion of different kinds of knowledge, by the intercourse which took place between different countries, proved useful in disseminating the knowledge of rearing the silk-worm, and preparing and manufacturing its valuable productions. Roger, king of Sicily, about the year 1130, returning from one of these frantic expeditions, brought with him from Athens and Corinth, several prisoners, who were acquainted with the management of silk-worms, and the manufacturing of silk. Under their superintendance, manufactories were established at Palermo and Cagliari in Sicily. This example was soon adopted, and followed in different parts of Italy and Spain. In the time of James I. an attempt was made to establish the silk-worm in England. For this purpose the culture of the mulberry-tree, on which the insects feed, was strongly recommended by that prince to his subjects; but the attempts which were made have been hitherto unsuccessful.

Scouring.

112. The fibres of silk are covered with a coating or natural varnish of a gummy nature. To this are ascribed its stiffness and elasticity. Besides this varnish, the silk which is usually met with in Europe is impregnated with a substance of a yellow colour, and for most of the purposes to which silk is applied, it is necessary that it should be deprived, both of the varnish and of the colouring matter. On this account it must be subjected to the operation of scouring; but for silks which are to be dyed, this process should not be carried so far as for those which are merely to be whitened; and different colours, it is observed, require different degrees of this operation. The quantity of soap constitutes the chief difference. A hundred pounds of silk boiled in a solution of 20 lbs. of soap for three or four hours, adding new portions of water during the evaporation, are sufficiently prepared for receiving common colours.

(c) According to an observation of Reaumur, rubbing any stuff with greasy wool, is sufficient to preserve it from moths.

colours. For blue colours, the proportion of soap must be increased; and scarlet, cherry-colour, &c. require a still greater proportion, for the ground must be whiter for these colours.

Process, when employed white.

113. Silk which is to be employed white, must undergo three operations. In the first the hanks are immersed in a hot but not boiling solution of 30lbs. of soap to 100 of silk. When the immersed part is freed from its gum, which is known by its whiteness, the hanks are shaken over, as the workmen term it, so that the part which was not previously immersed may undergo the same operation. They are then wrung out as the process is completed. In the second operation the silk is put into bags of coarse cloth, each bag containing 20 or 30 lbs. These bags are boiled for an hour and a half, in a solution of soap prepared as before, but with a smaller proportion of soap; and that they may not receive too much heat, by touching the bottom of the kettle, they must be constantly stirred during the operation. The object of the third operation is to communicate to the silk different shades, to render the white more agreeable. These are known by different names, as China-white, silver-white, azure-white, or thread-white. For this purpose a solution of soap is also prepared, of which the proper degree of strength is ascertained by its manner of frothing by agitation. For the China-white, which is required to have a slight tinge of red, a small quantity of anatto is added, and the silk is shaken over in it till it has acquired the shade which is wanted. In other whites, a blue tinge is given by adding a little blue to the solution of soap. The azure-white is communicated by means of indigo. To prepare the azure, fine indigo is well washed two or three times in moderately warm water, ground fine in a mortar, and boiling water poured upon it. It is then left to settle, and the liquid part only, which contains the finer and more soluble parts, is employed.

114. Some use no soap in the third operation; but when the second is completed, they wash the silks, fumigate with sulphur, and azure them with river water, which should be very pure. But all these operations are not sufficient to give silk that degree of brightness which is necessary, when it is to be employed in the manufacture of white stuffs. For this purpose it must undergo the process of sulphuration, in which the silk is exposed to the vapour of sulphur; for an account of which see Bleaching. But before the silk which has been treated in this way is fit for receiving colours, and retaining them in their full lustre, the sulphur which adheres to it must be separated by immersion and agitation for some time in warm water, otherwise the colours are tarnished and greatly injured.

Mode of extracting its colouring matter.

115. It has long been an object of considerable importance, to deprive silk of its colouring matter, without destroying the gum, on which its stiffness and elasticity depend. A process for this purpose was discovered by Beaumé, but as it was not made public, others have been led to it by conjecture and experiment. The following account, given by Berthollet, is all that has transpired concerning this process. A mixture is made with a small quantity of muriatic acid and alcohol. The muriatic acid should be in a state of purity, and particularly should be entirely free from nitric acid, which would give the silk a yellow colour. In the mixture, thus prepared, the silk is to be immersed. One of the most difficult parts of the process, especially when large quantities are operated upon, is to produce a uniform whiteness. In dyeing the whitened silk, there is also considerable difficulty to prevent its curling, so that it is recommended to keep it constantly stretched during the drying. The muriatic acid seems to be useful in this process, by softening the gum, and assisting the alcohol to dissolve the colouring particles which are combined with it. The alcohol which has been impregnated with the colouring matter may be again separated from it and purified, that it may serve for future operations, and thus render the process more economical. This may be done by means of distillation with a moderate heat, in glass or stone-ware vessels.

Aluming.

116. The preparation with alum is a very important preliminary operation in the dyeing of silk. Without this process, few colours would have either beauty or durability. Forty or fifty pounds of alum, previously dissolved in warm water, are mixed in a vat, with forty or fifty pailfuls of water; and to prevent the crystallization of the salt, the solution must be carefully stirred during the mixture. The silk being previously washed and beetled, to separate any remains of soap, is immersed in this alum liquor, and at the end of eight or nine hours is wrung out, and washed in a stream of water. A hundred and fifty pounds of silk may be prepared in the above quantity of liquor; but when it begins to grow weak, which may be known by the taste, 20 or 25 lbs. of dissolved alum are to be added, and the addition repeated till the liquor acquires a disagreeable smell. It may then be employed in the preparation of silk intended for darker colours, till its whole strength is dissipated. This preparation of silk with alum must be made in the cold; for when the liquor is employed hot, the lustre is apt to be impaired.

Sect. III. *Of Cotton.*

Origin.

117. Cotton is the down or wool contained in the pods of a shrubby plant, which is a native of warm climates. Of this genus of plants (*Gossypium* Lin.) there are four species, one of which only is perennial; the other three are annual plants; but of these there are many varieties, occasioned by the difference of soil or temperature in which they are produced. The principal differences among cottons consist in the length and fineness of the filaments, and in their strength and colour.

Structure.

118. The peculiar structure of the fibres of cotton is not well known. According to the microscopic observations of Leeuwenhoeck, they have two sharp sides, to which are ascribed the irritation and inflammation of wounds and ulcers, when they are dressed with cotton instead of lint. This peculiarity of structure, it is also supposed, may occasion some difference in the conformation, and number of the pores, on which alone the disposition of cotton to admit and retain colours better than linen, seems to depend. In this respect, however, it is inferior to wool and silk, because, on account of its vegetable nature, its affinity for colouring matter is less powerful.

Has a less affinity than wool for colouring matter.

119. It is well known that silk, cotton, and linen have a weaker affinity for colouring matter than wool. Le Pileur d'Apligny attempts to explain this by supposing

Of Sub-auces to colour-ed.

that the pores of these substances are smaller than those of wool, and that the colouring particles enter them less easily and freely. But according to the observation of Dr Bancroft, the reverse of this seems to be the fact; for there is little difficulty in making silk, cotton, and linen, imbibe colouring matter, even when it is applied cold, without any artificial dilatation of the pores, which is always necessary in the dyeing of wool. The only real difficulty is to make them retain the colours after the matter has been imbibed; because being admitted so readily into their undilated pores, the particles cannot be afterwards compressed and retained by the contraction of these pores, as is the case with wool. It requires double the quantity of cochineal which is necessary for wool to communicate a crimson colour to silk; a certain proof that it can take up a greater quantity, and consequently that the pores are sufficiently large and accessible. Unbleached cotton is always preferred for dyeing Turkey red; because in this state the colour is found to be most permanent; and this is ascribed to the pores or interstices being less open than after it has undergone the process of bleaching. The same thing is observed of raw or unscoured silk. It is found to combine more easily with the colouring matter, and to receive a more permanent colour in this state than after it has been scoured and whitened. "The openness of cotton and linen (says Dr Bancroft), and their consequent readiness to imbibe, both colouring particles, and the earthy or metallic bases employed to fix most of them, are circumstances upon which the art of dyeing and calico-printing is in a great degree founded *." But is not this too mechanical an explanation of the phenomenon? Might it not rather be alleged that it is owing to a difference of affinities which exists between the particles of colouring matter and the substance which is separated from the silk or cotton by the process of bleaching or scouring? This substance probably acts the part of a mordant; and having a stronger affinity for the stuff and for the colouring matter than the stuff has for the latter, the colour communicated is more durable when silk or cotton is dyed in the unbleached or unscoured state.

Prepara-tio for dy g.

120. To prepare cotton stuffs for receiving the dye, several operations are necessary. It must first undergo the process of scouring. By some it is boiled in sour water, or in alkaline ley. It should be kept boiling for two hours, then wrung out, and rinsed in a stream of water till the water comes off clear. The stuffs to be prepared should be soaked for some time in water, mixed with not more than $\frac{1}{10}$th part of sulphuric acid, and then carefully washed in a stream of water, and dried. In this operation the acid combines with a portion of calcareous earth and iron, which would have interrupted the full effect of the colouring matter in the process of dyeing.

Al ing.

121. Aluming is another preliminary process in the dyeing of cotton. The alum is to be dissolved in the manner already described, in preparing silk. Each pound of cotton stuff requires four ounces of alum. By some a solution of soda, about $\frac{1}{16}$th part of the alum, and by others a small quantity of tartar and arsenic are added. The thread is to be impregnated by working it in small quantities with this solution. The whole is then put into a vessel, and the remaining part of the liquor is poured upon it. In this state it is left for 24 hours, after which it is removed to a stream of water, and allowed to remain for an hour and a half, or two hours, to extract part of the alum. It is then to be washed. By this operation, cotton is found to gain an addition of about $\frac{1}{40}$th part of its weight.

Galling.

122. The operation of galling is another preparatory process in the dyeing of cotton stuffs. The quantity of astringent matter employed must be proportioned to its quality, and the amount of the effect required. Powdered galls are boiled for two hours in a proportion of water, regulated by the quantity of thread to be galled. This solution being reduced to such a temperature as the hand can bear, is divided into a number of equal parts, that the thread may be wrought pound by pound. The whole stuff is then put into a vessel, and the remaining liquor poured upon it, as in the former process. It is then left for 24 hours, if it is to be dyed black, but for other colours, 12 or 15 hours are found sufficient. It is then wrung out and dried.

In the galling of cotton stuffs, which have already received a colour, the precaution should be observed of performing this operation in the cold, otherwise the colour is subject to injury.

123. Berthollet informs us, that cotton which had been alumed acquired more weight in the galling than that which had not previously undergone that process; for although alum adheres but in small quantities to cotton, it communicates to it a greater power of combining, both with the astringent principle, and with the colouring particles. This, we may add, may be considered as a good instance of the action of intermediate affinities, and of the advantage to be derived to the art of dyeing, from investigating and observing this action.

SECT. IV. *Of Flax.*

Origin.

124. Flax and hemp nearly resemble each other in their general properties; and so far as relates to the process of dyeing, what is said of the one may be applied to the other. Flax or lint is obtained from the bark of *Linum usitatissimum*, and hemp from that of *Cannabis sativa*.

Watering.

125. Before flax is properly prepared to receive the dye, it must be subjected to several processes. One of the most important is that of watering, by which the fibrous parts of the plant are separated, and brought to that state in which they can be spun into threads. As the quantity and quality of the product depend much on this preliminary operation, it becomes of the greatest consequence that it be properly conducted. During this process, carbonic acid and hydrogen gas are given out. The extrication of these gases is owing to a glutinous juice which holds the green colouring part of the plant in solution, and which is the medium of union between its cortical and ligneous parts, undergoing a certain degree of putrefaction. This substance seems to resemble the glutinous part which is held dissolved in the juice obtained from plants by pressure; is separated from the colouring particles by means of heat; readily becomes putrid, and by distillation affords ammonia. But although it is held in solution with the expressed juice, it would appear that it cannot be separated from the cortical parts completely, by means of water; and hence it happens, that hemp or flax

---

* ilos. of P manent C ers, 71.

watered in too strong a current, has not the requisite softness and flexibility. But on the other hand, if the water employed in this operation be stagnant and in a putrid state, the hemp or flax becomes of a brown colour, and loses its firmness. In the one case, the putrefactive process is interrupted; in the other it is continued too long, and carried too far. This process, therefore, is performed with the greatest advantage in places near the banks of rivers, where the water may be changed so frequently as to prevent such a degree of putrefaction as would be injurious to the flax, as well as prejudicial to the workmen, from noxious exhalations; and, at the same time, not so frequently as to retard or interrupt those changes which are necessary for rendering the glutinous substance soluble in water.

126. By the process of watering flax, and by drying before and after that process, the green coloured particles undergo a similar change to that which is observed in the green substance of the plants exposed to the action of air and light. The next part of the process, therefore, after watering, is to spread it out upon the grass, and thus expose it for some time to the air and sun. By this means the colour of the lint is improved, and the ligneous part becomes so brittle, that it is easily separated from the fibrous part. This operation, as is well known, is usually performed by machinery.

Structure.

127. The fibres of lint possess no perceptible degree of elasticity, and they appear to be perfectly smooth. No ronghness or ineqnality can be detected by the feel, and no asperities can be perceived, even with the assistance of the microscope. Experience shows, that it produces no irritation on wounds or sores which are dressed with it, as is known to happen from a similar application of cotton stuffs.

Preparations for dyeing.

128. Flax which is intended for dyeing must be subjected to a similar series of operations with cotton, in the different processes of scouring, aluming and galling. A repetition of the mode of performing these operations is therefore unnecessary.

Chap. IV. *Of the Operations of Dyeing.*

129. Before we proceed to the detail of the processes of dyeing, we shall throw out a few hints on the operations in general, some of which may perhaps be useful to the practical dyer.

Advantages of large manufactories.

130. The works which are carried on in extensive manufactories, it has been observed, are followed with advantages which are unknown to those which are conducted ou a limited scale or in a detached manner. By the subdivision of labour, each workman directing his attention to one or a few objects, acquires a great facility and perfection of execution, by which means the saving of time and labour becomes considerable. This principle is particularly applicable to the art of dyeing, because the preparation which remains after one operation may often be advantageously employed in another. A bath from which the colouring matter has been in a great measure extracted in the first operation, may be used as a ground for other stuffs, or with the addition of a fresh portion of ingredients may form a new bath. The galls which have been applied to the galling of silk may answer a similar purpose for cotton or wool. From this it must appear that the limitations and restrictions under which the art of dyeing labours in some countries must tend to obstruct its progress and improvement. An extensive plan of operations, by which the different branches of the art are connected together, would effectually prevent the loss of ingredients, time, fuel, and labour.

Dye-hous

131. A dye-house, which should be set down as near as possible to a stream of water, should be spacious and well lighted. It should be floored with lime and plaster; and proper means should be adopted to carry off water or spent baths by forming channels or gutters, so that every operation may be conducted with the utmost attention to cleanliness.

Caldrons.

132. The size and position of the caldrons are to be regulated by the nature and extent of the operations for which they are designed. Excepting for scarlet and other delicate colours, in which the tin is used as a mordant, in which case tin vessels are preferable, the caldrons should be of brass or copper. Brass, being less apt than copper to be acted on by means of chemical agents, and to communicate spots to the stuffs, is fitter for the purpose of a dyeing vessel. It is scarcely necessary to say that it is of the greatest consequence that the coppers or caldrons be well cleaned for every operation; and that vessels of a large size should be furnished at the bottom with a pipe and stop-cock for the greater conveniency of emptying them: and there must be a hole in the wall or chimney above each copper to admit poles for the purpose of draining the stuffs which are immersed, so that the liquor may fall back into the vessel, and no part may be lost.

Apparatu for silk.

133. Dyes for silk, where a boiling heat is not found necessary, are prepared in troughs or backs, which are long copper or wooden vessels. The colours which are used for silk are extremely delicate. They must therefore be dried quickly, that they may not be long exposed to the action of the air, and there may be no risk of change. For this purpose, it is necessary to have a drying room heated with a stove. The silk is stretched on a moveable pole, which by the dyers is called a shaker. This is hung up in the heated chamber, and kept in constant motion to promote the evaporation.

For stuffs of cloth.

134. For pieces of stuffs, a winch or reel must be constructed; the ends of which are supported by two iron forks which may be put up at pleasure in holes made in the curb on which the edges of the copper rest. The manipulations in dyeing are neither difficult nor complicated. Their object is to impregnate the stuff to be dyed with the colouring particles, which are dissolved in the bath. For this purpose, the action of the air is necessary, not only in fixing the colouring particles, but also in rendering them more vivid; while those which have not been fixed in the stuff are to be carefully removed. In dyeing whole pieces of stuff, or a number of pieces at once, the winch or reel mentioned above must be employed. One end of the stuff is first laid across it, and by turning it quickly round, the whole passes successively over it. By turning it afterwards the contrary way, that part of the stuff which was first immersed, will be the last in the second immersion, and thus the colouring matter will be communicated as equally as possible.

For wool.

135. In dyeing wool in the fleece, a kind of broad ladder

ladder with very close rounds, called by the dyers of this country, a *scraw*, or *scray*, is used. This is placed over the copper, and the wool is put upon it, for the purpose of draining and exposure to the air, or when the bath is to be changed. If wool is dyed in the state of thread, or in skains, rods are to be passed through them, and the hanks turned upon the skain sticks in the liquor. This is called *shaking over*. When silk or thread is in the same state, it undergoes a similar operation.

136. To separate the superabundant colouring particles, or those which have not been fixed in the stuff, silk or thread, after being dyed, it must be wrung out. This operation is performed with a cylindrical piece of wood, one end of which is fixed in the wall, or in a post. This operation is often repeated a number of times successively, for the purpose of drying the stuffs more rapidly, and communicating a brighter lustre.

137. When, after a certain quantity of fresh ingredients is added to a liquor, and it is stirred about, it is said to be *raked*, because it is mixed with the rake.

138. In dyeing, one colour is frequently communicated to stuffs, with the intention of applying another upon it, and thus a compound colour is produced. The first of these operations is called *giving a ground*.

139. When it is found necessary to pass stuffs several times through the same liquor, each particular operation is called a *dip*.

140. A colour is said to be *rosed*, when a red colour having a yellow tinge, is changed to a shade inclining to a crimson or ruby colour; and the conversion of a yellow red to a more complete red, is called *heightening* the colour.

141. In addition to these general remarks, we might give more minute details of the different operations which are employed in dyeing; but as we cannot presume that they would be of much advantage to the practical dyer, we shall not indulge ourselves in useless description. "Although the manipulations of dyeing," says Berthollet, "are not very various, and appear extremely simple, they require very particular attention, and an experienced eye, in order to judge of the qualities of the bath, to produce and sustain the degree of heat suited to each operation; to avoid all circumstances that might occasion inequalities of colour, to judge accurately whether the shade of what comes out of the bath suits the pattern, and to establish the proper gradations in a series of shades *."

142. We shall conclude this chapter with a few observations on the qualities and effects of different kinds of water, which may be considered as one of the most essential agents in the art of dyeing. It is almost unnecessary to say, that water which is muddy, or contains putrid substances, should not be employed; and indeed no kind of water which possesses qualities distinguished by the taste, ought to be used. Water which holds in solution earthy salts, has a very considerable action on colouring matters, and it is chiefly by means of these salts. Such, for instance, are the nitrates of lime and magnesia, muriate of lime and magnesia, sulphate of lime, and carbonate of lime and of magnesia.

143. These salts which have earthy bases, oppose the solution of the colouring particles, and by entering into combination with many of them, cause a precipitation, by which means the colour is at one time deeper, and at other times duller and more faint than would otherwise be the case. Waters impregnated with the carbonates of lime and magnesia, yield a precipitate when they are boiled; for the excess of carbonic acid which held them in solution is driven off by the heat; the earths are thus precipitated, and adhering to the stuffs to be dyed, render them dirty, and prevent the colouring matter from combining with them.

144. It is of much consequence to be able to distinguish the different kinds of water which come under the denomination of *hard water*, that they may be avoided in the essential operations of dyeing; but to detect different principles contained in such waters, and to ascertain their quantity with precision, require great skill, and very delicate management of chemical operations, which the experienced chemist only can be supposed to possess. For the methods to be followed when such accuracy is required, we must refer to the analysis of mineral waters, of which a full view is given in the treatise on chemistry, and content ourselves with mentioning some simple tests which are of easy application.

145. One of these tests is the solution of soap, by which it may be discovered whether water contain so large a portion of any of these saline matters as may be injurious to the processes. Salts which have earthy bases, have the property of decomposing soap by the action of double affinity. The acid of the salt combines with the alkali of the soap, and remains in solution, while the earth of the salt and the oil of the soap enter into combination, and form an earthy soap which is insoluble in water, and produces the curdling appearance which is the consequence of this new combination. Water, then, which is limpid and not stagnant, which has no perceptible taste or smell, and has the property of dissolving soap without decomposition, may be considered as sufficiently pure for the processes of dyeing. All waters which possess these qualities will be found equally proper for these purposes.

Method of purifying.

146. But, as it is not always in the power of the dyer to choose pure water, means of correcting the water which would be injurious to his processes, and particularly for the dyeing of delicate colours, have been proposed. Water in which bran has been allowed to become sour, is most commonly employed for this purpose. This is known by the name of *sours*, or sour water. The method of preparing sour water is the following. Twenty-four bushels of bran are put into a vessel that will contain about 10 hogsheads. A large boiler is filled with water, and when it is just ready to boil, it is poured into the vessel. Soon after the acid fermentation commences, and in about 24 hours the liquor is fit to be applied to use. Water which is impregnated with earthy salts, after being treated in this way, forms no precipitate by boiling. It is probable that the sour water decomposes the carbonate of lime and magnesia, because the vegetable acid which is formed during the fermentation, combines with the earthy basis, and sets the carbonic acid at liberty.

147. Some of the substances, with which waters are impregnated, or those which are merely diffused in them in a state of very minute division, may be separated by means of mucilaginous matters. The mucilage coagulates

coagulates by means of heat, and carrying with it the earths separated by boiling, as well as those substances which are simply mixed with the water, and render it turbid, rises to the surface, and forming a scum, may be easily removed.

148. Saline matters having earthy bases, which in general are injurious in dyeing, may in some cases be useful, because by their action, modifications of different colours may be produced. A water of this kind, for instance, would have the effect of communicating to the colour of cochineal a crimson shade.

149. River water, which is apt to be impregnated with earthy salts, may, at different times, contain very different proportions of these salts; and although the dyer may follow exactly the same process, he may be surprised to find considerable variations in the shades of his colours. This arises from the different degrees of impregnation with these saline matters which the water undergoes, as the bed of the river is of greater or less extent, or the waters flow over those places from which they derive these earthy salts. To obtain the same result in the process, therefore, it would be necessary to make certain variations according to the state of impregnation of the water.

PART II. OF THE PRACTICE OF DYEING.

150. IN the preceding part, we have endeavoured to give a general view of the principles on which the art of dyeing depends. We have considered the physical and chemical properties of colours and colouring matters, the nature of the substances to which colours are communicated, and the agents or means by which this is effected; and from the experiments and observations of philosophers, whose investigations have been directed to this subject, it appears that these changes are entirely owing to chemical affinities, by which decompositions are effected, and new combinations formed, among the constituent parts of the substances employed. A precise and full knowledge of the effects of these chemical agents would render the theory of dyeing complete; and although much has been already done by the chemical philosophers whom we have had occasion frequently to quote, yet experiments and observations are still wanting to form a theory of this art on fixed and rational principles. This, it is obvious, can only be done by chemical investigations. To the practical dyer, therefore, the study of chemical science must be essentially requisite, as this only can be his true guide in estimating and managing the complicated changes in the different processes of his art. It is only by the application of the principles of chemistry that this art can be improved and perfected. But the application of these principles must be made by the practical dyer himself, not by the chemist in his laboratory, or during an occasional visit to the manufactory. For in the complicated processes of dyeing conducted on an extensive scale, a thousand circumstances will be overlooked by the most acute and discerning chemist, which will not escape the habitual observation of the philosophical artist. Convinced ourselves of the incalculable advantages which the art of dyeing may derive from chemical science, and the innumerable resources which ingenuity and address may discover in the proper application of its principles towards the improvement of the different processes of this art, we shall not be thought, we hope, too sanguine in looking forward to a degree of perfection which is little to be expected from its present state.

Importance of chemistry in dyeing.

The processes of the art of dyeing form the subject of the second part of this treatise, the consideration of which we are now to enter upon.

Division of colours.

151. Colours have been usually distributed by dyers into two classes. These have been denominated *simple* and *compound* colours. Simple colours, which are commonly reckoned four in number, are such as cannot be produced by the mixing together different colours. Colours denominated compound may be produced by the mixture of any two of the simple colours in different proportions. Thus red, yellow, and blue are incapable of being produced by any combination of others, and are therefore considered as simple colours. Blue and red, which compose a purple, blue and yellow, a green, and red and yellow, an orange, are compound colours; but none of these, by any composition whatever, will afford a red, yellow, or blue.

Dr Ban croft's.

152. Dr Bancroft, in his elaborate treatise on the philosophy of permanent colours, divides colouring matters into two classes. The first includes those colouring substances which, being in a state of solution, may be permanently fixed on any stuff without any mordant, or the intermediate action of earthy or metallic bases. In the second class are comprehended those matters which cannot be fixed without the action of mordants. The first he has denominated *substantive* colours; because the colour is fixed without the aid of any other body; and the second *adjective;* because they become permanent only with the addition of a mordant. The celebrated purple produced by the liquor obtained from shell-fish and indigo, are examples of substantive colours. Prussian blue and cochineal are adjective colours.

The usual division of colours into simple and compound seems to form an arrangement equally convenient and perspicuous. We shall therefore adopt it in the following chapters. In the first we shall treat of *simple* colours; in the second of *compound* colours; and to these we shall add a third chapter on topical dyeing, or calico printing.

CHAP. I. *Of Simple Colours.*

Simple lours.

153. SIMPLE colours, we have already observed, are such as cannot be produced by the mixture of other colours. They are the foundation of all other colours, and therefore come naturally to be first treated of. The simple colours are four, viz. 1. Red. 2. Yellow. 3. Blue. 4. Black. To these a fifth is added by some; namely, brown, or fawn colour; although it may be produced by the combination of other colours. The nature of the colouring substances which are employed to

to produce these colours, and the processes by which they are fixed on the several stuffs, will form the subject of the four following sections.

Sect. I. *Of Red.*

154. Red colours, from different degrees of intensity, have received different names, as crimson, scarlet, besides a great variety of shades which are less striking, and come under no particular denomination. In this section we shall treat of the nature and properties of the substances which are employed in dyeing red, and then give an account of the different processes which are followed in fixing these colouring matters on animal and vegetable productions.

1. *Of the Substances employed in Dyeing Red.*

The colouring matters which are principally employed in dyeing red, are *madder*, *cochineal*, *kermes*, *lac*, *archil*, *carthamus*, *brazil wood*, and *logwood*.

155. Madder is very extensively employed in dyeing. It is the root of a plant (*rubia tinctorum*, Lin.) of which there are two varieties. It is cultivated in different parts of Europe, and the best, it is said, is brought from Zealand. Madder, as it is prepared for dyeing, is distinguished into different kinds. What is called *grape madder*, is obtained from the principal roots; the *none grape* is produced from the stalks, which by being buried in the earth, are converted into roots, and are called layers. When the roots are gathered, these layers are separated, with such of the fibres of the roots as do not exceed a certain degree of thickness, as well as those which are too thick; the latter containing a great deal of woody matter. The best roots are about the thickness of a goose quill, they have some degree of transparency; are of a reddish colour, and have a strong smell, and a smooth bark. When the madder is gathered, it must be dried, to render it fit for being reduced to powder, and being preserved. This operation is performed in warm climates in the open air. In Holland, stoves are employed for the same purpose; but when treated in this way, it is often injured, from too great a degree of heat, and being mixed with particles of soot. The superiority of madder from the Levant is ascribed to its having been dried in the open air.

156. The roots being dried, and the earthy matters which adhere to them being separated, by shaking them in a bag, or beating them lightly on a wooden hurdle, they are reduced to powder by means of manual labour, or with the aid of machinery. All the parts of madder do not yield the same colouring matter. The outer bark, and the ligneous part within, give a yellowish dye, which injures the red. These parts may be separated, in consequence of the different degrees of facility with which they are reduced to powder. The outer bark and woody parts are more easily powdered than the parenchymatous parts, which contain the fine red dye. To effect the separation of these different parts, three operations are performed. After the first, the madder is passed through a sieve, by which, what is called the *short* madder, (*courte* of the French), intended for tan, and inferior colours, is obtained. What remains is again ground and sifted. What the French call *mirobèe*, is obtained by this operation. A third operation of the same kind affords the *robèe* or finer kind of madder.

157. The result of the experiments of D'Ambourney show, that the fresh root of madder may be used with as much advantage in dyeing, as when it is dried and powdered. Four pounds of fresh madder, he observed, are equal to one of the dry, although in drying it loses seven-eighths of its weight. When the fresh roots are to be used, they are to be well washed in a current of water, immediately after they are taken out of the ground, and afterwards cut into pieces and bruised. In dyeing with the fresh roots, allowance should be made for the quantity of water which they contain, so that a smaller proportion should be put into the bath. Beckmann seems to be of the same opinion with regard to the use of the fresh roots of madder, and yet he has frequently observed that it is more fit for dyeing after it has been preserved for two or three years.

158. The madder which is cultivated in the neighbourhood of Smyrna, and in the island of Cyprus, affords a brighter red than the European madder, and therefore it is preferred in the preparation of the *Adrianople red*. This is known by the name *lizari*. Berthollet informs us that it is cultivated in Provence in France, and Beckmann has been very successful in raising it at Gottingen.

Properties.

159. The colouring matter of madder is soluble in alcohol, and by evaporation a deep-red residuum is formed. In this solution sulphuric acid produces a fawn-coloured precipitate; fixed alkali, one of a violet colour, and the sulphate of potash, a precipitate of a fine red. Alum, nitre, chalk, acetate of lead, and muriate of tin, afford precipitates in the solution of madder in alcohol, of various shades. The colouring matter of madder is also soluble in water. By maceration in several portions of cold water successively, the last receives only a fawn colour, which appears entirely different from the peculiar colouring particles of this substance. It resembles what is extracted from woods and other roots, and perhaps exists only in the ligneous and cortical parts. By repeated boiling, Berthollet exhausted the madder of all its colouring particles which are soluble in water. It still retained, however, a deep colour, and yielded a considerable quantity of colouring matter to an alkali. There was an inconsiderable residuum, which still remained coloured. The pulp, therefore, appears entirely composed of colouring matter, part of which is insoluble in simple water. When oxymuriatic acid is employed in sufficient quantity, to change an infusion of madder from red to yellow, it produces a small portion of a pale-yellow precipitate; the supernatant liquor is transparent, and retains more or less of a deep yellow colour, according to the proportion and strength of the acid. Double the quantity of acid is required to discharge the colour of a decoction of madder of what is necessary to destroy that of the same weight of Brazil wood. This shows that the colouring matter of madder is more durable than that of Brazil wood. The infusion of madder in water is of a brownish orange colour. The colouring matter may be extracted, either by cold or hot water; in the latter the colour is most beautiful. The decoction is of a brownish colour. The colouring matter of madder

der cannot be extracted without a great deal of water.— Two ounces of madder require three quarts of water. Alum forms, in the infusion of madder, a deep brownish red precipitate; the supernatant liquor is yellowish, inclining to brown. Alkaline carbonates precipitate from this last liquor a lake of a blood-red colour; with the addition of more alkali, the precipitate is redissolved, and the liquor becomes red. Calcareous earth precipitates a darker and browner coloured lake than alkalies. Carbonate of magnesia forms a clear blood-red precipitate, which by evaporation produces a blood-red extract, soluble in water. The solution of this extract is employed as a red ink, but it becomes yellow by exposure to the sun. Metallic salts also form precipitates in a solution of madder. The precipitate with acetate of lead is of a brownish red colour; with nitrate of mercury and sulphate of manganese, a purplish brown; with sulphate of iron, a fine bright brown.

Cochineal.

History.

160. Cochineal, which furnishes a valuable dye stuff, and about the nature of which there was at first a good deal of uncertainty, is an insect. It is produced on different species of the *cactus*, or Indian fig. The most perfect variety of the cochineal insect, is that which breeds on the *cactus coccinillifer*, Lin. To this plant the Mexican Spaniards gave the name of *nopal*. When the Spaniards first arrived in Mexico, they saw the cochineal employed by the native inhabitants, in communicating colours to some part of their habitations, ornaments, and in dyeing cotton. Struck with its beautiful colour, they transmitted accounts of it to the Spanish ministry, who about the year 1523, ordered Cortes to direct his attention to the propagation of this substance. The inhabitants of Europe were long mistaken concerning the nature and origin of cochineal, by supposing it to be the grain or seed of a plant. This opinion was first contradicted in a paper published in the third volume of the Philosophical Transactions in 1668; and four years afterwards, Dr Lister, in the seventh volume of the same work, throws out a conjecture, that cochineal may be a sort of kermes. Different opinions concerning the origin of this substance were entertained, till about the beginning of the year 1757, Mr Ellis obtained some of the joints of the plant on which the insects breed, from South Carolina, and presented them the same year to the Royal Society. These specimens, Mr Ellis observes, were full of the nests of this insect, in which it appeared in its various states, in the most minute when it walks about, to the state when it becomes fixed, and wrapt up in a fine web, which it spins about itself. With the assistance of the microscope, Mr Ellis discovered the true male insect in the parcels which had been sent to him from America; and in August 1756, in consequence of Mr Ellis's discovery, Dr Garden caught a male cochineal fly, which he observes is rarely to be met with. He supposes that there may be 150 or 200 females for one male. These discoveries proved indisputably, that the cochineal is an animal production *.

161. The body of the female insect is flat on the belly, and hemispherical on the back, and transversely wrinkled. The skin is dark brown; it has no wings, but is furnished with six short brown legs. The body of the male, which is of a deep red colour, is rather long, and covered with two wings, extending horizontally, and crossing a little upon the back. It has two small antennæ, and six legs which are larger than those of the female. It has a fluttering kind of motion. The life of the male is only of a month duration, but the fecundated female lives a month longer. The female is sometimes oviparous and sometimes viviparous; but this is not a peculiarity confined to this insect. It belongs to some others, and seems to be regulated by the temperature and season of the year. The female cochineal insect adheres to the same spot of the tree on which it is produced during her whole life. At soon as the female is delivered of its numerous progeny, it becomes a mere husk and dies. In Mexico it is therefore an object of great importance to prevent this, and to collect them in the fecundated state. For this purpose they are picked from the plants, put into a linen bag, which is immersed in hot water, to destroy the life of the young insects, and then carefully dried. In this state they are imported into Europe.

Variet

162. There are two kinds of cochineal. The best, or domesticated kind, is called by the Spaniards, *grana fina*. This variety breeds upon the *cactus coccinillifer*, or nopal; and being of a larger size, and containing a greater proportion of colouring matter, it is always preferred. The other variety is the *grana sylvestra* of the Spaniards, or wild cochineal. It is produced from other species of the *cactus*. It is smaller than the other, and as it is covered with a downy matter, produced by the insect to defend itself against the cold, this increases the weight, but is of no use in dyeing. An equal weight of the wild cochineal yields a smaller quantity of colouring matter, and is therefore less valuable. It ought, however, to be observed, that it can be reared with greater facility, and at much less expence; and when it is bred upon the nopal, it acquires double the size, and has a smaller quantity of downy matter for its covering, so that it approaches, by this management, to the nature of fine cochineal.

163. As the quantity of cochineal consumed in Europe is very great (D), and as the Spaniards have hitherto enjoyed the exclusive advantages of rearing and supplying the market with this valuable substance, it has become an object with other nations to share them. Attempts have therefore been made to form establishments for rearing these insects in those colonies whose soil and climate seem suitable for the purpose.

164.

---

* *Philo Trans.*

(D) The average quantity, says Dr Bancroft, of fine cochineal annually consumed in Europe, amounts to about 3000 bags, or 600,000 lbs. weight, of which about 1200 bags, or 240,000 lbs. weight may be considered as the present annual consumption of Great Britain. A greater quantity comes to the kingdom, but the surplus is again exported to other countries. These 1200 bags may be supposed to cost 180,000l. sterling, valued at 15s. per lb. which has been about the average price for some years past. *Philosophy of Permanent Colours*, p. 258.

mpts ulti- e it.

164. One of the most successful of these attempts was made by M. Thiery de Menonville, in 1777. He exposed himself to great danger, by going to Mexico that he might observe the mode of rearing the cochineal insect, and procure that valuable production, to plant it in St Domingo. He proceeded by the Havannah to La Vera Cruz, where he was informed that the finest cochineal insects were reared at Guaxaca, 70 leagues distant. On the pretence of ill health, he received permission to use the baths of the river Magdalene: but instead of accepting this privilege, which was not his object, he directed his course, not without much difficulty and danger, to Guaxaca; where having obtained the information he wanted, and having purchased a quantity of nopals, covered with the insects of the fine or domestic breed, which he pretended were of great use in preparing an ointment for his feigned disorder, the gout, he put them into boxes along with other plants, and succeeded in bringing them away without notice or suspicion. On his return, he was driven by a storm into the bay of Campeachy, where he found a living cactus of a species which was fit for the nourishment of the fine cochineal. He returned in safety towards the end of the same year, to St Domingo, with his prize, and immediately formed a plantation of nopals, with the view of propagating both varieties of the cochineal. Soon after his return, he found the wild kind living naturally on the *cactus pereskia*, a native of that island. Unfortunately, however, for the establishment, Thiery de Menonville died in the year 1780, through disappointment and vexation, it is said, at seeing his patriotic endeavours so little assisted, and his services so sparingly rewarded by government; and soon after his death, the fine cochineal perished. But the discovery of the wild kind in St Domingo was not neglected. M. Bruley succeeded in his attempts to rear this species of cochineal. A posthumous work of Thiery de Menonville was published by the Royal Society of arts and sciences at Cape Françoise, containing minute instructions with regard to every thing respecting the cultivation of the nopal, and the other species of cactus, which may be more or less successfully substituted for breeding or rearing the cochineal. Of this Berthollet has given an extract in the 5th volume of the Annales de Chimie. Some of our own countrymen, a few years ago, succeeded in procuring some of the fine cochineal insects; and attempts have been made, with what success we know not, to rear them in the East Indies.

roperties.

165. Fine cochineal, if it has been properly prepared and kept, ought to be of a gray colour, with a shade of purple. The gray colour is owing to a powder with which it is naturally covered, and part of which it still retains. The colouring matter extracted by the water in which the insect has been killed, produces the purple shade. In a dry place, cochineal may be kept for a long time, without losing any of its properties. Hellot made experiments on cochineal 130 years old, and found that it produced the same effect as if it had been quite new. Cochineal yields its colouring matter to water; and the decoction, which is of a crimson colour, inclining to violet, may be kept for a long time, without losing its transparency, or becoming putrid. If this decoction be evaporated, and the residuum or extract be digested in alcohol, the colouring part dissolves, and leaves a residuum of the colour of wine lees, of which fresh alcohol cannot deprive it. The alcohol of cochineal affords, by evaporation, a transparent residuum of a deep red, which, being dried, has the appearance of a resin. A small quantity of sulphuric acid added to the decoction of cochineal, produces a red colour, inclining to yellow, and a small quantity of a beautiful red precipitate. With muriatic acid the same change is produced, but there is no precipitate. A solution of tartar converts the decoction to a yellowish red colour. A precipitate of a pale red colour is slowly formed, and the supernatant liquor remains yellow; but with the addition of an alkali becomes purple. With the yellow liquor, solution of tin forms a rose-coloured precipitate; solution of alum brightens the colour of the infusion, gives it a redder hue, and produces a crimson precipitate. With a mixture of alum and tartar the colour is brighter, more lively, and inclines to a yellowish red. Muriate of tin occasions a copious sediment of a beautiful red. The supernatant liquor is colourless and transparent, and no change is produced on it by adding an alkali. Sulphate of iron forms a brown violet precipitate, and the supernatant liquor remains clear, with a slight darkish hue. Sulphate of zinc gives a deep violet precipitate; the supernatant liquor remains colourless and transparent. The precipitate with sulphate of copper is of a violet colour, and forms slowly: the supernatant liquor is also violet and transparent. Acetate of lead gives a purple violet precipitate, and the supernatant liquor remains limpid.

166. The experiments of Berthollet and Bancroft shew, that the colouring matter of cochineal is not entirely extracted by means of water. Dr Bancroft found, that after the whole of it which could be extracted by water was obtained, by adding a little potash to the seemingly exhausted sediment, and pouring on it fresh boiling water, it yielded a new quantity of colouring matter, equal to one-eighth of what had been given out to the water; and Berthollet found the same effect produced with the addition of tartar; from which he concludes that tartar favours the solution of the colouring part of the cochineal.

Kermes.

167. Kermes (E), another animal substance, which is extensively employed in dyeing, is an insect, (*coccus ilicis*, Lin.) which breeds on a species of oak (*quercus coccifera*, Lin.) which grows in most of the southern parts of Europe, and in many parts in Asia. Kermes was known to the ancients, under the names of *coccum scarlatinum*, *coccus bapticus*, *coccus infectorius*, *granum tinctorium*. Kermes is chiefly obtained from Languedoc, Spain, and Portugal. The insects are collected in the month of May or June, when the female, which alone

History.

(E) This word is supposed to have been derived from the Arabic language, and signifies a *little worm*, *vermiculus*; and from this we have the word *vermilion*, the pigment in the manufacture of which it is the principal ingredient.

Of Simple Colours.

alone is useful, is distended with eggs. To destroy the young insects, the kermes is exposed to the steam of vinegar for about half an hour, or steeped in vinegar for 10 or 12 hours. They are afterwards dried on linen cloths, and brought to market.

Properties.

168. When the living insect is bruised, it gives out a red colour. The smell is somewhat pleasant; the taste is bitter and pungent. It gives out its colouring matter both to water and alcohol, to which also it imparts its smell and taste. The colour is also retained in the extract which is obtained, both from the tincture, and from the infusion. Kermes is one of the most ancient dyeing drugs; and although the colours which it communicates to cloth are less bright and vivid than those of cochineal, and on that account it has been less extensively employed in dyeing since the latter was known, yet they have been found to be exceedingly permanent. The fine blood-red colour which is to be seen on old tapestries in different parts of Europe, was produced from kermes, with an aluminous mordant, and seems to have suffered no change, though some of them are 200 or 300 years old. The colour obtained from kermes was formerly called scarlet in grain, because it was supposed that the insect was a grain; and from the chief manufactory having been at one time in Venice, it was called *Venetian scarlet.*

Lac.

169. *Lac* is an animal production which has been long known in India, and used for dyeing silk and other purposes. It is the *nidus* of the *coccus lacca*, Lin. and is generally produced on the small branches of the *croton lacciferum.* Three kinds of lac are well known in commerce: 1. Stick lac is the substance or comb, in its natural state, forming a crust on the small branches or twigs. Seed lac is said to be only the above, separated from the twigs, and reduced into small fragments. Mr Hatchett, who has examined this substance with his usual skill and precision, found the best specimens considerably deprived of their colouring matter *. According to the information which he received from Mr Wilkins, the silk dyers in Bengal produce the seed lac by pounding crude lac into small fragments, and extracting part of the colouring matter by boiling. 3. Shell lac is prepared from the cells, liquefied, strained, and formed into thin transparent laminæ. There is also a fourth kind called *lump lac*, which is obtained from the seed lac by liquefaction, and afterwards formed into cakes. The best lac is of a deep red colour; when it is pale, and pierced at the top, the value is greatly diminished, for then the insects have left their cells, and it can no longer be of use as a dye stuff.

History.

Properties.

170. The decoction of powdered stick lac in water, gives a deep crimson colour. With one-fifth of borax, lac becomes more soluble in water. Pure soda, and carbonate of soda, completely dissolve the different kinds of lac, and produce a deeper colour than that which is obtained by means of borax. Pure potash speedily dissolves all the varieties of lac; the colour approaches to purple. Pure ammonia and carbonate of ammonia readily act on the colouring matter of lac. Alcohol dissolves a considerable part of the lac; and according to Geoffroy, yields a fine red colour. When the solution is heated it becomes turbid. Sulphuric acid dissolves the colouring matter of lac, as well as muriatic and acetic acids. In the use of lac in dyeing, it has been considered superior to kermes, because it is able to bear the action of a solution of tin, without the colour being changed to yellow.

Archil.

171. Archil is a vegetable substance of great use in dyeing. It is employed in the form of a paste, which is of a red violet colour. It is chiefly obtained from two species of *lichen*, *roccella*, and *parellus*, Lin. The first, which is called *Canary archil*, because the lichen from which it is prepared grows abundantly in the Canary islands, is most valued. It is prepared by reducing the plant to a fine powder, which is afterwards passed through a sieve, and slightly moistened with stale urine. The mixture is daily stirred, each time adding a certain proportion of soda in powder, till it acquire a clove colour. It is then put into a wooden cask, and urine, lime-water, or a solution of sulphate of lime, (*gypsum*,) is added in sufficient quantity to cover the mixture. In this state it is kept; but to preserve it any length of time, it is necessary to moisten it occasionally with urine. By a similar preparation, other species of lichen may be used in dyeing. In this country the *lichen omphalodes* and *tartareus* are frequently employed for dyeing coarse cloths.

Proper

172. Archil gives out its colouring matter to water, ammonia, and alcohol. The infusion of archil is of a crimson colour, with a shade of violet. The addition of an acid converts it to a red colour. Fixed alkalies only render it of a deeper shade; because its natural colour has been already modified by the ammonia with which it is combined in the preparation. Alum produces in the solution of archil a dark-red precipitate; the supernatant liquor is of a yellowish red colour. With solution of tin a reddish precipitate is formed, which subsides slowly; and the liquor retains a slight tinge of red. This infusion loses its colour in a few days if it be entirely excluded from the air. To cold marble the aqueous infusion of archil communicates a fine violet colour, or blue inclining to purple. The affinity between the stone and the colouring matter is so strong, that it resists the action of the air longer than colours which it gives to other substances. The colour thus communicated to marble, has remained for two years unchanged.

Singul change

173. Archil is also soluble in alcohol. This tincture is employed for making spirit of wine thermometers. A singular phenomenon was observed by the Abbé Nollet when the tincture was excluded from the air. In a few years it was entirely deprived of its colour. The contact of air restored the colour; but it was again destroyed when deprived of it.

Carth

174. Carthamus, or bastard saffron, a vegetable substance used in dyeing, is the flower of an annual plant which is cultivated in Spain, Egypt, and the Levant. There are two varieties of this plant, the one with larger, the other with smaller leaves. The variety with larger leaves is cultivated in Egypt.

Prepar tion.

175. The method of preparing the flowers of carthamus in Egypt, as it is described by Hasselquist, is the following. After being pressed between two stones, to squeeze out the juice, they are washed several times with salt water, pressed between the hands, and spread out on mats in the open air to dry. In the day time they are covered, that they may not dry too fast with the heat of the sun, but they are left exposed to the dew of the night. When they are sufficiently dry, they are put

Simple ours.

put up, and kept for sale, under the name of *saffranon*. Care should be taken afterwards, not to keep it in too dry a place; for unless it is a little moist, its properties are considerably impaired.

Perties.

176. Carthamus contains two colouring substances, a yellow substance, which is soluble in water; and as it is of no use, it is extracted by the process mentioned above, by squeezing the flowers between stones till no more colour can be pressed out. The flowers become reddish in this operation, and lose nearly one half of their weight. The other colouring matter, which is red, is soluble in alkaline carbonates, and it is precipitated by means of an acid. A vegetable acid, as lemon juice, has been found to produce the finest colour. Next to this, sulphuric acid produces the best effect, provided too great a quantity, which would alter and destroy the colour, be not employed. The juice of the berries of the mountain-ash, or *rowan tree*, (*sorbus aucuparia*, Lin.) is recommended by Scheffer as a substitute for lemon juice, and it is thus prepared. The berries are bruised in a mortar with a wooden pestle, and the expressed juice, after it has been allowed to ferment, is bottled up. The clear part, which is most acid, becomes fitter for use the longer it is kept; but this operation requires a period of some months, and can only be conducted in summer.

Pra a- on ou

177. From the colouring matter extracted by means of an alkali, and precipitated with an acid, is procured the substance called *rouge*, which is employed as a paint for the skin. The solution of carthamus is prepared with crystals of soda, and precipitated with lemon juice which has stood some days to settle. After being dried on delft plates with a gentle heat, the precipitate is separated, and ground accurately with talc which has been previously reduced to a very subtile powder; and on the fineness of the talc depends the difference between the cheaper and dearer kinds of *rouge*.

ra oo

178. Brazil wood is of very extensive use in dyeing. It is the wood of the *cæsalpinia crista*, Lin. and is a native of America and the West Indies. It is known under different names, according to the place where it is produced; as, *Fernambouc*, *Braziletto*, *wood of St Martha*, and of *Sapan*. It has a very hard wood, and has so much density as to sink in water. When fresh cut, it is of a pale colour, but becomes reddish by exposure to the air; and it has a sweetish taste.

ropties.

179. The colouring matter of Brazil wood is soluble in water, and the whole of it may be extracted by continuing the boiling for a sufficient length of time. The decoction is of a fine red colour. The residuum, which is black, yields a considerable portion of colouring matter to alkalies. The colouring matter is also soluble in alcohol, and in ammonia, and the colour is deeper than that of the aqueous solution. The tincture of Brazil wood in alcohol gives to hot marble a red colour, which afterwards changes to violet. The fresh decoction yields, with sulphuric acid, a small portion of a red precipitate, inclining to fawn colour. Nitric acid first produces a yellow colour, but by adding more, a deep orange. Oxalic acid produces a precipitate of an orange red. Tartar furnishes a small precipitate: with the addition of a fixed alkali, the decoction becomes of a deep crimson or violet colour. Ammonia gives a brighter purple: alum produces a copious red precipitate, inclining to crimson. Sulphate of iron occasions a black colour in the tincture, with a copious precipitate of the same colour. Sulphate of copper also produces an abundant precipitate, the liquor remaining transparent, and of a brownish red. A copious precipitate, of a fine deep red, is produced with acetate of lead, and that obtained with muriate of tin is abundant, and of a fine rose colour. With the addition of corrosive sublimate, a light precipitate, which is of a brown colour, is obtained. The liquor remains transparent, and of a fine yellow colour. Brazil wood, which has been changed to a yellow colour by means of tartar and acetous acid, with a solution of nitro-muriate of tin, yields a copious rose-coloured precipitate; and if to the solution, rendered yellow by an acid, a greater quantity of the same acid, or a stronger acid, as the sulphuric, be added, the red colour is restored. Some salts also possess the property of restoring the red colour of Brazil wood, which has been destroyed by means of acids *. The decoction of Brazil wood, which is called juice of Brazil, is found to answer better for the process of dyeing, when it has been kept some time, and has even undergone some degree of fermentation, than when it has been fresh prepared. The colour, by keeping, becomes of a yellowish red.

Logwood.

180. Logwood, sometimes called India or Campeachy wood, (*Hæmatoxylon Campeachianum*, Lin.) is a tree which grows to a considerable size in Jamaica, and the eastern shore of the bay of Campeachy. Its specific gravity is greater than that of water; it has a fine grain, and is susceptible of a fine polish.

Properties.

Logwood yields its colouring matter, which is a fine red, readily and copiously to alcohol. It is more sparingly soluble in water, and the decoction inclines a little to violet or purple. When it is left some time to itself, it becomes yellowish, and at length black. It becomes yellowish also by the action of acids; alkalies produce a deeper colour, and convert it to a purple or violet. Sulphuric, nitric, and muriatic acids form a small proportion of precipitate, which separates slowly: the precipitate formed with sulphuric acid is of a dark red; with muriatic, a lighter red, and with the nitric, *feuille mort*. With sulphuric or muriatic acids, the supernatant liquor is of a deep red colour; with nitric it is yellowish, and in all transparent. Oxalic acid produces a precipitate of a light marone colour; the liquor remains transparent, and is yellowish red. Acetic acid produces a similar effect, but the colour of the precipitate is somewhat deeper. A similar precipitate is obtained by means of tartar; but the liquor, which is more inclined to yellow, remains turbid. No precipitate is produced by means of fixed alkali; the decoction becomes of a deep violet, which is afterwards converted to a brown colour. Alum yields a copious precipitate, of a lightish violet colour; the colour of the liquor remains the same, and it is nearly transparent. A copious, dark red precipitate is produced with alum and tartar; the liquor is yellowish red and transparent. Sulphate of iron occasions a bluish black colour; a copious precipitate of the same colour is formed, and the liquid remains long turbid. With sulphate of copper, a very copious precipitate, of a dark brown colour, is obtained; the liquor, which is also of a deep brown, or yellowish red, remains transparent. Acetate of lead yields a black precipitate, with

---

* Jour. de Phys. 1785.

with a slight tinge of red; the colour of the liquor is like that of pale beer, and it remains transparent. Nitro-muriate of tin gives a precipitate of a fine violet or purple colour; the liquor remains clear and colourless.

2. *Of the Processes for Dyeing Wool Red.*

181. All red colouring matters with which we are acquainted, come under that class of colours to which Dr Bancroft has given the name of *adjective* colours; that is, such colours as require the aid of mordants to render them permanent. Red colours, we have already observed, are of various shades, according to the nature and proportion of the colouring matters employed. Hence we have madder red, scarlet, crimson, and other shades.

Madder-red.

182. *Madder Red.*—Madder is only employed for dyeing coarse woollen stuffs, and the following is the process. The stuffs are first boiled for two or three hours with alum and tartar: they are then left to drain, slightly wrung out, put into a linen bag, and carried into a cool place, where they are to remain for some days. The quantities and proportions of the alum and tartar are varied according to the views of the dyer, and the shade of colour which is wanted. Some recommend five ounces of alum and one ounce of tartar to each pound of wool. By increasing the proportion of tartar to a certain degree, a deep and permanent cinnamon colour, instead of a red, is produced. This arises from the yellow tinge which is induced by means of the acid on the colouring particles of the madder. Others propose to diminish the proportion of tartar, and to employ only a seventh part. In conducting the process of dyeing with madder, the bath should not be brought to the boiling point, because at that temperature the fawn-coloured particles would be dissolved, and a different shade obtained from that which is desired. When the water is at that degree of temperature which the hand can bear, Hellot recommends the addition of half a pound of grape madder for every pound of wool to be dyed. It is then to be well stirred before the wool is introduced, which must remain for an hour without boiling, excepting for a few minutes towards the end of the process, that the combination of the colouring particles with the stuff may be more certain.

Process.

Rosing.

183. Madder reds are sometimes rosed, as it is called, with archil and Brazil wood. In this way they become more beautiful and velvety, but this brightness is not permanent. But madder reds, even when they are most perfect, are far inferior to those obtained from lac and cochineal, and even to that produced by kermes; but as the expence of the materials is comparatively small, they are employed, as we have already observed, for coarse stuffs.

Proportion of madder.

184. Different authors recommend different proportions of madder. Poerner proposes to employ one-third of the weight of the wool, while Scheffer limits the quantity to one-fourth. In one process, Poerner added to the alum and tartar, a quantity of solution of tin, equal in weight to the tartar, and after two hours boiling, allowed the cloth to remain in the bath, which had been left to cool for three or four days. He then dyed it in the usual way, and thus obtained a fine red. According to another process, he prepared the cloth by the common boiling, and dyed it in a bath slightly heated, with a larger proportion of madder, tartar, and solution of tin. The cloth remained 24 hours in the bath, and when it had become cold, he put it into another bath, made with madder only, where it remained for 24 hours. By this process he got a fine red, somewhat brighter than the common, but inclining a little to yellow. Scheffer informs us that he obtained an orange red by boiling wool with a solution of tin, and one-fourth of alum, and then by dyeing with one-fourth of madder. A cherry colour is obtained, according to Bergman, by dyeing with one part of a solution of tin, and two of madder, without previously boiling the wool. By exposure to the air, this colour becomes deeper. By boiling the wool for two hours with one-fourth of sulphate of iron, then washing it, and afterwards immersing it in cold water with one-fourth of madder, and then boiling for an hour, the result is a coffee colour. But if the wool has not been soaked, and if it be dyed with one part of sulphate of iron and two of madder, the colour is a brown approaching to red.

Different mordants.

185. When sulphate of copper is employed as the mordant, the madder dye yields a clear brown, inclining somewhat to yellow; and a similar colour may be produced by dyeing the wool simply soaked in hot water, with one part of sulphate of copper, and two of madder. But when this mordant and dye-stuff are used in equal proportions, the yellow is somewhat more obscure, approaching to green; and in both these instances, exposure to the air does not produce a darker colour. Berthollet informs us that he employed a solution of tin in various ways, both in the preparation and the application of the madder; and by the use of different solutions of tin, he found, that although the tint was somewhat brighter than what is obtained by the common process, it was always more inclined to yellow or fawn colour.

Scarlet.

186. *Scarlet.*—The finest and most splendid of all colours is scarlet. This, like other colours, is of various shades, according to the quality and proportion of the colouring matter employed. The scarlet dye is communicated to woollen stuffs by means of cochineal, the history and properties of which we have already detailed. The Mexicans, as appears from their history, employed alumina as the basis or mordant, to fix the colour of cochineal; and previous to the discovery of the solution of tin, the use of the same substance seems to have prevailed in Europe. The fine colour obtained from the latter, received, as we have already mentioned, different names in different places; as that of *bow dye* in England, *scarlet of the Gobelins* in France, and in Holland *Dutch scarlet.*

Process.

187. In the process for dyeing scarlet, two operations are necessary. The first is denominated the boiling, and the second is distinguished by the name of finishing or reddening. The operation of boiling, which is the first part of the process, is conducted in the following manner. For 100 pounds of cloth, 6 pounds of pure tartar are added to the water, which is made pretty warm. The bath is then to be briskly stirred, and when the heat has increased a little more, half a pound of powdered cochineal is to be added, and the whole is then to be well mixed. The next moment five pounds of a very clear solution of tin are to be poured

Boiling.

Simple lours.

poured in, and carefully mixed. When the bath begins to boil, the cloth is introduced, and briskly moved for two or three turns: after which it is moved more slowly. The boiling having continued for two hours, the cloth is taken out, exposed to the air, and carried to the river to be well washed.

R dening.

188. In the preparation of the second bath, which is for the reddening, the boiler is to be emptied, and when the bath has just reached the boiling point, five pounds and three quarters of cochineal, previously powdered and sifted, are to be added. These are to be carefully mixed; and after having ceased stirring, when a crust has formed on the surface, and opened of itself in several places, 13 or 14 pounds of solution of tin are poured in. Should the bath, during the boiling, rise above the edge of the boiler, it may be cooled with a little cold water. This solution being well mixed, the cloth is put in, and two or three times quickly turned. It is then boiled in the bath for an hour, taking care to keep it under the surface. It is afterwards taken out, exposed to the air, and when it has cooled, washed in the river and dried.

Pr ortion o gre- di s.

189. There are no determinate proportions of cochineal and solution of tin in either of these operations. Hellot informs us, that some dyers employ two-thirds of solution of tin, and one-fourth of cochineal, in the boiling or first operation, and the other one-third of the solution of tin with the remaining three-fourths of the cochineal in the second operation, or the reddening. He adds farther, that the use of tartar gives a greater degree of permanency to the colour, provided the proportion do not exceed one half the weight of the cochineal employed. According to Berthollet, several dyers at present adopt this practice. Tartar, he observes, promotes the solution of the colouring matter; and this effect is greater when it is ground with the cochineal, after which it is found that the residuum is more completely exhausted. But this consideration is of inferior consequence, when the operations are successively performed, because any colouring matter that may remain in the residuum, is employed in the next operation. It ought not, however, to be overlooked, that the tartar communicates to the colour a rosey hue.

Sh er pro s.

190. It is the practice of some dyers not to remove the cloth out of the boiling. They merely refresh it, and perform the operation of reddening in the same bath. When this is done, the infusion of cochineal, made in a separate vessel, and mixed with the proper proportion of solution of tin, is added. By conducting the process in this way the scarlet is supposed to be equally fine, and there is a considerable saving of time and fuel.

Bri ter ed.

191. To give scarlet the bright lively red which, as it approaches to the colour of fire, has been distinguished by the name of *fiery scarlet*, a yellow tinge is communicated by boiling fustic in the first bath, or by adding a little turmeric to the cochineal. A larger proportion of the solution of tin also produces this yellow shade, but it renders the cloth harsh, and limits the action of the colouring matter. The use of fustic or turmeric, therefore, although the colour obtained from them is not permanent, is preferable to an excess of the solution of tin. When these substances are used, the inside of the cloth, when it is cut, appears yellow; but in the ordinary processes, the cochineal, it is found, does not penetrate the cloth, for when no other substance is employed, the cloth is internally white.

Of Simple Colours.

Tin and copper boilers.

192. The use of tin boilers is recommended in dyeing scarlet. When copper boilers are employed, the acid acts on the metal, and thus forming a solution, injures the beauty of the colour. Tin boilers, however, are attended with several inconveniences. It is difficult to procure them of sufficient size, and they are apt to be melted by the incautious continuance of the fire, after they have been emptied. In the use of copper boilers, there are several necessary precautions. They must be kept very clean; the acid liquor should not be allowed to remain in them for any length of time, and some contrivance should be adopted to prevent the cloth from touching the metal, either by using a net, or a wicker basket.

Different proportion of ingredients.

193. Different proportions of materials, we have observed, are recommended by different authors. For the boiling, Scheffer directs an ounce and a half of solution of tin, with an equal quantity of starch, and as much tartar, to every pound of cloth. The effect of the starch is to give more uniformity to the colour. When the water boils, a dram of cochineal is to be added; it is then to be well stirred, and after the wool is introduced, to be boiled an hour, taken out, and washed. The proportions for the reddening bath, in which the wool is to be boiled half an hour, are half an ounce of starch, three-fourths of an ounce of solution of tin, half an ounce of tartar, and 7 drams of cochineal. In Scheffer's process, it may be observed, the proportion of solution of tin is smaller than in that of Hellot, but the quantity of tin in the solution of the former is greater than in that of the latter.

Poerner's process.

194. Poerner has described three principal processes, according to the variety of the shade of the scarlet. He uses no cochineal in the boiling; the materials of which are one ounce and six drams of tartar, and an equal weight of solution of tin, the latter being added after the tartar is dissolved, for every pound of cloth. As soon as the boiling has commenced, the cloth is introduced, and it is boiled for two hours. For the reddening of the first process he employs two drams of tartar and one ounce of cochineal, adding gradually afterwards two ounces of solution of tin. For the reddening of the second process, the same quantity of cochineal and solution of tin, without any tartar, is employed. In the reddening of the third process, two drachms of tartar with one ounce of solution of tin, one ounce of cochineal, and two ounces of common salt, are directed to be used. The colour produced in the first process has the deepest shade; that of the second is more lively, while that of the third is paler and brighter.

Different shades.

195. By the use of tartar in the reddening in different proportions, various shades of scarlet may be obtained. When it is employed, the shade is deeper and fuller; but when it is entirely omitted, the scarlet approaches to an orange colour. The shade of colour also is subject to considerable variety, from the different degrees of strength of the solution of tin. To ascertain this effect, Berthollet made a number of experiments. He found that a solution of tin composed of sixteen parts of nitric acid, two of muriate of ammonia,

monia, and three of tin, produced a deeper shade than when the proportions of the acid and muriate of ammonia were equal, with only two parts of tin. The last proportions, he observes, succeeded best. Four parts of water were mixed with the solution. When the proportion of muriate of ammonia amounted only to half a part, the colour was brighter, and inclining to orange.

Use of common salt.

196. Common salt has the effect of increasing the brightness of scarlet, while it is also attended with the advantage of causing the colour to penetrate deeper into the cloth. It seems difficult to explain why common salt, which gives a deeper shade to the colour of the infusion of cochineal, and indeed produces a similar effect on colours in general, should diminish the intensity of the colour of scarlet. The proportion of common salt mentioned above (194) is, according to Poerner, the greatest that can be employed. When less is used, the shade, though lighter, is more agreeable. By adding five ounces of white sugar to the ingredients of the second process, a fine colour, which is always lighter than that of the first process, will be obtained. The colour, it is said, is more permanent, and the shade more agreeable, when the cloth is left 24 hours in the boiler after it has cooled.

Process of dyeing scarlet with cochineal

197. It has been generally supposed, Dr Bancroft observes, that after the discovery of the effects of tin on the cochineal colour, to produce a scarlet, it was only necessary to apply the colour so produced as a dye to wool; or that a nitric or nitro-muriatic solution of tin might change the natural crimson of cochineal to a scarlet. This opinion, however, he considers to be quite erroneous; for the nitric solution of tin invariably produces with cochineal a crimson or rose colour, and not a scarlet, unless other means are employed to incline the cochineal colour to a yellow shade. This effect is produced by means of the tartar, which seems to have been accidentally stumbled upon, and has been for many ages used, without knowing its true effect. Tartar was long employed with the aluminous mordant, in the preparation of the ordinary boiling liquor for woollen cloths; and it is probable that its good effects being observed in this combination, the use of it was continued after the introduction of the solution of tin; and the more so, after the result of the combination was observed in the brilliancy of the colour which was produced. Dr Bancroft has particularly directed his attention to the process for dyeing scarlet; and in the progress of his investigations, he has found that it is by no means absolutely necessary to follow the usual process which we have described above. He has often, he says, produced that colour very well at a single boiling, by mixing the whole quantity of tartar, solution of tin, and cochineal together; the affinity of the wool for the colouring matter, and for the oxides of tin, being sufficiently strong to combine with them readily, and to retain them permanently. The only objection to simplifying the process in this manner is, that the colouring matter of the dyeing liquor is less perfectly exhausted than when two operations are performed. He farther adds, that he has often produced a beautiful scarlet, by preparing and boiling the cloth with the whole quantity of solution of tin and tartar at once, and afterwards dyeing it unrinsed, with the whole of the cochineal, dissolved only in pure water. In this way he found the colouring particles completely taken up; that the liquor had become quite colourless, and that the cloth had received a durable dye.

long stationary.

Dr Bancroft's experiments

Scarlet a compound colour.

198. "It is remarkable," says Dr Bancroft, "that during the 18th century, no considerable improvement has been made in the process for dyeing scarlet; a circumstance which is the more extraordinary, since the pre-eminent lustre and costly nature of this dye, have rendered it an object of particular attention, not only to dyers, but to eminent chemists, by whose researches we might have expected that at least every obvious improvement therein would have been long since attained." To attain this object, this ingenious philosopher instituted a set of experiments about the year 1786. Having, by repeated affusions of boiling water, extracted the whole of the colouring matter from powdered cochineal, he found that the addition of a little potash to the seemingly exhausted sediment, and a fresh quantity of boiling water, extracted a new portion of colouring matter, equal to about one-eighth of what had been given out to the pure water. He repeatedly extracted this colouring matter by means of potash, and afterwards dyed small pieces of cloth scarlet with it, which he found similar to other pieces dyed with the more soluble colouring matter of cochineal. It was in the course of these inquiries that he perceived scarlet to be a compound colour, consisting of about three-fourths of pure crimson or rose colour, and one-fourth of pure bright yellow. He conceived, therefore, that when the natural crimson of the cochineal is made scarlet, by the usual process, there must be a change produced, equivalent to a conversion of one-fourth of the colouring matter of cochineal from its natural crimson to a yellow colour. From this he concludes that there might be a great saving of cochineal, by substituting a cheaper substance, which at the same time might yield a better yellow colour. It was therefore his object to combine with this crimson or rose colour, a suitable portion of a lively golden yellow, capable of being permanently fixed, and reflected by the same basis. Such a yellow he had discovered in quercitron bark, (*quercus nigra*, Lin.) which will be afterwards described; and it had the advantage, not only of being the brightest, but also the cheapest, of all the yellows which he had tried.

199. With the view of diminishing the quantity of cochineal employed in producing a scarlet dye, Dr Bancroft made a number of experiments under the authority of government. In these experiments, the mordant used was the ordinary dyers spirit, or the nitro-muriate of tin; but he found that they were not attended with the advantages which he expected. In some of his earliest experiments, he observes, that the solution of tin by means of sulphuric acid destroyed the cochineal colour, and this naturally led him to reject the use of this acid, till accident brought him to dissolve a quantity of tin in muriatic acid, combined with one-fourth of sulphuric acid. The application of this solution in dyeing, was not accompanied with the corrosive effects of the muriate and nitro-muriate which he had employed in the experiments above alluded to, and which proved unsuccessful. After trying different proportions of these acids, he found the following to answer best. In a mixture of 2lbs. of sulphuric acid of the ordinary strength, and about 3lbs. of muriatic acid,

acid, he dissolved about 14 oz. of tin. The muriatic acid is first poured on a large quantity of granulated tin, in a large glass receiver, and the sulphuric acid is then slowly added. The solution is more rapidly promoted by means of a sand heat, but it will take place in the cold, requiring only a greater length of time. This murio-sulphate of tin is transparent and colourless, and may be kept for several years without any precipitation. It produces twice the effect of the dyers spirit, at less than one-third of the expence, and raises the colours not only more than the dyers spirit, but also full as much as the tartrate of tin, without converting the crimson of cochineal to a yellowish shade.

D Ban-'s pro-ces

200. In the use of this solution of tin as a mordant, to produce the compound scarlet colour with the cochineal crimson and quercitron yellow, Dr Bancroft recommends the following process. "Nothing," says he, "is necessary but to put the cloth, suppose 100 lb. weight, into a proper tin vessel, nearly filled with water, in which about eight pounds of the murio-sulphuric solution of tin have been previously mixed, to make the liquor boil, turning the cloth as usual through it, by the winch, for a quarter of an hour; then turning the cloth out of the liquor, to put into it about four pounds of cochineal, and two pounds and a half of quercitron bark in powder, and having mixed them well, to return the cloth again into the liquor, making it boil, and continue the operation as usual until the colour be duly raised, and the dyeing liquor exhausted, which will be the case in about fifteen or twenty minutes; after which the cloth may be taken out and rinsed as usual. In this way the time, labour, and fuel, necessary for filling and heating the dyeing vessel a second time, will be saved; the operation finished much more speedily than in the common way; and there will be a saving of all the tartar, as well as of two-thirds of the cost of spirit, or nitro-muriatic solution of tin, which for dyeing 100 lb. of wool, commonly amounts to 10s.; whereas 8 lb. of the muriosulphuric solution will only cost about 3s. There will be moreover a saving of at least one-fourth of the cochineal usually employed (which is generally computed at the rate of one ounce for every pound of cloth), and the colour produced will certainly not prove inferior in any respect to that dyed with much more expence and trouble in the ordinary way. When a rose-colour is wanted, it may be readily and cheaply dyed in this way, only omitting the quercitron bark, instead of the complex method now practised of first producing a scarlet, and then changing it to a rose by the volatile alkali contained in stale urine, set free or decomposed by potash or by lime: and even if any one should still unwisely choose to continue the practice of dyeing scarlet without quercitron bark, he need only employ the usual proportions of tartar and cochineal, with a suitable quantity of the murio-sulphate of tin, which, while it costs so much less, will be more effectual than the dyers spirit.

Saving of cochineal.

201. "Several hundreds of experiments warrant my assertion, that at least a fourth part of the cochineal generally employed in dyeing scarlet, may be saved by obtaining so much yellow as is necessary to compose this colour from the quercitron bark; and indeed nothing can be more self-evident, than that such an effect, *cæteris paribus*, ought necessarily to result from this combination of different colouring matters, suited to produce the compound colour in question. Let it be recollected that the cochineal crimson, though capable of being changed by tartar towards the yellow hue on one hand, is also capable by other means of being changed towards a blue on the other, and of thereby producing a purple without indigo or any other blue colouring matter: yet I am confident that nobody would believe a pound of cochineal so employed capable alone of dyeing as much cloth, of any particular shade of purple, as might be dyed with it, if the whole of its colouring matter were employed solely in furnishing the crimson part of the purple, whilst the other (blue) part thereof was obtained from indigo. To say that a pound of cochineal alone could produce as much effect or colour as a pound of cochineal and a pound of indigo together, would be an improbability much too obvious and palpable for human belief; and there certainly would be a similar improbability in alleging that a pound of cochineal, employed in giving another compound colour (scarlet), could alone produce as much effect as a pound of cochineal and a pound of quercitron bark, when the colour of this last was employed only in furnishing one of the component parts of the scarlet, for which a considerable portion of the colouring matter of the cochineal must otherwise have been expended, which certainly happens in the new mode of dyeing scarlet, because the colour produced with an addition of the quercitron yellow inclines no more towards a yellow, than the scarlet produced by yellowing a part of the cochineal colour in the usual method with tartar. I retain, therefore, at this moment, as much confidence as I ever had in the reality and importance of my proposed improvements in this respect (F).

Advantages of this process.

202. "The scarlet composed of cochineal crimson and quercitron yellow, is moreover attended with this advantage, that it may be dyed upon wool and woollen yarn without any danger of its being changed to a rose or crimson, by the process of fulling, as always happens to scarlet dyed by the usual means. This last being in fact nothing but a crimson or rose colour, yellowed by some particular action or effect of the tartar, is liable to be made crimson again by the application of many

---

(F) "Of the benefit which I formerly expected to obtain by employing potash to extract a part of the cochineal colour, which water alone did not appear capable of extracting, it must be remarked that I have some time since convinced myself of its being an illusion; for, by repeated trials, I have found that the solid parts of powdered cochineal remaining after it has been boiled with the solution of tin, as in the common dyeing process, yield no colour worth notice, upon the application of potash, the solution of tin enabling the water to extract the colour sufficiently; so that in truth there is no such waste of cochineal colour as I had supposed in the usual way of employing that drug."

many chemical agents, (which readily overcome the changeable yellow produced by the tartar), and particularly by calcareous earths, soap, alkaline salts, &c. But where the cochineal colouring matter is applied and fixed merely as a crimson or rose colour, and is rendered scarlet by superadding a very permanent *quercitron yellow*, capable of resisting the strongest acids and alkalies, (which it does when dyed with solutions of tin), no such change can take place, because the cochineal colour having never ceased to be crimson, cannot be rendered more so, and therefore cannot suffer by those impressions or applications which frequently change or spot scarlet dyed according to the present practice."

Effect of candle light on this scarlet dye.

203. "There is also a singular property attending the compound scarlet dyed with cochineal and quercitron bark; which is, that if it be compared with another piece of scarlet dyed in the usual way, and both appear by day-light exactly of the same shade, the former, if they be afterwards compared by candle-light, will appear to be at least several shades higher and fuller than the latter; a circumstance of some importance, when it is considered how much this and other gay colours are generally worn and exhibited by candle-light during a considerable part of the year."

Effects of murio-sulphuric solution of tin.

204. "To illustrate more clearly the effects of the murio-sulphuric solution of tin with cochineal in dyeing, I shall state a very few of my numerous experiments therewith; observing, however, that they were all several times repeated, and always with similar effects.

"1st, I boiled one hundred parts of woollen cloth in water, with eight parts of the murio-sulphuric solution of tin, during the space of ten or fifteen minutes; I then added to the same water four parts of cochineal, and two parts and a half of quercitron bark in powder, and boiled the cloth fifteen or twenty minutes longer; at the end of which it had nearly imbibed all the colour of the dyeing liquor, and received a very good, even, and bright scarlet. Similar cloth dyed of that colour at the same time in the usual way, and with a fourth part more of cochineal, was found upon comparison to have somewhat less body than the former; the effect of the quercitron bark in the first case having been more than equal to the additional portion of cochineal employed in the latter, and made yellow by the action of tartar."

"2d, To see whether the tartrite of tin would, besides yellowing the cochineal crimson, contribute to raise and exalt its colour more than the murio-sulphate of that metal, I boiled one hundred parts of cloth with eight parts of the murio-sulphuric solution, and six parts of tartar, for the space of one hour; I then dyed the cloth, unrinsed, in clean water, with four parts of cochineal, and two parts and a half of quercitron bark, which produced a bright aurora colour, because a double portion of yellow had been here produced, first by the quercitron bark, and then by the action of tartar upon the cochineal colouring matter. To bring back this aurora to the scarlet colour, by taking away or changing the yellow produced by the tartar, I divided the cloth whilst unrinsed into three equal parts, and boiled one of them a few minutes in water slightly impregnated with potash; another in water with a little ammoniac; and the third in water containing a very little powdered chalk, by which all the pieces became scarlet; but the two last appeared somewhat brighter than the first, the ammoniac and chalk having each rosed the cochineal colour rather more advantageously than the potash. The best of these, however, by comparison, did not seem preferable to the compound scarlet dyed without tartar, as in the preceding experiment; consequently this did not seem to exalt the cochineal colour more than the murio-sulphate of tin; had it done so, the use of it in this way would have been easy, without relinquishing the advantages of the quercitron yellow."

"3d, I boiled one hundred parts of woollen cloth with eight parts of the murio-sulphuric solution of tin, for about ten minutes, when I added four parts of cochineal in powder, which, by ten or fifteen minutes more of boiling, produced a fine crimson. This I divided into two equal parts, one of which I yellowed or made scarlet by boiling it for fifteen minutes with a tenth of its weight of tartar in clean water; and the other, by boiling it with a fortieth part of its weight of quercitron bark, and the same weight of murio-sulphuric solution of tin; so that in this last case there was an addition of yellow colouring matter from the bark, whilst in the former no such addition took place, the yellow necessary for producing the scarlet having been wholly gained by a change and diminution of the cochineal crimson; and the two pieces being compared with each other, that which had been rendered scarlet by an addition of quercitron yellow, was, as might have been expected, several shades fuller than the other."

"4th, I dyed one hundred parts of woollen cloth scarlet, by boiling it first in water with eight parts of murio-sulphate of tin, and twelve parts of tartar, for ten minutes, and then adding five parts of cochineal, and continuing the boiling for fifteen minutes. This scarlet cloth I divided equally, and made one part crimson, by boiling with a little ammoniac in clean water; after which I again rendered it scarlet, by boiling it in clean water, with a fortieth of its weight of quercitron bark, and the same weight of murio-sulphate of tin; and this last, being compared with the other half to which no quercitron yellow had been applied, was found to possess much more colour, as might have been expected. A piece of the cloth, which had been dyed scarlet by cochineal and quercitron bark, as in the first experiment, being at the same time boiled in the same water with ammoniac, did not become crimson, like that dyed scarlet without the bark.

205. "In this way of compounding a scarlet from cochineal and quercitron bark, the dyer will at all times be able, with the utmost certainty, to produce every possible shade between the crimson and yellow colours, by only increasing or diminishing the proportion of bark. It has indeed been usual at times, when scarlets approaching nearly to the aurora colour were in fashion, to superadd a fugitive yellow either from turmeric, or from what is called young fustic (*Rhus Cotinus*); but this was only when the cochineal colour had been previously yellowed as much as possible by the use of tartar, as in the common way of dyeing scarlet; and therefore that practice ought not to be confounded

confounded with my improvement, which has for its object to preclude the loss of any part of the cochineal crimson, by its conversion towards yellow colour, which may be so much more cheaply obtained than the quercitron bark. By sufficient trials, I have satisfied myself that the cochineal colours, dyed with the murio-sulphuric solution of tin, are in every respect at least as durable as any which can be dyed with any other preparation of that metal; and they even seem to withstand the action of boiling soap suds somewhat longer, and therefore I cannot avoid earnestly recommending its use for dyeing rose and other cochineal colours, as well as for compounding a scarlet with the quercitron bark."

206. Dr Bancroft afterwards tried a great variety of earthy and metallic salts, as mordants, for the purpose of fixing the colour of cochineal on wool; and he found that, besides the metallic oxides and solutions, the aluminous, calcareous and siliceous earths, as well as magnesia and barytes, might be employed with different success in dyeing with the colouring matter of cochineal: but for the detail of these experiments which he has given, we refer our readers to the treatise itself [*].

207. To produce different shades of scarlet, and the other colours which are derived from it, all that is necessary, is to vary the proportions of cochineal, tartar, and solution of tin; and for the shades which incline most to yellow, the addition of quercitron bark, or fustic, is requisite. The use of the tartar is to deepen the colour, and the solution of tin produces a shade of orange. When the shade of colour required to be communicated to the stuff is light, the time of continuing the process must be shortened [†].

208. *Crimson.*—The processes which are employed to dye wool a crimson colour, are two. The stuff is either dyed crimson at once, or the crimson shade is communicated to it, after being previously dyed of a scarlet colour. To dye crimson by a single process, a solution of two ounces and a half of alum, and an ounce and a half of tartar for every pound of stuff, is employed for the boiling, and the stuff is afterwards to be dyed with an ounce of cochineal. It is usual also to employ solution of tin, but in smaller proportion than for dyeing scarlet. The processes employed, it is scarcely necessary to observe, must vary, according as the shade wanted is deeper or lighter, or more or less distant from scarlet. Common salt is also employed by some in the boiling. To render the crimson deeper, and to give it more bloom, archil and potash are frequently used; but this bloom, it ought to be observed, is extremely fugacious. By adding tartar and alum, the boiling for crimson is sometimes prepared after a scarlet reddening, and it is said that the colour possesses more bloom, when both the boiling and reddening are made after scarlet, than when the crimson is dyed in a fresh bath prepared on purpose. In dyeing these colours, the wild cochineal may be employed, but as it contains a smaller proportion of colouring matter, the quantity must be greater.

209. Different substances, as the alkalies, alum, and earthy salts in general, convert the colour of scarlet to crimson, which is the natural colour of cochineal. To effect this, the stuff previously dyed scarlet is boiled for an hour in a solution of alum, the strength of which is to be regulated by the depth of shade required. In conducting this process, it is necessary to observe, that water impregnated with earthy salts has a considerable effect in varying the shade; so that the quantity of alum employed must be proportioned to the purity of the water. Hellot tried soap, soda, potash, and some other substances, and although they produced the crimson, yet it was of a deeper shade, and had less lustre, than what was produced by means of alum. Ammonia produced a good effect; but from its great volatility, a considerable proportion must be put into the bath, moderately heated, with a little sal ammoniac, and an equal quantity of potash. By this process the stuff became of a bright rosy colour, and thus rendered a smaller quantity of cochineal necessary. Poerner directs the stuff, previously dyed scarlet, to remain 24 hours in a cold solution of sal ammoniac and potash.

Of Simple Colours.

Half-grain crimson, &c.

210. To produce crimsons, as well as scarlets, in half grain, madder is to be substituted for half the quantity of the cochineal; or in other proportions, according to the shade desired. The same boiling is given as for scarlet in grain, and the other parts of the process are to be conducted as for reddening the scarlet or crimson. Even the common madder red assumes a greater degree of lustre, when the boiling is made after the reddening for scarlet [‡].

3. *Of the Processes for dyeing Silk Red.*

Different processes with madder.

211. *Madder red.*—The colour which is obtained from madder does not possess sufficient brightness for dyeing silk. We shall here, however, describe some of the processes which are employed for this purpose. That of De la Folie, is the following. Half a pound of alum is to be dissolved in each quart of hot water, and two ounces of potash are afterwards to be added. When the effervescence has ceased, and the liquor has become clear, the silk must be kept in it for two hours, after which it is to be washed, and put into the madder-bath. The silk which is dyed in this way becomes more beautiful by means of the soap proof. The process of Scheffer is somewhat different. For each pound of scoured silk, he directs a solution of four ounces of alum, and six drams of chalk, to be prepared. When the sediment has formed, the solution is to be decanted, and having become quite cold, the silk is immersed in it, and left for 18 hours. It is then taken out, and dried, and afterwards dyed with an equal weight of madder. The colour thus obtained is of a dark shade. Mr Guliche describes another process. For every pound of silk he proposes a bath of four ounces of alum and one ounce of solution of tin. When the liquor has become clear, it is decanted, and the silk carefully soaked in it for 12 hours, after which it is to be immersed in a bath with half a pound of madder softened by boiling, with an infusion of galls in white wine. The bath is to be kept moderately hot for an hour, and then made to boil for two minutes. The silk being taken from the bath is to be washed in a stream of water, and dried in the sun. The colour thus obtained is very permanent. By leaving out the galls it is clearer. The brightness of the first colour may be considerably increased, by passing the stuff through a bath of Brazil-wood, to which one ounce of solution of tin is added.

[‡] *Ibid.* ii. 198.

In this way the colour becomes extremely beautiful and durable.

Process with Brazil wood.

212. Silk is sometimes dyed with Brazil wood, and the colour thus obtained has been distinguished by the name of *false crimson*, to distinguish it from the more durable colour which is produced by cochineal. The silk, after being boiled with soap, is to be alumed. It is then to be refreshed at the river, and dipped in a bath more or less charged with Brazil juice, according to the depth of shade required. If pure water be employed, the colour will be too red for crimson; but to remedy this, the stuff may be passed through a weak alkaline solution, or a little alkali may be added to the bath, or the stuff may be washed in hard water till it has acquired the proper shade. To deepen the shade of false crimsons, or dark reds, the solution of logwood is added to the Brazil bath, the silk being previously impregnated with the latter; or a little alkali may be added, according to the shade required.

With cochineal.

213. The crimson produced by cochineal is called *grain crimson*, to distinguish it from false crimson. The silk, being well cleansed from the soap at the river, is to be immersed in an alum liquor of the full strength, and to remain for a night. It is then to be washed, and twice beetled at the river. The bath is prepared by filling a long boiler two-thirds with water, to which are added, when it boils, from half an ounce to two ounces of powdered white galls for every pound of silk. When it has boiled for a few moments, from two to three ounces of cochineal, also powdered and sifted, for every pound of silk, are put in, and afterwards one ounce of tartar to every pound of cochineal. When the tartar is dissolved, one ounce of solution of tin is added for every ounce of tartar. In the preparation of this solution of tin, the following proportions are recommended by Macquer. For every pound of nitric acid two ounces of sal ammoniac, six ounces of fine grain tin, and twelve ounces of water are employed. When these ingredients are mixed together, the boiler is to be filled up with cold water, and the proportion of the bath for every pound of silk is about eight or ten quarts of water. In this the silk is immediately immersed, and turned on the winch, till it appear to be of a uniform colour. The fire is then increased, and the bath is kept boiling for two hours, taking care to turn the silk occasionally. The fire is afterwards put out, and the silk put into the bath, where it is allowed to remain for a few hours longer. It is then taken out, washed at the river, twice beetled, wrung, and dried. Two processes are recommended by Scheffer and Macquer. In that of the former, a greater proportion of cochineal is employed in the dye-bath; but, in that of the latter, a yellow ground is previously communicated to the silk. The colour which is thus obtained resists the action of soap, and is more durable than that which is produced by means of carthamus.

214. To obtain other shades of red, the above processes must be varied. If, after the silk has been wrung out of the solution of tin, it is steeped for a night in a cold solution of alum, in the proportion of one ounce to a quart of water, wrung and dried, then washed and boiled with cochineal, it will only appear of a pale poppy-colour; but a fine poppy-red may be produced by steeping it twelve hours in the solution of tin, diluted with eight parts of water, then left all night in the solution of alum, washed, dried, and passed through two baths of cochineal, taking care to add to the second bath a small quantity of sulphuric acid. The same colour may be produced by dyeing the silk previously with anotta, and then passing it successively through a number of baths prepared with an alkaline solution of carthamus, to which lemon juice has been added, till it acquire a fine cherry-colour. To brighten the colour, the silk, after being dyed, may be immersed in hot water acidulated with lemon juice.

Poppy red.

Cher &c.

215. Other shades of red, as a cherry-red, and flesh-red, are also produced by means of carthamus. For a cherry-red, it is not necessary that the stuff be previously dyed with anotta, and the proportion of colouring matter is smaller. A flesh-red colour is obtained by adding a little soap to the bath, which has the effect of softening the colour, and of retarding the action of the colouring matter on the stuff. To produce dark shades, it is sometimes usual to mix archil, and by this means the expence is diminished.

Scarle

216. Those who have produced a colour on silk which comes nearest to scarlet, Berthollet observes, begin with dyeing the silk crimson. It is then dyed with carthamus, and lastly it is dyed yellow without heat. By this process a fine colour is obtained; but the dye of the carthamus is not permanent, as it is destroyed by the action of the air, and the colour becomes deeper. The following is Dr Bancroft's process. In a solution of murio-sulphate of tin, diluted with five times its weight of water, the silk is to be soaked for two hours; and after being taken out, it is to be wrung and partially dried. It is then to be dyed in a bath prepared with four parts of cochineal, and three of quercitron bark. In this way a colour approaching to scarlet is obtained. To give the colour more body, the immersion may be repeated both in the solution of tin, and in the dyeing bath; and the brightness of the scarlet is increased by means of the addition of carthamus. A lively rose-colour is produced by omitting the quercitron bark, and dyeing the silk with cochineal only; and by adding a large proportion of water to the cochineal, a yellow shade is obtained, which changes the cochineal to the compound scarlet colour *.

Rose-lour.

4. *Of the Process of dyeing Cotton and Linen Red.*

Madd red.

217. Madder is most commonly employed for dyeing cotton and linen a red colour; and indeed in this kind of dyeing it is the most useful of all colouring matters. The affinity of the colouring matter of madder for cotton is stronger than for linen; but it has been found that the processes which are most successful in dyeing the one are the most preferable for the other. There are two kinds of madder reds: the one is called *simple* madder red; and the other, which is much brighter, has been distinguished by the name of *Turkey* or *Adrianople* red, because it comes from the Levant, and has rarely been equalled in brightness and permanency. In communicating this beautiful red colour to cotton, by means of madder, a great many useless and ridiculous directions have been given. According to some processes, the period of a month is scarcely sufficient to finish all the operations which are considered as indispensably necessary for obtaining this dye.

---

* Phil Perm. 312.

Of Simple Colours.

218. The principal mordants which are employed in dyeing cotton with madder, are oil, gall-nuts, and alum. The colouring matter of madder cannot be fixed on cotton, till the latter has been impregnated with oil. A cold soapy liquor is formed by a combination of oil and a weak solution of soda. By the use of this alkaline ley the oil is diluted and divided, and can be easily and equally applied to all the parts of the cotton. According to Chaptal, potash produces the same effect as soda; and attention to this is of some importance, from the difference of price of the two substances. All kinds of soda or oil are not fit for this preliminary preparation. The soda must be in the caustic state, and its causticity must be the effect of calcination; because if it has been rendered caustic by means of lime, it becomes of a brown colour. The soda also should contain little muriate, for when this neutral salt prevails, the combination of the oil and the soda is greatly retarded. The most proper oil is not of a fine kind, but that which contains a large portion of the extractive principle. As the ley of soda is only employed for the purpose of diluting and conveying the oil equally to all the parts of the cotton, there must be a perfect combination of the oil and the soda. Indeed this is of so much importance, that many place the whole secret of a strong colour in the choice of good oil and soda. From this it follows, that the oil should be in excess, otherwise it would abandon the stuff in washing, and the colour would remain dry.

219. The cotton, being impregnated with oil, is subjected to the operation of galling. The use of gall-nuts is attended with several advantages. 1. The gallic acid which they contain decomposes the saponaceous liquor with which the cotton is impregnated, and fixes the oil on the stuff. 2. The other properties which the galls possess, predispose the cotton to receive the colouring matter. 3. The astringent principle unites with the oil, and forms with it a compound, which on drying becomes black, is not very soluble in water, and has a strong affinity with the colouring matter of madder.

220. From these principles some practical observations may be deduced. 1. Gall-nuts furnish the most proper astringent matter for this kind of dye. 2. To effect a speedy and perfect decomposition, the galls ought to be strained as hot as possible. 3. The galled cotton should be speedily dried, for otherwise it might assume a black colour, which would injure the brightness of the red. 4. The process of galling should be performed in dry weather, because when the weather is moist, the astringent principle produces a black colour, and dries slowly. 5. The cotton should be pressed together with great care, that the decomposition may be equally effected at every point of the surface. 6. It is necessary to attend to the proportion between the gall-nuts and the soap, for if the former predominate the colour is black, and if the soap is in excess, the portion of oil uncombined with the astringent principle, escapes in the washings, and impoverishes the colour.

221. Alum is also employed as a mordant in dyeing cotton red. This substance not only heightens the red of madder, but contributes also, by its decomposition, and the fixation of its alumina, to give solidity to the colour. When cotton, after it has been galled, is immersed in a solution of alum, it immediately changes its colour, and becomes gray. No precipitate appears in the bath, because the operation takes place in the tissue of the cloth itself. But if the solution of alum be employed at too high a temperature, part of the galls escapes from the stuff, and the decomposition of the alum is then effected in the bath. This, which should be guarded against, must obviously diminish the proportion of the mordant, and render the colour poorer.

Application of the mordant.

222. This mordant, which is the most complicated known in dyeing, requires great attention in its application. In this, indeed, consists the whole difficulty of dyeing cotton a madder or Turkey red. In this mordant there is a combination of three principles, oil, the astringent principle, and alumina; and on their proper combination, the perfection of the colour depends. When any one of them is employed separately, the colour is neither so bright, nor so completely fixed.

Process for dyeing red at Astracan.

223. After these preliminary observations, we shall now give a fuller detail of some of the processes which are followed in dyeing cotton Turkey red. The following is that which is practised at Astracan, of which an account has been given by Professor Pallas.

Preparation.

"The cotton to be dyed red is first washed exceedingly clean in running water, and, when the weather is clear, hung up on poles to dry. If it does not dry before the evening, it is taken into the house, on account of the saline dews so remarkable in the country around Astracan, and again exposed to the air next morning. When it is thoroughly dry it is laid in a tub, and fish oil is poured over it till it is entirely covered. In this state it must stand all night, but in the morning it is hung up on poles, and left there the whole day; and this process is repeated for a week, so that the cotton lies seven nights in oil, and is exposed seven days to the atmosphere, that it may imbibe the oil and free itself from all air. The yarn is then again carried to a stream, cleaned as much as possible, and hung up on poles to dry.

The mordant.

224. "After this preparation, a mordant is made of three materials, which must give the grounds of the red colour. The pulverized leaves of the sumach are first boiled in copper kettles; and when their colouring matter has been sufficiently extracted, some powdered galls are added, with which the liquor must be again boiled; and by these means it acquires a dark dirty colour. After it has been sufficiently boiled, the fire is taken from under the kettle, and alum put into the liquor yet hot, where it is soon dissolved. The proportion of these three ingredients I cannot determine with sufficient accuracy, because the dyers make use of different quantities at pleasure. The powder of the sumach leaves is measured into the kettle with ladles; the water is poured in according to a gauge, on which marks are made to shew how high the water must stand in the kettle to soak six, eight, ten, &c. puds of cotton yarn. The galls and alum are added in the quantity of five pounds to each pud of cotton. In a word, the whole mordant must be sufficiently yellow, strong, and of an astringent taste.

225. "As soon as the alum is dissolved, no time must be lost in order that the mordant may not be suffered to

to cool. The yarn is then put into hollow blocks of wood shaped like a mortar, into each of which such a quantity of the mordant has been poured as may be sufficient to moisten the yarn without any of it being left. As soon as the workman throws the mordant into the mortar, he puts a quantity of the yarn into it, and presses it down with his hand till it becomes uniformly moistened, and the whole cotton yarn has struck. By this it acquires only a pale yellow colour, which however is durable. It is then hung up on poles in the sun to dry, again washed in the stream, and afterwards dried once more.

226. "By the yellow dye of the sumach leaves, the madder dye becomes brighter and more agreeable; but the galls damp the superfluous yellow, and together with the alum prepare the yarn for its colour. Some dyers however omit the use of these leaves altogether, and prepare their mordant from galls and alum only, by first boiling the galls in due proportion with the requisite quantity of water, then dissolving the alum with boiling water in a separate vessel, afterwards pouring both liquors together into a tub, and suffering the cotton to remain in them an hour, or an hour and a half; after which it is dried gradually, then washed, and again dried once more. By this process the yarn acquires a dirty reddish colour.

Madder dye.

227. "The next part of the process is to prepare the madder dye. The madder, ground to a fine powder, is spread out in large troughs, and into each trough is poured a large cup full of sheep's blood, which is the kind that can be procured with the greatest facility by the dyers. The madder must be strongly mixed in it by means of the hand, and then stand some hours in order to be thoroughly soaked by it. The liquor then assumes a dark red appearance, and the madder in boiling yields more dye.

228. "After this process water is made hot in large kettles, fixed in brick-work; and as soon as it is warm the prepared red dye is put into it, in the proportion of a pound to every pud of cotton. The dye is then suffered to boil strongly; and when it is boiled enough, which may be tried on cotton threads, the fire is removed from under the kettle, and the prepared cotton is deposited near it. The dyer places himself on the edge of the brick-work that encloses the kettle; dips the cotton yarn, piece by piece, into the dye; turns it round, backwards and forwards; presses it a little with his hands; and lays each piece, one after the other, in pails standing ready for the purpose. As soon as all the cotton has received the first tint, it is hung up to dry: as the red, however, is still too dull, the yarn which has been already dyed once, and become dry, is put once more into the dyeing kettle, and must be left there to seethe for three hours over a strong fire, by which it acquires that beautiful dark red colour which is so much esteemed in the Turkey yarn. The yarn is now taken from the dye with sticks; the superfluous dye which adheres to it is shaken off; the hanks are put in order, and hung up, one after another, to dry. When it is thoroughly dry, it is washed in the pure stream and again dried. The only fault of the Astracan dyers is, that the colour is sometimes brighter and sometimes darker, probably because they do not pay sufficient attention to the proportions, or because the madder is not always of the same goodness.

Boiling. ley of so

229. "In the last place, the above-mentioned soda (kalakar) is dissolved with boiling water in tubs destined for that purpose; and it is usual here to allow twenty pounds of soda to forty pounds of cotton, or half the weight. Large earthen jars, which are made in Persia of very strong clay, a yard and a half in height, almost five spans wide in the belly, and ending in a neck a span and a half in diameter, enclosed by means of cement in brick-work over a fire-place, in such a manner that the necks only appear, are filled with the dyed cotton yarn. The ley of dissolved soda, which is blackish and very sharp, is then poured over it till the jars be filled; and some clean rags are pressed into their mouths, that the uppermost skains of yarns may not lie uncovered. A fire is then made in the fire-place below, and continued for 24 hours; and in the mean time the steam which arises from the jars is seen collected among the rags in red drops. By this boiling the dye is still more heightened, and is made to strike completely; every thing superfluous is removed, and all the fat matter which still adheres to the yarn is washed out: nothing more is then necessary for completing the dye of the yarn but to rinse it well several times in running water, and then to dry it.

The san colour b other means.

230. "That the dye of madder might be made very penetrating by other methods, and through the means of other oily and resinous substances, is shewn by the process of the Tungusians to dye horse, goat's and reindeer's hair, which they use for ornamenting their dresses, of a beautiful red colour, with the roots of the cross-wort, or northern madder (*galium*), and narrow-leaved woodroof (*asperula tinctoria*), which have a resemblance to those of madder. They boil the fresh or dried roots with about the same quantity of agaric (*agaricus officinarum*), which, as is well known, is abundant in resinous gummy particles, and is used by the people of Jakut instead of soap; they then lay in it the white hair which they wish to dye, and suffer it to seethe slowly until it be sufficiently red. Cotton cloth is dyed with madder at Astracan in the same manner: but many pursue a fraudulent process, by dyeing with red wood, and then sell their cloth as that which has been dyed in the proper manner."

The Gr cian m thod.

231. The processes which are employed in the Grecian manufactories for dyeing Turkey red, as they have been described by C. Felix, in a memoir in the French annals of chemistry, are somewhat different from the above. "In these manufactories," he observes, "the workmen dye at one time a mass of skains weighing thirty-five occas (G); each occa being equal to about fifty ounces. The first process is that of cleaning the cotton, for which purpose three leys are employed; one of soda, another of ashes, and a third of lime. The cotton is thrown into a tub, and moistened with the liquor of the three leys in equal quantities; it is then boiled in pure water, and washed in running water.

Prepara tion.

(G) Equal to 109 lb. 6 oz.

Simple olours.

ond h.

232. "The second bath given to the cotton is composed of soda and sheep's dung dissolved in water. To facilitate the solution, the soda and dung are pounded in a mortar. The proportions of these ingredients employed, are, one occa of dung, six of soda, and forty of water. When the ingredients are well mixed, the liquor expressed from them is strained, and being poured into a tub, six occas of olive oil are added to it, and the whole is well stirred till it becomes of a whitish colour, like milk. The cotton is then besprinkled with this water, and when the skains are thoroughly moistend, they are wrung, pressed, and exposed to dry. The same bath must be repeated three or four times, because it is this liquor which renders the cotton more or less fit for receiving the dye. Each bath is given with the same liquor, and ought to continue five or six hours. It is to be observed that the cotton, after each bath, must be dried without being washed, as it ought not to be rinsed till after the last bath. The cotton is then as white as if it had been bleached in the fields.

233. "The bath of sheep's dung is not used in our manufactories (H); it is a practice peculiar to the Levant. It may be believed that the dung is of no utility for fixing the colours; but it is known that this substance contains a great quantity of volatile alkali, in a disengaged state, which has the property of giving a rosy hue to the red. It is therefore probable that it is to this ingredient that the red dyes of the Levant are indebted for their splendour and vivacity. This much, at any rate, is certain, that the Morocco leather of the Levant is prepared with dog's dung; because it has been found that this dung is proper for heightening the colour of the black. The bath of dung is followed by the process of galling.

G ng an lum- in

234. "The galling is performed by immersing the cotton in a bath of warm water, in which five occas of pulverised gall-nuts have been boiled. This operation renders the cotton more fit for being saturated with the colour, and gives to the dye more body and strength. After the galling comes aluming, which is performed twice, with an interval of two days, and which consists in dipping the cotton into a bath of water in which five occas of alum have been infused, mixed with five occas of water alkalized by a ley of soda. The aluming must be performed with care, as it is this operation which makes the colouring particles combine best with the cotton, and which secures them in part from the destructive action of the air. When the second aluming is finished, the cotton is wrung; it is then pressed, and put to soak in running water, after being inclosed in a bag of thin cloth.

Of Simple Colours.

Dyeing.

235. "The workmen then proceed to the dyeing.—To compose the colours they put in a kettle five occas of water and thirty-five occas of a root which the Greeks call *ali-zari*, or painting colour, and which in Europe is known under the name of *madder*. The madder, after being pulverised, is moistened with one occa of ox or sheep's blood. The blood strengthens the colour, and the dose is increased or lessened according to the shade of colour required. An equal heat is maintained below the kettle, but not too violent; and when the liquor ferments, and begins to grow warm, the skains are then gradually immersed, before the liquor becomes too hot. They are then tied with packthread to small rods, placed crosswise above the kettle for that purpose, and when the liquor boils well, and in an uniform manner, the rods from which the skains were suspended are removed, and the cotton is suffered to fall into the kettle, where it must remain till two-thirds of the water is evaporated. When one-third only of the liquor remains, the cotton is taken out and washed in pure water.

Alkaline bath.

236. "The dye is afterwards brought to perfection by means of a bath alkalized with soda. This manipulation is the most difficult and the most delicate of the whole, because it is that which gives the colour its tone. The cotton is thrown into this new bath, and made to boil over a steady fire till the colour assumes the required tint. The whole art consists in catching the proper degree: a careful workman, therefore, must watch with the utmost attention for the moment when it is necessary to take out the cotton, and he will rather burn his hand than miss that opportunity. It appears that this bath, which the Greeks think of so much importance, might be supplied by a ley of soap; and it is probable that saponaceous water would give the colour more brightness and purity.

Methods of improving the colour.

237. "When the colour is too weak, the Levantines know how to strengthen it by increasing the dose of the colouring substances; and when they wish to give it brightness and splendour, they employ different roots of the country, and, in particular, one named *sussari*, specimens of which I have sent to France. The alizari, which is the principal colouring matter employed in the Greek dye-houses, is collected in Natolia, and is brought to Greece from Smyrna: some of it comes also from Cyprus and Mesopotamia. The superiority of this Levantine plant to the European madder is acknowledged by all those acquainted with the art of dyeing, and may arise from two causes: the manner in which it is cultivated, and the method employed for its desiccation (I)."

238. To

(H) The French manufactories.

(I) "The chief manufactories (continues our author), for dyeing spun cotton red, established in Greece, are in Thessaly. There are some at Baba, Rapsani, Tournavos, Larissa, Pharsalia, and in all the villages situated on the sides of Ossa and Pelion. These two mountains may be considered as the alembics that distil the eternal vapours with which Olympus is crowned, and which distribute them throughout the beautiful valleys situated around them. Of these valleys, that of Tempe has at all times been distinguished by the beauty of its shady groves and of its streams. These streams, on account of their limpidness, are very proper for dyeing, and supply water to a great number of manufactories, the most celebrated of which are those of Ambelakia.

"Ambelakia, on account of the activity which prevails in it, has a greater resemblance to a town of Holland than a village of Turkey. This village, by its industry, communicates life and activity to all the neighbouring country, and gives birth to an immense trade, which connects Germany with Greece in a thousand ways. Its population, Papillon's process.

238. To these processes we shall add the account of another, which was long successfully practised at Glasgow by Mr Papillon, a native of France, and was communicated by him, for a suitable premium, to the commissioners and trustees for manufactures in Scotland, to be by them published for the benefit of the public, at the end of a certain term of years. This transaction took place in 1790, and the period having expired, the trustees announced it to the public in 1803. The process, which consists of nine different steps, is the following.

Step I.

For 100 lib. cotton you must have
100 lib. of Alicante barilla,
20 lib. of pearl ashes,
100 lib. quicklime.

The barilla is mixed with soft water in a deep tub, which has a small hole near the bottom of it, stopped at first with a peg.—This hole is covered in the inside with a cloth supported by two bricks, that the ashes may be prevented from running out at it, or stopping it up while the ley filters through it.

Under this tub is another to receive the ley; and pure water is repeatedly passed through the first tub to form lees of different strength, which are kept separate at first until their strength is examined. The strongest required for use must swim or float an egg, and is called the ley of six degrees of the French hydrometer, or peseliqueur. The weaker are afterwards brought to this strength, by passing them through fresh barilla. But a certain quantity of the weak, which is of 2 degrees of the above hydrometer, is reserved for dissolving the oil, and gum, and the salt, which are used in subsequent parts of the process. This ley of 2 degrees is called the weak barilla liquor, the other is called the strong.

Dissolve the pearl-ashes in 10 pails, of 4 gallons each, of soft water, and the lime in 14 pails.

Let all the liquors stand till they become quite clear, and then mix ten pails of each.

Boil the cotton in the mixture five hours, then wash it in running water and dry it.

Step II. *Bainbie*, or *Gray Steep*.

Take a sufficient quantity (20 pails) of the strong barilla water in a tub, and dissolve or dilute in it 2 pails full of sheep's dung, then pour into it 2 quart bottles of oil of vitriol, and 1 lib. of gum arabic, and 1 lib. of sal ammoniac, both previously dissolved in a sufficient quantity of the weak barilla water, and lastly, 25 lib. of olive oil, which has been previously dissolved or well mixed with 2 pails of the weak barilla water.

The materials of this steep being well mixed, tramp or tread down the cotton into it, until it is well soaked; let it steep 24 hours, and then wring it hard and dry it.

Steep it again 24 hours, and again wring and dry it.

Steep it a third time 24 hours, after which wring and dry it, and lastly wash it well and dry it.

Step III. *The White Steep*.

This part of the process is precisely the same with the last, in every particular, except that the sheep's dung is omitted in the composition of the steep.

Step IV. *Gall Steep*.

Boil 25 lib. of galls bruised in 10 pails of river water until 4 or 5 are boiled away; strain the liquor into a tub, and pour cold water on the galls in the strainer, to wash out of them all their tincture.

As soon as the liquor is become milk-warm, dip your cotton hank by hank, handling it carefully all the time, and let it steep 24 hours.

Then wring it carefully and equally, and dry it well without washing.

Step V. *First Alum Steep*.

Dissolve 25 lib. of Roman alum in 14 pails of warm water, without making it boil, skim the liquor well, and add 2 pails of strong barilla water, and then let it cool until it be lukewarm.

Dip your cotton and handle it hank by hank, and let it steep 24 hours, and wring it equally and dry it well without washing.

Step VI. *Second Alum Steep*,

Is performed in every particular like the last, but after the cotton is dry, you steep it 6 hours in the river, and wash and dry it.

Step

---

population, which has been tripled within these fifteen years, amounts at present to 4000, and all these people exist by dyeing. None of those vices or cares produced by idleness are known here. The hearts of the inhabitants are pure, and their countenances unclouded. Servitude, which degrades the countries watered by the Peneus, has not ascended to these hills: no Turk can reside or live among these people; and they govern themselves, like their ancestors, by their *protoyeros* and their own magistrates. Twice have the savage mussulmans of Larissa, envious of their ease and happiness, attempted to scale their mountains in order to plunder their houses; and twice have they been repulsed by hands which suddenly quitted the shuttle to assume the musket.

"All hands, and even those of the children, are employed in the dye-houses of Ambelakia; and while the men dye the cotton, the women are spinning and preparing it. The use of wheels is not known in this part of Greece: all the cotton is spun on a distaff: the thread, indeed, is certainly not so round or equal, but it is softer, more silky, and more tenacious; it is less apt to break, and lasts longer; it is also more easily whitened, and more proper for being dyed. It is a pleasing spectacle to see the women of Ambelakia, each spinning from a distaff, and sitting conversing together on the threshold of their doors; but as soon as a stranger appears, they instantly retire and conceal themselves in their houses, manifesting, like Galatea, in their precipitate retreat, a desire of flying and of shewing themselves:

Et fugit ad salices, et se cupit ante videri."

STEP VII. *Dyeing Steep.*

The cotton is dyed by about 10 lib. at once, for which take 2½ gallons of ox blood, and mix it in the copper with 28 pails of milk-warm water, and stir it well; then add 25 lib. of madder, and stir all well together. Then having beforehand put the 10 lib. of cotton on sticks, dip it into the liquor, and move and turn it constantly one hour, during which you gradually increase the heat, until the liquor begin to boil at the end of the hour. Then sink the cotton, and boil it gently one hour longer; and, lastly, wash it and dry it.

Take out so much of the boiling liquor, that what remains may produce a milk-warm heat with the fresh water with which the copper is again filled up, and then proceed to make up a dyeing liquor as above, for the next 10 lib. of cotton.

STEP VIII. *The Fixing Steep.*

Mix equal parts of the gray steep liquor, and of the white steep liquor, taking 5 or 6 pails of each. Tread down the cotton into this mixture, and let it steep six hours, then wring it moderately and equally, and dry it without washing.

STEP IX. *Brightening Steep.*

Ten lib. of white soap must be dissolved most carefully and completely in 16 or 18 pails of warm water; if any little bits of the soap remain undissolved, they will make spots in the cotton. Add four pails of strong barilla water, and stir it well. Sink your cotton in this liquor, keeping it down with cross sticks, and cover it up and boil it gently two hours, then wash and dry it, and it is finished.

VESSELS.

The number of vessels necessary for this business is greater in proportion to the extent of the manufactory; but, in the smallest work, it is necessary to have four coppers of a round form.

1*st*, The largest, for boiling and for finishing, is 28 inches deep by 38 or 39 wide in the mouth, and 18 inches wide in the widest part.

2*d*, The second, for dyeing, is 28 deep, by 23 or 24 in the mouth.

3*d*, The third, for the alum steep, is like the second.

4*th*, The fourth, for boiling the galls, is 20 deep, by 28 wide.

A number of tubs or larger wooden vessels are necessary, which must all be of fir, and hooped with wood or with copper.

Iron must not be employed in their construction, not even a nail; but where nails are necessary, they must be of copper.

By the pail is always understood a wooden vessel, which holds four English gallons, and is hooped with copper.

In some parts of the above process, the strength of the barilla liquor or liquors is determined, by telling to what degree a peseliqueur or hydrometer sunk in them.

The peseliqueur is of French construction. It is similar to the glass hydrometer used by the spirit-dealers in this country; and any artist who makes these instruments, will find no difficulty in constructing one with a scale similar to that employed by M. Papillon, when he is informed of the following circumstances:

1*st*, The instrument, when plunged in good soft water, such as Edinburgh pipe water, at temperature 60 degrees, sinks to the 0, or beginning of the scale, which stands near the top of the stem.

2*d*, When it is immersed in a saturated solution of common salt, at the same temperature of 60 degrees, it sinks to the 26th degree of the scale only, and this falls at some distance from the top of the ball.

This saturated solution is made by boiling, in pure water, refined sea or common salt, till no more is dissolved, and by filtering the liquor when cold through blotting paper.

It should also be observed, that whenever directions are given to dry yarn, to prepare it for a succeeding operation, that this drying should be performed with particular care, and more perfectly than our dryest weather is in general able to effect. It is done therefore in a room heated by a stove to a great degree.

Haussmann's process for madder red.

239. There is still another process, which is recommended by Haussmann. This process, (says he) obtains a beautiful and durable red. He makes a caustic ley of one part of common potash dissolved in four of boiling water, and a half part of quicklime, which is afterwards slaked in it. He then dissolved one part of powdered alum in two of boiling water, and to this solution, while it was yet warm, he added that of the caustic ley. The solution of alumina being left at rest, formed, on cooling, a precipitate of sulphate of potash. A 33d part of linseed oil was then mixed with the alkaline solution of alumina, which then formed a milky saponaceous liquid. When the mixture is to be used, it ought to be well shaken, because the oil separates. The stuffs of cotton or linen must be successively immersed in it, and equally pressed, and must be dried under shelter from rain in summer, and in a warm place in winter; and being left in that state for 24 hours, are then washed in pure running water, and again dried. The same process in the immersion in alkaline ley is again to be repeated, taking care to introduce first those stuffs which were last in the first solution. The whole of the mixture should be consumed each time, as it would attract carbonic acid from the air, and suffer the alumina to be precipitated.

240. Two immersions in the alkaline solution of alumina mixed with linseed oil, afford a beautiful red: but by impregnating the stuffs a third, or even a fourth time, in the same manner, the most brilliant colours are obtained. The intensity of the colour is in proportion to the quantity of madder. A quantity of madder equal in weight to the stuffs, will yield a red, which, by clearing becomes of a rosy shade; and shades of crimson of different degrees of brightness are obtained, by using two, three, or four times the weight of madder; but unless the water employed in the processes contains some portion of lime, the addition of the chalk should never be omitted.

Scarlet with cochineal.

241. The scarlet colour communicated to cotton by means of cochineal, is far from being permanent; but if this colour is wished to be communicated to cotton, Dr Bancroft recommends to steep the cotton, previously moistened, for half an hour, in a diluted solution of murio-

murio-sulphate of tin, and then having wrung the cotton, to plunge it into water, in which as much potash has been dissolved as will neutralize the acid adhering to the cotton, so that the oxide of tin may be more copiously fixed on the fibres of the cotton. The stuff being afterwards rinsed in water, may be dyed with cochineal and quercitron bark, in the proportion of four pounds of the former, to two and a half or three pounds of the latter. A full bright colour is thus given to the cotton, which will bear slight washings with soap, and exposure to the air. Indeed the yellow part of the colour derived from quercitron bark will bear long boiling with soap, and will resist the action of acids.

Crimson.

242. With the aluminous mordant, as it is usually applied by calico printers for madder reds, cotton dyed with cochineal receives a beautiful crimson colour, which will bear several washings, and resist the weather for some time. It is not, however, to be considered as a fixed colour. Dr Bancroft is of opinion, that the addition of a small portion of cochineal in dying madder reds upon the finer cottons, would be highly advantageous to the calico-printers. By this addition the madder reds are rendered more beautiful, and the fawn colour, or brownish yellow hue, which injures these reds, would be thus overcome *.

SECT. II. *Of Yellow.*

243. In dyeing yellow, it is necessary to employ mordants, because the affinity of yellow colouring matters for either animal or vegetable stuffs is not sufficiently strong to produce durable colours. Yellow colours, therefore, belong to that class which Dr Bancroft has denominated *adjective colours*. As in the former section, we shall first give a short description of the nature and properties of the substances employed in dyeing yellow, and then point out the most approved modes of communicating their colours to woollen, silk, cotton, and linen stuffs.

The substances capable of giving a yellow colour to different stuffs are very numerous; they do not all produce similar quantities of colouring matter; their dye is not equally free; the colours they impart incline more or less to orange or green; they possess various degrees of brightness and permanency, and differ considerably in price; circumstances by which the choice of the dyer ought always to be regulated. But those commonly employed in dyeing yellow, are weld, fustic, anotta, and quercitron bark.

I. *Of the Substances employed in dyeing Yellow.*

Substances employed in dyeing yellow. Weld.

244. Weld (*reseda luteola*, Lin.) is a plant which grows wild in Britain, and in different European countries. Its leaves are long, narrow, and of a bright green, but the whole plant is made use of in the dyeing of yellow. There are two kinds of weld, cultivated and wild, the former of which is deemed more valuable than the latter, as it yields a much greater proportion of colouring matter. When this plant is fully ripe, it is pulled, dried, and bound up in bundles for the use of the dyer. The wild species grows higher and has a stronger stalk than that which is cultivated, by which the one may be readily distinguished from the other.

Properties.

245. A strong decoction of weld is of a brownish yellow colour, and if very much diluted with water the colour inclines to a green. An alkali gives to this decoction a deeper colour, and the precipitate it occasions is not soluble in alkalies. Most of the acids give it a paler tinge, occasioning a little precipitate which is soluble in alkalies. Alumina has so strong an affinity for the colouring matter of weld, that it can even abstract it from sulphuric acid, and the oxide of tin produces a similar effect. The greater part of metallic salts throw down similar precipitates, which vary in their shades of colour according to the metal employed. A solution of common salt renders the liquor turbid, and a solution of tin yields a copious yellow precipitate, while the liquor long continues turbid, and slightly coloured.

Fustic.

246. Fustic (*morus tinctoria*, Lin.) is procured from a tree of considerable magnitude, which grows in the West Indies. The wood is yellow, as its name imports, with orange veins. Ever since the discovery of America it has been used in dyeing, as appears from a paper in the Transactions of the Royal Society, of which Sir William Petty was the author. Its price is moderate, the colour it imparts is permanent, and it readily combines with indigo, which properties give it a claim to attention as a valuable ingredient in dyeing. Before it can be employed as a dye-stuff, it must be cut into chips and put into a bag, that it may not fix in, and tear the stuff, to which it is to impart its colouring matter.

Properties.

247. When a decoction of yellow wood or fustic is made very strong, the colour is of a reddish yellow, and when diluted it is of an orange yellow, which it readily yields to water. It becomes turbid by means of acids, its colour is of a pale yellow, and the greenish precipitate may be re-dissolved by alkalies. The sulphates of zinc, iron, and copper, as well as alum, throw down precipitates composed of the colouring matter and the different bases of the salts employed.

In examining the causes of the fixity of yellow colours, obtained from vegetables, Chaptal discovered that the durability of the pale yellow depended on the tanning principle, which is found united with the yellow colouring matter. He obtained by analyzing fustic, 1. A resinous or gummy matter, which can communicate a beautiful yellow colour. 2. An extractive matter, which is also yellow, and affords a beautiful colour. 3. A tanning principle of a pale yellow colour, which becomes black by boiling, or exposure to the air. This latter diminishes the brilliancy of the two former; but it may be separated by a simple process. Chaptal boiled with the wood some animal substance containing gelatinous matter, such as bits of skin, strong glue, &c. The tanning principle was thus precipitated with the gelatinous matter, and the bath held in solution only the colouring matters which yield a bright full yellow; and by means of this process he procured colours from several vegetables, equally bright with those which are communicated by yellow wood and quercitron bark *.

Anotta.

248. Anotta is a species of paste of a red colour, obtained from the berries of the *bixa orellana*, Lin. which is a native of America. The anotta of commerce is imported from America to Europe in cakes of two or three pound weight, where it is prepared from the seeds of the tree mentioned above; but the Americans are said to be in possession of a species of anotta superior to that which they export, both for the brilliancy and

---

* *Phil. of Perm. Col.* 317.

* *Phil. Mag.* i. 43

and permanency of the colour it imparts. They bruise the seeds with their hands moistened with oil, separating with a knife the paste as it is formed, and drying it in the sun; but the seeds are pounded with water when designed for sale, and allowed to undergo the process of fermentation.

247. Anotta yields its colouring matter more readily to alcohol than to water, on which account it is used in yellow varnishes to which an orange tinge is intended to be given. Acids form a precipitate with a decoction of anotta of an orange colour, which is soluble in alkalies; but solutions of common salt produce no sensible change. It yields an orange precipitate with a solution of alum, and the sulphates of copper and iron produce effects of nearly a similar nature. With a solution of tin, the precipitate is of a lemon colour and slowly deposited.

248. Quercitron, as it is denominated by Dr Bancroft, is the *quercus nigra* of Linnæus, and is a large tree which grows spontaneously in North America. The bark of it yields a considerable quantity of colouring matter, which was first discovered by Dr Bancroft in the year 1784, in whom the use and application of it in dyeing were exclusively vested for a certain term of years by virtue of an act of parliament. To prepare it for use, the epidermis is taken off and pounded in a mill, the result of which process is a number of filaments and a fine light powder; but as these do not contain equal quantities of colouring matter, it will be proper to employ them in their natural proportions.

249. Quercitron bark readily imparts its colouring matter to water at 100° of Fahrenheit, which is of a yellowish brown, capable of being darkened by alkalies, and brightened by acids. With muriate of tin the precipitate is copious, and of a yellow colour; with sulphate of tin it is a dark olive; and with sulphate of copper it is yellow, but inclining to an olive. Nitromuriate of tin yields a yellow extremely beautiful, probably owing to the oxide of tin combining with the colouring matter in a greater proportion than some other salts.

250. Besides the substances already mentioned as employed in the dyeing of yellow, we may add saw-wort to the number (*serratula tinctoria*, Lin.) a plant which yields a colouring matter nearly similar to that of weld, and may of consequence be used as a proper substitute. Dyers broom (*genista tinctoria*) produces a yellow of very indifferent nature, and is therefore only employed in dyeing stuffs of the coarsest kind. Turmeric (*curcuma longa*) is a native production both of the East and West Indies, and yields a more copious quantity of colouring matter than any other yellow dye-stuff; but it will probably never be of any essential service in dyeing yellow, as no mordant has yet been discovered, capable of giving permanency to its colour.

251. Chamomile (*anthemis tinctoria*) yields a faint yellow colour, the hue of which is not unpleasant, but is far from being durable, and even mordants are not capable of fixing it. Sulphate of lime, tartar and alum, bid fairest for success.

252. Fenugreek (*trigonella fœnugræcum*) yields seeds which, when ground, communicate to stuffs a pale yellow of tolerable durability; and the best mordants are found to be alum and muriate of soda, or common salt. American hiccory (*juglans alba*) is a tree, the bark of which yields a colouring matter in every respect resembling that of the *quercus nigra*, but in quantity greatly inferior. French berries (*rhamnus infectorius*) produce a tolerable yellow colour, but it is by no means permanent. When used in the process of dyeing, they are to be employed in the same manner as weld. According to Scheffer, a fine yellow colour may be imparted to silk, thread, and wool, by means of the leaves of the willow: but Bergman informs us that only the leaves of the sweet willow (*salix pentandra*) are proper for producing a permanent colour, as a few weeks exposure to the sun extracts that which is produced by the colouring matter from the leaves of the common willow.

253. In Switzerland and in England, the seeds of purple trefoil are sometimes employed in the art of dyeing, on which Vogler made a number of experiments, in order to ascertain what colours they would produce: and he found that a fine deep yellow was afforded by a bath made of a solution of these seeds with potash; that sulphuric acid yielded a light yellow, and sulphate of copper or blue vitriol, a yellow inclining to green. M. Dizé informs us, that the seeds of trefoil impart to wool a beautiful orange, and to silk a greenish yellow; and that while aluming is necessary in the process of dyeing with the seeds of trefoil, a solution of tin cannot be employed.

II. *Of the Processes for Dyeing Wool Yellow.*

With weld.

254. In dyeing woollen stuffs with weld, the mordants employed are alum and tartar, and by their means a pure, permanent yellow is obtained. The boiling is to be conducted in the usual way; and according to Hellot, four ounces of alum to one ounce of tartar are to be employed. Other dyers, however, employ half as much tartar as alum. The colour is rendered paler, but more lively, by means of the tartar.

Preparation of the bath.

255. The bath is prepared by boiling the plant inclosed in a thin linen bag, and keeping it from rising by means of a wooden cross. Some boil it till it sinks to the bottom of the vessel; while others, after it is boiled, take it out, and throw it away. From three to four lbs. of weld, and sometimes less, are allowed for every lb. of stuff; but the quantity must be regulated by the intensity of the shade desired. Some dyers add a small quantity of quicklime and ashes, which are found to promote the extraction of the colouring matter. These substances at the same time heighten the colour, but render it less susceptible of resisting the action of acids.

For different shades.

256. With other additions, and different management, different shades may be obtained. Thus, lighter shades are produced by dyeing after deeper ones, adding water at each dipping, and keeping the bath at the boiling temperature. These shades, however, are less lively than when fresh baths are employed, with a suitable proportion of weld. The addition of common salt or sulphate of lime to the weld bath communicates a richer and deeper colour. With alum it is paler and more lively, with tartar still paler, and with sulphate of iron the shade inclines to brown. According to Scheffer, by boiling the stuff two hours, with one-fourth of its weight of a solution of tin, and the same proportion of tartar, and then washing and boiling it with an equal weight of weld, a fine yellow is produced; but if the stuff

stuff be in the state of cloth, its internal texture is not penetrated. Poerner recommends a similar preparation as for dyeing scarlet, and by these means the colour is brighter, more permanent, and lighter.

With quercitron bark.

257. Dr Bancroft recommends the quercitron bark as one of the cheapest and best substances for dyeing wool yellow. The following is the simple process which he has proposed for its application. The bark is to be boiled up with about its weight, or one-third more, of alum, in a suitable proportion of water, for about 10 minutes. The stuff previously scoured is then to be immersed in the bath, taking care to give the higher colours first, and afterwards the paler straw colours. By this cheap and expeditious process, colours which are not wanted to be of a full or bright yellow, may be obtained. The colour may be considerably heightened by passing the unrinsed stuff a few times through hot water, to which a little clean powdered chalk, in the proportion of about 1½ lb. for each 100 lb. of stuff has been previously added. The bark, when used in dyeing, being first reduced to powder, should be tied up in a thin linen bag, and suspended in the liquor, so that it may be occasionally moved through it, to diffuse the colouring matter more equally.

Cheap process.

Process for permanent colours.

258. But although the above method possesses the advantages of cheapness and expedition, and is fully sufficient for communicating pale yellows; to obtain fuller and more permanent colours, the common mode of preparation, by previously applying the aluminous mordant, ought to be preferred. The stuff, therefore, should be boiled for about one hour or one hour and a quarter, with one-sixth, or one-eighth of its weight of alum, dissolved in a proper proportion of water. The stuff is then to be immersed, without being rinsed, into the dyeing bath, with clean hot water, and about the same quantity of powdered bark tied up in a bag, as that of the alum employed in the preparation. The stuff is then to be turned as usual through the boiling liquor, until the colour appears to have acquired sufficient intensity. One pound of clean powdered chalk for every 100 lb. of stuff is then to be mixed with the dyeing bath, and the operation continued for eight or ten minutes longer. This addition of the chalk raises and brightens the colour.

259. *Orange Yellow.*——To communicate a beautiful orange yellow to woollen stuffs, 10 lbs. of quercitron bark, tied up in a bag, for every 100 lb. of stuff, are to be put into the bath with hot water. At the end of six or eight minutes, an equal weight of murio-sulphate of tin is to be added, and the mixture well stirred for two or three minutes. The cloth, previously scoured, and completely wetted, is then immersed in the dyeing liquor, and briskly turned for a few minutes. By this process the colouring matter fixes on the cloth so quickly and equally, that after the liquor begins to boil, the highest yellow may be produced in less than 15 minutes.

For different shades.

260. High shades of yellow, somewhat similar to those obtained from quercitron bark by the above process, are frequently given with young fustic (*rhus cotinus*, Lin.) and dyers spirit, or nitro-muriate of tin; but this colour is much less beautiful and permanent, while it is more expensive than what is obtained from the bark.

261. *Bright golden Yellow.*——This colour is produced by employing 10 pounds of bark for every 100 lbs. of cloth, the bark being first boiled a few minutes, and then adding seven or eight lbs. of murio-sulphate of tin, with about five pounds of alum. The cloth is to be dyed in the same manner as in the process for the orange yellow.

262. Bright yellows of less body are produced by employing a smaller proportion of bark, as well as by diminishing the quantity of murio-sulphate of tin and alum. And indeed every variety of shade of pure bright yellow may be given by varying the proportions of the ingredients.

For gr- ish ye

263. To produce the lively delicate green shade, which, for certain purposes, is greatly admired, the addition of tartar, with the other ingredients, only is necessary, and the tartar must be added in different proportions, according to the shade which is wanted. For a full bright yellow, delicately inclining to the greenish tinge, it will be proper to employ eight pounds of bark, six of murio-sulphate of tin, with six of alum, and four of tartar. An additional proportion of alum and tartar renders the yellow more delicate, and inclines it more to the green shade; but when this lively green shade is wanted in the greatest perfection, the ingredients must be used in equal proportions. The delicate green lemon yellows are seldom required to have much fulness or body. Ten pounds of bark, therefore, with an equal quantity of the other ingredients, are sufficient to dye three or four hundred pounds of stuffs *.

For p green low.

264. To produce the exquisitely delicate and beautiful pale green shades, the surest method, Dr Bancroft observes, is to boil the bark with a small proportion of water, in a separate tin vessel for six or eight minutes, and then to add the murio-sulphate of tin, alum, and tartar, and to boil them together for about fifteen minutes. A small quantity of this yellow liquor is then to be put into a dyeing vessel, which has been previously supplied with water sufficiently heated. The mixture being properly stirred, the dyeing process is to be conducted in the usual way, and the yellow liquor, as it is wanted, gradually added from the first vessel. In this way, the most delicate shades of lively green lemon yellows are dyed with ease and certainty. Weld is the only dye-stuff from which similar shades of colour can be obtained; but it is four times more expensive. The yellows dyed from quercitron bark, Dr Bancroft adds, with murio-sulphate of tin and alum as mordants, do not exceed the expence of one penny for each pound of stuff; besides a considerable saving of time, labour, and fuel †.

Verdi used fo tartar.

265. A greenish shade may also be produced without tartar, by substituting verdigrise dissolved in vinegar, along with the bark; but it is neither so permanent, nor so bright and delicate, as that produced by means of tartar. Sulphate of indigo also, in very small proportion, communicates a similar shade, when it is employed with the bark, murio-sulphate of tin, and alum; but it is apt to take unequally on the stuff, and besides, in the language of the dyers, the colour has a tendency to *cast* or *fly* in the finishing.

Cochin and ma employ

266. Small proportions of cochineal, employed along with the bark and other ingredients, raise the colour to a beautiful orange, and even to an aurora. Madder may be also employed with the same view, for it heightens the yellow obtained from quercitron bark, although

---

* Banc 330.

† Ibid.

mple ours.

although the colour thus obtained is inferior in beauty to that from cochineal. The madder may also be employed with weld for the same purpose †.

rs quer- bark dur-

267. The colours obtained from quercitron bark, by the processes which we have now described, are very durable. They resist the action of the air, of soap, and of acids. It is by the effects of alum, but especially of tartar, that these colours become so fixed as to remain permanent by exposure to the air. It is observed of the highest yellows, even when they approach to the orange, and which are best dyed, either with muriate or murio-sulphate of tin and bark, that although they resist the action of soap and acids, they are apt to lose their lustre and become brown by the effect of the sun and air; but this also happens to yellows dyed with nitro-muriate of tin, both with the bark and with weld, but in a still greater degree with other yellow vegetable colouring matters. In some of these this defect is less easily obviated by alum and tartar, than it is in the yellow obtained from weld and quercitron bark *.

III. *Of the Processes for Dyeing Silk Yellow.*

ith weld.

268. To dye silk a plain yellow colour, the only ingredient which was formerly employed is weld. The following is the process. The silk being previously scoured in the proportion of 20 lbs. of soap to the 100 of stuff, and then alumed and washed after the aluming, or, as it is called, *refreshed*, the bath is prepared with two pounds of weld for every pound of silk; and, having boiled for 15 minutes, it is to be passed into a vat through a sieve or cloth. When the temperature is such as the hand can bear, the silk is introduced, and turned, until it has acquired a uniform colour. While this operation is going on, the weld is to be boiled a second time in fresh water; one half of the first bath is taken out, and its place supplied with a fresh decoction. The temperature of the fresh bath may be a little higher than the former, but it is necessary to guard against too great a degree of heat, that the colouring matter already fixed may not be dissolved. The stuff is to be turned as before, and afterwards taken out of the bath. A quantity of soda is to be dissolved in a part of the second decoction, and a larger or smaller proportion of this solution is to be added to the bath, according to the intensity of the shade required. When the silk has been turned a few times, a skain is wrung out, that it may be examined whether the colour be sufficiently full, and have the proper golden shade. To render the colour deeper, and to give it the gold cast, an addition of the alkaline solution is to be made to the bath, and to be repeated till the shade has acquired sufficient intensity. The alkaline solution may also be added along with the second decoction of the weld, observing the precaution, that the temperature of the bath be never too great.

a ep- colo

oth des

269. To produce other shades of yellow, having more of a gold or jonquille colour, a quantity of anotta, proportioned to the shade required, is to be added to the bath, along with the alkali. Lighter shades of yellow, such as pale lemon, or Canary-bird colour, are obtained, by previously whitening the silk, and regulating the proportion of ingredients in the bath by the shade required. To communicate a yellow having a tinge of green, a little indigo is added to the bath, if the silk has not been previously azured. To prevent the intensity of the shade from being too great, the silk may be more slightly alumed than usual.

Of Simple Colours.

A cheaper process.

270. But, according to Dr Bancroft, the different shades of yellow obtained from weld, may be given to silk with equal facility and beauty, and at a cheaper rate, by employing quercitron bark as a substitute. A quantity of bark powdered and enclosed in a bag, in proportion to the shade of colour wanted, as from one to two pounds for every twelve pounds of silk, is put into the dyeing vat while the water is cold. Heat is then applied; and when it has become rather more than blood warm, or of the temperature of 100°, the silk having previously undergone the aluming process, is to be immersed and dyed in the usual way. If a deep shade is wanted, a small quantity of chalk or pearl-ashes may be added towards the end of the operation. To produce a more lively yellow, a small proportion of murio-sulphate of tin may be employed; but it should be cautiously used, as it is apt to diminish the lustre of the silk. To produce such a shade, the proportions of the ingredients may be four pounds of bark, three of alum, and two of murio-sulphate of tin. These are to be boiled with a proper quantity of water for ten or fifteen minutes; and the temperature of the liquid being so much reduced as the hand can bear it, the silk is immersed and dyed as usual, till it has acquired the proper colour. Care should be taken to keep the liquor constantly agitated, that the colouring matter may be equally diffused *.

For an orange colour.

271. To dye silk of an aurora or orange colour, after being properly scoured, it may be immersed in an alkaline solution of anotta, the strength of which is to be regulated by the shade required; and the temperature of the bath should be between tepid and boiling water. When the desired shade has been obtained, the silks are to be washed and twice beetled, to free them from the superfluous colouring matter, which would injure the beauty of the colour. When raw silk is to be dyed, that which is naturally white should be selected, and the bath should be nearly cold; for otherwise the alkali, by dissolving the gum of the silk, destroys its elasticity. Silk is dyed of an orange shade with anotta, but the stuffs must be reddened with vinegar, alum, or lemon juice. The acid, by saturating the alkali employed to dissolve the anotta, destroys the yellow shade produced by the alkali, and restores its natural colour, which inclines to a red. But although beautiful colours are obtained by this process, they do not possess any great degree of permanency.

Yellow dye from mushrooms.

272. Several kinds of mushrooms afford lively and durable yellow dyes. A bright shining dye of this description has been extracted from the *boletus hirsutus*, which commonly grows on walnut and apple trees. The colouring matter is contained both in the tubular part, and also in the parenchyma of the body of the mushroom. To extract the colouring matter, it is pounded in a mortar, and the liquor which is thus obtained, is boiled for a quarter of an hour in water. An ounce of liquor is sufficient to communicate colouring matter to six pounds of water. After the liquor has been strained, the stuff to be dyed is immersed in it, and boiled for fifteen minutes. When silk is subjected to this process, after being dyed, it is made to pass through a bath of soft soap, by which it acquires a shin-

---

† croft, 35

* I 334.

* Ibid. 345.

ing golden yellow colour, which has a near resemblance to the yellow of the silk employed to imitate embroidery in gold. This has been hitherto brought from China, and bears a very high price, the method of dyeing it being unknown in Europe. All kinds of stuff receive this colour, but it is less bright on linen and cotton, and seems to have the strongest affinity for silk. The use of mordants, it is supposed, would modify and improve it greatly *.

IV. *Of the Processes for Dyeing Cotton and Linen Yellow.*

Processes with weld.

273. The process which has been usually followed in dyeing cotton and linen yellow, is by scouring it in a bath prepared in a ley with the ashes of green wood. It is afterwards washed, dried, and alumed, with one-fourth of its weight of alum. After 24 hours, it is taken out of the aluming, and dryed, but without being washed. The cotton is then dyed in a weld bath, in the proportion of one pound and a quarter of weld for each pound of cotton, and turned in the bath till it has acquired the proper colour. After being taken out of the bath, it is soaked for an hour and a half in a solution of blue vitriol (sulphate of copper), in the proportion of one-fourth of the weight of the cotton, and then immersed, without washing, for nearly an hour, in a boiling solution of white soap, after which it is well washed and dried.

For a deeper yellow

274. A deeper yellow is communicated to cotton, by omitting the process of aluming, and employing two pounds and a half of weld for each pound of cotton. To this is added a dram of verdigrise, mixed with part of the bath. The cotton is then to be dipped and worked till the colour become uniform. It is then taken out of the bath, that a little solution of soda may be added, after which it is returned, and kept for fifteen minutes. It is then wrung out and dried.

and other shades.

275. Other shades of yellow may be obtained, by varying the proportion of ingredients. Thus, a lemon colour is dyed by using only one pound of weld for every pound of cotton, and by diminishing the proportion of verdigrise, or using alum as a substitute †.

Cheaper and more permanent colours.

276. But a better method, as it affords more permanent and more beautiful colours, and at a smaller expence, is recommended by Dr Bancroft. This is by the use of quercitron bark, and the calico printers aluminous mordant, or the sugar of lead. The following is the process which he proposes to employ, for producing bright and durable yellow colours. One pound of sugar of lead, and three pounds of alum, are to be dissolved in a sufficient quantity of warm water. The cotton or linen, after being properly rinsed, is to be soaked in this mixture, heated to the temperature of 100°, for two hours. It is then taken out, moderately pressed over a vessel, to prevent the waste of the aluminous liquor. It is then dried in a stove heat, and after being again soaked in the aluminous solution, it is wrung out and dried a second time. Without being rinsed, it is to be barely wetted with lime water, and afterwards dried, and if a full, bright, and durable yellow is wanted, it may be necessary to soak the stuff in the diluted aluminous mordant, and after drying, to wet it a second time with lime water. After it has been soaked for the last time, it should be well rinsed in clean water, to separate the loose particles of the mordant, which might injure the application of the colouring matter. By the use of the lime-water, a greater proportion of alumina combines with the stuff, besides the addition of a certain proportion of lime.

Dyein bath.

277. In the preparation of the dyeing bath, from 12 to 18 lbs. of powdered quercitron bark are inclosed in a bag for every 100 lbs. of the stuff, varying the proportion according to the intensity of the shade desired. The bark is put into the water while it is cold; and immediately after, the stuff is immersed and agitated or turned for an hour, or an hour and a half, during which the water should be gradually heated, and the temperature raised to about 120°. At the end of this time the heat is increased, and the dyeing liquor brought to a boiling temperature; but at this temperature the stuff must remain in it only for a few minutes, because otherwise the yellow assumes a brownish shade. The stuff having thus acquired a sufficient colour, is taken out, rinsed and dried.

Advan of a dil mordan

278. Dr Bancroft observes, that when the aluminous mordant is employed, without the addition of water, one soaking only, and an immersion in lime water, may be sufficient; but he thinks that greater advantage is derived from the application of a more diluted mordant at two different times, or even by the immersion of the stuff a greater number of times, alternately in the diluted aluminous mordant, and lime water, and drying it after each immersion. By this treatment he found, that the colour always acquired more body and durability.

Nanke yellow.

279. Chaptal has proposed a process, for communicating to cotton a nankeen yellow, which at the same time that it affords a durable colour, has the advantage of being cheap and simple. When cotton is immersed in a solution of any salt of iron, it has so strong an affinity for the oxide, that it decomposes the salt, combines with the iron, and assumes a yellow colour. The process recommended by Chaptal is the following. The cotton to be dyed is put into a cold solution of copperas (sulphate of iron) of the specific gravity 1.02. It is afterwards wrung out, and immediately immersed in a ley of potash of the specific gravity 1.01. This ley must have been previously saturated with a solution of alum. When the stuff has been kept for four or five hours in this bath, it may be taken out, washed and dried. By varying the proportion of sulphate of iron, every variety of shade of nankeen yellow may be obtained.

By ano process.

280. We shall lay before our readers another process for dyeing nankeen colour, which is proposed and followed by Mr Brewer, a practical dyer. It is as follows.

"Mix as much sheep's dung in clear water as will make it appear of the colour of grass; and dissolve in clear water one pound of best white soap for every ten pounds of cotton yarn, or in that proportion for a greater or lesser quantity.

"Observe:—The tubs, boards, and poles, that are used in the following preparations must be made of deal; the boiling pan of either iron or copper.

First Operation.—"Pour the soap liquor prepared as above into the boiling pan; strain the dung liquor through a sieve; add as much thereof to the soap liquor in the pan as will be sufficient to boil the yarn, intended to be dyed, for five hours. When the liquors are

---

* *Phil. Mag.* v. 100.

† *Berthollet*, ii. 267.

are well mixed in the pan, enter the yarn, light the fire under the pan, and bring the liquor to boil in about two hours, observing to increase the heat regularly during that period. Continue it boiling for three hours; then take the yarn out of the pan, wash it, wring it, and hang it in a shed on poles to dry. When dry, take it into a stove or other room where there is a fire; let it hang there until it be thoroughly dry.

N. B. "The cotton yarn, when in the shed, should not be exposed either to the rain or sun: if it is, it will be unequally coloured when dyed.

Second Operation.—" In this operation use only one half of the soap that was used in the last, and as much dung liquor (strained as before directed) as will be sufficient to cover the cotton yarn, when in the pan, about two inches. When these liquors are well mixed in the pan, enter the yarn, light the fire, and bring the liquor to boil in about one hour; then take the yarn out, wring it out without washing, and hang it to dry as in the former operation.

Third Operation.—" This operation the same as the second in every respect.

Fourth Operation.—" For every ten pounds of yarn make a clear ley from half a pound of pot or pearl-ashes. Pour the ley into the boiling-pan, and add as much clear water as will be sufficient to boil the yarn for two hours; then enter the yarn, light the fire, and bring it to boil in about an hour. Continue it boiling about an hour, then take the yarn out, wash it very well in clear water, wring it, and hang it to dry as in former operations.

N. B. " This operation is to cleanse the yarn from any oleaginous matter that may remain in it after boiling in the soap and dung liquors.

Fifth Operation.—" To every gallon of iron liquor (K) add half a pound of ruddle or red chalk (the last the best) well pulverized.

" Mix them well together, and let the liquor stand four hours, in order that the heavy particles may subside; then pour the clear liquor into the boiling-pan, and bring it to such a degree of heat as a person can well bear his hand in it; divide the yarn into small parcels, about five hanks in each; soak each parcel or handful very well in the above liquor, wring it, and lay it down on a clean deal board. When all the yarn is handed through the liquor, the last handful must be taken up and soaked in the liquor a second time, and every other handful in succession till the whole is gone through; then lay the yarn down in a tub, wherein there must be put a sufficient quantity of ley made from pot or pearl-ashes, as will cover it about six inches. Let it lie in this state about two hours, then hand it over in the ley, wring it, and lay it down on a clean board. If it does not appear sufficiently deep in colour, this operation must be repeated till it has acquired a sufficient degree of darkness of colour: this done, it must be hung to dry as in former operations.

N. B. " Any degree of red or yellow hue may be given to the yarn by increasing or diminishing the quantity of ruddle or red chalk.

Sixth Operation.—" For every ten pounds of yarn make a ley from half a pound of pot or pearl-ashes; pour the clear ley into the boiling pan: add a sufficient quantity of water thereto that will cover the yarn about four inches; light the fire, and enter the yarn when the liquor is a little warm; observe to keep it constantly under the liquor for two hours; increase the heat regularly till it come to a scald; then take the yarn out, wash it, and hang it to dry as in former operations.

Seventh Operation.—" Make a sour liquor of oil of vitriol and water: the degree of acidity may be a little less than the juice of lemons; lay the yarn in it for about an hour, then take it out, wash it very well and wring it; give it a second washing and wringing, and lay it upon a board.

N. B. " This operation is to dissolve the metallic particles, and remove the ferruginous matter that remains on the surface of the thread after the fifth operation.

Eighth Operation.—" For every ten pounds of yarn dissolve one pound of best white soap in clear water, and add as much water to this liquor in your boiling-pan as will be sufficient to boil the yarn for two hours. When these liquors are well mixed, light the fire, enter the yarn, and bring the liquor to boil in about an hour. Continue it boiling slowly an hour; take it out, wash it in clear water very well, and hang it to dry as in former operations: when dry, it is ready for the weaver.

N. B. " It appears to me, from experiments that I have made, that less than four operations in the preparation of the yarn will not be sufficient to cleanse the pores of the fibres of the cotton, and render the colour permanent *."

Process followed in the east.

281. A method of dyeing cotton and linen a durable yellow colour is practised in the east. The object of this process, which is tedious, is to increase the affinity between the alumina and the stuff, so that it may adhere with sufficient force to produce a permanent colour. For this purpose three mordants are employed: these are oil, tan, and alum. The cotton is soaked in a bath of oil, mixed with a weak solution of soda. Animal oil, as it is found to answer best, is preferred. Glue has also been tried, and is found to answer very well. The soda must be in the caustic state, for in that state it combines with the oil, and produces on the cloth an equal absorption. The stuff is then to be washed, and afterwards put into an infusion of nut-galls of the white kind, and the infusion should be used hot. The tan combines with the oil, while the gallic acid carries off any portion of alkali which may adhere to the cloth. When the stuff is removed from the bath, it should be quickly dried; and too great an excess of galls beyond a proper proportion with the oil should be avoided, as it is apt to darken the shade of colour. After this preparation the stuff is to be immersed in a solution of alum; and in consequence of the affinity which exists between tan and alumina, the alum is decomposed, and its earth combines with the tan. After these preliminary steps, the cotton is to be dyed with quercitron bark, according to the process which has been already described.

SECT.

(K) Iron liquor is what the linen-printers use.

* Edin. Mag. xxii.

SECT. III. *Of Blue.*

282. The next of the simple colours is blue. We shall first treat of the substances which are employed in dyeing blue, and then describe the processes which are followed in fixing this colour.

I. *Of the Substances which are employed in Dyeing Blue.*

The only substances which are used in dyeing blue, are indigo and woad.

Indigo.

283. Indigo was not used for the purpose of dyeing in Europe till near the middle of the 16th century. A substance is mentioned by Pliny *, which was brought from India, and termed *indicum*, which seems to have been the same as the indigo of the moderns; but it does not appear that either the Greeks or the Romans knew how to dissolve indigo, or its use in dyeing, although it was applied as a paint. It was, however, long before known as a dye in India. The first indigo which was employed for the purpose of dyeing by Europeans, was brought by the Dutch from India. One of the species of the plant from which it is obtained, was discovered by the Portuguese in Brazil, where it grows spontaneously, as well as in other parts of America. Being afterwards successfully cultivated in Mexico, and some islands of the West Indies, the whole of the indigo employed in Europe was supplied from these countries. The indigo from the East Indies has, however, of late recovered its character, and is imported into Britain in considerable quantities.

introduced into Europe.

Three species.

284. There are three species of the indigo plant, which are usually cultivated in America. The first is the *indigofera tinctoria*, Linn. which besides being a smaller and less hardy plant, is inferior to the others on account of its pulp; but as it yields a greater proportion, it is generally preferred. The second is the *indigofera disperma*, Linn. or *Guatimala indigo plant*. This is a taller and hardier plant, and affords a pulp of a superior quality to the former. The third is the *indigofera argentea*, Linn. which is the hardiest of the three species; yields a pulp of the finest quality, though in smallest proportion.

Method of preparing indigo.

285. When the indigo plant has arrived at maturity, it is cut a few inches above the ground, disposed in strata in a large vessel or steeper, and being kept down with boards, is covered with water; and in this state it is left to ferment till the pulp is extracted. The process commences by the evolution of heat, and the emission of a great quantity of carbonic acid gas. When the fermentation has continued for a sufficient length of time, which is known by the tops becoming tender and pale, the liquor, which is now of a green colour, is drawn off into large flat vessels, called *beaters*, where it is agitated with buckets, or other convenient apparatus, till blue flocculæ begin to appear. To promote the granulation or separation of the flocculæ, it is usual to add clear lime water till the liquor in which they are suspended become quite colourless. The liquor being sufficiently impregnated with the lime water, is left at rest, to allow the particles of the colouring matter to precipitate; after which the supernatant liquor is drawn off, and the sediment collected into linen bags, which are suspended for some time to let the water drain off. It is then put into square boxes, or formed into lumps and dried in the shade. The indigo thus prepared is in a state fit for the market.

Varies in its qualities.

286. The indigo which is produced in this operation differs greatly, not only according to the quality of the plant from which it is obtained, but according to the mode of preparation. But the difference of quantity seems to depend entirely on the heterogeneous substances with which it is mixed, and on the degree of consistence which it has acquired in drying. The lightest kind, which is brought from Guatimala, is called *light indigo*; it is of a fine blue colour, and is the most valuable, because it is of the finest quality. Indigo exhibits various shades of colour, which is also owing to the mixture of foreign substances. The most common shades are blue, violet, and copper colour.

Is obtained from other plants.

287. Other plants have also been discovered, which by a process somewhat similar, afford indigo, and in particular the *nerium tinctorium*, or rose bay, an account of which, with the method of manufacturing indigo from its leaves, has been given by Dr Roxburgh. This tree grows in great abundance in different parts of the East Indies; and plantations of it, raised from seeds, have succeeded well in Bengal. The leaves of the nerium afford indigo, not only when they are fresh gathered, but also when they are nearly dried; but they yield the best indigo after being kept a day or two. The leaves collected the preceding day are put into a copper, so as nearly to fill it without pressing. The copper is filled with water till within three inches of the top; and hard spring water, which increases the quantity of indigo, and improves its quality, is preferred. The fire is then applied, and kept up, till the liquid becomes of a green colour in the vessel. The leaves then become of a yellowish colonr, and the heat of the liquor about 150°, or 160°. The leaves should be constantly agitated, that they may be equally heated, as well as to promote the operation, by the expulsion of the carbonic acid gas. When the process exhibits the above appearances, the liquor is to be drawn off, passed through a hair-cloth, and agitated while hot in the usual way, till granulation takes place, or the appearance of blue flakes is observed. About $\frac{1}{15}$th part of strong lime water is then added, to promote the precipitation of the indigo, and the remaining part of the process is similar to that described above, for the manufacture of indigo from *indigofera* †.

Nature of the substances extracted.

288. The object of the processes which are followed in the manufacture of indigo, is to extract from the plants which yield it, a green substance, which is soluble in water. This substance, which has a strong affinity for oxygen, gradually attracts it from the air, becomes of a blue colour, and is then insoluble in water. This absorption is greatly promoted by agitation, for then a greater surface is exposed to the action of the air; and the lime water, by combining with carbonic acid, which exists in the green matter, also promotes the separation of the indigo.

Properties of indigo.

289. Indigo is insoluble in water, alcohol, ether, and oils, and the only acids which produce any effect upon it, are the sulphuric and nitric. By the latter it is soon changed to a dirty white colour, and is at last entirely decomposed. When the acid is concentrated, the indigo is inflamed; but when it is diluted, the indigo becomes brown, and crystals like those of oxalic and

---

* *Lib.* xxxv.

† *Bancroft* 427.

and tartarous acids make their appearance: and when the acids and crystals are washed off, there remains behind a kind of resinous matter. Sulphuric acid in the concentrated state dissolves indigo, with the evolution of a great deal of heat. The solution is opaque and black, but when diluted with water, it changes to a deep blue colour. Dr Bancroft has denominated this solution *sulphate of indigo*, which has been long known by the name of *liquid blue*. The fixed alkalies in the state of carbonate precipitate slowly from sulphate of indigo, a blue coloured powder, which has the properties of indigo, but is found to be soluble in most of the acids and alkalies. Pure alkalies destroy the colour of sulphate of indigo, as well as that which is precipitated.

s employ- ed dye- in two tes.

290. Indigo is employed in dyeing, both in the state of liquid blue, or sulphate of indigo, from which is obtained the beautiful colour called *Saxon blue*; and also in the state of simple indigo, or the indigo of commerce. In dyeing with indigo, it must be reduced to the state of the green matter as it exists in the plants, or when it is first extracted from them. It must be deprived of the oxygen, to the combination of which the blue colour is owing. In this state it becomes soluble in water by means of the alkalies. To effect this separation of the oxygen, the indigo must be mixed with a solution of some substance which has a stronger affinity for oxygen than the green matter of indigo. Such substances are green oxide of iron and metallic sulphurets. Lime, green sulphate of iron, and indigo, are mixed together in water, and during this mixture the indigo is deprived of its blue colour, becomes green, and is dissolved, while the green oxide of iron, is converted into the red oxide. In this process, part of the lime decomposes the sulphate of iron, and as the green oxide is set at liberty, it attracts oxygen from the indigo, and reduces it to the state of green matter, which is immediately dissolved by the action of the rest of the lime. Indigo is also deprived of its oxygen, and prepared for dyeing, by another process. Some vegetable matter is added to the indigo mixed with water, with the view of exciting fermentation; and quicklime or an alkali is added to the solution, that the indigo, as it is converted into the green matter, may be dissolved.

Wo

291. Another plant, known under the name of *pastel* or *woad* (*isatis tinctoria*), is employed for dyeing blue. Another species (*isatis lusitanica*), which is a smaller plant, is also employed in dyeing. The *isatis tinctoria* is cultivated in France and in England. When the plant has reached maturity, it is cut down, washed in a river, and speedily dried in the sun. It is then ground in a mill, and reduced into a paste, which is formed into heaps, covered up to protect them from the rain, and at the end of a fortnight, the heap is opened to mix the whole well together. It is afterwards formed into round balls, which are exposed to the wind and sun, that the moisture may be separated, The balls are heaped upon one another, become gradually hot, and exhale the smell of ammonia. To promote the fermentation, which is stronger in proportion to the quantity heaped up, and the temperature of the season, the heap is to be sprinkled with water till it falls down in the state of coarse powder, in which state it appears in commerce. The blue colour obtained from woad is very permanent, but has little lustre. But its colour is not only inferior in beauty to that obtained from indigo; it affords also a smaller proportion of colouring matter, so that since the discovery of indigo, the use of woad has diminished.

II. *Of the Processes for Dyeing Wool Blue.*

Preparation of the vat.

292. The preparation for dyeing blue is made in a large wooden vessel or vat, which should be so constructed as to retain the heat, which is a matter of considerable importance in the process. The vat is therefore set up in a separate place from the coppers, and is sunk so far in the ground as to be only breast high above it. Before the introduction of indigo, blue was dyed with woad, which furnished a permanent, but not a deep colour; but a very rich blue is obtained by mixing indigo with the woad, and these are almost the only substances which are now employed for dyeing woollen stuffs. The proportions of these substances are varied by different dyers, and according to the shade which is required. The following is the account of the preparation of a vat, as it is given by Quatremere. Into a vat of about seven and a half feet deep, and five and a half in diameter, are thrown two balls of pastel or woad, which are previously broken, and together amount to about 400 pounds weight; 30 pounds of weld are boiled in a copper for three hours, in a sufficient quantity of water, to fill the vat. To this decoction are added 20 pounds of madder and a basket full of bran. The boiling is then continued half an hour longer. This bath is cooled with 20 buckets of water, and after it is settled, and the weld taken out, it is poured into the vat, which must be stirred with a rake all the time that it is running in, and for 15 minutes longer. The vat is then covered up very hot, and allowed to stand for six hours, when it is uncovered, and raked again for 30 minutes. The same operation must be repeated every three hours. When the appearance of blue streaks is perceived on the surface of the vat, eight or nine pounds of quicklime are added; the colour then becomes of a deeper blue, and the vat exhales more pungent vapours. Immediately after the lime, or along with it, the indigo, which has been previously ground in a mill, with the smallest possible quantity of water, is put into the vat. The quantity is to be regulated by the intensity of the shade required. From ten to thirty pounds may be put into a vat such as we have now described. If on striking the vat with a rake, a fine blue scum arises, no other previous preparation is required than to stir it with the rake twice in the space of six hours, to mix the ingredients completely. Great care should be taken not to expose the vat to the air, except during the time of stirring it. When that operation is finished, it is covered with a wooden lid, on which are spread thick cloths, to retain the heat as much as possible; but after all these precautions, at the end of eight or ten days it is greatly diminished, and is at last entirely dissipated, so that the liquor must be again heated, by pouring the greater part of the liquor of the vat into a copper under which a large fire is made. When the liquor has acquired a sufficient temperature, it is returned into the vat, and carefully covered up.

Accidents to which the vat is liable.

293. Vats of this description are sometimes liable to accidents. A vat is said to be repelled, when having previously afforded fine shades of blue, it appears black,

black, without any blue streaks; and if it be stirred, the black colour becomes deeper; the vat at the same time exhales, instead of a sweetish smell, a pungent odour; and the stuff dyed in a vat in this state, comes out of a dirty gray colour. These effects are ascribed to an excess of lime.

Means of obviating them,

294. Different means are employed to recover a repelled vat. Some are satisfied with merely reheating it; while others add tartar, bran, urine, or madder. Hellot recommends bran and madder as the best remedy. If the excess of lime be not very great, it is sufficient to leave it at rest five or six hours, putting in a quantity of bran and three or four pounds of madder, which are to be sprinkled on the surface, and then it is to be covered up, and after a certain interval, to be tried again. But if the vat has been so far repelled as to afford a blue only when it is cold, it must be left at rest to recover, and sometimes must remain whole days without being stirred with the rake. When it begins to afford a tolerable pattern, the bath must be reheated. In general, this revives the fermentation. The addition of bran or madder, or a basket or two of fresh woad, produces the same effect.

and remedying putrefaction.

295. This vat sometimes runs into the putrefactive process. When this happens, the colour of the vat becomes reddish, the paste rises from the bottom, and a fetid smell is exhaled. This accident is owing to a deficiency of lime, and it must be corrected by adding a fresh quantity. The vat is then to be raked; after two hours more lime is added, and the process of raking again performed. These operations are to be repeated till the vat is recovered.

Precautions in the use of lime.

296. Nothing requires more attention in treating a vat of this kind, than the distribution of the lime, the principal use of which is to moderate the tendency to putrefaction, and to limit the fermentation to that degree which is necessary to deprive the indigo of its oxygen. If too much lime be added, the necessary fermentation is retarded, and if there be too little, the putrefactive process commences.

Dyeing process.

297. Two hours previous to the dyeing operation, the vat should be raked; and to prevent the stuff coming in contact with the sediment, which would produce inequalities in the colour, a cross of wood is introduced. The stuff is then to be completely wetted with pure water a little heated; and being wrung out, it is dipped into the vat, where it is moved about for a longer or a shorter time, according to the depth of shade required. During this operation it is taken out occasionally, to be exposed to the air, the action of which is necessary to change the green colour of the bath into a blue. Stuffs dyed blue in this manner must be carefully washed, to carry off the loose particles of colouring matter; and when the shade of blue is deep, they ought even to be cleansed, by fulling with soap. This operation does not alter the colour.

Indigo vat.

298. When a vat is prepared entirely of indigo, without pastel or woad, it is called an *indigo vat.* The vessel employed for this purpose is of copper, into which water is poured according to its capacity, to the amount of 40 buckets, in which have been boiled six pounds of potash, twelve ounces of madder, and six pounds of bran. Six pounds of indigo ground in water are then put in, and after it has been carefully raked, the vat is to be covered. A slow fire is to be kept up, and twelve hours after it is filled, it is to be raked a second time. This operation is to be repeated every twelve hours, till it come to a blue colour, which will generally be the case in about 48 hours. If the bath is properly managed, it will be of a fine green, exhibiting on the surface coppery scales, and a blue scum or flower. In this vat the indigo is rendered soluble in water, by means of the alkali instead of lime. The dyeing operation is to be conducted in the same manner as the preceding.

Hellot's vats.

299. Two vats have been described by Hellot, in which the indigo is dissolved by means of urine. Madder is added to it, and in the one vinegar, in the other alum and tartar, of each a quantity equal in weight to that of the indigo. The proportion of urine must be considerable. In considering the theory of this process, it seems probable that the indigo, deprived of its oxygen by the urine and madder during the fermentation, is dissolved by the ammonia which is formed in the urine. When the solution of alum and tartar is added, an effervescence, which Hellot observed, is produced. This, it is probable, has a tendency to retard or stop the putrefaction. But in vats of this description, operations on a large scale cannot be carried on; they seem only adapted for small dye-houses.

III. *Of the Processes for Dyeing Silk Blue.*

With indigo.

300. Silk is dyed blue with indigo alone, without any proportion of woad. The proportion of indigo mentioned in the preparation of the indigo vat, and sometimes a larger proportion, is employed, with six pounds of bran, and about twelve ounces of madder. According to Macquer, half a pound of madder for each pound of potash, renders the vat greener, and produces a more fixed colour in the silk. When the vat is come to, it should be refreshed with two pounds of potash, and three or four ounces of madder; and after being raked, in the course of four hours it is fit for dyeing. The temperature should be so moderated, that the hand may be held in it without uneasiness.

Preparation of th silk.

301. The silk, after being boiled with soap, in the proportion of 30 pounds of soap to 100 of silk, and well cleaned by repeated beetlings in a stream of water, must be dyed in small portions, because it is apt to take on an uneven colour. When it has been turned once or oftener in the bath, it is wrung out, and exposed to the air, that the green colour may change to a blue. When the change is complete, it is thrown into clear water, and afterwards wrung out. Silk dyed blue should be speedily dried. In damp weather and in winter, it is necessary to conduct the drying in a chamber heated by a stove. The silk should be hung on a frame kept constantly in motion. To dye light shades, some dyers employ vats that are somewhat exhausted: but it ought to be observed, that the colour thus obtained is less beautiful and less permanent than when fresh vats, containing a smaller quantity of indigo, are employed.

For Turke blue.

302. Some addition is required to be made to the indigo, to give silk a deep blue. A previous preparation is necessary, by giving it another colour or ground. For the Turkey blue, which is the deepest, a strong bath of archil is first prepared. Cochineal is also sometimes used, instead of archil, for the ground, to render the colour more permanent. A blue is given to silk

O mple C urs.

silk by means of verdigrise and logwood, but possesses little durability. It might be rendered more permanent, by giving it a lighter shade in this bath, then dipping it in a bath of archil, and finally in the indigo vat.

D g ra ilk.

303. When raw silk is to be dyed blue, such as is naturally white should be selected. Being previously soaked in water, it is put into the bath in separate hanks, as already directed for scoured silks; and as raw silk is found to combine more readily with the colouring matter, the scoured silk, when it can be conveniently done, should be first put into the bath. If archil, or any of the other ingredients which have been already mentioned, are required to give more intensity to the colour, the mode of application is the same as that directed for scoured silk.

IV. *Of the Processes for Dyeing Cotton and Linen Blue.*

re ation t vat.

304. For dyeing cotton and linen blue, Pileur d'Apligny recommends a vat containing about 120 gallons. From six to eight pounds of indigo, reduced to powder, are boiled in a ley drawn off from a quantity of lime, equal in weight to the indigo, and a quantity of potash double its weight. During the boiling, which is to be continued till the indigo is completely penetrated with the ley, the solution must be constantly stirred, to prevent the indigo from being injured, by adhering to the bottom of the vessel.

305. During this process, another quantity of quicklime, equal in weight to the indigo, is to be slaked. Twenty quarts of warm water are added, in which is to be dissolved a quantity of copperas (sulphate of iron) equal to twice the weight of the lime. The solution being completed, it is poured into the vat, which is previously half filled with water. To this the solution of indigo is added, with that part of the ley which was not employed in the boiling. The vat must now be filled up to within two or three inches of the top. It must be raked twice or thrice a day till it is completely prepared, which is generally the case in 48 hours, and sometimes sooner, as it depends on the temperature of the atmosphere. A small proportion of bran, madder, and woad, is recommended by some, to be added to such a vat as we have now described.

imer ce

306. The process which is followed at Rouen, and described by Quatremere, is simpler. The vats, which are constructed of a kind of flint, are coated within and without with fine cement, and are arranged in one or more parallel lines. Each vat contains four hogsheads of water. The indigo, to the amount of 18 or 20 pounds, being macerated for a week in a caustic ley, strong enough to bear an egg, is ground in a mill; three hogsheads and a half of water are put into the vat, and afterwards 20 pounds of lime. The lime being thoroughly slaked, the vat is raked, and 36 pounds of copperas are added; and when the solution is complete, the ground indigo is poured in through a sieve. It is raked seven or eight times the same day, and after being left at rest for 36 hours, it is in a state fit for dyeing.

ces n rge t.

307. In extensive manufactories, it is necessary to have vats set at different times. In conducting the process of dyeing, the stuffs are first dipped in the most exhausted vat, and then regularly proceeding from the weakest to the strongest, if they have not previously attained the desired shade. The stuffs should remain in the bath only about five or six minutes, for in that time they combine with all the colouring matter they can take up. After the stuffs have been dipped in a vat, it should not be used again, till it has been raked, and stood at least 24 hours, unless it has been lately set, when a shorter period is sufficient.

Of Simple Colours.

308. After the stuffs have been dipped three or four times in a vat, it begins to change. It becomes black, and no blue or copper-coloured streaks are seen on the surface after raking it. It must then be renewed, by adding four libs. of copperas, with two of quicklime, after which it must be raked twice. In this way a vat may be renewed three or four times; but the additional quantity of ingredients must be diminished, as the strength of the vat is exhausted *.

Process of Bergman.

309. A vat which is still more simple and more easily prepared, has been recommended by Bergman. The proportion of the ingredients which he has directed to be employed, is the following. To three drachms of indigo reduced to powder, three drachms of copperas, and three of lime, add two pints of water. Let it be well raked, and in the course of a few hours it will be in a proper state for dyeing.

Haussmann's

310. Haussmann employs a still smaller proportion of indigo. For 3000 libs. of water, he takes 36 lbs. of quicklime slaked in 200 libs. of water, with which the indigo in the proportion of from 10 to 20 libs. well ground, is to be mixed. He then dissolves 30 libs. of copperas in 120 libs. of hot water. The whole being left at rest for fifteen minutes, the vat is filled, and gently and constantly stirred. When a deeper shade is wanted, and particularly when linen is to be dyed, the proportion of indigo should be greater; but the shade depends very much on the time the stuffs remain in the vat, and the times it has been used. When the vat becomes turbid, the process of dyeing must be interrupted, till it has been again raked, and the supernatant liquor become transparent. If the effects of the lime fail, a new quantity, fresh slaked, must be added; and if the iron cease to produce the effect on the indigo, a new portion must be also added, observing the precaution to have a greater quantity of lime than what is necessary to saturate the sulphuric acid. When the indigo seems to be exhausted, fresh portions ground in water are also to be added; the vat is to be raked several times, and allowed to settle, after which it is again fit for use. In this way Mr Haussmann informs us he preserved a vat for the space of two years; and had it not been for the accumulation of sediment, which prevented the stuffs from being immersed to a sufficient depth, it might have been continued in use for a much longer time. It is worth while to add, that Mr Haussmann found, that a pattern of cloth dipped in water acidulated with sulphuric acid, immediately after it was taken out of the bath, became of a much deeper blue than a similar pattern exposed to the air, or another dipped in river water.

311. Another convenient and expeditious vat is mentioned by Bergman, and described by Scheffer. Indigo reduced to fine powder, in the proportion of three drachms to a quart, is added to the strong ley of the soap boiler. After a few minutes, when the colouring matter is well penetrated by the ley, six drachms of powdered orpiment are to be added. In a few minutes after the bath has been well raked, it becomes green,

---

* *Berthollet*, ii. 90.

Of Simple Colours.

and the blue streaks appear on the surface. Heat is to be applied; when the operation of dyeing may commence.

312. The preparation employed for printing cottons is similar to the above bath, excepting in the proportions of orpiment and indigo, which are greater in the former; but these proportions are very different in different manufactories.

Discovery of Saxon blue.

313. *Saxon Blue.*—The colour which is obtained by dyeing with a solution of indigo in sulphuric acid is known under the name of *Saxon blue*, because the process was first carried on at Grossenhayn in Saxony, by Counsellor Barth, who made the discovery about the year 1740. This discovery was for some time kept secret, and the method seems to have been originally very complicated. Alumina, antimony, and some other substances, were previously added to the sulphuric acid. These, however, are now omitted, and the indigo alone is dissolved in the acid.

Preparation of the dye.

314. From a great number of experiments which were made on this process by Bergman, he concluded, that in those cases where the sulphate of indigo afforded only a fading colour, the acid employed had been too weak. Quatremere observes that, among several processes for dyeing with sulphate of indigo, he discovered only two, in which the stuffs were completely penetrated with colouring matter. To effect this, he employed an alkali, in the proportion of one ounce to an ounce of indigo, and six ounces of sulphuric acid. With these proportions of the ingredients he obtained a deep vivid blue, equally intense through every part of the stuff. Poerner, who has paid great attention to this preparation, also employs an alkali, by means of which a more pleasing colour, which penetrates deeper, is produced. The proportions which he recommends are four parts of sulphuric acid to one of indigo. The indigo is first reduced to a fine powder, and the sulphuric acid, in the concentrated state, is poured upon it. The mixture is stirred for some time, and having stood twenty-four hours, one part of dry potash in fine powder, is added; and after the whole is again stirred, it remains for twenty-four hours longer. It is then to be diluted with eight times its weight of water, which must be gradually added, or a greater or less proportion as may be wanted.

By Bancroft.

Dr Bancroft seems to be of opinion, that a more durable blue may be obtained by diluting the acid with an equal quantity of water, when the indigo is put in, and allowing the mixture to remain forty-eight hours; for he thinks by this slower and more moderate action, the basis of the indigo is less injured. Instead of the potash employed by Poerner, Dr Bancroft uses chalk; and even in such a quantity as to saturate the acid. In this case the indigo is precipitated along with the chalk; and, when collected into a solid mass, communicates a blue colour to wool, but more slowly than by the common method, in which the combination is very rapid and the dyeing unequal. This inconvenience he thinks might be obviated by the use of chalk *.

For woollen stuffs.

315. To produce a Saxon blue colour on woollen stuffs, they are prepared with alum and tartar. And in proportion to the shade required, the quantity of solution of indigo put into the bath must be regulated. When a deep shade of Saxon blue is wanted, the stuff must be passed different times through vessels containing such a quantity of colouring matter as is sufficient to give light colours. In this way, by repeated applications, the colours become more uniform.

For sil

316. The sulphate of indigo is also employed to dye silk. For this purpose, attempts have been made to unite the advantages of the indigo vat and its solution in sulphuric acid. A process of this kind is greatly recommended by Guhliche, which produces beautiful colours, and is at the same time cheap and convenient. The bath is composed of one pound of indigo, three pounds of quicklime, three of copperas, and one and a half of orpiment. The indigo is first to be carefully ground and mixed with water, put into a wooden vat, and diluted with water, according to the shade of colour wanted. The lime is then to be added, and the mixture being well stirred, it is covered up, and allowed to remain at rest for some hours. After this the copperas in the state of powder is added, the whole well stirred, and the vat covered up. And lastly, at the end of some hours, the orpiment reduced to powder is thrown in, and the whole left at rest for several hours. The mixture is afterwards to be stirred, and then left to settle, till the liquor becomes clear; when the blue streaks or flower which covers it is removed, and the silk previously dipped in warm water, is to be dyed hank by hank. When it is removed from the bath, it is to be washed in a stream of water, and dried.

317. This process is recommended as the means of obviating a greenish cast, which is sometimes observed in Saxon blue, and which is supposed to be owing to some change in the particles of indigo, by means of the sulphuric acid.

Engli blue.

318. The colour denominated *English blue* is produced by means of the sulphate of indigo. To give silk this colour, it is first to be dyed a light blue; and, when taken out of this bath, it is dipped in hot water, washed in a stream, and left in a bath composed of the sulphate of indigo, to which a little of the solution of tin has been added, until the proper shade is obtained, or the bath is exhausted. Previous to its being put into this bath, it may be dipped in a solution of alum, in which it should only remain a very short time. Silk, which has been dyed according to this process, is free from the reddish shade which it derives from the blue vat, as well as from the greenish cast of the Saxon blue †.

319. The sulphate of indigo has been hitherto only applied for the purpose of dyeing wool and silk. The affinity of indigo for vegetable substances is not sufficiently strong to effect the decomposition of the sulphate. It cannot, therefore, be employed with advantage in dyeing cotton and linen.

Dyein with sian b

320. Attempts have been made to dye with Prussian blue. The process which was followed by Macquer is the following. He soaked wool, silk, cotton, and thread, in a solution of alum and sulphate of iron, and afterwards in an alkaline solution, which was partly saturated with prussic acid. He then immersed the stuffs in water, acidulated with sulphuric acid, for the purpose of dissolving that part of the oxide of iron which remained uncombined with the prussic acid, and which the uncombined alkali had precipitated. By successive repetitions of these immersions he obtained a fine blue, but very unequal. Berthollet justly remarks on this experiment,

---

* Phil. of Perm. Col. 132.

† Ber let, ii.

imple
ours.

experiment, that an alkali saturated with prussic acid should be employed, or lime water or magnesia, both of which have the property of combining with that acid. In a second experiment Macquer boiled the stuffs in a solution of tartar and alum, and then passed them through a bath which contained prussian blue merely diffused in it. The colour was faint, and could not be made deeper; but it was equal, and soft to the touch.

per
ess.

321. In the process proposed by Abbé Menon for thread and cotton, they are first dyed black, and soaked for a few minutes in prussiate of alkali, and afterwards boiled in a solution of alum. In this way they acquired a deep blue. When a lighter blue is wanted, the stuffs must be passed through a weak acid.

De Pla-
iere's.

322. Similar to the second experiment of Macquer is the process of Roland de la Platiere. He takes prussian blue in the proportion of a pound to a piece of stuff, powdered, and passed through a very fine sieve, and adds muriatic acid till it is reduced to the consistence of syrup. It is to be constantly stirred for about half an hour while it ferments. It is then well diluted, and stirred every hour for a day, till the fermentation ceases. The particles are thus in a state of minute division. Seven or eight buckets of water for one piece of velvet, are put into a trough; then add the mixture, which has been previously well diluted in a separate vessel, and poured into the bath through a very fine sieve. When the piece is placed on the winch, over the trough, let the bath be briskly stirred, and the piece speedily let down; and the same operation must be continued as quickly as possible for several hours. This colour requires great management, for as the particles of the prussian blue are only in a state of minute division, and heavy, they are quickly deposited on the stuff. Hence the colour appears very unequal and in patches, even with the utmost care; and nothing can be done to avoid it, but repeating the operations again and again. The stuff should be put into the baths thoroughly wet, for when it is dry, it penetrates with difficulty, and is always unequal. Between the dryings the stuff is always to be washed and beetled, excepting the last time, when it is not washed, but dried in the open air, either in the sun or in the shade; observing, however, that it be well stretched. This beautiful colour is not changed by the air; it resists the action of acids, and is little altered by boiling with alum; but it is soon tarnished by friction, or particles of dust that adhere to it. It is scarcely necessary to add, that it is instantly decomposed by alkaline liquors. Guhliche employs a solution of tin in nitro-muriatic acid, as a substitute for muriatic acid, in the process of dyeing with prussian blue *.

Bethol-
t, ii. o.
andt's.

323. Dr Bancroft made a number of experiments in dyeing both vegetable and mineral matters, with prussian blue, and particularly with the view of obviating the difficulties which had occurred to others in the use of it. He boiled up copperas with quercitron bark, fustic, and logwood, separately, in what he thought the best proportions; and in each of these mixtures he dyed a piece of woollen cloth by boiling it for 10 or 15 minutes. The stuffs were afterwards separately immersed in warm diluted prussiate of potash neutralized by sulphuric acid. They acquired an equal and beautiful blue. This, however, was not the uniform result; for when too much copperas was employed in dyeing with quercitron bark, there was an excess of oxide of iron, which combining with the fibres of the wood, gave the prussian blue a greenish tinge; but this he found could be remedied, by passing the cloth through warm water, slightly acidulated with muriatic acid. The prussian colouring matter, Dr Bancroft observes, must always be applied in a moderate heat, otherwise it will be precipitated by the sulphuric acid, and rendered unfit for this purpose, till it is again dissolved by potash, lime, or some other substance.

Of Simple
Colours.

324. He then tried to fix prussian blue by means of the aluminous mordant; but at the end of 15 minutes, after being immersed in a solution of prussiate of potash, it had acquired no colour. The addition of a small proportion of a solution of iron in muriatic acid, communicated a blue colour. All parts of the cloth, as well as those to which the mordant had been applied, received the colour. The cloth being washed with soap, the whole of the colour was discharged, excepting where it had been impregnated with alumina, and even there it had become fainter. A piece of the same cotton was immersed in a solution of ammonia (volatile alkali); the pale blue was greatly heightened. Another piece was put into water slightly tinctured with a solution of copper in ammonia. The blue colour became suddenly of an intensely deep garter-blue or violet, and it resisted the action of soap. Into water mixed with a little of a solution of muriate of copper, he put another piece of the same cotton, and it soon became of a deeper blue, without any of the purple or violet shade. This resisted the action of soap, and after long exposure to the weather, the colour was little diminished; and when the colour remained in any degree weakened, immersion in water slightly acidulated with sulphuric acid, completely restored it. From these facts it would appear to be advantageous to prepare woollens by the usual boiling with alum, or alum and tartar, before they are dyed with copperas and quercitron bark, fustic or logwood, for a prussian blue; but a greater proportion of sulphuric acid, in the prussiate of potash or lime, that the excess of acid may discharge the vegetable colouring matters, becomes necessary *.

For silk and
cotton.

325. Dr Brancroft afterwards tried pieces of silk and cotton in the diluted prussiates of potash, soda, lime, &c. with solutions of most of the metals in different acids and alkalies; and from the different metallic solutions he obtained a very full, lively colour, which he calls the *red copper colour*, from the different solutions of copper in sulphuric, nitric, muriatic, and acetic acids; the same effect succeeded well from a solution in ammonia. He obtained also the same colour from the nitrates of silver and of cobalt. The prussian colouring matter fixed by these metallic mordants resisted the action of acids, washings with soap, and exposure to the weather for the greatest length of time; but in all these cases there must be a double application. The prussian colouring matter must first be applied to the linen, cotton or silk, which must be afterwards allowed to dry. It must then be immersed in the metallic solution, or the metallic solution must be applied first, and then the solution of prussiate of potash, soda, lime, &c.

SECT. IV. *Of Dyeing Black.*

The next of the simple colours is black, of which we shall treat as in the former sections; first describing the substances which are employed, and then giving an account

---

* *Phil. of Perm. Col.* 217.

account of the processes which are followed in dyeing different stuffs of a black colour.

I. *Of the Substances employed in Dyeing Black.*

Juices of plants.

326. There are few substances which have the property of producing a permanent black colour, without any addition. The juice of some plants produces this effect on cotton and linen. A black colour is obtained from the juice of the *cashew nut*, which will not wash out, and even resists the process of boiling with soap or alkalies. The cashew nut of India is employed for marking linen. That of the West Indies (*anacardium occidentale*, Lin.) also yields a permanent dye, but the colour has a brownish shade. The juice of some other plants, as that of the toxicodendron, or sloes, affords a durable blueish black colour; but these substances cannot be obtained in sufficient quantity, even if they afforded colours equal to those produced by the common processes.

Tan, &c.

327. The principal substances which are employed to give a black colour are gall-nuts which contain the astringent principle, or tan, and the red oxide of iron (L). For a particular account of the nature and properties of tan, see CHEMISTRY *Index*. The black colour is produced by the combination of the astringent principle with the oxide of iron, held in solution by an acid, and fixed on the stuff. When the particles are precipitated from the mixture of tan and a solution of iron, they have only a blue colour; but after they are exposed for some time to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. After the particles are fixed on the stuff, the shade becomes much deeper.

328. Logwood is not to be considered as affording a black dye, but is much employed to give a lustre to black colours. We have (180.) already described its nature and properties, among the substances from which red colouring matters are obtained.

Mordants necessary for black.

329. Black colours are rarely produced by a simple combination between the colouring matter and the stuff; but are usually fixed by means of mordants, as in the case of the black particles which are the result of a combination of the astringent principle and the oxide of iron, held in solution by an acid. But when the particles are precipitated from the mixture of an astringent and a solution of iron, they have only a blue colour. By being exposed to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. No fine black colour is ever obtained, unless the stuffs are freely exposed to the air. In dyeing black, therefore, the operations must be conducted at different intervals. Berthollet has observed, that black stuffs, when brought in contact with oxygen gas, diminish its volume, so that some portion of it is absorbed.

II. *Of the Processes for Dyeing Woollen Black.*

Must be first dyed blue.

330. In dyeing woollen stuffs black, if a full and fine deep colour is wanted, it is necessary that they are previously dyed of a deep blue colour. To remove all the particles of colouring matter which happen to be loosely attached to the stuff, it should be washed in a river as soon as it is taken out of the vat, and afterwards cleansed at the fulling mill. After these preliminary processes, the stuffs are ready to receive the black colouring matter. The process of Hellot is the following.

Hellot's process.

For every hundred pounds of stuff, ten pounds of logwood, and ten pounds of galls reduced to powder, are put into a bag, and boiled in a middle-sized copper, with a sufficient quantity of water, for 12 hours. A third of this bath is put into another copper, along with two pounds of verdigrise. The stuff is immersed in this bath, and continually stirred for two hours. The bath should be kept hot, but it ought not to boil. At the end of two hours the stuff is taken out, and a similar portion of the bath is put into the copper, with eight pounds of copperas (sulphate of iron). During the solution of the copperas, the fire is diminished, and the bath is allowed to cool for half an hour, stirring it well the whole time. The remainder of the bath is then to be added, and after making this addition, the bag containing the astringent matters should be strongly pressed, to separate the whole. A quantity of sumach from 15 to 20 pounds, is now to be added, and the bath is just raised to the boiling temperature; and when it has given one boil, it is to be immediately stopped with a little cold water. A fresh quantity of sulphate of iron, to the amount of two pounds, is then added, and the stuff is kept in it for another hour, after which it is taken out, washed and aired; it is again put into the copper, and constantly stirred for an hour. It is then carried to the river, well washed, and fulled. To soften the black colour, and make it more firm, another bath is prepared with weld. This is made to boil for a moment, and when it has cooled, the stuff is passed through it. By this process, which is indeed somewhat complicated, a beautiful black colour is produced.

Common process.

331. But the processes usually followed for dyeing black, are more simple. Cloth which has been previously dyed blue, is merely boiled in a vat of galls for two hours. It is then kept two hours, but without boiling, in the bath of logwood and sulphate of iron, and afterwards washed and fulled. According to Hellot's process, a bath is to be prepared of a pound and a half of yellow wood, five pounds of logwood, and ten pounds of sumach, which is the proportion of the ingredients

---

(L) Oak bark has been recommended as a substitute for gall-nuts in dyeing black, and particularly in dyeing hats; and it is said that the colour thus obtained is fuller, more beautiful and durable, while the operation is easier and less liable to accident. It was first proposed in the year 1782 by Stephanopoli, a Corsican, and a surgeon in the French army. The examination of the process was referred by the French government to Macquer, who gave a favourable report of it; and afterwards to Berthollet, who gave a different opinion. The process has since been examined, and promises to be more economical and advantageous, especially for dyeing hats *.

* Phil. Mag. vi. 176.

gredients for every 15 yards of deep blue cloth; and the cloth having boiled in this bath for three hours, ten pounds of sulphate of iron are added; the cloth is allowed to remain for two hours longer, when it is taken out to be aired, after which it is again returned to the bath for an hour, and then washed and fulled.

heaper ess.

332. When stuffs are to be dyed at a less expence, instead of the blue ground, a brown or root-coloured ground may be substituted. This brown or fawn colour is communicated by means of the root of the walnut tree, or green walnut peels. The stuffs are then to be dyed black, according to some of the processes already described.

ess of th Eng- li dyers.

333. The proportions of the ingredients employed by the English dyers are, for every hundred pounds of cloth previously dyed a deep blue, about five pounds of sulphate of iron, five pounds of galls, and 30 of logwood. The first step in the process is to gall the cloth, after which it is passed through the decoction of logwood, to which the sulphate of iron has been added.

A tus us for ga

334. The leaves of the *arbutus uva ursi* have been recommended, and employed as a substitute for galls. The leaves must be carefully dried, so that the green colour may be preserved. A hundred pounds of wool are boiled with 16 pounds of sulphate of iron, and eight of tartar, for two hours. The day following the cloth is to be rinsed as after aluming. A hundred and fifty pounds of the leaves of *uva ursi* are then to be boiled for two hours in water, and after being taken out, a small quantity of madder is to be added to the liquor, putting in the cloth at the same time, which is to remain about an hour and a half. It is then taken out and rinsed in water †. By this process, it is said, blue cloth receives a pretty good black, but white cloth becomes only of a deep brown. It is said, too, that the madder and tartar are useless ingredients.

pe- ati

335. After the different operations for dyeing the cloth have been finished, it is washed in a river, and fulled, till the water comes off clear and colourless. Soap suds are recommended by some in fulling fine cloths, but it is found difficult to free the cloth entirely from the soap. After the cloth has come from the fulling mill, some propose to give it a dip in a bath of weld, by which it is said to be softened, and the colour better fixed; but according to Lewis, this operation, which in other cases is of some advantage, is useless after the cloth has been treated with the soap suds.

III. *Of the Processes for Dyeing Silk Black.*

336. In communicating a black colour to silk, different operations are necessary, such as boiling, galling, repairing the bath, dyeing, and softening.

337. To give a deeper shade to silk, it is necessary to deprive it of the gummy substance to which its stiffness and elasticity are owing. This is done by boiling the silk four or five hours with one-fifth its weight of white soap, and afterwards beetling and carefully washing it.

alli.

338. In conducting the process of galling silk, three-fourths of its weight of galls are to be boiled for three or four hours, but the proportion of galls must depend on their quality. After the boiling, the liquor is allowed to remain at rest for two hours; the silk is then put into the bath, and left there from 12 to 36 hours, when it is to be taken out, and washed in the river. But as silk is capable of combining with a great proportion of the astringent principle, or tan, from which it receives a considerable increase of weight, it is allowed to remain for a longer or shorter time, as the silk is required to have more or less additional weight. To communicate, therefore, to silk, what is called a *heavy* black, it is allowed to remain longer in the gall liquor: the process is repeated oftener, and the silk is also dipped in the dye a greater number of times.

Dyeing.

339. While silk is preparing for the process of dyeing, the bath is to be heated, and should be occasionally stirred, that the grounds which fall to the bottom may not acquire too much heat. It should always be kept under the boiling temperature. Gum and solution of iron are added in different proportions, according to the different processes. When the gum is dissolved, and the bath near the boiling temperature, it is left to settle for about an hour. The silk, which in general is previously divided into three parts, that each may be successively put into the bath, is immersed in it. Each part is then to be three times wrung, and after each wringing hung up to air. The silk being thus exposed to the action of the air, acquires a deeper shade. This operation being finished, the bath is again heated, with the addition of gum and sulphate of iron; and this is repeated two or three times, according as the black required is light or heavy. When the process of dyeing is finished, the silk is rinsed in a vessel with some cold water, by turning or shaking it over.

Softening.

340. Silk, after it has been taken out of the dye, is extremely harsh, to remove which it is subjected to the operation of softening. A solution of four or five pounds of soap for every hundred pounds of silk, is poured through a cloth into a vessel of water. The solution being completed, the silk is immersed, and allowed to remain in it for about 15 minutes; it is then to be wrung out and dried.

Dyeing raw silk.

341. When raw silk is to be dyed, that which has a natural yellow colour is preferred. The galling operation must be performed in the cold, if it be proposed to preserve the whole of the gum, and the elasticity which it gives to the silk; but if part only of the gum is wished to be preserved, the galling is to be performed in the warm bath.

342. The dyeing operation is also performed in the cold. All that is necessary is to add the sulphate of iron to the water in which the stuff is rinsed. By this simple process, the black dye is communicated. It is then washed, once or twice beetled, and dried without wringing, that its elasticity may not be destroyed. Raw silk may be dyed by a more speedy process. After galling, it may be turned or shaken over in the cold bath; and thus by alternately dipping and airing the stuff, the operation may be completed. It is then to be washed and dried as in the former processes.

A speedier process.

Improved process for velvet.

343. The method of dyeing velvet at Genoa, which has been simplified and improved in France, is thus described by Macquer. For every 100 pounds of silk, 20 pounds of Aleppo galls, reduced to powder, are boiled in a sufficient quantity of water for an hour. The bath is allowed to settle till the galls have fallen to the bottom; they are then taken out, and two pounds and a half of sulphuric acid, twelve pounds of iron filings, and 20 pounds of gum, are put into a cop-

per

---

† Stockholm Tr. 75

per vessel, or cullender, furnished with two handles. This vessel is immersed in the bath, and supported that it may not touch the bottom. The gum, which is allowed to dissolve for an hour, is to be occasionally stirred; and if it appear that the whole of the gum is dissolved, three or four pounds more are to be added. Excepting during the operation of dyeing, the cullender is to remain in the copper, which must be kept hot the whole time, but at a temperature below the boiling point. In galling the silk, one-third of Aleppo galls is employed, and the stuff should remain six hours in the liquor the first time, and twelve hours the second. By frequent additions of sulphate of iron, and repeated immersions of the stuff, a fine black, according to Lewis, has been obtained. In the above process, the proportion of sulphate of iron is too small, and the gum, according to some, being carried off in the washing, may be considered as useless. Berthollet thinks that, although the quantity be excessive, it has some effect in keeping up the bath; and he adds, if it is to be diminished, it would be useful to add the sulphate of iron in separate portions during each interval.

Substitute for galls.

344. To diminish the quantity of galls, which are an expensive ingredient in dyeing silk black, other substances have been proposed as substitutes. With this view the following process is recommended.

The silk being boiled and washed, is immersed in a strong decoction of green walnut peels, and allowed to remain till the colouring matter of both is exhausted. It is then to be slightly wrung out, dried and washed (M). To give the silk a blue ground, logwood and verdigrise are employed, in the proportion of one ounce of the latter for every pound of silk. The verdigrise is dissolved in cold water, and the silk is allowed to remain two hours in this solution. It is then immersed in a strong decoction of logwood, slightly wrung out, dried, and afterwards washed at the river. The bath is prepared by macerating two pounds of galls and three of sumach in 25 gallons of water, over a slow fire, for twelve hours. The liquid being strained, three pounds of sulphate of iron, and the same quantity of gum arabic, are to be dissolved in it. The silk is dipped in this solution at two different times; it is to remain in the bath two hours each time, and it must be aired and dried between each dip. After being twice beetled at the river, it is dipped a third time, and left in the bath four or five hours, after which it is to be dried, washed and beetled as before. The temperature of the bath should not exceed 120°. After the first dipping, it may be necessary to add half a pound of sulphate of iron, and an equal quantity of gum arabic.

345. Silk which has been previously dyed blue with indigo, it is said, takes only a mealy black; but when it has been prepared with logwood and verdigrise, it acquires a velvety lustre. A fine black may be obtained from green walnut peel; but the addition of logwood and verdigrise renders a smaller quantity of sulphate of iron necessary, and this is of importance, because it is apt to weaken the silk. The only use of galls, according to some, is to increase the weight of the silk; for the purposes of dyeing, sumach is considered sufficient*.

IV. *Of the Processes for Dyeing Cotton and Linen Black.*

Must be previously dyed blue.

346. It is more difficult to communicate a fine black to linen or cotton than to silk or woollen stuffs. To succeed in producing a black colour of that degree of intensity which will resist soap, it is necessary to adopt particular processes. In dyeing animal matters black, as silk and wool, the best colours are obtained on those which have been previously dyed blue. This also is an essential preliminary process in dyeing linen and cotton black; for it is found that the process which succeeds best, is first to give a deep blue grain to the cotton or linen.

Galling.

347. The first part of the process is the operation of galling. The stuffs which have been previously dyed blue, wrung out and dried, are kept 24 hours in the gall-liquor, composed of four ounces of galls to every pound of thread. A bath is then prepared of a solution of iron in acetic acid. This solution is obtained by saturating the acid with oxide of iron. In France, vinegar, small beer, or small wine, is employed for this purpose. To promote the acid fermentation, rye meal, or some other substance, is added, and pieces of old iron are thrown into the liquid, which are allowed to remain for six weeks or two months, that the acid may be saturated with the iron. This solution, called *iron liquor* in this country, is prepared from fermented worts, to which old iron is added, as is described above.

Dyeing.

Five quarts of the iron-liquor for every pound of stuffs, are put into a vessel. In this the stuffs are wrought with the hand, pound by pound, for 15 minutes: they are then wrung out and aired. This operation is to be again repeated, taking care to add a fresh quantity of the iron-liquor, which should be carefully scummed, after which the stuffs are to be wrung out, aired, and washed at the river. In the next operation, a pound of alder bark for every pound of stuff is boiled in a sufficient quantity of water for an hour. One half of the bath which was employed in the galling, and about one half the quantity of sumach as of alder bark, are then added. The whole is boiled together for two hours, and strained through a sieve. When this liquid is cold, the stuffs are immersed, wrought pound by pound, and occasionally aired. They are afterwards put into the bath, and after remaining for 24 hours, are wrung out and dried. The above is the process which, according to D'Apligny, is followed at Rouen, for dyeing cotton and linen.

Another process.

348. The process followed at Manchester, which is described by Mr Wilson, is the following. For the operation of galling, galls or sumach are employed. The stuff is afterwards dyed in a bath consisting of a solution of iron in acetic acid. This bath is also frequently composed of alder bark and iron. After having passed through this bath, the stuff is dipped in a decoction of logwood, to which a small quantity of verdigrise has been added. This process is to be repeated

* Berthollet, ii. 20.

(M) The decoction of walnut peels is prepared by boiling for 15 minutes, after which it is taken from the fire. After it has subsided, the silk, which has been previously immersed in warm water, is dipped in it.

peated till a black of sufficient intensity is obtained, observing to wash and dry after each operation.

aration olution on.

349. According to Guhliche, a solution of iron may be prepared by the following process. A pound of rice is to be boiled in 12 or 15 quarts of water, till the whole is dissolved. A sufficient quantity of old iron made red hot, to reach half way to the surface of the liquor, is thrown into the solution. The vessel in which the solution is kept must be under cover, but exposed to the air and light, at least for a week. In another vessel, containing a quantity of warm vinegar equal to the solution of rice, an equal quantity of red-hot iron is to be put. This vessel must also be exposed in the same way to the air and light. After several days, the contents of both vessels are mixed together, and the mixture is to be exposed for a week to the open air, after which it is to be decanted and kept for use in a close vessel. To give a sufficient black to linen and cotton, it is only necessary, it is said, to steep them 29 hours in this solution: and if it should appear that the liquor is exhausted of colouring matter, a fresh portion is to be employed. In this way a fine permanent black is obtained. According to the same author, this solution may be advantageously employed as a substitute for sulphate of iron, in dyeing silk and wool. But to give them a fine black, silk and woollen stuffs must be dipped in a decoction of logwood after they are taken from the bath.

plica- tio

Sect. V. *Of Brown.*

350. The last of the simple colours is brown. This is also known under the name of *fawn* colour, (*fauve*, Fr.). It is that brown colour which has a shade of yellow, and might perhaps be considered as a compound colour, although it is communicated to stuffs by one process.

I. *Of the Substances employed in Dyeing Brown.*

351. The vegetable substances which are capable of inducing a fawn or brown colour on different stuffs, are very numerous, but those chiefly employed for this purpose are walnut peels and sumach. The peels constitute the green covering of the nut; they are internally of a white colour, which is converted into brown or black by exposure to the air. The skin, when impregnated with the juice of walnut peels, becomes of a brown or almost black colour. When the inner part of the peel, taken fresh, is put into weak oxymuriatic acid, it assumes a brown colour. If the decoction of walnut peels be filtered and exposed to the air, its colour becomes of a deep brown; the pellicles on evaporation are almost black, the liquor detached from these yields a brown extract completely soluble in water. The colouring particles are precipitated from a decoction of walnut peels, by means of alcohol, and they are soluble in water. No apparent change is at first produced by a solution of potash; but it gradually becomes turbid, and the colour is deepened. A copious precipitate of a fawn colour, approaching to an ash colour, is produced in a decoction of walnut peels by means of a solution of tin, and the remaining liquor has a slightly yellow tinge.

Wa t eel

opies.

352. A decoction of walnut peels yields a small quantity of fawn-coloured precipitate by means of a solution of alum, and the liquor remains of the same colour. Sulphate of copper renders it slowly turbid, and throws down a small quantity of precipitate of a brownish green colour, leaving the supernatant liquor of the same colour. Sulphate of iron deepens the colour; when diluted, the colour becomes brownish green, without the deposition of any sediment. Sulphate of zinc also deepens the colour, and produces no precipitate. The same properties are exhibited by a decoction of the walnut-tree wood, but the colouring matter is not obtained from it in such abundance as from the peels; and the bark may also be used with advantage in dyeing.

Advantages

353. The affinity of the colouring matter of walnut peels for wool is very strong; and it readily imparts to it a durable colour, which even mordants do not seem capable of increasing, but they are generally understood to give it additional brightness. A lively and very rich colour is obtained with the assistance of alum. Walnut peels afford a great variety of pleasing shades; and as they require not the intervention of mordants, the softness of the wool is preserved, and the process of dyeing becomes both cheap and simple.

Preparation

354. Walnut peels are not gathered till the nuts are completely ripe, when they are put into large casks, along with as much water as is sufficient to cover them. When used in dyeing at the Gobelins in Paris, Berthollet informs us, they are kept for upwards of a year, and very extensively used; but if not made use of till the end of two years, they yield a greater quantity of colouring matter, at which time their odour has become peculiarly disagreeable and fetid. The peels separated from the nuts before they arrive at maturity, may likewise be used in dyeing, but in this state they do not keep so long.

Sumach.

355. Sumach (*rhus coriaria*, Linn.) is a shrub produced naturally in Palestine, Syria, Portugal, and Spain, being carefully cultivated in the two last of these countries. Its shoots are annually cut down, dried, and reduced to powder in a mill, by which process they are prepared for the purposes of dyeing.

Properties.

356. The infusion of sumach, which is of a fawn colour with a greenish tinge, is changed into a brown by exposure to the air. A solution of potash has little action on the recent infusion of sumach; its colour is changed to yellow by the action of acids; the liquor becomes turbid by means of alum, a small quantity of precipitate being at the same time formed, and the supernatant liquor remaining yellow. A copious precipitate of a yellowish green colour is thrown down by sulphate of copper, and the liquor remains clear. No change is speedily produced by muriate of soda (common salt), but it becomes rather turbid at the end of some hours, and its colour is rather clearer. Sulphate of copper produces a copious precipitate of a yellowish green, which after standing some hours, changes to a brownish green; the supernatant liquor, which is slightly yellow, remains clear. Sulphate of zinc renders the liquor turbid, darkens its colour, and produces a deep blue precipitate; but when the sulphate of zinc is pure, the precipitate, which is of a brownish fawn colour, is in very small quantity. Acetate of lead gives a copious precipitate, of a yellowish colour; the supernatant liquor is of a clear yellow colour. No astringent has so strong a resemblance to galls as sumach; but the precipitate

precipitate thrown down from an infusion of it by a solution of iron, is not so copious as that which is yielded by an equal quantity of galls, on which account sumach may be generally employed as a substitute for galls, only its quantity will require to be increased.

Bark of birch.

357. The bark of the birch tree (*betula alba*, Lin.) yields a decoction of a clear fawn-colour, but it soon becomes turbid and brown. The addition of a solution of alum in the open air, produces a copious yellow precipitate; a solution of tin gives also a copious precipitate of a clear yellow colour. With solutions of iron the decoction of the birch-tree strikes a black colour, and it dissolves in considerable quantity the oxide of iron, but in smaller proportion than the decoction of walnut peels. On account of this property, it is employed in the preparation of black vats for dyeing thread.

Sandal wood.

358. Sanders or sandal wood, is also employed for the purpose of giving a fawn colour. There are three kinds of sandal wood, the white, the yellow, and the red. The last only, which is a compact heavy wood, brought from the Coromandel coast, is used in dyeing. By exposure to the air it becomes of a brown colour; when employed in dyeing, it is reduced to fine powder, and it yields a fawn colour with a brownish shade, inclining to red. But the colouring matter which it yields of itself is in small quantity, and it is said that it gives harshness to woollen stuffs. When it is mixed with other substances, as sumach, walnut peels, or galls, the quantity of colouring matter is increased; it gives a more durable colour, and produces considerable modifications in the colouring matter with which it is mixed. Sandal wood yields its colouring matter to brandy, or diluted alcohol, more readily than to water.

Soot.

359. Soot communicates to woollen-stuffs a fawn or brown colour, of a lighter or deeper shade, in proportion to the quantity employed; but the colour is fading, and its affinity for wool is not great; and besides leaving a disagreeable smell, it renders the fibres harsh. In some manufactories, it is employed for browning certain colours, and it produces shades which could not otherwise be easily obtained.

II. *Of the Processes for Dyeing Woollen, &c. a Fawn or Brown Colour.*

With walnut peels.

360. In dyeing with walnut peels, a quantity proportioned to the quantity of stuff, and the intensity of shade wanted, is boiled for fifteen minutes in a copper. All that is necessary in dyeing with this substance is, to moisten the cloth or yarn with warm water, previous to their immersion in the copper, in which they are to be carefully stirred till they have acquired the proper shade. This is the process, if the aluminous mordant is not employed. In dyeing cloth, it is usual to give the deepest shades first, and the lighter ones afterwards; but in dyeing woollen yarn, the light shades are given first, and the deeper ones afterwards. An additional quantity of peels is joined to each parcel.

Berthollet's experiments.

361. Berthollet made a number of experiments to ascertain the difference of colour obtained from the simple decoction of walnut peels, and the addition of metallic oxides as mordants. The oxide of tin, he found, yielded a clearer and brighter fawn colour than that of the simple decoction. The oxide of zinc produced a still clearer colour, inclining to ash or gray. The colour from oxide of lead had an orange cast, while that from oxide of iron was of a greenish brown *.

Dyeing with sumach.

362. A fawn colour, which has a shade of green, is obtained from sumach alone; but to cotton stuffs which have been impregnated with printers mordant, or acetate of alumina, sumach communicates a good and durable yellow. Here, however, some precaution is necessary in the use of this substance for this purpose; for as the colouring matter is of so fixed a nature, the ground of the stuff cannot be bleached by exposure on the grass. This inconvenience is avoided by impregnating the whole of the stuff with different mordants, producing in this way a variety of colours, and leaving no part white.

With sandal wood.

363. Vogler employed the tincture of sanders wood for dyeing patterns of wool, silk, cotton and linen, having previously impregnated them with a solution of tin, and afterwards washing and drying them. Sometimes he used the solution unmixed, and at other times added six or ten parts of water, and in whatever way he employed it, he obtained a poppy colour. When the mordant employed was solution of alum, the colour was a rich scarlet; with sulphate of copper it was a clear crimson, and with sulphate of iron a beautiful deep violet †.

CHAP. II. *Of Compound Colours.*

Nature of compound colours.

364. A MIXTURE of two colouring substances, it is well known, produces a very different shade from that of either of the uncombined colouring matters; hence compound colours are obtained, which are merely mixtures of simple colours. It would undoubtedly be a desirable thing to ascertain with acuracy the peculiar shade produced by the combination of two colouring matters; but these results can only be certainly known by experiment, because by the action of different substances in the bath, they are subject to great variations in their effects, according to the affinities which are brought into action, and the new combinations which are formed. What is natural to colouring particles is not to be considered as a constituent part of compound colours, but only the difference of shade which they ought to assume, with a particular mordant, or in a particular bath. The effects, therefore, of the chemical agents employed in these processes, and the result of different combinations, ought to be particularly attended to. It is in dyeing compound colours that skill and ingenuity are most conspicuous, and their application of greatest utility, to enable the dyer to vary his processes according to the shade desired, and at the same time to accomplish his operations by the shortest and cheapest means.

Great variety of shade.

365. As compound colours are obtained by the mixture of simple colours, very different shades will be obtained from different-proportions of the simple colours; hence compound colours exhibit an indefinite variety of shade, and the processes by which they are produced are very numerous. It would extend this treatise to an unusual length, were we to attempt to describe every variety of shade which is obtained from the mixture of simple colours. We shall therefore limit our observations to some of the principal compound colours, and an

---

* Elements of Dyeing, ii. 296.

† Crell Ann. 1790.

pound ours.

an account of the processes by which they are obtained, leaving it to our readers, who have made themselves familiar with the principles already detailed, to vary these colours, by employing different proportions and different combinations of simple colouring matters.

366. Compound colours have been usually divided into four classes, namely, green, purple, orange, and gray or drab colour. These are obtained from mixtures of the following simple colours.

1. Blue and yellow produce a green.
2. Red and blue, a purple, &c.
3. Red and yellow, orange.
4. Black and other colours, gray, &c.

The following sections will be occupied in a short detail of the methods which are usually employed in producing these different compound colours.

Sect. I. *Of the Mixture of Blue and Yellow, or Green.*

367. Green colours, from the great variety of shades which they exhibit, have been long known by different names, by which the intensity of shade is characterised, such as sea-green, apple-green, meadow or grass-green, pea-green, parrot-green, &c. Many plants afford a green colour, such as brome grass (*bromus secalinus*, Lin.) green berries of *rhamnus frangula*, wild chervil (*chærophyllum sylvestre*, Lin.), purple clover (*trifolium pratense*), common reed (*arundo phragmites*). These colours, however, do not possess sufficient permanency. According to D'Ambourney, indeed, a permanent green may be obtained from the fermented juice of the berries of the berry-bearing alder (*rhamnus frangula*). Having previously prepared the cloth with tartar, solution of nitrate of bismuth, and common salt, he added to the fermented juice of the berries, after it was warmed, a small proportion of acetate of lead; and in this bath he communicated to the cloth an intermediate shade between parrot and grass green. But it is usually from the mixture of blue and yellow that green is obtained; and it may be observed, that it requires much skill and experience, especially in giving light shades, to produce a colour which is uniform, and entirely without spots.

I. *Of the Processes for Dyeing Woollen Stuffs Green.*

368. To dye woollen green, either the yellow or the blue dye may be given to it first. But when the stuff is first dyed yellow, and in this state is introduced into the blue vat, part of the yellow colouring matter being dissolved in the vat, communicates to it a green colour, which renders it unfit for dyeing any other colour than green. To avoid this inconvenience, therefore, the blue colour is first given, and afterwards the yellow. It would be quite unnecessary to resume the account of any part of the processes for dyeing blue, which have been already detailed. It is proper, however, to add, that the intensity of the blue shade must be proportioned to the green, or to the depth of the green colour which is wished to be obtained. Thus, for instance, to produce a parrot green, a ground of sky blue is given, and for the green like that of a drake's neck, a deep blue is required. When the blue dye has been communicated, the yellow is afterwards given, according to some of the processes which have been already described for dyeing yellow. The proper ground being communicated to the cloths, they are washed in the fulling mill, and boiled as for the common process of welding; but when the shade is light, the proportion of salts should be less. Cloths which are to receive light shades are first boiled, and when these are taken out, tartar and alum are added in fresh portions, till the cloths which are intended for the darkest shades are boiled. The process of welding is conducted in the same way as for dyeing yellow, with this difference, that a larger proportion of weld is employed, excepting for lighter shades, when the proportion must be smaller. In dyeing green, it is usual to have a succession of shades at the same time; the process is begun with the deepest, and ends with the lightest. Between each dip there should be an interval of one-half or three quarters of an hour, and at each interval water is added to the bath. It is the practice of some dyers to give each parcel two dips, beginning the first time with the deep shades, and the second with the lighter ones; but when this practice is followed, the time of immersion should be shortened. In dyeing very light shades, the bath should never be permitted to reach the boiling temperature. For deep greens, a browning is given with logwood, and a small proportion of sulphate of iron.

Compound Colours.

Saxon green.

369. For some kinds of green, sulphate of indigo is employed; and in this case either the blue and yellow are dyed separately, or the whole of the ingredients are mixed together in the bath, and the whole process is finished at a single operation. The colour thus obtained has been distinguished by the name of *Saxon green*. The following is the process recommended by Dr Bancroft.

370. "The most beautiful Saxon green (says he) may be produced very cheaply and expeditiously, by combining the lively yellow which results from quercitron bark, murio-sulphate of tin, and alum, with the blue afforded by indigo when dissolved in sulphuric acid, as for dyeing the Saxon blue.

"To produce this combination most advantageously, the dyer, for a full-bodied green, should put into the dyeing vessel after the rate of six or eight pounds of powdered bark, in a bag, for every 100 lb. weight of cloth, with only a small proportion of water as soon as it begins to grow warm; and when it begins to boil, he should add about six pounds of murio sulphate of tin (with the usual precautions), and a few minutes after, about four pounds of alum; these having boiled together five or six minutes, cold water should be added, and the fire diminished so as to bring the heat of the liquor nearly down to what the hand is able to bear; and immediately after this, as much sulphate of indigo is to be added as will suffice to produce the shade of green intended to be dyed, taking care to mix it thoroughly with the first solution by stirring, &c.; and this being done, the cloth previously scoured and moistened, should be expeditiously put into the liquor, and turned very briskly through it for a quarter of an hour, in order that the colour may apply itself equally to every part, which it will certainly do in this way with proper care. By these means, very full, even, and beautiful greens may generally be dyed in half an hour; and during this space, it is best to keep the liquor at rather less than a boiling heat. Murio-sulphate of tin is infinitely preferable, for this use, to the dyer's spirit; because the latter consists chiefly of nitric acid, which, by its highly injurious action upon indigo, would render that part of the green colour very fugitive, as I have found by repeated trials. But no such effect can result from the murio-sulphate of tin, since the muriatic acid has no action upon indigo; and the sulphuric is that very acid which alone is proper to dissolve it for this use.

"Respecting the beauty of the colour thus produced, those who are acquainted with the unequalled lustre and brightness of the quercitron yellows, dyed with the tin basis, must necessarily conclude, that the greens composed therewith will prove infinitely superior to any which can result from the dull muddy yellow of old fustic; and in point of expence, it is certain that the bark, murio-sulphate of tin, and alum, necessary to dye a given quantity of cloth in this way, will cost less than the much greater quantity (six or eight times more) of fustic, with the alum necessary for dyeing it in the common way, the sulphate of indigo being the same in both cases. But in dyeing with the bark, the vessel is only to be filled and heated once; and the cloth, without any previous preparation, may be completely dyed in half an hour; whilst in the common way of producing Saxon greens, the copper is to be twice filled: and to this must be joined the fuel and labour of an hour and a half's boiling and turning the cloth, in the course of preparation, besides nearly as much boiling in another vessel to extract the colour of the fustic; and after all the dyeing process remains to be performed, which will be equal in time and trouble to the whole of the process for producing a Saxon green with the bark; so that this colour obtained from bark will not only prove superior in beauty, but in cheapness, to that dyed as usual with old fustic *."

II. *Of the Processes for Dyeing Silk Green.*

Preparation.

371. In giving silk a green colour, greater precaution is necessary, to preserve uniformity of colour, and to prevent spots and stripes. Silk which is intended to receive a green colour, is scoured in the same way as for other colours; but for light shades, the scouring must be as complete as for blue. Silk which is to be dyed green, is first dyed yellow, and being well alumed, it is slightly washed at the river, and divided into small parcels, that it may receive the colouring matter uniformly, and then carefully turned in the weld bath. When the ground is supposed to have acquired a sufficient degree of intensity, a pattern is put into the blue vat, to ascertain the proper shade. When this is the case, the silk is taken out of the bath, washed, and immersed in the blue vat. To produce a deeper colour, and at the same time to give variety of shade, a decoction of logwood, fustic, or anotta, is added to the yellow bath, after the weld has been taken out. For very light shades, such as apple and sea green, it is scarcely necessary to add, that a weaker ground is to be given. For all light shades, except sea green, the process is found to succeed better when the yellow is communicated by baths which have been already used; but these baths should not contain any logwood or fustic.

Saxon green.

372. Saxon green is produced by means of sulphate of indigo. This is a brighter, but less durable colour than the former. This process is conducted by boiling as for welding, after which the cloth is washed. Fustic in chips is enclosed in a bag, put into the same bath, and boiled for an hour and a half, when it is taken out, and the bath allowed to cool till the hand can bear it. A pound and a quarter of sulphate of indigo for each piece of cloth of eighteen yards, is added. The cloth is at first to be turned quickly, and afterwards more slowly, and it should be taken out before the bath boils. Some dyers put in only two-thirds of the solution at first; and after two or three turns, take out the cloth, and add the other one-third. By this means the colour is more uniform.

By one operation.

373. To produce Saxon green at one operation, the following process is recommended by Dr Bancroft. A bath is prepared of four pounds of quercitron bark, three pounds of alum, and two pounds of murio-sulphate of tin, with a sufficient quantity of water. The bath is boiled ten or fifteen minutes, and when the liquor is so far reduced in temperature as the hand can bear it, it is fit for dyeing. By adding different proportions of sulphate of indigo, various and beautiful shades of green may be obtained, and the colour thus produced is both cheap and uniform. Care should be taken to keep the bath constantly stirred, to prevent the colouring matter from subsiding. Those shades which are intended to incline most to the yellow, should be dyed first; and by adding sulphate of indigo, the green, having a shade of blue, may be obtained. This process, Dr Bancroft observes, is the most commodious and certain for dyeing most beautiful Saxon greens upon silk †.

English green.

374. To produce English green, which is more beautiful than common green, and is said to be more durable than the Saxon green, Guhliche gives the following process. He first dyes the silk of a light blue in the cold vat already described (316.), then soaks it in warm water, washes it in a stream, and dips it in a weak solution of alum. He then prepares a bath of sulphate of indigo, one ounce of solution of tin, with the tincture of French berries made with aceto-citric acid. The silk is kept in this bath till it has obtained the desired colour. It is then washed and dried in a shady place. Lighter shades may be dyed afterwards ‡.

III. *Of the Processes for Dyeing Cotton and Linen Green.*

Blue first given.

375. Cotton and linen, after being scoured in the usual way, are first dyed blue; and after being cleansed, they are dipped in the weld bath, to produce a green colour. The strength of the blue and yellow is proportioned to the shade of green which is wanted. But as it is difficult to give to cotton velvet an uniform colour in the blue vat, it is first dyed yellow with turmeric, and the process is completed by giving it a green with sulphate of indigo. The same result, however, will be obtained by commencing the process either with the yellow or the blue.

Process fo cotton velvet.

376. The process which D'Apligny describes for dyeing cotton velvet, or cotton thread, a sea or apple green, in one bath, is the following. A quantity of verdigrise is dissolved in vinegar, and the mixture is kept excluded from the air in the heat of a stove for fifteen days. A quantity of potash equal in weight to the verdigrise employed is dissolved in water, and four hours

---

* Phil. of Perm. Col. 336.

† Phil. of Perm. Col. 346.

‡ Berthollet, ii. 319

ompound olours.

hours before dyeing it is added to the solution of verdigrise. The mixture is to be kept hot. One ounce of alum in five quarts of water for each pound of stuff being prepared, the cotton thread or velvet is soaked in this solution. It is then taken out, and the verdigrise mixture being added to the solution of alum, it is again introduced to be dyed.

ive een.

377. The different shades of olive green, and drake's neck green, are given to thread after it has received a blue ground, by galling it, and dipping it in a weaker or stronger bath of iron liquor, then in the weld bath, to which verdigrise has been added, and afterwards in the bath with sulphate of copper. The colour is lastly to be brightened with soap.

een from ussian e.

378. Cotton dyed with Prussian blue may be dyed green by previously aluming while it is still wet with the blue, and then dipping in a weld bath, the strength of which is proportioned to the shade required. The colour from weld is more lively than that obtained from fustic. But fustic which gives a deeper shade than weld, and diminishes the brightness of the blue, is to be preferred when a green with an olive shade is wanted.

neral arks.

379. The shade of green given to any stuff, it is obvious, must vary according to the intensity of the blue shade, the strength of the yellow bath, and the nature of the yellow colouring matter employed. Yellow colours are rendered more intense by means of alkalies, sulphate of lime and ammoniacal salts; but become fainter by means of acids, alum, and solutions of tin. In dyeing Saxon green the result will be different according to the process which is followed. The effects will be different by adding a yellow to a Saxon blue, from the process in which the sulphate of indigo is mixed with the yellow ingredients; because in the latter case the sulphuric acid has a considerable action on the colouring matter, and thus diminishes the intensity of the yellow. As the particles of indigo have a stronger affinity for the stuff than the yellow colouring matter, in dyeing a succession of shades in a bath in which both are mixed, the bath being first exhausted of the indigo, the last shades incline more to the yellow on account of the predominance of the yellow colouring matter.

SECT. II. *Of the Mixture of Red and Blue, or Purple, &c.*

380. By the mixture of red and blue, violet, purple, dove-colour, lilac, and a great variety of other shades, according to the proportion of the substances employed, or the predominance of the blue or the red, are produced. In stuffs which are to be dyed violet, a deeper blue must be given, but for purple colours, the ground requires to be of a lighter blue; but in lilac and similar light colours, it is necessary that both the blue and the red have a light shade.

I. *Of Dyeing Wool Violet, Purple, &c.*

B first gi.

381. In the attempts which have been made to communicate a violet or purple colour to a scarlet ground, according to the observations of Hellot, the colour is very unequal. It becomes therefore necessary to give the blue colour first; and for violets or purples, the shade of blue ought not to be deeper than that of sky blue. The stuff being dyed blue, is boiled with alum, and two-fifths of tartar, and is afterwards dipped in a bath composed of nearly two-thirds the quantity of cochineal required for scarlet, with the addition of tartar. The same process, indeed, as for dyeing scarlet, is followed. It is a common practice to dye these colours after the reddening for scarlet, making such additions of cochineal and tartar as the intensity of the shade may require.

Compound Colours.

Lilac, &c.

382. For lighter shades, as lilacs, dove-colours, &c. the stuff may be dipped in the bath which has served for violet and purple, and is now somewhat exhausted, taking care to add a quantity of alum and tartar. For reddish shades, such as peach blossom, a small proportion of solution of tin is added. It may be observed, in general, that although the proportion of cochineal is less in dyeing lighter shades, the quantity of tartar must not be diminished.

Cheaper and shorter process.

383. To obtain the same colours, a shorter and less expensive process is recommended by Poerner. In this process he employs sulphate of indigo. He boils the stuff in a solution of alum, in the proportion of three ounces of the latter to one pound of the former, for an hour and a half, and afterwards allows it to remain in the liquid for a night after it has cooled. The dyeing bath is prepared with an ounce and a half of cochineal, and two ounces of tartar, which are boiled for three quarters of an hour: two ounces and a half of sulphate of indigo are then added, the whole is stirred, and boiled gently for 15 minutes. The dyeing operation is conducted in the usual way, and a beautiful violet is thus obtained. To have all the variety of shades which are produced by the mixture of red and blue, the proportion of the sulphate of indigo is increased or diminished. It is sometimes increased to five ounces, and diminished to five drachms, for each pound of stuff. The quantity of cochineal is also varied, but when it is less than an ounce, the colour is dull. Different proportions of tartar are also employed. To produce variety of shades, the stuff is also prepared with different proportions of solution of tin.

Purple from logwood.

384. To communicate a purple colour to wool, as well as some other shades, logwood, with the addition of galls, has been employed. The stuff is previously dyed blue, and to give a brown shade, sulphate of iron is used; but the colours thus obtained are not permanent. By the following process, described by Decroizille, a durable dye is produced, by means of this wood. He dissolved tin in sulphuric acid, to which were added common salt, red acidulous tartrite of potash, and sulphate of copper; or it may be more conveniently done by making a solution of tin in a mixture of sulphuric acid, common salt, and water, to which are to be added the tartrite and sulphate in the state of powder. Of this mordant not less than 1500 quarts were made in twenty-four hours, in a leaden vessel to which a moderate heat was applied. A very lucrative trade was carried on for three years by Decroizille, who sold it at the rate of 1s. 3d. sterling per pound.

Process.

385. If wool in the fleece is to be dyed, it will require a third of its weight of this mordant, while a fifth is a proportion sufficient for stuffs. A bath is prepared of such a degree of temperature as the hand can bear, with which the mordant is properly mixed, and the wool or stuff dipped in it and stirred, the same degree of

of temperature being kept up for two hours, and increased a little towards the end: after which it is taken out, aired, and well washed. A fresh bath of pure water is prepared at the same temperature, to which is added a sufficient quantity of the decoction of logwood; the stuff is then immersed, stirred, and the heat increased to the boiling temperature, which is to be continued for 15 minutes, after which the stuff being taken out, aired, and carefully rinsed, the process of dyeing is completed. If for every three pounds of wool, one pound of decoction of logwood has been used, and a proportionate quantity for stuffs which require less, a fine violet colour is produced, to which a sufficient quantity of Brazil wood imparts the shade known in France by the name of *prune de Monsieur*.

Different shades from other substances.

386. Logwood and Brazil, fustic and yellow wood, are colouring substances which may be fixed with advantage upon wool by means of this mordant. The colour communicated by the two first of these is liable to be changed in the fulling by the action of the soap or urine employed for that purpose; but this change, which is always produced by alkaline substances, is remedied by a slightly acid bath a little hot, called *brightening*, for which the sulphuric acid has the preference. The colour becomes as deep, and frequently much brighter than before the change. Wools which have been dyed by means of this mordant, are said to admit of being spun into a finer and more beautiful thread than by the use of alum. If the use of sulphate of copper is omitted, more beautiful colours are produced by fustic and yellow wood, as well as by weld. An orange red colour is communicated by madder, but not so deep as with a similar quantity of alum. When sulphate of copper is omitted, the wool is said to become much harsher, and the mordant thus prepared yields but indifferent colours with logwood, and in particular with Brazil wood. The use and carriage of this mordant are inconvenient, on account of the heavy sediment by which the vessel is half filled under a corrosive liquor, capable only of being kept in stone ware. These inconveniences may be remedied by the omission of the water in the receipt, which leaves only a paste more conveniently used, and the carriage of it two-fifths cheaper.

Nature of the process.

387. The above process is thus explained by Berthollet. The decomposition of the muriate of soda is effected by the action of the sulphuric acid; and the muriatic acid being thus disengaged, dissolves the tin, part of which is precipitated by means of the tartaric acid, producing the sediment already mentioned. The oxide of copper produces the blue with the colouring particles of the logwood; the violet is formed by the oxide of tin with the same wood, and the red, with the colouring matter of the Brazil wood. The same ingenious chemist farther observes, that as an excess of acid is retained in the liquor, it might probably be of advantage to employ acetate as a substitute for sulphate of copper, in which case the action of the free acid would be moderated. He thinks it would still be more adviseable to make use of verdigrise; because the uncombined part of the oxide of copper would, in that case, unite with the excess of acid, on which account a smaller quantity of acid would remain in the liquor; and probably the quantity of tartar might be diminished, as a smaller quantity of tin would thus be precipitated *.

II. *Of Dyeing Silk Violet or Purple.*

Two ki of violet.

388. Silk is capable of receiving two kinds of violet colours, denominated the fine and the false, the latter of which is produced by means of archil or Brazil wood. When the fine violet colour is required, the silk must first be passed through cochineal, and dipped afterwards in the vat. The preparation and dyeing of the silk with cochineal are the same as for crimson, with the omission of tartar and solution of tin, by means of which the colour is heightened. The quantity of cochineal made use of is always proportioned to the required shade, whether it is more or less intense; but the usual proportion for a fine violet colour is two ounces of cochineal for each pound of silk. When the silk is dyed, it is washed at the river, twice beetled, dipped in a vat more or less strong, in proportion to the depth of the violet shade, and then washed and dried with precautions similar to those which all colours require that are dyed in the vat. If the violet is to have greater strength and beauty, it is usual to pass it through the archil bath, a practice which, though frequently abused, is not to be dispensed with for light shades, which would otherwise be too dull.

Purple.

389. When silk has been dyed with cochineal according to the above directions, only a very light shade is requisite for purple; the shades which are deepest are dipped in a weak vat, while dipping them in cold water is sufficient for such as are lighter, the water having been incorporated with a small quantity of the liquor of the vat, because in the vat itself, however weak it might be, they would acquire too deep a tinge of blue. In this manner are the light shades of this colour, such as gilly-flower, peach blossom, &c. produced by diminishing the quantity of cochineal.

False vio lets.

390. There are various ways of imparting to silk what are denominated the false violets; but those which are most frequently used, and possessed of greatest beauty, are prepared with archil, the bath of which is, in point of strength, to be suited to the colour required. Having been beetled at the river after scouring, the silk is turned in the bath on the skein sticks; and when the colour is deemed sufficiently deep, a pattern is tried in the vat, to ascertain whether it takes the violet colour intended to be produced. If the shade is found to have acquired the proper depth, the silk is beetled at the river and dipped in the vat, in the same way as for the fine violet colours; and less either of the blue or of the archil colour is given, according as it is meant that the red or blue shade of the violet colour should predominate.

Process o Gubliche

391. The process recommended by Gubliche for communicating a violet colour to silk is the following. A pound of silk is to be soaked in a bath of two ounces of alum, and a like quantity of solution of tin, after having carefully poured off the sediment formed in the mixture. The dye-bath is prepared with two ounces of cochineal reduced to powder with a dram of tartar, and the remaining part of the bath which has answered the purpose of a mordant, with the addition of a sufficient quantity of water. When slightly boiled, such a quantity of solution of indigo is added as may communicate

---

* Berthol let, ii. 340.

cate to the bath a proper shade of violet; after which the silk is immersed, and boiled till it has acquired the intended shade. It is then wrung, washed in a stream, and like every other delicate colour, must be dried in the shade. The light shades exhaust the bath. But it ought to be observed, that this colour, which is said to be a beautiful violet, possesses but little durability, and is apt to assume a reddish tinge, owing to the colour of the indigo fading first.

A ther. 392. A violet colour may be imparted to silks, by immersing them in water impregnated with verdigrise, as a substitute for aluming, and next giving them a bath of logwood, in which they assume a blue colour, which is converted to a violet, either by the addition of alum to the bath, or by dipping them in a weaker or stronger solution of that substance, which communicates a red colour to the particles of logwood. This violet possesses but a small degree of beauty, and little durability, But if alumed silk be immersed in a bath of brazil-wood, and next in a bath of archil, after washing it at the river, a colour is obtained possessing a much higher degree of beauty and intensity. The process described above (385.), for dyeing wool, succeeds equally well, according to M. Decroizille, in communicating to silk a violet colour.

III. *Of Dyeing Cotton and Linen Violet.*

Co hon ess. 393. The most ordinary mode by which a violet colour is communicated to cotton and linen stuffs is first to give them a blue ground in the vat, proportioned to the required shade, and to dry them. They are afterwards galled, in the proportion of three ounces of galls to a pound of stuff, and being left in this bath for 12 or 15 hours, are wrung out and dried again. They are next passed through a decoction of logwood, and when thoroughly soaked and taken out, the bath receives an addition of two drams of alum, and one of dissolved verdigrise for each pound of cotton or thread. The skeins are then dipped again on the skein sticks, and turned for about 15 minutes, when they are taken out and aired. They are next immersed in the bath for 15 minutes, taken out and wrung. To complete the process, the vat employed is emptied; half of the decoction of logwood not formerly made use of is now poured in, with the addition of two drams of alum, and the thread is again dipped in it till it has acquired the shade proposed, which must always regulate the strength or weakness of the decoction of logwood. This colour resists in a considerable degree the action of the air, but in point of permanency is much inferior to that which is obtained from the use of madder.

Sect. III. *Of the Mixtures of Yellow and Red, or Orange.*

394. Orange is the usual result of a composition of yellow and red colours; but an almost endless variety of shades may be produced, according as we vary the proportion of the ingredients, and the particular nature of the yellow made use of. It is sometimes the practice of dyers to combine blue with yellow and red, the result of which is the colour denominated *olive.* Many varieties may be obtained from the use of weld, saw-wort, dyers-weed, and other yellows, and by employing tartar, alum, sulphate of zinc, or sulphate of copper in the bath, or in the preparation of the cloth.

I. *Of Dyeing Wool Orange.*

Orange by the scarlet process. 395. By a process exactly the same as that which is followed in communicating to stuffs a scarlet colour, an orange may be given to wool; but the quantity of red must be diminished, and that of the yellow increased. If wool is dyed a red colour by means of madder, and afterwards yellow with weld, the resulting compound is a cinnamon colour, and the most proper mordant in this case is a mixture of alum and tartar. The shades may be varied at pleasure by substituting other yellow dye stuffs instead of weld, and by varying the proportions as circumstances may require. Wool may receive a reddish yellow colour by passing it through a madder bath, after it has undergone the usual process for yellow, which has already been described. The strength of the madder bath is always to be proportioned to the shade required. Brasil-wood is sometimes employed with yellow substances, or mixed with cochineal and madder. Snuff, chesnut, musk, and other shades are produced, by substituting walnut-tree root, walnut peels or sumach, for weld.

II. *Of Dyeing Silk, Orange, &c.*

Marone, &c. 396. Logwood, brasil-wood, and fustic, communicate to silk a marone and cinnamon colour, together with all the intermediate shades. The silk is scoured in the usual manner, alumed, and a bath is prepared, by mixing together decoctions of the three different woods mentioned above, made separately, varying the quantity of each according to the shade intended to be given; but the proportion of fustic should be greatest. The silk is turned in the bath on the skein sticks, and when it is taken out, if the colour be uniform, it is wrung and again dipped in a second bath of these three ingredients, according to the effect produced by the first in order to obtain the shade required.

Olive. 397. The blue vat is not made use of, when an olive colour is to be communicated to silk. After being alumed, it is dipped in a bath of weld, which is made very strong. To this is afterwards added the juice of logwood, with a small quantity of solution of alkali when the silk is dipped. This converts it into green, and gives the olive colour. It is dipped again in this bath till it has acquired the shade wanted.

398. To communicate to it the colour known by the name of *rotten olive*, fustic and logwood are added to the bath after welding, without any alkali. If the colour wanted is to incline more to a red, the addition of logwood alone is sufficient. A sort of reddish olive may likewise be obtained, by dyeing the silk in a fustic bath, to which a greater or lesser quantity has been added of sulphate of iron and logwood.

III. *Of Dyeing Cotton and Linen Orange, &c.*

Cinnamon colour. 399. A cinnamon colour is communicated to thread and cotton, by commencing the process for dyeing them with verdigrise and weld; they are afterwards to be dipped in a solution of sulphate of iron, denominated by the French *bain d'assurage*, and then wrung out and dried. As soon as they are dried, they are galled in the

Compound Colours.

the proportion of three ounces to the pound of stuff; then dried again, alumed as for red colours, and maddered. After being washed and dried, they are put into hot soap suds, and turned till they have acquired a sufficient degree of brightness. It is the practice of some dyers to add to the aluming a decoction of fustic.

Olive.

400. By boiling four parts of weld and one of potash in a sufficient quantity of water, M. d'Apligny informs us, a fine olive colour is communicated to cotton and thread. Brasil wood, which has been steeped for a night, is boiled separately with a small quantity of verdigrise, and these solutions are mixed together in various proportions, according to the particular shade required. The thread or cotton is dipped in the compound solution in the usual way.

SECT. IV. *Of the mixture of Black with other Colours.*

Brown.

The compound colours which are obtained from the mixture of black and other colours, are brown, gray, drab, &c. according to the nature and proportions of the simple colours employed.

I. *Of Dyeing Woollen Stuffs Brown, Gray,* &c.

401. To give a browning to cloth, as soon as it has been dyed, it is dipped in a solution of sulphate of iron, with the addition of an astringent, which makes a *black bath*. It is more common to mix a small quantity of solution of iron with a bath of water, adding more till the dyed stuff dipped in it has received the intended shade. Sulphate of iron is sometimes added to the dye bath; but by dipping the dyed stuff in a solution of this salt, the end is more easily attained. It is the usual practice of M. Poerner to soak the stuff in a solution of sulphate of iron, to which other ingredients are sometimes added, and after having taken it out of the mordant, it is dipped in the dye bath.

Coffee colour.

402. In order to obtain coffee and damascene colours, with other shades of browns of the common dye, the first method is adopted; a colour more or less deep is communicated to them, according to the shade intended to be obtained by the browning; and a bath is made of galls, sumach, and alder bark, with the addition of sulphate of iron. Those stuffs are first dipped to which the lightest shades are to be communicated, and when these are finished, the browner ones are dipped; a quantity of sulphate of iron being added for each operation, proportioned to the effect intended to be produced.

Gray.

403. Blueish grays are communicated to stuffs, according to Poerner, by the solution of indigo in sulphuric acid, combined with a mixture of decoction of galls and sulphate of iron, varying the shades according to the different quantities of these ingredients made use of. If to a bath composed of cochineal, fustic and galls, sulphate of iron be added, other shades are obtained.

404. For marone, and such other colours as bear a strong resemblance to it, sanders and galls are employed, and sometimes a browning with the addition of logwood. If dyed in the remains of a cochineal bath, these colours may be made to incline to a crimson or purple, and the same effect is produced by adding a small quantity of madder or cochineal to the bath. A little tartar gives a greater degree of brightness to the colour. With a mixture of galls, fustic, and logwood, and a greater or smaller quantity of madder, with the addition of a little alum, those colours may be communicated to stuffs which are known by the name of *hazel*.

Hazel.

Puce colour.

405. M. Guhliche produces what is called a *puce* colour, by boiling for fifteen minutes a pound of woollen stuff with two ounces of alum, a certain proportion of vinegar and solution of iron, after which he leaves it in the mordant for twelve hours. He then makes a bath with the decoction of two ounces of white galls carefully poured off from the sediment, and mixed with four ounces of madder, in which, when it grows hot, the stuff is immersed, after being taken out of the mordant, allowing it to remain there, while the temperature is gradually increased, till the colour intended has been imparted to it; after which it is boiled for two minutes, washed, and dried in the sun. The colour thus obtained possesses a great degree of durability. It is of a deeper brown by the omission of the alum and vinegar in the mordant; and after these colours the lighter shades are dyed. Sumach may be employed as a substitute for half of the madder. Different brown colours possessing considerable permanency, may likewise be produced by the use of brasil and logwood, if more or less of a solution of iron be mixed with a decoction of these substances. The wool being previously alumed and galled, is dyed in it.

II. *Of Dyeing Silk with Mixtures of Black,* &c.

Purple violet.

406. M. Guhliche imparts to silk a purple violet without a blue ground, with a mixture of one part of galls dissolved in white wine, with three parts of water, in which a pound of silk is macerated for twelve hours, soaked in a mordant made up of two ounces of alum, one ounce of solution of tin, and half an ounce of muriatic acid. After wringing the stuff, it is dyed in a bath composed of two ounces of cochineal and a small quantity of solution of iron, till the intended shade has been communicated; and for shades which are lighter, the residua of these baths are sufficient, either separately or mixed together. Madder may be used in the same way, macerating a pound of silk in a solution of alum, mixed with an ounce of muriatic acid, and a quantity of solution of iron. When the stuff is wrung out, it is dyed in a bath made of eight ounces of madder. When deeper colours are wanted, some of the solution of galls in white wine is mixed with the madder and cochineal baths.

407. Silk may be dyed in a bath made of equal parts of brasil and logwood juice, adding a certain quantity of solution of iron, after the stuff has been soaked in a solution of two ounces of alum, and an ounce of muriatic acid. If solution of galls be added, the colour becomes deeper.

Brick colour.

Colours resembling that of brick, may be produced, by immersing silk in an anotta bath, after preparing it with a solution of galls mixed with a certain quantity of solution of iron. By the mixture of brasil, logwood, archil, and galls, and by a browning with sulphate of iron, a number of different shades are produced; but the whole of them have more or less

a

a tendency to fade, although their brightness is very pleasing to the eye.

III. *Of Dyeing Silk with Mixtures of Black*, &c.

408. A permanent violet colour may be given to thread and cotton, when scoured in the ordinary way, by preparing a mordant with two quarts of the bath of what is called the *black cask*, and four quarts of water for each pound of stuff, which is made to boil, and the scum is removed which forms on the surface, till it wholly disappears. The liquor is poured into a vat, and, when warm, four ounces of sulphate of copper and one ounce of nitre are dissolved in it. The skeins are left to soak in it for ten or twelve hours, wrung out, and dried. If it is required to produce a deep violet colour, two ounces of verdigrise must be added to the bath; and if the nitre be omitted, the colour becomes still deeper by galling the thread more or less, prior to its being put into the mordant. If the nitre be increased, and the sulphate of copper be diminished, the violet colour becomes more inclined to lilac. A number of various shades may be produced, by different modifications of the mordants employed.

409. Cotton is galled, dipped, and wrought in the common way, when different shades of marone colour are wanted. To the bath employed must be added more or less of the liquor of the black cask. The cotton is then washed in a bath mixed with verdigrise, next welded, and dyed to a fustic bath, to which a solution of soda and alum is sometimes added. When the cotton prepared in this manner has been thoroughly washed, it is next well maddered, dipped in a weak solution of sulphate of copper, and last of all in soap suds.

410. For some hazel and snuff colours, a browning is communicated to stuffs by means of soot, after the welding and madder bath, to which galls and fustic have been added; sometimes soot is mixed with this bath, and a browning is likewise imparted by means of a solution of sulphate of iron; and for browning colours, walnut peels are sometimes employed as a substitute for solutions of iron. For such wools as are designed for the manufacture of tapestry, they are very advantageous, because the colour is not changed into yellow by exposure to the air, as is the case in browning which is imparted by means of iron; but remains a considerable time without any sensible change. The hue is indeed rather dull; but its goodness and very moderate price are sufficient to recommend a more extensive use of it for grave colours, which in common stuffs are sometimes fashionable.

CHAP. III. *Of Calico-printing.*

411. THIS may be defined to be the art of communicating different colours to particular spots on the surface of cotton or linen cloth, while the rest of the stuff retains its original white colour.

The wonderful and truly ingenious art of calico-printing seems to have been first known in India, and for more than two centuries before the commencement of the Christian era. Although the Egyptians were well acquainted with this art in the days of Pliny, as he himself informs us, it can scarcely be doubted that they derived the knowledge of it from India, as that country rather than Egypt, produced the colouring and other materials for carrying it on. If we consider its present improved state, the elegance of different patterns, the beauty and durability of the colours which can now be imparted to cotton or linen stuffs, and the dispatch with which the various operations of this art are conducted, we must be astonished at the rapidity of its improvements, when we recollect that it has been known in Europe for little more than a century. Perhaps no other art has risen to such perfection in so short a period.

412. Our readers will not expect that our account of this subject should be tedious or elaborate, since the artist is presumed to be already acquainted with the different processes which are employed in calico-printing; and to such as wish only for a general knowledge of the art, in a theoretical point of view, prolixity would be disagreeable.

Nature of this art.

413. The art of calico-printing consists in impregnating with a mordant, such parts of cotton or linen stuffs as are to have particular colours communicated to them, and then dyeing them in the usual manner with some colouring substance. Those parts of the cloth only which receive the mordant are intimately united with the colouring matter, although the whole surface must be more or less tinged; but the parts which have not received the mordant are restored to their original brightness by means of washing, and afterwards bleaching it upon the grass for some days, taking care to turn the wrong side towards the sun. If red stripes are to be communicated to a piece of white cotton cloth, those parts of its surface upon which stripes are intended to appear, are marked out by a pencil dipped in acetate of alumina; after which it is dyed with madder in the usual way. When it is first taken out of the dyeing vessel, its whole surface is red; but when it is washed and bleached, it resumes its original whiteness, the stripes only excepted, which, being impregnated with the acetate of alumina, remain red. By a similar process may yellow or any other stripes be fixed upon cotton or linen, by the substitution of quercitron bark, weld, &c. in the room of madder.

To communicate different colours.

414. When different parts of the cloth are to receive different coloured stripes at the same time, different mordants must be employed. If stripes are delineated on its surface with the acetates of alumina and iron, and if it be then dyed with madder in the ordinary way, it will, after being washed and bleached as formerly directed, exhibit stripes of a red and brown colour. If the same mordants are employed, but quercitron bark used instead of madder, the stripes will then be *yellow*, and *olive* or *drab*.

Usual mordants.

415. The mordants known by the names of acetate of alumina and acetate of iron, which are made use of in calico-printing, may either be applied to stuffs with a pencil, as already mentioned, or still more expeditiously by means of blocks, on which the intended patterns are cut. Being designed only for particular parts of the surface of the cloth, great caution is necessary to prevent them from spreading to any part of it which is to remain white, and to prevent their interference when the application of more than one is required. Such a degree of consistence must of consequence be given to the mordants employed, as will prevent this disagreeable effect, which cannot fail to destroy the beauty and

and elegance of the print. If blocks are to be made use of, the mordants may be brought to a proper consistence by means of starch; but gum arabic must be mixed with them, when the pencil is to be employed. The thickness should not exceed what is absolutely necessary to prevent the mordants from spreading; because, if carried too far, the cotton is frequently not saturated with the mordant, in consequence of which the dye is but imperfectly communicated.

Application of the mordant.

416. To distinguish those parts of the cloth which are impregnated with mordants, it is a common practice to give the mordants some particular tinge by which they may be known; and for this purpose printers commonly make use of the decoction of brasil wood. Dr Bancroft objects to this practice, because he is of opinion that the process of dyeing is impeded by the colouring matter of brasil wood. The affinity of the dye stuff for the mordant displaces the colouring matter of the brasil wood; and without such affinity it would be impossible to strike the colour. Some of the dye stuff to be employed afterwards is recommended by Dr Bancroft for colouring the mordant, who prohibits the use of a larger quantity than what is sufficient to render it distinguishable when an application of it is made to the cloth. Should too large a quantity be united with the mordant, a considerable proportion of the latter would be combined with colouring matter, by which means its affinity for the cloth would be diminished, and therefore a permanent colour could not be expected to result from such a partial combination.

Cloth must be dried,

417. It is necessary to dry the cloth completely after the application of the mordants, for which purpose artificial heat may be employed, which has a tendency to promote the separation of the acetous acid from its base, and assist its evaporation, and thus the combination of the mordant with the cloth will be facilitated.

and then washed.

418. When the cloth is thoroughly dried, it is customary to wash it with warm water and cow-dung, till every particle of the starch or gum arabic which had been employed to give a proper consistence to the mordants, and those parts of them which do not combine with the cloth, are entirely removed. The loose particles of the mordant are entangled by means of the cow-dung, and prevented from being attached to those parts of the cloth which are to remain white. After this, it must be completely rinsed in pure water.

Colouring matters employed.

419. Indigo, madder, quercitron bark, and weld, are the chief dyeing ingredients made use of by calico-printers; but the last of these is seldom used by the printers of this country, except for the purpose of communicating yellows of a delicate greenish shade. Quercitron bark, on account of its inferior price, and capacity of imparting colours equally good, as well as requiring a less degree of heat, is employed as a substitute. It is usual to apply indigo at once, either by means of the block or pencil, because it requires not the intervention of a mordant to fix it. This preparation is made by boiling together indigo, potash reduced to the caustic state by means of quicklime, and orpiment; afterwards thickening the solution with gum. Dr Bancroft recommends the use of coarse brown sugar as a substitute for orpiment, which operates as powerfully in the decomposition of the indigo, and in promoting its solubility, answering at the same time all the purposes of gum.

Dyeing process.

420. When the cloth is thoroughly cleansed after it has been impregnated with the mordant, the dyeing process is conducted in the usual manner. As the whole of it receives a tinge of the dye, it must be completely washed and bleached for some days on the grass, as formerly mentioned, by which means the colour is entirely removed from those parts of the cotton not impregnated with the mordant, while all the other parts of it retain the colouring matter as powerfully as at first.

Nanke yellow,

421. One of the most common colours imparted to cotton prints is a species of nankeen yellow of different shades, and for the most part in stripes or spots. It is produced by means of a block on which is cut the intended pattern, rubbed over with acetate of iron brought to a proper consistence with gum or starch, and applied to the cotton; which, being dried and cleansed in the ordinary way, is immersed in a ley of potash. It is proper to observe, that the quantity of acetate of iron must be proportioned to the particular shade required.

Yellow.

422. In order to produce a yellow colour, the block is rubbed over with acetate of alumina; and the cloth, after being impregnated with this mordant, is dyed with quercitron bark in the common manner, and then bleached.

Red.

423. If madder be substituted for the quercitron bark, a red colour is given to cotton by the same process.

Blue.

424. To communicate to stuffs the fine light blue colours which we frequently behold upon cotton, the block is rubbed over with a composition consisting partly of wax, by means of which all those parts of its surface are to remain white. It is next dyed in a cold vat of indigo, and when it is dried, the wax composition may be removed by the use of hot water.

Lilac,

425. Lilac and blackish brown colours are communicated by acetate of iron, proportioning the quantity to the particular shade required, and adding a little sumach for such shades as are to be very deep. The cotton is then dyed with madder, and bleached in the usual manner. Dove colour and drab are produced by means of acetate of iron and quercitron bark.

How t ply diff ent col

426. When a variety of different colours are to be made on the same print, a greater number of operations are unavoidably necessary. Upon each of the blocks to be employed is cut that particular part of the pattern which is to have one appropriate colour; and when these blocks are rubbed over with their respective mordants and thus applied to the cloth, the dyeing process is afterwards conducted in the ordinary manner. If, for example, three different blocks are to be made use of, the first rubbed over with acetate of alumina brought to a proper consistence, the second with acetate of iron, and the third with a composition of these two, the colours resulting, after the dyeing and bleaching processes are finished, will be the following.

Acetate of alumina	yellow,
iron	olive, drab, dove,
From the compound	olive green, olive.

It is proper to observe, that these are the results when quercitron bark is employed; but by the substitution of madder the following colours will be obtained.

Acetate

Acetate of alumina	red,
iron	brown, black,
From the compound	purple.

When it is required to produce at the same time both those colours which are imparted by madder, and likewise by the use of quercitron bark, mordants are first applied for one part of the pattern, after which the cotton is dyed in a bath of madder, and then bleached. The rest of the mordants are then applied in a similar manner, after which the cotton is dyed with the quercitron bark, and bleached as before. The colours which the madder communicates are very little affected by the second dyeing, because the mordants by which their permanency is secured, are previously saturated. A new mordant may be applied to some of the colours resulting from the use of madder, by which means they receive a new durable colour from the bark. And by means of the indigo liquor other new colours may still be communicated after the last bleaching.

Va ty of co rs by di ent pr sses.

427. The following colours may be communicated to cotton, by means of the different processes which have been described.

Madder Dye.

Acetate of alumina	red,
iron	brown, black,
Ditto diluted	lilac,
Mixture of the two	purple.

Dark Dye.

Acetate of alumina	yellow,
iron	dove-drab,
Lilac and acetate of alumina	olive,
Red and acetate of alumina	orange.

Indigo Dye.

Indigo	blue,
Indigo and yellow	green.

Thus may twelve different colours be communicated to the same print by these different processes.

Co s or cil- ng.

428. If durable colours could be directly applied to cotton by means of the block or pencil, without the help of mordants, nothing could be conceived more simple than the art of calico-printing; but with the single exception of indigo, the communicating of permanent colours requires the process of dyeing. Yellow, indeed, which is a compound colour, and some others, may be communicated to cotton at once, by mixing together an infusion of quercitron bark and acetate of alumina, while the same mordant with a decoction of madder, imparts to it a red colour; but those which are produced in this way are far from being durable, since they are destroyed by washing, and sometimes even by exposure to the air.

Com si- ion r ell co. ou

429. But as it is not always practicable for calico-printers to avoid the application of colours in this manner, every endeavour to give them a greater degree of permanency becomes an object of importance. The following composition has been recommended for a yellow printing colour. Three pounds of alum, and three ounces of pure chalk are to be dissolved in a gallon of hot water, to which are to be added two pounds of acetate of lead. This mixture is to be occasionally stirred for 24 or 36 hours, after which it is to remain at rest during 12 hours. The clear liquor is then to be poured off, and as much more hot water added to the residuum, as will, after being stirred and allowed to settle, amount to three quarts when added to the first quantity. Into a tinned copper vessel put six pounds, or at most a quantity not exceeding eight pounds, of quercitron bark sufficiently ground, and boil it for an hour in four or five gallons of clean soft water, adding afterwards a little more water if the bark is not properly covered. When the liquor is thoroughly boiled, let it be removed from the fire, and left to settle for half an hour, when the clear decoction is to be poured off through a fine sieve. Six quarts more of pure water are then to be put upon the same bark, and boiled for a quarter of an hour, being previously well stirred. When it has stood a sufficient time to settle, the clear liquor is to be strained off, and being mixed with the former, both are put into a shallow wide vessel to be evaporated by boiling, till the whole, in addition to the mordant already mentioned, and the gum or paste for bringing it to a proper consistence, does not exceed three gallons. It will be proper not to add the three quarts of aluminous mordant till the decoction has been cooled down almost to the natural heat of blood. Let gum arabic or gum senegal be taken for thickening, if the pencil is to be used, and starch or flour when blocks are to be employed.

For bright yellow.

430. If a pound of murio-sulphate of tin be used as a substitute for the aluminous mordant in the composition described above, a mixture will be produced which is capable of imparting to cotton a very bright yellow, and considerably permanent.

Cinnamon colour.

431. A cinnamon colour possessed also of a sufficient degree of permanency may be given to cotton, by means of a mixture of sulphate of tin and a decoction of the quercitron bark.

Green.

432. If the decoctions of this bark and of logwood are boiled together, and proper quantities of sulphate of copper and verdigrise added to them, together with a small proportion of carbonate of potash, there results a compound which communicates to cotton a green colour. Although the expectations of Dr Bancroft were not fully answered by the trials which he made of this substance, he deemed his success sufficient to encourage him to a farther investigation of it.

Drab and olive.

433. A permanent drab colour may be given to cotton by means of acetate of iron mixed with a decoction of quercitron bark, and reduced to a proper consistence. This mixture will also produce an olive, if added to the olive colouring liquor already mentioned; and the colours may be made still more permanent, if a solution of iron in diluted nitric or muriatic acid be used as a substitute for iron liquor. They ought, however, to be used sparingly and with caution, that the texture of the cotton or linen to which they are applied may not be injured.

Colours from different mordants and the quercitron bark.

434. Dr Bancroft made a number of experiments with the decoction of quercitron bark, to ascertain its effects when combined with different metallic salts as mordants. The sulphate, nitrate, and muriate of zinc, with this decoction, yielded brownish yellow colours of different shades; but none of them were found sufficiently permanent when they were applied topically to linen or cotton. Mercury in the different acids pro-

Indian Method of Dyeing Red.

duced with the decoction of bark different shades of brown or yellowish brown colours; but they did not prove more durable than the former. The nitro-muriate of platina with a proper proportion of decoction of quercitron bark, afforded, when topically applied to linen or cotton, strong full-bodied snuff colours, which were found sufficiently permanent, and capable of resisting the action of acids, and of the sun and air. Nitrate of silver with a decoction of the bark, when applied topically to linen or cotton, produced strong dark brown and cinnamon colours of considerable durability. Nitrate of lead with the same decoction gave, by topical application, a drab colour which was not less durable than the former. Nitrate of bismuth produced with the decoction of bark a very full and strong brownish yellow. This colour, however, is attended with the inconvenience of becoming almost black when exposed to the action of the alkaline sulphurets, sulphurated hydrogen gas, or even by the action of common soap. Muriate of bismuth with the decoction gives a drab colour: sulphate of the same metal affords a yellow; but these colours when applied to cotton or linen are not durable. Nitro-muriate of antimony produced with the decoction of bark something of a snuff colour, which applied to linen and cotton possess some degree of durability. Nitrate and muriate of cobalt with the quercitron bark gave different shades of brown; but these colours were extremely fugitive; they soon faded by exposure to the sun and air.

Indian M thod o D yein Red.

435. The art of calico-printing has been hitherto almost solely limited to linens and cottons. Many colouring matters have such an affinity for these stuffs that they readily enter into combination with them at the ordinary temperature of the atmosphere. This is also the case with silk, so that colouring matters might be applied topically to the latter by means of similar operations as to linen and cotton. Attempts, however, have been made to extend the process of topical dyeing or printing to woollen stuffs, and particularly those kinds known by the name of kerseymeres, which are employed after being prepared in this way for waistcoat patterns. When it is recollected that woollen stuffs when they are to be dyed generally must be exposed to a considerable degree of heat, it is easy to conceive that it will be difficult to communicate spots or figures by printing to woollen stuffs. The means by which this difficulty is obviated in those manufactories where this operation is conducted have been hitherto kept secret. The preparation of colouring matter, whether such as may be employed simply or require the use of mordants to fix them, will be easily understood from what we have already fully detailed in the course of this treatise. The application of the colours is made in the usual way; and it is said that, after the woollen stuffs are printed, they are wrapped up in two or three folds of thick paper, to prevent the access of moisture which might cause the colours to run, and exposed to the steam of boiling water for such a length of time as may be supposed necessary for the colouring matter to combine with the stuffs†.

Woolle stuffs pri ted.

APPENDIX.

After that part of the preceding treatise to which it properly belongs, was printed off, the following account of the Indian method of dyeing cotton cloth and cotton thread a red colour came under our notice. It was communicated to the Society for the Encouragement of Arts, &c. by Mr Maclachlan of Calcutta. The insertion of it may perhaps excite the curiosity of some of our countrymen into farther inquiries into the state of this as well as of other arts in India, where, from being long known and practised, many of them have arrived at a high degree of simplicity and perfection.

Directions for dyeing a bright Red, four yards of three-fourths broad Cotton Cloth.

1st. The cloth is to be well washed and dried, for the purpose of clearing it of lime and congee, or starch, generally used in India for bleaching and dressing cloths; then put into an earthen vessel, containing twelve ounces of chaya or red root, with a gallon of water, and allow it to boil a short time over the fire.

2d. The cloth being taken out, washed in clean water, and dried in the sun, is again put into a pot with one ounce of myrobalans, or galls coarsely powdered, and a gallon of clear water, and allowed to boil to one half: when cool, add to the mixture a quarter of a pint of buffalo's milk. The cloth being fully soaked in this, take it out, and dry it in the sun.

3d. Wash the cloth again in clear cold water, and dry it in the sun; then immerse it into a gallon of water, a quarter of a pint of buffalo's milk, and a quarter of an ounce of the powdered galls. Soak well in this mixture, and dry in the sun. The cloth, at this stage of the process, feeling rough and hard, is to be rolled up and beetled till it becomes soft.

4th. Infuse into six quarts of cold water, six ounces of red wood shavings, and allow it to remain so two days. On the third day boil it down to two-thirds the quantity, when the liquor will appear of a good bright red colour. To every quart of this, before it cools, add a quarter of an ounce of powdered alum; soak in it your cloth twice over, drying it between each time in the shade.

5th. After three days wash in clean water, and half dry in the sun; then immerse the cloth into five gallons of water, at about the temperature of 120° of Fahrenheit, adding 50 ounces of powdered chaya, and allowing the whole to boil for three hours; take the pot off the fire, but let the cloth remain in it until the liquor is perfectly cool; then wring it gently, and hang it up in the sun to dry.

6th. Mix intimately together, by hand, about a pint measure of fresh sheep's dung, with a gallon of cold water, in which soak the cloth thoroughly, and immediately take it out, and dry it in the sun.

7th. Wash the cloth well in clean water, and spread it out in the sun on a sand-bank (which in India is universally preferred to a grass-plat) for six hours, sprinkling

---

† Bancr 189.

ling it from time to time, as it dries, with clean water, for the purpose of finishing and perfecting the colour, which will be of a very fine bright red.

Directions for dyeing of a beautiful red, eight ounces of Cotton Thread.

1st. Put one gallon and a half, by measure, of sap-wood ashes, into an earthen pot, with three gallons of water, and allow the mixture to remain twenty-four hours to perfect it for use.

2d. Put the following articles into an earthen pot, viz. three quarters of a pint of Gingelly oil; one pint, by measure, of sheep's dung, intimately mixed by hand in water; two pints of the above ley.—After mixing these ingredients well, pour the mixture gradually upon the thread into another vessel, wetting it only as the thread, by being squeezed and rolled about by the hand, imbibes it, continuing to do so until the whole is completely soaked up, and allow the thread to remain in this state until next day.

3d. Take it up, and put it in the sun to dry; then take a pint and a half of ash-ley, in which squeeze and roll the thread well, and allow it to remain till next day.

4th. Squeeze and roll it in a like quantity of ash-ley, and put it in the sun to dry; when dry, squeeze and roll it again in the ley, and allow it to remain till next day.

5th. Let the same process be repeated three or four times, and intermit till next day.

6th. Ley the thread once, as the day before, and, when well dried in the sun, prepare the following liquor: One gill of Gingelly oil; one pint and a half of ash-ley.—In this squeeze and roll the thread well, and leave it so till next day.

7th. Repeat the process of yesterday, and dry the thread in the sun.

8th. The same process to be repeated.

9th. First repeat the ash-ley process three or four times, as under the operations 3, 4, and 5, and then prepare the following mixture: One pint of sheep-dung water; one gill of Gingelly oil; one pint and a half of ash-ley.—In this squeeze and roll the thread well, and dry it in the sun.

Indian Method of Dyeing Red.

10th. Repeat the same process.
11th. Do. Do.
12th. Do. Do.
13th. Do. Do.
14th. Do. Do.

15th. Wash the thread in clean water, and squeeze and roll it in a cloth until almost dry; then put it into a vessel containing a gill of powdered chaya root, one pint by measure of cashan leaves, and ten pints of clear water; in this liquor squeeze and roll it about well, and allow it to remain so till next day.

16th. Wring the thread, and dry it in the sun, and repeat again the whole of the 15th process, leaving the thread to steep.

17th. Wring it well, dry it in the sun, and repeat the same process as the day before.

18th. Do. Do.
19th. Do. Do.

20th. Wring and dry it in the sun, and with the like quantity of chaya root in ten pints of water; boil the thread for three hours, and allow it to remain in the infusion until cold.

21st. Wash the thread well in clear water, dry it in the sun, and the whole process is completed.

INDEX.

DYNAMICS.

DYNAMICS.

Introduction.

Definition.

1. DYNAMICS is that branch of physico-mathematical science which includes the abstract doctrine of *moving forces;* that is, the necessary results of the relations of our thoughts concerning motion, the immediate causes of motion, and its changes.

Idea of motion.

2. Motion and its general properties are the first and principal object of mechanical philosophy. This science indeed presupposes the existence of motion; and we may consider it as universally admitted and recognised. With regard to the nature of motion, however, philosophers are greatly divided in opinion. The most obvious and simplest conception of motion is the successive application of the moving body to the different parts of indefinite space, which are considered as the place of the body. This idea of motion supposes a space whose parts are penetrable and immoveable; a doctrine directly contrary to that of the followers of Des Cartes, who regarded extension and matter as one and the same thing. To have a distinct idea of motion, it seems requisite to conceive two kinds of extension; the one, which is considered as impenetrable, and which constitutes what we properly call *matter* or *body;* the other, which being simply considered as extended, without taking any other property into account, is the measure of the distance of one body from another; and whose parts being supposed fixed and immoveable, enable us to judge of the rest or motion of bodies. We may therefore conceive bodies to be placed in indefinite space, whether real or supposed; and motion as a change in the state or condition of a body from one part of space to another. We must indeed consider motion as a state or condition of existence of a body, which would remain till it is changed by some cause; otherwise we could not have any idea of motion in the abstract. From the changes which we observe, we infer agency in nature; and in these changes we are to discover what we know of their causes.

Idea of space.

3. In mechanical disquisitions, the simplest, and at the same time the most usual conception of space, is mere extension. We think only of the distance between two places. The path along which any body moves in passing from one place or point in space to another, is said figuratively to be the path described by that body. Space is considered by the geometer not only as having length but also breadth. In this case it is called a *surface.* But to have a more complete notion of the capaciousness of any portion of space, thickness, as well as length and breadth, is taken into consideration. This is called a solid space. By this, however, is meant only the susceptibility of measure in three ways, or extension of three dimensions. The adjacent parts or portions of space are distinguished from each other by their mutual boundaries. Contiguous portions of a line are separated by points; contiguous portions of a surface are separated by lines; and contiguous portions of a solid are separated by surfaces. The boundaries of any portions of space are not to be considered as parts of the contiguous portions. They must be conceived as common to both; as the places where one portion ends and another begins. Space cannot be said to have any bounds or limits; it is therefore said to be infinite or unbounded.

Introduction.

Relative and absolute space.

4. Any portion of space may be considered in relation to its place or situation among other portions of space. This portion of space which is occupied by any body has been called the *relative place* of that body. But this portion of space may be considered as a determinate portion of infinite space; and this portion of infinite space occupied by any body has been called the *absolute place* of that body. Space, it is obvious, taken in this meaning, is immoveable; for it cannot be conceived that this identical portion of space can be removed from one place to another. The body which occupies that space may be removed, but the space remains. We have no perception of the absolute space of any object. This may be illustrated by the motion of the earth or that of a ship. A person in the cabin of a ship does not consider the table as changing its place while it remains fixed to the same spot on the deck. While a mountain is observed to retain the same situation among other objects, few persons think that it changes its place.

Idea of time.

5. The idea of time is acquired by means of the power of memory in observing the succession of events. We conceive time as unbounded, continuous, homogeneous, unchangeable in the order of its parts, and infinitely divisible. It is conceived as a proper quantity made up of its own parts, and measured by them. But as the relation of the parts of time is unknown, the only means which we can employ to discover this relation, is to find out some other relation which is more obvious and better known, to which it may be compared. We shall then have discovered the simplest measure of time, if we compare in the simplest manner possible the relation of the parts of time with those relations which are most familiar. Hence it follows, that uniform motion is the simplest measure of time. For, on the one hand, the relation of the parts of a right line is that which is most easily conceived; and, on the other hand, there are no relations more susceptible of comparison with each other than equal relations. Now, in uniform motion, the relation of the parts of time is equal to that of the corresponding parts of the line described. Uniform motion then gives us at once, both the means of comparing the relation of the parts of time with that which is most obvious to our senses, and also of making this comparison in the simplest manner. In uniform motion, then, we find the simplest measure of time. It may be added, that the measure of time by uniform motion, is, independent of its simplicity, that which is the most natural to think of employing. Indeed as there is no relation with which we are acquainted more accurate than that of the parts of space; and, as in general, a motion, the law of which is given, would lead us to discover the relation of the parts of time, by the known analogy with that of the parts of space passed over, it is evident that such a motion would be the most accurate measure of time, and

and that which ought to be employed in preference to every other. In the actual measurement of time, some event which is imagined always to require an equal time for its accomplishment is selected; and this time is employed as a unit of time or duration, in the same way as a foot rule is employed as a measure of extension. During any observed operation, as often as this event is accomplished, so often is it supposed that the time of the operation contains this unit. While a heavy body falls 16 feet, a pendulum, $39\frac{1}{8}$ inches long, makes one vibration; but it makes three vibrations, while the same body falls 144 feet. It is therefore said that the time of a body falling 144 feet, is thrice as great as the time of falling 16 feet.

Analogy between the affections of time and space.

6. Between the affections of time and space, there is an obvious analogy; and hence in most languages the same words are employed to express the affections of both. Thus it is that time may be represented by lines and measured by motion; since uniform motion is the simplest succession of events that can be conceived. In the order of situation all things are placed in space. In the order of succession all events happen in time.

Having made these preliminary observations, we propose to divide the following treatise into two parts. In the first, we shall consider motion in general. In the second, we shall treat of *moving forces*, or of *dynamics*.

PART I. OF MOTION.

BEFORE we enter on the consideration of the different kinds of motion, it may be necessary to notice some general circumstances regarding it.

7. It is impossible to conceive that any motion can be instantaneous. A moving body, in passing from the beginning to the end of its path, must pass through all the intermediate points. Now to suppose the motion along even the most minute portions of the space passed through instantaneous, is to suppose that the moving body is in every intervening point at the same instant; which is impossible.

8. Relative motion is the change of situation with regard to other objects. Absolute motion is the change of absolute place. These two motions, it may be observed, may not only be different, but even contrary to each other. From the relative motions of things which are the differences of their absolute motions, we cannot find out what are the absolute motions. It is often a subject of elaborate and intricate investigation to discover and determine the absolute motions, by means of observing the relative motions.

9. The affections or circumstances of motion are various with regard to its quantity and direction. That affection of motion by which the quantity is determined, is called *velocity*. The length of the line, which is uniformly described or passed over during some given portion or unit of time, is the proper measure of this velocity. When a ship sails six miles per hour, she describes a length of line equal to six miles in the space of a given portion or unit of time, namely the hour; and thus the velocity of the ship is said to be ascertained.

10. Another affection or circumstance of motion is its *direction*. This is the position of the straight line along which the motion is performed. The straight line which a body describes or tends to describe is called its direction. The motion is said to be in the direction AB, fig. 1. when the body moved passes along the line AB from A to B. In common language, it is not unusual to express the direction of motion in a manner quite the reverse of this. We have an instance of this kind in speaking of the direction of the winds. A current of air or wind which moves eastward is said to be a westerly wind, deriving its name from the point or quarter from which it proceeds, not as in other cases, and in strict expression, from the point to which it is directed.

Rectilineal motion.

11. Motions are of different kinds. They are either rectilineal, deflected, or curvilineal. In a rectilineal motion the direction remains unchanged during the whole time that the motion is continued, as when a body moves from A to B, fig. 1. In a deflected motion it is performed along two contiguous straight lines in succession. Thus if a body moves from A to B, fig. 2. and at the point B its direction is changed from that of AD to BC; this change has been called *deflection*, the quantity of which may be measured either by the angle DBC, or by a line DC drawn from the point D to which the body would have arrived in the same time, if its motion had remained unchanged, in which it has actually reached the point C. When a body in moving along describes the sides of a polygon, the deflections are repeated, with the intervention of undeflected motions. In curvilineal motion the deviation and deflection are supposed to be continual. Continual deflection therefore constitutes curvilineal motion. Let the motion be performed along a curve line ABCDE (fig. 3.), the direction is continually changing. When the body is in the point C the direction is that of the tangent CF; because this direction alone lies between any pair of polygonal directions, such as CE and C *a*, or CB and CD, however near the points A and E, or B and D, are taken to the point C.

Fig. 1. Deflected. Fig. 2. Curvilineal. Fig. 3.

Division of motions.

12. Motions have been divided into *uniform* motions, *variable*, *compound*, and *curvilineal*. These we shall consider separately in the following sections.

SECT. I. *Of Uniform Motion.*

Importance of fixed characters of uniform motions.

13. It is of great importance in mechanical disquisitions, to have the characters of uniform or unchanged motion fixed. For in our conceptions of motion in general, in which we do not turn the attention to its alterations, the motion is supposed to be equable and rectilineal. By the deviations from such motion only can we determine the marks and measures of all changes; and hence also we are to obtain the measures of all changing causes, or in other words of the mechanical powers of nature.

PROPOSITION I.

14. *In uniform motions, the velocities are in the proportions of the spaces described in the same or in equal times;*

times; or as it is sometimes expressed, *The velocities are proportional to the spaces described in equal times.*

The spaces described are the measures of the velocities, and things are proportional to their measures. Let the spaces described in the time T, be represented by S and s, and let the velocities be represented by V and v. We have the analogy $V : v = S : s$. Or, as it may be expressed by the proportional equation, $v \doteq s$.

Prop. II.

15. *In uniform motions with equal velocities, the times are in the proportion of the spaces described during their currency.* Or, as it is also expressed, *The times are proportional to the spaces described with equal velocities.*

For in uniform motions, equal spaces are described in equal times. The successive portions of time therefore are equal, in which equal spaces are described in succession; and the sums of the equal times must be proportional to the corresponding sums of equal spaces. In all cases, therefore, which are susceptible of being represented by numbers, this proposition is evident. And it may be extended to all other cases, in a way similar to that in which Euclid has demonstrated that triangles of equal bases are in the proportion of their bases.

16. As proportion can only take place between quantities of the same kind, all that is to be understood by the expressions in the above propositions, which are far from being accurate, is, that the proportions of the velocities and the times are the same with the proportions of the spaces. For as space and time are quantities of a different nature, it is evident that we cannot divide space by time. Thus when it is said that *the velocities are as the spaces divided by the times*, it is an abridged mode of expression, which signifies that the velocities are as the relations of the spaces to the same common measure, divided by the relations of the times to the same measure. Thus, for example, if we take a foot for the measure of the spaces, and a minute for the measure of the times, the velocities of two bodies which move uniformly, are to each other as the number of feet described, divided by the number of minutes which the bodies require to describe the portion of space passed through, and not as the feet divided by the same minutes.

Uniform motion a measure of time.

17. Hence it is that uniform motion is universally employed as a measure of time. But it is often difficult to find out whether the motion which is proposed for the measure of time be perfectly uniform. What then are the means to ascertain this? To this it may be answered that there is no motion which is not uniform, the law of which we can determine exactly; so that this difficulty only proves that we cannot ascertain the relation of the parts of time with mathematical precision; but it does not follow that uniform motion from its nature may not be the first and simplest measure. And having no strictly accurate measure of time, we endeavour to discover the measure which comes nearest in the motions which approach nearest to uniformity.

Method of ascertaining when a motion is nearly uniform.

18. There are three ways by which it may be ascertained that a motion is nearly uniform. 1. When the moving body describes equal spaces in times which we judge to be equal; and we can determine that the times are equal, after having observed from repeated experience that similar events take place in the same times. Thus we conclude that the times which the same clepsydra requires to be emptied are equal; so also the times in which the same quantity of sand runs in the sandglass; the times in which the shadow moves over the same space on the sun-dial; the times of the same number of vibrations of a pendulum of the same length; and the times of the revolution of the heavenly bodies through the same spaces—are equal. If then it is found by observation that a body during the same time passes over equal spaces, we conclude that the motion is uniform. 2. Another method of ascertaining how far any motion is uniform, is when the effect of the accelerating or retarding cause, if such operate, is imperceptible. It is by combining these two methods that we conclude the motion of the earth round its axis to be uniform; and this inference is not only not opposed by any of the celestial phenomena, but seems to be in perfect accord with them. 3. By a third method of determining the uniformity of any motion, we compare it with others; and when the same law is observed in both the one and the other, we may conclude that the motion compared is uniform. Thus if several bodies move at such a rate that the spaces described in the same time are always to each other, either precisely or very nearly so, in the same ratio, the motion of these bodies, we conclude, is either precisely, or at least very nearly uniform. For if a body A which moves uniformly passes through the space E during the time T taken at pleasure, and another body B also moving uniformly, passes through the space e during the same time T, the relation of the spaces E, e will be always the same, whether the two bodies have begun to move in the same or in different instants; and it is only to uniform motion that this property belongs. Wherefore if we divide the time into parts, whether equal or unequal, and if it be observed that the spaces passed through by two bodies during one part of the time, are always in the same relation, the greater the number the parts of the time taken, the more there is reason to conclude that the motion of each body is uniform. None of these methods, it has been observed, possssses geometrical precision; but they are sufficient, especially when they are repeated and taken together, to afford a satisfactory conclusion, if not with regard to absolute uniformity of motion, at least with regard to a near approximation to uniform motion.

Prop. III.

19. *In uniform motions, the spaces described are in the compound ratio of the velocities and the ratio of the times.* This proposition is frequently expressed otherwise thus; *The spaces described with a uniform motion are proportional to the products of the times and the velocities*: Or otherwise thus; *The spaces described with a uniform motion are proportional to the rectangles of the times and the velocities.*

For let S be the space described with the velocity V, in the time T, and let s be the space described with the velocity v, in the time t. Let another space Z be described in the time T with the velocity v.

Then by proposition 1st we have $S : Z = V : v$,
And by proposition 2d $Z : s = T : t$.

By composition of ratios therefore (or by VI. 23. Euclid), we have $=V\times T : v\times t = S\times Z : s\times Z$; that is, $=S : s$.

The above are all equivalent expressions which are demonstrated by the same composition of ratios. The products or rectangles of the times and velocities, are the products of numbers which are as the times, multiplied by numbers which are as the velocities; or the rectangles whose bases are as the times, and whose heights are as the velocities.

Corollary.

20. *If the spaces described in two uniform motions be equal, the velocities are in the reciprocal proportion of the times.*

For in this case the products VT and $v\,t$ are equal, and therefore $V : v = t : T$, or $V : v = \frac{1}{T} : \frac{1}{t}$. Or, because the rectangles AC, DF (fig. 4.) are in this case equal, we have (by VI. 14. Euclid) $AB : BF = BD : BC$, that is $V : v\ t : T$.

Prop. IV.

21. *In uniform motions, the times are as the spaces, directly, and as the velocities, inversely.*

For by Prop. III. $S : s = VT : v\,t$;
Therafore, $S\,v\,t = s VT$,
And, $T : t = S\,v : s\,V$.
Or, $T : t = \frac{S}{V} : \frac{s}{v}$,
And, $t \doteq \frac{s}{v}$.

Prop. V.

22. *In uniform motions, the velocities are as the spaces, directly, and as the times, inversely.*

For by Prop. IV. $S\,v\,t = s VT$,
Therefore $V : v = S\,t : s\,T$.
Or, $V : v = \frac{S}{T} : \frac{s}{t}$.
And, $v \doteq \frac{s}{t}$.

23. The values of the results of these propositions are not changed by the absolute magnitudes of the space and time, if both are changed in the same ratio. The value of $\frac{12\text{ feet}}{24''}$, or of $\frac{8\text{ feet}}{16''}$, is the same with half a foot per second. Therefore, if s' be the expression of an extremely minute portion of space described with this velocity in the small portion of time t', the velocity v is still accurately expressed by $\frac{s'}{t'}$. And the accurate expression of the time t' is $\frac{s'}{v}$.

Sect. II. *Of Variable Motions.*

24. In observing the phenomena of nature, it rarely happens that the motions to which our attention is directed are perfectly uniform. These motions, however, we distinctly conceive, with all their properties; and it is obviously of the utmost importance that all the deviations from uniform motions be clearly understood; because these deviations afford the only marks and measures of the variations, and therefore of the causes which produce these changes.

Variable Motions.

25. When a body continues to move uniformly in the same direction, its motion, or circumstances with respect to motion, have suffered no change. The condition of that body, therefore, must be allowed to be the same in any two portions of its path, whatever the distance of these portions may be. And because a change of place is involved in the very conception of motion, the difference of place does not imply any change. Two bodies, therefore, moving with the same velocity in this path, or in two lines parallel to it, their condition in respect of motion must be allowed to be the same. Their direction is the same, and their rate of motion is the same. The velocity, therefore, and the direction of a body, are the only circumstances which seem to enter into our conception of the state of a body, in respect of motion. Changes either in the velocity, or in the direction, or in both of these circumstances, include all the changes of which this condition is susceptible. Let us now consider the first of these changes, namely, changes of velocity.

Velocity and direction only conceived in motion.

Of Accelerated and Retarded Motions.

26. It has been ascertained by experiment and observation, that a stone in falling is carried downward with greater rapidity in every successive period of its fall. During the first second it falls 16 feet; during the next, it falls 48 feet; during the third, it falls 80 feet; during the fourth, it falls 112 feet; continuing to fall, during every successive second 32 feet more than during the preceding second. A body moving in this manner is said to have an *accelerated motion.* But if a body be projected perpendicularly upwards, the very reverse takes place in the circumstances of its motion. It is observed to rise with a motion which is continually *retarded.* These bodies therefore are conceived to be in every succeeding instant in different states of motion. The velocity of the falling body is conceived to be greater in a certain instant than in any preceding instant; as, for example, when it has fallen 144 feet, its velocity is said to be thrice as great as when it has fallen only 16 feet. But this inference, it is evident, cannot be made directly by comparing the spaces described in the following moments; for in these it falls 112 and 48 feet; or by comparing the spaces immediately preceding; for in these the body fell 80 and 16 feet. But in this expression it is supposed that the variable condition of a body, called its velocity, is in every instant susceptible of any accurate measure; and yet in no moment, however short, does the body describe uniformly a space which can be taken as the measure of its velocity at the beginning of that moment; because the space described in any moment is too great for measuring the velocity at the beginning of the moment, and too small for the measure of its velocity at the end of it. Till however such a measure is obtained, the mechanical condition of the body is not known.

27. But in a continually accelerated motion, no such measure can be obtained. No space is described

ed in an instant: for this requires time. In that instant, however, the body possesses what has been called a *potential velocity*, that is, a certain tendency or determination, which remaining unchanged, causes it to describe a certain space uniformly during some assignable portion of time. At another instant it has another determination, by which, if it be not changed, another space will be uniformly described in an equal portion of time. Now it is in the difference of those two determinations that its difference of mechanical condition consists. The marks and measures of these determinations are known from the spaces which would be uniformly described. These therefore must be carefully investigated as the measures of the velocities; and the proportions of these spaces are to be taken as the proportions of the velocities.

Prop. VI.

Fig. 5.

28. *Let the straight line* ABD (fig. 5.) *be described with a motion continually varied; it is required to determine the proportion of the velocity in the point* A, *to the velocity in any other point* C.

Let the right line *a b d*, represent the time of this motion along the path AD, so that the points *a*, *b c*, *d*, may denote the instants of the moving body being in A, B, C, D, and the proportions *a b*, *b c*, *c d*, may express the times of describing AB, BC, CD, that is, may be in the proportion of those times; and let *a e*, perpendicular to *a d*, express the velocity of the moving body at the instant *a*, or in the point A. Let *e g h* be a line, so related to the axis *a d*, that the areas *a b f e*, *b c g f*, *c d h g*, comprehended between the ordinates *a c*, *b f*, *c g*, *d h*, all perpendicular to *a d*, may be proportional to the spaces AB, BC, CD, described in the times *a b*, *b c*, *c d*, and let this relation hold in every part of the figure. Then the velocity in A is to the velocity in B, or C, or D, as *a e* to *b f*, or *c g*, or *d h*. Or it may be expressed in other words, *If the abscissa* a d, *of a curve* e g h, *be proportional to the time of any motion, and the areas interrupted by parallel ordinates be proportional to the spaces described, the velocities are proportional to those ordinates.*

Make *b c* and *c d* equal, so as to represent very small and equal moments of time, and make *p a* equal to one of them. Complete the rectangle *p a e q*. This will represent the space uniformly described in the moment *p a*, with the velocity *a e* (Propos. 3.). Let PA be that portion of space thus uniformly described in the moment *p a*. Let the lines *i m*, *k n*, parallel to *a d*, making the rectangles *b c m i*, and *c d n k*, respectively equal to the areas *b c g f*, and *c d h g*. If the motions along the spaces PA and BC had been uniform, the velocities would have been proportional to the spaces described (Propos. 1.) because the times *p a*, and *b c* are equal. That is, the velocity in A would be to the velocity in C, as the rectangle *p a e q* to the area *b c g f*, that is, as *p a e q* to *b c m i*, that is, as the base *a e* to the base *c m*, because the altitudes *p a* and *b c* are equal.

But the motion along the line BC is not represented as uniform; for the line *f g h* diverges from the axis *b d*, the ordinate *c g* being greater than *b f*. And therefore the spaces measured by these areas increase faster than the times; and thus the figure represents an accelerated motion. Therefore the velocity with which BC would be uniformly described during the moment *b c*, is less than the velocity at the end of that moment, that is, at the instant *c*, or in the point C of the path; and therefore it must be represented and measured by a line greater than *c m*.

In the same manner it is proved that *c k* represents and measures the velocity with which CD would be uniformly described during the moment *c d*. And therefore, since the motion along CD is also accelerated, the velocity at the beginning of that moment is less than the velocity with which it would be uniformly described in the same time, and must be represented by a line less than *c k*.

Therefore the velocity in A, is to that in C, in a less ratio than that of *a e* to *c m*, but in a greater ratio than that of *a e* to *c k*. But in this case, as long as the instant *b* is prior, and *d* posterior, to the instant *c*, *c m* is less, and *c k* is greater, than *c g*. Therefore the velocity in A is to that in C in a ratio that is greater than any ratio less than that of *a e* to *c g*. And, consequently the velocity in A is to that in C, as *a e* to *c g*.

It may be proved in the same way, with respect to the velocity in any other point D; and therefore the proposition may be considered as demonstrated. And had the motion along BCD, instead of being accelerated as in this case, been retarded, the same reasoning would still apply.

Corollaries.

29. Cor. 1. *The velocities in different points of the path* AD, *are in the ultimate ratio of the spaces described in equal small moments of time.* Draw *g o* parallel to *a d*. Then the velocity in the instant *a*, is to that in the instant *c*, as *a e* to *c g*, that is, as the rectangle *p e* to the rectangle *c o*, that is, as *p a e q* to *c d h g*, nearly. As the moments are diminished, the difference *g o h* between the rectangles *c g o d* and *c g h d*, diminishes nearly in the duplicate ratio of the moment. If then the moment be taken $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ of *c d*, the error *g o h* is diminished to $\frac{1}{4}$, $\frac{1}{9}$, or $\frac{1}{16}$: the corollary is now manifest; for the ultimate ratio of *c g o d* to *c g h d* is the ratio of equality. That is, the velocity in A is to that in C, in the ultimate ratio of PA to BC described in equal small moments.

There are many cases in which the spaces described in very small moments can be measured, and yet the ultimate ratio cannot be ascertained. These spaces must then be taken as measures of the velocity. And by taking half the sum of the spaces BC and CD, for the measure of the velocity in the point C, the error is almost reduced to nothing.

30. Cor. 2. *The momentary increments of the spaces described, are in the compound ratio of the velocities, and the ultimate ratio of the moments.*

For the increments PA, CD are as the rectangles *p e* and *c o* ultimately, (Propos. 3.); and these are in the compound ratio of the base *a e* to the base *d o*, and the ultimate ratio of the altitude *p a*, to the altitude *c d*. This may be expressed by the proportional equation $\dot{s} \doteqdot v\,\dot{t}$.

31. Consequently $v \doteqdot \frac{\dot{s}}{\dot{t}}$; and $\dot{t} \doteqdot \frac{\dot{s}}{v}$. The equation

$\dot{s}\doteqdot v\dot{t}$, $v\doteqdot\frac{\dot{s}}{\dot{t}}$, and $\dot{t}\doteqdot\frac{\dot{s}}{\dot{t}}$ seem to be the same with those in (23), but there the same space s' was described uniformly, and the equations were absolute. In 30 and 35, $\dot{s}$ does not represent a space uniformly described. But $\dot{S}:\dot{s}$ expresses the ultimate ratio of S' to s' when they are diminished continually, and vanish together. Therefore the meaning of the equation $\dot{s}\doteqdot v\dot{t}$ is, that the ultimate ratio of S' to s', is the same with that of VT' to vt'.

32. The following is the converse of this proposition.

If the abscissa a d *of the line* e f h, *represent the time of a motion along the line* ABD, *and if the ordinates* a e, b f, c g, &c. *be as the velocities in the points* A, B, C, &c. *then the areas are as the spaces described.* This is proved by an indirect demonstration, thus:

For if the spaces AB, AD, be not proportional to the areas *abfe*, *adhe*, they must be proportional to some other, *abf' e*, *adh' e*, of another line *ef' h'*, passing through *e*. Assuming this to be true, then (by Propos. 6.) the velocity in A is to that in B, as *ae* to *bf*. Therefore $ae:bf=ae:bf$, which is absurd.

33. The relation between the space described and the time which elapses is the only immediate observation to be made on these variable motions. By means of the foregoing proposition, the mechanical condition of the body, or rather the effect and measure of this condition, denominated *velocity*, is inferred. The same inference is made in another way. Sir Isaac Newton often represents the uniform lapse of time by the uniform increase of an area during the motion along the line taken for the abscissa. The velocities or determinations to motion in the different points of this line, are inversely proportional to the ordinates of the curve which bounds this area.

6. Along the straight line AD, (fig. 6.) let a point move with a motion any how continually changed, and let the curve line LIH be so related to AD, that the area LICB is to the area LHDB as the time of moving along BC to that of moving along BD. Let this be true in every point of the line AD. Let Cc, Dd, be two very small spaces described in equal times, draw the ordinate *ic*, *hd*, and draw *ik*, *hl* perpendicular to IC, HD.

The areas IC*ci*, and HD*dh* must be equal, because they represent equal moments of time. It is evident also, that as the spaces C*c* and D*d* are continually diminished, the ratio of IC*ci*, and HD*dh* to the rectangles *k*C*ci* and *l*D*dh* continually approximates to that of equality, and that the ratio of equality is the limiting or ultimate ratio. Since, therefore, the areas IC*ci* and HD*dh* are equal, the rectangles *k*C*ci* and *l*D*dh* are ultimately in the ratio of equality. Therefore their bases *ic* and *hd* are inversely as their altitudes C*c* and D*d*, that is, $ic:hd=Dd:Cc$. But as C*c* and D*d* are described in equal times, they are ultimately as the velocities in *c* and *d* (29). Therefore *ic* and *hd*, are inversely as the velocities in *c* and *d*. And as the same reasoning may be applied to every point of the abscissa, the proposition is demonstrated.

34. In all cases, then, in which the relation between the spaces described, and the times elapsed can be discovered by observation, we discover the mechanical condition of the moving body, or its velocity. But in the practical application of these conclusions, recourse must always be had to arithmetical conclusions; and the indications of these are the algebraic symbols of geometrical reasonings. Thus any ordinate *cg* (fig. 5.) is represented by v, and the portion *cd* of the abscissa by $\dot{t}$, and the area *cdhg*, or its equal, the rectangle *cdog*, by $v\dot{t}$. This rectangle then being as the corresponding portion CD of the line of motion, and CD being represented by $\dot{s}$, we have the equation $\dot{s}=v\dot{t}$. Variable Motions.

35. The mathematical consequences of these representations may now be assumed to be true; and therefore $\dot{t}=\frac{\dot{t}}{v}$, as in (23). Algebraic symbols being the representations of arithmetical operations, they represent more remotely the operations of geometry, and only because the area of a rectangle is analogous to the product of numbers which are proportional to its sides. The symbol $\int v\dot{t}$ being used to represent the sum of all these rectangles, expresses the whole area *adhe*, as well as the whole line of motion AD; and the equation may be stated $s=\int v\dot{t}$. In like manner $\int\frac{\dot{s}}{v}$ will be equivalent to $\int\dot{t}$, that is, to t, and will express the whole time *ad*. It is plain too that $\frac{\dot{s}}{v}$ represents the ordinate DH of the line LKIH (fig. 6.) because any portion D*d* of its abscissa, is properly represented by $\dot{s}$, and the ordinates are reciprocally proportional to the velocities, that is, are proportional to the quotients of some constant number divided by the velocities, and therefore to $\frac{1}{v}$. And as $\dot{t}$ is represented by the rectangle *k*C*ci*, which is also represented by $\dot{s}\times\frac{1}{v}$, we have $\dot{t}=\frac{\dot{s}}{v}$, and $t=\int\frac{\dot{s}}{v}$, as above. Fig. 6.

36. In one case of varied motion, when the line *efgh* (fig. 5.) is a straight line, the characters are very particular and useful. Let this case of motion be represented along the line AD (fig. 7.), and let *pa*, *bc*, *cd*, represent equal moments of time, in which the moving body describes PA, BC, CD; and draw *fm*, *gn*, *es*, parallel to the abscissa *ad*. Now it is evident that *mg* and *nh* are equal, or that equal increments of velocity are acquired in equal times; *eq*, *er*, *es*, are also proportional to *qf*, *rg*, *sh*, and therefore the increments *qf*, *rg*, *sh*, of velocity are proportional to the times *ab*, *ac*, *ad*, in which they are acquired. This motion may very properly be denominated *uniformly accelerated;* for here the velocity increases in the same ratio with the times, and equal increments are acquired in equal times. If the line *eh* cut the abscissa in *v*, it will represent a motion uniformly accelerated from rest during the time *vd*, and thus exhibit the relations between the spaces, velocities, and times in such motions. Fig. 5. Fig. 7.

Hence it follows from this mode of expressing these relations, that *in motions uniformly accelerated from a state of rest, the acquired velocities are proportional to the times from the beginning of the motion.* For $a\,e$, $b\,f$, $c\,g$, $d\,h$, represent the velocities gained during the times $v\,a$, $v\,b$, $v\,c$, $v\,d$, and are in the same proportion with those lines.

37.—1. Also, *the momentary increments of velocity, are as the moments in which they are acquired.*

2. Also, *the spaces described from the beginning of the motion, are as the squares of the times.*

3. Also, *the increments of the spaces are as the increments of the squares of the times; reckoning from the beginning of the motion.*

4. Also, *the spaces described from the beginning of the motion, are as the squares of the acquired velocities.*

5. Also, *the momentary increments of the spaces are as the momentary increments of the squares of the velocities.*

6. Also, *the space described during any portion of time by a motion uniformly accelerated from rest, is one half of the space uniformly described in the same time with the final velocity of the accelerated motion.*

7. *And the space described during any portion of the time of the accelerated motion, is equal to that which would be described in the same time with the mean between the velocities at the beginning and end of this portion of time.*

In the investigation of all other varied motions, the properties of uniformly accelerated motion stated above, will be found extremely useful, and especially in cases where approximation only can be easily obtained. But for the fuller illustration of these properties the reader is referred to Robison's Elements of Mechanical Philosophy, p. 38.

38. Supposing the acceleration to be always the same, we conceive of this constancy, that in equal times there are equal increments of velocity; and therefore that the augmentations of velocity are proportional to the times in which they are required. That acceleration then, according to this supposition, must be accounted double, or triple, &c. where the velocity acquired is double or triple. And, acceleration being considered as a measurable quantity, the augmentation of velocity uniformly acquired in any given time is its measure.

COROLLARY.

39. *Therefore accelerations are proportional to the spaces described in equal times, with motions uniformly accelerated from a state of rest.* For in this case the spaces are the halves of what would be uniformly described in the same time with the acquired final velocities, and are therefore proportional to these velocities, or to the accelerations, since the velocities were acquired in equal times.

40. It is then said *that accelerations are proportional to the increments of velocity uniformly acquired, directly, and to the times in which they are acquired, inversely.*

$$A : a = \frac{V}{T} : \frac{v}{t}.$$

This relation between acceleration, velocity, and time, is also true, in uniformly accelerated motion, with respect to all momentary changes of velocity, as well as to those cases of motion passing through all degrees of velocity from nothing to the final magnitude v. For the velocity increasing at the same rate with the time, we have $v : v' = t : t'$; and v' and t' express the simultaneous increments of velocity and time.

41. But if the augmentation of velocity be the measure of the acceleration, and therefore proportional to it, and if in uniformly accelerated motions, the velocity increases at the same rate with the times, the increments of velocity are as the accelerations and as the times jointly. Hence the proportional equation

$$v \doteqdot a\,t,$$
$$\text{and } v' \doteqdot a\,t'.$$

42. It appears from (39.), that when the velocity has uniformly increased from nothing, the spaces described in equal times are proper measures of acceleration. And in (37.—3.) uniformly accelerated motions, the spaces are as the squares of the times. Therefore, when the acceleration continues the same, the fraction $\frac{s}{t^2}$ must also remain of the same value, and a is proportional to $\frac{s}{t^2}$. And therefore, *accelerations are proportional to the spaces described with a motion uniformly accelerated from rest, directly, and to the squares of the times inversely.*

43. And since $a \doteqdot \frac{v}{t}$, we have $a \doteqdot \frac{vv}{v\,t}$; but $v\,t \doteqdot s$, therefore $a \doteqdot \frac{v^2}{s}$. Therefore we have another measure of acceleration, viz. Accelerations are directly as the squares of the velocities, and inversely as the spaces along which the velocities are uniformly augmented.

44. But when the spaces are equal, we have $a \doteqdot v^2$, and in uniformly accelerated motions, that is, when a remains constant, the space being increased in any proportion, v^2 increases in the same proportion; it follows that v^2 increases in the proportion both of the acceleration and of the space. And therefore, in general, we have $v^2 \doteqdot a\,s$. And, as in 41, 42, we shall have $v^2 \doteqdot a\,S$, and $V^2 - v^2 \doteqdot a\,S - a\,s$, or $\doteqdot S - s$, which may be thus expressed, $vv \doteqdot a\,s'$, that is, *in a motion uniformly accelerated, the momentary change of the square of the velocity is proportional to the acceleration and to the space jointly.* Thus it appears, that the acceleration continued during a given time t, or t', produces a certain augmentation of the simple velocity; but the acceleration continued along a given space s' or S', produces a certain augmentation of the square of the velocity.

45. But accelerations which are constant and uniform, and such as have been considered, are very rare in the phenomena of nature. They are as variable as velocities, and therefore it is not less difficult to discover their actual measure. By changes of velocity only we obtain any knowledge of the changing cause. From the continual acceleration of a falling body we learn, that the same power which makes it press on the hand, presses it downward, as it falls through the air; and whatever be the rapidity of its descent, it is from observing that it acquires equal increments of velocity in equal times, that we know the downward pressure to be the same.

In

able
ons.

In the same way that we obtain measures of a velocity which is continually varying, we may obtain accurate measures of a similarly varying acceleration. A line may be conceived to increase along with the velocity, and at the same rate; and this rate of increase of velocity is what is called *acceleration*, in the same way as the rate at which the line increases, is what is called *velocity*. If, then, we consider the areas (fig. 5.) or the line AD, as representing a velocity; the ordinates to the line *e g h*, which were demonstrated to be proportional to the rate of variation of the area, will be proportional to the variation of the velocity, that is, to the acceleration.

Prop. VII.

46. *If the abscissa* a d *of a curve line* e g h *represent the time of a motion, and if the areas* a b f e, a c g e, a d h e, &c. *are proportioned to the velocities at the instants* b, c, d, &c. *then the ordinates* a e, b f, c g, d h, &c. *are proportional ta the acceleration at the instants* a, b, c, d, &c.

By substituting the word acceleration for the word velocity, the same demonstration may be applied here as in Prop. 6. (28.). From this proposition may be deduced some corollaries of practical use in mechanical discussions.

47. *The momentary increments of velocity are as the accelerations, and as the moments jointly.*

For the increment of velocity in the moment *c d* is accurately represented by the area *c d h g*, or by the rectangle *c d n k*; and *c d* accurately represents the moment. Also, the ultimate ratio of *c k* to such another ordinate *b i*, is the ratio of *c g* to *b f*; that is, the ratio of the acceleration in the instant *o* to that in the instant *b*. And therefore the increment of velocity during the moment *p a* is to that during the moment *c d* as $pa \times ae$ to $cd \times dg$. Or it may be expressed by the proportional equation $v \doteqdot a\dot{t}$.

48. Conversely. The acceleration *a* is proportional to $\frac{\dot{v}}{\dot{t}}$, as in the case when the motion is uniformly accelerated (40.).

And as the area of this figure is analogous to the sum of all the inscribed rectangles, when the circumstances of the case admit of its being measured, it may be expressed by $\int a\dot{t}$; and thus is obtained the whole velocity acquired during the time AC, and we say $v \doteqdot \int a\dot{t}$.

The intensities (or at least their proportions) of the accelerating power of nature in the differents points of the path being frequently known, we wish to discover the velocities in those points. This may be done by the following proposition.

Prop. VIII.

g.

49. *If the abscissa* AE (fig. 8.) *of a line* a c e *be the space along which a body moves with a motion continually varied, and if the ordinates* A *a*, B *b*, C *c*, &c. *are proportional to the accelerations in the points* A, B, C, &c. *then the areas* AB *b a*, AD *d a*, AE *e a*, &c. *are proportional to the augmentations of the square of the velocity in* A *at the points* B, D, E, &c.

Compound Motions.

Take BC, CD, as two very small portions of the line AE, and draw *b f*, *c g*, parallel to AE. Then, supposing the acceleration B *b*, to continue through the space BC, the rectangle B *b f* C will express the augmentation made on the square of the velocity in B. In the same way C *c g* D will express the augmentation of the square of the velocity in C; and, in like manner, the rectangles inscribed in the remainder of the figure will express the increments of the squares of the velocity acquired, while the body moves over the corresponding portions of the abscissa. And, therefore, the whole augmentation of the square of the velocity in A (should there be any velocity in that point) during the time of moving from A to B, will constitute the aggregate of these partial increments. The same thing must be affirmed of the motion from B to E. And, when the subdivision of AE is carried on without end, it is plain that the ultimate ratio of the area AE *e a* to the aggregate of inscribed rectangles, is that of equality; that is, when the acceleration varies continually, the area AB *b a* will express the increment made on the square of the initial velocity in A, while the body moves along AB; and the same must be affirmed with respect to the motion along BE. And, therefore, the intercepted areas AB *b a*, BD *d b*, DE *e d*, are proportional to the changes made on the squares of the velocities in the points A, B, and D.

Corollaries.

50. Cor. 1. *If the body had no velocity in* A, *the areas* AB *b a*, AD *d a*, &c. *are proportional to the squares of the velocity acquired in the points* B, D, &c.

Cor. 2. *The momentary change on the square of the velocity, is as the acceleration and increment of the space jointly*; or we have $v\dot{v} = a\dot{s}$.

Cor. 3. $v\dot{v}$ *being equal to half the increment of the square of the velocity, it follows that the area* AE *e a*, *or the fluent* $\int a\dot{s}$ *is only equal to* $\frac{V^2 - v^2}{2}$, *taking* v *and* V *as the velocities in* A *and* E.

51. What has now been said of the acceleration of motion, is equally applicable to motions that are retarded, whether these motions be uniform or unequable. The momentary variations in this case are to be taken as decrements of velocity instead of increments. A moving body, subject to uniform retardation till it come to rest, will continue in motion during a time proportional to the initial velocity; and describe a space proportional to the square of this velocity; and the space which is so described, is one half what it would have been if the initial velocity had continued undiminished.

Sect. III. *Of Compound Motions.*

Characteristics in changes of direction.

52. Having obtained the marks and measures of every variation of velocity, we are to discover similar characteristics for every change of direction. In the above investigation of the general marks of any change of motion, it is plain that the change being the same in any two or more instances, the ostensible marks must also be the same, whatever may have been the previous

previous condition of the moving bodies. In every case of change, some circumstance in the difference between the former motions and the new motions must be observed, which is exactly the same both in respect of velocity and of direction. One of the bodies then may be supposed to have been at rest; and thus the change produced on it, is the motion which it has acquired, or the determination to this motion. Therefore, *a change of motion is itself a motion*, or *determination to motion.* In the above case, it is the new motion only; but it is not the new motion in every other case. For supposing the previous condition of the body to have been different from that of a body at rest, and supposing the same change produced on it, the new condition of the one body must be different from the new condition of the other. The change, therefore, being the same in both cases, the new condition cannot be that *change.* But, when the same change happens in any previous motion, the difference between the former motion and the new motion, must indicate something that is equivalent to the motion produced in a body previously at rest, or the same with that motion, this body having received the same change. And the difference between the new motions of the two bodies will be such as shall indicate the difference between the previous conditions of each body. The change of motion then is itself a motion; and this being assumed as a principle, we are now to endeavour to discover a motion which alone shall produce that difference from the former motion, which, in all cases, is observed in the new motion. This is to be considered as the proper characteristic of the change.

illustrated, 53. The following motions may serve as an illustration of these conditions. Let it be supposed that the straight line AB (fig. 9.) lies east and west, and that it is crossed by the line AC from north to south. Suppose this line AC to be a rod or wire, and to be carried along the line AB in one minute, but always in the same position, that is, lying north and south. The end of the rod or wire A having moved uniformly one-third of AB at the end of 20″, it will be in the position Dd∂; at the end of 40″ it will have the position Eeε; and at the end of the minute it will be in the position *B b*.

Fig. 9.

Let the line AB, in the mean time (supposing it also to be material) be uniformly moved from north to south, and always parallel to its first position AB. When it has passed over one-third of AC, at the end of 20″, it will be in the position m d n; at the end of 40″ it will have the position o e p, and A o is two-thirds of AC. At the end of the minute, it will have the position C ∂ ε b. It is evident that the common intersection of these two lines will be always in the diagonal A b of the parallelogram A C b B; for the parallelogram A m d D is similar to the parallelogram A C b B, because AD : AB=A m : AC; and, in like manner, A o e E is a parallelogram similar to A C b B. Therefore, these parallelograms are about a common diagonal A b.

Again, the motion of the point of intersection of these lines is uniform; for AD : AB=A d : A b, and AE : AB=A e : A b, &c. Therefore the spaces A d, A e, A b are proportional to the times.

Thus the intersection of two lines having each a uniform motion in the direction of the other, moves uniformly in the direction of the diagonal of the parallelogram, which is formed by the lines in their first or last position; and the velocity of the intersection is to the velocity of each of the motions of the lines as the diagonal is to the side in the direction of which the motions are made. This motion of the intersection is very properly said to be compounded of two motions in the direction of the sides; for when the point d of the line D ∂ moves eastward, the same point d of the line m d n is at the same instant moving southward. The point d, therefore, may be considered as a point of both lines, partaking in every instant of both motions. The motion along A b then contains both motions along AB and AC, and being identical with a motion compounded of these motions, indicates both, or the determination to both. In every situation of the point of intersection, its velocity is compounded of the velocity AB and AC. A body, therefore, whose motion continued unchanged, would have described AB in one minute; but when it reaches the point A, it turns aside, and describes A b uniformly in the same time; the change then which the body sustains in the point A is a motion AC. For suppose the body had been at rest in the point A, and it is observed to describe AC in one minute, the motion AC is the change which it has sustained. The motion A b is not the change: for if AF had been the primitive motion, the same motion A b would have been the result of compounding with it the motion AG. But since AF is different from AB, the same change cannot produce the same new conditions. But, farther, there is no other motion which, by compounding it with AB, will produce the motion A b; and the motion AC is the only circumstance of sameness between changing the motion AB into the diagonal motion A b, and giving the motion AC to a body which was previously at rest. —From these conditions it follows, *that a change of motion, is that motion, which by composition with the previous state of motion, produces the new motion.*

54. This composition of motion has been considered in a different way. While a body is supposed to move uniformly in the direction AB, the space in which this motion is performed, is supposed to be carried in the direction AC. But it cannot be conceived that any portion of space is moved from its place. A distinct notion of this composition may be obtained, by supposing a person walking along a line AB, while this is drawn on a piece of ice, and the ice is floating in the direction AC. But the motion on moving ice is not precisely a composition of two determinations to motion; for this is completed in the first instant. When the motion in the direction and with the velocity A b begins, no farther exertion is needed; the motion continues, and A b is described. It serves, however, to exhibit to the mind the mathematical composition of two motions. In the result of this combination, all the characteristics of the two determinations are to be found; for the point of intersection, in whatever way it is considered, partakes of both motions. and in other

55. Thus a general characteristic of a change of motion is obtained, and this corresponds with the mark and measure of every moving cause; for it is the very motion which it is conceived to produce. It may perhaps even be considered as the foundation of former measures; for in every acceleration, retardation, or deflection, there is a new motion compounded with the former.

Compound Motions.

former. What is taken for the beginning of motion in every observation of surrounding bodies, is nothing more than a change induced on a motion already produced.

56. The actual composition of motion being so general in the phenomena of the universe, it obtains in all motions and changes of motion produced or observed, and the characteristic which has been assumed of a change of motion being the same, whatever may have been the previous motion, and this being equally applicable to simple motions, it is evident that a knowledge of the general results of this composition of motion will be of essential service in acquiring a knowledge of mechanical nature.

57. The following is the general theorem to which all others may be reduced.

PROP. IX.

Two uniform motions, having the directions and velocities represented by the sides AB, AC, *of a parallelogram, compose a uniform motion in the diagonal.* The demonstration of this has been already given. The motion of the point of intersection of these two lines, each moving uniformly in all its points, in the direction of the other, is, in every instant, composed of the two motions. It is the same as if a point described AB uniformly, while AB is carried uniformly in the direction AC. This motion is along the diagonal A b, and it has been already shewn to be uniform. And, because AB and A b are described in the same time, the velocities of the motions along AB, AC, and A b are proportional to those lines.

COROLLARIES.

COR. 1. *The motion* A b, *which is compounded of the two simple motions* AB *and* AC, *is in the same plane with these motions. For a parallelogram lies all in the same plane.*

COR. 2. *The motion* A b *may be produced by the composition of any two uniform motions having the direction and velocities which are represented by the sides of any parallelogram,* AF b G, or AC b B, *which has* A b *for its diagonal.*

58. Cases are not unfrequent in which the directions of two simple motions composing an observed motion may be discovered; but the proportion of the velocities is unknown. This velocity may be ascertained by means of this last proposition. For the direction of the three motions, namely the two simple and the compound motions, determines not only the species of parallelogram, but also the ratio of the sides. Again, in those cases in which the direction and the velocity of one of the simple motions are known, and therefore its proportion to that of the observed compound motion, the direction and velocity of the other may be also found by means of the same proposition; because from these data the parallelogram may be determined.

59. This motion in the diagonal is called the *equivalent motion*, or the *resulting motion*; for it is equivalent to the combined motions in the sides. Thus, if the moving body first describe AB, and then B b or AC, it will be in the same point, as if it had described A b, namely, in the point b.

60. It is often highly useful in investigations of this kind to substitute such motions for an observed motion, as will produce it by composition. This has been denominated the *resolution of motions*. By this manner of proceeding, a ship's change of situation at the end of a day, having sailed in different courses, is computed. Thus the distance sailed to the eastward or the westward, as well as that to the northward or southward, on each course, is observed and marked. The whole of the eastings, and the whole of the southings, are added together; and then it is supposed that the ship has sailed for the whole day on that course, which would be produced by combining the same easting and southing.

61. It is also useful to consider how much the body has been advanced in a certain direction by means of the observed motion; let us suppose in the direction AB (fig. 10.). The motion CD is first considered as Fig. 10. composed of a motion CE parallel to the given line AB, and another motion CF perpendicular to AB. CD is the diagonal of a parallelogram CEDF, one of whose sides CE is parallel to AB, and the other CF is perpendicular to AB. It is evident, that the body has advanced in the direction of AB as much as if it had moved from G to H, instead of moving from C to D, so that the motion CF has no effect either in obstructing or promoting the progress in AB. This is called *estimating* a motion in a given direction, or *reducing* it to that direction.

62. A motion is also said to be estimated in a given plane, when it is considered as composed of a motion perpendicular to the plane, and of another parallel to it. In a given plane ABCD (fig. 11.), let EF be a Fig. 11. motion compounded of a motion GE perpendicular to the plane, and EH parallel to it. For if the lines GE, FH are drawn perpendicular to the plane, they cut it in two points e and f, and EH is parallel to e f.

63. In the same way a compound motion may be formed of any number of motions. Let AB, AC, AD, AE, &c. (fig. 12.) be any number of motions, of which Fig. 12. the motion AF is compounded. The motion which is the result of this composition is thus ascertained. The motion AG is compounded of AB and AC; and the motion AG compounded with AD, gives the motion AH; which latter being compounded with AE, produces the motion AF. And the same place, or final situation F, will be found by supposing the different motions AB, AC, AD, AE, to be performed successively. The moving body first describes AB; then BG, equal and parallel to AC; then GH, equal and parallel to AD; and lastly, HF, equal and parallel to AE. In this case it is not requisite that all the motions lie in the same plane.

64. Three motions which have the direction and proportions of the sides of a parallelopiped, compose a motion having the direction of its diagonal. Let AB, AC, AD (fig. 13.), be these motions, the compound- Fig. 13. ed motion is in the diagonal AF of the parallelopiped; because AB and AC compose the motion AE; and AE and AD compose the motion AF.

It is in this way that the mine-surveyor proceeds. He sets down a gallery of a mine, not directly by its real position, but marks the easting and westing, the northing and southing, as well as its dip and rise. All these measures are referred to three lines, of which one runs east and west, one north and south, and a third is perpendicular. These three lines are obviously analogous

gous to the angular boundaries of a rectangular box, as AC, AB, AD.

Other compound motions.

65. The composition of uniform motions only has yet been considered. But it is easy to conceive that any motions may be compounded. It is a case of this kind when a man is supposed to walk on a field of ice along a crooked path, while the ice floats down a crooked stream. Suppose a uniform motion in the direction AB (fig. 14.), to be compounded with a uniformly accelerated motion in the direction AC. A stone falling from the mast head of a ship, while she sails uniformly forward in the direction AB, affords an example of this kind of motion; for the stone will be observed to fall parallel to a plummet hung from the mast head. But the real motion of the stone is a parabolic arch A *bfg*, which AB touches in A; for while the mast head describes the equal lines AB, BF, FG, the stone has fallen to β and ϕ and γ, and the line AC is in the positions BB′, FF′, GG′, so that A ϕ is four times A β; and A γ is nine times A β. Therefore A β, A ϕ, A γ, are as the squares of $\beta\, b$, ϕf, γg, and the line A *bfg* is a *parabola*.

Fig. 14.

Condition of compound motions discovered from that of the simple motions.

66. Knowing the direction and velocities of each of the simple motions in any instant, of which two motions, however variable, are compounded, we may discover the direction and velocities of the compound motions in that instant. For it may be supposed that each motion at that instant proceeds unchanged: a parallelogram is then constructed; the sides of which have the direction and proportions of the velocities of the simple motions; and the diagonal of this parallelogram will express the direction and velocity of the compound motion. But, on the other hand, if the direction and velocity of the compound motion, with the directions of each of the simple motions, be known, we may discover their velocities.

Fig. 15.

67. In cases where a curvilineal motion, as ABC (fig. 15.), is the result of two motions compounded, of which the direction is known to be AD and AE, we discover the velocities of the three motions in any point B, by drawing the tangent BF, and the ordinate BG, parallel to one of the simple motions, and from any point H in that ordinate drawing HF parallel to the other motion, and cutting the tangent in the point F. The three velocities are in the proportion of the three lines FH, HB, and FB.

Danger of mistakes about changes of motion.

68. As the motions which are observed in nature are very different from what they are taken to be, it is not easy to avoid mistakes with respect to the changes of motion, and consequently with respect to the inference of its cause. Without considering the real motion of any body, we are apt to judge only of the changes of distance and direction in relation to ourselves. Thus it is that our inferences with regard to the planetary motions are very different from the motions themselves, if the rapid motion of our earth be considered.

PROP. X.

69. *The motion of one body in relation to another body, or as it is seen from another body, which is also in motion, is compounded of its own real motion, and the opposite of the real motion of the second body.*

Plate CLXXXV. fig. 16.

Let A (fig. 16.) be a body in motion from A to C, as seen from B, which is another body in motion from B to D the motion of A is componnded of its own real motion, and of the opposite to the real motion of B. Join AB, and draw AE equal and parallel to BD. Complete the parallelogram ACFE, and join ED and DC. Produce EA, and make AL equal to AE or BD. Complete the parallelogram LACK, and draw AK and BK. If then A had moved along AE while B moves along BD, the two bodies would have been at E and D, at the same time, and would have the same relative situation; they would have the same bearing and distance as before. And if the spectator in B is not sensible of his own motion, A will appear not to have changed its place. In the same way two ships becalmed in an unknown current, seem to the persons on board to be at rest. The real position, therefore, and distance DC, are the same with BK; and if a spectator in B imagines himself at rest, the line AK will be taken as the motion of A. And this motion, it is obvious, is composed of the motion AC its real motion, and the motion AL which is the equal and opposite motion to that of BD.

Again, if BH be drawn equal and opposite to AC, and the parallelogram BHGD be completed, and BG and AG be drawn, the diagonal BG will be the motion of B as it is seen from A. Now as KAGB is a parallelogram, the relative situation and distances of A and B at the end of the motion will appear to be the same as in the former case. For B appears to have moved along BG, which is equal and opposite to AK. Hence it follows that the apparent or relative motions of two bodies are equal and opposite, whatever their real motions may be; and therefore they do not afford any information of their real motions.

70. Suppose equal and parallel motions are compounded with all and each of the motions of any number of bodies, moving in any manner of way, then their relative motions are not consequently changed. For if it be compounded with the motion of any one of the bodies which may be called A, the real motion of this body is changed; but its apparent motion, as seen from another body B, is compounded of the real change, and of the opposite to the real change in A, which therefore destroys that change, and the relative motion of A is the same as before. Thus it is that the motions in the cabin of a ship are not affected by the ship's progressive motion; and the motion of the earth round the sun produces no perceptible effect on the relative motions on its surface. And indeed it is only by observing other bodies which are not affected by these common motions, and to which we refer as to fixed points, that we arrive at any knowledge of them.

SECT. IV. *Of Motions continually Deflected.*

Great riety curvil motio

71. CURVILINEAL motions are cases of continual deflection. They are susceptible of great varieties; and the investigation of their modifications and chief properties is attended with no small difficulty. Uniform motion in a circular arch is an example of the simplest case of curvilineal motion; for here the deflections from rectilineal motion are equal in equal times. If, however, the velocity be increased, the momentary deflection must also be augmented; for a greater arch will be described, and the end of this greater arch is at

tions nually ected.

at a greater distance from the tangent. But the proportion of this augmentation is difficult to be ascertained.

F 17.

When a uniform rectilineal motion AB (fig. 17.) is deflected into another BC, the lineal deflection is ascertained by drawing a line from the point *c*, at which point the body would have arrived, had it not been deflected to the point C at which it has arrived. The result is the same, whether the lines d D or c C be drawn in this manner; for being proportional to B *d*, B *c*, they always give the same measure of the velocities; and here the lines of deflection are all parallel, indicating the direction of the deflection in the point B. But this is not the case in any curvilineal motion. It rarely happens that dD, cC, are parallel; and it is never found that $dD : cC = Bd : Bc$. We cannot therefore discover which lines should be taken for the indication of the direction of the deflection at B, or for the measure of its magnitude. A greater velocity, then, in the same curve, produces a greater deflection; but if the path be more incurvated, an arch of the same length, described with the same velocity, causes a farther deviation from the tangent. If therefore a body have a uniform motion in a curve of variable curvature, the deflection is greatest where the curvature is greatest.

Thus it appears that the direction and measure of the deflections by which a body deviates continually into a curvilineal path cannot be ascertained, but by investigating the ultimate positions and ratios of the lines, which join the points of the curve with the simultaneous points of the tangent, as the points ∂ and C are taken nearer to B. In some cases, but rarely, the lines joining the simultaneous points are parallel. But in most cases the direction of the deflection is discovered by observing to what direction it approximates. The following proposition which was discovered by Newton is of great importance in this investigation.

Prop. XI.

Fi8.

72. *If a body describe a curve line* ABCDEF (fig. 18.) *being in the same plane, and if in this plane there be a point* S *so situated, that the lines* SA, SB, SC, &c. *drawn to the curve, cut off areas* ASB, ASC, ASD, &c. *proportional to the times of describing the arches* AB, AC, AD, &c. *then the deflections are always directed to the point* S.

Suppose first that the body describes the polygon ABCDEF, formed of the chords of this curve, and that it describes each chord uniformly, and is deflected only in the angles B, C, D, &c. Suppose also that the sides of the polygon are described in equal times, so that, according to the hypothesis, the triangles ASB, BSC, CSD, are all equal. Continue the chords AB, BC, &c. beyond the arches, making B *c* equal to AB, and C *d* equal to BC, and so on. Join *c* C, *d* D, &c. and draw *c* S, S *d*, &c.; draw C *b* parallel to *c* B or BA, cutting BS in *b*, and join *b* A, and draw CA, cutting B *b* in *o*. And lastly, make a similar construction at E.

Then, because *c* B is equal to BA, the triangles ASB and BS *c*, are equal, and therefore BS *c* is equal to BSC. And being on the same base SB, they are therefore between the same parallels; that is, *c* C is parallel to BS, and BC is the diagonal of a parallelogram B *b* C *c*. The motion BC is therefore compounded of the motions B *c* and B *b*, and B *b* is the deflection, by which the motion B *c* is changed into the motion BC; and therefore the deflection in B is directed to S. By similar reasoning it may be shown that *f* F, or E *i*, is the deflection at E, and is likewise directed to S; and the same demonstration will apply to every angle of the polygon.—This point S has been called the centre of deflection.

Motions continually deflected.

If the sides of the polygon are diminished, and their number infinitely increased, the demonstration remains the same, and continues, when the polygon coalesces with the curvilineal area, and its sides with the curvilineal arch.

But when the whole areas are proportional to the times, equal areas are described in equal times. In such motion, therefore, the deflections are always directed to S.

Prop. XII.

73. *If the deflection by which a curve line is described, be continually directed to a fixed point, the figure will be in one plane, and areas will be described round that point proportional to the times.* Let ADF (fig. 18.) be the curve line described, and let the deflections be directed to the point S, this curve line is in the same plane. For BC is the diagonal of a parallelogram, and is in the plane of SB and B *c*; and *c* C is parallel to BS, and the triangles SBC, SB *c*, and SBA, are equal. But equal areas are described in equal times; and therefore areas are described proportional to the times.

Fig. 18.

Corollaries.

74. Cor. 1. *The velocities in different points of the curve are inversely proportional to the perpendiculars* S r *and* S t (fig. 19.) *drawn from* S *on the tangents* A r, E t *in those points of the curve.* For since the elementary triangles ASB, ESF, are equal, their bases AB, EF, are inversely as their altitudes S *r*, S *t*. And these bases being described in equal times are as the velocities, and ultimately coincide with the tangents at A and E; and therefore the velocity in A is to that in E as S *t* to S *r*.

Fig. 19.

Cor. 2. *The angular velocities round* S *are inversely as the squares of the distances.* For if we describe round the centre S the small arches B a, F ∂, they may be considered as perpendiculars on SA and SE. Describe also with the distance SF the arch *g h*. It is evident that *g h* is to F ∂ as the angle ASB to the angle ESF. And since the areas ASB, ESF are equal, we have $Ba : F\partial = SE : SA$.

But $gh : Ba = SE : SA$
Therefore $gh : F\partial = SE^2 : SA^2$
And $ASB : ESF = SE^2 : SA^2$.

75. Let us now proceed to determine the magnitude of the deflection, or to compare its magnitude in any two points, as for example the magnitude in B (fig. 18.) with its magnitude in E. The deflection in B is to that in E as the line B *b* to the line E *i*; for B *b* and E *i* are the motions, which, by being compounded with the motions B *c* and E *f* make the body describe BC and EF. And therefore when the sides of the polygon

Motions continually deflected.

lygon are infinitely diminished, the ultimate ratio of Bb to Ei is the ratio of the deflection at B to the deflection at E.

To obtain a convenient expression of this ultimate ratio, let ABCXZY be a circle which passes through the points A, B, C. Draw BSZ through the point S, and draw CZ, AZ. Now the triangles BC*b* and AZC are similar, for C*b* was drawn parallel to *c*B or BA; and therefore the angle C*b*B is equal to the alternate angle *b*BA or ZBA, which is equal to the angle ZCA, because it is subtended by the same chord ZA; and because they stand on the same chord CZ, CB*b*, or CBZ, is equal to CAZ. And therefore the remaining angles *b*CB and CZA are equal, and the triangles are similar. Therefore $Bb : CA = BC : AZ$.

Now if the sides of the polygon are continually diminished, the points A and C continually approach to B, and CA continually approaches to *c*A, or to 2*c*B, or 2CB, and is ultimately equal to it; and AZ is ultimately equal to BZ.

Therefore ultimately, $Bb : 2BC = BC : BZ$, and $Bb \times BZ = 2BC^2$, and $Bb = \frac{2BC^2}{BZ}$.

Also, at the point E, we have E*i* ultimately equal to $\frac{2EF^2}{Ez}$, for E*z* is that chord of the circle through D, E, and F, which passes through *i*.

Therefore $Bb : Ei = \frac{2BC^2}{BZ} : \frac{2EF^2}{Ez}$.

The ultimate circle, when the three points A, B, C, coalesce, is called the *circle of equal curvature*, or the *equicurve circle*, which coalesces with the curve in B in the closest manner; and the chord BZ of this circle, having the direction of the deflection in B, is called its *deflective chord*. And since BC and EF are described in equal times, they are proportional to the velocities in B and E. This proposition therefore may be expressed as follows.

In curvilineal motions, the deflections in different points of the curve, are proportional to the square of the velocities in those points directly, and to the deflective chords of the equicurve circles, inversely.

It ought, however, to be remarked, that this theorem is not limited to curvilineal motions, in which the deflections tend always to the same fixed point; it may be extended to all curvilineal motions whatever. A symbolical expression of this theorem will be convenient. If therefore the deflective chord of the equicurve circle be represented by *c*, and the deflection by *d*, the theorem may be thus expressed,

$$d \doteqdot \frac{v^2}{c}, \text{ or } d = \frac{2\,\text{arch}^2}{c}.$$

76. The line B b is the linear deflection by which the uniform motion in the chord AB is changed into a uniform motion in the chord BC, or it is the deviation *c*C from the point to which the moving body would have arrived, if the deflection at B had not taken place. In the case of curvilineal motion which we are now considering, the lines B*b* and B*c* are expressions of the measures of the velocities of these motions. B*c* is to B*b* as the velocity of the progressive motion is to the velocity of the deflection, generated in the time that the arch BC is described. But the deflection in the arch has been continual, and, like acceleration, it may be measured by the velocity generated during any moment of time. It may therefore be measured by the velocity generated during the time the arch BC is described. This measure will therefore be double of the space through which the body is actually deflected from the tangent in B in that time. The space described will be BO, or only one half of B*b*. This is exactly what happens; for the tangent is ultimately parallel to OC, and it bisects *c*C; therefore the velocity gradually generated is that which constitutes the polygonal motion in the chords, although the deflection from the tangent to the curve is only half of the deflection from the produced chord to the curve.

Motion continua deflecte

77. In any point of a curvilineal motion, the velocity is that which would be generated by the deflection in that point, if continued through one fourth of the deflective chord of the equicurve circle. Take x for the space along which a body is to be accelerated that it may acquire the velocity BC.

We have Bb^2, or $4BO : BC^2 = B : x$ (37.—1.); and therefore $x = \frac{BC^2 \times BO}{4BO^2}, = \frac{BC^2}{4BO}$, and $4x = \frac{BC^2}{BO}$, or $BO : BC = BC : 4x$. But $BO : BC = BC : BZ$; therefore $x = \frac{1}{4}BZ$.

78. We have now obtained characteristic expressions or marks and measures of the principal affections of motion. These expressions may be brought into one view as follows.

The acceleration a is $\frac{\dot{v}}{\dot{t}}$ (48.), or $\frac{v\dot{v}}{\dot{s}}$ (49.), or $\frac{\dot{s}}{\dot{t}^2}$ (42.)

The momentary variation of velocity $\dot{v} = a\dot{t}$ (48.).

The momentary variation of the square of velocity

$$2v\dot{v} = 2u\dot{s} \text{ (49.)}.$$

The momentary deflection $d = \frac{\text{arc.}^2}{\text{chord}}$ (76.).

The deflective velocity $= \frac{2v^2}{c}$ (75.).

79. But for the application of these doctrines, it is necessary to select some point in any body of sensible magnitude, or in any system of bodies, by whose position or motion, a distinct and accurate notion of the position or motion of the body or system may be formed. The condition by which the propriety of this selection is ascertained, is, *that the position, distance, or motion of this point shall be the medium or average of the positions, distances, and motions of every particle of matter in the aggregate or system.*

Centre position

This will happen, if the point be so situated, that when a plane is made to pass through it in any direction whatever, and perpendiculars being drawn to this plane from every particle of matter in this aggregate or system, the sum of the perpendiculars on the one side of the plane is equal to the sum of the perpendiculars on the other side. And that such a point, which is called the *centre of position*, may be found in every body, is proved by the following demonstration.

Fig. 2

For let P (fig. 20.) be a point so situated, and let QR be the section of a plane perpendicular to the paper, and at any distance from it, the distance P*p* of the point P from this plane is the average of all the distances of each particle from it. Let the plane APB pass through P, and parallel to QR. The distance CS otions inually ected.

CS of any particle C from the plane QR is equal to DS—DC, or to Pp—DC. And the distance GT of a particle G on the other side of APB, is equal to HT+GH, or to Pp+GH. Let n be the number of particles on that side of AB which is nearest to QR, and let o be the number of particles on the other side of AB. Let m be the number of particles in the whole body; we have then $m=n+o$. It is evident that the sum of all the distances of all the particles such as CS, is $n\times Pp$—the sum of all the distances, such as CD. Also the sum of all the distances of the particles, such as G, is $o\times Pp$, + the sum of the distances GH. And therefore the sum of both sets is $n+o\times Pp$+the sum of GH—the sum of DC, or $m\times Pp$+the sum of GH—the sum of DC. But by the supposed property of the point P, the sum of GH wanting the sum of DC is nothing; and therefore $m\times Pp$ is the sum of all the distances, and Pp is the mth part of this sum, or the average distance.

g. 21.

Suppose the body to have changed both its place and its position with respect to the plane QR, and that P (fig. 21.) is still the same point of the body, and $\alpha P \beta$ a plane parallel to QR. Make $p\pi$ equal to pP of fig. 20. It is plain that Pp is still the average distance, and that $m\times Pp$ is the sum of all the present distances of the particles from QR, and that $m\times\pi p$ is the sum of all the former distances. Therefore $m\times P\pi$ is the sum of all the changes of distance, or the whole quantity of motion estimated in the direction πP. $P\pi$ is the mth part of this sum, and is therefore the average motion in this direction. The point P has therefore been properly selected; and its position, and distance, and motion, in respect of any plane, is a proper representation of the situation and motion of the whole.

Hence it follows, that if any particle C (fig. 20.) moves from C to N, in the line CS, the centre of the whole will be transferred from P to Q, so that PQ is the mth part of CN; for the sum of all the distances has been diminished by the quantity CN, and therefore the average distance must be diminished by the mth part of CN, or PQ is $=\frac{CN}{m}$.

But it may be doubted whether there is in every body a point, and but one point, such that if a plane pass through it, *in any direction whatever*, the sum of all the distances of the particles on one side of this plane is equal to the sum of all the distances on the other.

It is easy to shew that such a point may be found, with respect to a plane parallel to QR. For if the sum of all the distances DC exceed the sum of all the distances GH, we have only to pass the plane AB a little nearer to QR, but still parallel to it. This will diminish the sum of the lines DC, and increase the sum of the lines GH. We may do this till the sums are equal.

In like manner we can do this with respect to a plane LM (also perpendicular to the paper), perpendicular to the plane AB. The point wanted is somewhere in the plane AB, and somewhere in the plane LM. Therefore it is somewhere in the line in which these two planes intersect each other. This line passes through the point P of the paper where the two lines AB and LM cut each other. These two lines represent planes, but are, in fact, only the intersection of those planes with the plane of the paper. Part of the body must be conceived as being above the paper, and part of it behind or below the paper. The plane of the paper therefore divides the body into two parts. It may be so situated, therefore, that the sum of all the distances from it to the particles lying above it shall be equal to the sum of all the distances of those which are below it. Therefore the situation of the point P is now determined, namely, at the common intersection of three planes perpendicular to each other. It is evident that this point alone can have the condition required in respect of these three planes.

Motions continually deflected.

It still remains to be determined whether the same condition will hold true for the point thus found, in respect to *any other* plane passing through it; that is, whether the sum of all the perpendiculars on one side of *this fourth* plane is equal to the sum of all the perpendiculars on the other side.

Fig. 22.

Let AGHB (fig. 22.), AXYB, and CDEF, be three planes intersecting each other perpendicularly in the point C; and let CIKL be any other plane, intersecting the first in the line CI, and the second in the line CL. Let P be any particle of matter in the body or system. Draw PM, PO, PR, perpendicular to the first three planes respectively, and let PR, when produced, meet the oblique plane in V; draw MN, ON, perpendicular to CB. They will meet in one point N. Then PMNO is a rectangular parallelogram. Also draw MQ perpendicular to CE, and therefore parallel to AB, and meeting CI in S. Draw SV; also draw ST perpendicular to VP. It is evident that SV is parallel to CL, and that STRQ and STPM are rectangles.

All the perpendiculars, such as PR, on one side of the plane CDFE, being equal to all those on the other side, they may be considered as compensating each other; the one being considered as positive or additive qualities, the other as negative or subtractive. There is no difference between their sums; and the sum of both sets may be called 0 or nothing. The same must be affirmed of all the perpendiculars PM, and of all the perpendiculars PO.

Every line, such as RT, or its equal QS, is in a certain invariable ratio to its corresponding QC, or its equal PO. Therefore the positive lines RT are compensated by the negative, and the sum total is nothing.

Every line, such as TV, is in a certain invariable ratio to its corresponding ST, or its equal PM, and therefore their sum total is nothing.

Therefore the sum of all the lines PV is nothing; but each is in an invariable ratio to a corresponding perpendicular from P on the oblique plane CIKL. Therefore the sum of all the positive perpendiculars on this plane is equal to the sum of all the negative perpendiculars, and the proposition is demonstrated, viz. that in every body, or system of bodies, there is a point such, that if a plane be passed through it *in any direction whatever*, the sum of all the perpendiculars on one side of the plane is equal to the sum of all the perpendiculars on the other side.

80. If A and B (fig. 23.) be the centres of position of two bodies, whose quantities of matter (or numbers of equal particles) are a and b, the centre C lies in the straight line joining A and B, and AC : CB$=b:a$, or its distances from the centres of each are inversely as their quantities of matter. For let $\alpha C \beta$ be any plane passing

passing through C. Draw $A\alpha$, $B\beta$, perpendicular to this plane. Then we have $a \times A\alpha = b \times B\beta$, and $A\alpha : B\beta = b : a$, and, by similarity of triangles, $CA : CB = b : a$.

If a third body D, whose quantity of matter is d, be added, the common centre of position E of the three bodies is in the straight line DC, joining the centre D of the third body with the centre C of the other two, and $DE : EC = a+b : d$. For, passing the plane $\delta E \kappa$ through E, and drawing the perpendiculars $D\delta$, $C\kappa$, the sum of the perpendiculars from D is $\delta \times D\delta$; and the sum of the perpendiculars from A and B is $\overline{a+b} \times C\kappa$, and we have $d \times D\delta = \overline{a+b} \times C\kappa$; and therefore $DE : EC = a+b : d$.

In like manner, if a fourth body be added, the common centre is in the line joining the fourth with the centre of the other three, and its distance from this centre and from the fourth is inversely as the quantities of matter; and so on for any number of bodies.

81. If all the particles of any system be moving uniformly, in straight lines, in any directions, and with any velocities whatever, the centre of the system is either moving uniformly in a straight line, or is at rest.

For, let m be the number of particles in the system. Suppose any particle to move uniformly in any direction. It is evident from the reasoning in a former paragraph, that the motion of the common centre is the mth part of this motion, and is in the same direction. The same must be said of every particle. Therefore the motion of the centre is the motion which is compounded of the mth part of the motion of each particle. And because each of these was supposed to be uniform and rectilineal, the motion compounded of them all is also uniform and rectilineal; or it may happen that they will so compensate each other that there will be no diagonal, and the common centre will remain at rest.

COROLLARIES.

82. Cor. 1. *If the centres of any number of bodies move uniformly in straight lines, whatever may have been the motions of each particle of each body, by rotation or otherwise, the motion of the common centre will be uniform and rectilineal.*

Cor. 2. *The quantity of motion of such a system is the sum of the quantities of motion of each body, reduced to the direction of the centre's motion. And it is had by multiplying the quantity of matter in the system by the velocity of the centre.*

Cor. 3. *The velocity of the centre is had by reducing the motion of each particle to the direction of the centre's motion, and then dividing the sum of those reduced motions by the quantity of matter in the system.*

83. If on any two bodies of such an assemblage equal and opposite quantities of matter be impressed, the motion of the centre of the whole is not at all affected by it. Because the motion of the centre, arising from the motion of one of the bodies being compounded with the equal and opposite motion of the diagonal of the parallelogram, becomes a point; or these motions destroy one another; and therefore no change is effected on the motion of the centre.

PART II. OF MOVING BODIES.

84. HAVING in the former part considered the general doctrine of motion, which is the foundation of mechanical investigations, we now proceed to treat of *moving forces* or *dynamics*, properly so called.

Object of dynamics.

It has been already observed, that dynamics includes the abstract doctrine of moving forces, or the necessary results of the relations of our thought concerning motion, the immediate causes of motion, and its changes; and that from the changes observed, we infer agency in nature; and in these changes we are to discover what we know of their causes.

85. When we cast our eyes around us, it cannot escape observation, that the changes which we perceive in the state or condition of any body in respect of motion, are constantly and distinctly related to the situation and distance of other bodies. The motions of the moon, or of a stone projected through the air, have a palpable relation to the earth; the motions of the tides have also an obvious relation to the moon; and the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one of these bodies seems to be the occasion, at least, of the motions of the other; and the causes of these motions have an evident connection with, or dependence on, the other body. Such dependences have been called the *mechanical relations* of bodies. They are indications of properties or distinguishing qualities. They accompany the bodies wherever they are, and are usually conceived to be inherent in them. They at least ascertain and determine what is called the mechanical nature of bodies.

Mutual lation of bodies di ferently consider

86. The mutual relation of bodies is differently considered according to the interest we may have in the phenomenon. The cause of the approach of the iron to the magnet is generally ascribed to the magnet. It is said to attract the iron. The approach of a stone to the earth is ascribed to the stone. It is said to tend to the earth. But it is probable that the procedure of nature is the same in both; that both bodies are affected alike, and that the property is distinctive of both. For in all cases that have been observed, the indicating phenomenon is equally connected with both bodies; as in the case of magnetism the magnet and the iron approach each other; and an electrified body and another body near it approach each other. This property is therefore equally inherent in both bodies, between which there is a mutual attraction. But, according to some philosophers, no such mutual tendencies exist either in the one body or the other. The observed approaches or mutual separations of bodies, or their attractions and repulsions, are supposed to depend on the extraneous action of an ethereal fluid.

Powers, &c.

87. These qualities thus inherent in bodies, which constitute their mechanical relations, or the mechanical affections of matter, have been called *powers* or *forces*. The event which is indicated by their presence, is considered

sidered as the effect and mark of their agency. Thus the magnet is said to *act* on the iron, the earth is said to *act* on the stone which falls to its surface; and the iron and the stone are said to act on the magnet and the earth. But all this, it must be observed, is figurative language. *Power, force*, and *action*, when used in their original strict sense, express only the notions of the power, force, and action of sentient, active beings; and cannot be predicated of any thing but the exertions of such beings; for such beings only are agents. In strict propriety, it is perhaps only the exerted influence of the mind on the body which ought to be called action. Language having begun among simple men, such denominations were very properly given to their own exertions; because to move a body they found it necessary to exert their force or power, or to act. But when the changes of motion, observed in the occurrence or vicinity of bodies, were attended to by speculative men, and it was found that the phenomena greatly resembled the results or effects when they exerted their own strength, similar terms were employed to express these occurrences in nature. The old term was retained, in preference to the invention of a new language, to express things which had so near a resemblance. The danger of confounding things from the use of the same terms, was avoided from the differences in other circumstances of the case. It is not, however, to be imagined, that they supposed inanimate bodies exerted force or strength in the same way as living beings. But, in the progress of refinement, the word power or force came at last to be employed to express *any efficiency whatever;* and hence the common expressions, the *force* of arguments, the *action* of motives, the *power* of an acid to dissolve a metal, &c. It is to this idea of conveniency, that the use of the terms *attraction, repulsion, pressure, impulsion*, as well as of the words power and force, which express *efficiency* in general, is to be ascribed. But these terms, excepting in those cases when they are applied to the exertions or actions of living beings, are metaphorical. On account, however, of the resemblance between the phenomena and those which are observed when we draw a thing towards us, push it from us, forcibly compress it, or kick it away, these different actions being analogous to attraction, repulsion, pressure, and impulsion, these words are employed as terms of distinction. The action of the mind on the body is perhaps the only case of pure unfigurative action. But this action being always exerted with the view of effecting some change on external bodies, our attention is only directed to them. The instrument passes unnoticed; and hence it is said that we act on the external body. The *real* action is only the first movement in a long succession of events, and is only the remote cause of the interesting event. In many cases of mechanical phenomena, we find the resemblance to such actions to be very strong. The following is of this description. A ball is projected from a man's hand by the motion of his arm; and in the same way a ball is impelled by the unbending of a spring. In all circumstances there is a resemblance between these two events, excepting in the action of the mind on the corporeal organ. And, hence in general, because the ultimate results of the mutual influence of bodies on each other have a strong resemblance to the ultimate results of our actions on bodies, no new or appropriate terms have been invented; but, as has been already observed, mankind have remained satisfied with the use of those terms that are employed to express their own actions, or the exertions of their own powers or forces.

Action of mechanical powers.

88. When power or force is spoken of as existing or residing in a body, and the effect is ascribed to the exertion of this power, one body considered as possessing it, is said to *act* on another. Thus a magnet is said to act on a piece of iron; a billiard ball is said to act on one which it strikes. But if it be attempted to fix the attention on this action, independent both of the agent and the thing acted on, we shall find that there is no object of contemplation. The exertion or procedure of nature in effecting the change is kept out of view; and if we limit our attention to the action as a thing distinct from the agent, we shall find that it is not the action, strictly speaking, but the act, that is brought under consideration. And in the same way, it is only in the effect produced that the action of a mechanical power can be conceived.

Change implied in action.

89. In the very nature of action some change is implied. Without producing some effect, a man is never said to act. Thought is the act of a thinking principle; and the motion of the limb is the act of the mind on it. In mechanics too there is action only in so far as some mechanical effect is produced. For instance, to begin motion on a piece of ice, or to slide along it, we must act violently; we must exert force; and this force being exerted produces motion. In all cases, the productions of motion are conceived as the exertions of force; but to continue the motion which has been begun along the ice, no exertion seems requisite. Being conscious of no exertion, we ought to infer that no force is necessary for the continuation of motion. It is not the production of any new effect, but the permanency or continuation of an effect already produced. Motion is indeed considered as the effect of some action; but there would be no effect or no change, if the body were not moving. Motion is not to be considered as an action, but the effect of an action.

Division of mechanical forces.

90. Mechanical actions or forces have been divided into *pressures* and *impulsions*. The idea of pressure is very familiar; perhaps it enters into every distinct conception that we can form of a moving force, when the attention is endeavoured to be fixed on it. Changes of motion by the collision of moving bodies are produced by impulsion. Pressures and impulsions are usually considered as of different kinds, the actions or exertions of different powers. It is supposed that there is an essential difference between pressure and impulsion. That we may obtain all the knowledge that these distinctions can give us, let us state some examples of these kinds of forces, instead of attempting to define or describe them.

Examples of pressures,

Let us first take some examples of pressure. Pressure it is known is a moving force; for if a ball lying on the table be gently pressed on one side, it moves toward the other side of the table. If it be followed with the finger, the pressure being continued, its motion is continually increased. There is an acceleration of its motion. By pressing in the same way on the handle of a common kitchen jack, the fly begins to move; and if the pressure be continued on the handle, the motion of the fly becomes very rapid; and there

is

is also a continual acceleration. Such motions as these are the effects of genuine pressure. The unbending of a spring would urge the ball in the same way along the table, and would produce a continually accelerated motion; and a spring coiled up round the axis of the handle of the jack would, by uncoiling itself, urge round the fly with a similar accelerated motion. By comparing the pressure of the finger on the ball with the effects of the spring, we perceive distinctly the perfect similarity. These exertions or actions, or influences, are denoted by the word pressure, which is derived from the most familiar instance of them.

The same motion may be produced in the ball or fly, by pulling the ball or machine by means of a thread having a weight suspended to it. Both being motions accelerated in the same manner, the action of the thread on the ball or machine comes under the same denomination of pressure. Weight is therefore considered as a pressing power. And indeed the same compression is felt from the real pressure of a man on the shoulders and a load laid on them. But in the instance above, the weight acts by the intervention of the thread. By the pressure of the weight it pulls at that part of the thread to which it is attached; this part pulls at the next by the force of cohesion; and this at a third, and so on, till the most remote pulls at the ball or machine. In this way elasticity, weight, cohesion, and other forces, perform the office of a genuine power; and their result being always a motion beginning from nothing, and accelerating to any velocity by perceptible degrees, from this resemblance we are led to give them one familiar name.

91. If the thread by which the weight is suspended be cut, it falls with an accelerated motion. This also is ascribed to some pressing power which acts on the weight; and it is even considered as the cause of the body's weight, which word is a name by which this instance of pressing power is distinguished. Gravitation, therefore, comes under the denomination of pressure. For the same reason the attractions and repulsions of the magnet, or of electric bodies, belong to this class of phenomena; for on bodies placed between them they produce actual compressions, as well as motions which are continually accelerated, in the same way as gravitation does. To all these powers, therefore, the descriptive name of *pressures* may be given, although this name, properly speaking, belongs to one of them only. This great class has been subdivided by some philosophers into pressions and solicitations. Gravity is considered as a solicitation *ab extra*, by which a body is urged downward. The forces of electricity and magnetism, with many other attractions and repulsions, are also called solicitations. But this classification seems to be of little use.

and of impulsion.

92. We have a familiar instance of impulsion in one ball striking another, and putting it in motion. In this case the appearances are very different from the phenomena of pressure. For the body that is struck acquires in the instant of impulse a sensible quantity of motion. But after the stroke this motion is neither accelerated nor retarded, unless by the action of some other force. The rapidity of the motion, it is observed, depends on the previous velocity of the striking ball. If for instance a clay ball, moving with any velocity, strike another equal ball which is at rest, the ball which is struck moves with one half of the velocity of the other. It is farther observed that the striking ball always loses as much motion as the ball which is struck gains. From this remarkable fact there seems to have arisen an indistinct notion of a kind of transference of motion from one body to another. It is not said that the one ball produces motion or causes it in the other, but it is said to *communicate* motion to it; and the phenomenon is usually termed the communication of motion. This, however, is a very inaccurate mode of expression. We distinctly conceive the cause or communication of heat, the communication of saltness, of sweetness, and of many other things; but we have no clear conception of part of the identical motion which existed in one body being transferred to another. From this, therefore, it appears that motion is not a thing which can exist independently, and is susceptible of actual transference; but is a state or condition of which bodies are susceptible, which may be produced in bodies, and which is the effect or characteristic of certain natural properties or powers.

Communi cation o motion.

The notion of the actual transference of something formerly possessed by the striking body, and now separated from it, or transfused into the body which is struck, has obtained support from the remarkable circumstance in the phenomenon, that a rapid motion requiring for its production the action of a pressing power, continued for a sensible, and frequently a long time, is or seems to be effected instantaneously by impulsion. Here then we find room for the employment of metaphor, both in thought and language. We see the striking body affect the body which is struck. It possesses the power of impulsion, or of communicating motion, but it only possesses this power while it is itself in motion; and we therefore conclude that this power is the efficient distinguishing cause of its motion. Hence it has been called *inherent force*, the force inherent in a moving body, *vis insita corpori moto*. This force is communicated to the body impelled, or transfused into it; the transference is instantaneous, and the body thus impelled continues in motion till it is changed by a new force. But if we attend scrupulously to those feelings which have given rise to this metaphorical conception, we shall find, that although at first sight this train of observation seems very plausible, we should entertain very different notions. To begin the motion of sliding on a smooth piece of ice, we are conscious of exertion; but when the ice is very smooth, no exertion that we are conscious of seems requisite to continue the motion. No exertion of power is here necessary; and therefore we have no primitive feeling of power while we slide along. And indeed we cannot think of moving forward without effort otherwise than as a certain mode of existence. It has however been imagined that those who support this opinion have in some way deduced it from their feelings. To move forward in walking, we must continue the exertion with which we began; and unless this power of walking be continually exerted, we must stop our progress. But this is inaccurate observation. In the action of walking there is much more than the continuance in progressive motion. It is the repeated and continued lifting the body up a small height, and allowing it to come down again, and this repeated ascent requires repeated exertion.

93. From

Moving orces.

I ulse s to be i itely g ter t pres- s .

93. From the consideration of the instantaneous production of rapid motion by impulse, some distinguished philosophers have been led to suppose that the force or power of impulsion is not susceptible of being compared with a pressing power. It has been asserted that impulse when compared with pressure is infinitely great. But the similarity of the ultimate results of impulse and pressure, have always led them to adopt a different view. There is no difference between the motion of two balls which move with equal rapidity, one of which descends from a height by the force of gravity, while the other has been struck by another body. In this struggle of the mind attached to preconceived opinions, and at the same time accommodating these opinions to observed phenomena, other singular forms of expression have arisen. Pressure is considered as an effort to produce motion. And here we have another instance of metaphorical expression as well as thought. The weight of a ball on the table is called a power; and this weight is continually *endeavouring* to move the ball downward. But these efforts being ineffectual, the power in this case is said to be dead. It is called *vis mortua*, in contradistinction to the force of impulsion, which is called a living power, *vis viva*. But this mode of expression must appear very inaccurate, if we consider the case of the impelling ball falling perpendicularly on the other ball lying on the table. No motion is induced by this impulsion; and if the table be conceived to be annihilated, the power of gravity becomes a *vis viva*.

Su osed pr

To prove that impulse is infinitely greater than pressure, numerous familiar instances have been adduced by those who support this doctrine. A nail is driven with a moderate blow of a hammer, which would require a pressure many hundred times greater than the impelling effort of the person who employs the hammer. A hard body may be shivered to pieces with a moderate blow, which would support an inconceivable weight gradually applied. This prodigious superiority in impulsion leaves it a difficult matter to account for the production of motion by means of pressure; because the motion of the hammer might have been acquired in consequence of the continued pressure of the carpenter's arm. It is considered as the aggregate of an infinite number of succeeding pressures repeated in every instant of its continuance. The smallness of each effort is compensated by their number.

Th are not o kin of me nical forc

94. After all, it does not appear clear that there are two kinds of mechanical force which are essentially different in their nature. It is, indeed, in a great measure given up by those who support the doctrine that impulse is infinitely greater than pressure: Some method might perhaps be found of explaining satisfactorily this remarkable difference between the two modes of producing motion. But there seems to be no considerable advantage in thus arranging the phenomenon under two distinct heads.

Imp ion the use of ion,

95. The nature of the sole moving force in nature has given rise to much discussion among mechanicians, and produced no small diversity of opinion. According to some, all motion is the effect of pressure; for when impulse is considered as equivalent to the aggregate of an infinite number of pressures, every pressure, however small, is supposed to be a moving force.

Of Moving Forces.

The sole cause of motion, according to other philosophers, is impulsion. Bodies are observed in motion; they impel others, and produce motion in them; and this production of motion is said to be regulated by such laws, that there is only one absolute quantity of motion in the universe, which quantity remains invariably the same. Some portion of this motion, therefore, must be transferred or transfused when bodies come into collision with each other. But besides, there are some cases in which it is perfectly obvious that motion produces pressure. Cases, which are indeed both whimsical and complicated, have been adduced by Euler, to shew that an action, in all respects similar to pressure, may be produced by motion. Such a case is the following. If two balls are connected by a thread, they may be struck in such a way, that they shall not only move forward, but at the same time also wheel round. When this happens, the thread by which they are connected is stretched. Since then, according to this reasoning, motion is observed, and pressure is produced by motion, it would be absurd to suppose that pressure is any thing else than the result of certain motions. The philosophers who are attached to this doctrine of moving forces, proceed to account for those pressing powers or solicitations to motion which are observed in the acceleration of falling bodies, the phenomena of magnetism and electricity, and others of the same kind, where motion is induced on certain bodies which are in the vicinity of other bodies, or, as it is expressed in common language, by the action of other bodies at a distance. To say that a magnet can act on a piece of iron at a distance, is to say that it acts *where* it is not; which is no less absurd than to say that it acts, *when* it is not. Euler assumed it as an axiom, *nihil movetur, nisi à contiguo et moto.*

The methods proposed by these philosophers to produce pressure, are less ingenious and not more satisfactory than that adduced by Euler which was mentioned above; and indeed they do not seem to be very anxious about the manner in which these motions are produced. The phenomena of magnetism are induced, or a piece of iron is put in motion, when it is in the vicinity of a magnet, by a stream of fluid which issues from one pole of a magnet, passes in a circle round the magnet, and enters at the other pole. By this stream of fluid the iron is impelled, and brought to arrange itself in certain determined positions. In the same way all bodies are impelled in lines perpendicular to the surface of the earth by a stream of fluid which is in continual motion towards its centre. In the same way similar phenomena are accounted for, and thus these motions are reduced to simple cases of impulsion. But to say nothing worse of this doctrine, it is not very compatible with the dictates of common sense. It proceeds on the supposition that something acts which we do not see; and of the existence of which there is not the smallest proof.

or pressure.

96. Pressure, according to the opinion of others, is the only moving force in nature; but it is that kind of pressure which has been termed solicitation, not what arises from the mutual contact of solid bodies. Gravitation is an instance of the kind of pressure here alluded to. It is affirmed by these philosophers, that there is no such thing as contact on the instantaneous communication of motion by the real collision of bodies. It is said that the particles of solid bodies exert very strong

repulsions

repulsions to a small distance; and when they are brought by any motion sufficiently near to another body, they exert a repulsive force, and are equally repelled by this body. Motion is thus produced in the one body, while it is diminished in the other. It is then shown by scrupulously considering the state of the bodies, while the one advances and the other retires, in what way they attain a common velocity, the quantity of motion before collision remaining the same, and the one body gaining exactly as much as the other loses. Cases also are adduced, of such mutual action between bodies, where it is obvious they have never come into contact; but where the result is exactly the same as when the motion seemed to be instantaneously changed. And hence it is concluded that there is no such thing as instantaneous communication, or transfusion of motion, by contact in collision or impulse. All moving forces, according to these philosophers, are of that kind which have been named solicitations; such as gravity is.

Exertions of mechanical forces named from their result.

97. Different names have been given to the exertions of mechanical forces, according to the reference that is made to the result. In wrestling, when my antagonist exerts his strength to prevent being thrown down, and I am sensible of his exertion, I thus discover that he resists. But if I oppose him only to prevent him throwing me, I am said to resist. If I strike or endeavour to throw him, I am said to act. The same distinction is applied to the exertion of mechanical powers. If, for instance, one body A change the motion of another body B, the change in the motion of B may be considered either as the indication and measure of the power of A in producing motion, or as the indication and measure of the resistance made by A in being brought to rest, or having any change induced on its motion. The distinction which is here made is not in the thing itself, but exists only in the reference which we are disposed to make of its effect, from other considerations. If a change of motion take place when one of the powers ceases to be exerted, it is conceived that this power has resisted. But this language is metaphorical. Resistance, effort, endeavour, are all words which express motions that relate to sentient beings. There is perhaps no word preferable to the word *reaction*, to express the mutual force which is observed in all the operations of nature which have been successfully investigated.

Supposed to depend on attraction and repulsion.

98. A difficulty has been started with regard to the opinion of those who affirm that all mechanical phenomena are dependent on attracting and repelling forces; because it is here supposed that bodies act on each other at a distance, and however small this distance may be, this is conceived to be absurd. It may however be observed, that the mutual approaches or recesses of bodies may be ascribed to tendencies to, or from each other. Without thinking of any intermediate connection between the iron and the magnet, we conceive the iron to be affected by the magnet; and if this be conceivable, it is not absurd. Our knowledge of the essence or nature of matter is not such as to render this tendency of the iron to the magnet impossible. We do not indeed see intuitively why the iron should approach to the magnet; but this is by no means sufficient to pronounce it impossible or inconsistent with the nature of matter. To suppose therefore in the production of motion, the impulse of an invisible fluid, of which we know not any thing, and of whose existence there is no evidence, is a rash and unwarrantable assumption. But farther, if it be true that bodies do not come into contact, even when one ball strikes another, and drives it before it, the supposition of the existence of this invisible fluid will not assist us in solving the difficulty; for the same difficulty would occur in the action of any one particle of the fluid in the body. At any rate the production of motion without any observed contact, is more familiar to us than the production of motion by one body acting on another by impulsion. Every case of gravitation is an instance of this.

Attracti and repulsion explained.

99. In those cases where the exertions of any mechanical power are observed to be always directed toward any body, that body is said to *attract*. Thus a boat is attracted toward a man when he pulls it toward him by means of a rope. This is a case of pure *attraction*. But when the other body always moves off, the body exhibiting this phenomenon is said to repel; and it is a case of pure *repulsion* when a person pushes any body from him. And because there is a resemblance to the results of real attraction and repulsion, the same terms are employed to express the mechanical phenomena of nature. But that our conceptions may not be embarrassed or rendered obscure by the use of such metaphorical expressions, it is requisite to be careful not to allow these words to suggest to us any opinion about the manner in which mechanical forces produce their effects. If the opinion which is held of the existence of an invisible fluid on which mechanical action depends be well founded, it is obvious that there can be neither attraction nor repulsion in the universe.

Forces measurab quantitie

100. Forces are conceived as measurable quantities. Thus we conceive one man to possess double the strength of another man, when we observe that he can resist the combined efforts of two others. It is in this way that animal force is conceived as a quantity made up of its own parts and measured by them. This however seems not to be a very accurate conception. Our conception of one strain being added to another is obscure, although we have a distinct notion of their being combined. There are no words to express the difference of these two notions in our minds; but we think that the same difference is perceived by others. We have a clear conception of the addition of two lines or two minutes; but our notions of two forces combined are indistinct; although it cannot be affirmed that two equal forces are not double of one of them. They are measured by the effects which they are known to produce.

and such are mech nical.

101. In the same way mechanical forces are conceived as measurable by their effects, and thus become the subject of mathematical discussion. We speak of the proportions of magnetism, electricity, &c. and even of the proportion of gravity to magnetism. These, however, considered in themselves, are quite dissimilar, and do not admit of any proportion; but some of their effects are measurable, and these assumed measures being quantities of the same kind are susceptible of comparison. The acceleration of motion in a falling body, is one of the effects of gravity; magnetism accelerates the motion of a piece of iron; and these two accelerations may be compared together. But because none of the measurable effects of magnetism with which we are acquainted

acquainted, are of the same kind with any of the effects of heat, magnetism and heat are not susceptible of comparison.

parison e ef- s of ity.

When it is said that the gravitation of the moon is the 3600th part of the gravitation of a stone at the sea-shore, it is meant that the fall of a stone in a second is 3600 times greater than the fall of the moon in the same time. But to express the proportion of the tendency of gravitation more purely, if a stone hung on the spring of a steelyard, draw out the rod of the steelyard to the mark 3600, the same stone carried up to the distance of the moon will draw it out only to the mark one. And if the stone at the sea-shore draw out the rod to any mark, it will require 3600 such stones to draw the rod out to the same mark at the distance of the moon. Now, it is not in consequence of an immediate perception of the proportion of gravitation at the moon to that at the surface of the earth that such an assertion is made. It is because these motions being considered as its effects in such situations, and being magnitudes of the same kind, are susceptible of comparison, and have a proportion which can be determined by observation. And although the proportions of the causes or forces are spoken of, yet it is only the proportions of the effects which come under contemplation.

sures be the in and ee.

102. In order that these assumed measures may be accurate, they must be always connected with the magnitudes which they are employed to measure; and the connection must be of that kind, that the degrees of the one must change in the same manner with the degrees of the other. The same thing must also be known of the measure which is employed; the precise and constant relation must be seen. But how is this to be accomplished? Force as a separate existence is not a perceptible object. We do not perceive its proportions, so as to be able to ascertain that they are the same with the proportions of the measures. On the contrary, the very existence of this force is inferred from observation of the acceleration, and its degree is also an inference from the observed extent or magnitude of the acceleration. The measures which are thus assumed are therefore necessarily connected with the magnitudes, and their proportions are the same; the one is an inference from the other both in kind and degree.

Dy mics a on- str ve ci e.

103. It now appears that this subject is susceptible of mathematical investigation. After having selected our measnres, and observing certain mathematical relations of those measures, every inference deduced from the mathematical relations of the proportions of those representations is true of the proportions of the motions, and therefore it is also true of the proportions of the forces. Thus then Dynamics may be reckoned a demonstrative science.

Fo s dif- fer di- rec n.

104. Moving forces are considered as differing also in kind, that is, in direction. The direction of the observed change of motion is assigned to the force; which is not only the indication, but also the measure of the changing force. This force is called an accelerating, retarding, or deflecting force, according as it is observed, that the motion is accelerated, retarded, or deflected. And from these terms it must appear, that we have no knowledge of the forces different from our knowledge of the effects. They are either descriptive of the effects, or they have a reference to the substances in which the forces are supposed to be inherent. Thus of the first kind are the terms *accelerating*, *attractive*, or *repulsive* forces; of the second, are the terms *magnetism*, *electricity*, &c.

Of the Laws of Motion.

105. Such then being our notions of mechanical forces, of the causes of the production of motion and its changes, there are certain results, which by the constitution of the human mind, necessarily arise from the relations of these ideas. These results are laws of human judgment, independent of all experience of external nature. Some of these laws may be intuitive, presenting themselves to the mind as soon as the ideas which they involve are presented to it. These may be called axioms. Others may be as necessary results from the relations of these notions, are less obvious, and may require a process of reasoning to establish their truth.

Of these laws there are three, which were first distinctly proposed by Sir Isaac Newton. These may be considered as the first principles of all discussions in mechanical philosophy, give a sufficient foundation for all the doctrines of Dynamics, and to these principles we may refer for the elucidation of all the mechanical phenomena of nature.

First Law of Motion.

106. *Every body continues in a state of rest, or of uniform rectilineal motion, unless it is affected by some mechanical force.*

Importance of this proposition.

On the truth of this proposition the whole of mechanical philosophy chiefly depends. But with regard to its truth and the foundation on which it rests, the opinions of philosophers are very different. In general these opinions are obscure and unsatisfactory; and, as is usual, they influence the discussions of those who hold them in all their investigations.

Rest supposed to be the natural condition of body.

107. It is not only the popular opinion that a state of rest is the natural state of body, and that motion is something foreign to it, but the same opinion has been supported by many philosophers. They allow that matter unless it is acted on by some moving force will remain at rest; and nothing seems necessary for matter to remain where it is, but its continuing to exist. But the case is widely different, according to these philosophers, with respect to matter in motion. For here the relations of the body to other things are continually changing; and as there is the continual production of an effect, the continual agency of a changing cause is necessary. This metaphysical argument, it is said, is fully confirmed by the most familiar observations. All motions, whatever may have been their violence, terminate in rest, and for their continuance the continual exertion of some force is necessary.

Continual exertion of force necessary in motion.

108. It is affirmed by these philosophers, that the continual action of the moving cause is essentially requisite for the duration of the motion. But their opinions of the nature of this cause are not uniform. According to some, all the motions in the universe are produced and continued by the direct agency of the Deity himself. By others all the motions and changes of every particle of matter are ascribed to a sort of mind which is inherent in it. This is called an *elemental mind*. It is the same as the φυσις and the ὁσπερ ψυχη of Aristotle. Every thing, according to these philoso-

Of Moving Forces.

phers, which moves, is mind, and every thing which is moved is body. But this elemental mind is only known and characterized by the effects which are ascribed to its action; and these are observed in the motions or changes which are produced. These, we learn from uniform experience, are regulated by laws equally precise with the laws of mathematical truth. But there is nothing which indicates any thing like intention or purpose; none of the marks or characters by which mind was brought first into view. They resemble the effects produced by the exertions of corporeal force; and hence the word *force* has been applied to express the causes of motion.

No body is in absolute rest.

109. A state of rest, it has been supposed, is the natural state of matter. But it does not appear that the continued action of some cause is necessary for continuing matter in motion. Experience gives us no authority for supposing that the natural condition of matter is a state of rest. It cannot be affirmed of any body whatever, that it has ever been seen in absolute rest. All the parts of the planetary system are in motion; and even the sun himself with his attendant planets is carried in a certain direction with a great velocity. There is no unquestionable evidence that any of the stars are absolutely fixed; and many of them, it has been ascertained by observation, are in motion. Rest, therefore, being so rare a condition of matter, no experience which we have, supports the notion that this is its natural condition. This opinion seems to be derived from our own experiments on matter. To continue the motion of a body, we find that the continued action of some moving force is necessary, otherwise the motion becomes gradually slower, and at last terminates in rest. Since then we see that our own exertions are constantly necessary in the production of motion, and especially in those cases where we are interested; we are thus induced to ascribe to matter something that is naturally quiescent and inert, and even something that is sluggish and averse from motion. But this is an erroneous conception, which is suggested to our thoughts from the imperfection of language. We ascribe animation to matter, to give it motion, and endow it with a kind of moral character in order to explain the phenomena of motion.

Matter has no aptitude to rest.

110. But more accurate and more extended observation leads us to conclude that matter has no peculiar aptitude to a state of rest. Every observed retardation has a distinct reference to external circumstances. Wherever there is a diminution of motion, it is invariably accompanied by the removal of obstacles; as in the case when a ball moves through sand, or air, or water. The diminution of motion is also owing to opposite motions which are destroyed. And it is found that the more these obstacles are kept out of the way, the less is the diminution of motion. The vibration of a pendulum in water soon ceases; it continues longer in air; and much longer in the exhausted receiver. The conclusion then from these observations is, that if all obstacles could be completely removed, motion would continue for ever. This conclusion is strongly supported by the motions of the heavenly bodies. These motions, so far as we know, are retarded by no obstacles; and accordingly they have been observed to retain them without perceptible diminution for thousands of years.

This is de nied by others.

111. The inactivity of matter has been denied by other philosophers. According to them it is essentially active, and continually undergoing changes in its condition. Some traces of this doctrine are to be found in the writings of some of the ancient philosophers; but it was reduced to a systematic form by Leibnitz. According to this philosopher, every particle of matter is endowed with a principle of individuality. This he calls a *monad*, which is supposed to have a kind of perception of its place in the universe, and of its relation to all other parts of the universe. This monad too is supposed to act on the particle of matter in the same way as the soul acts on the body. The motion of the material particle is modified by the monad, and thus are produced, according however to unalterable laws, all the observed modifications of motion. And thus matter, or the particles of matter, are continually active and continually changing their situation. No information in any way useful can be obtained from this fanciful hypothesis. It is not unlike the system of elemental minds. And should its existence be admitted, it would not, any more than the actions of animals, invalidate the general proposition which is considered as the fundamental law of motion. The powers of the monads or of the elemental minds are supposed to be the causes of all the changes; but the particle of matter itself is subject to the law, and any change of motion which it exhibits is ascribed to the exertion of the monad.

This law deduced from the want of a determining cau

112. By another set of philosophers, the law of motion is deduced from the want of a determining cause. At the head of this sect is Sir Isaac Newton, who maintains the doctrine affirmed in the proposition. But these philosophers are not uniform in their opinion of the foundation on which it rests. It is asserted by some that it is a kind of necessary truth which arises from the nature of the thing. If, for instance, a body be in a state of rest, and if it be asserted that it will not remain at rest, it must move in some direction; and if it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal motion, it must be either accelerated or retarded; it must either turn to one side or to some other side. The event, whatever it be, is individual and determinate; but no cause which can determine it being supposed, the determination cannot take place, and no change with respect to motion will happen in the condition of the body. It will either remain at rest, or persevere in its rectilineal and equable motion. But to this argument of sufficient reason, as it has been called, considerable objections may be made. In the immensity and perfect uniformity of time and space, there is no determining cause why the visible universe should exist in one place rather than in another, or at this time rather than at another. It is essentially necessary that there should be a cause of determination; for a determination may be without a cause, as well as a motion without a cause.

and from experienc

113. Other philosophers deduce this law of motion from experience. They consider it merely as an experimental truth, of the universality of which there are innumerable proofs. When a stone is thrown from the hand, it is pressed forward, and when the hand has the greatest velocity that we can give it, the stone is let go, and it continues in that state of motion which it gradually acquired along with the hand. A stone may be thrown much farther by means of a sling, because with

a

a very moderate motion of the hand, the stone being whirled round acquires a very great velocity, and when it is let go, it continues its rapid motion. We have a similar illustration in the case of an arrow shot from a bow. The string which presses hard on the notch of the arrow carries it forward with an accelerated motion as it becomes a straight line by the unbending of the bow; and there being nothing to check the arrow, it flies off. In these simple cases of perseverance in a state of motion the procedure of nature is easily traced; it is perceived almost intuitively. In many other phenomena it is not less distinct, although somewhat more complicated. A man can stand on the saddle of a horse at a gallop, and step from it to the back of another horse that gallops along with him at the same rate; and this he seems to do with the same ease as if the horses were standing still. The man is carried along with the same velocity as the horse which gallops under him, and he retains the same velocity while he steps from the back of one horse to that of the other. But if the horse to which he steps were standing still, he would fly over his head, because he is carried forward with the velocity of the galloping horse; or if he stepped from the back of a horse standing still to that of one at a gallop, he would be left behind; because he has not acquired the velocity of the galloping horse. In the same way a man tosses oranges from one hand to the other while he is carried forward with the motion of a horse at a gallop, or while he swings on the slack-wire. In both cases the oranges have the same motion as the man, and while they are in the air are moving forward with the same velocity, so that they drop into the hand at a considerable distance from the place in which they were thrown from the other hand. While a ship sails forward with a rapid motion a ball dropped from the mast head falls at the foot of the mast: for it retains the motion which it had previous to its being dropped, and follows the mast during the whole time of its fall.

ases of ion

of rest.

114. Familiar instances may also be given of a body in a state of rest. A vessel filled with water drawn suddenly along the floor, leaves the water behind, which is dashed over the posterior side of the vessel; and when a boat or coach is suddenly dragged forward, the persons in it find themselves strike against the hinder part of the carriage or boat; or rather it should be said the carriage strikes on them, for it sooner acquires motion from the action of the force applied. A ball discharged from a cannon will pass through a wall and move onward; but the wall remains behind.

om- expe- e in- ent.

115. Common experience is perhaps insufficient for establishing the truth of this fundamental proposition. It must be granted, that we have never seen a body either at rest, or in uniform rectilineal motion; yet this seems necessary before it can be said that the proposition is experimentally established. What is supposed in our experiments to be putting a body, formerly at rest, into motion, is in fact only producing a change of a very rapid motion—a motion not less than 90,000 feet per second.

proof sary.

116. For the purpose of obtaining such experimental proof of the truth of this proposition, it will be necessary to resort to other observations. The relative motions of bodies, which are the differences of their absolute motions, only can be measured. We cannot measure their absolute motions. If then it can be shown by experiment that bodies have equal tendencies to resist the augmentation and diminution of their relative motions, they thus have equal tendencies to resist the augmentation or diminution of their absolute motions.

Let A and B two bodies be put into such a situation that they cannot persevere in their relative motions. The change which we observe produced on A is the effect and measure of the tendency of B to persevere in its former state. From the proportion of these changes therefore we derive the proportion of their tendencies to remain in their former condition. This will be illustrated by the following experiment, which should be made at noon.

117. Let the body moving at the rate of three feet per second to the westward, strike the equal body B which is apparently at rest. Different cases of the results of the changes thus produced may be supposed.

1st. Let A impel B forward without having its own velocity at all diminished. From this result it appears that B shows no tendency to maintain its motion unchanged, but that A retains its motion without diminution.

2d. Suppose that A stops, and that B remains at rest. This case shows that A does not resist a diminution of motion, and that the motion of B is not changed.

3d. Let it be supposed that both move westward at the rate of one foot per second. There is in this case a diminution of the velocity in A, equal to two feet per second. This then is to be considered as the effect and measure of the tendency of B to maintain its velocity unaugmented. B has received an augmentation of one foot per second in its velocity. From this change it appears that the tendency is but half of the former; and the result shows that the resistance to a diminution of velocity is only equal to one half of the resistance to augmentation; and perhaps equal only to one quarter, since the change on B has effected a double change on A.

4th. Let it be supposed that both bodies move forward with the velocity of one and a half feet per second. In this case it is obvious that the tendencies of the two bodies to maintain their states unchanged are equal.

5th. But suppose that $A=2B$, and that the velocity of both after collision is equal to two feet per second. The body B has then received an addition of two feet per second to its former velocity; and this is the effect and measure of the whole tendency of A to preserve its motion undiminished. One half of this change on C measures the persevering tendency of one half of A; but it is supposed that A, which formerly moved with the apparent or relative velocity three, now moves with the velocity two, and thus has lost the velocity of one foot per second. Therefore each half of A has lost this velocity; and the whole loss of motion is two. This then is the measure of the tendency of B to maintain its former state unaugmented; and it is the same with the measure of the tendency of A to preserve its former state undiminished. From such a result therefore the conclusion would be, that bodies have equal tendencies to maintain their former states of motion unaugmented and undiminished.

The suppositions made above in the 4th and 5th cases are the result of all the experiments which have been made; and in all the changes of motion which are produced by the mutual action of bodies on impulsion, this is the regulating law. To this there is no exception. And thus it appears that there exists in bodies no preferable tendency to rest. No fact can be adduced which should lead us to suppose that a motion having once begun should suffer any diminution without the intervening action of some changing cause.

The proof imperfect.

118. It must, however, be observed that this is a very imperfect way of establishing the first law of motion. It is inapplicable to those cases where experiment cannot be made; and at best it is subject to all the inaccuracy of the best managed experiments. If this proposition be examined by means of the general principles which have been adopted in the article PHILOSOPHY (which see), an accurate decision of this question may be given. These principles, which are the foundation of all our knowledge, shew that this proposition is an axiom or intuitive consequence of the relations of those ideas which we have of motion, of its changes, and of their causes.

Existence of forces inferences from motion.

119. Powers or forces, it has been shewn, are not the immediate objects of our perceptions. Their existence, kind, and degree, are inferences from the motions which we observe. And hence it follows, that when no change of motion is observed, no such inference is made; no force or power is supposed to act. But when any change of motion is observed, the inference is made; a power or force is supposed to have acted. By a similar conclusion, it is said, that when no change of motion is supposed, no force is thought of or supposed; and whenever a change of motion is supposed, it always implies a changing force. On the other hand, when the action of a changing force is supposed, the change of motion is also supposed; the action of this force and the change of motion being the same thing. The mind does not admit the idea of the action, without at the same time thinking of the indication of the action, and this indication is the change of motion. And in the same way, when we do not think of the changing force, or do not suppose the action of a changing force, we suppose, although it be not expressed in terms, that there is no indication of this changing force; that there is no change. If, therefore, it be supposed that no mechanical force acts on a body, we suppose in fact that the body remains in its former condition with respect to motion. And if it be supposed that nothing accelerates or retards, or deflects the motion, it is conceived as neither accelerated nor retarded, nor deflected. Hence it follows, that we suppose the body to continue in its former state of rest or motion, unless we suppose that it is changed by some mechanical force.

This law a necessary truth.

120. This proposition then does not depend on the properties of body as a matter of experience or contingency. It is to us a necessary truth. It is not so much any circumstances with regard to body that are expressed in the proposition, as the operations of the mind in considering these circumstances. The truth of the proposition will not be invalidated by taking into view, that it may be essential to move in some particular direction; that it may be essential to body to stop when the moving cause ceases to act; or gradually to diminish its motion, and at last to come to rest. The circumstances in the nature of body which render those modifications essentially necessary, are the causes of those modifications; and they are to be considered as changing forces.

If we should suppose that body of its own nature is capable of producing a change in its condition, this change must be effected according to some law which characterizes the nature of body. But the knowledge of this law can be obtained only by observing the deviations from uniform rectilineal motion. It then becomes indifferent whether external causes operate those changes, or they depend on the nature of the thing; for in considering the various motions of bodies, we must first consider the nature of matter as one of its mechanical affections which operates in every instance; and this brings us back to the law contained in the proposition. This is rendered more certain by reflecting, that the external causes, such for instance are gravity and magnetism, which are acknowledged to operate changes of motion, are not less unknown to us than this essential property of matter. They are, like it, only inferences from the phenomena.

Inadequa notions suggested by inacc rate expr sions.

121. Many philosophers, among which number may be included Newton himself, have introduced modes of expression, which suggest inadequate notions, and such as are incompatible with the doctrine of the proposition; for although they allow that rest is the natural condition of body, and that force is necessary for the continuation of motion, yet they speak of a *power* or *force* residing in a moving body by which it perseveres in its motion. This has been called the *vis insita*, or the *inherent force* of a moving body. Now if the motion be supposed to be continued in consequence of a force, that force must be supposed to be exerted, and it is supposed that if it were not exerted the motion would cease. The proposition, therefore, must be false. To obviate this objection, it is indeed sometimes said, that the body continues in uniform rectilineal motion, unless it is acted on by some external cause. This mode of expression, however, subjects us to the impropriety of asserting that gravity, electricity, and other mechanical forces, are external to the bodies on which they are supposed to act and to put in motion. Every thing which produces a change of motion is very properly called a force; and when a change of motion is observed, the action of such a force is very properly inferred. But to give the same name to what has not this property of producing a change, and to infer the action of a force when no change is observed, is not a very accurate or consistent expression. This error has arisen from the use of analogical language in philosophical discussions.

Motion a continu exertion, but an e fect.

122. But motion is not, as philosophers have imagined, the continual production of an effect. We can conceive there is such a thing as a moving cause, to which the name of *force* has been given. This produces motion, and the character of motion in body, which is a continual change of place. Motion is the effect of an action; and previous to the commencement of the motion, this action is equally incomplete as it is the minute after. The immediate effect of a moving force is a determination to motion, which if not obstructed by some cause would go on for ever. In this determination only the condition of the body differs from a state of rest. Motion then is a condition or mode of existence, which no more requires the continued agency of the moving cause than colour or figure. Some mechanical cause is required to change this condition into the state or condition of rest. When a moving

moving body is brought to rest, some cause of this cessation of motion never fails to occur to the mind. A cause is no less necessary to stop the motion of body than it is to produce it. Now this cause must either reside in the body or be external to it. If it reside in the body, then it possesses a self-determining power or force, by which it may be able to stop its own motion as well as to produce it.

123. Taking this view of the subject, the opinion of a force residing in a moving body by which its motion is continued must be given up; and the remarkable difference between a body in a state of motion and a state of rest must be explained on other principles. Motion, it cannot be doubted, is necessary in the impelling body to permit the forces which are inherent in one or both bodies to continue the pressure long enough for the production of sensible motion. But whether bodies be in the condition of motion or rest, these forces are inherent in them. If we reflect on the motions that are involved in the general conception of one body being impelled and put in motion by another, we shall see that there is nothing individual transferred from the one to the other. Before collision took place, the determination to motion existed only in the impelling body. After collision, both bodies possessed this condition or determination. But we have no conception, we can form no notion, of the thing transferred.

124. An expression not less vague and indefinite is also very common among mechanical philosophers. This is the phrase *inertia*, or *vis inertiæ*. This expression, which was introduced by Kepler, seems to have been generally employed by him, as well as by Newton, to express the fact of the perseverance of body in a state of motion or rest. Sometimes, however, it has been employed by these philosophers to express something like indifference to motion or rest; and this is supposed to be manifested by body requiring the same quantity of force to make an augmentation of its motion, as is necessary to produce an equal diminution of it. To suppose resistance from a body at rest seems to be in direct contradiction to the common use of the word *force;* and yet this expression *vis inertiæ* is very common. It is not less absurd to say that a body remains in the condition of rest by the exertion of a *vis inertiæ*, than to affirm that it maintains itself in a state of motion by the exertion of an inherent force. Such expressions, which are metaphorical, should be carefully avoided, because they are apt to lead to misconception of the procedure of nature.

125. In the phenomena of motion the force employed always produces its complete effect. No resistance whatever is observed. When one man throws down another, and he finds that no more force has been required than to throw down a similar and equal mass of inanimate matter, he concludes that no resistance has been made; but if more force be necessary, the conclusion is that resistance has been made. When, therefore, the exerted force produces its full effect, there is no such thing as resistance properly so called. It is therefore misconceiving the mode in which mechanical forces operate in the collision of bodies, to say that there is any resistance: for there is no more in these cases than in other natural changes of condition. It may be observed, that these terms, *inherent force* and *inertia*, may be employed for the purpose of abbreviating language, provided they are used only for expressing either the simple fact of persevering in the former state, or the necessity of a determinate force to produce a change on that state, being careful to avoid all thought of resistance.

Of Moving Forces.

Deviations from uniform motion indications of force.

126. Thus it appears that deviations from uniform motions are only the indications of the existence and agency of mechanical forces. This indication is simply change of place; and it can only indicate what is very simple, something competent to the production of the observed motion. The same thing is indicated by two similar changes of motion. A compass needle in a state of rest, can be moved some degrees by means of the finger, a magnet, an electrified body, or by the unbending of a spring, &c. in all which cases the indication is precisely the same; and therefore the thing indicated must also be the same. This is the intensity and direction of some moving power. The circumstances of resemblance by which the affections of matter are to be characterized are impulsiveness, intensity, and direction. This leads us to consider the second law of motion.

Second Law of Motion.

Every change of motion is proportional to the force impressed, and it is made in the direction of that force.

Is an identical proposition;

127. This law of motion also may almost be considered as an identical proposition. It is equivalent to saying that the changing force is to be measured by the change produced, and the direction of this force is the direction of the change. Considering the force only in the sense of its being the cause of motion, and withdrawing the attention from the manner or form of its exertion, there can be no doubt of this. In whatever way a body is put in motion, whether by the expansive force of the air, by the unbending of a spring, or by any similar pressure, when it moves off in the same direction, and with the same velocity, the force or the exertion of the force is considered as the same. Even when it is put in motion by instantaneous percussion from a smart stroke, although in this case the manner of the effect being produced is essentially different from the other cases, we cannot conceive the propelling force, as such, but as precisely one and the same. The expression of this law of motion by Newton is equivalent to saying, "that the changes of motion are taken as the measures of the changing forces, and the direction of the change is taken as the indication of the direction of the forces; for it cannot be said that it is a deduction from the acknowledged principle, that effects are proportional to their causes. This law is not affirmed from the proportion of the forces and the proportion of the changes, and that these proportions are the same, having been observed; and that this universally holds in nature. For forces are not objects of observation, and we do not know their proportions. In this way it would be established as a physical law, as indeed it is so in fact. But according to the definition of the term, this does not establish it as a law of motion; or as a law of human thought, the result of the relations of our ideas. Philosophers having attempted to prove this as a matter of observation, have produced great diversity of opinion in the mode of estimating forces. A bullet, it is well known, which moves with double velocity, penetrates four times as far. This is confirmed

but not deduced from the proportion of the forces.

confirmed by other similar facts; and to generate this double velocity in the bullet, it has been observed by philosophers, four times the force is expended, four times as much powder is required. This is the invariable result; and in cases of this kind, it would appear that the ratio of the forces employed has been very accurately ascertained. The conclusion therefore is, that moving forces are not proportional to the velocities produced, but to the squares of the velocities. This is strongly confirmed by observing that moving bodies seem to possess forces in this very proportion, and to produce effects in this proportion; when, for instance, the velocity is only twice as great, they penetrate four times as deep.

Incompatible with the velocity being proportional to the force.

128. If this mode of estimation be just, it is irreconcileable with the concession of those, who admit that the velocity is proportional to the force impressed, in those cases where no previous observation can be had of the ratio of the forces, and of its equality to the ratio of the velocities. Such a case is the force of gravity, which these philosophers also measure by its accelerating power, or the velocity generated in a given time. This must be granted; for there are cases in which the force can be measured by the actual pressure which it exerts. Thus a spring steelyard can be constructed, the rod of which is divided by hanging on successively a number of perfectly equal weights. In the different states of tension of the spring, its elasticity is proportional to the pressures of gravity which it balances. If it be found, that at Quito in Peru, a weight will pull out the rod to the mark 312, and that the same weight at Spitzbergen draws it out to 313, it seems to be a fair inference to say, that the pressure of gravity at Quito is to its pressure at Spitzbergen as 312 to 313; and this is affirmed on the authority of effects being proportional to their causes. Such cases, however, are very rare; for it is seldom, that the whole of a natural power, accurately measured in some other way, is employed in producing the observed motion. Part of it is generally otherwise expended, and therefore it frequently happens that the motions are not in the proportion with the supposed forces. And allowing that this could be done with accuracy, it would only be the proof of a general law or fact: but these philosophers attempt to establish it as an abstract truth.

129. It seems to be considered by Sir Isaac Newton only as a physical law. And in this sense good arguments are not wanting. A ball which moves with a double, triple, or quadruple velocity, generates by impulse in another, a double, triple, or quadruple velocity, or it generates the same velocity in a double, triple, or quadruple quantity of matter, and losing at the same time similar proportions of its own velocity.

Two bodies, having equal quantities of motion, meeting together mutually stop each other.

When two forces, which act similarly during equal times, produce equal velocity in a third body, they will, by acting together during the same time, produce a double velocity.

If a pressure which acts for a second, produce a certain velocity, a double pressure acting during a second, will produce in the same body a double velocity.

A force which is known to act equably, produces in equal times equal increments of velocity, whatever the velocities may be.

In all the examples above adduced, the forces are observed to be in the same proportion with the change of motion effected by them in a similar way.

Hooke's

But the curious discoveries of Dr Hooke, about the middle of the 17th century, seemed to shew, from a great collection of facts, forces to be in a very different proportion. In the production of motion it was found, that four springs equal in strength, and bent to the same degree, generated only a double velocity in the ball which they impelled: nine springs generated only a triple velocity, &c. In the extinction of motion, it was found, that a ball moving with a double velocity, will penetrate four times as deep into a uniformly resisting mass; and a triple velocity will make it penetrate nine times as far, &c.

130. These facts were brought forward by Leibnitz in support of his own pretensions to the discovery of the real nature and measure of mechanical action and force, which he said had been hitherto totally mistaken. He affirmed that the inherent force of a moving body, was in the proportion of the square of the velocity. In this argument he was supported by John Bernoulli, who adduced many simple facts to confirm the relation between the inherent force of a moving body and its velocity. One of the strongest arguments urged by Leibnitz is, that the inherent force of a moving body is to be estimated by all that it is able to do before the total extinction of its motion; and therefore when it penetrates four times as far, it is to be considered as having produced a quadruple effect. In this mode of estimation many things are gratuitously assumed, many contradictions are incurred; and it is only because forces are assumed as proportional to the velocities which they generate, that these facts come to be proportional to the squares of the same velocity. When Leibnitz assumes the quadruple penetration as the proof of the quadruple force of a body having twice the velocities, he has not considered that a double time is employed during this penetration. But a double force, acting equably during a double time, should produce a quadruple effect. This circumstance is lost sight of in all the facts which this philosopher has adduced. It may, however, be observed, that Leibnitz, as well as his followers, holds no difference of opinion in all the consequences which are deduced from the measure which is here adopted. They admit, that a force producing an uniformly accelerated motion must be constant; they agree with the followers of Des Cartes in the valuations both of accelerating and deflecting forces; and have assiduously and successfully cultivated the philosophy of Newton, which proceeds on the principle of estimating the measure of moving forces by the velocity generated.

Moving

131. It ought here to be observed, that *moving forces* only are taken into consideration. When a ball has acquired a certain velocity, whether it has been impelled by the elasticity of the air, by a spring, or struck off by a blow, or urged forward by means of a stream of air or water, or has obtained its velocity by falling; in all these cases it is conceived that it has sustained the same action of moving force. The only distinct notion, perhaps, which we are able to form, is pressure; but

but it is from experience that we derive the information that pressure produces motion. Whatever may be the difference of the circumstances of mechanical forces, in one, namely, production of motion, they all agree. In this circumstance of resemblance they are capable of comparison; and from this they derive a name, *moving force*, which is expressive of this comparison. And therefore the particular faculty of pressure, elasticity, &c. may be measured by the change of motion produced by pressure. In whatever proportion pressure may act on a body in a state of rest, the magnitude of the change of motion measures the pressure actually exerted in its production; and as this is the only change of mechanical condition effected by the pressure in the body moved by it, it may be measured by the velocity. When, therefore, pressure produces the same change of velocity on a soft clay ball, the pressure really exerted is the same whether the velocity has been augmented or diminished. In both cases the same dimple will be observed. The changes of motion, therefore, are proportional to the exerted pressures.

132. The notions which we form of a constant or invariable force lead to the same conclusion. By such a force equal effects or changes of motion are produced in equal times. But equal augmentations of motion are equal augmentations of velocity. This notion of an invariable accelerating force is confirmed by what is observed in the case of a falling body, which receives equal additions of velocity in equal times; and this force, so far as we know, is invariable. The inference then is, that whatever be the force exerted in one second, it will be four times as much in four seconds. And this is really the case, if it be granted that a quadruple velocity is the indication of a quadruple force; but it does not hold in any other estimation of force. Besides, it may be observed, that four springs applied to an ounce ball impel it only twice as fast as one spring does; and if the same four springs be applied to a four-ounce ball, they produce in it the same velocity that one spring produces on an ounce ball. In the last case, it may be demonstrated, that the four springs act during the same time with one spring.

133. The proper measure, therefore, of a changing force is a change of motion in all its circumstances of velocity and direction. This also is the proper measure of a moving force. For, in different states of motion, bodies may sustain the same change of motion. Supposing then one of these bodies to be previously in a state of rest, the change and the motion acquired are the same thing. The force, therefore, producing a change of motion in a moving body, is precisely the same with that force which produces in a body, previously at rest, a motion equivalent to this change; and in this case it is simply a moving force.

This opinion of Leibnitz about the measure of forces has influenced the sentiments of many writers, and in the mechanical investigations of some of them, has not a little affected their practical deductions. No dispute probably could have occurred if philosophers had not been led to consider force as something existing in body; the term on the contrary being only used to express the phenomenon, which is conceived to be its full effect and adequate measure. The simple change of motion observed is the measure of the force by which it is produced.

The following is the enunciation, adapted to the characteristic and measure of a change of motion.

Law of the Changes of Motion.

PROP. XII.

134. *In every change of motion, the new motion is compounded of the former motion, and of the motion which the changing produces in a body at rest.*

Let the change of motion be from AB (fig. 23.) to AD, this new motion AD is compounded of the former motion AB and of the motion AC. Fig. 23.

For it has been shewn, that the change in any motion, is that motion, which when compounded with the former motion, produces the new motion; and the new motion (55.) is the compound of the former motion and the changing motion. Since then the change of motion is the mark and measure of the changing force (133.) by which both the direction and intensity or velocity produced, are determined, the truth of the proposition will appear of course.

135. It has been already observed (54.), that the composition of motions and the similar composition of forces are very different things. The first is a pure mathematical truth; the second, is a physical question dependent on the nature of the mechanical forces as they exist in the universe. Our notions are not very distinct of two forces, each of which separately produces motions, having the directions and velocities expressed by the sides of a parallelogram, producing by their joint action a motion in the diagonal. The demonstrations which have been frequently given, are altogether inconclusive, and only include the composition of motions; while gratuitous postulates have been assumed by those who endeavoured to accommodate their reasonings to physical principles. The celebrated Daniel Bernoulli gave the first legitimate demonstration of this proposition, in which, however, he employs a series of many propositions, some of which are very abstruse. It was greatly simplified by D'Alembert, *Mem. Acad. des Sciences* 1769, still, however, requiring many propositions. Ingenious demonstrations have also been given by other celebrated mechanicians. In the following demonstration by Professor Robison, this distinguished philosopher has attempted to combine the demonstration of Bernoulli, D'Alembert, and others, thus rendering it more expeditious, and at the same time legitimate. This demonstration is entirely limited to pressures, without at all considering or employing the motions supposed to be produced by them.

(A) If two equal and opposite pressures or incitements to motion act at once on a material particle, it suffers no change of motion; for if it yields in either direction by their joint action, one of the pressures prevails, and they are not equal.

Equal and opposite pressures are said TO BALANCE each other; and such as balance must be esteemed equal and opposite.

(B) If a and b are two magnitudes of the same kind, proportional to the intensities of two pressures which act in the same direction, then the magnitude $a+b$ will measure the intensity of the pressure, which is equivalent, and may be called equal, to the combined effort of the other two; for when we try to form a notion of pressure as a measurable magnitude, distinct from motion

tion or any other effect of it, we find nothing that we can measure it by but another pressure. Nor have we any notion of a double or triple pressure different from a pressure that is equivalent to the joint effort of two or three equal pressures. A pressure a is accounted triple of a pressure b, if it balances three pressures, each equal to b, acting together. Therefore, in all proportions which can be expressed by numbers, we must acknowledge the legitimacy of this measurement; and it would surely be affectation to omit those which the mathematicians call *incommensurable*.

The magnitude $a—b$, in like manner, must be acknowledged to measure that pressure which arises from the joint action of two pressures a and b acting in opposite directions, of which a is the greatest.

Fig. 24. (C) Let ABCD and AbCd (fig. 24.) be two rhombuses, which have the common diagonal AC. Let the angles BAb, DAd, be bisected by the straight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each side of EA and FA, and if Gg, Hh be drawn, cutting the diagonal AC in I and L: then AI+AL will be greater or less than AQ, the half of AC, according as the angles GEH, gFh, are greater or less than GAH gAh.

Draw GH, gh, cutting AE, AF, in O and o, and draw Oo, cutting AC in K.

Because the angles AEG and EAG are respectively equal to AEH and EAH, and AE is common to both triangles, the sides AG, GE are respectively equal to AH, HE, and GH is perpendicular to AE, and is bisected in O; for the same reasons, gh is bisected in o. Therefore the lines Cg, Oo, Hh, are parallel, and IL is bisected in K. Therefore AI+AL is equal to twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI+AL is greater than AQ; and if the angle GEH be less than GAH, AI+AL is less than AQ.

Fig. 25. (D) Two equal pressures, acting in the directions AB and AC (fig. 25.) at right angles to each other, compose a pressure in the direction AD, which bisects the right angle; and its intensity is to the intensity of each of the constituent pressures as the diagonal of a square to one of the sides. It is evident, that the direction of the pressure, generated by their joint action, will bisect the angle formed by their directions; because no reason can be assigned for the direction inclining more to one side than to the other.

In the next place, since a force in the direction AD does, in fact, arise from the joint action of the equal pressures AB and AC, the pressure AB may be conceived as arising from the joint action of two equal forces similarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of these forces must be directed along AD, and the other along AE. In like manner, the pressure AC may arise from the joint action of a pressure in the direction AD, and an equal pressure in the direction AF. It is also plain that the pressures in the directions AE and AF, and the two pressures in the direction AD, must be all equal. And also any one of them must have the same proportion to AB or to AC, that AB or AC has to the force in the direction AD, arising from their joint action.

Therefore, if it be said that AD does not measure the pressure arising from the joint action of AB and AC, let Ad, greater than AD, be its just measure, and make Ad : AB=AB : Ag=AB : Ae. Then Ag and Ae have the same inclination and proportion to AB that AB and AC have to Ad. We determine, in like manner, two forces Af and Ag as constituents of AC.

Now Ad is equivalent to AB and AC, and AB is equivalent to Ae and Ag; and AC is equivalent to Af, and Ag. Therefore Ad is equivalent to Ae, Af, Ag, and Ag. But Ae and Af balance each other, or annihilate each other's effect; and there remain only the two forces or pressures Ag, Ag. Therefore their measure is a magnitude equal to twice Ag. But if Ad be greater than the diagonal AD of the square, whose sides are AB and AC; then Ag must be less than AI, the side of the square whose diagonal is AB. But twice Ag is less than AD, and much less than Ad. Therefore the measure of the equivalent of AB and AC cannot be a line Ad greater than AD. In like manner it cannot be a line Aδ that is less than AD. Therefore it must be equal to AD, and the proposition is demonstrated.

COROLLARY.

(E) Two equal forces AB, AC, acting at right angles, will be balanced by the force AO, equal and opposite to AD, the diagonal of the square whose sides are AB and AC; for AO would balance AD, which is the equivalent of AB and AC.

Fig. 26. (F) Let AECF (fig. 26.) be a rhombus, the acute angle of which EAF is half of a right angle. Two equal pressures, which have the directions and measures AE, AF, compose a pressure, having the direction and measure AC, which is the diagonal of the rhombus.

It is evident, in the first place, that the compound force has the direction AC, which bisects the angle EAF. If AC be not its just measure, let it be AP less than AC. Let ABCD be a square described on the same diagonal, and make AP : AQ=AE : AO, =AF : Ao. Draw KOG, Kog perpendicular to AE, AF; draw GIg, OHo, EG, EK, Fg, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Also the figures AEPF and AGEK are similar, because AP : AQ=AE : AO. Therefore FA : AP=KA : AE, and FA : AP=GA : AE. Therefore, in the same manner that the forces AE, AF are affirmed to compose AP, the forces AG and AK may compose the force AE, and the forces Ag and AK may compose the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, Ag, AK. But (D) AG and Ag are the sides of a square, whose diagonal is equal to twice AI: and the two forces AK, AK are equal to, or are measured by, twice AK. Therefore the four forces AG, AK, Ag, AK, are equivalent to 2 AI+2 AK, = 4 AH.

But because AP was supposed less than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2 AH is greater than AQ; and therefore 4 AH is greater than AC, and much greater

than

than AP. Therefore AP is not the just measure of the force composed of AE and AF.

In like manner, it is shewn, that AE and AF do not compose a force whose measure is greater than AC. It is therefore equal to AC; and the proposition is demonstrated.

(*G*) By the same process it may be demonstrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compose a force measured by AC. And the process may be repeated for a rhombus whose acute angle is one-eighth, one-sixteenth, &c. of a right angle; that is, any portion of a right angle that is produced by continual bisection. Two forces, forming the sides of such a rhombus, compose a force measured by the diagonal.

Fi 27.

(*H*) Let ABCD, A *b c d* (fig. 27.) be two rhombuses formed by two consecutive bisections of a right angle. Let AECF be another rhombus, whose sides AE and AF bisect the angles BA*b* and DA*d*.

The two forces AE, AF, compose a force AC.

Bisect AE and AF in O and *o*. Draw the perpendiculars GOH, *g o h*, and the lines GI*g*, OK *o*, HL *h*, and the lines EG, EH, F*g*, F*h*.

It is evident, that AGEH and A *g* F *h* are rhombuses; because AO=OE, and A *o*=*o* F. It is also plain, that since *b* A *d* is half of BAD, the angle GAH is half of *b* A *d*. It is therefore formed by a continual bisection of a right angle. Therefore (*G*) the forces AG, AH, compose a force AE; and A*g*, A *h*, compose the force AF. Therefore the forces AG, AH, A*g*, A *h*, acting together, are equivalent to the forces AE, AF acting together. But AG, A *g* compose a force = 2 AI; and the forces AH, A *h* compose a force = 2 AL. Therefore the four forces acting together are equivalent to 2 AI+2 AL, or to 4 AK. But because AO is $\frac{1}{2}$ AE, and the lines G*g*, O*o*, H*h*, are evidently parallel, 4 AK is equal to 2 AQ, or to AC; and the proposition is demonstrated.

Corollary.

(*I*) Let us now suppose, that by continual bisection of a right angle we have obtained a very small angle *a* of a rhombus; and let us name the rhombus by the multiple of *a* which forms its acute angle.

The proposition (*G*) is true of *a*, 2 *a*, 4 *a*, &c. The proposition (*H*) is true of 3 *a*. In like manner, because (*G*) is true of 4 *a* and 8 *a*, proposition (*H*) is true of 6 *a*; and because it is true of 4 *a*, 6 *a*, and 8 *a*, it is true of 5 *a* and 7 *a*. And so on continually till we have demonstrated it of every multiple of *a* that is less than a right angle.

ite' LXXVI fig. 28.

(*K*) Let RAS (fig. 28.) be perpendicular to AC, and let ABCD be a rhombus, whose acute angle BAD is some multiple of 2 *a* that is less than a right angle. Let A *b c d* be another rhombus, whose sides A *b*, A *d* bisect the angles RAB, SAD. Then the forces A *b* A *d* compose a force AC.

Draw *b* R, *d* S parallel to BA, DA. It is evident, that AR *b* B and AS *d* D are rhombuses, whose acute angles are multiples of *a*, that are each less than a right angle: Therefore (*I*) the forces AR and AB compose the force A *b*, and AS, AD compose A *d*; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore A *b* and A *d* are equivalent to AB and AD, which compose the force AC; and the proposition is demonstrated.

Corollary.

(*L*) Thus is the corollary of last proposition extended to every rhombus, whose angle at A is some multiple of *a* less than two right angles. And since *a* may be taken less than any angle that can be named, the proposition may be considered as demonstrated of every rhombus; and we may say,

(*M*) *Two equal forces, inclined to each other in any angle, compose a force which is measured by the diagonal of the rhombus, whose sides are the measures of the constituent forces.*

Fig. 29.

(*N*) Two forces AB, AC (fig. 29.) having the direction and proportion of the sides of a rectangle, compose a force AD, having the direction and proportion of the diagonal.

Draw the other diagonal CB, and draw EAF parallel to it; draw BE, CF parallel to DA.

AEBG is a rhombus; and therefore the forces AE and AG compose the force AB. AFCG is also a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together: But AE and AF annihilate each other's action, being opposite and equal (for each is equal to the half of BC). Therefore AB and AC acting together, are equivalent to AD, or compose the force AD.

Fig. 30.

(*O*) Two forces, which have the direction and proportions of AB, AC (fig. 30.) the sides of any parallelogram, compose a force, having the direction and proportion of the diagonal AD.

Draw AF perpendicular to BD, and BG and DE perpendicular to AC.

Then AFBG is a rectangle, as is also AFDE: and AG is equal to CE. Therefore, (*N*) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting together; that is, to AF and AE acting together; that is (*N*) to AD; or the forces AB and AC compose the force AD.

Hence arises the most general proposition.

Composition of all incitements to motion.

If a material particle be urged at once by two pressures or incitements to motion, whose intensities are proportional to the sides of any parallelogram, and which act in the directions of those sides, it is affected in the same manner as if it were acted on by a single force, whose intensity is measured by the diagonal of the parallelogram, and which acts in its direction: Or, two pressures, having the direction and proportion of the sides of a parallelogram, generate a pressure, having the direction and proportion of the diagonal.

136. Thus is demonstrated from abstract principles the perfect similarity of the composition of pressures and the composition of forces measured by the motions which are produced. A separate demonstration seems indispensably necessary; for what may be deduced from the one case is not always applicable to the other. The change produced on a motion already existing by a deflecting force, cannot be explained by any composition of pressure; because the changing pressure is the only one that exists, and there is none with which it may be compounded.

compounded. Nor, on the other hand, will our notions of the composition of motions explain the composition of pressures, without assuming that the pressures are proportional to the velocities.

137. Considering this law of motion merely as a universal fact or physical law, abundant proof may be adduced in support of it.

1. The joint action of different forces is quite familiar. A lighter, for example, is dragged in different directions by two ropes on different sides of the canal, the lighter moving in an intermediate direction, as if dragged in that direction by one rope only. A ball moving in a particular direction, which receives a stroke across this direction, takes a direction lying between that of the first motion and that of the transverse stroke.

Fig. 23. 2. If a particle of matter A (fig. 23.) be urged at once by two pressures in the directions AB and AC; and if AB and AC be proportional to the intensities of those pressures, the joint action of these two pressures is equivalent to the action of a third pressure in the direction of the diagonal AD, and having its intensity in the proportion of AD. This is proved by observing, that the point A is withheld from moving by a pressure AE, which is equal and opposite to AD. But pressures are moving forces, producing velocities when they act similarly during equal times, proportional to their intensities. The proportion, therefore, is true with respect to pressures, considered merely as such, and also with respect to the motions which may be produced by their composition.

3. The weight of a ball which is suspended by a thread, and drawn aside from its position in a state of rest, urges it downwards, and the ball is supported obliquely by the thread. Supposing this proposition to be true, the directions and intensities of the forces inciting it to motion in any position, as well as the result of the velocities, can be precisely ascertained.

4. The motions of the planets, computed on these principles of the composition of forces, do not exhibit any perceptible deviation from calculation, at the end of thousands of years.

Nothing, therefore, can be relied on with greater confidence than the perfect agreement between the composition of motions, and the composition of the forces, which, separately taken, would produce those motions, and which are measured by the velocities produced. But it ought to be remarked, that if the moving forces are measured by the squares of the velocities which they generate, the composition cannot possibly hold; namely, from two forces which are represented by the sides of a parallelogram made proportional to the squares of the velocities, there will not result a force which can be represented by the diagonal. But supposing the composition of forces to be as the velocities, nature exhibits them exactly.—This proposition, therefore, whether it be considered as an abstract truth or as a physical law, may be received as fully established. The following is the converse of this proposition.

Prop. XIII.

Fig. 23. 138. *The force by which the motion* AB (fig. 23.) *is changed into* AD, *is that which would produce in a body at rest, the motion* AC, *and this compounded with* AB *produces the observed motion* AD.

Prop. XIV.

139. *The force which will produce in a body at rest a motion having the direction and velocity represented by* AC, (fig. 23.) *when applied to a body moving with the velocity and in the direction* AB, *will change its motion into the motion* AD, *which is the diagonal of the parallelogram* ABDC. For the new motion must be that which is compounded of AB and AC, that is, it must be the motion AD. Fig. 23.

The combination of these two propositions gives rise to the following, which is still more general.

Prop. XV.

140. *A body* A (fig. 23.) *being urged at once by two forces which separately would cause it to describe* AB *and* AC, *the sides of a parallelogram* ABDC, *the body by their joint action will describe the diagonal* AD *in the same time.* Fig. 23.

For if the body had been already moving with the velocity and in the direction AB, and if it had been acted on in A by the force AC, it would describe AD in the same time. But it matters not at what time it acquired the determination to describe AB. Let it be then at the instant that the force AC is applied to it. And because its mechanical condition in A, which has the determination to the motion AB, is the same as in any other point of that line, it must describe AD.

Corollary.

Two forces acting on a body in the same or in opposite directions, will cause it to move with a velocity equal to the sum or to the difference of the velocities which it would have received from the forces separately. For if AC (fig. 23.) approach continually to AB by diminishing the angle BAC, the points C and D will at last fall on *c* and *d*, and then AD is equal to the sum of AB and AC. But if the angle BAC increase continually, the points C and D will at last fall on κ and δ, and then Aδ becomes equal to the difference of AB and AC. In the last case, it is evident, that if AC be equal to AB, the point D or δ will coincide with A, and the two forces being equal, and acting in opposite directions, there will be no motion. Fig. 23.

141. In such cases the equal and opposite forces AC and AB are said to *balance* each other; and it is generally said, that these forces, by whose joint operation no change of motion is produced, balance each other. Such forces are accounted equal and opposite, each producing on the body a change of motion equal to what it would produce on a body at rest, and at the same time equal to the motion produced by the other force on a body at rest. The two motions being equal and opposite, the forces are therefore equal and opposite.

142. What has been demonstrated concerning the affections with respect to the affections of compound motions, may now be applied to the combination of forces; taking care, however, to recollect the essential difference between the composition of motions and the composition of forces. In the combination of forces, the composition is complete, when the determination has been given to the body to move with the proper velocity in the diagonal. When the body has acquired this determination there is no farther composition; and it continues its uniform motion, till its condition be changed

changed by some new force. On the other hand, in the composition of two or more motions, the constituent motions are supposed to continue; and it is only during their continuance that the compound motion exists. If it be possible, which does not appear to be the case, that any force can generate a finite velocity by its instantaneous action, two such forces generate in an instant the determination in the diagonal. But supposing the action to continue for some time, to generate the velocities AB or AC, there must be a continuance of the joint action during the same time to produce the velocity AD. And although the moving powers of the two forces may vary in their intensity, yet it is necessary that they retain the same proportion to each other during the whole time of their joint action. Overlooking this circumstance, experiments have been made for the purpose of comparing this doctrine with the phenomena; and they have been found to exhibit very different results. But experiments made by the combination of pressures, such as weights pulling a body by means of threads, coincide precisely with this doctrine; for it is always found that two weights pulling in the directions AB, AC, and proportional to those lines, are balanced by a third weight in the proportion of AD, and pulling in the direction AE. In this way the composition of pressures is clearly proved; and having no other distinct conception of a moving force, these experiments may be considered as sufficient. But we may go farther; for there is the clearest proof by experiment, that pressures produce motions in proportion to their intensities by their similar action during equal times. In the planetary motions, the directions and intensities of the compound forces are accurately known as moving forces. These motions afford a complete proof of the physical law, by their perfect coincidence with the calculations which proceed on the principles of this doctrine. This coincidence must be acknowledged as a full proof of the propriety of the measure which has been assumed. The assumption of any other measure would exhibit results quite different from the phenomena.

143. Forces which produce motions along the sides of a parallelogram are called *simple forces* or *constituent forces*. And the force which singly produces the motion in the diagonal, is called the *equivalent force*, the *compound force*, or the *resulting force*.

144. Some general conclusions may now be pointed out, which will facilitate greatly the use of the parallelogram of forces.

GENERAL COROLLARIES.

1. The constituent and the resulting forces, or the simple and compound forces, act in the same plane; for the sides and diagonal of a parallelogram are in one plane.

2. The simple and the compound forces are proportional to the sides of any triangle which are parallel to their directions. For if any three lines *ab*, *bd*, *ad*, be drawn parallel to AB, AC, and AD (fig. 31.), they will form a triangle similar to the triangle ABD. For the same reasons they are proportional to the sides of a triangle *a'b'd*, which are respectively perpendicular to their directions.

Fi 31.

3. Therefore each is proportional to the sine of the opposite angle of this triangle; for the sides of any triangle are proportional to the sines of the opposite angles.

4. Each is proportional to the sine of the angle contained by the directions of the other two; for AD is to AB as the sine of the angle ABD to the sine of the angle ADB. Now the sine of ABD is the same with the sine of BAC contained between the directions AB and AC, and the sine of ADB is the same with the sine of CAD; also AB is to AC, or BD, as the sine of ADB (or CAD) to the sine of BAD.

Special uses of the parallelogram of forces.

145. Let us now proceed to the application of this fundamental proposition. And we observe, in the first place, that since AD may be the diagonal of an indefinite number of parallelograms, the motion or the pressure AD may result from the joint actions of many pairs of forces. It may be produced by forces which would separately produce the motions AF and AG. This generally gives us the means of discovering the forces which concur in its production. If one of them, AB, is known in direction and intensity, the direction AC, parallel to BD, and the intensity, are discovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is had by simply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is such as would have caused the body move from B to D in the same time. And, in the same manner, we get the compound motion AD, which arises from any two simple motions AB and AC, by supposing both of the motions to be accomplished in succession. The final place of the body is the same, whether it moves along AD or along AB and BD in succession.

Equivalent of many forces.

146. This theorem is not limited to the composition of two forces only; for since the combined action of two forces puts the body into the same state as if their equivalent alone had acted on it, we may suppose this to have been the case, and then the action of a third force will produce a change on this equivalent motion. The resulting motion will be the same as if only this third force and the equivalent of the other two had acted on the body. Thus, in fig. 32. the three forces AB, AC, AE, may act at once on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force resulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force resulting from the combined action of AB, AC, AE, and AG, and so on of any number of forces.

Fig. 32.

This resulting force and the resulting motion may be much more expeditiously determined, in any degree of composition, by drawing lines in the proportion and direction of the forces in succession, each from the end of the preceding. Thus draw AB, BD, DF, FH, and join AH; AH is the resulting force. The demonstration is evident.

147. In the composition of more than two forces, we are not limited to one plane. The force AD is in the same plane with AB and AC; but AE may be elevated above this plane, and AG may lead below it.

Of Moving Forces

AF is in the plane of AD and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence we derive a more general and very useful theorem.

Three forces having the proportion and direction of the three sides of a parallelopiped, compose a force having the proportion and direction of the diagonal.

148. In the investigation of very complicated phenomena, the mechanician considers every force as resulting from the joint action of three forces at right angles to each other, and he takes the sum or difference of these in the same or opposite directions. Thus he obtains the three sides of a parallelopiped, and from these computes the position and magnitude of the diagonal. This is the force resulting from the composition of all the partial ones. This process is called the *estimation* or *reduction of forces*. Forces may be estimated in the direction of a given line or plane, or they may be reduced to that direction, as has been done with respect to motion. See Cor. 2. Propos. 9. in art. 57.

The laws of motion which have now been considered, are necessary consequences of the relations of those conceptions which we form of motion and mechanical force, and they are universal facts or physical laws. To these Sir Isaac Newton has added another, which is the following.

Third Law of Motion.

149. *Every action is accompanied by an equal and contrary reaction, or the actions of bodies on one another are always mutual, equal, and in contrary directions.*

In all cases which can be accurately examined, this holds to be a universal fact. Newton has made this affirmation on the authority of what he conceives to be a law of human thought; namely, that the qualities discovered in all bodies on which experiments and observations can be made, are to be considered as universal qualities of body. But if the term law of motion be limited to those consequences that necessarily flow from our notions of motion, of the causes of its production and changes, this proposition is not such a result. Because a magnet causes the iron to approach toward it, it by no means follows, from this observation, that the pressure of the iron shall be accompanied by any motion or change of state of the magnet, or it does not appear to be necessarily supposed that the iron attracts the magnet. When this was observed, it was accounted a discovery, and a discovery which is to be ascribed to the moderns. Dr Gilbert, who first mentions it, affirms that the magnet and the iron are observed mutually to attract each other, as well as all electrical substances, and the light bodies which are attracted by them. The discovery was made by Kepler, that a mutual attraction exists between the earth and the moon. Newton discovered that the sun acts on the planets, and that the earth acts on the moon. It had been observed too by Newton that the iron reacts on the magnet, that the actions of electrified bodies are mutual, and that all the actions of solid bodies are accompanied by an equal and contrary reaction. On the authority of the rule of philosophizing which he had laid down, he affirmed that the planets react on the sun, and that the sun is not at rest, but is continually agitated by a small motion round the general centre of gravitation; and he pointed out several of the consequences of this reaction. As the celestial motions were more narrowly examined by astronomers, these consequences were found to obtain, and to produce disturbances in the planetary motions. This reciprocity of action is now found to hold with the utmost precision through the whole of the solar system; and therefore this third proposition of Newton is to be considered as a law of nature. And it is true with respect to all bodies on which experiment or observation can be made.

150. This then being a universal law, we cannot divest our minds of the belief that it depends on a general principle, by which all the matter in the universe is influenced. It strongly induces the persuasion of the ultimate particles of matter being alike, that a certain number of properties belong in the same degree to each atom, and that all the sensible differences of substance which are observed, arise from a different combination of those primary atoms in the formation of a particle of those substances. All this is no doubt perfectly possible. But if each primary atom be so constituted, no action of any kind of particle or collection of particles can take place on another, which is not accompanied by an equal reaction in the opposite direction.

151. Let us now direct our attention to the application of these laws. This answers a twofold purpose. The first is to discover the mechanical powers of natural substances by which they are fitted to become parts of a permanent universe. This is accomplished by observing the changes of motion which always accompany those substances. It is from those changes that the only characteristics of power are derived; and thus is discovered the power of gravity, of magnetism, &c. Another purpose in the employment of these laws is, that, after having obtained the mechanical character of any substance, we may ascertain what will be the result of its being in the vicinity of the bodies mechanically allied, or we may ascertain what is the change induced on the condition of the neighbouring bodies.

152. The mechanical powers of bodies occasionally produce accelerations, retardations, and deflections in the motions of other bodies. These names have been given, because nothing is known of their nature, or of the manner in which they are effective; they are therefore named, as they are measured by the phenomena which are observed and considered as their effects. Let us now attend a little to the principal circumstances relating to the action of these forces.

Of Accelerating and Retarding Forces.

153. Changes of motion are the only marks and measures of changing forces; and having no other mark of the force but the acceleration, it has obtained the name of an *accelerating force*. When the motion is retarded, it is called *retarding force*. Nor is there any other measure of the intensity of an accelerating force, but the acceleration which it produces. To investigate therefore the powers which produce all the changes of motion, it is necessary to obtain measures of the acceleration. What has been said of accelerations and retardations of motion is equally descriptive of the effects of accelerating and retarding forces. Hence the following proposition.

If the abscissa a d, fig. 5. *represent the time of and motion, and if the areas* a b f e, a c g e, &c. *are as the velocities at the instants* b c, &c. *the ordinates* a e, b f, c g, &c. *are as the accelerating forces at those instants.*

COROLLARIES.

Cor. 1. The momentary change of velocity is as the force *f* and the time *t* jointly. It may be thus expressed,

$$\dot{v}, \text{ or } -\dot{v} \doteqdot f\dot{t}.$$

Also, the accelerating or retarding force is proportional to the momentary variation of the velocity, directly, and to the moment of time in which it is generated, inversely (48.)

$$f \doteqdot \frac{\dot{v}}{\dot{t}}, \text{ or } \doteqdot \frac{-\dot{v}}{\dot{t}}.$$

Indeed all that we know of force is that it is something which is always proportional to $\frac{\dot{v}}{\dot{t}}$.

Cor. 2. *Uniformly accelerated or retarded motion is the indication of a constant or invariable accelerating force.* For, in this case, the areas *a b f e*, *a c g e*, &c. increase at the same rate with the times *a b*, *a c*, &c. and therefore the ordinates *a e*, *b f*, *c g*, &c. must all be equal; therefore the forces represented by them are the same, or the accelerating force does not change its intensity, or, it is constant. If, therefore, the circumstances mentioned in articles 37 and 38, are observed in any motion, the force is constant. And if the force is known to be constant, those propositions are true respecting the motions.

Cor. 3. *No finite change of velocity is generated in an instant by an accelerating or retarding force.* For the increment or decrement of velocity is always expressed by an area, or by a product $f\dot{t}$, one side or factor of which is a portion of time. As no finite space can be described in an instant, and the moveable must pass in succession through every point of the path, so it must acquire all the intermediate degrees of velocity. It must be *continually* accelerated or retarded.

Cor. 4. The change of velocity produced in a body in any time, by a force varying in any manner, is the proper measure of the accumulated or whole action of the force during this time. For, since the momentary change of velocity is expressed by $f\dot{t}$, the aggregate of all these momentary changes, that is, the whole change of velocity, must be expressed by the sum of all the quantities $f\dot{t}$. This is equivalent to the area of the figure employed in art. 148, and may be expressed by $\int f\dot{t}$.

154. *If the abscissa* AE (fig. 8.) *of the line* a c e *be the path along which a body is urged by the action of a force, varying in any manner, and if the ordinates* A *a*, B *b*, C *c*, &c. *be proportional to the intensities of the force in the different points of the path, the intercepted areas will be proportional to the changes made on the square of the velocity during the motion along the corresponding portions of the path.*

For, by art. 49. the areas are in this proportion when the ordinates are as the accelerations. But the accelerations are the measures of, and are therefore proportional to, the accelerating forces. Therefore the proposition is manifest.

COROLLARY.

Of Moving Forces.

The momentary change on the square of the velocity is as the force, and as the small portion of space along which it acts, jointly;

$$v\dot{v} \doteqdot f\dot{s}$$

and

$$f \doteqdot \frac{v\dot{v}}{\dot{t}}.$$

155. It deserves remark here, that as the momentary change of the simple velocity by any force *f* depends only on the time of its action, it being $= f\dot{t}$ (148.) Cor. 1. so the change on the square of the velocity depends on the space, it being $= f\dot{s}$. It is the same, whatever is the velocity thus changed, or even though the body be at rest when the force begins to act on it. Thus, in every second of the falling of a heavy body, the velocity is augmented 32 feet per second, and, in every foot of the fall, the square of the velocity increases by 64.

156. The whole area AE *e a*, expressed by $\int f\dot{s}$, expresses the whole change made on the square of the velocity which the body had in A, whatever this velocity may have been. We may therefore suppose the body to have been at rest in A. The area then measures the square of the velocity which the body has acquired in the point E of its path. It is plain that the change on v^2 is quite independent on the time of action, and therefore a body, in passing through the space AE with any initial velocity whatever, sustains the same change of the square of that velocity, if under the influence of the same force.

157. This proposition is the same with the 39th of the First Book of Newton's Principia, and is perhaps the most generally useful, of all the theorems in Dynamics, in the solution of practical questions. It is to be found, without demonstration, in his earliest writings, the Optical Lectures, which he delivered in 1669 and following years.

158. One important use may be made of it at present. It gives a complete solution of all the facts which were observed by Dr Hooke, and adduced by Leibnitz with such pertinacity in support of his measure of the force of moving bodies. All of them are of precisely the same nature with the one mentioned in art. 157, or with the fact, "that a ball projected directly upwards "with a double velocity, will rise to a quadruple height, "and that a body, moving twice as fast, will penetrate "four times as far into a uniformly tenacious mass." The uniform force of gravity, or the uniform tenacity of the penetrated body, makes a uniform opposition to the motion, and may therefore be considered as a uniform retarding force. It will therefore be represented, in fig. 8. by an ordinate always of the same length, and the areas which measure the square of the velocity lost will be portions of a rectangle AE *e a*. If therefore AE be the penetration necessary for extinguishing the velocity 2, the space AB, necessary for extinguishing the velocity 1, must be $\frac{1}{4}$ of AE, because the square of 1 is $\frac{1}{4}$ of the square of 2.

159. What particularly deserves remark here, is, that this proposition is true, *only on the supposition that forces are proportional to the velocities generated by them in equal times.* For the demonstration of this proposition proceeds entirely on the previously established measure

of acceleration. We had $\dot{v} \doteqdot f \dot{t}$; therefore $v \dot{v} \doteqdot f \dot{t} v$. But $\dot{t} v \doteqdot \dot{s}$; therefore $v \dot{v} \doteqdot f \dot{s}$, which is precisely this proposition.

160. Those may be called *similar* points of space, and *similar* instants of time, which divide given portions of space or time in the same ratio. Thus, the beginning of the 5th inch, and of the 2d foot, are similar points of a foot, and of a yard. The beginning of the 21st minute, and of the 9th hour, are similar instants of an hour, and of a day.

Forces may be said to act *similarly* when, in similar instants of time, or similar points of the path, their intensities are in a constant ratio.

Fig. 33. 161. *Lemma.* If two bodies be similarly accelerated during given times $a c$ and $h k$ (fig. 33.), they are also similarly accelerated along their respective paths AC and HK.

Let a, b, c, be instants of the time ac, similar to the instants h, i, k of the time $h k$. Then by the similar accelerations, we have the force $a e : h l = b f : i m$. This being the case throughout, the area $a f$ is to the area $h m$ as the area $a g$ to the area $h n$. These areas are as the velocities in the two motions (48.) Therefore the velocities in similar instants are in a constant ratio, that is, the velocity in the instant b is to that in the instant i, as the velocity in the instant c to that in the instant k.

The figures may now be taken to represent the times of the motion by their abscissæ, and the velocities by their ordinates, as in art. 28. The spaces described are now represented by the areas. These being in a constant ratio, as already shewn, we have A, B, C, and H, I, K, similar points of the paths. And therefore, in similar instants of time, the bodies are in similar points of the paths. But in these instants, they are similarly accelerated, that is, the accelerations and the forces are in a constant ratio. They are therefore in a constant ratio in similar points of the paths, and the bodies are similarly accelerated along their respective paths (155.).

162. *If two particles of matter are similarly urged by accelerating or retarding forces during given times, the whole changes of velocity are as the forces and times jointly; or* v $\doteqdot$ ft.

For the abscissæ $a c$ and $h k$ will represent the times, and the ordinates $a e$ and $h l$ will represent the forces, and then the areas will represent the changes of velocity, by art. 47. And these areas are as $a c \times a e$ to $h k \times h l$.

Hence $t \doteqdot \frac{v}{f}$, and $f \doteqdot \frac{v}{t}$.

163. *If two particles of matter are similarly impelled or opposed through given spaces, the changes in the squares of velocity are as the forces and spaces jointly; or* $\doteqdot$ f s.

This follows, by similar reasoning, from art. 49.

It is evident that this proposition applies directly to the argument so confidently urged for the propriety of the Leibnitzian measure of forces, namely, that four springs of equal strength, and bent to the same degree, generate, or extinguish only a double velocity.

164. *If two particles of matter are similarly impelled through given spaces, the spaces are as the forces and the squares of the times jointly.*

For the moveables are similarly urged during the times of their motion (converse of 156.). Therefore $v \doteqdot f t$, and $v^2 \doteqdot f^2 t^2$; but (158.) $v^2 \doteqdot f s$. Therefore $f s \doteqdot f^2 t^2$ and $s \doteqdot f t^2$.

COROLLARY.

$t^2 \doteqdot \frac{s}{f}$, and $f \doteqdot \frac{s}{t^2}$. That is, the squares of the times are as the spaces, directly, and as the forces, inversely; and the forces are as the spaces, directly, and as the squares of the times, inversely.

165. The quantity of motion in a body is the sum of the motions of all its particles. Therefore, if all are moving in one direction, and with one velocity v, and if m be the number of particles, or quantity of matter, $m v$ will express the quantity of motion q, or $q \doteqdot m v$.

166. In like manner, we may conceive the accelerating forces f, which have produced this velocity v in each particle, as added into one sum, or as combined on one particle. They will thus compose a force, which, for distinction's sake, it is convenient to mark by a particular name. We shall call it the MOTIVE FORCE, and express it by the symbol p. It will then be considered as the aggregate of the number m of equal accelerating forces f, each of which produces the velocity v on one particle. It will produce the velocity $m v$, and the same quantity of motion q.

167. Let there be another body, consisting of n particles, moving with one velocity u. Let the moving force be represented by π. It is measured in like manner by $n u$. Therefore we have, $p : \pi = m v : n u$, and $v : u = \frac{p}{m} : \frac{\pi}{n}$; that is,

The velocities which may be produced by the similar action of different motive forces, in the same time, are directly as these forces, and inversely as the quantities of matter to which they are applied.

In general, $\dot{v} \doteqdot \frac{p}{m}$.

And f being $= \frac{\dot{v}}{\dot{t}}$, $f \doteqdot \frac{p}{m \dot{t}}$.

REMARK.

168. In the application of the theorems concerning accelerating or retarding forces, it is necessary to attend carefully to the distinction between an accelerative and a motive force. The caution necessary here has been generally overlooked by the writers of Elements, and this has given occasion to very inadequate and erroneous notions of the action of accelerating powers. Thus, if a leaden ball hangs by a thread, which passes over a pulley, and is attached to an equal ball, moveable along a horizontal plane, without the smallest obstruction, it is known that, in one second, it will descend 8 feet, dragging the other 8 feet along the plane, with a uniformly accelerated motion, and will generate in it the velocity 16 feet per second. Let the thread be attached to three such balls. We know that it will descend 4 feet in a second, and generate the velocity 8 feet per second. Most readers are disposed to think that it should generate no greater velocity than $5\frac{1}{3}$ feet per second, or $\frac{1}{3}$ of 16, because it is applied to three times as much matter (162.). The

error

error lies in considering the motive force as the same in both cases, and in not attending to the quantity of matter to which it is applied. Neither of these conjectures is right. The motive force changes as the motion accelerates, and in the first case it moves two balls, and in the second it moves four. The motive force decreases similarly in both motions. When these things are considered, we learn by articles 202 and 207, that the motions will be precisely what we observe.

Of Deflecting Forces, in General.

169. It was observed, in art. 71, that a curvilineal motion is a case of *continual* deflection. Therefore, when such motions are observed, we know that the body is under the *continual* influence of some natural force, acting in a direction which crosses that of the motion in every point. We must infer the magnitude and direction of this deflecting force by the magnitude and direction of the observed deflection. Therefore, all that is affirmed concerning deflections in the 71st and subsequent articles, may be affirmed concerning deflecting forces. It follows, from what has been established concerning the action of accelerating forces, that no force can produce a finite change of velocity in an instant. Now, a deflection is a composition of a motion already existing with a motion accelerated from rest by insensible degrees. Supposing the deflecting force of invariable direction and intensity, the deflection is the composition of a motion having a finite velocity with a motion uniformly accelerated from rest. Therefore the linear deflection from the rectilineal motion must increase by insensible degrees. The curvilineal path, therefore, must have the line of undeflected motion for its tangent. To suppose any finite angle contained between them would be to suppose a polygonal motion, and a subsultory deflection.

Therefore *no finite change of direction can be produced by a deflecting force in an instant.*

170. The most general and useful proposition on this subject is the following, founded on art. 75.

The forces by which bodies are deflected from the tangents in the different points of their curvilineal paths are proportional to the squares of the velocities in those points directly, and inversely to the deflective chords of the equicurve circles in the same points. We may still express the proposition by the same symbol,

$$f \doteqdot \frac{v^2}{c},$$

where f means the intensity of the deflecting force.

171. We may also retain the meaning of the proposition expressed in article 76, where it is shewn that the actual linear deflection from the tangent is the third proportional to the deflective chord and the arch described in a very small moment. For it was demonstrated in that article (see fig. 18.) that BZ : BC=BC : BO.

We see also that B *b*, the double of BO, is the measure of the velocity, generated by the uniform action of the deflecting force, during the motion in the arch BC of the curve.

172. The art. 77. also furnishes a proposition of frequent and important use, viz.

The velocity in any point of a curvilinear motion is that which the deflecting force in that point would generate in the body by uniformly impelling it along the fourth part of the deflective chord of the equicurve circle.

Of Moving Forces.

REMARK.

137. The propositions now given proceed on the supposition that, when the points A and C of fig. 18. after continually approaching to B, at last coalesce with it, the last circle which is described through these three points has the same curvature which the path has in B. It is proper to render this mode of solving these questions more plain and palpable.

If ABCD (fig. 34.) be a material curve or mould, and a thread be made fast to it at D, this thread may be lapped on the convexity of this curve, till its extremity meets it in A. Let the thread be now unlapped or EVOLVED from the curve, keeping it always tight. It is plain that its extremity A will describe another curve line A *b c*. All curves, in which the curvature is neither infinitely great nor infinitely small, may be thus described by a thread evolved from a proper curve. The properties of the curve A *b c* being known, Mr Huyghens (the author of this way of generating curve lines) has shewn how to construct the evolved curve ABC which will produce it.

Fig. 34.

From this genesis of curves we may infer, 1st, that the detached portion of the thread is always a tangent to the curve ABC; 2dly, that when this is in any situation B *b*, it is perpendicular to the tangent of the curve A *b c* in the point *b*, and that it is, at the same time, describing an element of that curve, and an element of a circle *α b κ*, whose momentary centre is B, and which has B *b* for its radius. 3dly, That the part *b* A of the curve, being described with radii growing continually shorter, is *more* incurvated than the circle *b α*, which has B *b* for its constant radius. For similar reasons the arch *b c* of the curve A *b c* is *less* incurvated than the circle *α b κ*. 4thly, That the circle *α b κ* has the same curvature that the curve has in *b*, or is an equicurve circle. B *b* is the radius, and B the centre of curvature in the point *b*.

ABC is the CURVA EVOLUTA or the EVOLUTE. A *b c* is sometimes called the INVOLUTE of ABC, and sometimes its EVOLUTRIX.

174. By this way of describing curve lines, we see clearly that a body, when passing through the point *b* of the curve A *b c* may be considered as in the same state, in that instant, as in passing through the same point *b* of the circle *α b κ*; and the ultimate ratio of the deflections in both is that of equality, and they may be used indiscriminately.

The chief difficulty in the application of the preceding theorems to the curvilineal motions which are observed in the spontaneous phenomena of nature, is in ascertaining the direction of the deflection in every point of a curvilineal motion. Fortunately, however, the most important cases, namely those motions, where the deflecting forces are always directed to a fixed point, afford a very accurate method. Such forces are called by the general name of

Central Forces.

175. *If bodies describe circles with a uniform motion, the deflecting forces are always directed to the centres of the*

the circles, and are proportional to the square of the velocities, directly, and to their distances from the centre, inversely.

For, since their motion in the circumference is uniform, the areas formed by lines drawn from the centre are as the times, and therefore (72.) the deflections, and the deflecting forces (164.) are directed to the centre. Therefore, the deflective chord is, in this case, the diameter of the circle, or twice the distance of the body from the centre. Therefore, if we call the distance from the centre d, we have $f \doteqdot \frac{v^2}{d}$.

176. *These forces are also as the distances, directly, and as the square of the time of a revolution, inversely.*

For the time of a revolution (which may be called the PERIODIC TIME) is as the circumference, and therefore as the distance, directly, and as the velocity, inversely. Therefore $t \doteqdot \frac{d}{v}$, and $v \doteqdot \frac{d}{t}$, and $v^2 \doteqdot \frac{d^2}{t^2}$, and $\frac{v^2}{d} \doteqdot \frac{d}{t^2}$.

177. *These forces are also as the distances, and the square of the angular velocity, jointly.*

For, in every uniform circular motion, the angular velocity is inversely as the periodic time. Therefore, calling the angular velocity, a, $a^2 \doteqdot \frac{1}{t^2}$, and $\frac{d}{t^2} \doteqdot d\,a^2$, and therefore $f \doteqdot d\,a^2$.

178. *The periodic time is to the time of falling along half the radius by the uniform action of the centripetal force in the circumference, as the circumference of a circle is to the radius.*

For, in the time of falling through half the radius, the body would describe an arch equal to the radius (37.—6.) because the velocity acquired by this fall is equal to the velocity in the circumference (167.). The periodic time is to the time of describing that arch as the circumference to the arch, that is, as the circumference is to the radius.

179. *When a body describes a curve which is all in one plane, and a point is so situated in that plane, that a line drawn from it to the body describes round that point areas proportional to the times, the deflecting force is always directed to that point* (72.)

180. Conversely. *If a body is deflected by a force always directed to a fixed point, it will describe a curve line lying in one plane which passes through that point, and the line joining it with the centre of forces will describe areas proportional to the times* (73.)

The line joining the body with the centre is called the RADIUS VECTOR. The deflecting force is called CENTRIPETAL, or ATTRACTIVE, if its direction be always *toward* that centre. It is called REPULSIVE, or CENTRIFUGAL, if it be directed outwards *from* the centre. In the first case, the curve will have its *concavity* toward the centre, but, in the second case, it will be *convex* toward the centre. The force which urges a piece of iron towards a magnet is centripetal, and that which causes two electrical bodies to separate is centrifugal.

181. *The force by which a body may be made to describe circles round the centre of forces, with the angular velocities which it has in the different points of its curvilineal path, are inversely as the cubes of its distances from the centre of forces.* For the centripetal force in circular motions is proportional to $d\,a^2$ (172.). But when the deflections (and consequently the forces) are directed to a centre, we have $a \doteqdot \frac{1}{d^2}$ (75.) and $a^2 \doteqdot \frac{1}{d^4}$, therefore $d\,a^2 \doteqdot d \times \frac{1}{d^4}, \doteqdot \frac{1}{d^3}$, therefore $f \doteqdot \frac{1}{d^3}$.

This force is often called centrifugal, *the centrifugal force of circular motion;* and it is conceived as always acting in every case of curvilineal motion, and to act in opposition to the centripetal force which produces that motion. But this is inaccurate. We suppose this force, merely because we must employ a centripetal force, just as we suppose a *resisting* vis inertiæ, because we must employ force to move a body.

Fig. 35. 182. *If a body describe a curve line* ABC *by means of a centripetal* (fig. 35.) *force directed to* S, *and varying according to some proportion of the distances from it, and if another body be impelled toward* S *in the straight line* a b S *by the same force, and if the two bodies have the same velocity in any points* A *and* a *which are equidistant from* S, *they will have equal velocities in any other two points* C *and* c, *which are also equidistant from* S.

Describe round S, with the distance SA, the circular arch A a, which will pass through the equidistant point a. Describe another arch B b, cutting off a small arc AB of the curve, and also cutting AS in D. Draw DE perpendicular to the curve.

The distances AS and a S being equal, the centripetal forces are also equal, and may be represented by the equal line AD and $a\,b$. The velocities at A and a being equal, the times of describing AB and $a\,b$ will be as the spaces (14.). The force $a\,b$ is wholly employed in accelerating the rectilineal motion along a S. But the force AD, being transverse or oblique to the motion along AB, is not wholly employed in thus accelerating the motion. It is equivalent to the two forces AE and ED, of which ED, being perpendicular to AB, neither promotes nor opposes it, but incurvates the motion. The accelerating force in A therefore is AE. It was shewn, in art. 48, that the change of velocity is as the force and as the time jointly, and therefore it is as AE × AB. For the same reason, the change of the velocity at a is as $a\,b \times a\,b$, or $a\,b^2$. But, as the angle ADB is a right angle, as also AED, we have $\mathrm{AE} : \mathrm{AD} = \mathrm{AD} : \mathrm{AB}$, and $\mathrm{AE} \times \mathrm{AB} = \mathrm{AD}^2$, $= ab^2$. Therefore, the increments of velocity acquired along AB and $a\,b$ are equal. But the velocities at A and a were equal. Therefore the velocities at B and b are also equal. The same thing may be said of every subsequent increase of velocity, while moving along BC and $b\,c$; and therefore the velocities at C and c are equal.

The same thing holds when the deflecting force is directed in lines parallel to a S, as if to a point S′ infinitely distant, the one body describing the curve line VA′B′, while the other describes the straight line VS.

183. The propositions in art. 73. and 74. are also true in curvilineal motions by means of central forces.

When

When the path of the motion is a line returning into itself, like a circle or oval, it is called an ORBIT; otherwise it is called a TRAJECTORY.

The time of a complete revolution round an orbit is called the PERIODIC TIME.

184. The formula $f \doteqdot \frac{v^2}{c}$ serves for discovering the law of variation of the central force by which a body describes the different portions of its curvilineal path; and the formula $f \doteqdot \frac{d}{t^2}$ serves for comparing the forces by which different bodies describe their respective orbits.

185. It must always be remembered, in conformity to art. 77. that $f = \frac{v^2}{c}$ or $f = \frac{\text{arc}^2}{c}$ expresses the linear deflection from the tangent, which may be taken for a measure of the deflecting force, and that $f = \frac{2\,v^2}{c}$, or $f = \frac{2\,\text{arc}^2}{c}$ expresses the velocity generated by this force, during the description of the arc, or the velocity which may be compared directly with the velocity of the motion in the arc. The last is the most accurate, because the velocity generated is the real change of condition.

186. *A body may describe, by the action of a centripetal force, the direction of which passes through* C (fig. 36.), *a figure* VPS, *which figure revolves (in its own plane) round the centre of forces* C, *in the same manner as it describes the quiescent figure, provided that the angular motion of the body in the orbit be to that of the orbit itself in any constant ratio, such as that of* m *to* n.

For, if the direction of the orbit's motion be the same with that of the body moving in it, the angular motion of the body in every point of its motion is increased in the ratio of m to $n+m$, and it will be in the same ratio in the different parts of the orbit as before, that is, it will be inversely as the square of the distance from S (75.). Moreover, as the distances from the centre in the simultaneous positions of the body, in the quiescent and in the revolving orbit, are the same, the momentary increments of the area are as the momentary increments of the angle at the centre; and therefore in both motions, the areas increase in the constant ratio of m to $m+n$ (75.). Therefore the areas of the absolute path, produced by the composition of the two motions, will still be proportional to the times; and therefore (73.) the deflecting force must be directed to the centre S; or, a force so directed will produce this compound motion.

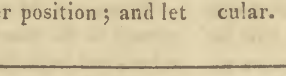
187. *The differences between the forces by which a body may be made to move in the quiescent and in the moveable orbit are in the inverse triplicate ratio of the distances from the centre of forces.*

Let VKSBV (fig. 36.) be the fixed orbit, and upk bu the same orbit moved into another position; and let $VpnNoNtQV$ be the orbit described by the body in absolute space by the composition of its motion in the orbit with the motion of the orbit itself. If the body be supposed to describe the arch VP of the fixed orbit while the axis VC moves into the situation uC, and if the arch up be made equal to VP, then p will be the place of the body in the moveable orbit, and in the compound path Vp. If the angular motion in the fixed orbit be to the motion of the moving orbit as m to n, it is plain that the angle VCP is to VCp as m to $m+n$. Let PK and pk be two equal and very small arches of the fixed and moving orbits. PC and pc are equal, as are also KC and kC, and a circle described round C with the radius CK will pass through k. If we now make VCK to VCn as m to $m+n$: the point n of the circle Kkn will be the point of the compound path, at which the body in the moving orbit arrives when the body in the fixed orbit arrives at K, and pn is the arch of the absolute path described, while PK is described in the fixed path.

In order to judge of the difference between the force which produces the motion PK in the fixed orbit and that which produces pn in the absolute path, it must be observed that, in both cases, the body is made to approach the centre by the difference between CP and CK. This happens, because the centripetal forces, in both cases, are greater than what would enable the body to describe circles round C, at the distance CP, and with the same angular velocities that obtain in the two paths, viz. the fixed orbit and the absolute path. We shall call the one pair of forces the *circular forces*, and the other the *orbital*. Let C and c represent the forces which would produce circles, with the angular velocities which obtain in the fixed and moving orbits, and let O and o be the forces which produce the orbital motions in these two paths.

These things being premised, it is plain that $o-c$ is equal to O—C, because the bodies are equally brought towards the centre by the difference between O and C and by that between o and c. Therefore $o-$O is equal to $c-$C (A). The difference, therefore, of the forces which produce the motions in the fixed and moving orbits is always equal to the difference of the forces which would produce a circular motion at the same distances, and with the same angular velocity. But the forces which produce circular motions, with the angular motion that obtains in an orbit at different distances from the centre of forces, are as the cubes of the distances inversely (175.). And the two angular motions at the same distance are in the constant ratio of m to $m+n$. Therefore the forces are in a constant ratio to each other, and their differences are in a constant ratio to either of the forces. But the circular force at different distances is inversely as the cube of the distance (121.). Therefore the difference of them in the fixed and moveable orbits is in the same proportion. But the difference of the orbital forces is equal to that of the circular. Therefore, finally, the difference of the centripetal

---



(A) For let A o, AO, A c, AC represent the four forces o, O, c, and C. By what has been said, we find that oc=OC. To each of these add O c, and then it is plain that o O=c C, that is, that the difference of the circular forces c and C is equal to that of the orbital forces o and O.

petal forces by which a body may be retained in a fixed orbit, and in the same orbit moving as determined in article 180. is always in the inverse triplicate ratio of the distances from the centre of forces.

In this example, the motion of the body in the orbit is in the same direction with that of the orbit, and the force to be joined with that on the fixed orbit is always additive. Had the orbit moved in the opposite direction, the force to be joined would have been subtractive, unless the retrograde motion of the orbit exceeded twice the angular motion of the body. But in all cases, the reasoning is similar.

188. Thus we have considered the motions of bodies influenced by forces directed to a fixed point. But we cannot conceive a mere mathematical point of space as the cause or occasion of any such exertion of forces. Such relations are observed only between existing bodies or masses of matter. The propositions which have been demonstrated may be true in relation to bodies placed on those fixed points. That continual tendency towards a centre, which produces an equable description of areas round it, becomes intelligible, if we suppose some body placed in the centre of forces, attracting the revolving body. Accordingly, we see very remarkable examples of such tendencies towards a central body in the motions of the planets round the sun, and of the satellites round the primary planet.

But, since it is a universal fact that all the relations between bodies are mutual, we are obliged to suppose that whatever force inclines the revolving body towards the body placed in the centre of forces, an equal force (from whatever source it is derived) inclines the central body towards the revolving body, and therefore it cannot remain at rest, but must move towards it. The notion of a fixed centre of forces is thus taken away again, and we seem to have demonstrated propositions inapplicable to any thing in nature. But more attentive consideration will shew us that our propositions are most strictly applicable to the phenomena of nature.

189. For, in the first place, the motion of the common centre of position of two, or of any number of bodies, is not affected by their mutual actions. These, being equal and opposite, produce equal and opposite motions, or changes of motion. In this case, it follows from art. 115. that the state of the common centre is not affected by them.

Fig. 37. 190. Now, suppose two bodies S and P, situated at the extremities of the line SP (fig. 37.). Their centre of position is in a point C, dividing their distance in such a manner that SC is to CP as the number of material atoms in P to the number in S or $SC : PC = P : S$. Suppose the mutual forces to be centripetal. Then, being equal, exerted between every atom of the one, and every particle of the other, the vis motrix may be expressed by $P \times S$. This must produce equal quantities of motion in each of the bodies, and therefore must produce velocities inversely as the quantities of matter. In any given portion of time, therefore, the bodies will move towards each other, to *s* and *p*, and S *s* will be to P *p*, as P to S, that is, as SC to PC. Therefore we shall still have $sC : pC = SC : PC$. Their distances from C will always be in the same proportion. Also we shall have $SC : SP = P : S+P$, and $sC : pC = P : S+P$; and therefore $SC : SP = sC : sP$. Consequently, in whatever manner the mutual forces vary by a variation of distance from each other, they will vary in the same manner by the same variation of distance from C. And, conversely, in whatever manner the forces vary by a change of distance from C, they vary in the same manner by the same change of distance from each other.

Let us now suppose that when the bodies are at S and P, equal moving forces are applied to each in the opposite directions SA and PB. Did they not attract each other at all, they would, at the end of some small portion of time, be found in the points A and B of a straight line drawn through C, because they will move with equal quantities of motion, or with velocities SA and PB inversely as their quantities of matter. Therefore $SA : PB = SC : PC$, and A, C, and B are in a straight line. But let them now attract, when impelled from S and P. Being equally attracted towards each other, they will describe curve lines S *a* and P *b*, so that their deflections A *a* and B *b* are as SC and PC; and we shall have $aC : bC = SC : PC$. As this is true of every part of the curve, it follows that they describe similar curves round C, which remains in its original place.

Lastly, If the motion of P be considered by an observer placed in S, unconscious of its motion, since he judges of the motion of P only by its change of direction and of distance, we may make a figure which will perfectly represent this motion. Draw the line EF equal and parallel to PS, and EG equal and parallel to *a b*. Do this for every point of the curve S *a* and P *b*. We shall then form a curve FG similar to the curves S *a* and P *b*, having the homologous lines equal to the sum of the homologous lines of these two curves. Thus the bodies will describe round each other curve lines which are similar and equal (lineally) to the lines which they describe round their common centre by the same forces. They may appear to describe areas proportional to the times round each other; and they really describe areas proportional to the times round their common centre of position, and the forces, which really relate to the body which is *supposed* to be central, have the same mathematical relation to their common centre.

Thus it appears that the mechanical inferences, drawn from a supposed relation to a mere point of space, are true in the real relations to the supposed central body, although it is not fixed in one place.

191. The time of describing any arch FG of the curve described round the other body at rest in a centre of forces (where we may suppose it forcibly withheld from moving) is to the time of describing the similar srch P *b* round the common centre of position in the subduplicate ratio of S+P to S, that is, in the ratio of $\sqrt{S+P}$ to $\sqrt{S}$. For the forces being the same in both motions, the spaces described by their similar actions, that is, their deflections from the tangent, are as the squares of the times T and *t* (204.). That is, $HG : Bb = T^2 : t^2$, and $T : t = \sqrt{HG} : \sqrt{Bb}, = \sqrt{S+P} : \sqrt{S}$.

Hence it follows that the two bodies S and P are moved in the same way as if they did not act on each other, but were both acted upon by a third body, placed in their common centre C, and acting with the same forces on each; and the law of variation of the forces by a change of distance from each other, and from this third body, is the same.

192. If a body P (fig. 38.) revolve around another body Fig. 38

Of Moving Forces.

body S, by the action of a central force, while S moves in any path ASB, P will continue to describe areas proportional to the times round S, if every particle in P be affected by the same accelerating force that acts, in that instant, on every particle in S. For, such action will compound the same motions P*p* and S *s* with the motions of S and P, whatever they are; and it was shown in art. 69. that such composition does not affect their relative motions. This is another way of making a body describe the same orbit in motion which it describes while the orbit is fixed (186.)

Such is the view of the abstract doctrines of motion and of moving forces which we proposed to lay before our readers. Those who have heard the excellent lecture of the late Professor Robison of the university of Edinburgh will probably see that we have availed ourselves of his valuable instructions; and the learned reader will readily perceive that we have enriched our treatise with much important matter by borrowing freely from the writings of the same distinguished philosopher.

Dynanometer ‖ Dyrrachium.

DYNANOMETER, an instrument for ascertaining the relative strength of men and animals. Of an instrument of this kind, invented by Regnier, and of which a description is given in vol. ii. *Jour. de l'Ecole Polytechnique*, the author thus speaks. "Some important knowledge, says he, might be acquired, had we the easy means of ascertaining, in a comparative manner, our relative strengths at the different periods of life, and in different states of health. Buffon and Gueneau, who had some excellent ideas on this subject, requested me to endeavour to invent a portable machine, which, by an easy and simple mechanism, might conduct to a solution of this question, on which they were then engaged. These philosophers were acquainted with that invented by Graham, and improved by Dr Desaguliers, at London; but this machine, constructed of wooden work, was too bulky and heavy to be portable; and, besides, to make experiments on the different parts of the body, several machines were necessary, each suited to the part required to be tried. They were acquainted also with the dynanometer of Citizen Leroy of the Academy of Sciences at Paris. It consisted of a metal tube 10 or 12 inches in length, placed vertically on a foot like that of a candlestick, and containing in the inside a spiral spring, having above it a graduated shank terminating in a globe. This shank, together with the spring, sunk into the tube in proportion to the weight acting upon it, and thus pointed out, in degrees, the strength of the person who pressed on the ball with his hand.

"This instrument, though ingenious, did not appear sufficient however to Buffon and Gueneau; for they wished not merely to ascertain the muscular force of a finger or hand, but to estimate that of each limb separately, and of all the parts of the body. I shall not here give an account of the attempts I made to fulfil the wishes of these two philosophers, but only observe, that in the course of my experiments I had reason to be convinced that the construction of the instrument was not so easy as might have been expected. Besides the use which an enlightened naturalist may make of this machine, it may be possible to apply it to many other important purposes. For example, it may be employed with advantage to determine the strength of draught cattle; and, above all, to try that of horses, and compare it with the strength of other animals. It may serve to make known how far the assistance of well-constructed wheels may favour the movement of a carriage, and what is its *vis inertiæ* in proportion to the load. We might appreciate by it, also, what resistance the slope of a mountain opposes to a carriage, and be able to judge whether a carriage is sufficiently loaded in proportion to the number of horses that are to be yoked to it. In the arts, it may be applied to machines of which we wish to ascertain the resistance, and when we are desirous to calculate the moving force that ought to be adapted to them. It may serve, also, as a Roman balance to weigh burdens. In short, nothing would be more easy than to convert it into an anemometer, to discover the absolute force of the wind, by fitting to it a frame of a determined size filled up with wax cloth; and it would not be impossible to ascertain by this machine the recoil of fire-arms, and consequently the strength of gun-powder.

"This dynanometer, in its form and size, has a near resemblance to a common graphometer. It consists of a spring twelve inches in length, bent into the form of an ellipsis; from the middle of which arises a semicircular piece of brass, having engraved upon it the different degrees that express a force of the power acting on the spring. The whole of this machine, which weighs only two pounds and a half, opposes, however, more resistance than may be necessary to determine the action of the strongest and most robust horse." For a fuller description, see Phil. Mag. vol. i.

DYNASTY, among ancient historians, signifies a race or succession of kings of the same line or family. Such were the dynasties of Egypt. The word is formed from the Greek δυναϛεια, of δυναϛευω, *to be powerful*, or *king*.

The Egyptians reckon 30 dynasties within the space of 36,525 years; but the generality of chronologers look upon them as fabulous. And it is very certain, that these dynasties are not continually successive, but collateral.

DYRRACHIUM, in *Ancient Geography*, a town on the coast of Illyricum, before called *Epidamnum*, or *Epidamnus*, an inauspicious name, changed by the Romans to *Dyrrachium*; a name taken from the peninsula on which it stood. Originally built by the Corcyreans. A Roman colony (Pliny). A town famous in story: its port answered to that of Brundusium, and the passage between both was very ready and expeditious. It was also a very famous mart for the people living on the Adriatic; and the free admission of strangers contributed much to its increase: A contrast to the conduct of the Apollonians; who, in imitation of the Spartans, discouraged strangers from settling among them.

DYSÆ, in *Mythology*, inferior goddesses among the Saxons, being the messengers of the great Woden, whose province it was to convey the souls of such as died in battle to his abode, called *Valhall*, i. e. the hall of slaughter; where they were to drink with him and their other gods *cervisia*, or a kind of malt liquor, in the skulls of their enemies. The *Dysæ* conveyed those who died a natural death to *Hela*, the goddess of hell, where they were tormented with hunger, thirst, and every kind of evil.

DYSCRASY, among physicians, denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

DYSENTERY, in *Medicine*, a diarrhœa or flux, wherein the stools are mixed with blood, and the bowels miserably tormented with gripes. See MEDICINE *Index*.

DYSENTERIC FEVER. See MEDICINE *Index*.

DYSERT, a borough town of Scotland, in the county of Fife, situated on the northern shore of the frith of Forth, about eleven miles north of Edinburgh.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach.

DYSPEPSY, a difficulty of digestion.

DYSPNOEA, a difficulty of breathing, usually called *asthma*. See MEDICINE *Index*.

DYSURY, in *Medicine*, a difficulty of making water, attended with a sensation of heat and pain. See MEDICINE *Index*.

DYTISCUS, WATER-BEETLE. See ENTOMOLOGY *Index*.

DYVOUR, in *Scots Law*; otherwise *Bare-man*: A person who, being involved in debt, and unable to pay the same,—for avoiding imprisonment and other pains, makes cession of his effects in favour of his creditors; and does his *devoir* and duty to them, proclaiming himself bare-man and indigent, and becoming debt bound to them of all that he has. The word is used in the same sense as BANKRUPT: see that article; and LAW *Index*.

E.

E, THE second vowel, and fifth letter of the alphabet. The letter E is most evidently derived from the old character Ǝ in the ancient Hebrew and Phœnician alphabets, inverted by the Greeks to this position E, and not from the Hebrew He ה. From the same origin is also derived the Saxon *e*, which is the first letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are used nearly in the same manner as in that letter.

It has a long and short sound in most languages. The short sound is audible in *bed*, *fret*, *den*, and other words ending in consonants: its long sound is produced by a final *e*, or an *e* at the end of words; as in *glebe*, *here*, *hire*, *scene*, *sphere*, *interfere*, *revere*, *sincere*, &c. in most of which it sounds like *ee*; as also in some others by coming after *i*, as in *believe*, *chief*, *grief*, *reprieve*, &c. and sometimes this long sound is expressed by *ee*, as in *bleed*, *beer*, *creed*, &c. Sometimes the final *e* is silent, and only serves to lengthen the sound of the preceding vowel, as in *rag*, *rage*, *stag*, *stage*, *hug*, *huge*, &c. The sound of *e* is obscure in the following words *oxen*, *heaven*, *bounden*, *fire*, *massacre*, *maugre*, &c.

The Greeks have their long and short *e*, which they call *epsilon* and *eta*. The French have at least six kinds of ε's: the Latins have likewise a long and short *e*; they also write *e* instead of *a*, as *dicem* for *dicam*, &c. and this is no doubt the reason why *a* is so often changed into *e* in the preter tense, as *ago*, *egi*; *facio*, *feci*, &c.

As a numeral, E stands for 250, according to the verse,

E, quoque ducentos et quinquaginta tenebit.

In music it denotes the tone *e-la-mi*. In the kalendar it is the fifth of the dominical letters. And in sea charts it distinguishes all the easterly points: thus, E alone denotes East; and E. by S. and E. by N. East by South, and East by North.

EACHARD, JOHN, an English divine of great learning and wit in the 17th century, bred at Cambridge, author (in 1670) of *The Grounds and Occasions of the Contempt of the Clergy and Religion inquired into.* In 1675 he was chosen master of Catharine-hall upon the decease of Dr John Lightfoot; and the year following was created D. D. by royal mandate. He died in 1696.

EACHARD, *Laurence*, an eminent English historian of the 18th century, nearly related to Dr John Eachard. He was the son of a clergyman, who, by the death of his elder brother, became master of a good estate in Suffolk. He was educated in the university of Cambridge, entered into holy orders, and was presented to the living of Welton and Elkington in Lincolnshire, where he spent above 20 years of his life, and distinguished himself by his writings, especially his History of England, which was attacked by Dr Edmund Calamy and by Mr John Oldmixon. His "General Ecclesiastical History from the Nativity of Christ to the first Establishment of Christianity by Human Laws under the emperor Constantine the Great," has passed through several editions. He was installed archdeacon of of Stowe and prebend of Lincoln in 1712. He died in 1730.

EADMERUS, an esteemed historian, was an Englishman; but his parents, and the particular time and place of his nativity, are not known. He received a learned education, and very early discovered a taste for history, by recording every remarkable event that came to his knowledge. Being a monk in the cathedral of Canterbury, he had the happiness to become the bosom friend and inseparable companion of two archbishops of that see, St Anselm and his successor Ralph. To the former of these he was appointed spiritual director by the pope; and that prelate would do nothing without his permission. In the year 1120, he was sent for by King Alexander I. of Scotland, to be raised to the primacy of that kingdom; and having obtained leave of King Henry and the archbishop of Canterbury, he departed for Scotland, where he was kindly received by the king; and on the third day after his arrival, he was elected bishop of St Andrew's with much unanimity. But on the day after his election, an unfortunate dispute arose between the king and him, in a private conference about his consecration. Eadmerus having been a constant companion of the late and of the present archbishop of Canterbury, was a violent stickler for the prerogatives of that see. He therefore told the king, that he was determined to be consecrated by none but the archbishop of Canterbury, who he believed to be the primate of all Britain. Alexander, who was a fierce prince, and supported the independency of his crown and kingdom with great spirit, was so much offended, that he broke off the conference in a violent passion, declaring, that the see of Canterbury had no pre-eminency over that of St Andrew's. This breach between the king and the bishop-elect became daily wider, till at length Eadmerus, despairing of recovering the royal favour, sent his pastoral ring to the king, and laid his pastoral staff on the high altar, from whence he had taken it, and abandoning his bishopric returned to England. He was kindly received by the archbishop and clergy of Canterbury, though they disapproved of his stiffness, and thought him too hasty in forsaking the honourable station to which he had been called. Nor was it long before Eadmerus became sensible of his error, and desirous of correcting it. With this view he wrote a long submissive letter to the king of Scotland, entreating his leave to return to his bishopric, promising compliance with his royal pleasure in every thing respecting his consecration, which was accompanied by an epistle to the same purpose from the archbishop. These letters, however, which were written A. D. 1122, did not produce the desired effect. But Eadmerus is most worthy of the grateful remembrance of posterity for his historical works, particularly for his excellent history of the affairs of England in his own time, from A. D. 1066 to A. D. 1122; in which he hath inserted many original papers, and preserved many important facts, that are nowhere else to be found. This work hath been highly commended, both by ancient and modern writers, for its authenticity, as well as for regularity of composition and purity of style. It is indeed more free from legendary tales than any other work of this period; and it is impossible to peruse it with attention, without conceiving a favourable opinion of the learning, good sense, sincerity, and candour of its author.

EAGLE. See FALCO, ORNITHOLOGY *Index*.

EAGLE, in *Heraldry*, is accounted one of the most noble bearings in armory; and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or for having done singular services to their sovereigns; in which case they may be allowed a whole eagle, or an eagle naissant, or only the head or other parts thereof, as may be most agreeable to their exploits.

The eagle has been borne by way of ensign or standard, by several nations. The first who seem to have assumed the eagle are the Persians; according to the testimony of Xenophon. Afterwards it was taken by the Romans; who, after a great variety of standards, at length fixed on the eagle, in the second year of the consulate of C. Marius: till that time, they used indifferently wolves, leopards, and eagles, according to the humour of the commander.

The Roman eagles, it must be observed, were not painted on a cloth or flag; but were figures in relievo, of silver or gold, borne on the tops of pikes; the wings being displayed, and frequently a thunderbolt in their talons. Under the eagle on the pike, were piled bucklers, and sometimes crowns. Thus much we learn from the medals.

Constantine is said to have first introduced the eagle with two heads, to intimate, that though the empire seemed divided, it was yet only one body. Others say, that it was Charlemagne who resumed the eagle as the Roman ensign, and added to it a second head; but that opinion is destroyed, by an eagle with two heads, noted by Lipsius, on the Antonine column; as also by the eagle's only having one head on the seal of the golden bull of the emperor Charles IV. The conjecture, therefore, of F. Menestrier appears more probable, who maintains that as the emperors of the East, when there were two on the throne at the same time, struck their coins with the impression of a cross, with a double traverse, which each of them held in one hand, as being the symbol of the Christians; the like they did with the eagle in their ensigns; and instead of doubling their eagles, they joined them together, and represented them with two heads. In which they were followed by the emperors of the West.

F. Papebroche wishes that this conjecture of Menestrier was confirmed by ancient coins; without which, he rather inclines to think the use of the eagle with two heads to be merely arbitrary; though he grants it probable, that it was first introduced on occasion of two emperors on the same throne.

The eagle on medals, according to M. Spanheim, is a symbol of divinity and providence; and, according to all other antiquaries, of empire. The princes on whose medals it is most usually found, are the Ptolemies and the Seleucides of Syria. An eagle with the word CONSECRATIO, expresses the apotheosis of an emperor.

EAGLES, a name found very frequently in the ancient histories of Ireland, and used to express a sort of base money that was current in that kingdom in the first

first years of the reign of Edward I. that is, about the year 1272. There were, besides the eagles, lionines, rosades, and many other coins of the same sort, named according to the figures they were impressed with.

The current coin of the kingdom was at that time a composition of copper and silver, in a determined proportion; but these were so much worse than the standard proportion of that time, that they were not intrinsically worth quite half so much as the others. They were imported out of France and other foreign countries. When this prince had been a few years established on the throne, he set up mints in Ireland for the coining sufficient quantities of good money, and then decried the use of these eagles, and other the like kinds of base coins, and made it death, with confiscation of effects, to import any more of them into the kingdom.

Eagle, in *Astronomy*, is a constellation of the northern hemisphere, having its right wing contiguous to the equinoctial. See Aquila.

There are also three several stars, particularly denominated among the Arab astronomers, *nasr*, i. e. "eagle." The first, *nasr sohail*, the "eagle of Canopus," called also *sitareh jemen*, the star of Arabia Felix, over which it is supposed to preside; the second, *nasr althair*, the "flying eagle;" and the third, *nasr alveke*, the "resting eagle."

White Eagle, is a Polish order of knighthood, instituted in 1325 by Uladislaus V. on marrying his son Casimir with a daughter of the great duke of Lithuania.

The knights of this order were distinguished by a gold chain, which they wore on the stomach, whereon hung a silver eagle crowned.

Black Eagle, was a like order, instituted in 1701 by the elector of Brandenburgh, on his being crowned king of Prussia.

The knights of this order wear an orange-coloured ribbon, to which is suspended a black eagle.

Eagle, in *Architecture*, is a figure of that bird anciently used as an attribute or cognizance of Jupiter, in the capital and friezes of the columns of temples consecrated to that god.

Eagle-flower. See Balsamine.

Eagle-stone, in *Natural History*, in a stone by the Greeks called *ætites*, and by the Italians *pietra d'aquila*, as being supposed to be sometimes found in the eagle's nest. It is of famous traditionary virtue, either for forwarding or preventing the delivery of women in labour, according as it is applied above or below the womb. Matthiolus tells us, that birds of prey could never hatch their young without it, and that they go in search of it as far as the East Indies. Bausch has an express Latin treatise on the subject. See Ætites.

EAGLET, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed *eaglets*.

EALDERMAN, or Ealdorman, among the Saxons, was of like import with earl among the Danes.

The word was also used for an elder, senator, or statesman. Hence, at this day, we call those *aldermen* who are associates to the chief officer in the common council of a city or corporate town.

EAR. See Anatomy *Index*.

Several naturalists and physicians have held, that cutting off the ear rendered persons barren and unprolific; and this idle notion was what first occasioned the legislators to order the ears of thieves, &c. to be cut off, lest they should produce their like.

The ear has its beauties, which a good painter ought by no means to disregard; where it is well formed, it would be an injury to the head to be hidden. Suetonius insists, particularly, on the beauties of Augustus's ears; and Ælian, describing the beauties of Aspasia, observes, she had short ears. Martial also ranks large ears among the number of deformities.

Among the Athenians, it was a mark of nobility to have the ears bored or perforated. And among the Hebrews and Romans, this was a mark of servitude.

Loss of one ear is a punishment enacted by 5 and 6 Edw. VI. cap. 4. for fighting in a churchyard; and by 2 and 3 Edw. VI. cap. 15. for combinations to raise the price of provisions, labour, &c. if it be the third offence, beside pillory, and perpetual infamy, or a fine of 40l.

By a statute of Henry VIII. maliciously cutting off the ear of a person is made a trespass, for which treble damages shall be recovered; and the offender is to pay a fine of ten pounds to the king, 37 Hen. VIII. cap. 6. § 4. In the Index to the Statutes at Large, it is said, that this offence may be punished as felony, by 22 and 23 Car. II. cap. 1. § 7. commonly called *Coventry's act;* but ear is not mentioned in that statute.

Ear of Fishes. See Anatomy *Index*.

Ear, in *Music*, denotes a kind of internal sense, whereby we perceive and judge of harmony and musical sounds. See Music.

In music we seem universally to acknowledge something like a distinct sense from the external one of hearing; and call it a *good ear*. And the like distinction we should probably acknowledge in other affairs, had we got distinct names to denote these powers of perception by. Thus a greater capacity of perceiving the beauties of painting, architecture, &c. is called a *fine taste*.

Ear is also used to signify a long cluster of flowers or seeds, produced by certain plants; usually called by botanists *spica*. The flowers and seeds of wheat, rye, barley, &c. grow in ears. The same holds of the flowers of lavender, &c. We say the stem of the ear, i. e. its tube or straw; the knot of the ear; the lobes or cells wherein the grains are enclosed; the beard of the ear, &c.

Ear-Ach. See Medicine *Index*.

EARING, in the sea language, is that part of the bolt rope which at the four corners of the sail is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard arms, and so the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are seized or bent at the clew.

Ear-Pick, an instrument of ivory, silver, or other metal, somewhat in form of a probe, for cleansing the ear. The Chinese have a variety of these instruments, with

with which they are mighty fond of tickling their ears; but this practice, Sir Hans Sloane observes, must be very prejudicial to so delicate an organ, by bringing too great a flow of humours on it.

Ear-Ring. See Pendent.

Ear-Wax. See Anatomy *Index.*

EARWIG. See Forficula, Entomology *Index.*

EARL, a British title of nobility, next below a marquis, and above a viscount.

The title is so ancient, that its original cannot be clearly traced out. Thus much, however, seems tolerably certain, that among the Saxons they were called *ealdormen, quasi* elder men, signifying the same with *senior* or *senator* among the Romans; and also *schiremen*, because they had each of them the civil government of a several division or shire. On the irruption of the Danes they changed their names to *eorels*, which, according to Camden, signified the same in their language. In Latin they are called *comites*, (a title first used in the empire), from being the king's attendants; *à societate nomen sumpserunt, reges enim tales sibi associant.* After the Norman conquest they were for some time called *counts*, or *countées*, from the French; but they did not long retain that name themselves, though their shires are from thence called *counties* to this day. It is now become a mere title; they having nothing to do with the government of the county; which is now entirely devolved on the sheriff, the earl's deputy, or *vicecomes.* In writs, commissions, and other formal instruments, the king, when he mentions any peer of the degree of an earl, usually styles him "trusty and well beloved *cousin*;" an appellation as ancient as the reign of Henry IV.; who being either by his wife, his mother, or his sisters, actually related or allied to every earl in the kingdom, artfully and constantly acknowledged that connection in all his letters and other public acts; whence the usage has descended to his successors, though the reason has long ago failed.

An earl is created by cincture of sword, mantle of state put upon him by the king himself, a cap and a coronet put upon his head, and a charter in his hand.

Earl Marshal. See Marshal.

EARNEST (arrhæ), money advanced to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain loses his earnest, and if the person who received the earnest give back, he is to return the earnest double. But with us, the person who gave it, is in strictness obliged to abide by his bargain; and in case he decline it, is not discharged upon forfeiting his earnest, but may be sued for the whole money stipulated.

EARTH, among ancient philosophers, one of the four elements of which the whole system of nature was thought to be composed. See Element.

Earths, in *Chemistry*, are such substances as have neither taste nor smell, are incombustible, are nearly insoluble in water, and have a specific gravity under 5. Such are lime, barytes, &c. See Chemistry *Index.*

Earth, in *Astronomy* and *Geography*, one of the primary planets; being this terraqueous globe which we inhabit.

For the astronomical facts with regard to the earth, see Astronomy; for its geographical history, see Geography; and for the opinions or theories of its formation and changes, see Geology *Index.*

EARTHQUAKE. See Geology *Index.*

EARTH-worm. See Helminthology *Index.*

EASEL pieces, among painters, such small pieces, either portraits or landscapes, as are painted on the easel, *i. e.* the frame whereon the canvas is laid. They are thus called to distinguish them from larger pictures drawn on walls, ceilings, &c.

EASEMENT, in *Law*, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit: such are, a way through his lands, a sink, or the like. These, in many cases, may be claimed.

EASING, in the sea language, signifies the slackening a rope or the like. Thus, to ease the bow line, or sheet, is to let them go slacker; to ease the helm, is to let the ship go more large, more before the wind, or more larboard.

EAST, one of the four cardinal points of the world; being that point of the horizon where the sun is seen to rise when in the equinoctial.

The word *east* is Saxon. In Italy, and throughout the Mediterranean, the east wind is called the *levante:* in Greek, ανατολη and απηλιωτης, because it comes from the side of the sun, απ' ἡλιȣ; in Latin *eurus.*

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection.

The Greeks call it *pasga*, the Latins *pascha*, a Hebrew word signifying *passage*, applied to the Jewish feast of the passover. It is called *easter* in English, from the goddess Eostre, worshipped by the Saxons with peculiar ceremonies in the month of April.

The Asiatic churches kept their easter upon the very same day the Jews observed their passover, and others on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice; when it was ordained that easter should be kept upon one and the same day, which should always be a Sunday, in all Christian churches in the world. For the method of finding easter by calculation, see Chronology.

Easter Island, an island in the South Sea, lying in N. Lat. 27. 5. W. Long. 109. 46. It is thought to have been first discovered in 1686 by one Davis an Englishman, who called it *Davis's Land.* It was next visited by Commodore Roggewein, a Dutchman, in 1722; who gave it the name of *Easter Island*, and published may fabulous accounts concerning the country and its inhabitants. It was also visited by a Spanish ship in 1770, the captain of which gave it the name of *St Carlos.* The only authentic accounts of this island, however, which have yet appeared, are those published by Captain Cook and Mr Forster, who visited it in the month of March 1774. According to these accounts, the island is about 10 or 12 leagues in circumference, and of a triangular figure; its greatest length from north-west to south-east is about four leagues, and its greatest breadth two. The hills are so high, that they may be seen at the distance of 15 or 16 leagues. The north and east points of the island are of a considerable height; between them, on the south-east side, the shore forms an open bay, in which Captain Cook thinks the Dutch anchored in 1722. He himself anchored on the west side of the island, three miles northward from the south point. This, he says, is a good road with easterly winds; but a dangerous one when the wind blows from the contrary quarter, as the other on the south-east side must be with easterly winds; so that there is no good accommodation to be had for shipping round the whole island.

The island itself is extremely barren; and bears evident marks not only of a volcanic origin, but of having been not very long ago entirely ruined by an eruption. As they approached the south point, Mr Forster informs us, that they observed the shore to rise perpendicularly. It consisted of broken rocks, whose cavernous appearance, and black or ferruginous colour, seemed to indicate that they had been thrown up by subterraneous fire. Two detached rocks lie about a quarter of a mile off this point: one of them is singular on account of its shape, and represents a huge column or obelisk; and both these rocks were inhabited by multitudes of sea fowls. On landing and walking into the country, they found the ground covered with rocks and stones of all sizes, which appeared to have been exposed to a great fire, where they seemed to have acquired a black colour and porous texture. Two or three shrivelled species of grasses grew among these stones, and in some measure softened the desolate appearance of the country. The farther they advanced, the more ruinous the face of the country seemed to be. The roads were intolerably rugged, and filled with heaps of volcanic stones, among which the Europeans could not make their way but with the greatest difficulty; but the natives leaped from one stone to another with surprising agility and ease. As they went northward along the island, they found the ground still of the same nature; till at last they met with a rock of large black melted lava, which seemed to contain some iron, and on which was neither soil nor grass, nor any mark of vegetation. Notwithstanding this general barrenness, however, there are several large tracts covered with cultivated soil, which produces potatoes of a gold yellow colour as sweet as carrots, plantains, and sugar canes. The soil is a dry hard clay; and the inhabitants use the grass which grows between the stones in other parts of the island as a manure, and for preserving their vegetables when young from the heat of the sun.

The most remarkable curiosity belonging to this island is a number of colossal statues; of which, however, very few remain entire. These statues are placed only on the sea coast. On the east side of the island were seen the ruins of three platforms of stone work, on each of which had stood four of these large statues; but they were all fallen down from two of them, and one from the third: they were broken or defaced by the fall. Mr Wales measured one that had fallen, which was 15 feet in length, and six broad over the shoulders; each statue had on its head a large cylindric stone of a red colour, wrought perfectly round. Others were found that measured near 27 feet, and upwards of eight feet over the shoulders; and a still larger one was seen standing, the shade of which was sufficient to shelter all the party, consisting of near 30 persons, from the rays of the sun. The workmanship is rude, but not bad, nor are the features of the face ill formed; the ears are long, according to the distortion practised in the country, and the bodies have hardly any thing of a human figure about them. How these islanders, wholly unacquainted with any mechanical power, could raise such stupendous figures, and afterwards place the large cylindric stones upon their heads, is truly wonderful! The most probable conjecture seems to be, that the stone is factitious; and that each figure was gradually erected, by forming a temporary platform round it, and raising it as the work advanced; but they are at any rate very strong proofs of the ingenuity and perseverance of the islanders in the age when they were built, as well as that the ancestors of the present race had seen better days than their descendants enjoy. The water of this island is in general brakish, there being only one well that is perfectly fresh, which is at the east end of the island: and whenever the natives repair to it to slake their thirst, they wash themselves all over; and if there is a large company, the first leaps into the middle of the hole, drinks, and washes himself without ceremony; after which another takes his place, and so on in succession. This custom was much disrelished by their new friends, who stood greatly in need of this valuable article, and did not wish to have it contaminated by such ablutions.

The people are of a middle size. In general they are rather thin; go entirely naked; and have punctures on their bodies, a custom common to all the inhabitants of the South Sea islands. Their greasest singularity is the size of their ears, the lobe of which is stretched out so that it almost rests on their shoulder; and is pierced with a very large hole, capable of admitting four or five fingers with ease. The chief ornaments for their ears are the white down of feathers, and rings which they wear in the inside of the hole, made of the sugar cane, which is very elastic, and for this purpose is rolled up like a watch spring. Some were seen clothed in the same cloth used in the island of Otaheite, tinged of a bright orange colour with turmeric; and these our voyagers supposed to be chiefs. Their colour is a chesnut brown; their hair black, curling, and remarkably strong; and that on the head as well as the face is cut short. The women are small, and slender limbed: they have punctures on the face, resembling the patches sometimes used by European ladies; they paint their face all over with a reddish brown ruddle, and above this they lay a fine orange colour extracted from turmeric root; the whole is then variegated with streaks of white shell lime. But the most surprising circumstance of all with regard to these people, is the apparent scarcity of women among them. The nicest calculation that could be made, never brought the number of inhabitants in this island to above 700, and of these the females bore no proportion in number to the males. Either they have but few females, or else their women were restrained from appearing during the stay of the ship; notwithstanding, the men showed no signs of a jealous disposition, or the women any scruples of appearing in public: in fact, they seemed to be neither reserved nor chaste; and the large pointed cap which they wore gave them the appearance of professed wantons. But as all the women who were seen were liberal of their favours, it is more than probable that all the married and modest ones had concealed themselves from their impetuous visitants in some inscrutable parts of the island; and what further strengthens this supposition is, that

Eau de Luce
‖
Ebionites.

that heaps of stones were seen piled up into little hillocks, which had one steep perpendicular side, where a hole went under ground. The space within, says Mr Forster, could be but small; and yet it is probable that these cavities served, together with their miserable huts, to give shelter to the people at night; and they may communicate with natural caverns, which are very common in the lava currents of volcanic countries. The few women that appeared were the most lascivious of their sex perhaps that have been ever noticed in any country; shame seemed to be entirely unknown to them.

EATON, a town of Buckinghamshire, situated on the north side of the Thames, opposite to Windsor, and famous for its collegiate school, founded by King Henry VI. being a seminary for King's College, Cambridge, the fellows of which are all from this school. See Eton.

EAU de Carmes. See Pharmacy.

Eau de Luce, a fragrant alkaline liquor which was some years ago in great repute, especially among the fair sex, and of which the leading perfection is, that it shall possess and retain a milky opacity.

Mr Nicholson, in the second number of his valuable Journal, tells us, that being informed by a philosophical friend, that the usual recipes for making this compound do not succeed, and that the use of mastic in it has hitherto been kept a secret, he made the following trials to procure a good eau de luce.

One dram of the rectified oil of amber was dissolved in four ounces of the strongest ardent spirit of the shops; its specific gravity being 840 at 60 degrees of Fahrenheit. A portion of the clear spirit was poured upon a larger quantity of fine powdered mastic than it was judged could be taken up. This was occasionally agitated without heat; by which means the gum resin was for the most part gradually dissolved. One part of the oily solution was poured into a phial, and to this was added one part of the solution of mastic. No opacity or other change appeared. Four parts of strong caustic volatile alkali were then poured in, and immediately shaken. The fluid was of a dense opaque white colour, affording a slight ruddy tinge when the light was seen through a thin portion of it. In a second mixture, four parts of the alkali were added to one of the solution of mastic; it appeared of a less dense and more yellowish white than the former mixture. More of the gum resinous solution was then poured in; but it still appeared less opaque than that mixture. It was ruddy by transmitted light. The last experiment was repeated with the oily solution instead of that of mastic. The white was much less dense than either of the foregoing compounds, and the requisite opacity was not given by augmenting the dose of the oily solution. No ruddiness nor other remarkable appearance was seen by transmitted light. These mixtures were left at repose for two days; no separation appeared in either of the compounds containing mastic; the compound, consisting of the oily solution and alkali, became paler by the separation of a cream at the top.

It appears, therefore, that the first of these three mixtures, subject to variation of the quantity of its ingredients, and the odorant additions which may be made, is a good eau de luce.

In a subsequent number of the same Journal, we have the following recipe by one of the author's correspondents, who had often proved its value by experience. "Digest ten or twelve grains of the whitest pieces of mastic, selected for this purpose and powdered, in two ounces of alcohol; and, when nearly dissolved, add twenty grains of elemi. When both the resins are dissolved, add ten or fifteen drops of rectified oil of amber, and fifteen or twenty of essence of bergamot: shake the whole well together, and let the fæces subside. The solution will be of a pale amber colour. It is to be added in very small portions to the best *aqua ammoniæ puræ*, until it assumes a milky whiteness, shaking the phial well after each addition, as directed by Macquer. The strength and causticity of the ammoniac are of most essential consequence. If, upon the addition of the first drop or two of the tincture, a dense opaque coagulated precipitate is formed, not much unlike that which appears on dropping a solution of silver into water slightly impregnated with common salt, it is too strong, and must be diluted with alcohol."

EAVES, in *Architecture*, the margin or edge of the roof of a house; being the lowest tiles, slates, or the like, that hang over the walls, to throw off water to a distance from the wall.

Eaves-Droppers, are such persons as stand under the eaves, or walls, and windows of a house, by night or day, to hearken after news, and carry it to others, and thereby cause strife and contention in the neighbourhood. They are called *evil members of the commonwealth* by the stat. of West. 1. c. 33. They may be punished either in the court leet by way of presentment and fine, or in the quarter sessions by indictment and binding to good behaviour.

EBBING of the Tides. See Tide.

EBDOMARIUS, in ecclesiastical writers, an officers formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, &c. To this purpose the ebdomary, at the beginning of his week, drew up in form a bill or writing of the respective persons, and their several offices, called *tabula*, and the persons there entered were styled *intabulati*.

EBDOME, Εβδομη, in antiquity, a festival kept on the seventh of every lunar month, in honour of Apollo, to whom all seventh days were sacred, because one of them was his birth-day; whence he was sometimes called *Ebdomagenes*. For the ceremonies of this solemnity see *Potter's Archæol. Græc.* lib. ii. cap. 20.

EBENUS, the Ebony Tree. See Botany *Index*.

EBERHARD, John Augustus, an eminent German theologian. See Supplement.

EBION, the author of the heresy of the Ebionites, was a disciple of Cerinthus, and his successor. He improved upon the errors of his master, and added to them new opinions of his own. He began his preaching in Judea: he taught in Asia, and even at Rome. His tenets infected the isle of Cyprus. St John opposed both Cerinthus and Ebion in Asia; and it is thought, that this apostle wrote his gospel, in the year 97, particularly against this heresy.

EBIONITES, ancient heretics, who rose in the church in the first ages, and formed themselves into a sect in the second century, denying the divinity of Jesus Christ.

Ebionites.

Origen takes them to have been so called from the Hebrew word *ebion*, which in that language signifies *poor*; because, says he, they were poor in sense, and wanted understanding. Eusebius, with a view to the same etymology, is of opinion they were thus called, as having poor thoughts of Jesus Christ, taking him for no more than a mere man.

It is more probable the Jews gave this appellation to the Christians in general out of contempt; because in the first times there were few but poor people that embraced the Christian religion. This opinion Origen himself seems to give into, in his book against Celsus, where he says that they called *Ebionites*, such among the Jews as believed that Jesus was truly the expected Messiah.

It might even be urged, with some probability, that the primitive Christians assumed the name themselves, in conformity to their profession. It is certain Epiphanius observes, they valued themselves on being poor, in imitation of the apostles. The same Epiphanius, however, is of opinion, that there had been a man of the name of Ebion, the chief and founder of the sect of Ebionites, contemporary with the Nazarenes and Cerinthians. He gives a long and exact account of the origin of the Ebionites, making them to have risen after the destruction of Jerusalem, when the first Christians, called *Nazarenes*, went out of the same to live at Pella.

The Ebionites were little else than a branch of Nazarenes: only that they altered and corrupted in many things the purity of the faith held among those first adherents to Christianity. For this reason Origen distinguishes two kinds of Ebionites, in his answer to Celsus; the one believed that Jesus Christ was born of a virgin; and the other, that he was born after the manner of other men.

The first were orthodox in every thing, except that to the Christian doctrine they joined the ceremonies of the Jewish law, with the Jews, Samaritans, and Nazarenes; together with the traditions of the Pharisees. They differed from the Nazarenes, however, in several things, chiefly as to what regards the authority of the sacred writings; for the Nazarenes received all for Scripture contained in the Jewish canon; whereas the Ebionites rejected all the prophets, and held the very names of David, Solomon, Isaiah, Jeremiah, and Ezekiel, in abhorrence. They also rejected all St Paul's epistles, whom they treated with the utmost disrespect.

They received nothing of the Old Testament but the Pentateuch; which should intimate them to have descended rather from the Samaritans than from the Jews. They agreed with the Nazarenes in using the Hebrew gospel of St Matthew, otherwise called the Gospel of the Twelve Apostles; but they had corrupted their copy in abundance of places; and particularly, had left out the genealogy of our Saviour, which was preserved entire in that of the Nazarenes, and even in those used by the Cerinthians.

Some, however, have made this gospel canonical, and of greater value than our present Greek gospel of St Matthew: See Nazarenes. These last, whose sentiments, as to the birth of our Saviour, were the same with those of the Ebionites, built their error on this very genealogy.

Besides the Hebrew gospel of St Matthew, the Ebionites had adopted several other books, under the names of St James, John, and the other apostles: they also made use of the Travels of St Peter, which are supposed to have been written by St Clement; but had altered them so, that there was scarce any thing of truth left in them. They even made that saint tell a number of falsehoods, the better to authorise their own practices. See St Epiphanius, who is very diffusive on the ancient heresy of the Ebionites, *Hær.* 30. But his account deserves little credit, as, by his own confession, he has confounded the other sects with the Ebionites, and has charged them with errors to which the first adherents of this sect were utter strangers.

EBONY of Crete. See Ebenus, Botany *Index*.

Ebony Wood is brought from the Indies, exceedingly hard and heavy, susceptible of a very fine polish, and on that account used in mosaic and inlaid works, toys, &c. There are divers kinds of ebony; the most usual among us are black, red, and green, all of them the product of the island of Madagascar, where the natives call them indifferently *hazon mainthi*, q. d. *black wood*. The island of St Maurice, belonging to the Dutch, likewise furnishes part of the ebonies used in Europe.

Authors and travellers give very different accounts of the tree that yields the black ebony. By some of their descriptions, it should be a sort of palm tree; by others a cytisus, &c. The most authentic of them is that of M. Falcourt, who resided many years in Madagascar as governor thereof; he assures us, that it grows very high and big, its bark being black, and its leaves resembling those of our myrtle, of a deep dusky green colour.

Tavernier assures us, that the islanders always take care to bury their trees when cut down, to make them the blacker, and to prevent their splitting when wrought. F. Plumier mentions another black ebony tree, discovered by him at St Domingo, which he calls *spartium portulacæ foliis aculeatum ebeni materiæ*. Candia also bears a little shrub, known to the botanists under the name of *Ebenus Cretica*, above described.

Pliny and Dioscorides say the best ebony comes from Ethiopia, and the worst from India; but Theophrastus prefers that of India. Black ebony is much preferred to that of other colours. The best is a jet black, free of veins and rind, very massive, astringent, and of an acrid pungent taste. Its rind, infused in water, is said to purge pituita, and cure venereal disorders; whence Matthiolus took guaiacum for a sort of ebony. It yields an agreeable perfume when laid on burning coals; when green, it readily takes fire from the abundance of its fat. If rubbed against a stone, it becomes brown. The Indians make statues of their gods, and sceptres for their princes, of this wood. It was first brought to Rome by Pompey, after he subdued Mithridates. It is now much less used among us than anciently, since the discovery of so many ways of giving other hard woods a black colour.

As to the green ebony, besides Madagascar and St Maurice, it likewise grows in the Antilles, and especially in the isle of Tobago. The tree that yields it is very bushy; its leaves are smooth, and of a fine green colour. Beneath its bark is a white blea, about two inches thick; all beneath which, to the very heart, is a deep green, approaching towards a black, though sometimes streaked with yellow veins. Its use is not

confined

confined to mosaic work: it is likewise good in dyeing, as yielding a fine green tincture. As to red ebony, called also *grenadilla*, we know little of it more than the name.

The cabinet-makers, inlayers, &c. make pear tree and other woods pass for ebony, by giving them the black colour thereof. This some do by a few washes of a hot decoction of galls; and when dry, adding writing ink thereon, and polishing it with a stiff brush, and a little hot wax; and others heat or burn their wood black.

EBORACUM, in *Ancient Geography*, a famous city of the Brigantes in Britain, the residence of Septimius Severus and Constantius Chlorus, and where they both died; a Roman colony; and the station of the Legio Sexta Victrix. Now *York*. W. Long. 50. Lat. 54. *Caer-frock*, or *Caer-effroc*, in British (Camden).

EBRO, anciently IBERUS, a large river of Spain, which, taking its rise in Old Castile, runs through Biscay and Arragon, passes by Saragossa, and, continuing its course through Catalonia, discharges itself with great rapidity into the Mediterranean, about 20 miles below the city of Tortosa.

EBUDÆ, or HEBUDES, in *Ancient Geography*, islands on the west of Scotland. The ancients differ greatly as to their situation, number, and names; said in general to lie in the north of Ireland and west of Scotland. Now called the *Western Isles*, also *Hebrides*; this last a modern name, the reason of which does not appear, unless it be a corruption of *Hebudes*. By Beda called *Mevaniæ*, an appellation equally obscure.

EBULLITION, the same with BOILING. The word is also used in a synonymous sense with EFFERVESCENCE.

EBUSUS, in *Ancient Geography*, the greater of the two islands called Pityusæ, in the Mediterranean, near the east coast of Spain, to the south-west of Majorca. Famous for its pastures for cattle, and for its figs. Now *Ivica*, 100 miles in compass, without any noxious animals but rabbits, who often destroy the corn.

ECALESIA, Εκαλησια, in antiquity, a festival kept in honour of Jupiter, surnamed *Hecalus*, or *Hecalesius*, from *Hecale*, one of the borough towns in Attica.

ECASTOR, in antiquity, an oath wherein Castor was invoked. It was a custom for the men never to swear by Castor, nor the women by Pollux.

ECATEA, Εκατεια, in antiquity, statues erected to the goddess Hecate, for whom the Athenians had a great veneration, believing that she was the overseer of their families, and that she protected their children.

ECATESIA, Εκατησια, in antiquity, an anniversary solemnity, observed by the Stratonicensians, in honour of Hecate. The Athenians likewise had a public entertainment or supper every new moon, in honour of the same goddess. The supper was provided at the charge of the richer sort; and was no sooner brought to the accustomed place but the poor people carried all off, giving out that Hecate had devoured it. For the rest of the ceremonies observed on this occasion, see *Pott. Arch. Græc.* lib. ii. cap. 20.

ECATOMBÆON, Εκατομβαιων, in *Chronology*, the first month of the Athenian year. It consisted of 30 days, and began on the first new moon after the summer solstice, and consequently answered to the latter part of our June and beginning of July. The Bœotians called it *Hippodromus*, and the Macedonians *Lous*. See MONTH. The word is a derivation from the Greek ἑκατομβη, a *hecatomb*, because of the great number of hecatombs sacrificed in it.

ECAVESSADE, in the manege, is used for a jerk of the cavesson.

ECBATANA, in *Ancient Geography*, the royal residence and the capital of Media, built by Deioces king of the Medes, according to Herodotus: Pliny says, by Seleucus; but that could not be, because it is mentioned by Demosthenes. It was situated on a gentle declivity, distant 12 stadia from Mount Orontes, and was in compass 150 stadia. Here stood the royal treasury and tombs. It was an open unwalled town, but had a very strong citadel, encompassed with seven walls, one within and rising above another. The extent of the outmost was equal to the whole extent of Athens, according to Herodotus; the situation favouring this construction, as being a gentle ascent, and each wall was of a different colour.—Another *Ecbatana* of Persia, a town of the Magi (Pliny).—A third of Syria.

ECCENTRICITY. See EXCENTRICITY.

ECCHELLENSIS, ABRAHAM, a learned Maronite, whom the president Le Jai employed in the edition of his Polyglott Bible. Gabriel Sionita, his countryman, drew him to Paris, in order to make him his fellow labourer in publishing that Bible. They fell out; Gabriel complained to the parliament, and cruelly defamed his associate; their quarrel made a great noise. The congregation *de propaganda fide* associated him, 1636, with those whom they employed in making an Arabic translation of the Scriptures. They recalled him from Paris, and he laboured in that translation at Rome in the year 1652. While he was professor of the Oriental languages at Rome, he was pitched upon by the great duke Ferdinand II. to translate from Arabic into Latin, the 5th, 6th, and 7th books of Apollonius's Conics; in which he was assisted by John Alphonso Borelli, who added commentaries to them. He died at Rome in 1644.

ECCHYMOSIS, from εκχυω, to *pour out*, or from εξ, *out of*, and χυμος, *juice*. It is an effusion of humours from their respective vessels, under the integuments; or, as Paulus Ægineta says, "When the flesh is bruised by the violent collision of any object, and its small veins broken, the blood is gradually discharged from them." This blood, when collected under the skin, is called *ecchymosis*, the skin in the mean time remaining entire; sometimes a tumour is formed by it, which is soft and livid, and generally without pain. If the quantity of blood is not considerable, it is usually resorbed; if much, it suppurates; it rarely happens that any further inconvenience follows; though, in case of a very bad habit of body, a mortification may be the result, and in such case regard must be had thereto.

ECCLAIRCISSEMENT. See ESCLAIRCISSEMENT.

ECCLESIASTES, a canonical book of the Old Testament, the design of which is to shew the vanity of all sublunary things.

It was composed by Solomon; who enumerates the several

Ecclesiastes, Ecclesiastical.

several objects on which men place their happiness, and then shows the insufficiency of all worldly enjoyments.

The Talmudists made King Hezekiah to be the author of it: Grotius ascribes it to Zorobabel, and others to Isaiah; but the generality of commentators believe this book to be the produce of Solomon's repentance, after having experienced all the follies and pleasures of life.

ECCLESIASTICAL, an appellation given to whatever belongs to the church: thus we say, ecclesiastical polity, jurisdiction, history, &c.

Blackst. Comment.

Ecclesiastical *Courts.* In the time of the Anglo-Saxons there was no sort of distinction between the lay and the ecclesiastical jurisdiction: the county court was as much a spiritual as a temporal tribunal: the rights of the church were ascertained and asserted at the same time, and by the same judges, as the rights of the laity. For this purpose the bishop of the diocese, and the alderman, or in his absence the sheriff of the county, used to sit together in the county court, and had there the cognizance of all causes as well ecclesiastical as civil; a superior deference being paid to the bishop's opinion in spiritual matters, and to that of the lay judges in temporal. This union of power was very advantageous to them both: the presence of the bishop added weight and reverence to the sheriff's proceedings; and the authority of the sheriff was equally useful to the bishop, by enforcing obedience to his decrees in such refractory offenders as would otherwise have despised the thunder of mere ecclesiastical censures.

But so moderate and rational a plan was wholly inconsistent with those views of ambition that were then forming by the court of Rome. It soon became an established maxim in the papal system of policy, that all ecclesiastical persons, and all ecclesiastical causes, should be solely and entirely subject to ecclesiastical jurisdiction only: which jurisdiction was supposed to be lodged in the first place and immediately in the Pope, by divine indefeasible right and investiture from Christ himself, and derived from the Pope to all inferior tribunals. Hence the canon law lays it down as a rule, that "*sacerdotes à regibus honorandi sunt, non judicandi;*" and places an emphatical reliance on a fabulous tale which it tells of the emperor Constantine, That when some petitions were brought to him, imploring the aid of his authority against certain of his bishops accused of oppression and injustice; he caused, (says the holy canon) the petitions to be burnt in their presence, dismissing them with this valediction: "*Ite, et inter vos causas vestras discutite, quia dignum non est ut nos judicemus Deos.*"

It was not, however, till after the Norman conquest, that this doctrine was received in England, when William I. (whose title was warmly espoused by the monasteries which he liberally endowed, and by the foreign clergy whom he brought over in shoals from France and Italy, and planted in the best preferments of the English church) was at length prevailed upon to establish this fatal encroachment, and separate the ecclesiastical court from the civil: whether actuated by principles of bigotry, or by those of a more refined policy, in order to discountenance the laws of King Edward abounding with the spirit of Saxon liberty, is not altogether certain. But the latter, if not the cause, was undoubtedly the consequence of this separation: for the Saxon laws were soon overborne by the Norman justiciaries, when the county court fell into disregard by the bishop's withdrawing his presence, in obedience to the charter of the Conqueror; which prohibited any spiritual cause from being tried in the secular courts, and commanded the suitors to appear before the bishop only, whose decisions were directed to conform to the canon law.

King Henry I. at his accession, among other restorations of the laws of King Edward the Confessor, revived this of the union of the civil and ecclesiastical courts. Which was, according to Sir Edward Coke, after the great heat of the conquest was past, only a restitution of the ancient law of England. This however was ill relished by the Popish clergy, who, under the guidance of that arrogant prelate Archbishop Anselm, very early disapproved of a measure that put them on a level with the profane laity, and subjected spiritual men and causes to the inspection of the secular magistrates; and therefore, in their synod at Westminster, 3 Hen. I. they ordained, that no bishop should attend the discussion of temporal causes; which soon dissolved this newly effected union. And, when upon the death of King Henry I. the usurper Stephen was brought in and supported by the clergy, we find one article of the oath which they imposed upon him was, that ecclesiastical persons and ecclesiastical causes should be subject only to the bishop's jurisdiction. And as it was about that time that the contest and emulation began between the laws of England and those of Rome, the temporal courts adhering to the former, and the spiritual adopting the latter as their rule of proceeding; this widened the breach between them, and made a coalition afterwards impracticable; which probably would else have been effected at the general reformation of the church.

Ecclesiastical courts are various; as the Archdeacon's, the Consistory, the court of Arches, the Peculiars, the Prerogative, and the great court of appeal in all ecclesiastical causes, viz. the Court of Delegates. See these articles.

Black Comm

As to the method of proceeding in the spiritual courts, it must (in the first place) be acknowledged to their honour, that though they continue to this day to decide many questions which are properly of temporal cognizance, yet justice is in general so ably and impartially administered, in those tribunals (especially of the superior kind), and the boundaries of their power are now so well known and established, that no material inconvenience at present arises from this jurisdiction still continuing in the ancient channel. And, should any alteration be attempted, great confusion would probably arise, in overturning long established forms, and new-modelling a course of proceedings that has now prevailed for seven centuries.

The establishment of the civil law process in all the ecclesiastical courts was indeed a masterpiece of papal discernment, as it made a coalition impracticable between them and the national tribunals, without manifest inconvenience and hazard. And this consideration had undoubtedly its weight in causing this measure to be adopted, though many other causes concurred. In particular, it may be here remarked, that the Pandects, or or collections of civil law, being written in the Latin tongue, and referring so much to the will of the prince and his delegated officers of justice, sufficiently recommended them to the court of Rome, exclusive of their intrinsic merit. To keep the laity in the darkest ignorance, and to monopolize the little science which then existed entirely among the monkish clergy, were deep-rooted principles of papal policy. And as the bishops of Rome affected in all points to mimic the imperial grandeur, as the spiritual prerogatives were moulded on the pattern of the temporal, so the canon law process was formed on the model of the civil law; the prelates embracing, with the utmost ardour, a method of judicial proceedings, which was carried on in a language unknown to the bulk of the people, which banished the intervention of a jury (that bulwark of Gothic liberty), and which placed an arbitrary power of decision in the breast of a single man.

The proceedings in the ecclesiastical courts are therefore regulated according to the practice of the civil and canon laws; or rather to a mixture of both, corrected and new-modelled by their own particular usages, and the interposition of the courts of common law. For, if the proceedings in the spiritual court be ever so regularly consonant to the rules of the Roman law, yet if they be manifestly repugnant to the fundamental maxims of the municipal laws, to which, upon principles of sound policy, the ecclesiastical process ought in every state to conform (as if they require two witnesses to prove a fact, where one will suffice at common law); in such cases, a prohibition will be awarded against them. But under these restrictions, their ordinary course of proceeding is, first, by *citation*, to call the party injuring before them. Then by *libel* (*libellus*, "a little book"), or by articles drawn out in a formal *allegation*, to set forth the complainant's ground of complaint. To this succeeds the *defendant's answer* upon oath; when, if he denies or extenuates the charge, they proceed to *proofs* by witnesses examined, and their depositions taken down in writing by an officer of the court. If the defendant has any circumstances to offer in his defence, he must also propound them in what is called his *defensive allegation*, to which he is entitled in his turn to the *plaintiff's answer* upon oath, and may from thence proceed to *proofs* as well as his antagonist. The canonical doctrine of *purgation*, whereby the parties were obliged to answer upon oath, to any matter, however criminal, that might be objected against them (though long ago overruled in the court of chancery, the genius of the English law having broken through the bondage imposed on it by its clerical chancellors, and asserted the doctrines of judicial as well as civil liberty), continued till the middle of the last century to be upheld by the spiritual courts; when the legislature was obliged to interpose, to teach them a lesson of similar moderation. By the statute of 13 Car. II. c. 12. it is enacted, that it shall not be lawful for any bishop, or ecclesiastical judge, to tender or administer to any person whatsoever, the oath usually called the oath *ex officio*, or any other oath whereby he may be compelled to confess, accuse, or purge himself of any criminal matter or thing, whereby he may be liable to any censure or punishment. When all the pleadings and proofs are concluded, they are referred to the consideration, not of a jury, but of a single judge; who *takes information* by hearing advocates on both sides, and thereupon forms his *interlocutory decree* or *definitive sentence*, at his own discretion, from which there generally lies an *appeal*, in the several stages mentioned in the articles above referred to; though, if the same be not appealed from him in 15 days, it is final, by the statute 25 Henry VIII. c. 19.

But the point in which these jurisdictions are the most defective, is that of enforcing their sentences when pronounced; for which they have no other process but that of *excommunication;* which would be often despised by obstinate or profligate men, did not the civil law step in with its aid. See EXCOMMUNICATION.

ECCLESIASTICAL Corporations, are where the members that compose them are *spiritual* persons. They were erected for the furtherance of religion and perpetuating the rights of the church. See CORPORATIONS.

ECCLESIASTICAL State. See CLERGY.

ECCLESIASTICUS, an apocryphal book, generally bound up with the Scriptures; so called, from its being read in the church, *ecclesia*, as a book of piety and instruction, but not of infallible authority.

The author of this book was a Jew, called *Jesus the son of Sirach*. The Greeks call it the *Wisdom of the son of Sirach*.

ECCOPROTICS, in *Medicine*, laxative or loosening remedies, which purge gently, by softening the humours and excrements, and fitting them for expulsion.—The word is composed of the Greek particle εκ, and κοπρος, *excrement*.

ECDICI, Εκδικοι, among the ancients, patrons of cities, who defended their rights, and took care of the public money. Their office resembled that of the modern syndics.

ECHAPE, in the manege, a horse begot between a stallion and a mare of different breeds and countries.

ECHAPER, in the manege, a gallicism used in the academies, implying to give a horse head, or to put on at full speed.

ECHENEIS, the REMORA. See ICHTHYOLOGY *Index*.

ECHEVIN, in the French and Dutch polity, a magistrate elected by the inhabitants of a city or town, to take care of their common concerns, and the decoration and cleanliness of the city.

At Paris, there is a prevôt and four echevins; in other towns, a mayor and echevins. At Amsterdam, there are nine echevins; and at Rotterdam, seven.

In France, the echevins take cognizance of rents, taxes, and the navigation of rivers, &c. In Holland, they judge of civil and criminal causes; and if the criminal confesses himself guilty, they can see their sentence executed without appeal.

ECHINATE, or ECHINATED, an appellation given to whatever is prickly, thereby resembling the hedgehog.

ECHINITES, in *Natural History*, the name by which authors call the fossil centronia, frequently found in chalk pits.

ECHINOPHORA. See BOTANY *Index*.

ECHINOPS. See BOTANY *Index*.

ECHINUS, a genus of animals belonging to the order of vermes mollusca. See HELMINTHOLOGY *Index*.

ECHINUS, in *Architecture*, a member or ornament near the bottom of the Ionic, Corinthian, and Composite capitals.

ECHITES. See BOTANY *Index*.

ECHIUM, VIPER'S BUGLOSS. See BOTANY *Index*.

ECHO, or ECCHO, a sound reflected or reverberated from a solid, concave, body, and so repeated to the ear †. The word is formed from the Greek ηχος, *sound*, which comes from the verb ηχεω, *sono*.

† See Acoustics, N° 26

The ancients being wholly unacquainted with the true cause of the echo, ascribed it to several causes sufficiently whimsical. The poets, who were not the worst of their philosophers, imagined it to be a person of that name metamorphosed, and that she affected to take up her abode in particular places; for they found by experience, that she was not to be met with in all. (See below, ECHO in *fabulous history*). But the moderns, who know sound to consist in a certain tremor or vibration in the sonorous body communicated to the contiguous air, and by that means to the ear, give a more consistent account of echo.

For a tremulous body, striking on another solid body, it is evident, may be repelled without destroying or diminishing its tremor; and consequently a sound may be redoubled by the resilition of the tremulous body, or air.

But a simple reflection of the sonorous air is not enough to solve the echo: for then every plain surface of a solid hard body, as being fit to reflect a voice or sound, would redouble it, which we find does not hold.

To produce an echo, therefore, it should seem that a kind of concameration or vaulting were necessary, in order to collect, and by collecting to heighten and increase, and afterwards reflect, the sound; as we find is the case in reflecting the rays of light, where a concave mirror is required.

In effect, as often as a sound strikes perpendicularly on a wall, behind which is any thing of a vault or arch, or even another parallel wall, so often will it be reverberated in the same line, or other adjacent ones.

For an echo to be heard, therefore, it is necessary the ear be in the line of reflection: for the person who made the sound to hear its echo, it is necessary he be perpendicular to the place which reflects it: and for a manifold or tautological echo, it is necessary there be a number of walls, and vaults or cavities, either placed behind or fronting each other.

A single arch or concavity, &c. can scarce ever stop and reflect all the sound; but if there be a convenient disposition behind it, part of the sound propagated thither, being collected and reflected as before, will present another echo: or, if there be another concavity, opposed at a due distance to the former, the sound reflected from the one upon the other will be tossed back again by this latter, &c.

Many of the phenomena of echoes are well considered by the bishop of Leighs, &c. who remarks, that any sound, falling either directly or obliquely on any dense body of a smooth, whether plain or arched, superficies, is reflected, or echoes, more or less. The surface, says he, must be smooth; otherwise the air, by reverberation, will be put out of its regular motion, and the sound thereby broken and extinguished. He adds, that it echoes more or less, to show, that when all things are as before described, there is still an echoing, though it be not always heard, either because the direct sound is too weak to beat quite back again to him that made it; or that it does return to him, but so weak, that it cannot be discerned; or that he stands in a wrong place to receive the reflected sound, which passes over his head, under his feet, or on one side of him; and which therefore may be heard by a man standing in the place where the reflected sound does come, provided no interposed body intercepts it, but not by him that first made it.

Echoes may be produced with different circumstances. For, 1. A *plane* obstacle reflects the sound back in its due tone and loudness; allowance being made for the proportionable decrease of the sound, according to its distance.

2. A *convex* obstacle reflects the sound somewhat smaller and somewhat quicker, though weaker, than otherwise it would be.

3. A *concave* obstacle echoes back the sound, bigger, slower, and also inverted; but never according to the order of words.

Nor does it seem possible to contrive any single echo, that shall invert the sound, and repeat backwards; because, in such case, the word last spoken, that is, which last occurs to the obstacle, must be repelled first; which cannot be. For where in the mean time should the first words hang and be concealed; or how, after such a pause, be revived, and animated again into motion?

From the determinate concavity or archedness of the reflecting bodies, it may happen that some of them shall only echo back one determinate note, and only from one place.

4. The echoing body being removed farther off, it reflects more of the sound than when nearer; which is the reason why some echoes repeat but one syllable, some one word, and some many.

5. Echoing bodies may be so contrived and placed, as that reflecting the sound from one to the other, either directly and mutually, or obliquely and by succession, out of one sound, a multiple echo or many echoes shall arise.

Add, that a multiple echo may be made, by so placing the echoing bodies at unequal distances, that they may reflect all one way, and not one on the other; by which means, a manifold successive sound will be heard; one clap of the hands, like many; one *ha*, like a laughter; one single word, like many of the same tone and accent; and so one viol, like many of the same kind, imitating each other.

Lastly, Echoing bodies may be so ordered, that from any one sound given, they shall produce many echoes different both as to tone and intension. By which means a musical room may be so contrived, that not only one instrument playing therein shall seem many of the same sort and size, but even a concert of different ones, only by placing certain echoing bodies so, that any note placed shall be returned by them in 3ds, 5ths, and 8ths.

ECHO is also used for the place where the repetition of the sound is produced or heard.

Echoes are distinguished into divers kinds, viz.

1. *Single*, which return the voice but once. Whereof some are *tonical*, which only return a voice when modulated into some particular musical tone: Others, *polysyllabical*, which return many syllables, words, and sentences. Of this last kind is that fine echo in Woodstock park, which Dr Plot assures us, in the day time, will return very distinctly seventeen syllables, and in the night twenty.

2. *Multiple* or *tautological;* which return syllables and words the same oftentimes repeated.

In echoes, the place where the speaker stands is called the *centrum phonicum*, and the object or place that returns the voice, the *centrum phonocampticum*.

At the sepulchre of Metella, wife of Crassus, was an echo, which repeated what a man said five times. Authors mention a tower at Cyzicus, where the echo repeated seven times. One of the finest echoes we read of is that mentioned by Barthius, in his notes on Statius's *Thebais*, lib. vi. 30. which repeated the words a man uttered 17 times: it was on the banks of the Naha, between Coblentz and Bingen. Barthius assures us, he had proved what he writes; and had told 17 repetitions. And whereas, in common echoes, the repetition is not heard till some time after hearing the word spoke, or the notes sung; in this, the person who speaks or sings is scarce heard at all; but the repetition most clearly, and always in surprising varieties; the echo seeming sometimes to approach nearer, and sometimes to be further off. Sometimes the voice is heard very distinctly, and sometimes scarce at all. One hears only one voice, and another several; one hears the echo on the right, and another on the left, &c. At Milan in Italy, is an echo which reiterates the report of a pistol 56 times; and if the report is very loud, upwards of 60 reiterations may be counted. The first 20 echoes are pretty distinct; but as the noise seems to fly away, and answer at a greater distance, the reiterations are so doubled, that they can scarce be counted. See an account of a remarkable echo under the article PAISLEY.

ECHO, in *Architecture*, a term applied to certain kinds of vaults and arches, most commonly of the elliptic and parabolic figures, used to redouble sounds, and produce artificial echoes.

ECHO, in *Poetry*, a kind of composition wherein the last words or syllables of each verse contain some meaning, which, being repeated apart, answers to some question or other matter contained in the verse; as in this beautiful one from Virgil:

Crudelis mater magis, an puer improbus ille?
Improbus ille puer, crudelis tu quoque mater.

The elegance of an echo consists in giving a new sense to the last words; which reverberate, as it were, the motions of the mind, and by that means affect it with surprise and admiration.

ECHO, in fabulous history, a daughter of the Air and Tellus, who chiefly resided in the vicinity of the Cephisus. She was once one of Juno's attendants, and became the confidant of Jupiter's amours. Her loquacity, however, displeased Jupiter, and she was deprived of the power of speech by Juno, and only permitted to answer to the questions which were put to her. Pan had formerly been one of her admirers, but he never enjoyed her favours. Echo, after she had been punished by Juno, fell in love with Narcissus; but being despised by him, pined herself to death, having nothing but her voice left.

ECHOMETER, among musicians, a kind of scale or rule, with several lines thereon, serving to measure the duration and length of sounds, and to find their intervals and ratios.

ECHOUERIES. See under TRICHECUS.

ECKIUS, JOHN, an eminent and learned divine, professor in the university at Ingolstadt, memorable for the opposition he gave to Luther, Melancthon, Caralostadius, and other leading protestants in Germany. He wrote many polemical tracts; and among the rest, a *Manual of Controversies*, printed in 1535, in which he discourses upon most of the heads contested between the Protestants and Papists. He was a man of uncommon learning, parts, and zeal, and died in 1543.

ECLECTICS, (*eclectici*), a name given to some ancient philosophers, who without attaching themselves to any particular sect, took what they judged good and solid from each. Hence their denomination; which, in the original Greek, signifies, "that may be chosen," or "that chooses;" of the verb εκλεγω, *I choose.*—Laertius notes, that they were also, for the same reason, denominated *analogetici;* but that they call themselves *Philalethes*, i. e. lovers of truth.

The chief or founder of the eclectici was one Potamon of Alexandria, who lived under Augustus and Tiberius; and who, weary of doubting of all things with the Sceptics and Pyrrhonians, formed the eclectic sect; which Vossius calls the *eclective.*

Towards the close of the second century, a sect arose in the Christian church under the denomination of *Eclectics*, or modern *Platonics*. They professed to make truth the only object of their inquiry, and to be ready to adopt from all the different systems and sects such tenets as they thought agreeable to it.—However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who at this time laid the foundation of that sect, afterwards distinguished by the name of the new *Platonics*, in the Alexandrian school. See AMMONIUS and PLATONISTS.

ECLECTICS were also a certain sect of physicians among the ancients, of whom Archigenes, under Trajan, was the chief, who selected from the opinions of all the other sects that which appeared to them best and most rational; hence they are called *eclectics*, and their prescriptions *medicina eclectica.*

ECLIPSE, in *Astronomy*, the deprivation of the light of the sun, or of some heavenly body, by the interposition of another heavenly body between our sight and it. See ASTRONOMY *Index.*

ECLIPTA, in *Botany*, a genus of the polygamia superflua order, belonging to the syngenesia class of plants. The receptacle is chaffy; there is no pappus, and the corollulæ of the disk quadrifid.

ECLIPTIC, in *Astronomy*, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about

23° 30′, which is the sun's greatest declination; or, more strictly speaking, it is that path or way among the fixed stars, that the earth appears to describe to an eye placed in the sun. See ASTRONOMY *Index*.

Some call it *via solis*, "the way of the sun;" because the sun in his apparent annual motion never deviates from it, as all the other planets do more or less.

ECLIPTIC, in *Geography*, a great circle on the terrestrial globe, not only answering to, but falling within, the plane of the celestial ecliptic. See GEOGRAPHY.

ECLOGUE, in *Poetry*, a kind of pastoral composition, wherein shepherds are introduced conversing together. The word is formed from the Greek εκλογη, *choice;* so that, according to the etymology, *eclogue* should be no more than a select or choice piece; but custom has determined it to a farther signification, viz. a little elegant composition in a simple natural style and manner.

Idyllion and eclogue, in their primary intention, are the same thing: thus, the idyllia, ειδυλλια, of Theocritus, are pieces wrote perfectly in the same vein with the *eclogæ* of Virgil. But custom has made a difference between them, and appropriated the name *eclogue* to pieces wherein shepherds are introduced speaking: *idyllion*, to those wrote like the eclogue, in a simple natural style, but without any shepherds in them.

ECLUSE, a small but strong town of the Dutch Low Countries, with a good harbour and sluices. The English besieged it in vain in 1405, and the people of Bruges in 1436. It is defended by several forts, and stands near the sea. E. Long. 3. 20. N. Lat. 51. 21.

ECONOMISTS, a sect of philosophers, who have explained and illustrated the principles of political science. See SUPPLEMENT.

ECONOMY, POLITICAL. See *POLITICAL Economy*.

ECPHRACTICS, in *Medicine*, remedies which attenuate and remove obstructions. See ATTENUANTS, and DEOBSTRUENTS, MATERIA MEDICA *Index*.

ECSTACY. See EXTASY.

ECSTATICI, Εκϛατικοι, from εξιϛεμι, *I am entranced*, in antiquity, a kind of diviners who were cast into trances or ecstasies, in which they lay like dead men, or asleep, deprived of all sense and motion; but, after some time, returning to themselves, gave strange relations of what they had seen or heard.

ECTHESIS, in church history, a confession of faith, in the form of an edict, published in the year 639, by the emperor Heraclius, with a view to pacify the troubles occasioned by the Eutychian heresy in the eastern church. However, the same prince revoked it, on being informed that Pope Severinus had condemned it, as favouring the Monothelites; declaring at the same time, that Sergius, patriarch of Constantinople, was the author of it.

ECTHLIPSIS, among Latin grammarians, a figure of prosody, whereby the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verse: thus they read *mult' ille*, for *multum ille*.

ECTROPIUM, in *Surgery*, is when the eyelids are inverted, or retracted, so that they show their internal or red surface, and cannot sufficiently cover the eye.

ECTYLOTICS, in *Pharmacy*, remedies proper for consuming callosities.

ECU, or ESCU, a French crown; for the value of which, see MONEY.

EDAY, one of the Orkney isles, is about five miles and a half long, and about a mile and a half broad. It has several good harbours, and contains about 600 inhabitants.

EDDA, in antiquities, is a system of the ancient Icelandic or Runic mythology, containing many curious particulars of the theology, philosophy, and manners, of the northern nations of Europe; or of the Scandinavians, who had migrated from Asia, and from whom our Saxon ancestors were descended. Mr Mallet apprehends that it was originally compiled, soon after the Pagan religion was abolished, as a course of poetical lectures, for the use of such young Icelanders as devoted themselves to the profession of a *scald* or poet. It consists of two principal parts; the *first* containing a brief system of mythology, properly called the *Edda;* and the *second* being a kind of art of poetry, and called *scalda* or *poetics*. The most ancient Edda was compiled by Soemund Sigfusson, surnamed the *Learned*, who was born in Iceland about the year 1057. This was abridged, and rendered more easy and intelligible, about 120 years afterwards, by Snorro Sturleson, who was supreme judge of Iceland in the years 1215 and 1222; and it was published in the form of a dialogue. He added also the second part in the form of a dialogue, being a detail of different events transacted among the divinities. The only three pieces that are known to remain of the more ancient Edda of Soemund, are the Volupsa, the Havamaal, and the Runic chapter. The Volupsa, or prophecy of Vola or Fola, appears to be the text, on which the Edda is the comment. It contains, in two or three hundred lines, the whole system of mythology disclosed in the Edda, and may be compared to the Sibylline verses, on account of its laconic yet bold style, and its imagery and obscurity. It is professedly a revelation of the decrees of the Father of nature, and the actions and operations of the gods. It describes the chaos, the formation of the world, with its various inhabitants, the functions of the gods, their most signal adventures, their quarrels with Loke their great adversary, and the vengeance that ensued; and concludes with a long description of the final state of the universe, its dissolution and conflagration, the battle of the inferior deities and the evil beings, the renovation of the world, the happy lot of the good, and the punishment of the wicked. The Havamaal, or Sublime Discourse, is attributed to the god Odin, who is supposed to have given these precepts of wisdom to mankind; it is comprised in about 120 stanzas, and resembles the book of Proverbs. Mr Mallet has given several extracts of this treatise on the Scandinavian ethics. The Runic chapter contains a short system of ancient magic, and especially of the enchantments wrought by the operation of Runic characters, of which Mr Mallet has also given a specimen. A manuscript copy of the Edda of Snorro is preserved in the library of the university of Upsal; the first part of which hath been published with a Swedish and Latin version by M. Goranson. The Latin version is printed as a supplement to M. Mallet's Northern Antiquities. The first edition of the Edda was published by Resenius, professor at Copenhagen, in a large quarto volume, in the year 1665; containing the text of the Edda, a Latin translation by an Icelandic priest, a Danish version, and various readings from different MSS. M. Mallet has also given an English translation of the first part, accompanied with remarks; from which we learn, that the Edda teaches the doctrine of the Supreme, called the *Universal Father*, and *Odin*, who lives forever, governs all his kingdom, and directs the great things as well as the small; who formed the heaven, earth, and air; made man, and gave him a spirit or soul, which shall live after the body shall have mouldered away; and then all the just shall dwell with him in a place *Gimle* or *Vingolf*, the palace of friendship; but wicked men shall go to Hela, or death, and from thence to Niflheim, or the abode of the wicked, which is below in the ninth world. It inculcates also the belief of several inferior gods and goddesses, the chief of whom is Frigga or Frea, i. e. *lady*, meaning hereby the earth, who was the spouse of Odin or the Supreme God; whence we may infer that, according to the opinion of these ancient philosophers, this Odin was the active principle or soul of the world, which uniting itself with matter, had thereby put it into a condition to produce the intelligences or inferior gods, and men and all other creatures. The Edda likewise teaches the existence of an evil being called *Loke*, the calumniator of the gods, the artificer of fraud, who surpasses all other beings in cunning and perfidy. It teaches the creation of all things out of an abyss or chaos; the final destruction of the world by fire; the absorption of the inferior divinities, both good and bad, into the bosom of the grand divinity, from whom all things proceeded, as emanations of his essence, and who will survive all things; and the renovation of the earth in an improved state.

EDDISH, or EADISH, the latter pasture or grass that comes after mowing or reaping; otherwise called *eagrase* or *earsh*, and *etch*.

EDDOES, or EDDERS, in *Botany*, the American name of the ARUM *esculentum*.

EDDY, (Saxon), of *ed*, "backward," and *ea*, "water," among seamen, is where the water runs back contrary to the tide; or that which hinders the free passage of the stream, and so causes it to return again. That eddy water, which falls back, as it were, on the rudder of a ship under sail, the seamen call the *dead water*.

EDDY *Wind* is that which returns or is beat back from a sail, mountain, or any thing that may hinder its passage.

EDELINCK, GERARD, a famous engraver, born at Antwerp, where he was instructed in drawing and engraving. He settled at Paris, in the reign of Louis XIV. who made him his engraver in ordinary. Edelinck was also counsellor in the Royal Academy of Painting. His works are particularly esteemed for the neatness of the engraving, their brilliant cast, and the prodigious ease apparent in the execution; and to this facility is owing the great number of plates we have of his; among which are excellent portraits of a great number of illustrious men of his time. Among the most admired of his prints, the following may be specified as holding the chief place. 1. A battle between four horsemen, with three figures lying slain upon the ground, from Leonardo da Vinci. 2. A holy family, with Elizabeth, St John, and two angels, from the famous picture of Raphael in the king of France's collection. The first impressions are before the arms of M. Colbert were added at the bottom of the plate; the second are with the arms; and in the third the arms are taken out, but the place where they had been inserted is very perceptible. 3. Mary Magdalen bewailing her sins, and trampling upon the riches of the world, from Le Brun. The first impressions are without the narrow border which surrounds the print. 4. Alexander entering into the tent of Darius, a large print on two plates, from Le Brun. This engraving belongs to the three battles, and triumphal entry of Alexander into Babylon, by Girard Audran, and completes the set. The first impressions have the name of *Goyton* the printer at the bottom. 5. Alexander entering into the tent of Darius (finished by P. Drevet), from Peter Mignard. Edelinck died in 1707, in an advanced age, at the Hotel Royal at the Gobelins, where he had an apartment. He had a brother named *John*, who was a skilful engraver, but died young.

EDEN, (Moses) the name of a country, with a garden, in which the progenitors of mankind were settled by God himself: The term denotes pleasure or delight. It would be endless to recount the several opinions concerning its situation, some of them very wild and extravagant. Moses says, that "a river went out of Eden to water the garden, and from thence it was parted and became into four heads." The river is supposed to be the common channel of the Euphrates and Tigris, after their confluence; which parted again, below the garden, into two different channels; so that the two channels before, and the other two after their confluence, constitute the heads mentioned by Moses. Which will determine the situation of the garden to have been in the south of Mesopotamia, or in Babylonia. The garden was also called *Paradise*; a term of Persic original, denoting a garden. See PARADISE.

EDGINGS, in *Gardening*, the series of small but durable plants set round the edges or borders of flower beds, &c. The best and most durable of all plants for this use is box; which, if well planted and rightly managed, will continue in strength and beauty for many years. The seasons for planting this are the autumn, and very early in the spring: and the best species for this purpose is the dwarf Dutch box.

Formerly, it was also a very common practice to plant borders, or edgings, of aromatic herbs; as thyme, savory, hyssop, lavender, and the like; but these are all apt to grow woody, and to be in part, or wholly, destroyed in hard winters. Daisies, thrift, or sea july-flower, and chamomile, are also used by some for this purpose: but they require yearly transplanting, and a great deal of trouble, else they grow out of form; and they are also subject to perish in very hard seasons.

EDHILING, EDHILINGUS, an ancient appellation of the nobility among the Anglo-Saxons.

The Saxon nation, says Nithard (Hist. lib. iv.) is divided into three orders or classes of people; the *edhilingi*, the *frilingi*, and the *lazzi*: which signify the nobility, the freemen, and the vassals or slaves.

Instead of *edhiling*, we sometimes meet with *atheling*, or *ætheling*; which appellation was likewise given to the king's son, and the presumptive heir of the crown. See Atheling.

EDICT, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects. We find frequent mention of the edicts of the prætor, the ordinances of that officer in the Roman law.

EDINBURGH.

1 Origin of the name.

EDINBURGH, a city of Mid-Lothian, in Scotland, situated in W. Long. 3°, and N. Lat. 56°, near the southern bank of the river Forth.—The origin of the name, like that of most other cities, is very uncertain. Some imagine it to be derived from Eth, a supposed king of the Picts; others from Edwin, a Saxon prince of Northumberland, who overran the whole or greatest part of the territories of the Picts, about the year 617; while others choose to derive it from two Gaelic words *Dun Edin*, signifying the face of a hill. The name *Edinburgh* itself, however, seems to have been unknown in the time of the Romans. The most ancient title by which we find this city distinguished is that of *Castelh Mynyd Agned;* which, in the British language, signifies "the fortress of the hill of St Agnes." Afterwards it was named *Castrum Puellarum*, because the Pictish princesses were educated in the castle (a necessary protection in those barbarous ages) till they were married.—The ages in which these names were given cannot indeed now be exactly ascertained: but the town certainly cannot boast of very great antiquity; since, as Mr Whittaker informs us, the celebrated King Arthur fought a battle on the spot where it is situated towards the end of the fifth century.

2 Time of its foundation uncertain.

The Romans, during the time they held the dominion of part of this island, divided their possessions into six provinces. The most northerly of these was called *Valentia*, which comprehended all the space betwixt the walls of Adrian and Severus. Thus Edinburgh, lying on the very outskirts of that province which was most exposed to the ravages of the barbarians, became perpetually subject to wars and devastations; by means of which, the time of its first foundation cannot now be guessed at.

The castle is certainly very ancient. It continued in the hands of the Saxons or English from the invasion of Octa and Ebusa in the year 452 till the defeat of Egfrid king of Northumberland in 685 by the Picts, who then repossessed themselves of it. The Saxon kings of Northumberland reconquered it in the ninth century; and it was retained by their successors till the year 956, when it was given up to Indulphus king of Scotland. In 1093 it was unsuccessfully besieged by the usurper Donald Bane. Whether the city was at that time founded or not is uncertain. Most probably it was: for as protection from violence was necessary in those barbarous ages, the castle of Edinburgh could not fail of being an inducement to many people to settle in its neighbourhood; and thus the city would gradually be founded and increase.—In 1128, King David I. founded the abbey of Holyroodhouse, for certain canons regular: and granted them a charter, in which he styled the town *Burgo meo de Edwinesburgh*, "my borough of Edinburgh." By the same charter he granted these canons 40 shillings yearly out of the town revenues; and likewise 48 shillings more from the same, in case of the failure of certain duties payable from the king's revenue; and likewise one half of the tallow, lard and hides, of all the beasts killed in Edinburgh.

3 Castle rendere the Eng

In 1174, the castle of Edinburgh was surrendered to Henry II. of England, in order to purchase the liberty of King William I. who had been defeated and taken prisoner by the English. But when William recovered his liberty, he entered into an alliance with Henry, and married his cousin Ermengarde; upon which the castle was restored as part of the queen's dower.

In 1215, this city was first distinguished by having a parliament and provincial synod held in it.—In 1296, the castle was besieged and taken by Edward I. of England; but was recovered in 1313 by Randolph earl of Moray, who was afterwards regent of Scotland during the minority of King David II. At last King Robert destroyed the fortress, as well as all others in Scotland, lest they should afford shelter to the English in any of their after incursions into Scotland.—It lay in ruins for a considerable number of years; but was afterwards rebuilt by Edward III. of England, who placed a strong garrison in it.

In 1341 it was reduced by the following stratagem. A man pretending to be an English merchant, came to the governor, and told him that he had on board his ship in the Forth, some wine, beer, biscuits, &c. which he would sell him on very reasonable terms. A bargain being made, he promised to deliver the goods next morning at a very reasonable rate: but at the time appointed, twelve men, disguised in the habit of sailors, entered the castle with the goods and supposed merchant: and having instantly killed the porter and centinels, Sir William Douglas, on a preconcerted signal, rushed in with a band of armed men, and quickly made himself master of the place, after having cut most of the garrison in pieces.

4 Cruel e cution the mur derers James I

The year 1437 is remarkable for the execution of the earl of Athol and his accomplices, who had a concern in the murder of James I. The crime, it must be owned, was execrable; but the punishment was altogether shocking to humanity. For three days successively the assassins were tortured by putting on their heads iron crowns, heated red hot, dislocating their joints, pinching their flesh with red hot pincers, and carrying them in that dreadful situation through the streets upon hurdles. At last an end was put to their sufferings, by cutting them up alive, and sending the parts of their mangled bodies to the principal towns of the kingdom.

5 Edinbur becomes the capi of Scotla

About the end of the 14th century it was customary to consider Edinburgh as the capital of the kingdom. The town of Leith, with its harbour and mills, had been bestowed upon it by Robert I. in 1329; and his grandson John earl of Carrick, who afterwards ascended the throne by the name of Robert III. conferred upon all the burgesses the singular privilege of building houses in the castle, upon the sole condition that they should be persons of good fame; which we must undoubtedly consider as a proof that the number of these burgesses was at that time very small. In 1461, a very considerable privilege was conferred on the city by Henry VI. of England when in a state of exile; viz. that its inhabitants should have liberty to trade to all the English ports on the same terms with the city of London. This extraordinary privilege was bestowed in consequence of the kindness with which that king was treated in a visit to the Scottish monarch at Edinburgh; but as Henry was never restored, his gratitude was not attended with any benefit to this city. From this time, however, its privileges continued to be increased from various causes. In 1482 the citizens had an opportunity of liberating King James from the oppression of his nobles, by whom he had been imprisoned in the castle. On this account the provost was by that monarch made hereditary high sheriff within the city, an office which he continues still to enjoy. The council at the same time were invested with the power of making laws and statutes for the government of the city; and the trades, as a testimony of the royal gratitude for their loyalty, received the banner known by the name of the *Blue Blanket*; an ensign formerly capable of producing great commotions, but which has not now been displayed for many years past. However, it still exists; and the convener of the trades has the charge of keeping it.

Ve real dis e im- po d.

It was not long after the discovery of America that the venereal disease, imported from that country, made its way to Edinburgh. As early as 1497, only five years after the voyage of Columbus, we find it looked upon as a most dreadful plague; and the unhappy persons affected with it were separated as effectually as possible from society. The place of their exile was Inchkeith, a small island, near the middle of the Forth; which, small as it is, has a spring of fresh water, and now affords pasture to some sheep.

Or h of the wn gua

By the overthrow of James IV. at the battle of Flowden, the city of Edinburgh was overwhelmed with grief and confusion, that monarch having been attended in his unfortunate expedition by the earl of Angus, then provost, with the rest of the magistrates, and a number of the principal inhabitants, most of whom perished in the battle. After this disaster, the inhabitants being alarmed for the safety of their city, it was enacted that every fourth man should keep watch at night; the fortifications of the town were renewed, the wall being also extended in such a manner as to enclose the Grassmarket, and the field on which Heriot's Hospital, the Grey Friars Church, and Charity Workhouse, stand. On the east side it was made to enclose the College, Infirmary, and High School; after which, turning to the north, it met the old wall at the Netherbow port. After this alarm was over, the inhabitants were gradually relieved from the trouble of watching at night, and a certain number of militia appointed to prevent disturbances; who continue to this day, and are known by the name of the *Town Guard*. Before these new enclosures, most of the principal people lived in the Cowgate without the wall; and the burying place was situated where the Parliament Close now is. In our days of peace, when no alarm of an enemy is at all probable, great part of the walls, with all the gates, have been taken down, and the city laid quite open, in order to afford more ready passage to the great concourse of people with whom the street is daily filled. But at the period we speak of, not only were the inhabitants much less numerous by reason of the small extent of the city, but it was depopulated by a dreadful plague; so that, to stop if possible the progress of the infection, all houses and shops were shut up for 14 days, and some where infected persons had died were pulled down altogether.

8
Erection of wooden houses.

In 1504, the tract of ground called the *Burrough Muir* was totally overgrown with wood, though now it affords not the smallest vestige of having been in such a state. So great was the quantity at that time, however, that it was enacted by the town council, that whoever inclined to purchase as much wood as was sufficient to make a new front for their house, might extend it seven feet into the street. Thus the city was in a short time filled with houses of wood instead of stone; by which, besides the inconvenience of having the street narrowed 14 feet, and the beauty of the whole entirely marred, it became much more liable to accidents by fire: but almost all these are now pulled down; and in doing this a singular taste in the masonry which supported them is said to have been discovered.

9
Edinburgh destroyed by the English

In 1542, a war with England having commenced through the treachery of Cardinal Beaton, an English fleet of 200 sail entered the Forth; and having landed their forces, quickly made themselves masters of the towns of Leith and Edinburgh. They next attacked the castle, but were repulsed from it with loss; and by this they were so enraged, that they not only destroyed the towns of Edinburgh and Leith, but laid waste the country for a great way round.—These towns, however, speedily recovered from their ruinous state; and, in 1547, Leith was again burned by the English after the battle of Pinkey, but Edinburgh was spared.

10
Siege of the castle in Queen Elizabeth's time.

Several disturbances happened in this capital at the time of the Reformation, of which an account is given under the article SCOTLAND; but none of these greatly affected the city till the year 1570, at which time there was a civil war on account of Q. Mary's forced resignation. The regent, who was one of the contending parties, bought the castle from the perfidious governor (Balfour) for 5000l. and the priory of Pittenweem. He did not, however, long enjoy the fruits of this infamous bargain. Sir William Kirkaldy, the new governor, a man of great integrity and bravery, declared for the queen. The city in the mean time was sometimes in the hands of one party and sometimes of another; during which contentions, the inhabitants, as may easily be imagined, suffered extremely. In the year 1570 above mentioned, Queen Elizabeth sent a body of 1000 foot and 300 horse, under the command of Sir William Drury, to assist the king's party. The castle was summoned to surrender; and several skirmishes happened during the space of two years, in which a kind of predatory war was carried on. At last a truce was agreed on till the month of January 1573; and this opportunity the earl of Morton, now regent,

regent, made use of to build two bulwarks across the high street, nearly opposite to the tolbooth, to defend the city from the fire of the castle.

On the first of January, early in the morning, the governor began to cannonade the city. Some of the cannon were pointed against the fish-market, then held on the high street; and the bullets falling among the fishes, scattered them about in a surprising manner, and even drove them up so high in the air, that they fell down upon the tops of the houses. This unusual spectacle having brought a number of people out of their houses, some of them were killed, and others dangerously wounded. Some little time afterwards, several houses were set on fire by shot from the castle, and burned to the ground, which greatly enraged the people against the governor. A treaty was at last concluded between the leaders of the opposite factions; but Kirkaldy refused to be comprehended in it. The regent therefore solicited the assistance of Queen Elizabeth, and Sir William Drury was again sent into Scotland with 1500 foot and a train of artillery. The castle was now besieged in form, and batteries raised against it in different places. The governor defended himself with great bravery for 33 days; but finding most of the fortifications demolished, the well choked up with rubbish, and all supplies of water cut off, he was obliged to surrender. The English general, in the name of his mistress, promised him honourable treatment; but the queen of England shamefully gave him up to the regent, by whom he was hanged.

11
The city incurs the displeasure of James VI.

Soon after this, the spirit of fanaticism, which succeeded the Reformation, produced violent commotions, not only in Edinburgh, but through the whole kingdom. The foundation of these disturbances, and indeed of most others which have ever happened in Christendom on account of religion, was that pernicious maxim of Popery, that the church is independent of the state. It is not to be supposed that this maxim was at all agreeable to the sovereign; but such was the attachment of the people to the doctrines of the clergy, that King James found himself obliged to compound matters with them. This, however, answered the purpose but very indifferently; and at last a violent uproar was excited. The king was then sitting in the court of session, which was held in the tolbooth, when a petition was presented to him by six persons, lamenting the dangers which threatened religion; and being treated with very little respect by one Bruce, a minister, his majesty asked who they were that dared to convene against his proclamation? He was answered by Lord Lindsay, that they dared to do more, and would not suffer religion to be overthrown. On this the king perceiving a number of people crowding into the room, withdrew into another without making any reply, ordering the door to be shut. By this the petitioners were so much enraged, that on their return to the church the most furious resolutions were taken; and had it not been for the activity of Sir Alexander Home the provost, and Mr Watt the deacon convener, who assembled the crafts in his majesty's behalf, it is more than probable that the door would have been forced, and an end put to his life. This affront was so much resented by the king, that he thought proper to declare Edinburgh an unfit place of residence for the court or the administration of justice. In consequence of this declaration, he commanded the college of justice, the inferior judges, and the nobility and barons, to retire from Edinburgh, and not to return without express license. This unexpected declaration threw the whole town into consternation, and brought back the magistrates and principal inhabitants to a sense of their duty. With the clergy it was far otherwise. They railed against the king in the most furious manner, and endeavouring to persuade the people to take up arms, the magistrates were ordered to imprison them; but they escaped by a timely flight. A deputation of the most respectable burgesses was then sent to the king at Linlithgow, with a view to mitigate his resentment. But he refused to be pacified; and on the last day of December 1596 entered the town between two rows of his soldiers who lined the streets, while the citizens were commanded to keep within their houses. A convention of the estates was held in the tolbooth, before whom the magistrates made the most abject submissions, but in vain. The convention declared one of the late tumults, in which an attack had been made upon the king's person, to be high treason; and ordained, that if the magistrates did not find out the authors, the city itself should be subjected to all the penalties due to that crime. It was even proposed to raze the town to the foundation, and erect a pillar on the spot where it had stood, as a monument of its crimes. The inhabitants were now reduced to the utmost despair; but Queen Elizabeth interposing in behalf of the city, the king thought proper to abate somewhat of his rigour. A criminal prosecution, however, was commenced, and the town council were commanded to appear at Perth by the first of February. On their petition, the time for their appearance was prolonged to the first of March; and the attendance of 13 of the common council was declared sufficient, provided they had a proper commission from the rest. The trial commenced on the 5th day of the month; and one of the number having failed in his attendance, the cause was immediately decided against the council; they were declared rebels, and their revenues forfeited.

12
Is again ceived in favour.

For 15 days the city continued in the utmost confusion; but, at last, on their earnest supplication, and offering to submit entirely to the king's mercy, the community were restored on the following conditions, which they had formerly proffered: That they should continue to make a most diligent search for the authors of the tumult in order to bring them to condign punishment; that none of the seditious ministers should be allowed to return to their charges, and no others admitted without his majesty's consent; and that in the election of their magistrates they should present a list of the candidates to the king and his lords of council and session, whom his majesty and their lordships might approve or reject at pleasure. To these conditions the king now added some others; viz. that the houses which had been possessed by the ministers should be delivered up to the king; and that the clergymen should afterwards live dispersed through the town, every one in his own parish: That the town council house should be appointed for accommodating the court of exchequer: and that the town should become bound for the safety of the lords of session from any attempts of the burgesses, under a penalty of 40,000 merks; and, lastly, that

that the town should immediately pay 20,000 merks to his majesty.

Upon these terms a reconciliation took place; which appears to have been very complete, as the king not only allowed the degraded ministers to be replaced, but in 1610 conferred a mark of his favour on the town, by allowing the provost to have a sword of state carried before him, and the magistrates to wear gowns on public occasions. In 1618 he paid his last visit to this city, when he was received with the most extravagant pomp and magnificence. See SCOTLAND.

Proceed-
ngs of the
ma
trates, &c.

The events which, during this period, regard the internal police of the city, were principally the following. After the unfortunate battle at Pinkey, the magistrates, probably apprehending that now their power was enlarged by reason of the present calamity, proceeded in some respects in a very arbitrary manner; forcing the inhabitants to furnish materials for the public works; enjoining merchants to bring home silver to be coined at the mint; and ordering lanterns to be hung out at proper places to burn till nine at night, &c. Another invasion from England being apprehended in 1558, the city raised 1450 men for its defence, among whom there are said to have been 200 tailors, so that their profession seems to have been in a very flourishing state at that time. During the disturbances which happened at the Reformation, and of which a particular account is given under the article SCOTLAND, it was enacted, that the figure of St Giles should be cut out of the town standard, and that of a thistle inserted in its place. It was likewise enacted, that none but those who professed the reformed religion should serve in any office whatever; and the better to preserve the extraordinary appearance of sanctity which was affected, a pillar was erected in the North Loch, for the purpose of ducking fornicators.

In 1595, the boys of the High School rose against their masters; and such was the barbarism of those days, that one of these striplings shot a magistrate with a pistol, who had come along with the rest to reduce them to obedience. The reason of the uproar was, that they were in that year refused two vacations, which had been customary in former times: however, they were at last obliged to submit, and ever since have been allowed one for about six weeks in the autumn. The same year the house of one of the bailies was assaulted by the tradesmen's sons, assisted by journeymen who had not received the freedom of the town; he escaped with his life, but the offenders were banished the city for ever.

ist an-
es i he
me
har I.

In the beginning of the reign of Charles I. a perfect harmony seems to have subsisted between the court and the city of Edinburgh; for in 1627 King Charles I. presented the city with a new sword and gown to be worn by the provost at the times appointed by his father James VI. Next year he paid a visit to this capital, and was received by the magistrates in a most pompous manner; but soon after this the disturbances arose which were not terminated but by the death of that unfortunate monarch. These commenced on an attempt of Charles to introduce Episcopacy into the kingdom; and the first step towards this was the erection of the three Lothians and part of Berwick into a diocese, Edinburgh being the episcopal seat, and the church of St Giles the cathedral. An account of the disturbance occasioned by the first attempt to read the prayer book there, is given under the article BRITAIN; but though the attempt was given over, the minds of the people were not to be quieted. Next winter they resorted to town in such multitudes, that the privy-council thought proper to publish two acts; by one of which the people were commanded, under severe penalties, to leave the town in 24 hours; and by the other, the court of session was removed to Linlithgow. The populace and their leaders were so much enraged by the latter, that Lord Traquair and some of the bishops narrowly escaped with their lives; and next year (1638)matters became still more serious. For now, the king having provoked his subjects throughout all Scotland with the innovations he attempted in religion, Edinburgh was made the general place of rendezvous, and the most formidable associations took place; an account of which has already been given under the article BRITAIN. Each of the towns in Scotland had a copy; and that which belonged to Edinburgh, crowded with 5000 names, is still preserved among the records of the city. Notwithstanding this disagreement, however, the king once more visited Edinburgh in 1641, and was entertained by the magistrates at an expence of 12,000l. Scots. It does not appear that after this the city was in any way particularly concerned with the disturbances which followed either throughout the remainder of the reign of Charles I. the commonwealth, or the reign of Charles II. In 1680 the duke of York with his duchess, the princess Anne, and the whole court of Scotland, were entertained by the city in the Parliament House, at the expence of 15,000l. Scots. At this time it is said that the scheme of building the bridge over the North Loch was first projected by the duke.

15
Regulations made by the magistrates.

From the time that King James VI. paid his last visit to Edinburgh in 1618, till the time of the union in 1707, a considerable number of private regulations were made by the magistrates; some of them evidently calculated for the good of the city, others strongly characteristic of that violent spirit of fanaticism which prevailed so much in the last century. Among the former was an act passed in 1621, that the houses, instead of being covered with straw or boards, should have their roofs constructed of slate, tiles, or lead. This act was renewed in 1667; and in 1668 an act was passed regulating their height also. By this they were restrained to five stories, and the thickness of the wall determined to be three feet at bottom. In 1684 a lantern with a candle was ordered to be hung out on the first floor of every house, in order to light the streets at night; and there were two coaches with four horses each ordered to be bought for the use of the magistrates; but it does not appear how long they continued to be used. In 1681 the court of session discontinued its sittings in summer: but as this was found to be attended with inconvenience, an act was passed for their restoration, which has continued ever since. During the time of the civil war in 1649, the city was visited by the plague, which is the last time that dreadful distemper hath made its appearance in this country. The infection was so violent, that the city was almost depopulated, the prisoners were discharged from the tolbooth, and an act was made for giving one Dr Joannes Politius a salary of 80l. Scots per month, for visiting those who were infected with the disease. In 1677 the first coffee-houses were allowed to be opened, but none without a license: and the same year the town council regulated the price of penny weddings; ordaining the men to pay no more than two shillings, and the women 18 pence; very extravagant prices having been exacted before.

In contradistinction to these salutary acts, we may state those which show an extravagant desire of preserving the appearance of virtue in the female sex, as if it had been possible for others to inspire them with virtuous notions if they had not imbibed them of themselves. In 1633 an act of council was passed, by which women were forbidden to wear plaids over their faces, under penalty of five pounds and the forfeiture of the plaid for the first fault. Banishment was the punishment of the third. The reason assigned for this act was, that matrons were not known from strumpets and loose women, while the plaid continued to be worn over the face. This act was renewed in 1637 and 1638. Succeeding town councils continued to show the same regard to these matters; for in 1695 they enacted, that no innkeeper, vintner, or aleseller, should for the future employ women as waiters or servants, under the penalty of five shillings sterling for each.

The following anecdote may perhaps make the virtues of these legislators themselves wear a suspicious aspect. In 1649 the city having borrowed 40,000l. Scots, in order to raise their quota of men for his majesty, the payment of it was absolutely refused by the town-council when a demand was made for that purpose. That they might not, however, depend entirely upon their own opinion in a matter of such importance, they took that of the General Assembly upon the subject; and it was determined by these reverend divines, that they were not in conscience bound to pay for an unlawful engagement which their predecessors had entered into. But in 1652, Cromwell's parliament, who pretended to no less sanctity than they, declared themselves of a very different opinion; and on the application of one of the creditors, forced them to repay the sum.

16 Infamous treatment of the marquis of Montrose.

The treatment which the brave marquis of Montrose met with, likewise fixes an indelible stigma both upon the magistrates and clergy at that time. Having been put under sentence of excommunication, no person was allowed to speak to him or to do him the least office of friendship. Being met without the city by the magistrates and town guard, he was by them conducted in a kind of gloomy procession through the streets bareheaded, and in an elevated cart made for the purpose; the other prisoners walking two and two before him. At the time of his execution he was attended by one of the ministers, who, according to his own account, did not choose to return till *he had seen him casten over the ladder*.

17 Loyalty of the city 1715 an 1725.

The union in 1707 had almost produced a war between the two kingdoms which it was designed to unite; and on that occasion Edinburgh became a scene of the most violent disturbances, of which a particular account is given under the article Britain. During the time the act was passing, it was found absolutely necessary for the guards and four regiments of foot to do duty in the city. The disturbances were augmented by the disagreement of the two members of parliament; and notwithstanding the victory gained at that time by the court party, Sir Patrick Johnston the provost, who voted for the union, was obliged afterwards to leave the country. In 1715 the city remained faithful to the royal cause, and proper measures were taken for its defence. A committee of safety was appointed, the city guard increased, and 400 men raised at the expence of the town. The trained bands likewise were ordered out, 100 of whom mounted guard every night: by which precautions the rebels were prevented from attempting the city: they, however, made themselves masters of the citadel of Leith; but fearing an attack from the duke of Argyll, they abandoned it in the night time. A scheme was even laid for becoming masters of the castle of Edinburgh; for which purpose they bribed a serjeant to place their scaling ladders. Thus some of the rebels got up to the top of the walls before any alarm was given; but in the mean time the plot being discovered by the serjeant's wife, her husband was hanged over the place where he had attempted to introduce the rebels. The expence of the armament which the city had been at on this occasion amounted to about 1700l. which was repaid by government in the year 1721.

The loyalty of this city was still farther remarkable in the year 1725, when disturbances were excited in all parts of the kingdom, particularly in the city of Glasgow, concerning the excise bill; for all remained quiet in Edinburgh, nothwithstanding the violent outcries that were made elsewhere; and so remarkable was the tranquillity in the metropolis, that government afterwards returned thanks to the magistrates for it. In 1736, however, the city had again the misfortune to fall under the royal dipleasure, on the following account. Two smugglers having been detected in stealing their own goods out of a customhouse, were condemned to be hanged. The crime was looked upon as trivial; and therefore a general murmur prevailed among the populace, which was no doubt heightened by the following accident. At that time it had been customary for persons condemned to die to be carried each Sunday to the church, called from that circumstance the *Tolbooth church*. The two prisoners just mentioned were conducted in the usual way, guarded by three soldiers, to prevent their making their escape: but having once gone thither a little before the congregation met, one of the prisoners seized one of the guards in each hand, and the other in his teeth, calling out to his companion to run; which he immediately did with such speed, that he soon got out of sight, and was never heard of afterwards. The person who had thus procured the life of his companion without regard to his own, would no doubt become a general object of compassion; and of course, when led to the place of execution, the guard were severely pelted by the mob, and some of them, according to the testimony of the witnesses who were sworn on the occasion, pretty much wounded. By this Captain Porteous, who commanded the guard, was so much provoked, that he gave orders to fire, by which six people were killed and eleven wounded. The evidence, however, even of the fact that the orders to fire were given, appears not to have been altogether unexceptionable; nevertheless, on this he was tried and condemned to be executed. At that time the king was absent in Hanover, having

18 Captai Porteou execute by a m

having left the regency in the hands of the queen; and the case of the unfortunate Porteous having been represented to her, she was pleased to grant him a reprieve: but such was the inveteracy of the people against him, that they determined not to allow him to avail himself of the royal clemency. On the night previous to the day that had been appointed for his execution, therefore, a number of people assembled, shut the gates of the city, and burnt the door of the prison, the same which the mob would formerly have broken open in order to murder King James. They then took out Porteous, whom it was found impossible to rescue out of their hands, though every method that the magistrates could take for that purpose in such a confusion was made use of. It was even proved that the member of parliament went to the commander in chief, and requested that he would send a party of soldiers to quell the disturbance, but was absolutely denied this request, because he could not produce a written order from the provost to this purport; which, in the confusion then existing in the city, could neither have been expected to be given by the provost, nor would it have been safe for any person to have carried it about him. Thus the unhappy victim was left in the hands of his executioners; and being dragged by them to the place destined for receiving his fate, was hanged on a dyer's sign post. As they had not brought a rope along with them, they broke open a shop where they knew they were to be had; and having taken out what they wanted, left the money upon the table, and retired without committing any other disorder.

Such an atrocious insult on government could not but be highly resented. A royal proclamation was issued, offering a pardon to any accomplice, and a reward of 200l. to any person who would discover one of those concerned. The proclamation was ordered to be read from every pulpit in Scotland the first Sunday of every month for a twelvemonth: but so divided were the people in their opinions about this matter, that many of the clergy hesitated exceedingly about complying with the royal order, by which they were brought in danger of being turned out of their livings; while those who complied were rendered so unpopular, that their situation was rendered still worse than the others. All the efforts of government, however, were insufficient to produce any discovery; by which, no doubt, the court was still more exasperated; and it was now determined to execute vengeance on the magistrates and city at large. Alexander Wilson, the provost at that time, was imprisoned three weeks before he could be admitted to bail; after which, he and the four bailies, with the lords of justiciary, were ordered to attend the house of peers at London. On their arrival there a debate ensued, whether the lords should attend in their robes or not? but at last it was agreed that they should attend in their robes at the bar. This, however, was refused by their lordships, who insisted that they should be examined within the bar; upon which the affair of their examination was dropped altogether. A bill at last passed both houses, by which it was enacted that the city of Edinburgh should be fined 2000l. for the benefit of Porteous's widow (though she was prevailed upon to accept of 1500l. for the whole); and the provost was declared incapable of ever serving government again in any capacity whatever. To prevent such catastrophes in time coming, the town council enacted, that, on the first appearance of an insurrection, the chief officers in the different societies and corporations should repair to the council to receive the orders of the magistrates for the quelling of the tumult, under the penalty of 8l. 6s. 8d. for each omission.

20 The city taken by the rebels in 1745.

In 1745, the city was invested by the Pretender's army; and on the 17th of September, the Netherbow gate being opened to let a coach pass, a party of Highlanders, who had reached the gate undiscovered, rushed in, and took possession of the city. The inhabitants were commanded to deliver up their arms at the palace of Holyroodhouse; a certain quantity of military stores was required from the city, under pain of military execution; and an assessment of 2s. 6d. upon the pound was imposed upon the *real* rents within the city and liberties for defraying that expence.

The pretender's army guarded all the avenues to the castle; but no signs of hostilities ensued till the 25th of the month, when the garrison being alarmed from some unknown cause, a number of cannon were discharged at the guard placed at the West Port, but with very little effect. This gave occasion to an order to the guard at the Weigh-house, to prevent all intercourse between the city and castle; and then the governor acquainted the provost by letter, that unless the communication was preserved, he would be obliged to dislodge the guard by means of artillery. A deputation was next sent to the Pretender, acquainting him with the danger the city was in, and entreating him to withdraw the guard. With this he refused to comply; and the Highland centinels firing at some people who were carrying provisions into the castle, a pretty smart cannonading ensued, which set on fire several houses, killed some people, and did other damage. The Pretender then consented to dismiss the guard, and the cannonading ceased. After the battle of Culloden, the provost of Edinburgh was obliged to stand a very long and severe trial, first at London and then at Edinburgh, for not defending the city against the rebels; which, from the situation and extent of the walls, every one must have seen to be impossible.

During this trial a very uncommon circumstance happened; the jury having sat two days, insisted that they could sit no longer, and prayed for a short respite. As the urgency of the case was apparent, and both parties agreed, the court, after long reasoning, adjourned till the day following, taking the jury bound under a penalty of 500l. each; when the court continued sitting two days longer, and the jury were one day enclosed. The event was, that the provost was exculpated.

21 Government of the city restored.

After the battle of Culloden the duke of Cumberland caused fourteen of the rebel standards to be burned at the cross; that of the Pretender was carried by the common executioner, the others by chimney-sweepers; the heralds proclaiming the names of the commanders to whom they belonged as they were thrown into the fire. At this time the city of Edinburgh felt a temporary inconvenience from the election of their magistrates not having taken place at the usual time; so that it became necessary to apply to his majesty for the restoration of the government of the city. This was readily granted, the burgesses being allowed a poll tax; after which an entire new set of magistrates was returned,

returned, all of them friends to the house of Hanover; and soon after the freedom of the city in a gold box was presented to the duke of Cumberland.

With these transactions all interferences betwixt government and the metropolis of Scotland were ended; the rest of its history therefore only consists of internal occurences, the regulations made by its own magistrates for the benefit of the city, their applications to government for leave to improve it, or the execution of these improvements; of which we shall now give a brief detail.

22
Salary bestowed on the provost.

In the year 1716, the city first bestowed a settled salary on the provost, in order to enable him to support the dignity of the first magistrate. This was at first 100l.; was afterwards augmented to 500l. and now we believe is a larger sum. In 1718 it was recommended to the magistrates to distinguish themselves by wearing coats of black velvet, for which they were allowed 10l. but this act being abrogated in 1754, gold chains were assigned as badges of their office, which they continue to wear. Provost Kincaid happened to die in office in the year 1777; which being a rare occurrence, perhaps the only one at that time of the kind to be met with in the records of Edinburgh, he was buried with great solemnity. A similar funeral procession took place at the death of Mr Coulter in 1809.

23
Account of tumults.

Tumults have been frequent in Edinburgh, chiefly on account of the dearness of provisions. In 1740 Bell's mills were first attacked by the populace, and afterwards Leith mills; nor could the rioters be dispersed till the military had fired among them and wounded three, of whom one died; and it was found necessary to order some dragoons into the city in order to preserve tranquillity. In 1742, another violent tumult took place, owing to a custom of stealing dead bodies from their graves for anatomical purposes, which had then become common. The populace beat to arms, threatened destruction to the surgeons; and, in spite of the efforts of the magistrates, demolished the house of the beadle at St Cuthbert's. In 1756 new disturbances, which required the assistance of the military, took place: the cause at this time was the impressing of men for the war which was then commencing. A disturbance was likewise excited in 1760. This was occasioned by the footmen, who till then were allowed to follow their masters into the playhouse, and now took upon them to disturb the entertainment of the company; the consequence of which was, that they were turned out, and have ever since been obliged to wait for their masters. In 1763 and 1765, the tumults on account of the price of provisions were renewed; many of the mealmongers had their houses broken open and their shops destroyed. The magistrates, as usual, were obliged to call in a party of dragoons to quell the disturbance; but at the same time, to put an effectual stop, as far as was in their power, to these proceedings for the future, they gave security, that people who brought grain or provision into the market should be secured in their property. Since that time there have been no tumults directly on the account of provisions; though in 1784 a terrible riot and attack of a distillery at Canonmills took place, on a supposition that the distillers enhanced the price of meal by using unmalted grain. The attack was repelled by the servants of the distillery; but the mob could not be quelled until the sheriff called the soldiers quartered in the castle to his assistance. The same night a party of rioters set out for Ford, a place ten miles to the southward, where there was likewise a large distillery; which, as there was none to make any opposition, they soon destroyed. One man was killed in this riot at Edinburgh by the fire of a servant of the distillery, and several of the rioters were afterwards secured and punished.

In the years 1778 and 1779 two very alarming disturbances happened, which threatened a great deal of bloodshed, though happily they were terminated without any. The first was a mutiny of the earl of Seaforth's Highland regiment, who were at this time quartered in the castle. These having been ordered to embark, for some reason or other unanimously refused, and posted themselves on the top of Arthur's seat, where they continued for two days. Troops were collected to prevent their escape, and the inhabitants were ordered to keep within doors at the first toll of the great bell, which was to be a signal of violence about to take place; but fortunately all the fears, naturally arising from the expectation of this event, were dissipated by an accommodation. The other happened on account of the attempt to repeal the penal laws against the Papists; and was much more alarming than the other, as being the effect of a premeditated scheme and determined resolution to oppose government. On the second of February 1779 a mob assembled in the evening, burned a Popish chapel, and plundered another. Next day they renewed their depredations; destroying and carrying off the books, furniture, &c. of several Popish priests and others of that persuasion. The riot continued all that day, though the assistance of the military was called in; but happily no lives were lost, nor was there any firing. The city was afterwards obliged to make good the damage sustained by the Catholics on this occasion, which was estimated at 1500l. This year also an unlucky accident happened at Leith. About 50 Highland recruits having refused to embark, a party of the South Fencibles was sent to take them prisoners. Unexpectedly, however, the Highlanders stood upon their defence; when, after some words, a firing commenced on both sides, and about one half of the Highlanders were killed and wounded, the remainder being taken prisoners and carried to the castle. Captain Mansfield and two or three privates were killed in this affray.

24
General history the improveme

We shall close this history of Edinburgh with a general account of the improvements which have lately taken place in it, and of which a particular description will afterwards be given. These began in the year 1753, when the foundation-stone of the Exchange was laid, at which time there was a grand procession, and the greatest concourse of people ever known in Edinburgh. A triumphal arch was erected for the purpose, through which the procession passed, and medals were scattered among the populace. In 1756 the high street was cleared by the removal of the cross; though many regretted this, on account of its being a very ancient and elegant building. In the middle it had an unicorn placed on the top of a pillar 20 feet high; but this fine ornament was broken to pieces by the giving way of the tackle by which it was attempted to remove it. It is now again erected at Drum, a seat formerly belonging to Lord Somerville, about four miles

miles from Edinburgh. In 1763 the first stone of the North bridge was laid by Provost Drummond; and in 1767 an act of parliament was obtained for extending the royalty of the city over the fields to the northward, where the New Town is now situated. About the same time a spot of ground upon the south side of the town was purchased by a private person for 1200l. which being feued out for building, gave rise to the increase of the town in that quarter; and this proceeded the more rapidly, as the houses built there were free from the duties imposed upon others subject to the royalty. In 1774 the foundation of the Register Office was laid. In 1784 the project for rendering the access to the town equally easy on both sides was begun to be put in execution by laying the foundation of the South bridge. At the same time a great improvement was made by reducing the height of the street several feet all the way from the place where the cross stood to the Netherbow; by which means the ascent is rendered more easy, not only for carriages, but also for persons who walk on foot. At the same time, the street was farther cleared by the removal of the town guard house, which had long been complained of as an encumbrance. The taking down of the Luckenbooths in 1802-3, removed a still greater encumbrance. The old jail at the west end, and the land over Mr Creech's shop at the east end, however, still remained to disfigure the street till 1817, when both were pulled down, and the street laid completely open. By the removal of these buildings, and of the old council chamber, the cathedral of Saint Giles is now exposed to view on all sides. As several of its parts are much decayed, and the whole has rather a dilapidated appearance, it is in contemplation to case it over with new stone, preserving the original plan and style of building. The last improvement which requires to be mentioned, is the magnificent new road over the Calton hill, which was begun in 1816, and opened in 1820. It is connected with Prince's street by the Regent bridge, a single arch of 50 feet span, but finished in the upper part in a very handsome style, and adorned with two fine ranges of buildings. This new road, with the Regent bridge, forms a very fine approach to the city on the east, and is admired by all travellers for its singular appearance, and the picturesque views it affords of the town.

Having thus given a concise history of the city from its earliest foundation, we shall now proceed to describe it in its most improved state.

Description of Ed- urgh.

Edinburgh is situated upon a steep hill, rising from east to west, and terminating in a high and inaccessible rock, upon which the castle stands. At the east end or lower extremity of this hill stands the abbey of Holyroodhouse, or king's palace, distant from the castle upwards of a mile; and betwixt which, along the top of the ridge, and almost in a straight line, runs the High street. On each side, and parallel to this ridge or hill, is another ridge of ground lower than that in the middle, and which does not extend so far to the east: that on the south being intercepted by Salisbury rocks and Arthur's seat, a hill of about 800 feet of perpendicular height; and that on the north by the Calton hill, considerably lower than Arthur's seat; so that the situation of this city is most singular and romantic; the east or lower part of the town lying between two hills; and the west or higher part rising up towards a third hill, little inferior in height to the highest of the other two, upon which, as has been observed, the castle is built, and overlooks the town.

The buildings of the town terminate at the distance of about 200 yards from the castle gate; which space affords a most delightful as well as convenient and healthful walk to the inhabitants. The prospect from this spot is perhaps the finest anywhere to be met with, for extent, beauty, and variety.

In the valley or hollow betwixt the mid and the south ridges, and nearly parallel to the High street, is another street called the Cowgate; and the town has now extended itself over most part of that south ridge also. Betwixt the mid and the north ridges was a loch, which, till of very late, terminated the town on that side. From the High street towards the loch on the north, and Cowgate on the south, run narrow cross streets or lanes, called *wynds* and *closes*, which grow steeper and steeper the farther west or nearer the castle; so that, were it not for the closeness and great height of the buildings, this city, from its situation and plan, might naturally be expected to be the best aired, as well as the cleanest, in Europe. The former, notwithstanding these disadvantages, it enjoys in an eminent degree; but we cannot compliment it upon the latter, notwithstanding every possible means has been used by the magistrates for that purpose.

26 Account of the gradual increase of Edinburgh.

The gradual increase of the city of Edinburgh may in some degree be understood from the traces of its ancient walls that still remain. James II. in 1450, first bestowed on the community the privilege of fortifying the city with a wall, and empowered them to levy a tax upon the inhabitants for defraying the expence. When the city was first fortified, the wall reached no farther than the present water-house, or reservoir, on the Castle hill: from thence to the head of Halkerston's wynd, just below the new bridge, the city was defended by the North Loch; an inconsiderable morass, which, being formerly overflowed, formed a small lake that has since been drained. From this place to the foot of Leith wynd, it does not appear how the city was fortified: but from the foot of Leith wynd to the Nether-bow port it was defended only by a range of houses; and when these had become ruinous, a wall was built in their place. The original wall of Edinburgh, therefore, began at the foot of the north-east rock of the castle. Here it was strengthened by a small fortress, the ruins of which are still to be seen, and are called the *Well-house tower*, from their having a spring in their neighbourhood. When the wall came opposite to the reservoir, it was carried quite across the hill, having a gate on the top for making a communication between the town and castle. In going down the hill, it went slanting in an oblique direction to the first angle in going down the West-bow, where was a gate named the *Upper-bow Port*, one of the hooks of which still remains. Thence it proceeded eastward in such a manner, as would have cut off not only all the Cowgate, but some part of the Parliament house; and being continued as far as the Mint close, it turned to the north-east, and connected itself with the buildings on the north side of the High street, where was the original

Nether-bow Port, about 50 yards west from that which afterwards went by the same name.

Soon after the building of this wall, a new street was formed on the outside of it, named the *Cowgate*, which in the 16th century became the residence of the nobility, the senators of the college of justice, and other persons of the first distinction. After the fatal battle of Flowden, however, the inhabitants of the Cowgate became very anxious to have themselves defended by a wall as well as the rest. The wall of the city was therefore extended to its present limits. This new wall begins on the south-east side of the rock on which the castle is built, and to which the town wall comes quite close. From thence it descends obliquely to the West Port; then ascends part of a hill on the other side, called the *High Riggs;* after which, it runs eastward with but little alteration in its course, to the Bristo and Potter-row ports, and from thence to the Pleasance. Here it takes a northerly direction, which it keeps from thence to the Cowgate port; after which the enclosure is completed to the Nether-bow by the houses of St Mary's wynd. The original Nether-bow port, being found not well adapted for defence, was pulled down, and a new one built in 1571 by the adherents of Queen Mary. In 1606, the late handsome building was erected about 50 yards below the place where the former stood. It was two stories high, and had an elegant spire in the middle; but being thought to encumber the street, and the whole building being in a crazy situation, it was pulled down by order of the magistrates in 1764.

In the original wall of Edinburgh there was, as has been already observed, a port on the Castle-hill. On the extension of the wall, after building the houses in the Cowgate, this gate was pulled down. That in the upper or West-bow stood for a much longer time, and was pulled down within the memory of some persons lately or perhaps still living. Besides these, there was a third, about 50 yards above the head of the Canongate; but whether there were any more, is uncertain. The ports or gates of the new walls were, 1. The *West Port*, situated at the extremity of the Grass Market; beyond which lies a suburb of the town and a borough of regality, called *Portsburgh.* Next to this is a wicket, struck out of the town wall in 1744, for the purpose of making an easier communication between the town and the public walks in the meadows, than by Bristo port. The next to this was *Bristo Port*, built in 1515; beyond which lies a suburb called *Bristo Street.* At a small distance from Bristo was the *Potter-row Port*, which took this name from a manufactory of earthen ware in the neighbourhood. Formerly it was called *Kirk of Field Port.* Between this and the Cowgate port stood another, called *St Mary's Wynd Port*, which extended from east to west across the foot of the Pleasance, and which was demolished only since the middle of the last century. Close to the middle of this stood the *Cowgate Port;* which opened a communication between the Cowgate and St Mary's wynd, and the Pleasance. The *Nether-bow Port* has been already spoken of. At the foot of Leith wynd was another gate, known by the name of *Leith Wynd Port;* and within it was a wicket giving access to the church of Trinity College, and which still remains. At the foot of Halkerston's wynd was another, which, as well as the former, was built about the year 1560. Both of these were pulled down some years ago, and all the rest in 1785. Another still remains at the foot of the Canongate, known by the name of the *Water-gate.*

For 250 years the city of Edinburgh occupied the same space of ground, and it is but very lately that its limits have been so considerably enlarged. In the middle of the 16th century, it is described as extending in length about an Italian mile, and about half as much in breadth; which answers very nearly to its present limits, the late enlargements only excepted. This space of ground, however, was not at that time occupied in the manner it is at present. The houses were neither so high nor so crowded upon each other as they are now. This was a consequence of the number of inhabitants increasing, which has occasioned the raising of the houses to such a height as is perhaps not to be paralleled in any other part of the world. Till the time of the Reformation, the burying ground of the city extended over all the space occupied by the Parliament square, and from thence to the Cowgate. The lands lying to the southward of the Cowgate were chiefly laid out in gardens belonging to the convent of Black friars, and the church of St Mary in the Field. These extended almost from the Pleasance to the Potterrow port. From the Bristo to the West port the ground was laid out in gardens belonging to the Gray friars. The magistrates, on their application to Queen Mary, obtained a grant of the Gray friars gardens for a burying place; for which it was given as a reason, that they were somewhat distant from the town. Here, however, it must be understood, that these gardens were distant from the houses, and not without the walls; for they had been enclosed by them long before. In the time of James I. the houses within the walls, seem to have been in general, if not universally, covered with thatch or broom; and not above 20 feet high. Even in the year 1621, these roofs were so common, that they were prohibited by act of parliament, in order to prevent accidents from fire. In the middle of the 17th century, there were neither courts nor squares in Edinburgh. The Parliament close or square is the oldest of this kind in the city. Miln's square, James's court, &c. were built long after; and Argyle's and Brown's squares about the years 1750 or 1760. 27

New To

The *New Town* was projected in the year 1752; but as the magistrates could not then procure an extension of the royalty, the execution of the design was suspended for some time. In 1767, an act was obtained, by which the royalty was extended over the fields to the northward of the city; upon which advertisements were published by the magistrates, desiring proper plans to be given in. Plans were given in accordingly, and that designed by Mr James Craig architect was adopted. Immediately afterwards, people were invited to purchase lots from the town council; and such as purchased became bound to conform to the rules of the plan. In the mean time, however, the town council had secretly reserved to themselves a privilege of departing from their own plan; which they afterwards made use of in such a manner as produced a law-suit. According to the plan held forth to the purchasers, a canal was to be made through that place

place where the North Loch had been, and the bank on the north side of it laid out in terraces: but instead of this, by an act of council, liberty was reserved to the town to build upon this spot; and therefore, when many gentlemen had built genteel houses in the new town on faith of the plan, they were surprised to find the spot appointed for terraces and a canal, beginning to be covered with mean irregular buildings, and work houses for tradesmen. This deviation was immediately complained of; but as the magistrates showed no inclination to grant any redress, a prosecution was commenced against them before the Lords of Session. In that court the cause was given against the pursuers, who thereupon appealed to the House of Lords. Here the sentence of the Court of Session was reversed, and the cause remitted to the consideration of their Lordships. At last, after an expensive contest, matters were accommodated. The principal term of accommodation was, that some part of the ground was to be laid out in terraces and a canal; but the time of disposing it in that manner, was referred to the Lord President of the Court of Session and the Lord Chief Baron of the Exchequer. The fall of part of the bridge, hereafter mentioned, proved a very considerable disadvantage to the New Town; as it necessarily induced a suspicion that the passage, by means of the bridge, could never be rendered safe. An oversight of the magistrates proved of more essential detriment. A piece of ground lay to the southward of the Old Town, in a situation very proper for building. This the magistrates had an opportunity of purchasing for 1200l.; which, however, they neglected, and it was bought by a private person, who immediately feued it out in lots for building, as has been already mentioned. The magistrates then began to see the consequence, namely, that this spot being free from the duties to which the royalty of Edinburgh is subject, people would choose to reside there rather than in the New Town. Upon this they offered the purchaser 2000l. for the ground for which he had paid 1200l.; but as he demanded 20,000l. the bargain did not take place. Notwithstanding these discouragements, the New Town is now almost finished; and from the advantages of its situation, and its being built according to a regular plan, it has undoubtedly a superiority over any city in Britain. By its situation, however, it is remarkably exposed to storms of wind, which at Edinburgh sometimes rage with uncommon violence.

It has three streets, almost a mile in length, running from east to west, intersected with cross streets at proper distances. Queen's street, the most northerly, till lately that Heriot row and Great King street were built, is 100 feet broad, and commands an extensive prospect of the Forth, the county of Fife, and the shipping in the river. That called *George's Street*, which is in the middle, is no less than 115 feet wide. It is terminated at each end by two very elegant and extensive squares; that on the east end is called *St Andrew's Square;* the other, which is not yet finished, is called *Charlotte's Square.* Prince's street is the most southerly; and extends from the northern extremity of the bridge, quite to the west end of the town. It was only finished in 1805. From the west end of Prince's street, a spacious street (Maitland street) has been opened to join the two roads to Glasgow by Airdrie and Whitburn. This has greatly improved the approach to the town from the west. The northern part of the New Town, which is now in progress, is distinguished from the older part, by the superior style of the architecture. Heriot row, with its continuation Abercromby place, and Great King street now building, are peculiarly beautiful in their design and decorations.

The most remarkable public buildings in Edinburgh are—

28
Public buildings described.

1. *The Castle.* This stands on a high rock, accessible only on the east side. On all others it is very steep, and in some places perpendicular. It is about 300 feet high from its base: so that, before the invention of artillery, it might well have been deemed impregnable; though the event showed that it was not. The entry to this fortress is defended by an outer barrier of pallisadoes; within this is a dry ditch, draw-bridge, and gate, defended by two batteries which flank it; and the whole is commanded by a half moon mounted with brass cannon, carrying balls of 12 pounds. Beyond these are two gate-ways, the first of which is very strong, and has two portcullises. Immediately beyond the second gateway, on the right hand, is a battery mounted with brass cannon, carrying balls of 12 and 18 pounds weight. On the north side are a mortar and some gun batteries. The upper part of the castle contains a half-moon battery, a chapel, a parade for exercise, and a number of houses in the form of a square, which are laid out in barracks for the officers. Besides these, there are other barracks sufficient to contain 1000 men; a powder magazine, bomb proof; a grand arsenal, capable of containing 8000 stand of arms; and other apartments for the same use, which can contain 22,000 more: so that 30,000 stand of arms may be conveniently lodged in this castle. On the east side of the square above mentioned, were formerly royal apartments; in one of which King James VI. was born, and which is still shown to those who visit the castle. In another, the regalia of Scotland were deposited on the 26th of March 1707; but as they were never shown to any body, a suspicion had arisen that they were carried to London. This has however been removed. Commissioners, with the necessary powers, opened a large oaken chest in February 1818, in which were found the Scottish crown, sceptre, and sword of state, of elegant workmanship, and in perfect preservation.

The governor of the castle is generally a nobleman, whose place is worth about 1000l. a-year; and that of deputy governor, 500l. This last resides in the house appointed for the governor, as the former never inhabits it. There is also a fort-major, a store-keeper, master-gunner, and chaplain; but as this last does not reside in the castle, worship is seldom performed in the chapel. The parliament house was formerly included in the great square on the top, and the royal gardens were in the marsh afterwards called the *North Loch;* the king's stables being on the south side, where the houses still retain the name, and the place where the barns were still retains the name of Castlebarns.

The castle is defended by a company of invalids, and four or five hundred men belonging to some marching regiment, though it can accommodate 1000, as above mentioned; and this number has been sometimes kept in it. It could not, in all probability, withstand, even for a few hours, a well directed bombardment: for no part but the powder magazine is capable of resisting these destructive machines; and the splinters from the rock on which the castle is built, could not fail to render them still more formidable. Besides, the water of the well, which is very bad, and drawn up from a depth of 100 feet, is apt to subside on the continued discharge of artillery, which produces a concussion in the rock.

2. *The Palace of Holyroodhouse.* This, though much neglected, is the only royal habitation in Scotland that is not entirely in ruins. It had a handsome square of 230 feet in the inside, surrounded with piazzas. The front, facing the west, consists of two double towers joined by a beautiful low building, adorned with a double balustrade above. The gate-way in the middle is decorated with double stone columns, supporting a cupola in the middle, representing an imperial crown, with a clock underneath. On the right hand is the great staircase which leads to the council chamber and the royal apartments. These are large and spacious, but unfurnished: in one of them the Scotch peers meet to elect 16 of their number to represent them in parliament. The gallery is on the left hand, and measures 150 feet by 27½. It is adorned with the supposed portraits of all the kings of Scotland. In the apartments of the duke of Hamilton, which he possesses as hereditary keeper of the palace, Queen Mary's bed of crimson damask, bordered with green fringes and tassels, is still to be seen, but almost reduced to rags. Here also strangers are shown a piece of wainscot, hung upon hinges, which opens to a trap stair communicating with the apartments below. Through this passage Darnley and the other conspirators rushed in to murder the unhappy Rizzio. Towards the outward door of these apartments are large dusky spots on the floor, said to be occasioned by Rizzio's blood, which could never be washed out. In the lodgings assigned to Lord Dunmore is a picture by Van Dyke, esteemed a masterly performance, of King Charles I. and his queen going a-hunting. There are likewise the portraits of their present majesties at full length by Ramsay. The lodgings above the royal apartments are occupied by the duke of Argyle as heritable master of the household.

The front of this palace is two stories high; the roof flat; but at each end the front projects, and is ornamented with circular towers at the angles. Here the building is much higher, and the rest of the palace is three stories in height. The north-west towers were built by James V. for his own residence: his name is still to be seen below a niche in one of these towers. During the minority of Queen Mary, this palace was burned by the English; but soon after repaired and enlarged beyond its present size. At that time it consisted of five courts, the most westerly of which was the largest. It was bounded on the east by the front of the palace, which occupied the same space it does at present; but the building itself extended further to the south. At the north-west corner was a strong gate with Gothic pillars, arches, and towers, part of which was not long ago pulled down. Great part of the palace was burnt by Cromwell's soldiers; but it was repaired and altered into the present form after the Restoration. The fabric was planned by Sir William Bruce a celebrated architect, and executed by Robert Mylne mason. The environs of the palace afford an asylum for insolvent debtors; and adjoining to it is an extensive park, all of which is a sanctuary.

The abbey church was formerly called the *monastery of Holyroodhouse*, and built by King David I. in 1128. He gave it the name of *Holyroodhouse*, in memory, as is said, of his deliverance from an enraged hart, by the miraculous interposition of a cross from heaven. This monastery he gave to the canons regular of St Augustine: on whom also he bestowed the church of Edinburgh castle, with those of St Cuthbert's, Corstorphin, and Libberton, in the shire of Mid Lothian, and of Airth in Stirlingshire; the priories of St Mary's Isle in Galloway, of Blantyre in Clydesdale, of Rowadill in Ross, and three others in the Western Isles. To them he also granted the privilege of erecting a borough between the town of Edinburgh and the church of Holyroodhouse. From these canons it had the name of the *Canongate*, which it still retains. In this new borough they had a right to hold markets. They had also portions of land in different parts, with a most extensive jurisdiction, and right of trial by duel, and fire and water ordeal. They had also certain revenues payable out of the exchequer and other funds, with fishings, and the privilege of erecting mills on the water of Leith, which still retain the name of *Canon mills*. Other grants and privileges were bestowed by succeeding sovereigns; so that it was deemed the richest religious foundation in Scotland. At the Reformation, its annual revenues were 442 bolls of wheat, 640 bolls of bear, 560 bolls of oats, 500 capons, two dozen of hens, as many salmon, 12 loads of salt; besides a great number of swine, and about 250l. sterling in money. At the Reformation, the superiority of North Leith, part of the Pleasance, the barony of Broughton, and the Canongate, were vested in the earl of Roxburgh; and were purchased from him by the town council of Edinburgh in 1636. In 1544, the church suffered considerably by the invasion of the English; but was speedily repaired. At the Restoration, King Charles II. ordered the church to be set apart as a chapel royal, and prohibited its use as a common parish church for the future. It was then fitted up in a very elegant manner. A throne was erected for the sovereign, and 12 stalls for the knights of the order of the Thistle: but as mass had been celebrated in it in the reign of James VII. and it had an organ, with a spire, and a fine chime of bells on the west side, the Presbyterians at the Revolution entirely destroyed its ornaments, and left nothing but the bare walls.—Through time, the roof of the church became ruinous; on which the duke of Hamilton represented its condition to the barons of exchequer, and craved that it might be repaired. This request was complied with: but the architect and mason who were employed, covered the roof with thick flag stones, which soon impaired the fabric; and on the 2d of December 1768, the roof fell in. Since that time, no attempt has been made to repair it, and it is now entirely fallen to ruin.

The ruins of this church, however, are still sufficient to discover the excellency of the workmanship. Here some of the kings of Scotland are interred; and an odd kind of curiosity has been the occasion of exposing some bones said to be those of Lord Darnley and a countess of Roxburgh who died several hundred years ago. Those said to belong to the former were very large, and the latter had some flesh dried upon them. The chapel was fitted up in the elegant manner above mentioned by James VII. but such was the enthusiasm of the mob, that they not only destroyed the ornaments, but tore up even the pavement, which was of marble.

To the eastward of the palace is the bowling green, now entirely in disorder; and behind it is a field called *St Ann's Yards*. Beyond this is a piece of ground called *the King's Park;* which undoubtedly was formerly overgrown with wood, though now there is not a single tree in it. It is about three miles in circumference; and was first enclosed by James V. It contains the rocky hills of *ARTHUR's Seat* and Salisbury Craigs, which last afford an inexhaustible stone quarry; and upon the north side of the hill stands an old ruinous chapel, dedicated to St Anthony. The stones are used in building, as well as for paving the streets and highways. The park was mortgaged to the family of Haddington for a debt due to them. A good number of sheep and some black cattle are fed upon it. A footpath, completed in 1820, along the north-west side of Salisbury Craig, affords one of the most beautiful and romantic walks in existence.

3. *St Giles's Church* is a venerable Gothic building, measuring in length 206 feet. At the west end, its breadth is 110; in the middle, 129; and at the east end, 76 feet. It has a very elevated situation, and is adorned with a lofty square tower; from the sides and corners of which arise arches of figured stone work: these meeting with each other in the middle, complete the figure of an imperial crown, the top of which terminates in a pointed spire. The whole height of this tower is 161 feet.

This is the most ancient church in Edinburgh. From a passage in an old author called *Simeon Dunelmensis*, some conjecture it to have been built before the year 854; but we do not find express mention made of it before 1359. The tutelar saint of this church, and of Edinburgh, was St Giles, a native of Greece. He lived in the sixth century, and was descended of an illustrious family. On the death of his parents, he gave all his estate to the poor; and travelled into France, where he retired into a wilderness near the conflux of the Rhone with the sea, and continued there three years. Having obtained the reputation of extraordinary sanctity, various miracles were attributed to him; and he founded a monastery in Languedoc, known long after by the name of *St Giles's*.—In the reign of James II. Mr Preston of Gorton, a gentleman whose descendants still possess an estate in the county of Edinburgh, got possession of an arm of this saint; which relick he bequeathed to the church of Edinburgh. In gratitude for this donation, the magistrates granted a charter in favour of Mr Preston's heirs, by which the nearest heir of the name of Preston was entitled to carry it in all processions. At the same time, the magistrates obliged themselves to found an altar in the church of St Giles's, and appoint a chaplain for celebrating an annual mass for the soul of Mr Preston; and likewise, that a tablet, containing his arms, and an account of his pious donation, should be put up in the chapel.—St Giles's was first simply a parish church, of which the bishop of Lindisfarn or Holy Island, in the county of Northumberland, was patron. He was succeeded in the patronage by the abbot and canons of Dunfermline, and they by the magistrates of Edinburgh. In 1466, it was erected into a collegiate church by James III. At the Reformation, the church was, for the greater convenience, divided into several parts. The four principal ones are appropriated to divine worship, the lesser ones to other purposes. At the same time the religious utensils belonging to this church were seized by the magistrates. They were,—St Giles's arm, enshrined in silver, weighing five pounds three ounces and a half; a silver chalice, or communion cup, weighing 23 ounces; the great *eucharist* or communion cup, with *golden weike and stones;* two cruets of 25 ounces; a golden bell, with a heart, of four ounces and a half; a golden unicorn; a golden pix, to keep the host; a small golden heart, with two pearls; a diamond ring; a silver chalice, patine, and spoon, of 32 ounces and a half: a communion table cloth of gold brocade; *St Giles's coat*, with a little piece of red velvet which hung at his feet; a round silver *eucharist;* two silver censers, of three pounds fifteen ounces; a silver ship for incense; a large silver cross, with its base, weighing sixteen pounds thirteen ounces and a half; a triangular silver lamp; two silver candlesticks, of seven pounds three ounces; other two, of eight pounds thirteen ounces; a silver chalice gilt, of 20½ ounces; a silver chalice and cross, of 75 ounces; besides the priests robes, and other vestments, of gold brocade, crimson velvet embroidered with gold, and green damask.—These were all sold, and part of the money applied to the repairs of the church; the rest was added to the funds of the corporation.

In the steeple of St Giles's church are three large bells brought from Holland in 1621; the largest weighing 2000lb. the second 700, and the third 500. There are also a set of music bells, which play every day between one and two o'clock, or at any time in the case of rejoicings. The cathedral is divided by partition walls; and the principal apartments are used as four separate churches, which are distinguished by the names of the *New* or *High Church*, the *Old Church*, the *Tolbooth Church*, which is contiguous to the prison, and the *Little Church*, or *Haddow's Hole Church*, which derives its latter name from a gentleman who had been confined in it. The principal division is called the *High Church*, which has been elegantly repaired and new seated. There is a very elegant and finely ornamented seat for his majesty, with a canopy supported by four Corinthian pillars decorated in high taste. This seat is used by the king's commissioner during the time the General Assembly sits. On the right hand is a seat for the lord high constable of Scotland, whose office it is to keep the peace within doors in his majesty's presence; it being the duty of the earl marshal to do the same without. The seats belonging to the lords of council and session are on the right of the lord high constable; and on the left of the throne was a seat for the lord high chancellor of Scotland; but that office being now abolished, the seat is occupied by others. On the left of this sit the barons of exchequer; and, to the left of them, the lord provost, magistrates, and town council. The pulpit, king's seat, and galleries, are covered with crimson velvet with gold and silk fringes.

The aisle of St Giles's church is fitted up with seats for the general assembly, who meet here; and there is a throne for his majesty's commissioner, with a canopy of crimson silk damask, having the king's arms embroidered with gold, presented by the late Lord Cathcart to his successor in office. In this church is a monument dedicated to the memory of Lord Napier, baron of Merchiston, well known as the inventor of logarithms; a second, to the earl of Murray, regent of Scotland during the minority of James VI.; and a third, to the great marquis of Montrose.

4. *The Parliament House*, in the great hall of which the Scottish parliament used to assemble, is a magnificent building. The hall is 123 feet long and 42 broad, with a fine arched roof of oak, painted and gilded. In this the lawyers and agents now attend the courts, and single judges sit to determine causes in the first instance, or to prepare them for the whole court, who sit in an inner room formerly appropriated to the privy council. Since the division of the court into two bodies in 1808, an additional chamber has been built for the second division, on the west side of the large hall. The statue of President Forbes is now placed in this room. The statue of President Blair was placed in the chamber of the first division in 1818; and in the same year a marble statue of Lord Melville was erected in the outer or large hall. Two smaller apartments were built for the use of the judge ordinaries, at the south end of the large hall in 1820. In this hall, there are also full-length portraits of King William III. Queen Mary his consort, and Queen Anne, all done by Sir Godfrey Kneller; also of George I. John duke of Argyle, and Archibald duke of Argyle, by Mr Aikman of Cairney.

The Scottish Court of Exchequer occupies the new apartments above and to the east of the Parliament house, on the second floor. The valuable library of the Faculty of Advocates, occupies the ground floor of the Parliament house; but a splendid new room above that of the writers to the signet is preparing. Besides 30,000 printed volumes, it contains many scarce and valuable manuscripts, medals, and coins: here is also an entire mummy in its original chest, presented to the faculty (at the expence of 300l.) by the earl of Morton, late president to the Royal Society. As these rooms are immediately below the hall where the parliament sat, they are subject to a search by the lord high constable of Scotland ever since the gunpowder plot; and this is specified in the gift from the city to the faculty. This library was founded in the year 1682, by Sir George Mackenzie lord advocate. Among other privileges, it is entitled to a copy of every book entered in Stationers hall. Before the great door is a noble equestrian statue of Charles II. the proportions of which are reckoned exceedingly just. Over the entrance are the arms of Scotland, with Mercy and Truth on each side for supporters.

5. *The Tolbooth* was erected in 1561, not for the purposes merely of a prison, but likewise for the accommodation of the parliament and other courts; but it has since become so very unfit for any of these purposes, that it is now proposed to pull it down, and rebuild it in some other place, especially as it is very inconvenient in its present situation on account of its encumbering the streets. The provost is captain of the tolbooth, with a gaoler under him: and the latter has a monopoly of all the provisions for the prisoners; a circumstance which must certainly be considered as a grievous oppression, those who are least able to purchase them being thus obliged to do so at the highest price. There is a chaplain who has a salary of 30l. a year.

6. *Bridewell.* "On the Calton-hill, to be seen from the North Bridge, is a correction-house or *Bridewell*, built within these few years. It is a strong stone fabric. The principal part of the building is in the form of the letter D, with a house for the governor at some distance opposite to the northern or rectilineal part of it. The whole is surrounded by lofty walls, betwixt which and the house is an area laid out as a garden.

"This is said to be one of the most complete buildings of the kind in Britain. It consists of five stories; the uppermost of which is used as an hospital for sick prisoners and for store-rooms, &c. The other four stories are laid out in the following manner: A passage goes along the middle of the semicircular part of the building, with apartments on each hand. The apartments on the outward side of the curvature are smaller than those on the inner side, They are double the number, and are used as separate bed-chambers for each of the persons confined. The apartments on the inner side of the semicircle, of which there are thirteen in each story, are allotted for labour. They have a grate in front, and look into the inner court. Opposite to them, in the flat side of the building, is a dark apartment with narrow windows, from which, without being seen, the governor can see how the prisoners in the apartments for work are employed. The court, or space in the middle between the flat and semicircular part of the building, is roofed in at the top; and a great part of it is covered with glass, so as to light the whole. On the floor of the area is a stove, which during winter heats the whole apartments allotted to labour. There is also a pulpit, from which a chaplain preaches on Sundays; and the prisoners come into the front apartments to attend the service.

"The bed-chambers, looking outwards to the country, are lighted by a long narrow windows in each. The window is glazed. The frame in which the glass is fixed is of iron. It turns on pivots fixed at the top and bottom, so as to be opened and shut at pleasure. Each bed-chamber, which is about eight feet long by seven broad, is furnished with a bed and a bible. The frame of the bed is of iron, the bed consists of a straw mattress of the best quality. The whole floors and partitions of the building are of stone. No wood is used excepting for the doors of the apartments. There are cells, however, for solitary confinement for male criminals, in which the frames of the beds are of wood, lest, by breaking them, tools or weapons of a dangerous nature should be obtained. Large cisterns, supplied with water from the city's reservoir, are placed at the top of the house, from which the water is distributed to the different stories, and to a kitchen, washing house, and baths, on the ground floor.

"The institution is managed with great care. Besides being superintended by the magistrates of Edinburgh, the

the sheriff of the county once each month visits every corner of it. It is kept in a state of the most perfect cleanness. The prisoners, when first received, are clothed in a uniform belonging to the place; and their own clothes, after being cleaned, are preserved for them till their dismission. They remain during the day in the apartments allotted to labour, from which they are always dismissed as soon as it becomes dark to their bedchambers. The women spin, and the men pick oakum. Their food consists of oatmeal porridge with small beer, for breakfast and supper; and for dinner, of broth made of fat and vegetables, resembling what in Scotland is called *shearer's kail* (reaper's broth). Those that exert any tolerable industry are allowed bread to their broth, and also a larger portion of porridge. Only one death has occurred in the house during the last four years; and in that case the individual who died had come into Bridewell under a complication of diseases. In truth, the food, clothing, good air, and comfortable lodging, which are enjoyed in this place, are far superior to what the greater number of inhabitants can expect to obtain on their return to the world at large. To reside here, therefore, is a punishment from moral and not from physical causes; that is to say, because it is attended with the loss of freedom and of society, and because it is a place of infamy."

B ties of Sc and, vo . p. 4.

7. The society of Writers to the Signet have a very fine hall, 136 feet long, and adorned with a double row of Corinthian columns. It is in the new buildings at the north end of the Parliament House. The office of keeper of the signet is very lucrative, and he is allowed a depute and clerks under him. Before any one enters into this society he must attend the college for two years, and serve five years as an apprentice to one of the society. There is a very excellent library belonging to this hall, which is rapidly increasing. Each member of this society pays 100l. of apprentice fee, and 100l. when he enters.

8. *The Exchange* is a large and elegant building, with a court of about 90 feet square in the middle. On the north side are piazzas where people can walk under cover, the other three sides being laid out in shops; but the merchants have never made use of it to meet in, still standing in the street as formerly. The back part of the building formerly used for the general customhouse of Scotland, where the commissioners met to transact business, is now occupied by the offices for the city business, including the apartments of the town council. There are above 20 rooms for the different departments, to which the access is by a hanging stair 60 feet in height. In looking over the window before he ascends this stair, a stranger is surprised to find himself already 40 feet from the ground, which is owing to the declivity on which the Exchange is built. The fine mansion of Bellevue, north of the New Town, is now converted into apartments for the customhouse.

The Trustees Office for the improvement of fisheries and manufactures in Scotland is in the south-west corner of the Exchange; the fund under their management being part of the equivalent money given to Scotland at the Union. This is distributed in premiums amongst those who appear to have made any considerable improvement in the arts.

9. *The North Bridge*, which forms the main passage of communication betwixt the Old and New Towns, was founded, as has already been observed, in 1763, by Provost Drummond; but the contract for building it was not signed till August 21. 1764. The architect was Mr William Mylne, who agreed with the town council of Edinburgh to finish the work for 10,140l. and to uphold it for 10 years. It was also to be finished before Martinmas 1769: but on the 3d of August that year, when the work was nearly completed, the vaults and side walls on the south fell down, and five people were buried in the ruins. This misfortune was occasioned by the foundation having been laid, not upon the solid earth, but upon the rubbish of the houses which had long before been built on the north side of the High street, and which had been thrown out into the hollow to the northward. Of this rubbish there were no less than eight feet between the foundation of the bridge and the solid earth. Besides this deficiency in the foundation, an immense load of earth which had been laid over the vaults and arches in order to raise the bridge to a proper level, had no doubt contributed to produce the catastrophe above mentioned.—The bridge was repaired, by pulling down some parts of the side walls, and afterwards rebuilding them; strengthening them in others, with chain bars; removing the quantity of earth laid upon the vaults, and supplying its place with hollow arches, &c. The whole was supported at the south end by very strong buttresses and counterforts on each side; but on the north it has only a single support.—The whole length of the bridge, from the High street in the Old Town to Prince's street in the New, is 1125 feet; the total length of the piers and arches is 310 feet. The width of the three great arches is 72 feet each: of the piers, 13½ feet; and of the small arches, each 20 feet. The height of the great arches from the top of the parapet to the base, is 68 feet; the breadth of the bridge within the wall over the arches is 40 feet, and the breadth at each end 50 feet.—On the southern extremity of this bridge stands the General Post Office for Scotland; a neat plain building, with a proper number of apartments for the business, and a house for the secretary.

The communication betwixt the two towns by means of this bridge, though very complete and convenient for such as lived in certain parts of either, was yet found insufficient for those who inhabit the western districts. Another bridge being therefore necessary, it was proposed to fill up the valley occasionally with the rubbish dug out in making the foundations of houses in the New Town; and so great was the quantity, that this was accomplished so as to be fit for the passage of carriages in little more than four years and a half.

10. *The South Bridge*, is directly opposite to the other, so as to make but one street, crossing that called the *High Street* almost at right angles. It consists of 19 arches of different sizes: but only one of them is visible, viz. the large one over the Cowgate; and even this is small in comparison with those of the North Bridge, being no more than 30 feet wide and 31 feet high. On the south it terminates at the University on one hand, and the Royal Infirmary on the other. The Tron Church, properly called *Christ Church*, stands at the northern extremity, facing the High Street, and in the middle of what is now called *Hunter's Square*, in memory of the worthy chief magistrate who planned those improvements, but did not live to see them executed.

executed. On the west side of this square the Merchant Company have built a very handsome hall for the occasional meetings of their members. This bridge was erected with a design to give an easy access to the great number of streets and squares on the south side, as well as to the country on that quarter from whence the city is supplied with coals. The street on the top is supposed to be as regular as any in Europe; every house being of the same dimensions, excepting that between every two of the ordinary construction there is one with a pediment on the top, in order to prevent that sameness of appearance which would otherwise take place. So great was the rage for purchasing ground on each side of this bridge for building, that the areas sold by public auction at 50l. per foot in front. By this the community will undoubtedly be considerable gainers; and the proprietors hope to indemnify themselves for their extraordinary expence by the vast sale of goods supposed to attend the shops in that part of the town; though this seems somewhat more dubious than the former.

11. The *Concert Hall*, called also *St Cecilia's Hall*, stands in Niddery's street; and was built in 1762, after the model of the great opera theatre in Parma. The plan was drawn by Sir Robert Mylne, architect of Blackfriars bridge. The musical room is of an oval form, the ceiling being a concave elliptical dome, lighted from the top by a lanthorn. The society for which this hall was built has gradually fallen into neglect, and the tenement, after being occupied by a congregation of Baptists for some time, was sold to the grand lodge in 1812, and now bears the name of *Freemasons Hall.*

The Musical Society was first instituted in the year 1728. Before that time, several gentleman had formed a weekly club at a tavern kept by one Steil, a great lover of music, and a good singer of Scots songs. Here the common entertainment consisted in playing on the harpsichord and violin the concertos and sonatas of Handel, just then published. The meeting, however, soon becoming numerous, they instituted, in the year above mentioned, a society of 70 members, for the purpose of holding a weekly concert. The affairs of the society were regulated by a governor, deputy-governor, treasurer, and five directors, who were annually chosen by the members. The meetings were continued ever since that time on much the same footing as at first, and the number of members increased to 200. The weekly concerts were on Friday; the tickets being given gratis by the directors, and attention paid in the first place to strangers. Oratorios were occasionally performed throughout the year; and the principal performers had also benefit concerts. The band were excellent in their several departments; and several of the members being also good performers, took their part in the orchestra. There were always many applications on the occasion of a vacancy; and such was generally the number of candidates, that it was no easy matter to be admitted. This society, however, as already stated, has been long neglected, and the hall disposed of for other purposes.

12. *The University.* In the year 1581, a grant was obtained from King James VI. for founding a college or university within the city of Edinburgh; and the citizens, aided by various donations from well disposed persons, purchased a situation for the intended new college, consisting of part of the areas, chambers, and church of the collegiate provostry and prebends of the Kirk-a-field, otherwise called *Templum et Præfectura Sanctæ Mariæ in campis*, lying on the south side of the city. Next year, a charter of confirmation and erection was obtained also from King James VI. from which the college to be built did afterwards derive all the privileges of an university.

In 1583, the provost, magistrates, and council, the patrons of this new institution, prepared the place in the best manner they could for the reception of teachers and students; and in the month of October the same year, Robert Rollock, whom they had invited from a professorship in St Salvator's College in the university of St Andrew's, began to teach in the new college of Edinburgh. Other professors were soon after elected; and in the year 1586, Rollock was appointed principal of the college, and the following year also professor of divinity, immediately after he had confered the degree of M. A. on the students who had been under his tuition for four years. The offices of principal and professor of divinity remained united till the year 1620.

In the 1617, King James VI. having visited Scotland after his accession to the crown of England, commanded the principal and regents of the college of Edinburgh to attend him in Stirling castle; and after they had there held a solemn philosophical disputation in the royal presence, his majesty was so much satisfied with their appearance, that he desired their college for the future might be called *The College of King James*, which name it still bears in all its diplomas or public deeds.

For several years the college consisted only of a principal, who was also professor of divinity, with four regents or professors of philosophy. Each of these regents instructed one class of students for four years, in Latin, Greek, school logic, mathematics, ethics, and physics, and graduated them at the conclusion of the fourth course. A professor of humanity or Latin was afterwards appointed, who prepared the students for entering under the tuition of the regents; also a professor of mathematics, and a professor of Hebrew or oriental languages. It was not till about the year 1710 that the four regents began to be confined each to a particular profession; since which time they have been commonly styled *Professors of Greek, Logic, Moral Philosophy, and Natural Philosophy.*—The first medical professors instituted at Edinburgh, were Sir Robert Sibbald and Doctor Archibald Pitcairn, in the year 1685[*]. These, however, were only titular professors; and for 30 years afterwards, a summer lecture on the officinal plants, and the dissection of a human body once in two or three years, completed the whole course of medical education at Edinburgh. In 1720, an attempt was made to teach the different branches of physic regularly; which succeeded so well, that ever since, the reputation of the university as a school for medicine hath been constantly increasing, both in the island of Britain, and even among distant nations.

The college is endowed with a very fine library, founded in 1580 by Mr Clement Little advocate, who bequeathed it to the town council. They ordered a house to be built for it in the neighbourhood of St Giles's church, where it was for some time kept

under

---

[*] See C lege of P sicians.

under the care of the eldest minister of Edinburgh, but was afterwards removed to the college. This collection is enriched, as well as others of a similar kind, by receiving a copy of every book entered in Stationers hall, according to the statute for the encouragement of authors. Besides this, the only fund it has is the money paid by all the students at the university, except those of divinity, upon their being matriculated; and a sum of 5l. given by each professor at his admission. The amount of these sums is uncertain, but has been estimated at about 150l. annually. The students of divinity, who pay nothing to this library, have one belonging to their own particular department.

Here are shown two skulls, one almost as thin as paper, pretended to be that of the celebrated George Buchanan; and, by way of contrast, another said to have been that of an idiot, and which is excessively thick. Here also are preserved the original protest against the council of Constance for burning John Huss and Jerome of Prague in 1417; the original contract of Queen Mary with the dauphin of France, and some valuable coins and medals. There are also several portraits; particularly of Robert Rollock the first principal of the university, King James VI. John Napier the inventor of logarithms, John Knox, Principal Carstairs, Mr Thomson the author of the Seasons, &c. The museum contains a good collection of natural curiosities, the number of which is daily increasing. The anatomical preparations are worth notice, as are also those belonging to the professor of midwifery.

The celebrity of this college has been greatly owing to the uniform attention of the magistracy in filling up the vacant chairs with men of known abilities in their respective departments.

The university of Edinburgh "having been instituted after the Reformation, among a frugal people that had no love for ecclesiastical dignities, it differs greatly from the wealthy foundations which receive the name of *universities* and *colleges* in England, or in the catholic countries of the continent of Europe. The university of Edinburgh consists of a single college, which enjoys the privilege of conferring degrees. It consists of a principal, with a salary of 111l. 2s. 0$\frac{2}{3}$d. whose office is in a great measure nominal, and of a professor in each of the following departments:

Faculty of Theology.

	Salaries.		
Divinity	L.161	2	0$\frac{2}{3}$
Church history	100	0	0
Oriental languages	119	12	8

Faculty of Law.

Law of Nature and Nations.—Salary variable, but always above	300	0	0
Civil Law	100	0	0
Scots Law	100	0	0
Civil History and Antiquities	100	0	0

Faculty of Medicine.

	Salaries.		
Anatomy and Surgery	50	0	0
Practice of Medicine		—	—
Botany	77	15	6$\frac{2}{3}$
Materia Medica		—	—
Chemistry		—	—
Theory of Medicine		—	—
Midwifery		—	—
Clinical Surgery	100	0	0
Military Surgery	100	0	0
Medical Jurisprudence	100	0	0
Natural History	70	0	0

Faculty of Arts.

Moral Philosophy	102	4	5$\frac{1}{3}$
Rhetoric and Belles Lettres	70	0	0
Greek	52	4	5$\frac{1}{3}$
Latin	52	10	0
Natural Philosophy	52	4	5$\frac{2}{3}$
Mathematics	113	6	8
Practical Astronomy	100	0	0
Logic	52	4	5$\frac{1}{3}$
Agriculture	50	0	0

"Of these, the professors of church history and natural history, botany, clinical and military surgery, medical jurisprudence, astronomy, law of nature and nations, and rhetoric, are in the gift of the crown. The professor of agriculture was nominated by Sir William Pultney, founder of the institution. The remaining chairs are in the gift of the town-council of Edinburgh. Besides these classes here enumerated, the medical professors alternately give clinical lectures upon the cases of the patients in the royal infirmary of Edinburgh."

Beauties of Scotland, I. 45.

The university is now attended by not less than 2000 students in the different departments of science and literature.

The old buildings being very mean, and unfit for the reception of so many professors and students, and quite unsuitable to the dignity of such a flourishing university, as well as inconsistent with the improved state of the city, the Lord Provost, Magistrates, and Council, set on foot a subscription for erecting a new structure, according to a design of Robert Adam, Esq. architect. Part of the old fabric has in consequence been pulled down, and the new building is already in considerable forwardness. The foundation stone was laid on Monday the 16th of November, with great solemnity, by the Right Hon. Francis Lord Napier, grand master mason of Scotland, in the presence of the Right Hon. the Lord Provost, Magistrates, and Town Council of the city of Edinburgh, with the principal, professors, and students of the university of Edinburgh, a number of nobility and gentry, and the masters, officers, and brethren of all the lodges of free masons in the city and neighbourhood, who marched in procession from the Parliament House down the High street. After the different masonic ceremonials were performed, two crystal bottles, cast on purpose at the glass house of Leith, were deposited in the foundation stone. In one of these were put different coins of the present reign, each of them being previously enveloped in crystal, in such an ingenious manner, that the legend on the coins could be distinctly read without breaking the crystal. In the other bottle were deposited seven rolls of vellum, containing a short account of the original foundation and present state of the university, together with several other papers, in particular the different newspapers, containing advertisements relative to the college, &c. and a list of the names of the principal and professors, also of the present lord provost and magistrates, and officers of the

the grand lodge of Scotland. The bottles being carefully sealed up, were covered with a plate of copper wrapt in block tin; and upon the under side of the copper were engraved the arms of the city of Edinburgh and the university; likewise the arms of the Right Hon. Lord Napier, grand master mason of Scotland. Upon the upper side, a Latin inscription, of which the following is a copy:

ANNUENTE DEO OPT. MAX.
REGNANTE GEORGIO III. PRINCIPE
MUNIFICENTISSIMO;
ACADEMIÆ EDINBURGENSIS
ÆDIBUS,
INITIO QUIDEM HUMILLIMIS,
ET JAM, POST DUO SECULA, PENE RUINOSIS;

CONSULE THOMA ELDER,
ACADEMIÆ PRÆFECTO GULIELMO
ROBERTSON,
ARCHITECTO ROBERTO ADAM.
Q. F. F. Q. S.

The building went on rapidly for some time; but the funds being far from sufficient for the extent of the plan, it was necessarily stopped, and remained for many years a useless pile resembling a ruin. At length in 1815, by the exertions of Sir John Marjoribanks, member for the city, a grant of 10,000l. per annum for seven years was obtained from parliament, to be expended under the direction of commissioners appointed in the bill. With this aid the western side of the building has been entirely finished, and great progress is making with the other parts. The east and west fronts extend 255 feet, and the south and north 358. A new plan was adopted, designed by Mr Playfair, and modifying in some degree that of Mr Adams. The library, occupying the south side of the square, is to be divided into two floors, the lower of which is separated into five compartments. The upper floor will form one magnificent saloon. The museum of natural history, which occupies the west side of the area, and is now finished, consists of two floors 90 feet long, and fitted in the most tasteful and beautiful style. The fine collection it contains is in excellent order, and admirably arranged.

The botanical garden belonging to the university is situated at the distance of about a mile, on the road between Edinburgh and Leith. It consists of about five acres of ground; and is furnished with a great variety of plants, many of them brought from the most distant quarters of the globe. The professor is botanist to the king, and receives a salary of 120l. annually for the support of the garden. A monument to the memory of the celebrated botanist Linnæus, was erected here by the late Dr Hope, who first planned the garden, and brought it to perfection.

The university of Edinburgh, like the others in this kingdom, sends one member to the General Assembly of the church of Scotland; and the widows of the professors have a right to the funds of those of ministers, the professors being trustees on that fund along with the presbytery of Edinburgh.

"In the year 1772, the Board of Trustees for the encouragement of Manufactures, &c. in Scotland, appointed Mr Alexander Runciman, painter, to teach 20 boys or girls drawing, allowing him a yearly salary of 120l. He was succeeded in this office by Mr Allan; to whom followed Mr Graham, who was succeeded by Mr A. Wilson in 1818. This institution being appropriated for the use of manufactures, is not properly a school of painting. In this last art, however, very eminent teachers are to be found in Edinburgh, but no public establishment exists for its encouragement.

"Near the University there is also a *Riding School*, called the *Royal Academy for teaching Exercises*. The teacher of this academy receives a salary of 200l. a-year from the crown, and is accommodated with a riding school of 120 feet in length by 40 in breadth, and stables to a considerable extent.

"In Edinburgh there is established, in imitation of that in London, a *Royal Society*, which has published some volumes of transactions. It contains a number of members of great respectability; but in Edinburgh men of letters are apt to be extremely jealous and unsociable with regard to each other. This illiberality of temper prevents the Royal Society from being of much value. Great numbers of the most accomplished and active men of letters are unconnected with it; while it contains others who have been introduced to it merely by their rank in the world, or the circumstance of having attained to distinguished literary situations by the patronage of men in power, who of late years have, in this country, displayed little of that anxiety to discriminate and bring into notice men of literary talents, which once formed the most honourable characteristic of the nobles and statesmen of Scotland." Beau of Scotl I. 59.

13. *The Royal Infirmary* was first thought of by the College of Physicians in 1725. A fishing company happening to be dissolved at that time, the partners contributed some of their stock towards the establishment of the Infirmary. A subscription was also set on foot, and application made to the General Assembly to recommend the same throughout their jurisdiction. This was readily complied with, and the assembly passed an act for that purpose; but very little regard was paid to it by the clergy. Notwithstanding this, however 2000l. being procured, a small house was opened for the reception of the sick poor in August 1729. In 1736, the contributors towards the Infirmary were erected into a body corporate by royal statute; and after this the contributions increased very considerably: by which means the managers were enabled to enlarge their scheme from time to time; and at last to undertake the present magnificent structure, the foundation of which was laid in 1738. During 25 years, when this institution was in its infancy, Lord Hopetoun bestowed upon it an annuity of 400l. In 1750, Doctor Archibald Ker bequeathed to this incorportion 200l. a-year in the island of Jamaica. In 1755, the lords

lords of the treasury made a donation to it of 8000l. which had been appointed for the support of invalids. In return for this, the managers of the Infirmary constantly keep 60 beds in readiness for the reception of sick soldiers. This year also sick servants began to be admitted into the Infirmary, and a ward was fitted up for their reception.

This institution, however, was more indebted to George Drummond, Esq. than to any other person. He was seven times chosen lord provost of Edinburgh; and always directed his attention to the improvement of the city, particularly to that of the Royal Infirmary. So sensible were the managers of their obligations to him, that, in their hall, they erected a bust of him with this inscription, "George Drummond, to whom this country is indebted for all the benefit which it derives from the Royal Infirmary."—In 1748, the stock of the Infirmary amounted to 5000l.; in 1755, to 7076l. besides the estate left by Doctor Ker; in 1764, to 23,426.; and in 1778, to 27,074l.

The Royal Infirmary is attended by two physicians chosen by the managers, who visit their patients daily in presence of the students. All the members of the College of Surgeons were obliged to attend in rotation, according to seniority. If any surgeon declined attendance, he was not allowed to appoint a depute; and the patients were committed to the care of one of four assistant surgeons, chosen annually by the managers: this was formerly the mode of attendance, but the managers have in consequence of a decision of the high court of judicature assumed to themselves the sole right of electing the surgeons.—From the year 1762 to 1769, there were admitted 6261 patients; which number added to 109 who were in the hospital at the commencement of the year 1762, made, in all, 6370. Of these, 4395 were cured; 358 died: the rest were either relieved, dismissed incurable, for irregularities, or by their own desire, or remained in the hospital.—From 1770 to 1775, the patients annually admitted into the Infirmary were, at an average, 1567; of whom 63 died. In 1766, there were admitted 1668, of whom 57 died; and in 1777, the number admitted was 1593, and of deaths 52. In the year 1786, there were admitted 1822 patients: Of these 1354 were cured; 166 relieved; 84 died. In 1818 there were in the Infirmary and in the Fever Hospital at Queensberry House, 3453 patients, of whom 189 only died.

The building consists of a body and two wings, each of them three stories high, with an attic story and garret, and a very elegant front. The body is 210 feet long, and 36 broad in the middle, but at the ends only 24 feet broad. There is a bust of King George II. in a Roman dress, above the great door. The wings are 70 feet long, and 25 broad. In the centre is a large staircase, so wide that sedan chairs may be carried up. In the different wards, 228 patients may be accommodated, each in a different bed. There are cold and hot baths for the patients, and also for the citizens; and to these last the patients are never admitted.

Besides the apartments necessary for the sick, there are others for the officers and servants belonging to the house. There are likewise rooms for the managers, a consulting room for the physicians and surgeons, a waiting room for the students, and a theatre that will hold upwards of 200 people, for performing chirurgical operations. There is a military ward, supported by the interest of the 8000l. already mentioned; and in consequence of which a small guard is always kept at the Infirmary. The wards for sick servants are supported by collections at the church doors. Besides the surgical attendance already mentioned, there are two physicians belonging to the house, who are elected by the managers, and have a salary: there is likewise a house surgeon and apothecary. Students who attend the Infirmary, paid formerly 3l. 3s. which is increased to 5l. 5s. annually, which brings in a considerable revenue towards defraying the expence of the house. Two wards are set apart for the patients whose cases are supposed to be most interesting; and the medical professors in the university give clinical lectures upon them by rotation. In 1818, when typhus fever was very prevalent, Queensberry House was set apart as a fever hospital, and it is still in use for this purpose.

14. *The Public Dispensary* was founded by Dr Duncan in 1776, for the poor whose diseases are of such a nature as to render their admission into the Infirmary either unnecessary or improper. Here the patients receive advice gratis four days in a week; a register is kept of the diseases of each, and of the effects produced by the medicines employed. All patients not improper for dispensary treatment are admitted on the recommendation of the elder or church warden of the parish where they reside. The physicians officiate and give lectures gratis; so that the apothecary who lodges in the house, and the medicines, are the only expences attending this useful institution. The expence of the whole is defrayed by public contributions, and from a small annual fee paid by the students who attend the lectures. It is under the direction of a president, two vice-presidents and 20 directors elected annually from among the contributors. One guinea entitles a contributor to recommend patients and be a governor for two years, and five guineas gives the same privilege for life. Under the same management there is an institution for the gratuitous inoculation for the cowpox.

15. *The High School.* The earliest institution of a grammar school in Edinburgh seems to have been about the year 1519. The whole expence bestowed upon the first building of this kind amounted only to about 40l. sterling. Another building, which had been erected for the accommodation of the scholars in 1578, continued, notwithstanding the great increase of their number, to be used for that purpose till 1777. The foundation of the present new building was laid on the 24th of June that year by Sir William Forbes, Grand Master of the Free Masons. The total length of this building is 120 feet from south to north; the breadth in the middle 36, at each end 38 feet. The great hall where the boys meet for prayers, is 68 feet by 30. At each end of the hall is a room of 32 feet by 20, intended for libraries. The building is two stories high, the one 18, the other 17, feet in height. The expence of the whole was reckoned at 4000l.

There is a rector and four masters, who teach about 800 scholars annually. The salaries are trifling, and the fees depend upon the reputation they have obtained for teaching. There is a janitor, whose place is supposed to be worth about 70l. a-year. His business is to take care of the boys on the play ground; and there is a woman who lives on the spot as under-janitor, whose place may be worth about 25l. annually. There is a library, but not large, as each of the boys pays only one shilling annually to its support.

There are four established English schools in Edinburgh, the masters of which receive a small salary, upon express condition that they shall not take above a limited sum per quarter from any of their scholars. There are likewise many other private schools in Edinburgh for all languages; and, in general, every kind of education is to be had here in great perfection and at a very cheap rate.

16. *The Mint* is kept up by the articles of Union, with all the offices belonging to it, though no money is ever struck here. It stands in the Cowgate, a little to the west of the English church, but is in a ruinous state, though still inhabited by the different officers, who have free houses; and the bellman enjoys his salary by regularly ringing the bell. This place, as well as the abbey of Holyroodhouse, is an asylum for debtors.

17. *The English Chapel* stands near the Cowgate Port, and was founded on the 3d of April 1771. The foundation stone was laid by General Oughton. It is a plain handsome building, neatly fitted up in the inside, and somewhat resembling the church of St Martin's in the Fields, London. It is 90 feet long, 75 broad, and ornamented with an elegant spire of considerable height. This building was sold to a congregation of dissenters in 1817, when the Episcopalian congregation removed to their new chapel in York Place.

18. *St Paul's Chapel* in York Place was founded in 1816, and completed in 1818. It is built in the Gothic style as it prevailed in the reign of Henry VI. It consists of a nave with four octagon towers at the angles. The outside length is 122 feet, and breadth 73. The ceiling of the nave is a flat Gothic arch, covered with ornamented tracery mouldings, as are also the ceilings under the side aisles. The great eastern window is fitted up with painted glass.

19. *St John's Chapel* stands at the west end of Prince's Street, on the south side. The architecture is of the florid Gothic. It is 113 feet long by 62 in breadth. The height of the great eastern window, which is finished with stained glass, is 30 feet. The wall is supported by buttresses, and adorned at top by minarets and niches with tracery work. It has a square tower at the west end 120 feet high. Around it is a terrace, covering arched burial vaults. There is no gallery, but two rows of very light Gothic columns support the roof. This chapel was begun in 1816, and finished in 1819, at an expence exceeding 15,000l. sterling.

20. *St George's Chapel*, which stands in York Place, is small, but finished in a very neat style.

21. *The Roman Catholic Chapel* stands at the eastern termination of York Place, close by the Pantheon. The body of the building is plain, but it is ornamented with a very handsome Gothic façade.

22. *Heriot's Hospital* owes its foundation to George Heriot, goldsmith to James VI. who acquired by his business a large fortune. At his death, he left the magistrates of Edinburgh 23,625l. 10s. "for the maintenance, relief, and bringing up of so many poor and fatherless boys, freemen's sons of the town of Edinburgh," as the above sum should be sufficient for. This hospital is finely situated on the west end of the south ridge, almost opposite to the castle, and is the most magnificent building of the kind in Edinburgh. It was founded in July 1628, according to a plan (as is reported) of Inigo Jones; but the work being interrupted by the civil wars, it was not finished till the year 1650. The expence of the building is said to have been upwards of 30,000l. (A): and the hospital is now possessed of an income of about 5000l. a-year; though this cannot be absolutely ascertained, as the rents are paid in grain, and of course must be fluctuating.

It stands on a rising ground to the south-west of the city, and is a square of 162 feet without, having a court 94 feet square in the inside, with piazzas on three of the sides. There is a spire with a clock over the gateway, and each corner of the building is ornamented with turrets; but notwithstanding the magnificent appearance of the outside, the inner part is far from being convenient. There is a statue of the founder over the gateway, in the dress of the times, and a very good painting of him in the governors room, with a picture of the late treasurer Mr Carmichael. There is a chapel 61 feet long and 22 broad, which is now repairing in such a manner as will make it worthy of notice. When Cromwell took possession of Edinburgh after the battle of Dunbar, he quartered his sick and wounded soldiers in this hospital. It was applied to the same purpose till the year 1658, when General Monk, at the request of the governors, removed the soldiers; and on the 11th of April 1659, it was opened for the reception of boys, 30 of whom were admitted into it. The August after, they were increased to 40; and in 1661, to 52. In 1753 the number was raised to 130, and in 1763, to 140. In 1819 the number was 180.—In this hospital the boys are instructed in reading, writing, arithmetic, and a knowledge of the Latin tongue. With such as choose to follow any kind of trade, an apprentice fee of 30l. is given when they leave the hospital; and those who choose an academical education, have an annuity of 10l. a-year bestowed on them for four years. The whole is under the oversight of the treasurer, who has under him a house governor, housekeeper, and schoolmasters.

(A) It is to be observed, that money then bore 10 per cent. interest.—The above sums are taken from Mr Arnot's History of Edinburgh, who subjoins the following note. "Where Maitland had collected his most erroneous account of George Heriots effects we do not know. He makes the sum received, out of Heriot's effects, by the governors of the hospital, to be 43,608l. 11s. 3d. being almost double of what they really got. This blunder has been the cause of many unjust murmurings against the magistrates of Edinburgh, and even the means of spiriting up lawsuits against them."

23. *Watson's Hospital* has its name from the founder George Watson, who was at first clerk to Sir William Dick provost of Edinburgh in 1676, then accountant of the bank of Scotland; after that he became receiver of the city's impost on ale, treasurer to the Merchants Maiden Hospital, and to the Society for propagating Christian knowledge. Dying a bachelor in 1723, he left 12,000l. for the maintenance and education of the children and grandchildren of decayed members of the merchant company of Edinburgh. The scheme, however, was not put into execution till the year 1738, when the sum originally left had accumulated to 20,000l. The present building was then erected, in which 70 boys are maintained and educated (1819). It is much less magnificent than Heriot's Hospital, but the building is far from being despicable. It stands to the southward of the city at a small distance from Heriot's Hospital, and was erected at the expence of 5000l.: its present revenue is about 1700l. It is under the management of the master, assistants, and treasurer of the Merchant Company, four old bailies, the old dean of guild, and the two ministers of the Old church. The boys are genteelly clothed and liberally educated. Such as choose an university education are allowed 10l. per annum for five years: those who go to trades have 20l. allowed them for their apprentic fee, and at the age of 25 years, if they have behaved properly, and not contracted marriage without consent of the governors, they receive a bounty of 50l. The boys are under the immediate inspection of the treasurer, schoolmaster, and housekeeper.

24. *The Merchants Maiden Hospital* was established by voluntary contribution about the end of the last century, for the maintenance of young girls, daughters of the merchants burgesses of Edinburgh. The governors were erected into a body corporate, by act of parliament, in 1707. The annual revenue amounts to 3000l. Eighty girls are maintained in it; who, upon leaving the house, receive 9l. 6s. 8d. The old building in Bristo street having become inadequate, a new one was erected in Lauriston lane, and was finished in 1819. It is 180 feet in length, by 60 in depth, and is in the Grecian style.

25. *The Trades Maiden Hospital* was founded in the year 1704 by the incorporations of Edinburgh, for the maintenance of the daughters of decayed members, on a plan similar to that of the Merchants hospital. To this, as well as to the former, one Mrs Mary Erskine, a widow gentlewoman, contributed so liberally, that she was by the governors styled *joint foundress* of the hospital. Fifty girls are maintained in the house, who pay of entry money 1l. 13s. 4d.; and, when they leave it, receive a bounty of 5l. 11s. $1\frac{1}{2}$d. The revenues are estimated at 600l. a-year.

26. *The Orphan Hospital* was planned in 1732, by Andrew Gairdner merchant, and other inhabitants. It was promoted by the society for propagating Christian knowledge, by other societies, by voluntary subscriptions, and a collection at the church doors.—In 1733, the managers hired a house, took in 30 orphans, maintained them, gave them instructions in reading and writing, and taught them the weaving business. In 1735, they were erected into a body corporate by the town of Edinburgh: and, in 1742, they obtained a charter of erection from his late majesty, appointing most of the great officers of state in Scotland, and the heads of the different societies in Edinburgh, members of this corporation; with powers to them to hold real property to the amount of 1000l. a-year. The revenue is inconsiderable; but the institution is supported by the contributions of charitable persons. Into this hospital orphans are received from any part of the kingdom. None are admitted under seven, nor continued in it after 14 years of age.

The orphan hospital is situated to the east of the North bridge; and is a handsome building, consisting of a body and two wings, with a neat spire, furnished with a clock and two bells. The late worthy Mr Howard admits, that this institution is one of the most useful charities in Europe, and is a pattern for all institutions of the kind. The funds have been considerably increased, and the building greatly improved, through the attention and exertions of Mr Thomas Tod formerly treasurer.

27. *The Trinity Hospital.* This was originally founded and amply endowed by King James II.'s queen. At the Reformation it was stripped of its revenues; but the regent afterwards bestowed them on the provost of Edinburgh, who gave them to the citizens for the use of the poor. In 1585, the town council purchased from Robert Pont, at that time provost of Trinity college, his interest in these subjects; and the transaction was afterwards ratified by James VI. The hospital was then repaired, and appointed for the reception of poor old burgesses, their wives and unmarried children, not under 50 years of age. In the year 1700, this hospital maintained 54 persons; but, since that time, the number has decreased.—The revenue consists in a real estate of lands and houses, the gross rents of which are 762l. a year, and 5500l. lent out in bonds at 4 per cent.

This hospital is situated at the foot of Leith wynd, The inmates are supplied with roast or boiled meat every day for dinner, have money allowed them for clothes, and likewise a small sum for pocket money. There is a small library for their amusement, and they have a chaplain to say prayers. The funds are under the management of the town council. The number of persons on the establishment in 1819 was 80 men, and 30 women, besides 93 out-pensioners who receive each 6l. per annum. None are received under fifty years of age.

28. *The Charity Workhouse* was erected in 1743 by voluntary contribution. It is a large plain building, on the south side of the city. Here the poor are employed, and are allowed twopence out of every shilling they earn. The income of the house for the year ending 1st July 1818, including 2000l. of borrowed money, amounted to 10,309l. 14s. 7d. while the expenditure for the same period was 10,857l. 4s. 7d. The number of persons in the house in 1818 was 890, but considerable sums are paid to out-pensioners. The average expence of maintaining each person in the house is 8l. 8s. 6d. The only permanent fund for defraying this expence is a tax of five per cent. on the valued rents of the city. The rest is derived from collections at the church doors and voluntary contributions; but as these always fall short of what is requisite, recourse must frequently be had to extraordinary collections. The sum arising from the rents of the city, however, is

constantly increasing; but the members of the college of justice are exempted from the tax.

29. "To the south-west of the castle, near a suburb called the *Wrights Houses*, on the site of a very ancient building, which was demolished to make way for it, *Gillespie's Hospital* has lately been erected. Its appellation is derived from the founder, an eminent manufacturer of snuff in Edinburgh. It is intended for the support of aged persons; and those bearing the name of the founder are preferred. It is a neat stone building, executed in a style of moderate expence, with a small tower in the centre and a parapet, and Gothic turrets at suitable distances around the roof.

"Besides these there are to be found in Edinburgh several charitable establishments, which, though not furnished with costly buildings, are not of a less benevolent or valuable nature. Of these, one of the most distinguished is the Hospital or Workhouse, or *Asylum*, as it is called, *for the Industrious Blind*; which is supported by the contributions of charitable persons, and by the price of the articles manufactured in it. Here the blind are taught such trades as may enable them to earn a subsistence, or at least aid them in contributing to their own support. They manufacture baskets, matts, &c.; and some of them have been taught to act as weavers, for which purpose they use the fly-shuttle.

"The *Magdalene Asylum* also deserves notice; in which a most laudable attempt has of late years been made, by a benevolent society, to reclaim, from vice and misery, women who have degraded themselves by public prostitution, but who think fit to retire thither with the view of abandoning their mode of life, and of supporting themselves by industry. This institution is managed with a degree of care and delicacy which does the highest credit to its patrons. The objects of this charity are kept concealed: they reap the fruits of their own labour; and every effort is made to procure employment for them. In particular, needle-work of all sorts is executed in it in the neatest manner; and linen is washed, at moderate prices, for such persons in the city as think fit to transmit these articles to the society.

"Besides all these charities, there is an hospital in the city for *Lying-in Women*, under the care of the professor of midwifery: which is an institution analogous to that of the Royal Infirmary.—There is a *Society for the Relief of the Destitute Sick*, which has received considerable public countenance, though it has no appropriate building or local establishment.—An institution of a peculiar nature, not unconnected with the present subject, called the *Repository*, ought not to pass unnoticed. It is a shop or ware-room on South Bridge Street, to which ladies in straitened circumstances have an opportunity of sending for sale curious, beautiful, or useful articles of needle-work, with the price affixed. When a purchaser has been found for the goods, the proceeds are transmitted in such a manner as to prevent its being known to the public by whom the articles were prepared. This institution has been promoted by the duchess of Buccleugh and many other persons of rank."

Beauties of Scotland, i. 69.

There are two other charity workhouses in the suburbs, much on the same plan with that now described: one in the Canongate, and the other in St Cuthbert's or West kirk parish.

To this account of the charitable establishments in Edinburgh, we shall add that of some others; which, though not calculated to decorate the city by any public building, are perhaps no less deserving of praise than any we have mentioned. The first is that of Captain William Horn; who left 3500l. in trust to the magistrates, the annual profits to be divided on Christmas day to poor out-day labourers, who must at that season of the year be destitute of employment; five pounds to be given to those who have large families, and one half to those who have smaller.

Another charity is that of Robert Johnston, LL.D. of London, who in 1640 left 3000l. to the poor of this city; 1000l. to be employed in setting them to work, another 1000l. to clothe the boys in Heriot's Hospital, and the third 1000l. to bursars at the university.

About the beginning of this century John Strachan left his estate of Craigcrook, now upwards of 300l. a-year in trust to the presbytery of Edinburgh, to be by them disposed of in small annual sums to poor old people not under 65 years of age, and to orphans not above 12.

There is besides a society for the support of the industrious poor, another for the indigent sick, and there are also many charity schools.

Having thus given an account of the most remarkable edifices belonging to Old Edinburgh, we shall now proceed to those of the New Town. This is terminated on the east side by the Calton hill, round which there is a pleasant walk, and which affords one of the finest prospects that can be imagined, varying remarkably almost at every step. On this hill is a burying ground, which contains a fine monument to the memory of David Hume the historian.—On the top is an observatory, the scheme for building which was first adopted in the year 1736; but the disturbance occasioned by the Porteous mob prevented any thing from being done towards the execution of it at that time. The earl of Morton afterwards gave 100l. for the purpose of building an observatory, and appointed Mr M'Laurin professor of mathematics, together with the principal and some professors of the university, trustees for managing the sum. Mr M'Laurin added to the money above mentioned the profits arising from a course of lectures which he read on experimental philosophy; which, with some other small sums, amounted in all to 300l.; but Mr M'Laurin dying, the design was dropped.—Afterwards the money was put into the hands of two persons who became bankrupt; but a considerable dividend being obtained out of their effects, the principal and interest, about the year 1776, amounted to 400l. A plan of the building was made out by Mr Craig architect; and the foundation stone was laid by Mr Stodart, lord provost of Edinburgh, on the 25th of August 1776. About this time, however, Mr Adam architect happening to come to Edinburgh, conceived the idea of giving the whole the appearance of a fortification, for which its situation on the top of the Calton hill was very much adapted. Accordingly a line was marked out for enclosing the limits of the observatory with a wall constructed

structed with buttresses and embrasures, and having Gothic towers at the angles. Thus the money designed for the work was totally exhausted, and the observatory still remains unfinished; nor is there any appearance of its being soon completed either by voluntary subscription or any other way.

30. Proceeding to the westward, the first remarkable building is the *Theatre*, which stands opposite to the Register Office, in the middle of Shakespeare Square. The building is plain on the outside, but elegantly fitted up within, and is generally open three days in the week, and when full will draw about 150l. a-night; so that the manager generally finds himself well rewarded when he can procure good actors.

Entertainments of the dramatic kind came very early into fashion in this country. They were at first only representations of religious subjects, and peculiarly designed to advance the interests of religion; the clergy being the composers, and Sunday the principal time of exhibition. In the 16th century, the number of playhouses was so great, that it was complained of as a nuisance, not only in Edinburgh, but throughout the kingdom. They soon degenerated from their original institution; and the plays, instead of being calculated to inspire devotion, became filled with all manner of buffoonery and indecency.—After the Reformation, the Presbyterian clergy complained of these indecencies; and being actuated by a spirit of violent zeal, anathematised every kind of theatrical representation whatever. King James VI. compelled them to pass from their censures against the stage; but in the time of Charles I. when fanaticism was carried to the utmost length at which perhaps it was possible for it to arrive, it cannot be supposed that stage plays would be tolerated.—It seems, however, that amusements of this kind were again introduced at Edinburgh about the year 1684, when the duke of York kept his court there. His residence at Edinburgh drew off one half of the London company, and plays were acted in Edinburgh for some little time. The misfortunes attending the duke of York, however, and the establishment of the Presbyterian religion (the genius of which is unfavourable to amusements of this kind), soon put a stop to the progress of the stage, and no theatrical exhibition was heard of in Edinburgh till after the year 1715. The first adventurer was Signora Violante, an Italian, remarkable for feats of strength, tumbling, &c. In this way she first exhibited in a house at the foot of Carruber's close, which has since been employed by different sectaries for religious purposes. Meeting with good success, she soon invited a company of comedians from London; and these being also well received, Edinburgh continued for some years to be entertained with the performances of a strolling company, who visited it annually. Becoming at last, however, obnoxious to the clergy, they were in 1727 prohibited by the magistrates from acting within their jurisdiction. But this interdict was suspended by the court of session, and the players continued to perform as usual.

Still, however, theatrical amusements were but rare. The town was visited by itinerant companies only once in two or three years. They performed in the Taylor's Hall in the Canongate; which, when the house was full, would have drawn (at the rate of 2s. 6d. for pit and boxes, and 1s. 6d. for the gallery) 40l. or 45l. a night. About this time an act of parliament was passed, prohibiting the exhibition of plays, except in a house licensed by the king. Of this the presbytery of Edinburgh immediately laid hold; and at their own expence brought an action on the statute against the players. The cause was by the court of session decided against the players; who thereupon applied to parliament for a bill to enable his majesty to license a theatre in Edinburgh. Against this bill petitions were presented in 1739 to the house of commons by the magistrates and town council, the principal and professors of the university, and the dean of guild and his council; in consequence of which, the affair was dropped. All this opposition, however, contributed in reality to the success of the players; for the spirit of party being excited, a way of evading the act was easily found out, and the house was frequented more than usual, insomuch that Taylor's Hall was found insufficient to contain the number of spectators.

The comedians now fell out among themselves, and a new playhouse was erected in the Canongate in the year 1746. The consequence of this was, that the old one in Taylor's Hall became entirely deserted, and through bad conduct the managers of the new theatre soon found themselves greatly involved. At last, a riot ensuing through dissensions among the performers, the playhouse was totally demolished.—When the extension of the royalty over the spot where the New Town is built was obtained, a clause was likewise added to the bill, enabling his majesty to license a theatre in Edinburgh. This was obtained, and thus the opposition of the clergy for ever silenced. Mr Jackson's patent having expired in 1809, it was renewed in the name of trustees as formerly, and acquired by Mr Henry Siddons. Mr Siddons on his becoming manager, fitted up Corri's rooms as a theatre, in which performances were continued for two seasons. Mr Siddons then acquired the property of the old theatre, on becoming bound to pay 2000l. annually, for 21 years from the date of the patent.

Not far from this building, an amphitheatre was opened in 1790, on the road to Leith, for equestrian exhibitions, pantomime entertainments, dancing, and tumbling. The circus was 60 feet in diameter; and in the forenoon ladies and gentlemen were taught to ride. The house held about 1500 people. The building has been since converted into a concert room, and applied to various other uses.

31. *The Register Office.* This work was first suggested by the late earl of Morton, lord register of Scotland, with a view to prevent the danger which attended the usual method of keeping the public records. In former times, indeed, these suffered from a variety of accidents. Edward I. carried off or destroyed most of them, in order to prevent any marks of the former independence of the nation from remaining to posterity. Afterwards Cromwell spoiled this nation of its records, most of which were sent to the Tower of London. At the time of the Restoration many of them were sent down again by sea; but one of the vessels was shipwrecked, and the records brought by the other have ever since been left in the greatest confusion.—The earl of Morton taking this into consideration, obtained from his majesty a grant of 12,000l. out of the forfeited estates, for the purpose of building a register office,

office, or house for keeping the records, and disposing them in proper order. The foundation was laid on the 27th of June 1774, by Lord Frederick Campbell lord-register, Mr Montgomery of Stanhope lord advocate, and Mr Millar of Barskimming lord justice clerk; three of the trustees appointed by his majesty for executing the work. The ceremony was performed under a discharge of artillery, in presence of the judges of the courts of session and exchequer, and in the sight of a multitude of spectators. A brass plate was put into the foundation stone with the following inscription: CONSERVANDIS TABULIS PUBLICIS POSITUM EST, ANNO M.DCC.LXXIV, MUNIFICENTIA OPTIMI ET PIETISSIMI PRINCIPIS GEORGII TERTII. In a glass vase hermetically sealed, which is also placed in the foundation stone, are deposited specimens of the different coins of his present majesty.

The front of the building directly faces the bridge, extends from east to west 100 feet, and is 40 feet back from the line of Prince's street. In the middle of the front is a small projection of three windows in breadth. Here is a pediment, having in its centre the arms of Great Britain, and the whole is supported by four Corinthian pilasters. At each end is a tower projecting beyond the rest of the building, having a Venetian window in front, and a cupola on the top. The front is ornamented from end to end with a beautiful Corinthian entablature. In the centre of the building is a dome of wooden work covered with lead. The inside forms a saloon 50 feet diameter and 80 high, lighted at top by a copper window 15 feet in diameter. Round the whole is a hanging gallery of stone, with an iron ballustrade, which affords conveniency for presses in the walls for keeping the records. The whole number of apartments is 97; all of which are vaulted beneath, and warmed with fire-places. This building, which is the most beautiful of Mr Adam's designs, was executed in a substantial manner, in about 16 years, at the expence of near 40,000l. and is one of the principal ornaments of the city. A serjeant's guard is placed here from the castle, for the further protection of the records.

32. On the east side of St Andrew's square stands the *General Excise Office*, built by the late Sir Lawrence Dundas for his own residence, but sold by his son for the above purpose. It is a very handsome building, with a pediment in front ornamented with the king's arms, and supported by four Corinthian pilasters; and, in conjunction with the two corner houses, has a fine effect.

33. *St Andrew's Church* stands on the north side of George's street. It is of an oval form; and has a very neat spire of 186 feet in height, with a chime of eight bells, the first and only one of the kind in Scotland. It has also a handsome portico in front.

34. *St George's Church* stands on the west side of St Andrew's square, so as to close the perspective of George street, It was founded in 1811, and finished in 1814, at an expence of 33,000l. The front to the square is 112 feet, and consists of a portico or vestibule, with four columns, and two pilasters of the Ionic order, 35 feet high. Behind the portico rises a dome to the height of 150 feet, upon a basement of 40 feet square. The extreme breadth of the building is 128 feet.

35. Opposite to St Andrew's church is the *Physicians Hall*, designed for the meetings of the faculty, and which has a portico resembling that of the church.

36. Farther to the westward, on the south side, stand the *Assembly Rooms*, which though a heavy looking building on the outside, are nevertheless extremely elegant and commodious within. The largest is 100 feet long and 40 broad, being exceeded in its dimensions by none in the island, the large one at Bath excepted. Weekly assemblies are held here for dancing, and card-playing, under the direction of a master of ceremonies; admission tickets five shillings each.

There are four Banking Companies in Edinburgh established by statute, or by royal charters. These are the Bank of Scotland, commonly called the Old Bank, the Royal Bank of Scotland, the British Linen Company, and the Commercial Bank.

37. The *Bank of Scotland*, commonly called the *Old Bank*, was erected by act of parliament, A. D. 1695. By the statute of erection, the company was empowered to raise a joint stock of 1,200,000l. Scots, or 100,000l. sterling, for the purpose of carrying on a public bank. The smallest share which any person could hold in the bank was declared to be 1000l. Scots; and the largest sum for which any one was allowed to subscribe was 20,000l. of the same money. Eight thousand are declared to be the qualification necessary to entitle any one to be elected governor; 6000l. deputy-governor; and 3000l. for each director. The management of the affairs of the company was vested in a governor, deputy-governor, and twenty-four directors; and in choosing these managers, each proprietor was declared to have a vote for every 1000l. of stock held by him.

The office of this company was held in a house down a narrow lane at the south side of that part of the High street called the Lawn-market; but, at a great expence, they erected for their accommodation a building which is situated at the foot of Bank street, to the northward of the High street, in full view of Prince's street. This is at once a magnificent and beautiful fabric. The back of the building is towards Prince's street; and here, while erecting, it had the disadvantage, from its vast height, of having somewhat the aspect of a tower. This effect, however, is now removed by restoring the earth for the purpose of covering up the lower part of it, and by a wall of considerable height in the nature of a curtain, which has been added to augment its apparent breadth. It forms, upon the whole, a beautiful and most superb fabric. As a work of magnitude, it is seen to most advantage from the mound of earth which connects the Old and the New Town, at that part of the mound which is in the direction of the north-west angle of the building. Here the eye is filled by the full view of two sides of the fabric, and by a display of its great height. The result of which is, that as a magnificent and stupendous structure, it seems to have no rival in this country.

"This banking company has established branches in every considerable town in Scotland, excepting Glasgow, which, in consequence of an amicable adjustment to avoid rivalship, is left to the Royal Bank. By agreement, the latter has a branch in Glasgow, and no branch in any other town in Scotland.

38. "The *Royal Bank* was established in the following manner: By the articles of union, Scotland was declared to be liable to the same duties which were levied by way of customs or excise in England. As these duties had, in the latter of these nations, been appropriated for the discharge of debts contracted by England before the union, it was found reasonable to give Scotland an equivalent for this additional burthen. The sum, given by way of equivalent, was ordained to be paid for certain purposes, and to certain persons or bodies corporate, mentioned in the articles of union and in posterior statutes. The proprietors of these sums, to the extent of 248,550l. sterling, were erected into a body corporate, under the name of the *Equivalent Company*; and the said sum of 248,550l. was declared to be the joint stock of the company. Upon application by this company, they obtained a royal charter, empowering such of them as inclined to subscribe their shares in the joint stock for that purpose, to carry on the business of banking. By this charter the subscribers to this banking business were, in A. D. 1727, erected into a body corporate, to be called, "*The Royal Bank of Scotland*." They were vested with the requisite powers, and the management of the company's affairs declared to be in a governor, deputy-governor, nine ordinary and nine extraordinary directors. The qualifications of these managers were declared to be, that of the governor to hold stock to the extent of 2000l.; of the deputy-governor, of 1500l.; of the ordinary directors, of 1000l.; and of the extraordinary directors, of 500l. The sum originally subscribed was 111,000l.; but by a charter passed in favour of the Royal Bank, A. D. 1738, explaining the privileges formerly bestowed upon them, and enabling them to increase their capital, they were empowered to raise their stock to a sum not exceeding in whole, when joined to their original funds, 150,000l. By the charter of erection of this company, a share of 300l. entitles a proprietor to one vote, one of 600l. to two, of 1200l. to three, and of 2000l. to four; and no proprietor can have more than four votes.

39. "The *British Linen Company*, with a capital of 100,000l. was incorporated by royal charter in 1746, with a view to encourage the manufacture of linen in Scotland. By the constitution of this company, its affairs are declared to be under the management of a governor, deputy-governor, and five directors. It is declared a necessary qualification in the governor to be possessed of a share in the company's stock to the amount of 1000l.; of the deputy governor, 500l.; and of each director, of 300l. A share of 200l. entitles a proprietor to vote in the choice of these managers, of 500l. to two votes, and of 1000l. to four votes; but it is declared that no proprietor shall possess more than four votes.

"This company carries on the business of banking, and issues promissory notes like the two former companies; but the banking business is carried on separately from the linen trade. The Linen Hall remains in the Canongate; but the apartments of the bank are removed to a large house in St Andrew's square, next to the Excise Office.

40. The *Commercial Bank* was established in 1810, with a capital of three millions. It is managed by ordinary and extraordinary directors like the other banks. It occupies a building erected by themselves in the Old Assembly close, High street. All these banks issue promissory notes for various sums not under one pound sterling.

"Besides these there are several private banking houses of great reputation in Edinburgh, which do not issue promissory notes for small sums payable on demand, but which carry on the other branches of the banking trade, by transmitting money, discounting bills, and accommodating individuals with cash accounts."

Beauties of Scotland, I. 91.

29
Religious establishments.

It now remains only to speak something of the religious and civil establishments of this metropolis. The highest of the former is the General Assembly of the church of Scotland, who meet there annually in the month of May, in an aisle of the church of St Giles fitted up on purpose for them. The throne is filled by a commissioner from his majesty, but he neither debates nor votes. He calls them together, and dissolves them at the appointed time in the name of the king; but they call and dissolve themselves in the name of the Lord Jesus Christ. This assembly consists of 350 members chosen out of the various presbyteries throughout the kingdom; and the debates are often very interesting and eloquent. This is the supreme ecclesiastical court in Scotland, to which appeals lie from the inferior ones.

The ecclesiastical court next in dignity to the Assembly is the Synod of Lothian and Tweeddale, who meet in the same place in April and November; and next to them is the Presbytery of Edinburgh. These meet on the last Wednesday of every month, and are trustees on the fund for ministers widows. They have a hall in Scott's close, where there is a good picture of Dr Webster by Martin, which was put up at the expence of the trustees, out of gratitude for the trouble he took in planning and fully establishing the fund.

The Society for propagating Christian Knowledge in the Highlands and Islands of Scotland, was established a body corporate by Queen Anne in the year 1709, for the purpose of erecting schools to instruct poor children in the principles of Christianity, as well as in reading and writing. The society have a hall in Warriston's close, where their business is transacted. From time to time they have received large contributions, which have always been very properly applied; and for much the same purpose his majesty gives 1000l. annually to the generally assembly of the church of Scotland, which is employed by a committee of their number for instructing the poor Highlanders in the principles of the Christian religion.

The Erse church at Edinburgh was built about 30 years ago by subscriptions for the same laudable purpose. Great numbers of people resort to the metropolis from the Highlands, who understand no other language but their own, and consequently have no opportunity of instruction without it; and a most remarkable proof of the benefit they have received from it is, that though the church is capable of holding 1000 people, yet it is not large enough for those who apply for seats. The minister has 100l. per annum arising from the seat rents, and holds communion with the church of Scotland. A larger church for their accommodation has since been built at the head of the Horse wynd.

30
Political constitution.

With regard to the political constitution of Edinburgh, the town council have the direction of all public

lic affairs. The *ordinary* council consists only of 25 persons; but the *council ordinary and extraordinary*, of 33. The whole is composed of merchants and tradesmen, whose respective powers and interests are so interwoven, that a balance is preserved between the two bodies. The members of the town council are partly elected by the members of the 14 incorporations, and they partly choose their own successors. The election is made in the following manner: First, a list or *leet* of six persons is made out by each incorporation; from which number, the deacon belonging to the incorporation must be chosen. These lists are then laid before the ordinary council of 25, who "shorten the *leets*," by expunging one half of the names from each; and from the three remaining ones the deacon is to be chosen. When this election is over, the new deacons are presented to the ordinary council, who choose six of them to be members of their body, and the six deacons of last year then walk off. The council of 25 next proceed to the election of the three merchant and two trades counsellors. The members of council, who now amount to 33 in number, then make out *leets*, from which the lord provost, dean of guild, treasurer, and bailies, must be chosen. The candidates for each of these offices are three in number; and the election is made by the 30 members of council already mentioned, joined to the eight *extraordinary* council deacons.

The lord provost of Edinburgh, who is styled *right honourable*, is high sheriff, coroner, and admiral, within the city and liberties, and the town, harbour, and road of Leith. He has also a jurisdiction in matters of life and death. He is preses of the convention of royal boroughs, colonel of the train bands, commander of the city guard and of Edinburgh jail. In the city he has the precedency of all the great officers of state and of the nobility; walking on the right hand of the king or of his majesty's commissioner; and has the privilege of having a sword and mace carried before him. Under him are four magistrates called *bailies*, whose office is much the same with that of aldermen in London. There is also a dean of guild, who has the charge of the public buildings, and without whose warrant no house nor building can be erected within the city. He has a council to consult with, a nominal treasurer, who formerly had the keeping of the town's money, which is now given to the chamberlain. These seven are elected annually; who with the seven of the former year, three merchants and two trades counsellors, and 14 deacons or preses of incorporated trades, making in all 33, form the council of the city, and have the sole management and disposal of the city revenues; by which means they have the disposal of places to the amount of 20,000l. annually. Formerly the provost was also an officer in the Scots parliament. The magistrates are sheriffs depute and justices of the peace; and the town council are also patrons for all the churches in Edinburgh, patrons of the university, and electors of the city's representative in parliament. They have besides a very ample jurisdiction both civil and criminal. They are superiors of the Canongate, Portsburgh, and Leith; and appoint over these certain of their own number, who are called *baron bailies*: but the person who presides over Leith has the title of *admiral*, because he hath there a jurisdiction over maritime affairs. The baron bailies appoint one or two of the inhabitants of their respective districts to be their substitutes, and these are called *resident bailies*. They hold courts in absence of the baron bailies, for petty offences and discussing civil causes of little moment.

31 Town guard

No city in the world affords greater security to the inhabitants in their persons and properties than Edinburgh. Robberies are here very rare, and street murder hardly known in the memory of man; so that a person may walk the streets at any hour of the night in perfect security. Formerly this was attributed to the *town guard*. This institution originated from the consternation into which the citizens were thrown after the battle at Flowden. At that time, the town council commanded the inhabitants to assemble in defence of the city, and every fourth man to be on duty each night. This introduced a kind of personal duty for the defence of the town, called *watching and warding*; by which the trading part of the inhabitants were obliged in person to watch alternately, in order to prevent or suppress occasional disturbances. This, however, becoming in time extremely inconvenient, the town council, in 1648, appointed a body of 60 men to be raised, the captain of which was to have a monthly pay of 11l. 2s. 3d. two lieutenants of 2l. each, two serjeants of 1l. 5s. and the private men of 15s. each. No regular fund was established for defraying this expence: the consequence of which was, that the old method of watching and warding was resumed; but the people on whom this service devolved were now become so relaxed in their discipline, that the magistrates were threatened with having the king's troops quartered in the city if they did not appoint a sufficient guard. On this 40 men were raised in 1679, and in 1682 the number was increased to 108. After the Revolution, the town council complained of the guard as a grievance, and requested parliament that it might be removed. Their request was immediately granted, and the old method of watching and warding was renewed. This, however, was now so intolerable, that the very next year they applied to parliament for leave to raise 126 men for the defence of the city, and to tax the citizens for their payment. This being granted, the corps was raised and continued under the name of the *town guard*, till the establishment of the present police. The establishment consisted of three officers and about 90 men, who mounted guard by turns. The officers had a lieutenant's pay; the serjeants, corporals, drummers, and common soldiers, the same with those of the army. Their arms were the same with those of the king's forces: but when called upon to quell mobs, they used Lochaber axes, a part of the ancient Scottish armour only in use among themselves.

32 Militia or trained bands.

The militia or trained band of the city consist of 16 companies of 100 men each. They were in use to turn out every king's birth day; but only the officers now remain, who are chosen annually. They consist of 16 captains and as many lieutenants and ensigns; the provost, as has already been mentioned, being the colonel.

The town guard were paid chiefly by a tax on the trading people; these being the only persons formerly subject to watching and warding. The tax, however, amounted only to 1250l.; and as the expence of

the

the guard amounted to 1400l. the magistrates were obliged to defray the additional charge by other means.

But in the year 1805, in consequence of a new system of police being established, the city guard was reduced to one lieutenant, two serjeants, two corporals, two drummers, and thirty men, the lord provost for the time being to be captain, without pay, and the company to be armed and clothed at the expence of the city, but their pay to be defrayed out of the general fund raised under the new police act; and the duty of this company is to attend upon his majesty's commissioner to the general assembly of the church of Scotland, the magistrates and town council, the supreme courts of justice, and to act in general for the support of the new system of police.

33 S em of pe e.

The system of police above alluded to, was established in 1805 by act of parliament, under the authority of which the city and suburbs were divided into six districts or wards for the more convenient execution of the purposes to which the act extended. The regulations included under this system of police relate to cleansing and lighting the streets and passages in the city and suburbs, apprehending and punishing vagrants and disorderly persons, suppressing common begging, preventing nuisances and obstructions, and for other purposes connected with the preservation of peace and good order. The management of the whole affairs under this system of police was entrusted to the general and resident commissioners. The general commissioners appointed by the act, were, the lord provost and magistrates of the city of Edinburgh, with the lord president of the court of session, the lord justice clerk, the lord chief baron of the court of exchequer, the law officers of the crown, and several other public characters, in conjunction with the whole resident commissioners in the different wards. There were to be seven resident commissioners in each ward, the two highest in the list to go out, and two others to be elected in their stead annually; the commissioners to be occupiers of houses valued at twenty pounds sterling of free rent yearly, excepting in two wards, where occupying a house of twelve pounds rent is a sufficient qualification. In each ward there were to be elected by the resident commissioners, with the approbation of the general commissioners, an inspector, and such a number of officers of police and watchmen as might be necessary, the officers of police and watchmen upon duty having the authority and possessing the powers given by the law of Scotland to the office of constable.

The general commissioners had the power of choosing a superintendant or master of police for the whole city and suburbs included in the act, and to appoint a clerk who shall do the duty of clerk to the general meetings, as well as to the court of police to be held by the superintendant. The general commissioners also were authorized to fix the number of officers and watchmen to be employed in the different wards. The superintendant of police having been appointed by the commissioners, was to receive from the sheriff depute of the county of Edinburgh the authority of a sheriff substitute, as well as a commission of sheriff depute within the city and liberties from the lord provost, who was principal sheriff within these bounds, that the superintendant acting as master or judge of police may have the full powers of a magistrate in the execution of his duty. By the powers with which the superintendant was invested, he might commit offenders to the tolbooth or to bridewell for a period not exceeding 60 days, and impose fines for offences not exceeding 40 shillings sterling, and give judgment in damages for any sum not exceeding three pounds sterling with the expences in either case. From the sentences of the superintendant there was no appeal to the sheriff depute of the county, or to the lord provost as sheriff principal within the city. The superintendant of police was also the billet-master within his bounds, and the inspectors of wards were billet-masters within their several wards. The inspectors also had the powers of procurator fiscals with respect to all prosecutions for offences committed within their bounds.

The expences necessary to carry the above act into execution, were to be defrayed from a fund raised by assessment on the inhabitants, of three per cent. on the free rent of houses, shops, or warehouses; and for the expences of clothing and alimenting the persons committed to bridewell a farther assessment, not exceeding $\frac{1}{4}$ per cent. of the free rent of such houses, &c. For the purpose of ascertaining rents, surveyors were appointed; and if the rent fixed by them should be overrated, an appeal might be made to a committee of the general commissioners specially appointed.

After a trial of seven years this bill was found objectionable in many points; and therefore in 1812 a new bill was procured, which abolished the office of judge of police, divided the city into 26 wards, with three resident commissioners for each. The sheriff of the county, and magistrates of Edinburgh, were appointed judges. A superintendant, with a salary of 500l. a-year, was appointed, assisted by a clerk with 200l. and three lieutenants at 80l. each. The total expence of the establishment in 1817 was 18,482l.

34 Number of inhabitants.

The number of inhabitants in the city of Edinburgh is somewhat uncertain, and has been very variously calculated. By a survey made in the year 1775, it appears that the number of families in the city, Canongate, and other suburbs, and the town of Leith, amounted to 13,806. The difficulty therefore is to fix the number of persons in a family. Dr Price fixes this number at 4$\frac{1}{10}$; Mr Maitland, at 5$\frac{1}{2}$; and Mr Arnot, at 6; so that, according to this last gentleman, the whole number of inhabitants is 82,836; to which he thinks 1400 more may be added for those in the garrisons, hospitals, &c.

The following table exhibits a comparative view of the population of the city of Edinburgh with Leith and suburbs taken in different years. The enumeration made in 1801 by act of parliament is supposed to be considerably defective in the real amount of the inhabitants, as an alarm was industriously spread that it was done with a view to the imposition of new taxes.

1678	35,500
1722	40,420
1755	57,195
1775	70,430
1791	84,886
1801	82,560
1811	102,987

According to this last enumeration the males were 43,982, the females 59,005, a most surprising difference, if correct. The number of families was 23,104.

There are in Edinburgh 14 incorporations, capable of choosing their own deacons, viz. The royal college of surgeons; the corporations of goldsmiths, skinners, furriers, hammermen, wrights and masons, taylors, bakers, butchers, shoemakers, weavers, waukers, bonnet-makers, and merchant company.

The markets of Edinburgh are plentifully supplied with all sorts of provisions. Fresh butcher meat, as well as fowl and fish, if the weather permit, may be had every day; and no city can be better supplied with garden stuffs. The Edinburgh strawberries particularly are remarkably large and fine. A striking instance of the plenty of provisions with which Edinburgh is supplied was observed in the year 1779, when several large fleets, all of them in want of necessaries, arrived in the Forth, to the amount of about 500 sail, and having on board at least 20,000 men; yet the increased consumption of provisions, which certainly ensued upon the arrival of so many strangers, made not the least increase in the rate of the markets, insomuch that several victualling ships sent down by the navy board returned without opening their hatches. The city mills are let to the corporation of bakers in Edinburgh: and the bread made in the city is remarkable for its good quality.

Edinburgh is supplied with water brought for some miles in pipes, and lodged in two reservoirs, from whence it is distributed through the city both to public wells and private families. A revenue accrues to the town from the latter, which must undoubtedly increase in proportion as the city extends in magnitude.

There are but few merchants in Edinburgh, most of them residing at the port of Leith: so that the support of the city depends on the consumption of the necessaries as well as the superfluities of life. There are five different sorts of people on whom the shopkeepers, publicans, and different trades depend: 1. The people of the law, who are a very respectable body in the city. 2. The number of young people of both sexes who come to town for their education, many of the parents of whom come along with them. 3. The country gentlemen, gentlemen of the army and navy, and people who have made their fortunes abroad, &c. all of whom come to attend the public diversions, or to spend their time in such a manner as is most agreeable to them. 4. The vast concourse of travellers from all parts. 5. Most of the money drawn for the rents of country gentlemen is circulated among the bankers or other agents. See EDINBURGH, SUPPLEMENT.

EDINBURGHSHIRE, or MIDLOTHIAN, is bounded on the north by the frith of Forth, and the river Amond, which divides it from Westlothian or Linlithgow; on the east by Haddingtonshire; on the south by the counties of Lanark, Peebles, and Berwick; and at the west corner by part of the county of Linlithgow. It extends about 30 miles in length, and its breadth varies from 16 to 20: containing in all about 354 square miles, or 226,560 English acres. The surface of the country is pleasant, having much level ground, interspersed with some hills, watered with many agreeable streams, and sheltered and decorated with woods. The arable land, which may be calculated about one third of the whole, is in a state of high cultivation, and affords excellent crops. The two great ridges of hills which pass through the county, called the *Moorfoot* and the *Pentland* hills, afford pasture; the former is far superior in quality to the latter:-in these hills it is generally remarked that the north side of the hill is the finest and best pasture, contrary to what we should be apt, *à priori*, to imagine. Like the other parts of the country, this district experiences the consequences of an insulated situation; being subject to that instability and uncertainty, that the climate in one day exhibits the weather of every season of the year; the cold east winds in the spring are exceedingly detrimental to fruit, and in autumn the *haars* or mists from the sea, are apt to whiten and wither the corns before they are ripe. The immediate vicinity of many of the farms to the metropolis affords the opportunity of procuring street dung easily, and has been of material advantage in improving the land; it has this disadvantage, however, that by long continuance the fields become very full of weeds, particularly the *scaller*, or wild mustard; it is imagined that this would be obviated by throwing the field out in pasture for a few years, and afterwards liming it well before ploughing. The chief rivers of the county of Edinburgh, are the *North* and *South Esks*, which, uniting, fall into the frith of Forth at the town of Musselburgh; the *Amond*, which falls into the same frith at the village of Cramond, and the water of *Leith*, which forms the harbour of that town; all of these abound with trout. The islands of Inchkeith and Cramond, and of Inchmickery, also belong to this county. Few districts of Scotland afford more minerals than the county of Edinburgh; it abounds everywhere with coal, limestone, and freestone of superior quality; and iron ore of different species is very abundant; compound stone, called *petuntse*, is found in great quantity in the Pentland hills, and has been successfully employed in the manufacture of British porcelain. In the parish of Ratho is found a fine species of whetstone or hone; and in the parish of Duddingstone, at Brickfield, is found clay, fit for making earthen ware. The hills are composed of *porphyry* and *basalt* or *whinstone*, which in many places, particularly Arthur's Seat and Craig-Lockhart, exhibit regular forms. Near Glencross, and in the Braid-hills, are found great veins of the heavy spar, or barytes, which is often an attendant on metallic veins, especially of lead and copper. All the hills contain specimens of zeolites, jaspers, spars, &c. From the vicinity to the metropolis, numerous seats of nobility and gentry are everywhere to be seen. Besides the city of Edinburgh and its suburbs, in which we may include the town of Leith, this county contains several large towns and villages, as Dalkeith, Musselburgh, Liberton, Lasswade, and Gilmerton, and is divided into 31 parishes, of which the following is the population at two different periods.

Edrisi.

EDITOR, a person of learning, who has the care of an impression of any work, particularly that of an ancient author: thus, Erasmus was a great editor; the Louvain doctors, Scaliger, Petavius, F. Sirmond, Bishop Walton, Mr Hearne, Mr Ruddiman, &c. are likewise famous editors.

EDOM, or ESAU, the son of Isaac and brother of Jacob. The name of Edom, which signifies *red*, was given him, either because he sold his birthright to Jacob for a mess of red pottage, or by reason of the colour of his hair and complexion. Idumæa derives its name from Edom, and is often called in Scripture the land of Edom. See the next article.

EDOM, or IDUMÆA, in *Ancient Geography*, a district of Arabia Petræa; a great part also of the south of Judæa was called *Idumæa*, because occupied by the Idumæans, upon the Jewish captivity, quite to Hebron. But the proper Edom or Idumæa appears not to have been very extensive, from the march of the Israelites, in which they compassed it on the south eastwards, till they came to the country of the Moabites. Within this compass lies Mount Hor, where Aaron died; marching from which the Israelites fought with King Arad the Canaanite, who came down the wilderness against them (Moses.) And this is the extent of the *Idumæa Propria* lying to the south of the Dead sea; but in Solomon's time extending to the Red sea, (1 Kings ix. 26.).

EDUCATION.

Ed tion.

Def ion.

EDUCATION may be defined that series of means by which the human understanding is gradually enlightened, and the dispositions of the human heart are formed and called forth, between earliest infancy and the period when we consider ourselves as qualified to take a part in active life, and, ceasing to direct our views solely to the acquisition of new knowledge or the formation of new habits, are content to act upon the principles which we have already acquired.

Part lars
com
end un-
er de-
nit .

This comprehends the circumstances of the child in regard to local situation, and the manner in which the necessaries and conveniences of life are supplied to him; the degree of care and tenderness with which he is nursed in infancy; the examples set before him by parents, preceptors, and companions; the degree of restraint or licentiousness to which he is accustomed; the various bodily exercises, languages, arts, and sciences, which are taught him, and the method and order in which they are communicated; the moral and religious principles which are instilled into his mind; and even the state of health which he enjoys during that period of life.

lan

1st, In this article we propose to give an account of some of the most remarkable institutions for the education of youth which have been legally established or have accidentally prevailed among various nations and in various periods of society. 2dly, An account of the most judicious and the most fanciful plans which have been proposed by those authors who have written on the subject of education. And, lastly, To offer the result of our own observations and recollections on this important head.

Education.

4
Education in a savage state.

In the infancy of society, very little attention can be paid to the education of youth. Before men have risen above a savage state, they are almost entirely the creatures of appetite and instinct. The impulse of appetite hurries them to propagate their species. The power of instinctive affection is often, though not always, so strong as to compel them to preserve and nurse the fruit of their embraces. But even when their wants are not so urgent, nor their hearts so destitute of feeling as to prompt them to abandon their new-born infants to the ferocity of wild beasts or the severity of the elements, yet still their uncomfortable and precarious situation, their ignorance of the laws of nature, their deficiency of moral and religious principles, and their want of dexterity or skill in any of the arts of life; all these together must render them unable to regulate the education of their children with much attention and sagacity. They may relate to them the wild inconsistent tales, in which all their notions concerning superior beings, and all their knowledge of the circumstances and transactions of their ancestors, are contained; they may teach them to bend the bow, to point their arrows, to hollow the trunk of a tree into a canoe, and to trace the almost imperceptible path of an enemy or a wild beast over dreary mountains or through intricate forests: but they cannot impress their minds with just ideas concerning their social relations, or concerning their obligations to a Supreme Being, the framer and upholder of nature; they teach them not to repress their irregular appetites, nor to restrain the sallies of passion when they exceed just bounds or are improperly directed; nor can they inform their understandings with very accurate or extensive views of the phenomena of nature. Besides, they know not how far implicit obedience to his parents commands is to be acquired of the boy, nor how far he ought to be left to the guidance of his own reason.

5 Among savages the influence of parental authority soon expires, nor is the parent solicitous to maintain it. As the eagle expels his young from his lofty nest as soon as they become able to support themselves in the air; so the savage generally ceases to care for his child, or assume any power over him, as soon as he becomes capable of procuring the means necessary for his own subsistence. Savages being scarce connected by any social ties, being unacquainted with the restraint of civil laws, and being unable to contribute in any great degree to the maintenance or protection of one another; each individual among them, as soon as he attains that degree of strength and dexterity which may enable him to procure the necessaries of life, stands single and alone, independent on others, and scorning to submit to their commands. The parent, conscious of his inability to confer any important benefits on his child, after he has advanced even a very short way towards manhood, no longer endeavours to controul his actions; and the child proud of his independence, scarce submits to ask his parents advice. And even before his reaching this period of independence, so few are the benefits which parents can bestow (being confined to supplying the necessaries of life, and communicating the knowledge of a very few of the rudest simplest arts), that children regard them with little deference, nor do *they* always insist on implicit submission. Want of natural affection, and consciousness of superior strength, often prompt the parent to abuse the weakness of his child. Yet though small the skill with which the savage can cultivate the understanding or form the dispositions of his child, though few the arts which he can teach him, and though not very respectful or submissive the obedience or deferences which he requires; yet there is one quality of mind which the savage is more careful to inspire than those parents who are directed in educating their children by all the lights of civilized society. That quality indeed is absolutely necessary to fit the savage for his situation; without it, the day on which he ceased to enjoy the protection of his parents would most probably be the last day of his life: That quality is Fortitude. We may perhaps think, that the hardships to which the young savage is from the period of his birth unavoidably exposed, might be enough to inspire him with fortitude; but as if these were insufficient, other means are applied to inspire him with what the Stoics have regarded as the first of virtues. He is compelled to submit to many hardships, unnecessary but from a view to this. Children are there called to emulate each other in bearing the severest torments. Charlevoix relates, that he has seen a boy and girl bind their arms together, place a burning coal between them, and try who could longest endure without shrinking the pain to which they thus exposed themselves.

6 The sa indebte chiefly nature a circums ces for educati

Still, however, the young savages owes his education rather to nature, and to the circumstances in which he is placed and the accidents which befal him, than to the kindness or prudence of his parents. Nature has endowed him with certain powers of understanding, sentiments, sensations, and bodily organs; he has been placed in certain circumstances, and is exposed to a certain train of events; and by these means chiefly, not by the watchful industry of instructors, does he become such as he appears when he has reached the years of maturity.

7 Educati in an im proved state of ciety.

But man was not designed by his wise and beneficent Creator to remain long in a savage state; the principles of his nature incline him to social life. Reason, distinguishing the superior advantages to be enjoyed in society, concurs with the social principle in his breast, in prompting him to seek the company and conversation of others of the human race. When men enter into society, they always unite their powers and talents, in a certain degree, for the common advantage of the social body. In consequence of this, laws come in time to be instituted; new arts are invented; progress is made in the knowledge of nature; moral duties are better understood and defined; juster ideas are gradually acquired of all our social relations; friendship, love, filial, parental, and conjugal affection, all are heightened and refined. All these advantages do not instantly result from men's entering into a social state; the improvement of the human mind, and the civilization of society, are gradual and progressive: But as it is natural for men to unite in a social state, so it is no less natural for society to be gradually improved and civilized till it attain a high degree of perfection and refinement.

8 Attentio to the e cation o youth a tural co sequenc civilization

When men have attained to such knowledge and improvement as to be entitled to a more honourable appellation than that of savages, one part of their improvements generally consists in their becoming more judicious and attentive in directing the education of their youth. They have now acquired ideas of dependence and subordination; they have arts to teach and knowledge to communicate; they have moral principles to instil; and have formed notions of their relations and obligations to superior powers, which they are desirous that their children should also entertain. Their affection to their offspring is now also more tender and constant. We observe at present in that state of society in which we live, that the poor who can scarce earn for themselves and their children the necessaries of life, are generally less susceptible of parental affection, in all its anxious tenderness, than the rich, or those whom Providence hath placed in easy circumstances; and we may make use of this fact in reasoning concerning the different degrees of the same affection felt by the savage and the member of a civilized society.

ty. The savage may be considered as the poor man, who with difficulty procures the necessaries of life even for himself; the other, as the man in affluent circumstances, who is more at leisure to listen to the voice of tender and generous affection.

In this improved state of society, the education of youth is viewed as an object of higher importance. The child is dearer to his parent; and the parent is now more capable of cultivating the understanding and rectifying the dispositions of his child. His knowledge of nature, and his dexterity in the arts of life, give him more authority over a child than what the savage can possess. Obedience is now enforced, and a system of education is adopted; by means of which the parent attempts to form his child for acting a part in social life. Perhaps the legislature interferes; the education of the youth is regarded as highly worthy of public concern: it is considered that the foolish fondness or the unnatural caprice of parents may, in the rising generation, blast the hopes of the state.

9
Pu[illegible] e-[illegible]sh-[illegible] for education am[illegible] the an[illegible]ts.

In reviewing ancient history, we find that this actually took place in several of the most celebrated governments of antiquity. The Persians, the Cretans, and the Lacedæmonians, were all of them too anxious to form their youth for discharging the duties of citizens to entrust the education of the children solely to the parents. Public establishments were formed among those nations, and a series of institutions enacted, for carrying on and regulating the education of their youths: Not such as our European universities, in which literary knowledge being the sole object of pursuit, the student is maintained solely at his parents expence, and attends only if his parents think proper to send him; but of a very different nature, and on a much more enlarged plan.

[illegible]
Am[illegible] the [illegible]t Per[illegible]s.

The Persians, according to the elegant and accurate account delivered by Xenophon in the beginning of his Cyropædia, divided the whole body of their citizens into four orders; the boys, the youth, the full-grown men, and those who were advanced beyond that period of life during which military service was required. For each of these orders particular halls were appropriated. Each of them was subjected to the inspection of twelve rulers. The adults and the superannuated were required to employ themselves in the performance of particular duties, suitable to their age, their abilities and their experience; while the boys and the youth were engaged in such a course of education as seemed likely to render them worthy and useful citizens.

The boys were not employed in their places of instruction, in acquiring literary accomplishments; for to such the Persians were strangers. They went thither to learn justice, temperance, modesty; to shoot the bow, and to launch the javelin. The virtues and the bodily exercises were what the Persians laboured to teach their children. These were the direct, and not subordinate, purposes of their system of education. The masters used to spend the greatest part of the day in dispensing justice to their scholars; who carried before them actions for thefts, robberies, frauds, and other such grounds of complaint against one another.—Such were the means by which the Persians endeavoured to instil, even in early youth, a regard for the laws of natural equity, and for the institutions of their country. Till the age of 16 or 17, the boys were busied in acquiring those parts of education. At that period they ceased to be considered as boys, and were raised to the order of the youths. After they entered this order, the same views were still attended to in the carrying on of their education. They were still inured to bodily labour. They were to attend the magistrates, and to be always ready to execute their commands. They were led out frequently to the chase; and on such expeditions they were always headed by the king, as in time of war. Here they were taught to expose themselves fearlessly to danger; to suffer, without repining or complaint, hunger, thirst, and fatigue; and to content themselves with the coarsest, simplest fare, for relieving the necessities of nature. In short, whether at home or out on some hunting expedition, they were constantly employed in acquiring new skill and dexterity in military exercises, new vigour of mind and body, and confirmed habits of temperance, fortitude, abstinence, patience, patriotism, and noble integrity. After spending ten years in this manner, their course of education was completed; they were admitted into the class of the adults, and were esteemed qualified for public offices. It must not escape our notice, that the citizens were not compelled to send their children to pass through this course of education in the public halls; but none except such as passed through this course of education were capable of civil power, or admitted to participate in public offices or public honours.

Such are the outlines of that system of education which Xenophon represents as publicly established among the Persians. Were we able to preserve in a translation all the manly and graceful simplicity of that enchanting author, we would have offered to the perusal of our readers the passage in which he has described it: but conscious of being inadequate to that task, we have presumed only to extract the information which it contains.

11
Remarks on Xenophon's account of Persian education.

Perhaps, however, this system of education did not subsist precisely as the eloquent disciple of Socrates describes it among that rude and simple people. On other occasions he has commemorated such instances of their barbarity, as would tempt us to think them incapable of so much order and so much wisdom. Perhaps, as the discoverers of the new world have sometimes conferred on the inhabitants of that hemisphere, in the accounts of them with which they entertained their friends in Europe, amazing degrees of moral and political wisdom, of skill and dexterity in the arts, of industry and valour, which those uncivilized children of nature were afterwards found not to possess; so the Athenian philosopher has also ascribed to the Persians prudence and attention in regulating the education of their youth beyond what people in so rude a state can possibly exert.

But if we examine into the principles on which this system of education proceeds, without concerning ourselves whether it once actually prevailed among the Persians, or is the production of the fine imagination of Xenophon, we will find it peculiarly suitable for a nation just emerging from the rudeness and ignorance of barbarity to a knowledge of social and civil relations, and of the duties connected with such relations. They have sacrificed their independence to obtain the comfort and security of a social state. They now glory in the appellation of citizens, and are desirous to discharge the duties incumbent on a citizen. They must inform their children in the nature of their social relations, and impress them with habits of discharging their social duties; otherwise the society will soon be dissolved, and their posterity will fall back into the same wild miserable state from which they have emerged. But perhaps the circumstances, or abilities, or dispositions of individuals, render them unequal to this weighty task. It becomes therefore naturally an object of public care. The whole social body find it necessary to deliberate on the most proper means for discharging it aright. A plan of education is then formed; the great object of which is, to fit the youth for discharging the duties of citizens. Arts and sciences are hitherto almost wholly unknown: and all that can be communicated to the youth is only a skill in such exercises as are necessary for their procuring subsistence, or defending themselves against human enemies or beasts of prey; and habits of performing those duties, the neglect of which must be fatal to the society or the individual.

Such is the system of education which we have surveyed as established among the Persians; and perhaps we may now be less suspicious than before of Xenophon's veracity. It appears natural for a people who have reached that degree of civilization in which they are described, and have not yet advanced farther, to institute such an establishment. Some such establishment also appears necessary to prevent the society from falling back into their former barbarity. It will prevent their virtue and valour from decaying, though it may perhaps at the same time prevent them from making any very rapid progress in civilization and refinement. Yet the industry, the valour, the integrity, and the patriotism which it inspires, must necessarily produce some favourable change in their circumstances; and that change in their circumstances will be followed by a change in their system of education.

12
Among the Cretans.

The Cretans, too, the wisdom of whose laws is so much celebrated in the records of antiquity, had a public establishment for the education of their youth. Minos, whom they revered as their great legislator, was also the founder of that establishment. Its tendency was similar to that of the course of education pursued among the Persians,—to form the soldier and the citizen. We cannot present our readers with a very particular or accurate account of it; but such as we have been able to procure from the best authorities we think it our duty to lay before them.

The Cretans were divided into three classes; the boys, the youth, and the adults. Between seven and seventeen years of age, the boy was employed in learning to shoot the bow, and in acquiring the knowledge of his duties as a man and a citizen, by listening to the conversation of the old men in the public halls, and observing their conduct. At the age of seven, he was conducted to the public halls to enter on this course of education. He was taught to expose himself boldly to danger and fatigue; to aspire after skill and dexterity in the use of arms and in the gymnastic exercises; to repeat the laws and hymns in honour of the gods. At the age of seventeen he was enrolled among the youth. Here his education was still continued on the same plan. He was to exercise himself among his equals in hunting, wrestling, and the military exercises; and while thus engaged, his spirits were roused and animated by strains of martial music played on such instruments as were then in use among the inhabitants of Crete. One part of the education of the Cretan youth, in which they were particularly desirous to excel, was the Pyrrhic dance; which was the invention of a Cretan, and consisted of various military evolutions performed to the sound of instruments.

Such were the principles and arts in which the Cretan legislature directed the youth to be instructed. This course of education could not be directed or superintended by the parent. It was public, and carried on with a view to fit the boy for discharging the duties of a citizen when he should attain to manhood.

It is easy to see, that such a system of education must have been instituted in the infancy of society, before many arts had been invented, or the distinctions of rank had arisen; at a time when men subsisted in a considerable degree by hunting, and when the intercourse of nations was on such a footing, that war, instead of being occasional, was the great business of life. Such a system of life would then naturally take place, even though no sage legislator had arisen to regulate and enforce it.

Lycurgus, the celebrated lawgiver of Lacedæmon, thought it necessary to direct the education of youth in a particular manner, in order to prepare them for paying a strict obedience to his laws. He regarded children as belonging more properly to the state than to their parents, and wished that patriotism should be still more carefully cherished in their breasts than filial affection. The spirit of his system of education was pretty similar to that of those which we have just viewed as subsisting among the Persians and the Cretans.

As soon as a boy was born, he was submitted to the inspection of the elders of that tribe to which his parents belonged. If he was well shaped, strong, and vigorous, they directed him to be brought up, and assigned a certain portion of land for his maintenance. If he was deformed, weak, and sickly, they condemned him to be exposed, as not being likely ever to become an useful citizen. If the boy appeared worthy of being brought up, he was intrusted to the care of his parents till he attained the age of seven years; but his parents were strictly charged not to spoil either his mind or his bodily constitution by foolish tenderness. Probably, too, the state of their manners was at that time such as not to render the injunction peculiarly necessary,

At the age of seven, however, he was introduced to a public class, consisting of all the boys of the same age. Their education was committed to masters appointed by the state; and what was chiefly inculcated on them in the course of it, was submissive obedience and respect to their superiors; quickness and brevity in their conversation, and replies to such questions as were put to them; dexterity and address in performing what was commanded them, and firmness and patience in bearing every pain or hardship to which they might be exposed. One of the means used to form them to habits of activity and address, was to permit, nay,

nay, to direct them to commit little acts of theft; which, if they performed them so dexterously as to avoid detection, they might afterwards boast of as noble exploits: but if detected in such enterprises, the awkward artless boy was exposed both to punishment and disgrace. To avoid the punishment and disgrace incurred by being discovered in an act of theft, the Spartan boy would often suffer with unshrinking fortitude the severest torments. It is related of one of them, that rather than be detected with a young fox under his cloak, which he had stolen, he suffered the little animal to tear open his bowels. Not cóntent with beholding the children suffer by submitting voluntarily to such hardships, the Spartans also endeavoured to form them to fortitude, by whipping them on their religious festivals, sometimes with such severity that they expired under the lash. The Lacedæmonian youth were also taught such bodily exercises, and the use of such warlike weapons, as were necessary to render them expert and skilful soldiers.

5 Remarks.

They too, as well as the Cretans and Persians, among whom we have seen similar modes of education adopted, were to be citizens and soldiers, not husbandmen, mechanics, artists, merchants, &c. Their mode of education, therefore, was simple and uniform. Its aim was, to make them acquainted with the nature of their social duties, and to form them to such vigour of body and such firmness of mind as might render them fit for the station in which they were to be placed, and adequate to the part which they were to act. This establishment for education was perfectly consistent with the other parts of that legislature which was instituted by Lycurgus. Youth educated among the Lacedæmonians could hardly fail to become worthy members of that singular republic. Let us not, however, regard the Spartans as singularly inhumane in their treatment of youth. Let us reascend, in imagination, to that period in the progress of society from rudeness to refinement, which they had reached when Lycurgus arose among them. What were then their circumstances, their arts and manners, their moral principles, and military discipline? Not very different from those which the laws of Lycurgus rendered so long stationary among them. He, no doubt, rectified some abuses, and introduced greater order and equality. But man is not to be so easily metamorphosed into a new form. As you cannot, at once, raise an acorn to a venerable oak; so neither will you be able to change the savage, at once, into the citizen. All the art or wisdom of Lycurgus, even though assisted by all the influence of the prophetic Apollo, could never have established his laws among his countrymen, had not their character and circumstances previously disposed them to receive them. But, grant this, and you must, of consequence, allow, that, what to us may appear cruel and inhumane, must have affected their feelings in a different manner. The change introduced in the treatment of youth by the establishment of this system of education, was probably recommended by its being more humane than what before prevailed. Corrupted as are our manners, and effeminate our modes of education; yet we would not perhaps act wisely in laying them aside, to adopt in their stead those of ancient Sparta. But the Spartan education was peculiarly well fitted to form citizens for the republic of Lycurgus; it was happily adapted to the state of society in which it was introduced. And, if we should inquire by what means Lycurgus was enabled to fix the arts, the manners, and in short the civilization of his country, for so long a period, in a stationary state; we would perhaps find reason to ascribe that effect to the public establishment which he instituted for the education of youth; to his confining the Spartan citizens to the profession of arms, and assigning all servile offices to the Helots; and to his prohibiting the use of gold and silver. Among these however his establishment for education occupies the chief place. Never was any state adorned with more patriotic citizens than those of Sparta: With them every private affection seemed to be swallowed up by the *amor patriæ:* the love of their country was at least their ruling passion. Pœdaretes being rejected when he offered himself a candidate for a seat among the council of three hundred, returned home, rejoicing that there were in Sparta no fewer than three hundred whom his countrymen found reason to regard as better citizens than himself. This was not a seeming joy, assumed to conceal the pain which he suffered from the disappointment; it was heartfelt and sincere. Such were the effects of their system of education.

16 Education among the other nations of antiquity.

When we turn our eyes from the Persians, the Cretans, and the Spartans, to the other nations of antiquity; we nowhere behold so regular a system of public education. Among the Athenians and the Romans, the laws did not descend to regulate in so particular a manner the management of the youth. These nations gradually emerged from a state of the rudest barbarity, to that polished, enlightened, and civilized state, which rendered them the glory and the wonder of the heathen world: but in no part of their progress from the one state to the other do we find any such establishment subsisting among them. So various, however, are the circumstances which form and diversify the character of nations, that we cannot reasonably conclude, because no such establishments existed among the Athenians and Romans, that therefore their existence was unnatural among those nations who possessed them. But though the education of youth was managed in a different manner among these and most other nations in the ancient world, than by public establishments, which detached children from the care of their parents; yet still it was everywhere regarded as an object of the highest importance. As the manners of mankind gradually improved to a state of refinement; as the invention of arts, and the discovery of science gradually introduced opulence and luxury; connubial, parental, and filial affection gradually acquired greater strength and tenderness. Of consequence, children experienced more of their parents care; and that care was directed to form them for acting a becoming part in life. According to the circumstances of each nation, the arts which they cultivated, and the form of government under which they lived; the knowledge which they sought to communicate to their children, and the habits which they endeavoured to impress upon them, were different from those of other nations: And again, according to the different circumstances, tempers, abilities, and dispositions of parents, even the children of each family were brought up in a manner different from that

that in which those of other families were managed. The Athenians, the Romans, the Carthaginians, conducted each of them the education of their youth in a different manner, because they had each different objects in view. But having considered the most singular establishments for education which prevailed in the ancient world, it seems unnecessary for us to descend to a particular account of the manner which every nation, or fantastic individual, thought proper to pursue in bringing up their youth. It will probably be more useful and entertaining to our readers, if we next present them with a view of some of the most judicious or fanciful plans of education which have been proposed by the writers on that subject.

17 Quinctilian.

One of the most respectable writers on education among the ancients is the celebrated Quinctilian. He taught rhetoric in Rome during the reign of Domitian, and under several of the other emperors. When he retired from the exercise of his employment as a teacher of rhetoric, he spent his leisure in the composition of a treatise, not merely on rhetoric, but on the most proper means for educating a boy so as to render him both an eloquent orator and a good man.

In that valuable treatise, he enters into a minute detail of all that appears to him most likely to conduce to those important ends.

As soon as the boy enters the world, he would have the greatest care to be used in selecting those who are to be placed about him. Let his nurse have no impediment of speech. It will be happy for him, if his parents be persons of sense and learning. Let his tutor, at least, possess these qualifications. As soon as he attains the distinct use of his organs of speech, let him be initiated in the first elements of literature. For as he is capable of distinguishing and remembering at a very early age; so his faculties cannot possibly be employed in a more advantageous manner. And even at this early period of life, let maxims of prudence and the first principles of morals be inculcated upon his mind by the books which are put into his hands, and even by the lines which he copies in learning the art of writing. The Greek language was to the Romans in the days of Quinctilian, what the Latin and Greek and French are to us at present, an acquisition held indispensably necessary to those who aspired to a liberal education; and Quinctilian judges it proper that the boy should begin his application to letters with the Greek language in preference to his mother tongue.

This judicious writer next examines a question which has been often agitated. Whether a domestic or a public education is liable to the fewest inconveniences, and likely to be attended with the greatest advantages? And he is of opinion, that in a domestic education the boy is in danger of being corrupted by injudicious fondness and evil example; is not roused by the spur of emulation; and is deprived of proper opportunities for acquiring a just idea of his own power, or that activity and dexterity which he will afterwards find so necessary when he comes to act a part in life: While in a public education, which was preferred by some of the most renowned nations of antiquity, the morals are not greatly exposed to corruption, emulation is roused, friendships are formed, all the powers of the mind are called forth to act with new vigour, and the youth is prepared for performing his part on the great theatre of the world. Quinctilian, therefore, wishes that parents would place their children in public seminaries of education.

When a boy is committed to a master's care, the master's attention must be first directed to discover his dispositions and the extent of his capacity. Of his capacity he will form a favourable judgment, not from his sprightliness, nor even from his quickness of apprehension, but from his modesty, docility, and virtuous dispositions. If the boy possess these last qualifications, the master will rejoice in him, as likely to give him satisfaction and do him honour. According to his temper and dispositions, let the boy be treated with mildness or severity; but never let severity extend to blows. Let the boy be allured and led, by the most artful and insinuating treatment, to do his duty; there will then be no occasion to punish him for neglecting it.

As Quinctilian's professed object was, not merely to give general directions for forming the heart and cultivating the understanding, but to form a particular character in life, the scholar and the orator; he finds it necessary to enter into minute details concerning the manner in which the boy is to be instructed in speaking, writing, grammar, and composition; of which it does not appear necessary for us take particular notice in this place. Music and geometry, he thinks, ought to make a part of the young orator's studies; as being useful to render him accurate in reasoning, and capable of relishing the beauties of the poets. He is also of opinion, that the boy should not be confined to one branch of study, without being allowed to attempt others till he have made himself master of that. Let several parts of literature engage his attention by turns: let him dedicate a considerable portion of his time to them. He may thus acquire habits of industrious application which will remain with him through life.

With the tender attention of a good man, this sensible and elegant writer still accompanies his pupil through the course of his studies; anxiously insists that he be placed under a master distinguished for purity of morals, and for no mean abilities in his profession; directs his memory to be stored with the noblest passages of the poets, orators, and historians; and carefully discusses and refutes those opinions which represent genius as above industry. The remaining part of his work being employed on the principles of rhetoric, without containing any thing on the subject of education in general, it is not necessary that we should here present an analysis of it to our readers. But since Quinctilian was so distinguished, not only as a rhetorician, but as an instructor of youth, and displays so much good sense and so solid a judgment, formed on long experience, in whatever he advances on the subject of education; we could not, without extreme negligence, omit taking notice of him under this article, and affording our readers an opportunity of being instructed by listening to his sentiments on this head.

18 Milton's Treatis Educat

The name of John Milton is so much revered in Britain, that his sentiments on any subject are interesting to Britons. His life was dedicated to study: During a part of it, he was employed in the task of instructing youth;

youth; and among his other works we find a treatise on education. He had himself been educated according to that plan which has long been established in the English universities; but with that mode of education he was not satisfied. The object of his directions is chiefly to form a scholar. He considered himself as qualified to exhibit a model of "a better education, in extent and comprehension far more large, and yet of time far shorter, and of attainment far more certain, than any that had yet been in practice." The following is the substance of his treatise.

As the end of learning is to cultivate our understandings, and to rectify our dispositions; therefore the design of our applying to the study of languages cannot be merely that we may commit to memory the words of which they consist, or that we may acquire a knowledge of their analogy and structure; but that we may enrich our minds with the treasures of wisdom which they contain. But in the present modes of education this design does not appear to be kept in view. The learner of Latin is burdened with rules, and themes, and verses, and orations; but no care is taken to make him master of the valuable knowledge which the classics contain. And when he advances a little farther, he is driven into the thorny paths of logic and metaphysics. So, when his studies are completed, and he is considered as having received a liberal education, he is almost as destitute of real knowledge as when he first entered a school.

But to render learning truly beneficial instead of the school and university education which youth at present receive, let the place of both school and university be supplied by an academy, in which they may acquire all that is taught at either, except law and physic. Let the academy afford accommodation for 150 persons; 20 of whom may be servants and attendants. As many academies as are necessary may be afterwards erected on the model of this one. Let the youth who are introduced into this academy begin their studies with learning the principal rules of grammar from some good elementary book. In their pronunciation of Latin, let them be taught to follow the pronunciation of the Italians; as that of the English is indistinct, and unsuitable to the genius of the language. Next, read to them some entertaining book on education; such as, the three first books of Quinctilian in Latin, and Cebes, Plutarch, or some other of the Socratic discourses, in Greek; and be careful to seize every opportunity of inspiring them, by seasonable lectures and explanations, with love for learning, admiration of great and virtuous characters, and a disposition to cheerful obedience. At the same time, but at a different hour of the day, let them be instructed in the rules of arithmetic and the elements of geometry. Between supper and bedtime, instruct them in the principles of religion and the sacred history. From the writers on education let your pupils pass to the authors on agriculture, to Cato, Varro, and Columella. Before half these authors be read, they cannot but be pretty well qualified to read most of the prose authors in the Latin language; and they may now, with great propriety, learn the use of the globes, and make themselves acquainted with the ancient and modern maps. Let them, about the same time, begin the study of the Greek tongue, and proceed in it as in the Latin: they will not fail to overcome, in a short time, all the difficulties of grammar; after which they will have access to all the treasures of natural knowledge to be found in Aristotle and Theophrastus. In the same manner they may make themselves acquainted with Vitruvius, Seneca, Mela, Celsus, Pliny, and Solinus. And having thus passed through the principles of arithmetic, geometry, astronomy, and geography, with a general compact of physics; let them next turn their attention to mathematics, in which they may begin with the practical branch of trigonometry, which will serve as an introduction to fortification, architecture, and navigation. To teach them the knowledge of nature, and instruct them in the arts of life, let them have the assistance and instructions, not merely of masters who are acquainted only with books, but of men whose skill has been obtained by actual practice, even of artists and mechanics. Next, let the poets obtain their attention; and they will now read them with ease and pleasure. From the poets let your pupils proceed to the moralists; and, after acquainting themselves with them, they may be allowed the entertainment of some of the best Greek, Latin, and Italian dramatic compositions. From these let them proceed to politics; let them here study the law of Moses, the admirable remains of the ancient lawgivers of Greece, the Roman tables, edicts, and pandects, concluding with the institutions of their mother country. Now let them be more particularly instructed in the principles of theology; for by this time they may have acquired the Hebrew language, together with the Chaldee and the Syriac dialect, and may therefore read the Scriptures in their original language. When their minds are thus furnished, they will be able to enter into the spirit of the noblest historians and poets. To get by heart, and repeat in a proper manner, passages from the writings of some of these, will have the happiest effects in elevating their genius. Let this stately edifice be crowned with logic and rhetoric. Far different would be the effects of such a course of education, from those produced by any which is at present pursued. We should then see abler writers, more eloquent speakers, and wiser statesmen. Similar to this, probably, was the course taught in the famous schools of Pythagoras, Plato, Isocrates, and Aristotle. This would unite the advantages of an Athenian and a Spartan education: for our pupils should be taught the exercises of wrestling and fencing, and the whole military discipline.

19
Remarks.

Such are the ideas of our admired Milton on the subject of education. An enthusiastic admirer of the sciences, arts, and institutions of Greece and Rome; from his religious and political principles, no friend to the universities; it was natural for a man of his learning and ingenuity, in an age of innovation, and influenced by such prejudices, to form such a project as that which we have surveyed. He seems not to have reflected, that it is necessary for children to be long occupied in obtaining a familiar acquaintance with words, before they can gain from books any knowledge of things; overlooking this circumstance, and perceiving plainly that the mode of education which then prevailed confined the attention of youth almost wholly to words, he could not but regard the scheme which he proposed as likely to produce very happy effects. His observation, that the appearances of external nature are among the first objects which attract the attention of youth, which he communicates by directing his pupils to peruse the writers on agriculture and natural history as near the beginning of their studies as possible; if not altogether just, yet must be allowed to be nearly so. Perhaps human actions and passions, and the series of events which happen around us, are, by the time at which we begin our application to learning, the objects which most frequently and strongly engage our attention: But the appearances of external nature are at least the next object of our regard.

20
Locke's Treatise on Education.

Mr Locke, to whose abilities and noble desire to be useful to the world his country is so much indebted, has written, among other things, on the education of youth. He was capable of thinking for himself; but more desirous of rendering himself useful, than of being admired for singularity. He is therefore an author to whom we ought to listen, at least, with respectful attention. If Quinctilian and Milton had been employed as teachers of youth, Mr Locke had been conversant with the world, had inquired into the principles of human nature, and had no doubt endeavoured to examine without prejudice the effects of those modes of education of which he disapproves. When we consider, that, to render himself useful to the rising generation, he could descend from the heights of science to translate the fables of Æsop, and to perform other humble tasks in literature, which a philosopher of less benevolence and virtue would have disdained; we cannot but look with veneration and gratitude on so exalted a character. In his Treatise on Education, the two great objects which Mr Locke keeps in view are, 1st, To preserve and strengthen the bodily constitution; 2dly, To inform the understanding with useful knowledge, and to cherish good dispositions in the heart.

21
Bodily constitution.

In his directions on the first of these heads, he seems extremely anxious to prevent parents and others, in whose hands children are placed, from injuring them by ill-directed tenderness. Plain fare, simple and light clothing, abstinence from physic and from strong liquors, he earnestly recommends as the most judicious means for preserving and confirming the health of the child. In all his gratifications let the strictest moderation be observed. If you permit him to indulge pretty freely in sleep, at least cause him to get up at an early hour in the morning. In one thing, however, few parents will be willing to comply with Mr Locke's advice. He not only directs that the child's feet be frequently bathed in cold water, but even expresses a wish, that his shoes were always kept in such a condition as to admit water freely. This he thinks likely to fortify the constitution of the body in such a manner, as to render him less liable, in the course of life, to such diseases as arise from any unusual exposure to wetness or cold, than others whose feet have been more carefully kept dry. Though he had prosecuted his studies with a design to enter into the profession of physic, yet so unfavourable an opinion did he entertain of the effects produced by medical preparations on the human constitution, that he earnestly insists on the parent to beware of administering any of them to his child. From the desire which Mr Locke discovers to have children exposed to hardship, and restrained from indulgence, in order to confirm the health and invigorate the constitution, we may conjecture him to have been an admirer of that severe mode of education which usually prevails in the earlier periods of the existence of society. He seems to have thought, that if a boy be brought up like a Huron or a Spartan, he must necessarily become robust and healthy; without reflecting, that of those children who are subjected to such a course of education, too great a proportion are unable to survive it: such is the natural delicacy of the human frame.

22
Cultivat
of the po
ers of the
mind.

When he turns his attention to the cultivating of the understanding, and the forming of the dispositions, Mr Locke still deservedly claims the regard of the parent and the preceptor. With a virtuous indignation he reprobates that negligence and folly by which we generally corrupt the heart and spoil the temper of children, even in that period of infancy; so as to render them incorrigible when they advance farther in life. Their appetites are pampered, all their desires are gratified: and if we are at any time disposed to refuse what they ask, they have an all-powerful engine to compel our compliance with their wishes. They assail us with tears; and we then yield to their requests, however hurtful to themselves or inconvenient to us. We often studiously instruct them in vicious tricks, and call forth their evil passions. At so early an age, their rage or cunning can scarcely injure us; and we reflect not that habits of peevishness and deceit must be peculiarly hurtful to themselves.

But though all the foolish desires of children ought not to be gratified, and though we should carefully avoid leading them into any bad habit; yet it is not necessary nor prudent to treat them with harshness or severity. Let them be formed to obedience from their earliest years: let them be accustomed to submit implicitly to the direction of those on whom they depend. But beware of souring their temper and depressing their spirits by harshness: and, on the other hand, remember that it is no less improper to give the boy a habit of neglecting his duty, except when he is allured to it by the hopes of reward. As he advances towards manhood, and attains the use of reason, you may admit him to greater familiarity, and allow him to follow his own inclinations more than at an earlier period: and if, instead of indulging all his freaks in childhood, you have carefully accustomed him to obedience and submission, without enforcing these by improper means, he will now be able to regulate his conduct with some degree of prudence.

But while caution is to be used in bestowing rewards and inflicting punishments, still rewards and punishments are indispensably necessary in the management of the child. Inspire your boy with a sense of shame, and with a generous thirst for praise. Caress and honour him when he does well: treat him with neglect when he acts amiss. This conduct will produce much better effects than if you were at one time to chide and beat him; at another, to reward him with a profusion of sweetmeats and play-things.

Think not that children are to be taught propriety of conduct by loading their memory with rules, directing

recting them how to act on every particular occasion. Burden them not with rules, but impress them with habits.

Be not desirous of forming them at too early an age, to all that politeness and propriety of manners which you wish to distinguish them when they become men. Let them be taught an easy, graceful carriage of body: but give yourself no concern, though they now and then blunder against the punctilios of good breeding; time will correct their awkwardness.

With regard to that important question, whether children ought to be sent to a public school, or are likely to be better trained up in a domestic education? so impossible is it for one master to extend his attention to a number of boys, and so likely is the contagion of vice to be caught among the crowd of a public school, that a private seems more favourable than a public education to virtue, and scarce less favourable to learning.

When you resolve to give your son a domestic education, be careful to regulate that domestic education in a judicious manner. Keep him at a distance from evil example: choose the most favourable seasons for communicating instruction: strictly enforce obedience; but never by blows, except in case of obstinacy, which you find otherwise incurable. If his engagements in life prevent the parent from superintending and directing his son's education personally, let him commit him to the care of a virtuous and judicious tutor. Let the tutor be rather a man of experience in the world than of profound learning; for it is more necessary that the pupil be formed for conducting himself with prudence in the world, and be fortified against those temptations to which he will be exposed when he enters upon active life, than that his head be stuffed with Latin and logic.

Here Mr Locke, notwithstanding that his own mind was stored with the treasures of Grecian and Roman literature, takes occasion to declare himself pretty freely against that application to ancient learning, which was then indispensably required in the education of youth. He considers languages and philosophy as rather having a tendency to render the youth unfit for acting a prudent and becoming part in life than forming for it; and he therefore insists that these should be but in a subordinate degree the objects of his attention.

Let the tutor encourage the child under his care to a certain degree of familiarity; let the pupil be accustomed to give his opinion on matters relative to himself: let him be taught justice, by finding injustice to others prejudicial to himself; let him be taught liberality, by finding it advantageous; let him be rendered superior to teasing his parents or tutor with complaints, by finding his complaints unfavourably received. That you may teach him to restrain every foolish or irregular desire, be sure never to indulge his wishes, save when you find the indulgence proper for him and convenient for yourself. Curiosity, however, is a principle which ought to be industriously roused in the breast of the child, and cherished there by meeting always the readiest gratification. However you may oppose the boy's inclinations in other things, yet refuse him not a proper portion of recreation: let him indulge in play, while he continues to play with keenness and activity; but suffer him not to loiter about in listless indolence. To restrain your child from foolhardy courage, point out to him the dangers to which it exposes him: to raise him above timorous cowardice, and inspire him with manly fortitude, accustom him from the earliest period of life to an acquaintance with such things as he is most likely to be afraid of: subject him now and then to pain, and expose him to danger; but let such trials be judiciously conducted.

Idleness or curiosity sometimes leads children to cruelty in the treatment of such animals as are placed within their power. Dogs, cats, birds, and butterflies often suffer from their inhumanity. But when they seem inclined to such cruelty, let them be carefully watched, and let every means be used to awake their hearts to generous sensibility. Allow them to keep tame birds, dogs, &c. only on condition of their using them with tenderness. Perhaps this unhappy disposition to cruelty is occasioned, or at least fostered, by people's laughing when they behold the impotent efforts of children to do mischief; and often going so far as even to encourage them in maltreating those creatures which are within their reach. We entertain them, too, with stories of fighting and battles; and represent characters distinguished for atrocious acts of inhumanity as great and illustrious. But let such practice be carefully refrained from, if you wish to inspire your child with generous and humane sentiments. Teach him gentleness and tenderness, not only to brute animals, but also to servants and companions.

Curiosity is to be roused and cherished in the breast of the child: but by what means? Answer his inquiries readily: though his questions be put in awkward language, let not that hinder you from attending to the objects of them. Curiosity is natural to the human mind; and if you repress not the curiosity of the child, he will often be moved by its impulse to the pursuit of knowledge. Let him find his eagerness in the pursuit of knowledge a source of applause and esteem. Avoid the folly of those who sport with the credulity of children, by answering their questions in a ludicrous or deceitful manner.

You must, however, not only listen with obliging attention to his questions, and strive to gratify his curiosity; but even whenever he attempts to reason on such subjects as are offered to his observation, be careful to encourage him; praise him if he reasons with any degree of plausibility; even if he blunders, beware of ridiculing or laughing at him. With regard to the boy's playthings: while you indulge him freely in innocent diversions, give him such playthings as may be necessary in the amusements in which he engages, provided they be such as he cannot make himself; but it will be still better for him to exercise his dexterity and ingenuity in making them himself.

After throwing out these things concerning the general principles on which education should be carried on, Mr Locke next proceeds to those particular parts of knowledge in which he thinks every young gentleman ought to be instructed. In virtue, wisdom, breeding, and learning, he comprehends all that is necessary to enable his pupil to act a respectable part in life.

In forming the boy to virtue, the first thing to be done is to inform him of the relation subsisting between human creatures and a supreme independent Being, their creator, preserver, and governor; and to teach him,

that

that obedience and worship are due to that Being. But when you inform the child of the existence of an invisible Being, beware of impressing his mind with any notions concerning spirits or goblins, which may render him incapable of bearing darkness or solitude. In infancy our minds are, by the indiscretion of those about us, generally impressed with such prejudices concerning a thousand frightful forms, ever ready to assail or haunt us under the shade of night, that we become incapable of manly fortitude during the course of life: the soldier who will boldly face death in the field of battle, shall perhaps tremble and take to flight at the rustling of a few leaves, or the grunting of a hog in the dark. But were the imaginations of children not crazed with wild stories concerning spirits and hobgoblins, darkness would be no more alarming to them than light. After informing the child of the existence of a Deity, and teaching him to pray to him; next labour to impress his mind with a veneration for truth, and habituate him to a strict adherence to it on every occasion. Endeavour also to render him gentle and good-natured.

The best means you can use to teach him wisdom or prudence in conducting himself in the ordinary business and intercourse of life, is to teach him to despise the mean shifts of cunning. The rest must be learned by actual experience in life.

The decencies of life, comprehended under the word Good Breeding, form no inconsiderable part of a good education. In teaching these, two things are to be attended to: Inspire the youth with a disposition to please and oblige all with whom he is conversant; next, teach him how to express that disposition in a becoming manner. Let boisterous roughness, haughty contempt of others, censoriousness, impertinent raillery, and a spirit of contradiction, be banished from his temper and behaviour. At the same time, beware of leading him to regard the mere forms of intercourse as a matter of the highest importance. Remember that genuine good breeding is only an easy and graceful way of expressing good sense and benevolence in his conversation and deportment.

Mr Locke, when he comes to give his opinion concerning those parts of learning which are proper to be taught a young gentleman, and the manner in which they ought to be communicated, advises to initiate the child in the art of reading, without letting him know that he is engaged about a matter of any importance, or learning an accomplishment which you are solicitous that he should acquire. Present it to him in the form of an amusement, or teach him to consider it as an high honour to be permitted to learn his alphabet; otherwise he will turn from it with disgust. When by insinuating arts you have allured him to apply to reading, put into his hands such books as are plain, entertaining, and instructive. Insist not on his reading over the Bible: instead of gaining any advantage from an indiscriminate perusal of it at this period of life, he is likely to acquire the most confused notions of religion, and an indifference for the sacred volume during the rest of life: yet it may be highly proper to cause him to peruse some of its beautiful historical passages, and to familiarize him with its elegant and simple moral precepts. After learning to read his mother tongue, the boy's attention ought to be next directed to the art of writing. The easiest way to teach him that art, is to get a plate engraved, after the model of any hand which you think most proper for his imitation. With this plate get a number of copies cast with red ink; the letters of these the learner may trace with his pen filled with black ink: and he will thus in a short time, and without much trouble to you or himself, acquire a decent hand. As drawing is useful on many occasions in life, if the boy be not naturally incapable of acquiring it, he may with great propriety dedicate some part of his time and attention to that art.

When the scholar has attained a tolerable degree of skill in writing, and in reading and speaking his native language, he must next begin an acquaintance with other languages. Among these, the first object of his study will naturally be the Latin. Yet let none waste their time in attempting to acquire a knowledge of Latin, but such as are designed for some of the learned professions, or for the life of a gentleman without a profession. To these last it may be useful; to others it is wholly unserviceable. But in learning the Latin tongue, a much happier method than burdening and perplexing him with rules of grammar, would be to make him speak it with a tutor who was sufficiently master of it for that purpose. Thus might he spend that time which is usually occupied in acquiring this language, in learning some other necessary branches of education. But if you cannot conveniently have the boy taught the language by the way of conversation, let the introductory books be accompanied with an English version, which he may have easy recourse to for the explanation of the Latin. Never perplex him with grammatical difficulties. Reflect that, at his age, it is impossible to enter into the spirit of those things. Render every thing as easy and pleasing as possible: for the attention will not fail to wander, even though you labour not to render the task disagreeable. Skill in grammar may be useful; but it is to those whose lives are to be dedicated to the study of the dead languages: that knowledge which the gentleman and the man of the world may have occasion to derive from the treasures contained in the ancient languages, may be acquired, without a painful study of prosody or syntax. As the learning of any language is merely learning words; if possible, let it be accompanied with the acquisition of some real knowledge of things; such as the nature of plants, animals, &c. their growth and propagation. But if you cannot or will not give your boy a private education, and are still resolved to send him to school, to be whipped through the usual course of Greek and Latin; at least act with so much good sense and humanity, as to insist that he be not burdened and tormented with the composition of Latin themes and verses. Neither let his memory be oppressed with whole pages and chapters from the classics. Such ridiculous exercises have no tendency, whatever prejudice may urge to the contrary, to improve him either in the knowledge of languages or of nature.

Mr Locke seems to wish that the French language, which in his days had attained to higher refinement and a more regular analogy than any of the other modern languages of Europe;—he seems to wish that the French were learned along with the Latin: and he wishes the study of these languages to be accompanied with the study of arithmetic, geography, history, and chronology. Let these branches of knowledge be communicated

communicated to the learner in one of the two languages; and he will thus acquire the language with greater facility. He next points out the advantages of the branches of knowledge which he recommends as proper to be learned together with the languages; but on that head he says nothing singular. One method which he recommends for facilitating the study of language is, to put into the youth's hands, as soon as he has acquired a tolerable knowledge of chronology, some of the most entertaining Latin historians: the interesting nature of the events which they relate will not fail to command his attention, in spite of the difficulty which he must find in making out their meaning. The Bible and Tully's Offices will be his best guides in the study of ethics. The law of nature and nations, as well as the civil and political institutions of his country, will form to him an important object, which he ought to study with the most careful attention. Rhetoric and logic, though generally regarded as objects of great importance in a liberal education, can neither of them contribute much, with all their rules and terms, to render him an acute reasoner or an eloquent speaker; and it is therefore unnecessary for him to honour them with very particular attention. Tully and Chillingworth will be more beneficial in teaching him to reason and to persuade, than all the treatises on rhetoric and logic which he can possibly peruse, or all the lectures on those arts which he can gain opportunities to hear. In every art and every science, practice and experience are infinitely better than rules. Natural philosophy, as contributing to inspire the breast with warmer sentiments of devotion, and serving also to many useful purposes in life, ought to make a part in the young gentleman's studies. But the humble experimental writers on that subject are to be put into his hands in preference to the lofty builders of systems. As for Greek, our pupil is not to be a professed scholar, but a gentleman and a man of the world: and therefore it does not appear necessary that Greek should make a part in the system of his education. But in none of these studies will the pupil ever attain any proficiency, unless he be accustomed to method and regularity in the prosecution of them. In languages, let him gradually ascend from what is simplest to what is most difficult: in history, let him follow the order of time; in philosophy, that of nature.

Dancing, as contributing to ease and gracefulness of carriage, ought to make part in our young gentleman's education. Fencing and riding being fashionable, cannot well be denied him. As he is likely, in the course of life, to have some leisure hours on his hands, and to be sometimes disposed to active recreation, let him learn some mechanical trade, with the exercise of which he may agreeably fill up some of those hours. If he is to possess any property, let him not be unskilled in the management of accounts. Travel, instead of being useful, appears more likely to be hurtful to the understanding and morals of the traveller, unless deferred to a later period than that at which young men are usually sent out to complete their education by traversing through foreign countries.

Here Mr Locke concludes his work with observing, that he does not offer it to the world as a full or comprehensive treatise on the subject of education, but merely as the outlines of what occurred to him as most proper to be observed in breeding up a young gentleman not intended for any learned profession or mechanical employment, but for acting a respectable part in life at the head of a competent hereditary fortune.

23
Remarks.

In considering the sentiments of this respectable philosopher on the subject of education, we perceive, that as he was, on the one hand, superior to those prejudices which render us incapable of distinguishing the defects or absurdities of any custom or institution which has long prevailed; so, on the other hand, he was free from that silly vanity which disposes those who are subject to its influence to affect novelty and singularity of sentiment on every subject which they consider. Though a member of one of the universities, he hesitates not to declare himself against a very laborious attention to classical learning; and his reasoning is, through the whole of his treatise, rather plain and solid than subtle or refined.

Yet, however we respect the soundness of his understanding or the benevolence of his intentions, we cannot avoid observing, that his opinions are not always such as experience justifies. He had no doubt taken notice of some instances in which the too great anxiety of parents about the preservation of their children's health was the very means of rendering their constitution feeble and tender through the course of life; and from that circumstance might be led to propose those expedients which he mentions for preserving the health and strengthening the constitution of children. But a little more observation or inquiry would have easily convinced him, that some of his expedients, instead of strengthening the child's constitution, would in all probability shorten his days.

He had perhaps seen some of the heroes of classical literature, who were familiar with Demosthenes and Cicero, and had Homer and Virgil at their finger ends, —he had seen some of those gentlemen so overloaded with their cargo of Greek and Latin as to be unfit for the ordinary business and intercourse of life; and such instances might tempt him to forget the advantages which he himself, and a long series of philosophers, patriots, and statesmen, with whose names the annals of our country are adorned, had derived from a regular classical education. But as we are afterwards to deliver our own sentiments on the subject, we will not here extend our observations on Mr Locke to a greater length.

24
Rousseau.

An author more distinguished than Mr Locke for tenderness of sentiment, singularity, eloquence, and whim, has presented the public with a work on the subject of education, in which, with unexampled boldness, he inveighs against all the established modes, as well as reprobates whatever had been advanced by former writers on the subject; and at the same time delineates a plan of education which he would persuade us is infinitely superior to those which he explodes. This writer is the amiable and pathetic Rousseau: And though he be often vain, paradoxical, and whimsical; yet the charms of genius and sentiment which adorn his writings will at least engage our attention while he unfolds his opinions.

25
Imprudent management of children in infancy.

He sets out with observing, that our business in the bringing up of children should be, to second and to call forth nature, and that, instead of this, we almost always oppose her intentions and operations. As soon as the child sees the light, he is wrapped in swathing bands. His limbs are thus restrained from that free motion which is necessary to their growth and vigour; and even the internal parts of his frame are rendered incapable of their proper functions. Mothers are too proud or indolent, or too fond of gaiety and dissipation, to submit to the task of nursing their own children. The poor infants are committed to some hireling nurse, who not being attached to them by natural affection, treats them with negligence or inhumanity. But is that mother capable of any delicacy of sentiment, who can permit another to suckle her child, and to share with her, or perhaps wholly supplant her, in the filial affection of that child?

Again, When parents undertake the care of their infant children, they often injure them by mistaken tenderness. They pamper them with delicate meats, cover them with warm clothes, and anxiously keep them at a distance from all that has the appearance of danger: not attending to the economy of nature, who subjects us in infancy to a long train of epidemical distempers, and exposes us during the same period to innumerable dangers; the design of which doubtless is, to teach us a prudent concern for our own safety, and to strengthen and confirm our constitutions.

A child no sooner enters into life, than it begins to cry; and during a great part of infancy continues frequently to shed tears. We either attempt to soothe it into good nature, or seek to silence it by harsher means; and it is thus we infuse into its infant mind those evil passions which we afterwards presume to impute to nature.

As the mother generally disdains to nurse her own child, so the father is seldom at leisure to take any share in the management of his education: he is put into the hands of a tutor. But that tutor whose time and attention can be purchased for money is unworthy of the charge. Either be yourself your son's preceptor, or gain a friend whose friendship to you shall be his sole motive to undertake the task.

26 Management of Emilius during infancy.

After a few preliminary observations to the above purport, our author introduces his Emilius; in whose education he delineates that plan which he prefers. The preceptor whom he would assign Emilius must be young; and must dedicate his attention to Emilius alone, from the time when his pupil enters the world till he attain the full age of manhood. Emilius, to receive the full benefit of his preceptor's system of education, and to afford full scope to it, must possess a genius of the middle class; no prodigy of parts, nor singularly dull; he must have been born to affluent circumstances and an elevated rank in life. His preceptor is invested with the rights, and takes upon him the obligations, of both father and mother. Emilius is, when put into the hands of his preceptor, a well-shaped, vigorous, and healthy child. The first care of the preceptor is to provide him with a nurse, who, as he is new born, must be newly delivered? it is of still higher importance that she be clean, healthy, virtuous, and of mild dispositions. While suckling her charge, she shall feed plentifully, chiefly on a vegetable diet. The child must be frequently bathed, in cold water if possible; if you begin with warm, however, use it by degrees colder and colder, till at length he is able to bear it entirely cold. He is not to be wrapped in swaddling clothes or rollers, or bound with staybands; but put in good warm blankets, and in a roomy cradle: Let him stretch and move his limbs at freedom, and crawl about on hands and knees at his pleasure. The greatest care must now be taken to prevent the child from contracting any habits whatever: Suffer him not to use one arm more than another, or to eat or sleep at stated hours. Prepare him for the enjoyment of liberty, by preserving to him the exercise of his natural abilities, unfettered by any artificial habits.

As soon as the child begins to distinguish objects, let his education begin. Some objects are naturally agreeable, others frightful. Accustom him to look upon any object that may come in his way without being affrighted. Children are at first ignorant of local relations, and learn to distinguish them only by experience; and while Emilius is yet an infant, incapable of speaking or walking, he may be assisted in acquiring the knowledge of these.

In his feeble helpless condition, the child must feel many wants and much uneasiness; tears are the language which nature has given him to make known his distresses and wants. When the child cries, it would be much more prudent and humane to examine what he suffers or stands in need of, than, as is usually done, to rock or sing him asleep; or, when these means succeed not, to threaten or use him brutally.

In managing children, as nature has endowed them with no superfluous powers, we ought not to confine them from the free use of those which they are able to exert. It is our duty to supply their deficiency both of mental and bodily powers; but while we are ready to administer on every occasion to their real wants, we must beware of gratifying their caprice or unreasonable humours. In order to distinguish between their natural and fantastic wants, we must study the language and signs by which they express their wishes and emotions. Though crying be the means which nature has given infants to enable them to procure relief or assistance, yet when they cry they are not always in need of either. They often cry from obstinacy or habits of peevishness. But if, instead of attempting to soothe them by diverting their attention to other objects, we would on such occasions entirely neglect them, they would soon cease to indulge in such fits of crying.

When children begin to speak, we are usually anxious about their language and articulation, and are every moment correcting their blunders. But instead of hoping to teach them purity or correctness of speech by such means as these, let us be careful to speak easily and correctly before them, and allow them to express themselves in the best manner they can. By such means we will be much more likely to obtain our wishes in this matter. When they speak, let us not listen with such solicitude as to relieve them from the necessity of using an open distinct articulation.

When the child attains the power of expressing himself in artificial language, he may then be considered as having reached the second period of infancy. He needs not now make known his wants by tears, and should therefore be discouraged from the use of them. Let his tears be entirely neglected. He now begins to run about, and you are anxious to prevent him from hurting himself; but your anxiety can only render him peevish

peevish or timid. Remove him from any very alarming danger, and then suffer him to run about at his pleasure. He will now and then bleed, and hurt himself; but he will become bold, lively, and cheerful.

In regulating the conduct of your child, let him know that he is dependant; but require not of him an implicit submission to your will. Let his unreasonable desires be opposed only by his natural inability to gratify them, or by the inconveniences attending the gratification. When he asks what is necessary or reasonable, let him instantly obtain it; when he asks what is unreasonable or improper, lend a deaf ear to all his entreaties and demands. Beware of teaching him to establish his authority over you by means of the forms of politeness. A child will scarcely take the trouble to address you with *If you please*, unless he has been made to regard these as a set of magic syllables, by the use of which he may subject every person to his will. His *If you please* then means *I please; pray*, with him, stands for *do*. Though you put in his mouth the words of humility, his tone and air are those of authority that *will* be obeyed.

Sacrifice not the present happiness of your child for the sake of any distant advantage.

Be not too anxious to guard him against natural evil. The liberty which he enjoys while he is now and then permitted to expose himself to blows, or cold, or wetness, is more than a sufficient compensation for all that he thus suffers.

Seek not to impress him with ideas of *duty* or *obligation*. Till children reach the years of discretion, they are incapable of any notions of the distinctions of morality. Avoid therefore even the use of the terms by which they are expressed in their hearing. While they continue to be affected only by sensible objects, seek not to extend their ideas beyond the sphere of sensation. Try all the powers of language, use the plainest and most familiar methods you can contrive; you shall still be unable to give the boy at this age any just ideas of the distinction between right and wrong. He may readily conceive, that for one set of actions you will punish him, and that by another he will obtain your approbation; but farther than this his ideas of *right* and *wrong*, of *virtue* and *vice*, cannot yet be carried.

The powers of the human mind are gradually unfolded. At first, the infant is capable only of perception; by and by, his instincts and passions begin to exert their force; at length, as he advances towards manhood, reason begins to act, and he becomes able to feel the beauty of virtue and the deformity of vice.

But though you seek not to regulate his conduct by notions of *duty*, yet let him feel the yoke of necessity. Let him know, that as he is weaker than you, he must not, therefore, expect that you should be subject to his will; and that, as he has neither skill nor strength to controul the laws of nature, and make every object around him bend to his pleasure, he cannot hope to obtain the gratification of all his wishes. Thus you teach him virtue before he knows what virtue is; and call forth his reason without misleading or perverting it. Let him feel his impotence; but forbid him not to think, that if he had power there would be no reason why he might not at pleasure even turn the world upside down.

Hitherto you have given your pupil no verbal instructions, nor must you yet attempt to instruct him by any other means than experience; let all his knowledge be literally of his own acquisition.

Let not the parent who has observed the conduct of children brought up in the usual way be afraid that, if his child should be treated like our pupil, he would become stupid and vicious. Nature sends not human beings into the world with a predisposition to vice: we sow the seeds of it in the infant heart; and by our absurd modes of treatment, we also enfeeble and pervert the powers of the understanding.

But from the hour of his birth till he attain the age of twelve, the education of Emilius shall be purely negative. Could we but bring him up healthy and robust, and entirely ignorant, till that period, the eyes of his understanding would then be open to every lesson: free from the influence of habit and prejudice, his passions would not then oppose us; and we might render him the wisest and most virtuous of men. If we can but lose time, if we can but advance without receiving any impressions whatever, our gains are unspeakable. Nature gives the powers of every mind some particular direction: but that particular bias, impressed by the hand of nature, cannot be distinguished before the period we have mentioned; and if you counteract nature, instead of seconding her views, the consequences cannot but be highly unfavourable both to the heart and the understanding of your pupil.

Perhaps, in the midst of society, it may be difficult to bring up our pupil without giving him some idea of the relations between man and man, and of the morality of human actions. Let that, however, be deferred as long as possible.

Were Emilius to witness a scene of anger, and to ask the cause of the appearances which he beheld, he should be told that the persons were affected with a fit of sudden illness. We might thus perhaps prevent the unhappy effects of such an example.

The first moral notions which should be communicated to the child are those of property. To communicate the ideas of property to our pupil, we will direct him to take possession of something; for instance, of a piece of ground belonging to some other person, and in a state of cultivation. Let him cultivate this spot of ground anew, sow it with seeds, and look eagerly forward to the time of harvest in the hopes of reaping the fruit of his labours. In the mean time, let the proprietor of the ground take notice of what is done, destroy your pupil's rising crop, and complain of the injustice done him. While the boy laments his loss and the disappointment of his hopes, in all the bitterness of grief, let the proprietor of the ground still insist on the injury done him, and complain of what he suffers by the purpose for which he himself had cultivated and sown the ground being frustrated. Our pupil, now sensible of the reasonableness of the other's claims, will desist from his lamentations, and only beg to have some other spot assigned him which he may cultivate at his pleasure without offending any person. This he will justly consider as his own property, to the productions of which raised by his own labour he has an exclusive right, and in the occupying of which none ought to molest him. In some such manner as this may the nature of property, the idea of which easily refers in the instance to the first occupier, and afterwards the exchange of property, be explained to him.

Another instance of the manner in which the pupil is now to be managed may not be improper in this place. He is possibly so rude and boisterous as to spoil or break whatever is within his reach. Be not angry with him, however: if he break the utensils which he has constant need of, be in no haste to supply him with others in their room; let other things be removed out of his way: if he break the windows of his apartment, let him be exposed night and day to the cold; complain not of the inconvenience yourself, but order matters so that he may feel it. After some time, let them be mended up; and if he break them again, change your method. Tell him calmly, "These windows are mine; I took care to have them put there; and I will prevent their being again broken, by confining you in a dark room." Let all his endeavours to avoid this prove ineffectual. Let him be actually confined, and be liberated only on proposing and agreeing to the condition of breaking no more windows. When he proposes this condition, be ready to listen to him; observe that it is well thought on, and that it is a pity he did not think of it sooner. Consider this engagement between you as sacred; treat him as before, and you cannot fail to attain the end in view.

The moral world now opens to us: But no sooner are we able to distinguish between right and wrong, than we become desirous to conceal those instances in which we act wrong. Lying is therefore a vice of which your pupil is now apt to be guilty: you cannot always prevent, but you can punish; but let the punishments which you inflict appear to the child only the natural consequences of his conduct. If he is in any instance convicted of a lie, let his assertions no longer gain credit. By this means, sooner than by precepts, or any other species of punishment, will you be able to reclaim him from the habit of lying.

The methods generally taken to render children virtuous are preposterous and foolish. To render them generous and charitable, we give them money, and bid them bestow it in alms, while we ourselves give nothing; but the parent or master, and not the child, should bestow the alms. Example might produce the wished-for effect. Besides, children are strangers to the value of money. A gingerbread cake is more to them than a hundred guineas. Though you teach them to give away money, till you persuade them to part readily with those things which they value most, you do not inspire them with generosity. Would you make them liberal by showing them that the most liberal is always best provided for? this is to teach covetousness, not liberality. Example is the only means by which you can, at this period, hope to teach your pupil any of the virtues.

The only lesson of morality that can with any propriety be inculcated on children, is to injure no person. Even the positive precept of doing good, must be considered as subordinate to this negative one of doing no harm. The most virtuous and the most exalted of characters, is the man who does the least harm to his fellow creatures.

In a public education, it will be necessary to attempt the communication of moral instruction at an earlier period than in a private one. In a private education, it will always be best to allow the moral powers of children to ripen as much as possible before you endeavour to inform and direct them by precepts.

There is an inequality among geniuses; and fond mothers and fathers may be disposed to plead for exceptions in favour of such of their children as they view with a partial eye. "The boy's mind is more capacious, his powers are riper, than those of others." But however great the seeming disparity of geniuses may be, it is at bottom but inconsiderable. Let the age of children be therefore regarded as a common measure by which their treatment is to be regulated.

However quick and tenacious the memories of children may seem, they can derive little advantage from the exertions of memory till such time as judgment begins to act. All the knowledge that they acquire in the course of the usual system of education, is merely the knowledge of words. The languages, geography, chronology, in short all that they are taught, and called to display so ostentatiously at this period of life, serve no other purpose than to fill their minds with words.

29
History, how far proper to be put in the hands of boys.

History is esteemed a proper thing to be put into the hands of children. But except you wish to confine their attention to the external and physical actions, it is almost nothing they can acquire by the perusal of it. And if divested of the moral distinctions of actions, of the workings of the passions, and the complication of interests, what is there to render history entertaining? We may indeed easily teach them to repeat the words *kings*, *emperors*, *wars*, *conquests*, *revolutions*, *laws*: but of the things which you use these words to denote, you will find they are hitherto incapable of forming any clear ideas.

But the mere knowledge of words is not science; make your pupil acquainted with things, and he will not fail to acquire their names. Emilius must never be set to get any composition by heart, not even fables: be careful to place before him those scenes and objects, the images of which it may be useful for him to have impressed on his memory; but by no other means seek to assist him to improve that faculty.

Emilius shall not even learn to read till he attain the age of twelve: for, before that period, it can be of no benefit to him; and the labour would only make him unhappy during that period of life which is naturally the golden part of our days. But when he has attained the proper age, matters shall be so ordered, that he shall find his ignorance of letters an inconvenience. A card shall be sent him, which being unable to read, he will apply to some of those about him. They may be unwilling to oblige him, or otherwise engaged. If, at length, it is read to him, that may be when it is now too late to take advantage of some agreeable invitation which it contained. This may be two or three times repeated. At length he becomes eager to learn to read; and accomplishes that almost without assistance.

The principle on which we proceed, is to leave the pupil almost wholly under his own direction, seemingly at at least; to lead him to acquire new accomplishments, solely from the desire of increasing his powers, and extending his influence; and humbly to follow nature, not to force her.

As we are desirous of cultivating his understanding, the means which we employ for that purpose is, to cultivate those abilities on which it depends; he is always active and in motion. Let us first make him a man in point of health and vigour, and he will soon become a man in understanding.

By our constant attention to the welfare of children, we render it unnecessary for them to attend to it themselves. What occasion has your son or pupil to observe whether the aspect of the sky threaten rain, when he knows that you will take care to have him sheltered from a shower; or to regulate the length of his excursions, when he is sure that you will not suffer him to lose his dinner?

While matters are so ordered that Emilius thinks himself subject only to his own will, though all his motions are regulated according to your pleasure; instead of becoming fantastic and capricious, he insenibly acquires the habit of keeping utility in view in all his actions.

The first objects which engage the attention of children are the appearances of the material world around them: our first study is a kind of experimental philosophy; our instruments and instructors are our hands, our feet, and our eyes. By exercising these bodily organs, the boy will acquire more real knowledge even in the period of childhood, than if he should dedicate nine-tenths of his time to books, from the age of six to sixty. All who have examined, with any sagacity, the characters, circumstances, and manners of the ancients, have agreed in attributing to their gymnastic exercises that superior strength of body and mind which renders them objects of admiration to the moderns.

Our pupil's clothes cannot be too light and easy. If tight and close, they fetter and confine his joints and limbs, and likewise obstruct the circulation of the blood; if accustomed to warm clothing, he will soon become incapable of bearing cold.

In every thing let him be habituated to what is plain and hardy. Let his bed be coarse and hard, his clothes plain, his fare simple. Infants must be freely indulged in sleep: but as Emilius is now advanced beyond infancy, he must be accustomed at times to go to bed late and get up early, to be sometimes hastily waked from sleep; and thus to prepare himself for what he may afterwards have occasion to submit to in the course of life.

As this period is in a particular manner that of exercise, and Emilius is encouraged to take as much exercise as he chooses; we must endeavour to prompt, but without seeming to direct him to such as are most proper. Swimming, though not generally attended to, is yet one of the first which a boy ought to learn. It may, on many occasions in life, be of the greatest advantage, by enabling us to save our own life or the life of others. Emilius shall be taught to swim; he shall be taught whatever can really enlarge the sphere of his power: "could I teach him to fly in the air, I would make him an eagle; if to bear the fire, a salamander."

To exercise the senses is not merely to make use of them; it is to learn to judge by them. Call not your pupil to exert his strength on every occasion; but let him learn to judge of the truth of the information which he receives from one sense, by having recourse to the evidence of another.

It is not impossible to improve the senses to a higher degree of perfection than that which they usually attain. Blind men generally possess the sense of touch in a more exquisite degree, than we who have also eyes to guide and inform us. But they acquire this superior delicacy and acuteness of sensation, only by their finding it necessary to have more frequent recourse to the information of that sense. Here is then a wide field for improvement and agreeable exercise to our pupil.

31
Darkness and ghosts.

What a variety of useful diversions might he be led to entertain himself with in the course of the night. The hours of darkness are generally hours of terror, not only to men, but also to the brute animals. Even reason, knowledge, and courage, are not always sufficient to render us superior to the terror which darkness inspires.

This timidity is usually attributed to the tales of ghosts and goblins with which we are frightened in infancy. But it originates from another cause: our ignorance of what is passing around us, and our inability to distinguish objects during that period of darkness. The passion of fear was implanted by nature in the human breast, in order that it might serve to put us on our guard against danger. But in consequence of our being subject to the influence of that passion, when we are ignorant of what surrounds us, imagination calls up dangers on all hands. And such is the cause from which our terror in darkness naturally arises.

But the only way to free our pupil from this tyranny of imagination, is to oppose to it the power of habit. A bricklayer or tyler is never giddy on looking down from the roofs of houses. Neither will our pupil be alarmed by the terrors of darkness, if he be accustomed to go frequently abroad under night. It is easy to contrive a number of little amusements, the agreeableness of which may, for a time, overcome our pupil's aversion for darkness; and thus may a habit be at length impressed.

Let us give yet another instance of the means by which children may be led to do what we wish, without our imposing any restraint on their will. Suppose Emilius is lazy and inactive, and we wish to make him learn to run. When walking out with the young sluggard after dinner, I would sometimes put a couple of his favourite cakes in my pocket; of these each of us should eat one in the course of our walk. After some time I would show him I had put a third cake in my pocket. This he would not fail to ask after finishing his own: no say I, I can eat it myself, or we will divide it;—or stay, we had better let these two little boys there run a race for it. Accordingly I propose the race to the boys; who readily accept the conditions, and one of them carries off the prize. After seeing this several times repeated, Emilius begins to think himself qualified to obtain the third cake as well as any of the little boys, and to look upon running as an accomplishment of some consequence. He seeks an opportunity of being permitted to enter the lists. He runs; and after being two or three times outstripped, is at length successful, and in a short time attains an undoubted superiority.

32 Drawing. As children naturally imitate almost whatever they behold, they are often disposed to attempt drawing. In this our pupil might be obliged, not merely for the sake of the art, but to give him a steady hand and a good eye. But he should draw from nature, not from other drawings or from prints. Were he to draw the likeness of a horse, he should look at the animal: if to attempt a representation of a house, he should view the house itself. In this method he will, no doubt, scratch for a long time without producing any likeness: but he will acquire what we proposed as the ends of his attempting to draw; namely, steadiness of hand and justness of sight, by this method, sooner than by any other.

33 Geometry. Geometry, when taught in the usual way, is certainly above the capacity of children; they cannot go along with us in our reasonings: yet they are not totally incapable of acquiring even this difficult science; if, when they are prosecuting their amusements, you lead them insensibly to observe the properties of the circle, the triangle, and the square, and place them now and then in circumstances when they may have occasion to apply their knowledge of these to real uses in life.

A child has been taught the various relations between the outlines, surfaces, and contents of bodies, by having cakes set before him, cut into all manner of regular solids; by which means he was led to master the whole science of Archimedes, by studying which form contained the greatest quantity.

There is a period between infancy and the age of puberty, at which the growth and improvement of our faculties exceed the increase of our desires. About 12 or 13, when the appetite for the sex has not yet begun to make itself felt, when unnatural wants are yet unknown, no false appetites yet acquired; at that period, though weak as a man, as a child the youth is strong.

This interval, when the individual is able to effect more than is necessary for the gratification of his wishes, contains the most precious moments of his life, which ought to be anxiously filled up in an useful manner. This is the best time for employment, for instruction, for study.

Now, let us begin to consider what is useful; for, hitherto, we have only inquired what was necessary. In entering on our studies, we will make no account of any but such as instinct directs us to pursue: those which the pedant and the pretended philosopher are impelled to pursue solely from the desire of attracting the admiration of mankind, are unworthy of our notice.

The earth which we inhabit, and the sun by whose beams we are enlightened, are the first objects which claim our attention. We will therefore direct the attention of our pupil to the phenomena of nature. We will lead him to the knowledge of geography, not by maps, spheres, and globes: we will lead Emilius out on some beautiful evening to behold the setting sun. Here we take particular notice of such objects as mark the place of his going down. Next morning we visit the spot to contemplate the rising of the glorious luminary. After contemplating for some time the successive appearances which the scene before us assumes, and making Emilius observe the hills and the other surrounding objects, I stand silent a few moments, affecting to be occupied in deep meditation: At last I address him thus: "I am thinking, that when the sun set last night, it went down yonder; whereas this morning you see he is risen on the opposite side of the plain here before us. What can be the meaning of this?" I say nothing more at this time, but rather endeavour to direct his attention to other objects.

This is our first lesson on cosmography.

Our last observation was made about Midsummer; we will next view the rising sun on some fine morning in the middle of winter. This second observation shall be made on the very same spot which we chose for the former. When Emilius and I perceive the sun now emerging above the horizon, we are struck at the change of the place of his rising. By such lessons as these may the pupil be gradually taught a real, not a seeming, acquaintance with the relative motions of the sun and the planets and with geography.

During the first period of childhood, the great object of our system of education was to spend our time as idly as possible, in order that we might avoid employing it to an ill purpose: but our views are now changed with our pupil's progress in life; and we have scarce enough of time for the accomplishment of our necessary pursuits. We therefore proceed as quickly as possible in making ourselves acquainted with the nature of the bodies around us, and the laws by which their motions and appearances are regulated. We keep to this study at present, as being necessary for the most important purposes in life, and as being the most suitable to the present state of our pupil's powers. We still begin with the most common and obvious phenomena of nature, regarding them as mere facts; and, advancing from these, we come to generalize by degrees. 34 Objects ring the cond per of childhood.

As soon as we are so far advanced as to be able to give our pupil an idea of what is meant by the word *useful*, we have attained a considerable influence over his future conduct. On every occasion after this, a frequent question between us will be, Of what use is this? This shall be the instrument by means of which I shall now be able to render him absolutely submissive to my wishes. However, I will allow him to make use of it in his turn, and will be careful not to require of him to do or learn any thing the utility of which he cannot comprehend.

Books only teach people to talk about what they do not understand. Emilius shall have as little recourse as possible to books for instruction. Yet if we can find a book in which all the natural wants of man are displayed in a manner suitable to the understanding of a child, and in which the means of satisfying those wants are gradually displayed with the same ease and simplicity; such a book will be worthy of his most attentive study. There is such a book to be found; but it is neither Aristotle, nor Pliny, nor Buffon; it is Robinson Crusoe. Emilius shall have the adventures of Robinson put into his hands: he 35 Robins Cruso shall imitate his example; even affect his dress; and, like Robinson, learn to provide for himself without the aid of others.

Another employment of Emilius at this period shall be, to visit the shops of various artisans; and when he enters a shop, he shall never come out without lending a hand to the work, and understanding the nature and the reason of what he sees going forward.

Still, however, we are careful to afford not a hint concerning those social relations, the nature of which he is not able to comprehend.

The value and importance of the various arts are ordinarily estimated, not according to their real utility, but by a very injudicious mode of estimation: Those which contribute in a particular manner to the gratification of the fantastic wishes of the rich, are preferred to those which supply the indispensable necessaries of life. But Emilius shall be taught to view them in a different light. Robinson Crusoe shall teach him to value the stock of a petty ironmonger above that of the most magnificent toy-shop in Europe. Let us establish it as a maxim, that we are to lead our pupil to form just notions of things for himself, not to dictate to him ours. He will estimate the works both of nature and art by their relation to his own convenience; and will therefore regard them as more precious than gold—a shoemaker or a mason, as a man of more importance than the most celebrated jeweller in Europe.

The intercourse of the arts consists in the reciprocal exchange of industry; that of commerce, in the exchange of commodities; and that of money, in the exchange of bills and cash. To make our pupil comprehend the nature of these, we have now only to generalize and extend to a variety of examples those ideas of the nature of property, and of the exchange of property, which we formerly communicated to him. The nature of money, as bearing only a conventional value, which it derives from the agreement of men to use it as a sign for facilitating commerce, may be now explained to Emilius, and will be easily comprehended by him. But go no farther: seek not yet to explain to the child, in what manner money has given rise to the numerous chimeras of prejudice and caprice; nor how countries which abound most in gold and silver, come to be the most destitute of real wealth.

Still our views are directed to bring up our pupil in such a manner that he may be qualified to occupy any place in the order of society into which even the caprice of fortune can throw him. Let us make him a man; not a slave, a lord, or a monarch. How much superior the character of a king of Syracuse turned schoolmaster at Corinth, of a king of Macedon become a notary at Rome, to an unhappy Tarquin incapable of supporting himself in a state of independence when expelled from his kingdom!

Whatever be our situation in the world, we can contribute nothing but our personal abilities to society. To exert them is therefore the indispensable duty of every one who enjoys the advantages of a social state; and to cultivate them in our pupil to the best purpose, ought to be the great aim of every course of education. Emilius has already made himself familiar with all the labour of industry; I can therefore bid him cultivate the land which he inherits from his father. But if it should be lost, what shall be his resource? He shall learn a trade, that he may be provided against such an accident. And he shall not be a politician, a painter, a musician, or an architect; to gain employment for his talents in any of these three arts, would cost him no less trouble than to regain his lost estate. He shall learn some simple mechanical art: he will then need only to step into the first shop he sees open, to perform his day's labour, and receive his wages.

It may be here proper to take notice of a mistake into which people generally fall in determining the trade or profession in which they are to place their children. Some accident disposes the child to declare himself for a particular employment: the parent regards that as the employment to which his talents are fitted by the design of nature; and permits him to embrace it without inquiring whether another would have been more suitable or advantageous. But because I am pleased with my occupation, I am not on that account necessarily qualified for it. Inclinations do not confer abilities. It requires more careful and accurate observation than is generally imagined, to distinguish the particular taste and genius with which nature has endowed the mind of a child. We view him carelessly, and of consequence we are apt to mistake casual inclination for original disposition.

But Emilius needs not now to hesitate about the occupation which he is to choose. It is to be some mechanical employment. All the distinction we have now to make is, to prefer one that is cleanly and not likely to be injurious to his health. We shall make choice of that of a joiner. We cannot dedicate all our time to the trade; but at least for two days in the week we will employ ourselves in learning our trade. We will have no workshop erected for our convenience, nor will we have a joiner to wait on us in order to give us the necessary instructions: but for the two days in every week which we dedicate to the purpose of learning a trade, we will go to our master's workshop; we will rise before him in the morning; work according to his orders; eat at his table; and, after doing ourselves the honour of supping with his family, return to our own hard mattresses at night. We shall be treated only according to the merit of our performances. Our master shall find fault with our work when clumsily or negligently done, and be pleased with it only when well executed.

37
New ideas suggested to Emilius by his application to a trade.

While my pupil has been accustomed to bodily exercise and manual labour, his education has been hitherto conducted in such a manner as to give him insensibly a taste for reflection and meditation. Before he has been long a workman, therefore, he will begin to become more sensible of that equality of ranks which takes place in the order of society. He will therefore take notice of his own dependence, and of my apparent wealth, and will be desirous to know why I contribute not my personal exertions to society. I put off the question with telling him, that I bestow my superfluous wealth on him and the poor; and will take to make a bench or table every week, that I may not be quite useless to the public.

And now, when about to enter the most critical period of life, when just on the brink of that age at which the heart and blood begin to feel the impulse of

38 Progress that Emilius has made before the age of puberty.

a new appetite, what progress has our pupil made? what knowledge has he acquired? All his science is merely physical. Hitherto he has scarce acquired any ideas of moral relations; but the essential relations between men and things he has attentively studied. He knows the general qualities of certain bodies; but upon those qualities he has not attempted to reason. He has an idea of abstract space by means of geometrical figures; of abstract quantity, by means of algebraical signs. He has no desire to find out the essence of things; their relations alone interest him. He values nothing external but from its relation to himself. The general consent of mankind, or the caprice of custom, have not yet given any thing a value in his eyes; utility alone is his measure of estimation. He is laborious, temperate, patient, resolute, and bold. His imagination never exaggerates danger. He scarce knows as yet what death is; but should it approach him, he is prepared to submit to necessity. He is virtuous in every thing relative merely to himself. He is prepared to become a virtuous member of society as soon as he shall be made acquainted with the nature of his social relations. He is free from vice and error as far as is possible for human nature. He considers himself as unconnected with others; requires nothing from any person, and thinks none has a right to require any thing of him. Sure a youth arrived thus at his fifteenth year has not mispent the period of his infancy.

39 New measures to be adopted in his education at that age.

But now our pupil has reached the most critical period of life. He now feels the influence of the passion for the sex; and as soon as we become subject to the influence of that passion, we are no longer unsocial beings. The want of a mistress soon produces the want of a friend.

As hitherto we have been careful not to force or anticipate nature, so even now our attention must be directed to divert the impulses of that dangerous appetite which now begins to make itself felt. To confine the growing passions within proper limits, let it be our care to defer as long as possible the time at which they begin to display themselves. For this purpose, let us cautiously guard our words and actions in the presence of our pupil. Let us be careful to give him no premature instructions.

To excite and cherish that sensibility of mind which now first begins to show itself, to extend the care of the youth beyond himself, and to interest him in the welfare of his fellow creatures, let us be careful to put such objects in his way as have a tendency to call forth and refine the feelings. It is not possible for the human heart to sympathize with those who are happier than ourselves: our sympathy is moved only by the sight of misery. We pity in others only those distresses to which we ourselves are liable: and our pity for the misfortunes of others is measured, not by the quantity of the evil, but by the supposed sensibility of the sufferer. Let these observations serve to direct us in what manner we are to form the minds of children to humanity and compassion.

In prosecution of our design, to retard rather than accelerate the growth of the passions, let us, when that critical period which we have so much feared comes on, seclude him as much as possible from the intercourse of society, where so many objects appear to inflame the appetites. Let us be circumspect in the choice of his companions, his employment, his pleasures. Let all our care be directed to nourish his sensibility without inflaming his desires. As his moral powers now begin to unfold themselves, in cultivating them let us proceed not by way of lecture, or by directing his attention to books, but still by leading him to acquire experience. At length the period will arrive for communicating to him some religious instruction. When he knows the nature of his relations to society, he may be informed of his relation to, and dependence upon, a Deity.

[The creed of the Savoyard curate, containing those sentiments concerning religious matters which Rousseau seems to propose as the most proper to be inculcated on his pupil, comes next in the order of the work; but it does not appear to be so closely connected with the subject of education as to render it proper for us to give a view of it in this place. The sentiments which he there advances, the reasonings which he urges, are evidently hostile to revealed religion; and the power of his eloquence has adorned slight and superficial arguments with such a charm, that even the sternest believer, if not absolutely destitute of taste and feeling, must read them with delight.]

And now, notwithstanding all my arts, I can no longer keep back that moment which I have endeavoured to defer to as late a period as possible. As soon as I perceive that it has entirely arrived, I no longer treat Emilius as my pupil or disciple, but as my friend. His affections are now expanded beyond himself; his moral powers have begun to exert themselves, and have received some cultivation; he also is become capable of religious sentiments, and instructed in the nature of his relation to a supreme Being. Besides, it is now requisite, if we consider the period to which nature has conducted him, that he should no longer be treated as a simple child. Hitherto ignorance has been his guardian, but now he must be restrained by his own good sense.

Now is the time for me to give him in my accounts; to show him in what manner his time and mine have been employed; to acquaint him with his station and mine, with our obligations to each other, his moral relations, the engagements he has entered into with regard to others, the degree of improvement which he has attained, the difficulties he will hereafter meet with, and the means by which he may surmount them; —in a word, to point out to him his critical situation, and the new perils which surround him; and to lay before him all the solid reasons which should engage him to watch with the utmost attention over his conduct, and to be cautious of indulging his youthful desires.

40 Means ployed preserv the pur of his ners.

Books, solitude, idleness, a sedentary and effeminate life, the company of women and young people, are what we must carefully avoid at this age. He has learned a trade, he is not unskilled in agriculture; these may be means, but not our only means, for preserving him from the impulse of sensual desire. He is now too familiar with these; he can exercise them without taking the trouble to reflect; and while his hands are busy, his head may be engaged about something quite different from that in which he is employed. He must have some new exercise which may at once fix his attention and cause him to exert his bodily powers.

powers. We can find none more suitable for this purpose than hunting. Now, therefore, Emilius shall eagerly join in the chase; and though I do not wish him to acquire that cruelty of disposition and ferocity of temper which usually distinguish those who dedicate their lives to that barbarous diversion, yet at present it may have the happiest effects in suspending the influence of the most dangerous of passions.

When I have now conducted my pupil so far; have informed him of what I have done for him, and of the difficulty of his situation; and have resigned my authority into his hands; he is so sensible of the dangers to which he is exposed, and of the tender solicitude with which I have watched over him, that he still wishes to continue under my direction. With some feigned difficulty I again resume the reins. My authority is now established. I may command obedience; but I endeavour to guard against the necessity of using it in this manner.

To preserve him from indulging in licentious pleasures, I let him know that nature has designed us for living in a state of marriage, and invite him to go in search of a female companion. I will describe to him the woman whom he is to consider as worthy of his attachment in the most flattering colours. I will array her in such charms, that his heart shall be hers before he has once seen her. I will even name her: her name shall be Sophia. His attachment to this imaginary fair one will preserve him from all the allurements of unlawful love. Besides, I take care to inspire him with such reverence for himself, that notwithstanding all the fury of his desires, he will not condescend to pursue the enjoyments of debauchery. And though I may now sometimes intrust him to his own care, and not seek to confine him always under my eye; yet still I will be cautious to watch over his conduct with careful circumspection.

But as Emilius is to be shortly introduced to his Sophia, it may perhaps be proper for us to inquire into her character, and in what manner she has been brought up.

Dist tive ha ters f th two exe

There is a natural difference between the two sexes. The difference in the structure of their bodies shows them to be destined by nature for different purposes in life, and must necessarily occasion a distinction between their characters. It is vain to ask which of them merits the pre-eminence: each of them is peculiarly fitted to answer the views of nature. Woman is naturally weak and timid, man strong and courageous; the one is a dependant, the other a protector. As the guardian of her virtue, and a restraint on her desires, woman is armed with native modesty. Reason is the guide and governor of man. When a man or a woman are united by conjugal vows, a violation of those vows is evidently more criminal in the woman than in the man. The wife ought to be answerable for the genuineness of the offspring with which she has been intrusted by nature. It is no doubt barbarous and wicked for the husband to defraud his wife of the only reward which she can receive for the severe duties of her sex: but the guilt of the faithless wife is still more atrocious; and the consequences of her infidelity are still more unhappy.

But if nature has established an original distinction between the characters of the two sexes; has formed them for different purposes, and assigned them different duties; it must follow, that the education of the one sex ought to be conducted in a manner different from that of the other. The abilities common to the two sexes are not equally divided between them; but if that share which nature has distributed to woman be scantier than what she has bestowed on man, yet the deficiency is more than compensated by the qualities peculiar to the female. When the woman confines herself to assert her proper rights, she has always the advantage over man; when she would usurp those of the other sex, the advantage is then invariably against her.

But we require not that woman should be brought up in ignorance. Let us consider the delicacy of her sex, and the duties which she is destined to perform; and to these we may accommodate the education which we bestow upon her. While boys like whatever is attended with motion and noise, girls are fond of such decorations as please the eye. Dolls are the favourite plaything of the sex in their infant years. This is an original taste, of the existence of which we have the plainest evidence. All therefore that we ought to do is, to trace and bring it under proper regulation. Allow the girl to decorate her baby in whatever manner she pleases; while employed about that, she will acquire such skill and dexterity in those arts which are peculiar to her sex, that with scarce any difficulty she will acquire needle-work, embroidery and the art of working lace. Her improvements may even be extended as far as designing, an art somewhat connected with taste in dress; but there is no reason that their skill in this art should be carried farther than to the drawing of foliage, fruits, flowers, drapery, and such parts of the art as bear some relation to dress. Always assign reasons for the employment which you give to young girls, but be sure you keep them constantly busy. They ought to be accustomed to laborious industry, as well as to bear the abridgement of their liberty. Use every art to prevent their work from becoming disagreeable to them. For that purpose, let the mother be careful to make herself agreeable. A girl who loves her mother or her aunt, will work cheerfully by them all day; while she to whom her mother is not dearer than all the world besides, seldom turns out well. Never suffer girls, even at their diversions, to be entirely free from restraint, nor allow them to run from one amusement to another. If you now and then detect your daughter using a little artifice to excuse herself from obedience, reflect that artifice is, in a certain degree, natural to the fair sex; and as every natural inclination, when not abused, is upright and good, why should it not be cultivated? In order to give girls proper notions of dress, let them be taught to consider splendour and elegance of dress, as designed only to conceal the natural defects of the person; and to regard it as the noblest triumph, the highest praise, of beauty, to shine with unborrowed lustre in the simplest attire. Forbid not young women to acquire those arts which have a tendency to render them agreeable. Why refuse them the indulgence of learning to dance, to sing, and to study such other accomplishments as afterwards enable them to entertain their husbands? Girls are more disposed to prattle, and at an earlier age, than boys. We may now and then find it necessary

cessary to restrain their volubility. But the proper question to them on such occasions is not, as to boys, *Of what use is this?* but *What effects will this produce?* At this early period, when they are yet strangers to the distinction between good and evil, and therefore unable to form a just judgment concerning any person's conduct, we ought to restrain them carefully from saying what may be disagreeable to those with whom they converse.

Girls are no less incapable than boys of forming distinct notions of religion at an early age. Yet, and even for that very reason, religious instruction should be communicated to them much sooner than to the youth of the other sex. Were we to wait the period when their mental faculties arrive at maturity, we might perhaps lose the happiest time, from our inability to make a right distinction. Since a woman's conduct is subject to public opinion, her belief ought therefore to depend, not on reason, but on authority. Every girl ought to follow the religion of her mother, every married woman that of her husband. They cannot derive a rule of faith from their own inquiry. Let us therefore seek, not so much to instruct them in the reasons of our belief, as to give them clear distinct notions of those articles which we require them to believe. Be more careful to instruct her in those doctrines which have a connexion with morality, than in those mysterious articles which we are required to believe, though we cannot comprehend them.

Such are the principles on which the education of Emilius's unknown mistress has been conducted.

[Notwithstanding the merit of that part of this treatise in which the author entertains us with the courtship between his Emilius and Sophia, it does not appear to be so intimately connected with the subject of education as to render it proper for us to present our readers with a view of it. We therefore pass over the courtship, to give a view of our author's sentiments concerning the advantages to be derived from travelling, and the manner in which it ought to be directed.]

42
Emilius attached to a mistress.

When Emilius has formed a firm attachment to Sophia, and by his assiduities has been so fortunate as to gain her affections, his great wish now is, to be united with her in the bonds of marriage. But as he is still young, is but imperfectly acquainted with the nature of those duties incumbent on him as a member of a particular society, and is even ignorant of the nature of laws and government, I must separate him from his Sophia, and carry him to gain a knowledge of these things, and of the character and circumstances of mankind, in various countries, and under various forms of civil government, by travelling. Much has been said concerning the propriety of sending young people to travel, in order to complete their education. The multiplicity of books is unfavourable to real knowledge. We read with avidity, and think that by reading we render ourselves prodigiously wise. But we impose on ourselves: the knowledge which we acquire from books is a false species of knowledge, that can never render us truly wise.

43
Travel.

To obtain real knowledge, you must observe nature with your own eyes, and study mankind. But to gain this knowledge by travelling, it is not necessary that we should traverse the universe. Whoever has seen ten Frenchmen has beheld them all; and whoever has surveyed and compared the circumstances and manners of ten different nations may be said to know mankind.

To pretend that no advantages may be derived from travelling, because some of those who travel return home without having gained much real improvement, would be highly unreasonable. Young people who have had a bad education, and are sent on their travels without any person to direct or superintend their conduct, cannot be expected to improve by visiting foreign countries. But they whom nature has adorned with virtuous dispositions, and who have been so happy as to receive a good education, and go abroad with a real desire of improvement, cannot but return with an increase of virtue and wisdom. In this manner shall Emilius conduct his travels. To induce him to improve in the most attentive manner that time which he should spend in travelling, I would let him know, that as he had now attained an age in which it might be proper for him to form some determination with regard to the plan of his future life, he ought therefore to look abroad into the world, to view the various orders in society, to observe the various circumstances of mankind under different forms of government, and in different parts of the globe; and to choose his country, his station, and his profession. With these views should Emilius set out on his travels: and with these views, in the course of our travels, we should inquire into the origin of society and government, into the nature of those principles by means of which men are united in a social state, into the various circumstances which have given rise to so many different forms of government, and into the necessary relation between government and manners. Our stay in the great towns should be but short: for as in them corruption of manners has risen to a great height, and dissipation reigns, a long stay in any great town might be fatal to the virtuous dispositions of Emilius. Yet his attachment to Sophia would alone be sufficient to save him from the dangers to which his virtue is exposed. A young man must either be in love, or be a debauchee. Instances may be pointed out in which virtue has been preserved without the aid of love; but to such instances I can give little credit.

44
Return from his travels, and marriage.

Emilius, however, may now return to his Sophia. His understanding is now much more enlightened than when he set out on his travels. He is now acquainted with several forms of government, their advantages and defects, with the characters of several different nations, and with the effects which difference in circumstances may be expected to produce on the characters of nations. He has even been so fortunate as to get acquainted with some persons of merit in each of the countries which he has visited. With these advantages gained, and with affection unchanged and unabated, he returns to his Sophia. After having made him acquainted with the languages, the natural history, the government, the arts, customs, and manners, of so many countries, Emilius eagerly informs me that the period which we had destined for our travels is now expired. I ask, What are then his purposes for life? He replies, that he is satisfied with the circumstances in which nature has placed him, and with my endeavours to render him independent on fortune, and wishes only for his Sophia to be happy. After giving him a few

advices

advices for the regulation of his conduct in life, I conduct him to his Sophia, and behold him united with her in marriage. I behold him happy; with affectionate gratitude he blesses me as the author of his happiness; and I thus receive the reward of all the pains with which I have conducted his education.

45
arks.
Such are the outlines of the system of education proposed by this singular and original genius. For originality of thought, affecting sentiment, enchanting description, and bold vehement eloquence, this book is one of the noblest pieces of composition, not only in the French language, but even in the whole compass of ancient and modern literature. The irregularity of his method, however, renders it a very difficult task to give an abridged view of his work. He conducts his pupil, indeed, from infancy to manhood: But instead of being barely a system of education, his work is besides a treasure of moral and philosophical knowledge. He has chosen a path, and follows it from the bottom to the summit of the hill: yet whenever a flower appears on the right or left hand, he eagerly steps aside to pluck it; and sometimes, when he has once stepped aside, a new object catches his eye and seduces him still farther. Still, however, he returns. His observations are in many places loosely thrown together; and many things are introduced, the want of which would by no means have injured either the unity or the regularity of his work. If we attempt to review the principles on which he proceeds in reprobating the prevalent modes of education, and pointing out a new course, his primary and leading one seems to be, that we ought to watch and second the designs of nature, without anticipating her. As the tree blossoms, the flowers blow, and the fruit ripens at a certain period; so there is a time fixed in the order of nature for the sensitive, another for the intellectual, and another for the moral powers of man to display themselves. We in vain attempt to teach children to reason concerning truth and falsehood, concerning right and wrong, before the proper period arrive: We only confound their notions of things, and load their memories with words without meaning; and thus prevent both their reasoning and moral powers from attaining that strength and acuteness of which they are naturally capable. He attempts to trace the progress of nature, and to mark in what manner she gradually raises the human mind to the full use of all its faculties. Upon the observations which he has made in tracing the gradual progress of the powers of the human mind towards maturity, his system is founded.

As it is impossible to communicate to the blind any just ideas of colours, or to the deaf of sounds: so it must be acknowledged, that we cannot possibly communicate to children ideas which they have not faculties to comprehend. If they are, for a certain period of life, merely sensitive animals, it must be folly to treat them during that period as rational and moral beings. But is it a truth that they are, during any part of life, guided solely by instinct, and capable only of sensation? Or, how long is the duration of that period? Has nature unkindly left them to be, till the age of twelve, the prey of appetite and passion? So far are the facts of which we have had occasion to take notice, concerning the history of infancy and childhood, from leading to such a conclusion, that to us it appears undeniable that children begin to reason very soon after their entrance into life. When the material world first opens on their senses, they are ignorant of the qualities and relations of surrounding objects: they know not, for instance, whether the candle which they look at be near or at a distance; whether the fire with which they are agreeably warmed may also affect them with a painful sensation. But they remain not long in this state of absolute ignorance. They soon appear to have acquired some ideas of the qualities and relative situation of bodies. They cannot, however, acquire such ideas, without exerting reasoning powers in a certain degree. Appearances must be compared, and inferences drawn, before knowledge can be gained. It is not sensation alone which informs us of the relative distances of bodies; nor can sensation alone teach us, that the same effects which we have formerly observed will be again produced by the same cause.

But if children appear capable of reasoning at a very early period, they appear also to be at a very early period subject to the influence of the passions: they are angry or pleased, merry or sad, friends or enemies, even while they hang at the breast; instead of being selfish, they are naturally liberal and social. And if we observe them with candid attention, we will find that the passions do not display themselves sooner than the moral sense. As nature has wisely ordered, that we should not see, and hear, and feel, without being able to compare and draw inferences from our perceptions; so it is a no less certain and evident law of nature, that the passions no sooner begin to agitate the human breast, than we become able to distinguish the beauty and the deformity of virtue and vice. The child is not only capable of gratitude and attachment to the person who treats him with kindness; he is also capable of distinguishing between gratitude and ingratitude, and of viewing each with proper sentiments. He cries when you refuse to gratify his desires; but he boldly insists that he is injured when you use him cruelly or unjustly. It is indeed impossible to attend to the conduct of children during infancy, without being convinced that they are, even then, capable of moral distinctions. So little are they acquainted with artificial language, that we and they do not then well understand each other. But view their actions; consider those signs by which nature has taught them to express themselves. Our limbs, our features, and our senses, are not gradually and by piecemeal bestowed as we advance towards maturity; the infant boy comes not into the world mutilated or defective: why then, in point of mental abilities, should we be for a while brutes, without becoming rational and moral beings till the fulness of time be accomplished? All the differences between the phenomena of manhood and those of infancy and childhood may be accounted for, if we only reflect, that when children come into the world, they are totally unacquainted with all the objects around them; with the appearances of nature, and the institutions of society; that they are sent into the world in a feeble state, in order that the helplessness occasioned by their ignorance may attract the notice and gain the assistance of those who are able to help them; and that they attain not full strength in the powers either of mind or body, nor a sufficient acquaintance with nature, with artificial language, and with the arts and institutions of society, till they arrive at manhood.

Even Rousseau, notwithstanding the art with which he lays down his system, cannot avoid acknowledging indirectly, on several occasions, that our social dispositions, our rational and our moral powers, display themselves at an earlier period than that at which he wishes us to begin the cultivation of them.

But though the great outlines of his system be merely theory, unsupported by facts, nay plainly contradictory to facts; yet his observations on the impropriety or absurdity of the prevalent modes of education are almost always just, and many of the particular directions which he gives for the conducting of education are very judicious. He is often fanciful, and often deviates from the common road, only to show that he is able to walk in a separate path. Yet why should he be opposed with so much virulence, or branded with so many reproachful epithets? His views are liberal and extensive: his heart seems to have glowed with benevolence: his book contains much observation of human actions; displays an intimate acquaintance with the motives which sway the human heart; and if not a perfect system for education, is yet superior to what any other writers had before done upon the subject. It is surely true, that we ourselves often call forth evil passions in the breasts of children, and impress them with bad habits: it is no less true that we put books in their hands, and load their memory with words, when we ought rather to direct their attention to things, to the phenomena of nature, and the simplest arts of life. The form in which he has chosen to communicate his sentiments on the subject of education renders the perusal of it more pleasing, and his precepts more plain, than they would otherwise have been: it is nearly that dramatic form with which we are so much delighted in some of the noblest compositions of the ancients.

After viewing the public establishments for education which existed in some of the most renowned states of antiquity; and after listening to the sentiments of the experienced Quinctilian, the learned Milton, the judicious Locke, and the bold fanciful Rousseau, on this interesting subject; it may now be proper to lay before the reader our own sentiments concerning the education of youth under a few distinct heads.

Indeed, if we were disposed to give abridgements of all the books which have been written on the subject of education, or even to hint at all the various modes which have been recommended by teachers or theorists, we might swell this article to an amazing size: Nay, were we only to take notice of the many elegant and sensible writers who have of late endeavoured to call the attention of the public to this subject, we might extend it to an immoderate length. A Kames, a Priestley, a Knox, a Madame de Sillery, and a Berquin, might well attract and fix our attention. But as, among such a crowd of writers, every thing advanced by each cannot be original; and even of those things which are original, only a certain, and that perhaps even a moderate, proportion, can be just and judicious; and as they often either borrow from one another, or at least agree in a very friendly manner, though in some things they profess a determined hostility; therefore we shall content ourselves with having taken notice of four of the most respectable writers on the subject.

In presenting to our readers the result of our own observations and reflections, we shall throw our thoughts nearly under the following heads. The management of children from their birth till they attain the age of five or six; from that period till the age of puberty; and from that age till manhood; private and public education; religion and morals; the languages; natural philosophy; the education of people of rank and fortune; education of persons designed for a mercantile employment, and for the other humbler occupations in active life not particularly connected with literature; education of the female sex; foreign travel; knowledge of the world; and entrance into active life. We do not pretend to be able to include under these heads every thing worthy of notice in the subject of education: but under these we will be able to comprehend almost every thing of importance that has occurred to us on the subject.

I. *On the Management of Infants from the Time of their Birth till they attain the Age of five or six.*

THE young of no other animal comes into the world in so helpless a state, or continues so long to need assistance, as that of the human species. The calf, the lamb, and the kid, are vigorous and lively at the instant of their birth; require only, for a very short period, nourishment and protection from their respective dams; and soon attain such degrees of strength and activity as to become entirely independent. The infancy of the oviparous animals is not of longer continuance: And, indeed, whatever department of the animal world we may choose to survey, we still find that no species is subject to the same severe laws as man during the first period of life.

46
Man com
pared to
other ani
mals, in r
spect to
the help-
lessness
infancy.

Yet the character and the views of man are so very different from those of the other animals, that a more careful attention to these may perhaps induce us to regard this seeming severity rather as an instance of the peculiar kindness of the author of nature. From every observation which has been hitherto made on the powers and operations of the inferior animals, we are led to consider them as guided and actuated chiefly, if not solely, by instinct, appetite, and sensation: their views extend not beyond the present moment; nor do they acquire new knowledge or prudence as they advance in life. But the character of the human race is much more exalted. We have also powers and organs of sensation, instincts and appetites; but these are the most ignoble parts of our nature: our rational faculties and moral powers elevate us above the brutes, and advance us to an alliance with superior beings. These rational faculties and moral powers render us capable of social life, of artificial language, of art, of science, and of religion. Now, were one of the species to come into the world full grown, possessed of that bodily strength and vigour which distinguishes manhood, his ignorance would still render him inadequate to the duties of life; nay, would even render him unable to procure means for his subsistence; while his manly appearance would deprive him of the compassion and benevolent assistance of others; and his strength and vigour would also render him less docile and obedient than is necessary, in order that

that he may receive instruction in the duties and arts of life. Again, were the period of infancy as short to the human species as to the other animals; were we to be no longer subjected to a parent's authority, or protected by his care, than the bird or the quadruped; we should be exposed to the dangers and difficulties of the world before we had acquired sufficient knowledge or prudence to conduct us through them, before we had gained any acquaintance with the ordinary phenomena of nature, or were able to use the language or practise the arts of men in a social state.

Since then, it is by the benevolence of nature that we are feeble and helpless at our entrance into life, and that our progress towards maturity is slow and gradual; since nature has destined us to be for a considerable time under the care and authority of our parents; and since the manner in which we are managed during that early part of life has so important an influence on our future character and conduct: it is therefore incumbent on parents to direct that tenderness, which they naturally feel for their offspring, in such a manner as to second the views of nature.

When children come into the world, instinct directs them to receive nourishment from the breast, and to claim attention to their pains and wants by crying. We attend to their signs, and strive to render them as easy as we can. They are washed, clothed with such garments as we think most suitable, and suckled either by their mother or by some other woman who is considered as proper for the purpose. The absurd mode of swaddling up infants in such a manner as to confine them almost from all motion, and leave scarce a limb at liberty, which has been so often exclaimed against and represented as highly injurious to the symmetry and vigour of the human frame, is now almost entirely laid aside; and therefore we need not raise our voice against it. Still, however, there are certainly too many pins and bandages used in the dress of infants: these are unfavourable to the circulation of the blood, impede the growth, and often occasion those tears and that peevishness which we rashly attribute to the natural ill humour of the poor creatures. Their dress ought to be loose and cool, so as to press hard on no joint, no vein nor muscle; and to leave every limb at liberty. If too heavy and close, it may occasion too copious a perspiration, and at the same time confine the matter perspired on the surface of the skin; than which nothing can be more prejudicial to the health of the child. It may also, however, be too thin and cool: for as moderate warmth is necessary to the vegetation of plants; so it is no less necessary for promoting the growth of animals: and, therefore, though the dress of infants ought to be loose and easy, yet still it should be moderately warm.

47 D of in- fa

Nur

It is common for mothers in affluent or even in comfortable circumstances, to forego the pleasure of nursing their own children, that they may avoid the fatigues with which it is attended. This practice has long prevailed in various ages and among various nations: it has been often reprobated with all the warmth of passion, and all the vehemence of eloquence, as dishonourable, inhuman, contradictory to the designs of nature, and destructive of natural affection: yet still it prevails; fathers and mothers are still equally deaf to the voice of nature and the declamations of philosophers. Indeed, in a luxurious age, such a practice may be naturally expected to prevail. In such an age, they who are possessed of opulence generally persuade themselves, that, to be happy, is to spend their time wholly amid diversions and amusements, without descending to useful industry, or troubling themselves about the ordinary duties of life. Influenced by such notions, they think it proper for them to manage their family affairs, and to nurse and educate their children, by proxy; nay, to do for themselves nothing that another can perform for them. It is vain to make a serious opposition to these absurd notions; the false views of happiness, the pride and the indolence produced by luxury, will still be too powerful for us. We must not hope to persuade the mother, that to receive the caresses, to behold the smiles, and to mark the bodily and mental powers of her child in their gradual progress towards maturity, would be more than a sufficient compensation for all the fatigues which she would undergo in nursing and watching over him in his infant years. We need not mention, that the mutual affection between a mother and her child, which is partly the effect of instinct, depends also, in no inconsiderable degree, on the child's spending the period of infancy in its mothers's arms; and that when she substitutes another in her place, the child naturally transfers its affection to the person who performs to it the duties of a mother. We need not urge these, nor the various other reasons which seem to recommend to every mother the province of suckling her own children, and watching over their infant years; for we will either not be heard, or be listened to with contempt. Yet we may venture to suggest, that if the infant must be committed to a stranger, some degree of prudence may be employed in selecting the person to whom he is to be intrusted. Her health, her temper, and her manner of speaking, must be attended to. A number of other qualifications are also to be required in a nurse: but it is rather the business of the physician to give directions with regard to these. If her habit of body be any way unhealthy, the constitution of the infant that sucks her milk cannot but be injured: if her temper be rough or peevish, the helpless child subjected to her power will be often harshly treated; its spirit will be broken, and its temper soured: if her pronunciation be inarticulate or too rapid, the child may acquire a bad habit when it first begins to exert its vocal organs, which will not be easily corrected.

49 Influence of treatment in infancy on the abilities and dispositions.

In the milder seasons of the year, infants ought to be frequently carried abroad. Not only is the open air favourable to health, but the freshness, the beauty, the variety, and the lively colours of the scenes of nature, have the happiest effects on the temper, and have even a tendency to enliven and invigorate the powers of the mind. At this period, the faculties of the understanding and the dispositions of the heart generally acquire that particular bias, and those distinguishing features, which characterize the individual during the future part of his life, as quick or dull, mild or passionate; and which, though they be generally attributed to the original conformation of the mind by the hand of nature, yet are owing rather to the circumstances in which we are placed, and the manner in which we are treated, during the first part of life.

When children begin to walk, our fondness disposes us to adopt many expedients to assist them. But these seem to be improper. It is enough for us to watch over them so as to guard them from any danger which they might otherwise incur by their first attempts to move about. Those who advise us not to be too anxious to preserve children from those slight hurts to which they are exposed from their disposition to activity, before they have acquired sufficient strength or caution, certainly give a judicious piece of advice which ought to be listened to. By being too attentive to them, we teach them to be careless of themselves; by seeming to regard every little accident which befals them as a most dreadful calamity, we inspire them with timidity, and prevent them from acquiring manly fortitude. When children begin to lisp out a few words or syllables, the pleasure which we feel at hearing them aim at the use of our language, disposes us to listen to them with such attention as to relieve them from the necessity of learning an open distinct articulation. Thus we teach them to express themselves in a rapid, indistinct, and hesitating manner, which we often find it difficult, sometimes even impossible, to correct, when they are farther advanced. Would we teach them a plain distinct articulation, we ought not only to speak plainly and distinctly in their presence, but also to disregard their questions and requests, if not expressed with all the openness and distinctness of pronunciation of which they are capable.

Man is naturally an imitative animal. Scarce any of our natural dispositions is displayed at an earlier period than our disposition to imitation. Children's first amusements are dramatic performances, imitative of the arts and actions of men. This is one proof among others, that even in infancy our reasoning faculties begin to display themselves; for we cannot agree with some philosophers that children are actuated and guided solely by instinct in their attempts at imitation.

However that be, the happiest use might be made of this principle which discovers itself so early in the infant mind. Whatever you wish the child to acquire, do in his presence in such a manner as to tempt him to imitate you. Thus, without souring his mind by restraint during this gay innocent period of life, you may begin even now to cultivate his natural powers. Were it impossible at this time to communicate any instruction to the boy, without banishing that sprightly gaiety which naturally distinguishes this happy age, it would be best to think only how he might lose his time in the least disadvantageous manner. But this is far from being necessary. Even now the little creature is disposed to imitation, is capable of emulation, and feels a desire to please those whose kindness has gained his affection. Even now his sentiments and conduct may be influenced by rewards when prudently bestowed, and by punishments when judiciously inflicted. Why then should we hesitate to govern him by the same principles, by which the laws of God and society assert their influence on our own sentiments and conduct? Indeed, the imprudent manner in which children are too generally managed at this early period, would almost tempt us to think it impossible to instruct them, as yet, without injuring both their abilities and dispositions. But this is owing solely to the carelessness, stupidity, or capricious conduct of those under whose care they are placed.

50
Obedience whether, and when, to be exacted.

Is implicit obedience to be exacted of children? and at what period of life should we begin to enforce it? As children appear to be capable both of reasoning and of moral distinctions at a very early age; and as they are so weak, so inexperienced, so ignorant of the powers of surrounding bodies, and of the language, institutions, and arts of men, as to be incapable of supporting or conducting themselves without direction or assistance; it seems therefore proper that they be required even to submit to authority. To the necessity of nature both they and we must on many occasions submit. But if the will of a parent or tutor be always found scarce less unalterable than the necessity of nature, it will always meet with the same respectful submissive resignation. It may not perhaps be always proper to explain to children the reasons for which we require their obedience: because, as the range of their ideas is much less extensive than ours; as they do not well understand our language, or comprehend our modes of reasoning; and as they are now and then under the influence of passion and caprice, as well as people who are farther advanced in life; we are therefore likely to fail in making them comprehend our reasons, or in convincing them that they are well grounded. And as it is proper to exact obedience of children; so we should begin to require it as soon as they become capable of any considerable degree of activity. Yet we must not confine them like slaves, without allowing them to speak, to look, or to move, but as we give the word. By such treatment we could expect only to render them peevish and capricious. It will be enough, at first, if we let them know that obedience is to be exacted; and if we restrain them only where, if left at liberty, they would be exposed to imminent danger.

If then, at so early a time of life as before the age of five or six, it is possible to render children obedient, and to communicate to them instruction; what arts, or what learning, ought we to teach them at that period? To give a proper answer to this question, is no easy matter. It seems at first difficult to determine, whether we ought yet to initiate them in letters. But as their apprehension is now quick, and their memory pretty tenacious, there cannot be a more favourable time for this very purpose. As soon as they are capable of a distinct articulation, and seem to possess any power of attention, we may with the greatest propriety begin to teach them the alphabet. The most artful, alluring methods may be adopted to render the hornbook agreeable; or we may use the voice of authority, and command attention for a few minutes; but no harshness, no severity, and scarce any restraint. At the same time, it will be proper to allow the little creatures to run much about in the open air, to exercise their limbs, and to cultivate those social dispositions which already begin to appear, by playing with their equals.

Such are the thoughts which have suggested themselves to us concerning the management of children in mere infancy. What an amiable little creature would the boy or girl be, who were brought up in a manner not inconsistent with the spirit of these few hints? Behold him healthy and vigorous, mild, sprightly, and cheerful:

ful: He is submissive and docile, yet not dull or timid; he appears capable of love, of pity, and of gratitude. His mind is hitherto, however, almost wholly uninformed: he is acquainted but with a few of the objects around him; and knows but little of the language, manners, and institutions of men: but he feels the impulse of an ardent curiosity, and all the powers of his mind are alive and active.

II. *On the Management of Children between the Age of five or six and the Age of Puberty.*

At this period it may be proper, not only to exact obedience, and to call the child's attention for a few minutes now and then to those things of which the knowledge is likely to be afterwards useful to him: but we may now venture to require of him a regular steady application, during a certain portion of his time, to such things as we wish him to learn. Before this time it would have been wrong to confine his attention to any particular task. The attempt could have produced no other effect than to destroy his natural gaiety and cheerfulness, to blunt the natural quickness of his powers of apprehension, and to render hateful that which you wished him to acquire. Now, however, the case is somewhat different: The child is not yet sensible of the advantages which he may derive from learning to read, for instance; or even though he were able to foresee all the advantages which he will obtain by skill in the art of reading through the course of life; yet is it the character of human nature, at every stage of life, to be so much influenced by present objects in preference to future views, that the sense of its utility alone would not be sufficient to induce him to apply to it. Even at the age of 12, of 20, of 50; nay, in extreme old age, when reason is become very perspicacious, and the passions are mortified; still we are unable to regulate our conduct solely by views of utility. Nothing could be more absurd, therefore, than to permit the child to spend his time in foolish tricks, or in idleness, till views of utility should prompt him to spend it in a different manner. No; let us begin early to habituate him to application and to the industrious exertion of his powers. By endowing him with powers of activity and apprehension, and rendering him capable of pursuing with a steady eye those objects which attract his desires, nature plainly points out to us in what manner we ought to cultivate his earlier years. Besides, we can command his obedience, we can awaken his curiosity, we can rouse his emulation, we can gain his affection, we can call forth his natural disposition to imitation, and we can influence his mind by the hope of reward and the fear of punishment. When we have so many means of establishing our authority over the mind of the boy without tyranny or usurpation; it cannot surely be difficult, if we are capable of any moderation and prudence, to cultivate his powers, by making him begin at this period to give regular application to something that may afterwards be useful.

And if the boy must now begin to dedicate some portion of his time regularly to a certain task, what task will be most suitable? Even that to which children are usually first required to apply; continue teaching him to read. Be not afraid that his abilities will suffer from an attention to books at so early an age. Say not that it is folly to teach him words before he have gained a knowledge of things. It is necessary, it is the design of nature, that he should be employed in acquiring a knowledge of things, and gaining an acquaintance with the vocal and written signs by which we denote them, at the same time. These are intimately connected; the one leads to the other. When you view any object, you attempt to give it a name, or seek to learn the name by which men have agreed to distinguish it: in the same manner, when the names of substances or of qualities are communicated to us, we are desirous of knowing what they signify. At the same time, so imperfect is the knowledge of nature which children can acquire from their own unassisted observation, that they must have frequent recourse to our assistance before they can form any distinct notions of those objects and scenes which they behold. Indeed language cannot be taught, without teaching that it is merely a system of signs, and explaining what each particular sign is designed to signify. If, therefore, language is not only necessary for facilitating the mutual intercourse of men, but is even useful for enabling us to obtain some knowledge of external nature, and if the knowledge of language has a natural tendency to advance our knowledge of things; to acquaint ourselves with it must therefore be regarded as an object of the highest importance: it must also be regarded as one of the first objects to which we ought to direct the attention of children. But the very same reasons which prove the propriety of making children acquainted with those artificial vocal signs which we use to express our ideas of things, prove also the propriety of teaching them those other signs by which we express these in writing. It is possible indeed, nay it frequently happens, that we attempt to instruct children in language in so improper a manner as to confound their notions of things, and to prevent their intellectual powers from making that improvement of which they are naturally capable; but it is also possible to initiate them in the art of reading, and in the knowledge of language, with better auspices and happier effects. The knowledge of language may be considered as the key by which we obtain access to all the stores of natural and moral knowledge.

52
Confinement, how far proper.

Though we now agree to confine our pupil to a certain task, and have determined that his first task shall be to learn to read; yet we do not mean to require that he be confined to his task during the greatest part of the day, or that his attention be seriously directed to no other object. To subject him to too severe restraint would produce the most unfavourable effects on his genius, his temper, and his dispositions. It is in consequence of the injudicious management of children, while they are sometimes suffered to run riot, and at other times cruelly confined like prisoners or slaves; it is in consequence of this, that we behold so many instances of peevishness, caprice, and invincible aversion to all serious application at this period of life. But were a due medium observed, were restraint duly tempered with liberty and indulgence, nothing would be more easy than to dispose children to cheerful obedience, and to communicate to them instruction at this age. That part of their time which they are left to enjoy at liberty, they naturally dedicate to their little sports.

The favourite sports of boys are generally active; those of girls, sedentary. Of each we may take advantage, to prepare them for the future employments of life. However, neither are the amusements of boys invariably active, nor those of girls always sedentary; for as yet, the manners and dispositions of the two sexes are distinguished rather by habit or accident than by nature. The disposition to activity which characterizes children, is no less favourable to health than to their improvement in knowledge and prudence; their active sports have a tendency to promote their growth, and add new vigour to their limbs. Perhaps, even at this time, children might be enticed to learn the elements of natural philosophy and natural history amid their amusements and sports. Birds, butterflies, dogs, and other animals, are now favourite objects of their care; their curiosity is powerfully roused by the appearance of any strange object; and many of the simplest experiments of natural philosophy are so pleasing, that they cannot fail to attract the attention even of those who are least under the influence of curiosity. Yet it would be improper to insist on their attention to these things as a task: if we can make them regard them as amusements, it will be well; if not, we must defer them to some happier season. They might also, by proper management, be led to acquire some skill in the arts. They build mimic houses, and fill them with suitable furniture; they construct little boats, and sail them; they will fence-in little gardens, and cultivate them; and we even see them imitate all the labours of the husbandman. Such is the pleasure which man naturally feels in exerting his powers, and in acting with design. Let us encourage this disposition. These are the most suitable amusements in which they can engage.

53 What books most proper.

As the boy's attention to literary objects is still supposed to be continued, he will soon be able to read with some correctness and facility. It becomes an object of importance, and of no small difficulty, to determine what books are to be put into his hands, and in what manner his literary education is to be conducted. After the child is made acquainted with the names and powers of the letters, with their combination into syllables, and with the combination of these again into words, so that he can read with tolerable facility; it will be proper that the pieces of reading which are put into his hands be such as are descriptive of the actions of men, of the scenes of external nature, and of the forms and characters of animals. With these he is already in some degree acquainted; these are the objects of his daily attention; beyond them the range of his ideas does not yet extend; and therefore other subjects will be likely to render his task disagreeable to him. Besides, our present object is to teach him words: in order to teach him words, we must let him know their signification; but till he have acquired a very considerable knowledge of language, till he have gained a rich fund of simple ideas, it will be impossible for him to read or to hear with understanding on any other subject but these. And let us not as yet be particularly anxious to communicate to him religious or moral instruction, otherwise than by our example, and by causing him to act in such a manner as we think most proper. Our great business at present is, to make him acquainted with our language, and to teach him in what manner we use it to express our ideas. By his own observation, and by our instruction, he will soon become capable of comprehending all that we wish to communicate: But let us not be too hasty: the boy cannot long view the actions of mankind, and observe the economy of the animal and the vegetable world, without becoming capable of receiving both religious and moral instruction when judiciously communicated.

54 Writi

As soon as the pupil can read and spell with tolerable facility, and has acquired sufficient strength of arm and fingers to hold a pen, it may be proper to initiate him in the art of writing. If this art is not made disagreeable by the manner in which his application to it is required, he will learn it without difficulty. Children's natural disposition to imitate, particularly whatever depends on manual operation, renders this art peculiarly easy and pleasing to them, when they are not harshly forced to apply to it, nor suffered to get into a habit of performing their task with haste and negligence.

55 Restra

It requires indeed the most cautious prudence, the nicest delicacy, and the most artful address, to prevail with children to give a cheerful and attentive application to any appointed task. If you are too stern and rigid in enforcing application, you may seemingly obtain your object: the child sits motionless, and fixes his eye on his book or copy; but his attention you cannot command; his mind is beyond your reach, and can elude your tyranny; it wanders from the present objects, and flies with pleasure to those scenes and objects in which it has found delight. Thus you are disappointed of your purpose; and, besides, inspire the child with such aversion both to you and to those objects to which you wish him to apply, that perhaps at no future period will he view learning otherwise than with disgust.

56 Gentle

Again, gentleness, and the arts of insinuation, will not always be successful. If you permit the child to apply just when he pleases; if you listen readily to all his pretences and excuses; in short, if you seem to consider learning as a matter not of the highest importance, and treat him with kindness while he pays but little attention and makes but slow progress; the consequences of your behaving to him in this manner will be scarce less unfavourable than those which attend imprudent and unreasonable severity. It is, however, scarce possible to give particular directions how to treat children so as to allure them to learning, and at the same time to command their serious attention. But the prudent and affectionate parent and the judicious tutor will not always be unsuccessful; since there are so many circumstances in the condition of children, and so many principles in their nature, which subject them to our will.

57 Arithm tic.

The principles of arithmetic ought to make a part in the boy's education as soon as his reasoning powers appear to have attained such strength and quickness that he will be able to comprehend them. Arithmetic affords more exercise to the reasoning powers of the mind than any other of those branches of learning to which we apply in our earlier years: and if the child's attention be directed to it at a proper period, if he be allowed to proceed slowly, and if care be taken to make him comprehend fully the principles upon which each particular

particular operation proceeds, it will contribute much to increase the strength and the acuteness of the powers of his understanding.

Where the learned languages are regarded as an object worthy of attention, the boy is generally initiated in them about this time, or perhaps earlier. We have reserved to a separate head the arguments which occur to us for and against the practice of instructing children in the dead languages; and shall therefore only observe in this place, that the study of them ought not to engross the learner's attention so entirely as to exclude other parts of education.

From arithmetic our pupil may proceed to the practical branches of the mathematics: And in all of these, as well as in every other branch of learning, what you teach him will be best remembered and most thoroughly understood, if you afford him a few opportunities of applying his lessons to real use in life. Geometry and geography are two most important branches of education; but are often taught in such a manner, that no real benefit is derived from the knowledge of them. The means which Rousseau proposes for initiating young people in these and in several other of the arts and sciences are excellent; and if judiciously applied, could hardly fail of success.

While boys are engaged in these and in the languages, they may also attend to and cultivate the bodily exercises; such as dancing, fencing, and horsemanship. Each of these exercises is almost absolutely necessary for one who is designed to have intercourse with the world; and besides, they have a tendency to render the powers of the body active and vigorous, and even to add new courage and firmness to the mind.

When our pupil has acquired some knowledge of his own and of the learned languages, has gained some skill in the principles of arithmetic and of practical mathematics, and has received some instruction in the principles of morality and religion, or even before this time, it will be proper to begin him to the practice of composition. Themes, versions, and letters, the first exercises in composition which the boy is usually required to perform, none of them seems happily calculated for leading him to increase his knowledge, or to acquire the power of expressing himself with ease and elegance. Without enlarging on the impropriety or absurdity of these exercises, we will venture to propose something different, which we cannot help thinking would conduce more effectually to the end in view. It has been already observed, that the curiosity of children is amazingly eager and active, and that every new object powerfully attracts their regard: but they cannot view any object without taking notice of its most obvious qualities; any animal, for instance, without taking notice of its shape, its colour, its seeming mildness or ferocity; and they are generally pretty ready to gave an account of any thing extraordinary which they have observed. How easy then would it be to require them to write down an account of any new object exposed to their observation? The task would not be difficult; and every new piece of composition which they presented to us would add so much to their knowledge of nature. We might even require such specimens of their accuracy of observation and skill in language, at times when they enjoyed no opportunities of beholding new or surprising objects: a tree, a flower, a field, a house, an animal, any other simple object, should be the subject of their exercise. After some time, we might require them to describe something more various and complex. They might give an account of several objects placed in a relative situation; as, a stream, and the vale through which it flows; or, a bird, and the manner in which it constructs its nest; or, of one object successively assuming various appearances, as the bud, the flower, the apple. Human actions are daily exposed to their observation, and powerfully attract their attention. By and by, therefore, their task should be to describe some action which had lately passed in their presence. We need not pursue this hint farther; but, if we mistake not, by these means young people might sooner, and much more certainly, be taught to express themselves with ease and correctness in writing, than by any of the exercises which they are at present caused to perform with a view to that. Besides, they would at the same time acquire much more real knowledge. The study of words would then be rendered truly subservient to their acquiring a knowledge of things.

We cannot descend to every particular of that series of education in which we wish the boy to be engaged from that period when he first becomes capable of serious application till he reach the age of puberty. It is not necessary that we should, after having given abstracts of what has been offered to the world by so many respectable writers on the subject.

The few hints which we have thrown out will be sufficient to show, in general, in what manner we wish the youth's education to be conducted during this period. Let the parent and the tutor bear in mind, that much depends on their example, with regard to the disposition and manners of the youth; and let them carefully strive to form him to gentleness, to firmness, to patient industry, and to vigorous courage; let them, if possible, keep him at a distance from that contagion with which the evil example of worthless servants and playfellows will be likely to infect him. Now is the time for sowing the seeds of piety and virtue: if carefully sown now, they will scarce fail to grow up, and bear fruit in future life.

III. *From Puberty to Manhood.*

THIS age is every way a very important period in human life. Whether we consider the change which now takes place in the bodily constitution, or the passion which now first begins to agitate the breast, still we must regard this as a critical season to the youth. The business of those to whose care he is still intrusted, is to watch over him so as to prevent the passion for the sex from hurrying him to shameful and vicious indulgence, and from seducing him to habits of frivolity and indolence; to prevent him from becoming either the shameless rake, or the trifling coxcomb. Though so furious is the impulse of that appetite which now fires the bosom and shoots through the veins of the youth, that to restrain him from the excesses to which it leads can be no easy task; yet if his education has been hitherto conducted with prudence, if he is fond of manly exercises, active, sober, and

and temperate, and still influenced by modesty and the sense of shame; even this may through the blessing of heaven be accomplished. It is impossible to give better directions than those of Rousseau for this purpose. Let the young man know his situation; set before him in a striking light the virtue which he may practise by restraining appetite, and the frightful fatal vices into which he may be hurried. But trust not to precept, nor to any views which you can lay before him, either of the disgracefulness and the pernicious consequences of vice, or of the dignity and the happy fruits of virtue. Something more must be done. Watch over him with the attention of an Argus; engage him in the most active and fatiguing sports. Carefully keep him at a distance from all such company, and such books, as may suggest to his mind ideas of love, and of the gratification at which it aims. But still all your precautions will not counteract the designs of nature; nor do you wish to oppose her designs. The youth under your care must feel the impulse of desire, and become susceptible of love. Let him then fix his affections on some virtuous young woman. His attachment to her will raise him above debauchery, and teach him to despise brutal pleasures: it will operate as a motive to dispose him to apply to such arts, and to pursue such branches of knowledge, as may be necessary for his future establishment in the world. The good sense of Rousseau on this head renders it less necessary for us to enlarge on it; especially as we are to treat of some articles separately which regard the management of youth at this period.

IV. *Religion and Morals.*

60
At what age the principles of religion may be taught.

In pointing out the general plan of education which appears to us the most proper to be pursued in order to form a virtuous and respectable member of society, we took but slight notice of the important objects of religion and morals. At what period and in what manner, ought the principles of religion and morality to be instilled into the youthful mind? It has been before observed, that children are capable of reasoning and of moral distinctions even at a very early age. But they cannot then comprehend our reasonings, nor enter into our moral distinctions; because they are strangers to our language, and to the artificial manner in which we arrange our ideas when we express them in conversation or in writing. It follows, then, that as soon as they are sufficiently acquainted with our language, it must be proper to communicate to them the principles and precepts of morality and religion. Long before this time, they are diligent and accurate observers of human actions. For a short period it is merely the external act which they attend to and observe: soon, however, they penetrate farther; conscious themselves of reflection and volition, they regard us also as thinking beings; conscious of benevolent and of unfriendly dispositions, they regard us as acting with design, and as influenced by passion: naturally imitative animals, they are disposed in their conduct to follow the example which we set before them. By our example we may teach them piety and virtue long before it can be proper to offer them religious or moral instruction in a formal manner.

We cannot presume to determine at what particular period children ought to be first informed of their relations to God and to society, and of the duties incumbent on them in consequence of those relations. That period will be different to different children, according to the pains which have been taken, and the means which have been employed, in cultivating their natural powers. Perhaps even where the most judicious maxims of education have been adopted, and have been pursued with the happiest effects, it cannot be sooner than the age of eight or nine. But even before this period much may be done. Show the child your reverence for religion and virtue; talk in his presence, and in the plainest, simplest terms, though not directly to him, of the existence of God the creator, the preserver and the governor of the world; speak of the constant dependence of every creature on the gracious care of that Being; mention with ardour the gratitude and obedience which we owe to him as our great parent and best benefactor; next, speak of the mutual relations of society; of the duties of children and parents, of masters and servants, of man to man. At length, when his mind is prepared by such discourses which have passed in his presence without being addressed to him, you may begin to explain to him in a direct manner the leading doctrines of religion. He will now be able to comprehend you, when you address him on that important subject: the truths which you communicate will make a powerful impression on his mind; an impression which neither the corruption and dissipation of the world, nor the force of appetite and passion, will ever be able to efface.

61
Habit.

Some writers on this subject have asserted, that youth are incapable of any just ideas of religion till they attain a much more advanced age; and have insisted, that, for this reason, no attempts should be made to communicate to them the articles of our creed in their earlier years. This doctrine, both from its novelty and from its pernicious tendency, has provoked the keenest opposition. It has, however, been opposed rather with keenness than with acuteness or skill. Its opponents seem to have generally allowed that children are incapable of reasoning and of moral distinctions; but they have ascribed wonderful effects to habit. Enrich the memories of children, say they, with the maxims of morality, and with the doctrines of religion; teach them prayers, and call them to engage in all the ordinances of religion. What though they comprehend not the meaning of what they learn? What though they understand not for what purpose you bid them repeat their prayers, nor why you confine them on the Lord's day from their ordinary amusements? Their powers will at length ripen, and they will then see in what they have been employed, and derive the highest advantage from the irksome tasks to which you confined them. You have formed them to habits which they will not be able to lay aside: After this they cannot but be religious at some period of life, even though you have inspired them with a disgust for the exercises of religion. Those good people have also talked of the principle of *the association of ideas*. As no man stands alone in society, say they; so no one idea exists in the mind single and unconnected with others: as you are connected with your parents, your children, your friends, your countrymen; so the idea of a tree, for instance, is connected ed with that of the field in which it grows, of the fruit which it bears, and of contiguous, dissimilar, and resembling objects. When any one set of related ideas have been often presented to the mind in connexion with one another, the mind at length comes to view them as so intimately united, that any particular one among them never fails to introduce the rest. Revisit the scenes in which you spent your earliest years; the sports and companions of your youth naturally arise to your recollection. Have you applied to the study of the classics with reluctance and constraint, and suffered much from the severity of parents and tutors for your indifference to Greek and Latin; you will, perhaps, never through the course of life see a grammar school, without recollecting your sufferings, nor look on a Virgil or Homer without remembering the stripes and confinement which they once occasioned to you. In the same manner, when religious principles are impressed on the mind in infancy in a proper manner, a happy association is formed which cannot fail to give them a powerful influence on the sentiments and conduct in a future life. But if we have advanced to manhood before being informed of the existence of a Deity, and of our relation to him, the principles of religion, when communicated, no longer produce the same happy effects: the heart and the understanding are no longer in the same state; nor will the same associations be formed.

2 Dr Priest- ey opinion con- cerning as- ociation of idea

This doctrine of *the association of ideas* has been adduced by an ingenious writer, distinguished for his discoveries in natural philosophy, and for his labours in controversial divinity, as an argument in behalf of the propriety of instructing youth in the principles of religion even in their earliest years. We admire, we esteem, the spirit which has prompted him to discover so much concern for the interests of the rising generation; but at the same time we will not conceal our opinion, that even this argument ought to be urged with caution. Many of the phenomena of human nature may indeed be explained, if we have recourse to the principle of *association*. The influence of any principle, religious or moral, depends in a great measure on the ideas and images which, in considering it, we have been accustomed to associate with it in our minds. But what are the ideas or images most likely to be associated by children with the doctrines and duties of religion, if we call them to listen to the one and perform the other at too early a period? Will they be such as may assist the influence of religion on their sentiments and conduct in the future part of life? Observe the world: Are those who, in infancy, have been most rigidly compelled to get their catechisms by rote, either the most pious or the best informed in religious matters? Indeed, when we consider what has been said of the influence of habit, and of the association of ideas, we cannot help thinking, that any arguments which on the present occasion may be adduced from either of these, tend directly to prove, not that we ought to pour in religious instruction into the minds of children, without considering whether they be qualified to receive it; but, on the contrary, that we ought cautiously to wait for and catch the proper season;—that season when the youthful mind, no longer a stranger to our language, our sentiments, our views of nature, or our manner of reasoning, will be able to go along with us, when we talk to him of a supreme Being, or our condition as dependant and accountable creatures, of truth, benevolence, and justice.

We flatter ourselves, then, that our readers will readily agree with us, 1st, That the moral and reasoning powers of children begin to display themselves at a very early age, even in infancy. 2dly, That as soon as they have made themselves acquainted with the most obvious appearances of nature, and have gained a tolerable knowledge of our language and our manner of arranging our ideas in reasoning, we may with the greatest propriety begin to instruct them in the principles of religion. 3dly, That the most careful and judicious observation is necessary to enable us to distinguish the period at which children become capable of receiving religious instruction; because, if we either attempt to communicate to them these important truths too early, or defer them till towards manhood, we may fail of accomplishing the great end which we have in view.

63 Catechisms.

If we can be so fortunate as to choose the happiest season for sowing the first seeds of piety in the infant mind, our next care will be to sow them in a proper manner. We must anxiously endeavour to communicate the principles of religion and morality, so as they may be easiest comprehended by the understanding of the learner, and may make the deepest impression on his heart. It would be a matter of the greatest difficulty to give particular directions on this head. The discretion of the parent or tutor must here be his guide. We are afraid that some of the catechisms commonly taught are not very happily calculated to serve the purpose for which they are intended. Yet we do not wish that they should be neglected while nothing more proper is introduced in their room. In instructing children in the first principles of religion, we must beware of arraying piety in the gloomy garb, or painting her with the forbidding features, in which she has been represented by anchorites, monks, and puritans. No; let her assume a pleasing form, a cheerful dress, and an inviting manner. Describe the Deity as the affectionate parent, the benefactor, and though the impartial yet the merciful judge of mankind. Exhibit to them Jesus Christ, the generous friend and Saviour of the posterity of Adam, who with such enchanting benevolence hath said, "Suffer little children to come unto me." Represent to them his yoke as easy, and his burden as light. Insist not on their saying long prayers or hearing tedious sermons. If possible, make the doctrines of religion to appear to them as glad tidings, and its duties as the most delightful of tasks.

V. *The Languages.*

Is the time usually spent in learning the languages usefully occupied? What advantages can our British youth derive from an acquaintance with the languages and the learning of Greece and Rome? Would we listen to many of the fathers, the mothers, and the polite tutors of the present age, they will persuade us, that the time which is dedicated to grammar-schools, and to Virgil, Cicero, Homer, and Demosthenes, is foolishly thrown away; and that no advantages

advantages can be gained from the study of classical learning. They wish their children and pupils to be not merely scholars: they wish them to acquire what may be useful and ornamental when they come to mingle with the world; and for this purpose, they think it much better to teach their young people to smatter out French, to dance, to fence, to appear in company with invincible assurance, and to dress in such a manner as may attract the attention of the ladies. Besides, the tenderness and humanity of those people are amazing. They are shocked at the idea of the sufferings which boys undergo in the course of a classical education. The confinement, the stripes, the harsh language, the burdens laid on the memory, and the pain occasioned to the eyes, during the dreary period spent in acquiring a knowledge of Greek and Latin, affect them with horror when they think of them as inflicted on children. They therefore give the preference to a plan of education in which less intense application is required and less severity employed.

64 Prejudices against classical education.

65 Prejudices for it.

But, again, there are others who are no less warm in their eulogiums on a classical education, and no less industrious in recommending the study of Greek and Latin, than those are eager in their endeavours to draw neglect on the polished languages of antiquity. With this second class, if an adept in Greek and Latin, you are a great and learned man; but without those languages, contemptible for ignorance. They think it impossible to inspire the youthful mind with generous or virtuous sentiments, to teach the boy wisdom, or to animate him with courage, without the assistance of the ancient philosophers, historians, and poets. Indeed their superstitious reverence for the ancient languages, and for those writers whose compositions have rendered Greece and Rome so illustrious, leads them to ascribe many other still more wonderful virtues to a classical education.

With which of these parties shall we join? or shall we mediate between them? Is it improper to call youth to the study of the languages? Is it impossible to communicate any useful knowledge without them? Or are they, though highly useful, yet not always indispensably necessary?

66 Utility of classical learning towards the improvement of our mother tongue.

We have formerly taken notice of one circumstance in favour of a classical education, to which it may be proper to recal the attention of our readers. We observed, that the cultivation of classical learning has a favourable influence on the living languages. It has a tendency to preserve their purity from being debased, and their analogy from becoming irregular. In studying the dead languages, we find it necessary to pay more attention to the principles of grammar than in acquiring our mother tongue. We learn our native language without attending much to its analogy and structure. Of the numbers who speak English through the British dominions, but few are skilled in the inflection of its nouns and verbs, or able to distinguish between adverbs and conjunctions. Desirous only of making their meaning understood, they are not anxious about purity or correctness of speech. They reject not an expression which occurs to them, because it is barbarous or ungrammatical. As they grew up they learned to speak from their mothers, their nurses and others about them; they were soon able to make known their wants, their wishes, and their observations, in words. Satisfied with this, or called at a very early period to a life of humble industry, they have continued to express themselves in their mother tongue without acquiring any accurate knowledge of its general principles. If these people find occasion to express themselves in writing, they are scarce more studious of correctness and elegance in writing than in speaking; or, though they may aspire after those properties, yet they can never attain them. But such writers or speakers can never refine any language, or reduce it to a regular analogy. Neither can they be expected to distinguish themselves as the guardians of the purity and regularity of their native tongue, if it should before have attained a high degree of perfection. But they who, in learning a language different from their native tongue, have found it necessary to pay particular attention to the principles of grammar, afterwards apply the knowledge of grammar which they have thus acquired in using their mother tongue; and by that means become better acquainted with its structure, and learn to write and speak it with more correctness and propriety. Besides, the languages of Greece and Rome are so highly distinguished for their copiousness, their regular analogy, and for various other excellencies, which render them superior to even the chief of modern languages, that the study of them has a natural tendency to improve and enrich modern languages. If we look backwards to the 15th century, when learning began to revive in Europe, and that species of learning which began first to be cultivated was classical literature, we find that almost all the languages then spoken in Europe were wretchedly poor and barbarous. Knowledge could not be communicated, nor business transacted, without calling in the aid of Latin. Classical learning, however, soon came to be cultivated by all ranks with enthusiastic eagerness. Not only those designed to pursue a learned profession, and men of fortune whose object was a liberal education without a view to any particular profession; but even the lower ranks, and the female sex, keenly studied the languages and the wisdom of Greece and Rome. This avidity for classical learning was followed by many happy effects. But its influence was chiefly remarkable in producing an amazing change on the form of the living languages. These soon became more copious and regular; and many of them have consequently attained such perfection, that the poet, the historian, and the philosopher, can clothe their thoughts in them to the greatest advantage. Could we derive no new advantage from the study of the ancient languages, yet would they be worthy of our care, as having contributed so much to raise the modern languages to their present improved state. But they can also conduce to the preservation and support of those noble structures which have been reared by their assistance. The intercourse of nations, the affectation of writers, the gradual introduction of provincial barbarisms, and various other causes, have a tendency to corrupt and debase even the noblest languages. By such means were the languages of Greece and Rome gradually corrupted, till the language used by a Horace, a Livy, a Xenophon, and a Menander, was lost in a jargon unfit for the purposes of composition. But if we would not disdain to take advantage of them, the classical works in those languages might

prevent

prevent that which we use from experiencing such a decline. He who knows and admires the excellencies of the ancient languages, and the beauties of those writers who have rendered them so celebrated, will be the firm enemy of barbarism, affectation, and negligence, whenever they attempt to debase his mother tongue. We venture therefore to assert, that when the polished languages of antiquity cease to be studied among us, our native tongue will then lose its purity, regularity, and other excellencies, and gradually decline till it be no longer known for the language of Pope and of Addison; and we adduce it as an argument in behalf of classical learning, that it has contributed so much to the improvement of the living languages, and is almost the only means that can prevent them from being corrupted and debased.

7
Fo uring
to dustry.

In those plans of education of which the study of the dead languages does not make a part, proper means are seldom adopted for impressing the youthful mind with habits of industry: nor do the judgment, the memory, and the other powers of the mind, receive equal improvement, as they pass not through the same exercises as in a classical education. Let us enter those academies where the way to a complete education leads not through the thorny and rugged paths of classical literature; let us attend to the exercises which the polite teachers cause their pupils to perform. Do they insist on laborious industry or intense application? No; they can communicate knowledge without requiring laborious study. They profess to allow their pupils to enjoy the sweets of idleness, and yet render them prodigies of learning. But are their magnificent promises ever fulfilled? Do they indeed cultivate the understandings of the young people intrusted to their care? They do not: their care is never once directed to this important object. To adorn them with showy and superficial qualities, is all that those gentlemen aim at. Hence, when their pupils come to enter the world and engage in the duties of active life, they appear destitute of every manly qualification. Though they have attained the age, and grown up to the size of manhood, their understandings are still childish and feeble: they are capricious, unsteady, incapable of industry or fortitude, and unable to pursue any particular object with keen, unremitting perseverance. That long series of study and regular application, which is requisite in order to attain skill in the ancient languages, produces much happier effects on the youthful mind. The power of habit is universally felt and acknowledged. As he who is permitted to trifle away the earliest part of his life in idleness or in frivolous occupations, can scarce be expected to display any manly or vigorous qualities when he reaches a more mature age; so, on the contrary, he whose earlier days have been employed in exercising his memory and furnishing it with valuable treasures, in cultivating his judgment and reasoning powers by calling the one to make frequent distinctions between various objects, and the other to deduce many inferences from the comparison of the various objects presented to the understanding, and also in strengthening and improving the acuteness of his moral powers by attending to human actions and characters, and distinguishing between them, as virtuous or vicious, as mean or glorious: he who has thus cultivated his powers, may be naturally expected to distinguish himself when he comes to perform his part in active life, by prudence, activity, firmness, perseverance, and most of the other noble qualities which can adorn a human character. But in the course of a classical education, the powers of the mind receive this cultivation; and therefore these happy effects may be expected to follow from it. The repetitions which are required afford improving exercise to the memory, and store it with the most valuable treasures; the powers of the understanding are employed in observing the distinctions between words; in tracing words to the substances and qualities in nature which they are used to represent; in comparing the words and idioms of different languages, and in tracing the laws of their analogy and construction; while our moral faculties are at the same time improved by attending to the characters which are described, and the events and actions which are related, in those books which we are directed to peruse in order to acquire the ancient languages. We assert therefore that the study of the ancient languages is particularly useful for improving and strengthening all the powers of the mind; and by that means, for preparing us to act our part in life in a becoming manner: and this our readers will readily agree with us in considering as a weighty argument in behalf of that plan of education.

68
Fund of useful and elegant knowledge which ancient authors afford.

But if, after all, classical learning is still to be given up, where shall we find the same treasures of moral wisdom, of elegance, and of useful historical knowledge which the celebrated writers of Greece and Rome afford? Will you content yourself with the modern writers of Italy, France, and England? Or will you deign to survey the beauties of Homer and Virgil through the medium of a translation? No surely; let us penetrate to those sources from which the modern writers have derived most of the excellencies which recommend them to our notice; let us disdain to be imposed upon by the whims or the ignorance of a translator.

Juvat integros accedere fontes.

Farther, classical learning has long been cultivated among us; and both by the stores of knowledge which it has conveyed to the mind, and the habits which it has impressed, has contributed in no small degree to form many illustrious characters. In reviewing the annals of our country, we will scarce find an eminent politician, patriot, general, or philosopher, during the two last centuries, who did not spend his earlier years in the study of the classics.

Yet though we have mentioned these things in favour of classical literature, and were we to descend to minute particulars might enumerate many more facts and circumstances to recommend it; we mean not to argue that it is absolutely impossible to be a wise, a great, or a good man, unless you are skilled in Greek and Latin. Means may, no doubt, be adopted to inspire the young mind with virtuous dispositions, to call forth the powers of the youthful understanding, and to impress habits of industry and vigorous perseverance, without having recourse to the discipline of a grammar school. But we cannot help thinking, for the reasons which we have stated to our readers, that a classical education is the most likely to produce these happy effects.

As we are afterwards to take particular notice of the course of education most suitable for those who are to occupy the humble stations in society, we shall not here inquire whether it be proper to introduce them to an acquaintance with the Greek and Latin classes.

VI. *On the Education of People of Rank and Fortune.*

69 Duties of people of rank.

THOSE whom the kindness of providence has placed in an elevated station, and in affluent circumstances, so that they seem to be born rather to the enjoyment of wealth and honours than to act in any particular profession or employment, have notwithstanding a certain part assigned them to perform, and many important duties to fulfil. They are members of society, and enjoy the protection of the civil institutions of that society to which they belong; they must therefore contribute what they can to the support of those institutions. The labours of the industrious poor are necessary to supply them with the luxuries of life; and they must know how to distribute their wealth with prudence and generosity among the poor. They enjoy much leisure; and they ought to know how to employ their leisure hours in an innocent and agreeable manner. Besides, as their circumstances enable them to attract the regard and respect of those who are placed in inferior stations, and as the poor are ever ready to imitate the conduct of their superiors; it is necessary that they endeavour to adorn their wealth and honours by the most eminent virtues, in order that their example may have a happy influence on the manners of the community.

70 How to form the temper of a young man of fortune.

Their education ought therefore to be conducted with a view to those ends. After what we have urged in favour of a classical education, our readers will naturally presume that we regard it as highly proper for a man of fortune. The youth who is destined to the enjoyment of wealth and honours, cannot spend his earlier years more advantageously than in gaining an acquaintance with the elegant remains of antiquity. The benefits to be derived from classical learning are particularly necessary to him. Care must be taken to preserve him from acquiring a haughty, fierce, imperious temper. The attention usually paid to the children of people of fortune, and the foolish fondness with which they are too often treated, have a direct tendency to inspire them with high notions of their own importance, and to render them passionate, overbearing, and conceited. But if their temper acquire that bias even in childhood, what may be expected when they advance towards manhood, when their attention is likely to be oftener turned to the dignity and importance of that rank which they occupy, and to the pitiful humility of those beneath them? Why, they are likely to be so proud, insolent, resentful, and revengeful, as to render themselves disagreeable and hateful to all who know them: and besides, to be incapable of those delightful feelings which attend humane, benevolent, and mild dispositions. Let the man of fortune, therefore, as he is concerned for the future happiness and dignity of his child, be no less careful to prevent him from being treated in such a manner as to be inspired with haughtiness, caprice, and insolence, than to prevent his mind from being soured by harsh and tyrannical usage.

The manly exercises, as they are favourable to the health, the strength, and even the morals; so they are highly worthy of engaging the attention of the young gentleman. Dancing, fencing, running, horsemanship, the management of the musket, and the motions of military discipline, are none of them unworthy of occupying his time at proper seasons. It is unnecessary to point out the advantages which he may derive from dancing; these seem to be pretty generally understood. Perhaps our men of fortune would be ashamed to make use of their legs for running; but occasions may occur, on which even this humble accomplishment may be useful. Though we wish not to see the young man of fortune become a jockey; yet to be able to make a graceful appearance on horseback, and to manage his horse with dexterity, will not be unworthy of his station and character. If times of public danger should arise, and the state should call for the services of her subjects against any hostile attack, they whose rank and fortune place them in the most eminent stations will be first expected to stand forth; but if unacquainted with those exercises which are connected with the military art, what a pitiful figure must they make in the camp, or on the field of battle?

71 Law.

As the man of fortune may perhaps enjoy by hereditary right, or may be called by the voice of his fellow citizens, to a seat among the legislative body of his country; he ought in his youth to be carefully instructed in the principles of her political constitution, and of those laws by which his own rights and the rights of his fellow citizens are determined and secured.

72 Philosop

Natural philosophy, as being both highly useful and entertaining, is well worthy of the attention of all who can afford to appropriate any part of their time to scientific pursuits; to the man of fortune a taste for natural philosophy might often procure the most delightful entertainment. To trace the wonders of the planetary systems, to mark the process of vegetation, to examine all the properties of that fine element which we breathe, to trace the laws by which all the different elements are confined to their proper functions, and above all to apply the principles of natural philosophy in the cultivation of the ground, are amusements which might agreeably and innocently occupy many of the leisure hours of the man who enjoys a splendid and independent fortune.

73 History morals.

Neither do we suppose civil history and the principles of morals to be overlooked. Without being acquainted with these, how could any just or accurate knowledge of the laws and political constitution of his country be acquired by the young gentleman? History exposes to our observation the fortune and the actions of other human beings, and thus supplies in some measure the place of experience; it teaches prudence, and affords exercise to the moral sense. When history condescends to take notice of individuals, they are almost always such as have been eminent for virtue, for abilities, or for the rank which they held in life; to the rich and great it ought to speak with peculiar efficacy, and they ought to be carefully invited to listen to its voice.

Such then is the manner in which we wish the education of young men of rank and fortune to be conducted,

ducted, in order that they may be prepared for enjoying their opulence and honours with becoming dignity. Let them be early inured to habits of vigorous industry and persevering firmness, by passing through a regular course of classical learning in a free school; let them play and converse with their equals, and not be permitted to form high ideas of their own importance, nor to domineer over servants or inferiors: Let them be carefully instructed in the principles of morality and religion: Let them be taught the manly exercises: Let them be carefully informed of the nature of the political constitution of their country, and of the extent of those civil and political rights which it secures to them and their fellow citizens: Let them be called to trace the annals of mankind through the records of history; to mark the appearances and operations of nature, and to amuse themselves by pursuing these to their general causes. We say nothing of causing the young man of fortune to learn some mechanical art: We think skill in a mechanical art might now and then afford him an innocent and pleasing amusement; but we do not consider it as absolutely necessary, and therefore do not insist on his acquiring it. With those accomplishments we hope he might become an useful member of society, might adorn the rank and fortune to which he is born, and might find wealth and high station a blessing, not a curse. It is peculiarly unfortunate for our age and country, that people of rank and fortune are not so studious that their children acquire these as the more superficial accomplishments.

VII. *On the Education of People designed for a Mercantile Employment, and for the humbler Occupations in Life not particularly connected with Literature.*

Were modern literature in a less flourishing state; were the English and French languages adorned with fewer eminent poetical, historical, and philosophical compositions; we might perhaps insist on it as necessary to give the boy, who is designed for a mercantile employment, a classical education. At present this does not appear absolutely necessary; yet we do

4 Elegant literature. not presume to forbid it as improper. Even the merchant will scarce find reason to repent his having been introduced to the acquaintance of Plato and Cicero. But still, if the circumstances of the parent, or any other just reason, should render it inconvenient, to send the young man who is intended for trade to a free school to study the ancient languages, means may be easily adopted to make up for his loss. Confine him not to writing and accounts alone. These, though particularly useful to the merchant, have no great power to restrain the force of evil passions, or to inspire the mind with generous and virtuous sentiments. Though you burden him not with Latin and Greek, yet strive to inspire him with a taste for useful knowledge and for elegant literature. Some of the purest and most elegant of our poets, the excellent periodical works which have appeared in our language, such as the Spectator, the Adventurer, the Mirror, and the compositions of our British historians, together with some of the best translations of the classics which we possess; these you may with great propriety put into his hands. They will teach him how to think and reason justly, and to express himself in conversation or in writing with correctness and elegance: they will refine and polish his mind, and raise him above low and gross pleasures. And as no man, who has any occasion to speak or write, ought to be entirely ignorant of the principles of grammar, you will therefore be careful to instruct the young man who is designed for a mercantile occupation in the grammar of his mother tongue.

75 Integrity. A sacred regard to his engagements, and an honesty which may prevent him from taking undue advantages or exacting unreasonable profits, are the virtues which a merchant is most frequently called to exercise: punctuality and integrity are the duties most particularly incumbent on the mercantile profession. Temptations will now and then arise to seduce the merchant to the violation of these. But if superior to every such temptation, he is one of the most illustrious characters, and is likely to be one of the most successful merchants. From his earliest years, then, labour to inspire the child whom you intend for trade with a sacred regard for truth and justice: let him be taught to view deceit and fraud, and the violation of a promise, with abhorrence and disdain. Frugality is a virtue which, in the present age, seems to be antiquated or proscribed. Even the merchant often appears better skilled in the arts of profusion than in those of parsimony. The miser, a character at no time viewed as amiable, is at present beheld with double detestation and contempt. Yet, notwithstanding these unfavourable circumstances, fear not to impress upon the young merchant habits of frugality. Let him know the folly of beginning to spend a fortune before he have acquired it. Let him be taught to regard a regular attention to confine his expences within due bounds, as one of the first virtues which can adorn his character.

76 Industry. Frugality and industry are so closely connected, that when we recommend the one of them to the merchant, we will be naturally understood to recommend the other also. It is easy to see, that without industrious application, no man can reasonably expect to meet with success in the occupation in which he engages; and if the merchant thinks proper to leave his business to the management of clerks and shop-keepers, it is not very probable that he will quickly accumulate a fortune. It is, therefore, no less necessary, that he who is intended for trade be early accustomed to habits of sober application, and be carefully restrained from volatility and levity, than that he be instructed in writing, arithmetic, and keeping of accounts.

With these virtues and qualifications the merchant is likely to be respectable, and not unsuccessful, while he continues to prosecute his trade: and if, by the blessing of Providence, he be at length enabled to accumulate a moderate fortune, his acquaintance with elegant literature, and the various habits which he has acquired, will enable him to enjoy it with taste and dignity. Indeed, all the advantages which a man without taste, or knowledge, or virtue, can derive from the possession of even the most splendid fortune, are so inconsiderable, that they can be no adequate reward for the toil which he undergoes, and the mean arts which he practises in acquiring it. At the head of a great fortune a fool can only make himself more ridiculous, and a man of a wicked

wicked and vicious character more generally abhorred, than if fortune had kindly concealed their crimes and follies by placing them in a more obscure station.

77 Education of persons in the lowest ranks.

A considerable part of the members of society are placed in such circumstances, that it is impossible for them to receive the advantages of a liberal education. The mechanic and the husbandman, who earn a subsistence by their daily labour, can seldom afford, whatever parental fondness may suggest, to favour their children with many opportunities of literary instruction. Content if they can provide them with food and raiment till such time as they acquire sufficient strength to labour for their own support, parents in those humble circumstances seldom think it necessary that they should concern themselves about giving their children learning. Happily it is not requisite that those who are destined to spend their days in this low sphere should be furnished with much literary or scientific knowledge. They may be taught to read their mother tongue, to write, and to perform some of the most common and the most generally useful operations of arithmetic: for without an acquaintance with the art of reading, it will scarce be possible for them to acquire any rational knowledge of the doctrines and precepts of religion, or of the duties of morality; the invaluable volume of the sacred Scriptures would be sealed to them: we may allow them to write, in order that they may be enabled to enjoy the sweet satisfaction of communicating accounts of their welfare to their absent friends; and, besides, both writing and arithmetic are necessary for the accomplishment of those little transactions which pass among them. It would be hard, if even the lowest and poorest were denied these simple and easily acquired branches of education; and happily that degree of skill in them which is necessary for the labourer and the mechanic may be attained without greater expence than may be afforded by parents in the meanest circumstances. Let the youth who is born to pass his days in this humble station, be carefully taught to consider honest patient industry as one of the first of virtues: let him be taught to regard the sluggard as one of the most contemptible of characters: teach him contentment with his lot, by letting him know that wealth and honour seldom confer superior happiness: Yet scruple not to inform him, that if he can raise himself above the humble condition to which he was born, by honest arts, by abilities virtuously exerted, he may find some comfort in affluent circumstances, and may find reason to rejoice that he has been virtuous, industrious, and active. In teaching him the principles of religion, be careful to show him religion as intimately connected with morality: teach him none of those mysterious doctrines, whose sole tendency is to foster that enthusiasm which naturally prevails among the vulgar, and to persuade them that they may be pious without being virtuous. Labour to inspire him with an invincible abhorrence for lying, fraud, and theft. Inspire him with a high esteem for chastity, and with an awful regard to the duties of a son, a husband, and a father. Thus may he become respectable and happy, even in his humble station and indigent circumstances; a character infinitely superior, in the eyes of both God and man, to the rich and great man who misemploys his wealth and leisure in shameful and vicious pursuits.

VIII. *On the Education of the Female Sex.*

The abstracts which we have given of some of the most celebrated and original treatises on education, as well as our own observations on this subject, have been hitherto either relative to the education of both sexes, or directed chiefly to the education of the male sex. But as there is a natural difference between the characters of the two sexes, and as there are certain duties peculiar to each of them; it is easy to see that the education of the boy and that of the girl cannot, ought not, to be conducted precisely in the same manner. And since the duties of the female sex are so important to society, and they form so considerable a part of our species, their education, therefore, merits the highest attention.

78 Similari of the ch racters o both sexe in the fi period of life.

In infancy, the instincts, the dispositions, and the faculties of boys and girls seem to be nearly the same. They discover the same curiosity, and the same disposition to activity. For a while they are fond of the same sports and amusements. But by and by, when we begin to make a distinction in their dress; when the girl begins to be more confined to a sedentary life under her mother's eye, while the boys are permitted to ramble about without doors; the distinction between their characters begins to be formed, and their taste and manners begin to become different. The boy now imitates the arts and the active amusements of his father; digs and plants a little garden, builds a house in miniature, shoots his bow, or draws his little cart; while the girl, with no less emulation, imitates her mother, knits, sews, and dresses her doll. They are no longer merely children; the one is now a girl, the other a boy. This taste for female arts, which the girl so easily and naturally acquires, has been judiciously taken notice of by Rousseau, as affording a happy opportunity for instructing her in a very considerable part of those arts which it is proper to teach her. While the girl is busied in adorning her doll, she insensibly becomes expert at needle work, and learns how to adjust her own dress in a becoming manner. And therefore, if she be kindly treated, it will not be a matter of difficulty to prevail with her to apply to these branches of female education. Her mother or governess, if capable of managing her with mildness and prudence, may teach her to read with great facility. For being already more disposed to sedentary application than the boy of the same age, the confinement to which she must submit in order to learn to read will be less irksome to her. Some have pretended that the reasoning powers of girls begin to exert themselves sooner than those of boys. But, as we have already declared our opinion, that the reasoning powers of children of both sexes begin to display themselves at a very early period; so we do not believe that those of the one sex begin to appear or attain maturity, sooner than those of the other. But the different occupations and amusements in which we cause them to engage from their earliest years, naturally call forth their powers in different manners, and perhaps cause the one to imitate our modes of speaking and behaviour sooner than the other. However, as we wish both boys and girls to learn the art of reading at a very early age, even as soon as they are capable of any

any serious application; so we wish girls to be taught the art of writing, arithmetic, and the principles of religion and morals, in the same order in which these are inculated on boys.

We need not point out the reasons which induce us to regard these as accomplishments proper for the female sex: they seem to be generally considered as not only suitable, but necessary. It is our most important privilege, as beings placed in a situation different from that of the inferior animals, that we are capable of religious sentiments and religious knowledge; it therefore becomes us to communicate religious instruction with no less assiduity and care to the youth of the female sex, than to those of our own. Besides, as the care of children during their earlier years belongs in a particular manner to the mother; she, therefore, whom nature has destined to the important duties of a mother, ought to be carefully prepared for the proper discharge of those duties, by being accurately instructed, in her youth, in such things as it will be afterwards requisite for her to teach her children.

Erudition, ow far be-oming in adies

Ladies have sometimes distinguished themselves as prodigies of learning. Many of the most eminent geniuses of the French nation have been of the female sex. Several of our countrywomen have also made a respectable figure in the republic of letters. Yet we cannot approve of giving girls a learned education. To acquire the accomplishments which are more proper for their sex, will afford sufficient employment for their earlier years. If they be instructed in the grammar of their mother tongue, and taught to read and speak it with propriety; be taught to write a fair hand, and to perform with readiness the most useful operations of arithmetic: if they be instructed in the nature of the duties which they owe to God, to themselves, and to society; this will be almost all the literary instruction necessary for them. Yet we do not mean to forbid them an acquaintance with the literature of their country. The periodical writers, who have taught all the duties of morality, the decencies of life, and the principles of taste, in so elegant and pleasing a manner, may with great propriety be put into the hands of our female pupil. Neither will we deny her the historians, the most popular voyages and travels, and such of our British poets as may be put into her hands without corrupting her heart or inflaming her passions. But could our opinion or advice have so much influence, we would endeavour to persuade our countrymen and countrywomen to banish from among them the novelists, those panders of vice, with no less determined severity than that with which Plato excludes the poets from his republic, or that with which the converts to Christianity, mentioned in the Acts, condemned their magical volumes to the flames. Unhappily, novels and plays are almost the only species of reading in which the young people of the present age take delight; and nothing has contributed more effectually to bring on that dissoluteness of manners which prevails among all ranks.

80 namental accomplishments.

81 Dancing.

But we will not discover so much austerity as to express a wish that the education of the female sex should be confined solely to such things as are plain and useful. We forbid not those accomplishments which are merely ornamental, and the design of which is to render them amiable in the eyes of the other sex. When we consider the duties for which they are destined by nature, we find that the art of pleasing constitutes no inconsiderable part of these; and it would be wrong, therefore, to deny them those arts, the end of which is to enable them to please. Let them endeavour to acquire taste in dress: to dress in a neat graceful manner, to suit colours to her complexion, and the figure of her clothes to her shape, is no small accomplishment for a young woman. She who is rigged out by the taste and dexterity of her maid and her milliner, is nothing better than a doll sent abroad to public places as a sample of their handywork. Dancing is a favourite exercise: nay, we might almost call it the favourite study of the fair sex: So many pleasing images are associated with the idea of dancing; dress, attendance, balls, elegance and grace of motion irresistible, admiration, and courtship: and these are so early inculcated on the young by mothers and maids, that we need not be surprised if little Miss consider her lesson of dancing as a matter of much more importance than either her book or sampler. And indeed, though the public in general seem at present to place too high a value on dancing; and though the undue estimation which is paid to it seems owing to that taste for dissipation, and that rage for public amusements, which naturally prevail amid such refinement and opulence; yet still dancing is an accomplishment which both sexes may cultivate with considerable advantage. It has a happy effect on the figure, the air, and the carriage; and we know not if it be not favourable even to dignity of mind: Yet as to be even a first-rate poėt or painter, and to value himself on his genius in these arts, would be no real ornament in the character of a great monarch; so any very superior skill in dancing must serve rather to disgrace than to adorn the lady or the gentleman. There are some arts in which, though a moderate degree of skill may be useful or ornamental, yet superior taste and knowledge are rather hurtful, as they have a tendency to seduce us from the more important duties which we owe to ourselves and to society. Of those, dancing seems to be one: It is said of a certain Roman lady, by an eloquent historian, "that she was more skilled in dancing than became a modest and virtuous woman."

82 Music.

Music, also, is an art in which the youth of the female sex are pretty generally instructed; and if their voice and ear be such as to enable them to attain any excellence in vocal music, it may conduce greatly to increase their influence over our sex, and may afford a pleasing and elegant amusement to their leisure hours. The harpsichord and the spinet are instruments often touched by female hands; nor do we presume to forbid the ladies to exercise their delicate fingers in calling forth the enchanting sounds of these instruments. But still, if your daughter have no voice or ear for music, compel her not to apply to it.

83 Drawing.

Drawing is another accomplishment which generally enters into the plan of female education. Girls are usually taught to aim at some scratches with a pencil: but when they grow up, they either lay it totally aside, or else apply to it with so much assiduity as to neglect their more important duties. We do not consider skill in drawing, any more than skill in poetry, as an accomplishment very necessary for the ladies; yet we agree with Rousseau, that as far as it can contribute to improve their taste in dress, it may not be improper for them

them to pursue it. They may very properly be taught to sketch and colour flowers; but we do not wish them to forget or lay aside this as soon as the drawing-master is dismissed; let them retain it to be useful through life. Though pride can never be lovely, even in the fairest female form; yet ought the young woman to be carefully impressed with a due respect for herself. This will join with her native modesty to be the guardian of her virtue, and to preserve her from levity and impropriety of conduct.

Such are the hints which have occurred to us on the education proper for the female sex, as far as it ought to be conducted in a manner different from that of the male.

IX. *Public and Private Education.*

One question usually discussed by the writers on this subject has not hitherto engaged our attention. It is, Whether it be most proper to educate a young man privately, or send him to receive his education at a public school? This question has been so often agitated, and by people enjoying opportunities of receiving all the information which experience can furnish on the subject, that we cannot be expected to advance any new argument of importance on either side. Yet we may state what has been urged both on the one and the other.

84 Arguments for private education.

They who have considered children as receiving their education in the house and under the eye of their parents, and as secluded in a great measure from the society of other children, have been sometimes led to consider this situation as particularly favourable for their acquiring useful knowledge, and being formed to virtuous habits. Though we reap many advantages from mingling in social life, yet in society we are also tainted with many vices to which he who passes his life in solitary retirement is a stranger. At whatever period of life we begin to mix with the world, we still find that we have not yet acquired sufficient strength to resist those temptations to vice with which we are there assailed. But if we are thus ready to be infected with the contagion of vice, even at any age, no other argument can be necessary to shew the propriety of confining children from those dangerous scenes in which this infection is so easily caught. And whoever surveys the state of morals in a public school with careful and candid attention, even though it be under the management of the most virtuous, judicious, and assiduous teachers, will find reason to acknowledge, that the empire of vice is established there not less fully than in the great world. Nothing, therefore, can be more negligent or inhuman, than for parents to expose their children to those seductions which a great school presents, at a time when they are strongly disposed to imitate any example set before them, and have not yet learned to distinguish between such examples as are worthy of imitation, and those which ought to be beheld with abhorrence. Even when under the parent's eye, from intercourse with servants and visitors their native innocence is likely to suffer considerably. Yet the parent's care will be much more likely to preserve the manners of his child uncorrupted in his own house, than any assiduity and watchfulness of his teachers in a school.

The morals and dispositions of a child ought to be the first objects of our concern in conducting his education: but to initiate him in the principles of useful knowledge is also an important object; and it will be happy, if in a private education virtue be not only better secured, but knowledge also more readily acquired, than in a public. But this actually happens. When one or two boys are committed to the care of a judicious tutor, he can watch the most favourable seasons of communicating instruction; he can awake curiosity and command attention by the gentle arts of insinuation: though he strive not to inflame their breasts with emulation, which leads often to envy and inveterate hatred; yet he will succeed in rendering learning pleasing, by other means less likely to produce unfavourable effects on the temper and dispositions of his pupils. As his attention is not divided among a number, he can pay more regard to the particular dispositions and turn of mind of each of his pupils: he can encourage him who is modest and slow, and repress the quickness and volatility of the other; and he can call forth and improve their powers, by leading them at one time to view the scenes of nature and the changes which she successively undergoes through the varying seasons: at another, to attend to some of the most entertaining experiments of natural philosophy; and again alluring them artfully to their literary exercises. With these he may mix some active games; and he may assume so much of the fondness of the parent, as to join in them with his little pupils. These are certainly circumstances favourable both to the happiness and to the literary improvement of youth; but they are peculiar to a private education. Besides, in a private education, as children spend more of their time with grown-up people than in public; those, therefore, who receive a domestic education, sooner acquire our manner of thinking, of expressing ourselves, and of behaving in our ordinary intercourse with one another. For the very same reason for which girls are often observed to be capable of prudence and propriety of behaviour at an earlier age than boys, those boys who receive a family education will begin sooner to think and act like men, than those who pass their earlier days in a public seminary. And though you educate your son at home, there is no reason why he should be more accustomed to domineer over his inferiors, or to indulge a capricious or inhumane disposition, than if he were brought up among fifty boys, all of the same age, size, and rank, with himself. He may also, in a private education, exercise his limbs with the same activity as in a public one. He cannot indeed engage in those sports for which a party of companions is necessary; but still there are a thousand objects which will call forth his activity: if in the country, he will be disposed to fish, to climb for bird nests, to imitate all that he sees performed by labourers and mechanics: in short, he will run, leap, throw and carry stones, and keenly exert himself in a variety of exercises, which will produce the most favourable effects on the powers both of his mind and body. It may indeed be possible for you to oppose the designs of nature so effectually, if you take pains for that purpose, as to repress the natural activity of your child or pupil, and cause him to pine away his time in listless indolence; but you will thus do violence to his dispositions, as well as to those instincts which nature has for wise purposes implanted in his breast.

And

And the bad consequences which may result from this management are not to be considered as the natural effects of a domestic education, but as the effects of an education carelessly or imprudently conducted.

But there is another consideration which will perhaps be still more likely than any of those which we have hitherto urged, to prevail with the fond parent to give his child a private education. As the infant who is abandoned by its mother to the care of an hireling nurse, naturally transfers its affection from the unnatural parent to the person who supplies her room and performs the duties incumbent upon her; so the boy who is banished from a parent's house at a time when he has scarce begun to know the relation in which he stands to his father and mother, brothers or sisters, soon ceases to regard them with that fondness which he had contracted for them from living in their company and receiving their good offices. His respect, his affection, and his kindness, are bestowed on new objects, perhaps on his master or his companions; or else his heart becomes selfish and destitute of every tender and generous feeling; and when the gentle and amiable affections of filial and fraternal love are thus, as it were torn up by the roots, every evil passion springs up, with a rapid growth, to supply their place. The boy returns afterwards to his father's house: but he returns as a stranger; he is no longer capable of regarding his parents and relations with the same tenderness of affection. He is now a stranger to that filial love which springs up in the breast of the child who is constantly sensible of the tender care of his parents, and spends his earlier years under their roof, in such a manner as to appear the effect of instinct rather than of habit. Selfish views are now the only bond which attaches him to his parents and relations; and by coming under their influence at so early a period of life, he is rendered for ever incapable of all the most amiable virtues which can adorn human nature. Let the parent, therefore, who loves his child, and wishes to obtain from him a mutual return of affection, beware of excluding him from his house, and devolving the sole charge of him upon another, in his childhood.

These views represent a private education as the most favourable to virtue, to knowledge, and to the mutual affection which ought always to unite the parent and his child. But let us now listen to the arguments which are usually urged in behalf of a public education.

rguments r public ucation.

In the first place, it has been asserted, that a public education is much more favourable than a private to the pupil's improvement in knowledge, and much more likely to inspire him with an ardour for learning. In a private education, with whatever assiduity and tenderness you labour to render learning agreeable to your pupil, still it will be but an irksome task. You may confine him to his books but for a very short space in the course of the day, and allow him an alternation of study and recreation. Still, however, you will never be able to render his books the favourite objects of his attention. He will apply to them with reluctance and careless indifference; even while he seems engaged on his lesson, his mind will be otherwise occupied; it will wander to the scenes where he pursues his diversions, and to those objects which have attracted his desires. If the period during which you require his application be extremely short; during the first part of it, he will still be thinking of the amusements from which you have called him, and regretting his confinement; during the last, he will fondly anticipate the moment when he is to be set at liberty, and think of new amusements. Again, if you confine him during a longer period, still more unfavourable effects will follow. Peevishness, dulness, and a determined aversion to all that bears the name of literature, will be naturally impressed on his mind by such treatment. How can it be otherwise? Books possess so few of those qualities which recommend any object to the attention of children, that they cannot be naturally agreeable. They have nothing to attract and detain the eye, the ear, or any of the senses; they present things with which children are unacquainted, and of which they know not the value: children cannot look beyond the letters and words, to the things which these represent; and even though they could, yet it is much more pleasing to view scenes and objects as they exist originally in nature, than to trace their images in a faint and imperfect representation. It is vain, therefore, to hope that children will be prevailed with to pay attention to books by means of any allurements which books can of themselves present. Other means must be used; but those in a private education you cannot command. In a public seminary, the situation of masters with respect to their pupils is widely different. When a number of boys meet together in the same school, each of them soon begins to feel the impulse of a principle which enables the master to command their attention without difficulty, and prompts them to apply with cheerful ardour to tasks which would otherwise be extremely irksome. This principle is a generous emulation, which animates the breast with the desire of superior excellence, without inspiring envy or hatred of a competitor. When children are prudently managed in a great school, it is impossible for them not to feel its impulse. It renders their tasks scarce less agreeable than their amusements, and directs their activity and curiosity to proper objects. View the scholar at a public school, composing his theme, or turning over his dictionary; how alert! how cheerful! how indefatigable! He applies with all the eagerness, and all the perseverance, of a candidate for one of the most honourable places in the temple of fame. Again, behold and pity that poor youth who is confined to his chamber with no companion but his tutor; none whose superiority can provoke his emulation, or whose inferiority might flatter him with thoughts of his own excellence, and thus move him to preserve by industrious application the advantages which he has already gained. His book is before him; but how languid, how listless his posture! how heavy and dull his eye! Nothing is expressed in his countenance but dejection or indignation. Examine him concerning his lesson; he replies with confusion and hesitation. After a few minutes observation, you cannot fail to be convinced that he has spent his time without making any progress in learning; that his spirits are now broken, his natural cheerfulness destroyed; and his breast armed with invincible prejudices against all application in the pursuit of literary knowledge. Besides, in a school there is something more than emulation to render learning

ing less disagreeable than it naturally is to children. The slightest observation of life, or attention to our own conduct in various circumstances, will be sufficient to convince us, that whenever mankind are placed in circumstances of distress, or subjected to any disagreeable restraint, that which a single person bears with impatience or dejection will make a much less impression on his mind if a number of companions be joined with him in his suffering or restraint. It is esteemed a piece of much greater severity to confine a prisoner in a solitary cell, than where he is permitted to mix with others in the same uncomfortable situation. A journey appears much less tedious to a party of travellers, than to him who beats the path alone. In the same manner, when a number of boys in a great school are all busied on the same or on similar tasks, a spirit of industry and perseverance is communicated from one to another over the whole circle; each of them insensibly acquires new ardour and vigour; even though he feel not the spur of emulation, yet, while all are busy around him, he cannot remain idle. These are facts obvious to the most careless observer.

Neither are public schools so unfavourable to the virtue of their members as they have been represented to be. If the masters are men of virtue and prudence, careful to set a good example before their pupils, attentive to the particular character and behaviour of each individual among them, firm to punish obstinate and incorrigible depravity, and even to expel those who are more likely to injure the morals of others than to be reclaimed themselves, and at the same time eager to applaud and to encourage amiable and virtuous dispositions wherever they appear; under the government of such masters, a public school will not fail to be a school of virtue. There will no doubt be particular individuals among the pupils of such a seminary, whose morals may be corrupt and their dispositions vicious; but this, in all probability, will arise from the manner in which they were managed before entering the school, or from some other circumstances, rather than from their being sent for their education to a public school. Again, at a public school, young people enjoy much greater advantages for preparing them to enter the world, than they can possibly be favoured with if brought up in a private and solitary manner. A great school is a miniature representation of the world at large. The objects which engage the attention of boys at a school are different from those which occupy their parents; the views of the boys are less extensive, and they are not yet capable of prosecuting them by so many base and mean arts: but, in other respects, the two scenes, and the actors upon them, nearly resemble each other; on both you behold contending passions, opposite interests, weakness, cunning, folly, and vice. He therefore who has performed his part on the miniature scene, has rehearsed as it were for the greater; if he has acquitted himself well on the one, he may be also expected to distinguish himself on the other; and even he who has not distinguished himself at school, at least enters the world with superior advantages when viewed in comparison with him who has spent his earlier days in the ignorance and solitude of a private and domestic education. Besides, when a number of boys meet at a public seminary of education, separated from their parents and relations; nearly of the same age, engaged in the same studies, and fond of the same amusements; they naturally contract friendships with one another which are more cordial and sincere than any that take place between persons farther advanced in life. A friendship is often formed between two boys at school which continues through life, and is productive of the happiest consequences to each of them. While at school, they mutually assist and encourage each other in their learning; and their mutual affection renders their tasks less burdensome than they might otherwise find them. As they advance in life, their friendship still continues to produce happy effects on their sentiments and conduct: perhaps they are mutually useful to each other by interest or by personal assistance in making their way in the world; or when they are engaged in the cares and bustle of life, their intercourse and correspondence with each other may contribute much to console them amid the vexations and fatigues to which they may be exposed.

Such are the chief arguments usually adduced in favour of a public education. When we compare them with those which have been urged to recommend a private education, we shall perhaps find that each has its peculiar advantages. A public education is the more favourable to the acquisition of knowledge, to vigour of mind, and to the formation of habits of industry and fortitude. A private education, when judiciously conducted, will not fail to be peculiarly favourable to innocence and to mildness of disposition; and notwithstanding what has sometimes been advanced by the advocates for a public education, it is surely better to keep youth at a distance from the seductions of vice till they be sufficiently armed against them, than to expose them to them at an age when they know not to what dangers they lead, and are wholly unable to resist them. Were we to give implicit credit to the specious talk of the two parties, either a private or a public education would form characters more like to angels than to those men whom we ordinarily meet in the world: but they speak with the ardour of enthusiasts; and therefore we must listen with caution both to the facts which they adduce, and to the inferences which they draw. Could we, without exposing children to the contagion of a great town, procure for them the advantages of both a public and a private education at the same time, we would by this means probably succeed best in rendering them both respectable scholars and good men. If we may presume to give our opinion freely, we would advise parents never, except when some unavoidable necessity of circumstances obliges them, to expel their children from under their own roof till they be advanced beyond their boyish years: let the mother nurse her own child; let her and the father join in superintending its education: they may then expect to be rewarded, if they have acted their parts aright, by commanding the gratitude, the affection, and the respect of their child, while he and they continue to live together. Let matters be so ordered, that the boy may reside in his father's house, and at the same time attend a public school: but let the girl be educated wholly under her mother's eye.

X. On

X. *On Travel.*

ANOTHER question which has been often discussed comes here under our review. The philosophers of ancient Greece travelled in search of knowledge. Books were then scarce, and those few which were to be obtained were no very rich treasuries of useful information. The rhapsodies of a poet, the rude legends of some ill-informed and fabulous historian, or the theories of fanciful philosophers, were all that they could afford. Thales, Lycurgus, Solon, Plato, travelled, seeking that knowledge among more civilized nations which they could not find in their native country. In the course of their travels, they heard the lectures of celebrated philosophers; consulted the priests, who were the guardians of the traditions of antiquity, concerning the nature and origin of those traditions; and observed the institutions of those nations which were most renowned for the wisdom of their legislature. When they set out to visit foreign countries, they seemed to have proposed to themselves a certain end; and by keeping that end steadily in view during the course of their travels, they gained such improvement as to be able on their return to command the veneration of their countrymen by means of the knowledge which they were enabled to communicate. Many besides the philosophers of ancient Greece have travelled for improvement, and have succeeded in their views. But ancient history does not relate to us, that travelling was considered by the Greeks or Romans as necessary to finish the education of their young men of fortune before they entered the scenes of active life. It is true, after Greece became a province of the Roman empire, and the Romans began to admire the science and elegance of Greece, and to cultivate Grecian literature, the young noblemen of Rome often repaired to Rhodes and Athens to complete their studies under the masters of philosophy and eloquence who taught in those cities. But they went thither with the same views with which our youth in modern times are sent to free schools and universities, not to acquire knowledge by the observation of nature, of the institutions, manners, and customs of nations; but merely to hear lectures, read books, and perform exercises. In modern times, a few men of reflection and experience have now and then travelled for improvement: but the greatest part of our travellers, for a long time, were enthusiastic devotees who went in pilgrimage to visit the shrine or relics of some favourite saint; soldiers, who wandered over the earth to destroy its inhabitants; or merchants, whose business as factors between widely distant countries and nations, led them to brave every danger in traversing from one corner of the globe to another. But since the nations of modern Europe have begun to emerge from rudeness, ignorance, and servile depression, they have formed one great commonwealth, the members of which are scarce less intimately connected with each other than were the states of ancient Greece. The consequence of this mutual connexion and dependence is, that almost all the nations of Europe have frequent intercourse with one another; and as some of them are, and have long been, more enlightened and refined than others, those nations who have attained the highest degree of civilization and refinement have naturally attracted the admiration and homage of the rest. Their language has been studied, their manners and arts have been adopted, and even their dress has been imitated. Other nations have thronged to pay the homage due to their superior merit, and to study under them as masters. Hence has arisen the practice which at present prevails among us of sending our youth to complete their education by travelling, before we introduce them to active life, or require them to engage in business. Formerly young men were not sent to travel till after they had proceeded through the forms of a regular education, and had at least attained such an age that they were no longer to be considered as mere boys. But the progress of luxury, the desire of parents to introduce their children into the world at an early age, that they may early attain to wealth and honours, and various other causes, have gradually introduced the practice of sending mere boys to foreign countries, under pretence of affording them opportunities of shaking off prejudices, of storing their minds with truly useful knowledge, and of acquiring those graceful manners and that manly address which will enable them to acquit themselves in a becoming manner when they are called to the duties of active life. How much travelling at such an early age contributes to fulfil the views of parents, a slight survey of the senate-house, the gambling-houses, the race-course, and the cockpit, will convince the sagacious observer.

But we wish to foster no prejudices against neighbouring nations; we entertain no such prejudices in favour of Britain, as to wish to confine our countrymen within the sea-girt isle. Let us inquire what advantages may be gained by travelling, and at what age it may be most proper to set out in pursuit of those advantages.

88
Travel necessary to the acquisition of knowledge.

After all that bookish men have urged, and notwithstanding all that they may continue vehemently to urge, in behalf of the knowledge to be derived from their beloved books; it must still be acknowledged, that books can teach us little more than merely the language of men. Or, if we should grant that books are of higher importance, and that language is the least valuable part of the knowledge which they teach, yet still we need to beware that they lead us not astray; it is better to examine nature with the naked eye, than to view her through the spectacles of books. Neither the theories nor experiments of philosophers, nor the narratives of travellers, nor the relations of historians, though supported by a numerous train of authorities, are worthy of implicit credit. You retire from the world, confine yourself for years to your closet, and read volume after volume, historians, philosophers, and poets; at last you fancy that you have gained an immense store of knowledge: But leave your retirement, return into the world, compare the knowledge which you have treasured up with the appearances of nature; you will find that you have laboured in vain, that it is only the semblance of knowledge which you have acquired, and will not serve for a faithful guide in life, nor even enable you to distinguish yourself for literary merit. Compare the relations of travellers with one another; how seldom do they agree when they describe the same scenes and the same people! Turn your attention to the most respectable historians, compare their accounts of the same events; what disagreement! what contrariety! Where shall truth be found? Listen to the cool, the candid philosophers; what contradictory theories do they build on the same system of facts!

We agree, then, that it is better to seek knowledge by actual observation and experiment, than to receive it at second hand from the information of others. He who would gain an acquaintance with the beauties of external nature, must view them with his own eyes; he who would know the operations of the human understanding, must reflect upon what passes in his own mind; he who would know the customs, opinions, and manners of any people, must mingle with them, must observe their conduct, and listen to their conversation. The arts are acquired by actual practice; the sciences by actual observation in your own person, and by deducing inferences from your observations.

If therefore to extend our knowledge can contribute in any degree to render us happier, wiser, or better; travelling, as being more favourable to knowledge than the study of books, must be highly advantageous. Get well acquainted with your own country; with the manners, the customs, the laws, and the political situation of your countrymen: Get also a knowledge of books; for books would not be altogether useless, though they could serve no other purpose but to teach us the language in which mankind express themselves: And then, if your judgment have attained maturity; if curiosity prompt you; if your constitution be robust and vigorous, and your spirits lively; you may imitate the Solons, Homers, and Platos, of old, and visit foreign countries in search of knowledge, and with a view to bring home something which may be of real utility to yourself and your country. You will, by this time, be so much master of the language of your own country, that you will not lose it while you are learning the languages of foreign nations; your principles of taste and of right and wrong will be so formed and fixed, that you will not despise any institution or custom or opinion merely because it prevails not in your own country; nor yet will you be ready to admire and adopt any thing, merely because it prevails among a foreign nation who are distinguished for profound and extensive knowledge, or for elegance of taste and manners. No; you will divest yourself of every prejudice, and judge only by the fixed unalterable principles which determine the distinction between right and wrong, between truth and falsehood, between beauty and deformity, sublimity and meanness. Your object will not be to learn exotic vices, to mingle in frivolous amusements, or to form a catalogue of inns. Your views, your inquiries, will have a very different direction. You will attend to the state of the arts, of the sciences, of morals, manners, and government; you will also contemplate with eager delight, the grand or beautiful scenes of nature, and examine the vegetable productions of the various regions through which you pass, as well as the different tribes of animals which inhabit them; you will observe what blessings the beneficence of nature has conferred on the inhabitants of each particular division of the globe, and how far the ingenuity and industry of man have taken advantage of the kindness of nature. Thus surveying the face of the earth, and considering how advantages and disadvantages are balanced with each other, through every various region and climate, from one extremity of the globe to another; you will admire and revere that impartiality with which the Author of nature has distributed his benefits to the whole human race. When from the chilly climes and stubborn soil of the north, you turn your eyes to the fertile genial regions of the south, where every tree is loaded with exquisite fruits, and every vegetable is nourishing and delicious; you will be pleased to find, that the inhabitants of the north, by their superior ingenuity and vigour, are able to raise themselves to circumstances no less comfortable and respectable than those which the nations inhabiting between the tropics enjoy: when you behold the French shaking off the yoke of despotism, and aspiring to the sweets of liberty as well as their British neighbours; you will be pleased to see, that the natural gaiety and cheerfulness of the former nation render them not incapable of the energy of the latter. You will be pleased to view the remains of antiquity, and the noble monuments of art; but you will think it below you to trifle away your time in gazing at palaces and churches, and collecting rusty medals and fragments of marble; you will seek the society of eminent men, and eagerly cultivate an acquaintance with the most distinguished artists and men of science who adorn the nations among whom you may happen to sojourn. Knowing that the knowledge which is to be acquired in great towns, is by no means an adequate compensation for the vicious habits which you are liable to contract in them; and besides, that the luxuries, the arts, the manners, the virtues, and the vices of all great towns are nearly the same, so that when you have seen one, you have seen all others; you will avoid taking up your residence for any considerable time in any of the great towns through which you have occasion to pass in the course of your travels. The traveller who has attained the previous accomplishments which we have mentioned as necessary, who sets out with the views which we have supposed him to entertain, and who conducts his travels in this manner, cannot fail to return home enriched with much useful knowledge; he cannot but derive more real improvement from travelling, than he could have gained by spending the same period of time in solitary study: when he returns to his native country, he will appear among his countrymen as more than a philosopher; a sage, and a benefactor. His knowledge is so extensive and accurate, his views are so liberal and enlarged, and he is so superior to prejudices, without being the enemy of any useful establishments, that he will be enabled to command universal esteem, by performing his part in life with becoming dignity and propriety, and perhaps to render his name illustrious, and his memory dear to future times, by some important services to the community to which he belongs, or even to mankind in general.

But though we have thus far, and we hope for obvious and solid reasons, decided in favour of travelling, as being more likely than a solitary application to books, to furnish the mind with useful and ornamental knowledge; yet we do not see that our British youth either take care to furnish themselves with the previous knowledge which we consider as indispensably necessary in order to prepare them for travelling with advantage, or set out with proper views, or prosecute

secute their travels in a prudent judicious manner. After receiving a very imperfect education, in which religious and moral instruction are almost wholly neglected, and no means are used to inspire the youthful mind with solid, virtuous, manly qualities; but every art is tried to make the young man appear learned, while his mind is destitute of all useful information, and to teach him to assume the confidence of manhood before he has attained even to a moderate degree of sense and prudence;—after an education conducted in this manner, and with these views, the stripling is sent abroad to view the world, and is expected to return home a finished character, an ornament and a comfort to his parents and all his connexions. He is hitherto unacquainted, perhaps, even with the simple events of the history of his native country; and either totally ignorant of classical literature, or but very superficially instructed in it. He has not yet viewed with a discerning eye the manners and customs prevailing among his countrymen; he knows not the nature of the government under which he lives, nor the spirit of those laws by which his civil conduct must be regulated. He has no fixed principles; no clear, distinct views. But to supply all his wants of this nature, he is put into the hands of a travelling governor, who is to be entirely submissive to his will, and yet to serve him both for eyes and intellect. This governor is generally either some macaroni officer, who is considered as well bred, and thought to know the world; or else, perhaps, some cringing son of literature, who, having spent much time among his books, without acquiring such strength or dignity of mind as to raise him above frivolity of manners and conversation or pitiful fawning arts, is therefore regarded as happily qualified for this important charge. This respectable personage and his pupil are shipped off for France, that land of elegant dissipation, frivolity, and fashion. They travel on with eager impatience, till they reach the capital. There the young man is industriously introduced to all the gay scenes which Paris can display. He is, at first, confounded; by and by his senses are fascinated; new desires are awaked in his breast; all around him he sees the sons of dissipation wallowing in debauchery, or the children of vanity fluttering about like so many gaudy insects. The poor youth has no fixed principles: he has not been taught to regard vanity as ridiculous, or to turn from vice with abhorrence. No attempt is made to allure him to these objects, an attention to which can alone render travelling truly beneficial. Hitherto his mind had been left almost wholly uncultivated; and now the seeds of vice are plentifully sown in it. From one great town he is conveyed to another, till he visit almost every place in Europe where profligacy of manners has attained to any uncommon height. In this happy course of education he probably continues to pursue improvement till he is well acquainted with most of the post roads, the principal inns, and the great towns at least in France and Italy; and perhaps till he has worn out his constitution, and rendered his mind totally incapable of any generous sentiments or sober reflection. He then revisits his native country, to the inexpressible happiness of his parents, who now eagerly long to embrace their all-accomplished child. But how miserably are the poor folks disappointed, when they find his constitution wasted, his understanding uninformed, his heart destitute of every manly or generous sentiment: and perceive him to possess no accomplishment, but such as are merely superficial? Perhaps, however, his parents are prevented by their partiality both for their child and for the means which they have adopted in conducting his education, from viewing his character and qualifications in a true light. Perhaps they overlook all his defects, or consider them as ornaments, and regard their dear son as the mirror of perfection. But, unfortunately, though they be blind to the hideous deformity of the monster which they have formed, they cannot hinder it from being conspicuous to others; though they may view their son's character as amiable and respectable, they cannot render it useful, they cannot prevent it from being hurtful to society. Let this youth whose education has been thus wisely conducted, let him be placed at the head of an opulent fortune, advanced to a seat in the legislative body of his country, or called to act in any public character; how will he distinguish himself? As the virtuous patriot, the honest yet able statesman, the skilful general, or the learned upright judge? How will he enjoy his fortune? Will he be the friend of the poor, the steady supporter of the laws and constitution under whose protection he lives? Will he show himself capable of enjoying *otium cum dignitate?* If we reason by the usual laws of probability, we cannot expect that he should: and if we observe the manners and principles of our men of wealth and high birth who have been brought up in this manner, we find our reasonings confirmed.

Such are the opinions which candid observation leads us to entertain with regard to the advantages which may be gained by travelling.

He whose mind has been judiciously cultivated, and who has attained to maturity of judgment, if he set out on his travels with a view to obtain real improvements, and persist invariably in the prosecution of that view, cannot but derive very great advantages from travelling.

But again, those young men whose minds have not been previously cultivated by a judicious education, who set out without a view to the acquisition of real knowledge, and who wander among foreign nations, without attention to any thing but their luxuries, their follies, and their vices, those poor young men cannot gain any real improvement from their travels.

Our countrymen, who travel for improvement, do not appear to derive so much advantage from their travels as were to be wished, because they generally receive too superficial an education, set out at too early a period of life, and direct not their views to objects of real utility and importance.

XI. *On Knowledge of the World, and Entrance into Life.*

90
Unhappy effects of too early introduction into the world.

Much has been said concerning the utility of a knowledge of the world, and the advantage of acquiring it at an early period of life. But those who have the most earnestly recommended this knowledge of the world, have generally explained themselves in so inaccurate a matter concerning it, that it is difficult to understand what ideas they affix to it. They seem to wish,

wish, that, in order to acquire it, young people may be early made acquainted with all the vices and follies of the world, introduced into polite company, carried to public places, and not confined even from the gaming table and the stews. Some knowledge of the world may, no doubt, be gained by these means. But it is surely dearly purchased; nor are the advantages which can be derived from it so considerable, as to tempt the judicious and affectionate parent to expose his child to the infection of vanity, folly, and vice, for their sake. Carry a boy or girl into public life at the age of fourteen or fifteen; show them all the scenes of splendid vanity and dissipation which adorn London or Paris; tell them of the importance of dress, and of the ceremonies of good breeding and the forms of intercourse; teach them that fashionable indifference and assurance which give the *ton* to the manners of our fine gentlemen and fine ladies of the present age. What effects can you expect the scenes into which you introduce them, and the mysteries which you now teach them, to produce on the minds of the children? They have a direct tendency to inspire them with a taste for vanity, frivolity, and dissipation. If you wish them to be like the foolish, the dissipated, and the gay, you are likely to obtain your purpose; but if, on the contrary, your views are to prepare them for discharging the duties of life, you could not adopt more improper means; for though they be well acquainted with all those things on which you place so much value, yet they have not thereby gained any accession of useful knowledge. They are not now more able that before to estimate the real value of objects; nay, their judgment is now more liable than before to be misled in estimating the value of the objects around them. Luxury, vanity, and fashion, have stamped on many things an ideal value. By mingling at an early age in those scenes of the world where luxury, vanity, and fashion, reign with arbitrary away, young people are naturally impressed with all those prejudices which these have a tendency to inspire. Instead of acquiring an useful knowledge of the world, they are rendered incapable of ever viewing the world with an unprejudiced and discerning eye. If possible, therefore, we should rather labour to confine young people from mingling in the scenes of gay and dissipated life till after they have attained maturity of age and judgment. They will then view them in a proper light, and perhaps be happy enough to escape the infectious contagion of vice.

91 What knowle of the world m be safely communi cated t young pe ple.

But there is another and a more valuable knowledge of the world, which we ought industriously to communicate to them as soon as they are capable of receiving it. As soon as they are made thoroughly acquainted with the distinctions between right and wrong, between virtue and vice, between piety and impiety, and have become capable of entering into our reasonings; we ought then to inform them concerning the various establishments and institutions which exist in society; concerning the customs, opinions, and manners of mankind; and concerning the various degrees of strength or weakness of mind, of ingenuity or dulness, of virtuous or vicious qualities, which discriminate those characters which appear in society.

When at length the period arrives at which they must be emancipated from subjection, and committed to the guidance of their own conscience and reason, and of those principles which we have laboured to inculcate on their minds; let us warn them of the dangers to which they are about to be exposed; tell them of the glory and the happiness to which they may attain; inspire them, if possible, with disdain for folly, vanity, and vice, whatever dazzling or enchanting forms they may assume; and then dismiss them to enrich their minds with new stores of knowledge by visiting foreign nations; or, if that should be inconvenient, to enter immediately on the duties of some useful employment in active life. See EDUCATION, SUPPLEMENT.

Edulcoration.

EDULCORATION, properly signifies the rendering substances more mild. Chemical edulcoration consists almost always in taking away acids and other saline substances; and this is effected by washing the bodies to which they adhere in a large quantity of water. The washing of diaphoretic antimony, powder of algaroth, &c. till the water comes off quite pure and insipid, are instances of chemical edulcoration.—In pharmacy, juleps, potions, and other medicines, are said to be *edulcorated*, by adding sugar or syrup.

EDWARD, the name of several kings of England. See (*History of*) ENGLAND.

EDWARDS, GEORGE, fellow of the royal and antiquarian societies, was born at Stratford, a hamlet belonging to Westham in Essex, on the 3d of April 1694. After having spent some time at school, he was put apprentice to a tradesman in Fenchurch street. His master, who was eminent both for his piety and skill in the languages, treated him with great kindness; but about the middle of his apprenticeship, an accident happened which totally put a stop to the hopes of young Edwards's advancing himself in the way of trade. Dr Nicolas, a person of eminence in the physical world, and a relation of his master's, happened to die. The Doctor's books were removed to an apartment occupied by Edwards, who eagerly employed all his leisure hours, both in the day and great part of the night, in perusing those which treated of natural history, sculpture, painting, astronomy, and antiquities. The reading of these books entirely deprived him of any inclination for mercantile business he might have formerly had, and he resolved to travel into foreign countries. In 1716, he visited most of the principal towns in Holland, and in about a month returned to England. Two years after, he took a voyage to Norway, at the invitation of a gentleman who was disposed to be his friend, and who was nephew to the master of the ship in which he embarked. At this time Charles XII. was besieging Fredrickshall; by which means our young naturalist was hindered from making such excursions into the country as otherwise he could have done, for the Swedes were very careful to confine such strangers as could not give

Edwards, Edystone.

give a good account of themselves. But notwithstanding all his precaution, he was confined by the Danish guard, who supposed him to be a spy employed by the enemy to get intelligence of their designs. However, by obtaining testimonials of his innocence, a release was granted. In 1718 he returned to England, and next year visited Paris by the way of Dieppe. During his stay in this country he made two journeys of 100 miles each; the first to Chalons in Champagne, in May 1720; the second on foot, to Orleans and Blois; but an edict happening at that time to be issued for securing vagrants, in order to transport them to America, as the banks of the Mississippi wanted population; our author narrowly escaped a western voyage. On his arrival in England, Mr Edwards closely pursued his favourite study of natural history, applying himself to drawing and colouring such animals as fell under his notice. A strict attention to natural, more than picturesque beauty, claimed his earliest care: birds first engaged his particular attention; and having purchased some of the best pictures of these subjects, he was induced to make a few drawings of his own; which were admired by the curious, who encouraged our young naturalist to proceed, by paying a good price for his early labours. Among his first patrons and benefactors may be mentioned James Theobalds, Esq. of Lambeth; a gentleman zealous for the promotion of science. Our artist, thus unexpectedly encouraged, increased in skill and assiduity; and procured, by his application to his favourite pursuit, a decent subsistence and a large acquaintance. However, he remitted his industry in 1731; when, in company with two of his relations, he made an excursion to Holland and Brabant, where he collected several scarce books and prints, and had an opportunity of examining the original pictures of several great masters at Antwerp, Brussels, Utrecht, and other cities. In December 1733, by the recommendation of the great Sir Hans Sloane, Bart. president of the College of Physicians, he was chosen librarian, and had apartments in the college. This office was peculiarly agreeable to his taste and inclination, as he had the opportunity of a constant recourse to a valuable library, filled with scarce and curious books on the subject of natural history, which he so assiduously studied. By degrees he became one of the most eminent ornithologists in this or any other country. His merit is so well known in this respect, as to render any eulogium on his performances unnecessary: but it may be observed, that he never trusted to others what he could perform himself; and often found it so difficult to give satisfaction to his own mind, that he frequently made three or four drawings to delineate the object in its most lively character, attitude, and representation. In 1743, the first volume of the History of Birds was published in quarto. His subcribers exceeding even his most sanguine expectations, a second volume appeared in 1747. The third volume was published in 1750. In 1751, the fourth volume came from the press. This volume being the last he intended to publish at that time, he seems to have considered it as the most perfect of his productions in natural history; and therefore devoutly offered it up to the great God of nature, in humble gratitude for all the good things he had received from him in this world. Our author, in 1758, continued his labours under a new title, viz. *Gleanings of Natural History*. A second volume of the Gleanings was published in 1760. The third part, which made the seventh and last volume of his works, appeared in 1764. Thus our author, after a long series of years, the most studious application, and the most extensive correspondence to every quarter of the world, concluded a work which contains engravings and descriptions of more than 600 subjects in natural history, not before described or delineated. He likewise added a general index in French and English; which was afterwards perfected, with the Linnæan names, by that great naturalist Linnæus himself, who frequently honoured him with his friendship and correspondence. Some time after Mr Edwards had been appointed library keeper to the Royal College of Physicians, he was, on St Andrew's day, in the year 1750, presented with an honorary compliment by the president and council of the Royal Society, with the gold medal, the donation of Sir Godfrey Copley, Bart. annually given on that day to the author of any new discovery in art or nature, in consideration of his natural history just then completed. A copy of this medal he had afterwards engraved, and placed under the title in the first volume of his history. He was a few years afterwards elected fellow of the Royal Society, and of the Society of Antiquaries, London; and also a member of many of the academies of sciences and learning in different parts of Europe. In compliment to those honorary distinctions from such learned bodies, he presented elegant coloured copies of all his works to the Royal College of Physicians, the Royal Society, and Society of Antiquarians, and to the British museum: also to the Royal Academy of Sciences at Paris, from whom he received the most polite and obliging letter of thanks by their then secretary Monsieur Defouchy. His collection of drawings, which amounted to upwards of 900, were purchased by the earl of Bute. They contain a great number of British as well as foreign birds, and other animals hitherto not accurately delineated or described. After the publication of the last work, being arrived at his 70th near, he found his sight begin to fail, and his hand lost its wonted steadiness. He retired from public employment to a little house which he purchased at Plaistow; previous to which, he disposed of all the copies, as well as plates of his works. The conversation of a few select friends, and the perusal of a few select books, were the amusement of the evening of his life; and now and then he made an excursion to some of the principal cities in England, particularly to Bristol, Bath, Exeter, and Norwich. Some years before his death, the alarming depredation of a cancer, which baffled all the efforts of medical skill, deprived him of the sight of one of his eyes: he also suffered much from the stone, to which at different periods of his life he had been subject. But in the severest paroxysms of pain, he was scarcely known to utter a single complaint. Having completed his 80th year, emaciated with age and sickness, he died, deservedly lamented, on the 23d of July 1772.

EDYSTONE, a lighthouse in the British channel, built on rocks of the same name, which are supposed to have got this appellation from the great variety of contrary sets of the current among them, both upon the tide of flood and the tide of ebb. They are situated nearly south-

south-south-west from the middle of Plymouth sound, according to the true meridian; and the distance, as nearly as can be collected, is 12 miles and a half; and from the same point in the Sound to the Jetty Head, called the Barbican, in the port of Plymouth, is a mile and a half more, which makes the distance of the Edystone from the port of Plymouth to be nearly 14 miles.

"The promontory called Ram Head is the nearest point of land to the Edystone, which bears from thence south scarcely one point west, distant about ten miles, and consequently by the compass is nearly south-west by south.—Those rocks are nearly in a line, but somewhat within that line which joins the *Start* and the *Lizard* Points; and as they lie nearly in the direction of vessels coasting up and down the channel, they must, before a lighthouse was established thereon, have been very dangerous, and often fatal to ships under such circumstances: and many rich ships and other vessels have, in former times, been actually lost upon those rocks, particularly such as were homeward-bound from foreign parts; it being even now a common thing, in foggy and thick hazy weather, for homeward-bound ships from long foreign voyages to make the Edystone lighthouse as the first point of land of Great Britain; so that in the night, and nearly at high water, when the whole range of these rocks is covered, the most careful mariner might run his ship upon them, if nothing was placed there by way of warning.

"The many fatal accidents which so frequently happened, made it a thing very desirable to have a lighthouse built thereon, and that for many years before any competent undertaker appeared. At length, however, we learn, that in the year 1696 Mr Henry Winstanley, of Littlebury in the county of Essex, Gent. was not only hardy enough to undertake it, but was furnished with the necessary powers to put it in execution. This, it is supposed, was done in virtue of the general powers lodged in the master, wardens, and assistants of the Trinity-house at Deptford Strond to erect sea marks, &c. by a statute of Queen Elizabeth, whereby they are impowered 'to erect and set up beacons, marks, and signs for the sea, needful for avoiding the dangers; and to renew, continue, and maintain the same.' But whether Mr Winstanley was a proprietor or sharer of the undertaking under the Trinity-house, or only the directing engineer employed in the execution, does not now appear.

This gentleman had distinguished himself in a certain branch of mechanics, the tendency of which is to raise wonder and surprise. He had at his house at Littlebury a set of contrivances, such as the following:—Being taken into one particular room of his house, and there observing an old slipper carelessly lying on the middle of the floor,—if, as was natural, you gave it a kick with your foot, up started a ghost before you: If you sat down in a certain chair, a couple of arms would immediately clasp you in, so as to render it impossible to disentangle yourself till your attendant set you at liberty: And if you sat down in a certain arbour by the side of a canal, you was forthwith sent out afloat to the middle of the canal, from whence it was impossible for you to escape till the manager returned you to your former place.—Whether those things were shewn to strangers at his house for money, or were done by way of amusement to those that came to visit the place, is uncertain; as Mr Winstanley is said to have been a man of some property: but it is at least certain, that he established a place of public exhibition at Hyde park corner, called *Winstanley's water-works;* which were shewn at stated times at one shilling each person. The particulars of those water-works are not now known; but, according to the taste of the times, we must naturally suppose a great variety of *Jets d'eau*, &c. (A).

"The lighthouse Mr Winstanley built was begun in the year 1696, and was more than four years in building; not (says the architect) for the greatness of the work, but for the difficulty and danger in getting backwards and forwards to the place. The difficulties were many, and the dangers not less. At length, in the third year, all the work was raised, which to the vane was eighty feet. Being all finished, with the lantern, and all the rooms that were in it, they ventured to lodge there soon after midsummer, for the greater dispatch of the work. But the first night the weather came bad, and so continued, that it was eleven days before any boats could come near them again, and not being acquainted with the height of the sea rising, they were almost all the time drowned with wet, and their provisions in as bad a condition, though they worked night and day to make shelter for themselves. In this storm they lost some of their materials, although they did what they could to save them; but the boat then returning, they all left the house to be refreshed on shore; and as soon as the weather permitted, they returned again and finished all, and put up the light on the 14th of November 1698; which being so late in the year, it was three days before Christmas before they had relief to get on shore again, and were almost at the last extremity for want of provisions; but by good providence, then two boats came with provisions, and the family that was to take care of the light.

"The fourth year, finding in the winter the effects the sea had upon the house, and burying the lantern at times, although more than 60 feet high; Mr Winstanley early in the spring encompassed the building with a new work of four feet thickness from the foundation, making all solid near 20 feet high; and taking down the upper part of the first building, and enlarging every part in its proportion, he raised it forty feet higher than it was at first; and yet the sea, in time of storms, flew up in appearance 100 feet (B) above the vane; and at times covered half the side of the house and the lantern as if they were under water.

"On the finishing this building, it was generally said, that in the time of hard weather, such was the height of

---

(A) It appears that the exhibition of these water-works continued some years after the death of Mr Winstanley, as they were existing in the month of September 1709, being mentioned in the Tatler of that date.

(B) Mr Smeaton says this is short of its real height 50 feet.

of the seas, that it was very possible for a six-oared boat to be lifted up upon a wave, and driven through the open gallery of the lighthouse.

"In November 1703, the fabric wanted some repairs, and Mr Winstanley went down to Plymouth to superintend the performance of them. The opinion of the common people was, that the building would not be of long duration. Mr Winstanley, however, held different sentiments. Being amongst his friends previous to his going off with his workmen on account of those reparations, the danger was intimated to him; and it was said, that one day or other the lighthouse would certainly be overset. To this he replied, "He was so well assured of the strength of his building, he should only wish to be there in the greatest storm that ever blew under the face of the heavens, that he might see what effect it would have upon the structure."

"In this wish he was soon gratified; for while he was there with his workmen and light-keepers, that dreadful storm began which raged the most violently upon the 26th November 1703, in the night; and of all the accounts of the kind which history furnishes us with, we have none that has exceeded this in Great Britain, or was more injurious or extensive in its devastation.

"The next morning, when the storm was abated, nothing of the lighthouse was to be seen. The following account of its destruction was printed at the time, by Daniel Defoe, in a book entitled *The Storm.*"

"The loss of the lighthouse called the Edystone, at Plymouth, is another article of which we never heard any particulars, other than this, that at night it was standing, and in the morning all the upper part of the gallery was blown down, and all the people in it perished, and, by a particular misfortune, Mr Winstanley the contriver of it; a person whose loss is very much regretted by such as knew him, as a very useful man to his country. The loss of that lighthouse is also a considerable damage, as it is very doubtful whether it will ever be attempted again; and it was a great security to the sailors, many a good ship having been lost there in former times.

"It was very remarkable, that, as we are informed at the same time the lighthouse aforesaid was blown down, the model of it in Mr Winstanley's house at Littlebury in Essex, above 200 miles from the lighthouse, fell down and was broken to pieces.

"At Plymouth they felt a full proportion of the storm in its utmost fury. The Edystone has been already mentioned; but it was a double loss, in that the lighthouse had not been long down when the *Winchelsea*, a homeward-bound Virginia-man, was split upon the rock where that building stood, and most of her men drowned."

"The great utility of Mr Winstanley's lighthouse had been sufficiently evident to those for whose use it was erected; and the loss of the Winchelsea Virginia-man, before mentioned, proved a powerful incentive to such as were interested, to exert themselves in order for its restoration. It was not, however, begun so soon as might have been expected. In spring of the year 1706, an act of parliament passed enabling the Trinity house to rebuild, but it was no earlier than July that it was begun. The undertaker was a Captain Lovell or Lovett, who took it for the term of ninety-nine years, commencing from the day that a light should be exhibited.

"To enable him to fulfil his undertaking, Captain Lovett engaged Mr John Rudyerd to be his engineer or architect; and his choice, though Mr Rudyerd does not appear to have been bred to any mechanical business or scientifical profession, was not ill made. He at that time kept a linen-draper's shop upon Ludgate-hill. His want of experience, however, was in a degree assisted by Mr Smith and Mr Notcutt, both ship-wrights from the king's yard at Woolwich, who worked with him the whole time he was building the lighthouse.

"It is not very material in what way this gentleman became qualified for the execution of the work: it is sufficient that he directed the performance thereof in a masterly manner, and so as perfectly to answer the end for which it was intended. He saw the errors in the former building, and avoided them: instead of a polygon, he chose a circle for the outline of his building, and carried up the elevation in that form. His principal aim appears to have been use and simplicity; and indeed, in a building so situated, the former could hardly be acquired in its full extent without the latter. He seems to have adopted ideas the very reverse of his predecessor; for all the unwieldy ornaments at top, the open gallery, the projecting cranes, and other contrivances, more for ornament and pleasure than use, Mr Rudyerd laid totally aside: he saw, that how beautiful soever ornaments might be in themselves, yet when they are improperly applied, and out of place, they shew a bad taste, and betray ignorance of its first principle, judgment.

"The building was begun in July 1706, a light was put up in it the 28th July 1708, and it was completely finished in 1709. The quantity of materials expended in the construction, was 500 tons of stone, 1200 tons of timber, 80 tons of iron, and 35 tons of lead; of trenails, screws, and rack-bolts 2500 each.

"Louis XIV. being at war with England during the proceeding with this building, a French privateer took the men at work upon it, together with their tools, and carried them to France; and the captain was in expectation of a reward for the achievement. While the captives lay in prison, the transaction reached the ears of that monarch. He immediately ordered them to be released, and the captors to be put in their place; declaring, that though he was at war with England, he was not at war with mankind; he therefore directed the men to be sent back to their work with presents; observing, that the Edystone lighthouse was so situated, as to be of equal service to all nations having occasion to navigate the channel that divides France from England."

In the year 1715, Captain Lovett being dead, his property in the Edystone lighthouse was sold before a master in chancery to Robert Weston, Esq. —— Noyes, Esq. of Gray's Inn; and —— Cheetham, Esq. an alderman of Dublin, who divided the same into eight shares. After a few years some repairs were found wanting; and in 1723, Mr Rudyerd being, we suppose then dead, Mr John Holland, foreman ship-wright in the dock-yard at Plymouth, became overseer and director of the necessary reparations; which office he again executed in 1734.

Edystone.

"The catastrophe of this light-house took place on the 2d December 1755, when the light-keeper upon watch, about two o'clock in the morning, went into the lantern as usual to snuff the candles; he found the whole in a smoke; and upon opening the door of the lantern into the balcony, a flame instantly burst from the inside of the cupola: he immediately endeavoured to alarm his companions; but they being in bed, and asleep, were not so ready in coming to his assistance as the occasion required. As there were always some leather buckets kept in the house, and a tub of water in the lantern, he attempted to extinguish the fire by throwing water from the balcony upon the outside cover of lead. By this time his companions arriving, he encouraged them to fetch up water with the buckets from the sea; but the height of the place, added to the consternation which must attend such an unexpected event, rendered their efforts fruitless. The flames gathered strength every moment; the poor man with every exertion, having the water to throw four yards higher than himself, found himself unable to stop the progress of the conflagration, and was obliged to desist.

"As he was looking upward with the utmost attention to see the effect of the water thrown, a position which, physiognomists tell us, occasions the mouth naturally to be a little open, a quantity of lead dissolved by the heat of the flames suddenly rushed like a torrent from the roof, and fell upon his head, face, and shoulders, and burnt him in a dreadful manner: from this moment he had a violent internal sensation, and imagined that a quantity of this lead had passed his throat, and got into his body. Under this violence of pain and anxiety, as every attempt had proved ineffectual, and the rage of the flames was increasing, it is not to be wondered that the terror and dismay of the three men increased in proportion; so that they all found themselves intimidated, and glad to make their retreat from the immediate scene of horror into one of the rooms below. They therefore descended as the fire approached, with no other prospect than that of securing their immediate safety, with scarcely any hopes of being saved from destruction.

"How soon the flames were seen on the shore is uncertain; but early in the morning they were perceived by some of the Cawsand fishermen, and intelligence thereof given to Mr Edwards, of Rame, in that neighbourhood, a gentleman of some fortune, and more humanity, who immediately sent out a fishing-boat and men to the relief of the distressed objects in the light-house (c).

"The boat and men got thither about ten o'clock, after the fire had been burning full eight hours; in which time the three light-keepers were not only driven from all the rooms and the staircase, but, to avoid the falling of the timber and red-hot bolts, &c. upon them, they were found sitting in the hole or cave on the east side of the rock under the iron ladder, almost in a state of stupefaction; it being then low water.

"With much difficulty they were taken off; when finding it impossible to do any further service, they hastened to Plymouth. No sooner were they set on shore, than one of the men ran away, and was never afterwards heard of. This circumstance, though it might lead to suspicions unfavourable to the man, Mr Smeaton is of opinion ought not to weigh any thing against him, as he supposes it to have arisen from a panic which sometimes seizes weak minds, and prevents their acting agreeable to the dictates of right reason.

"It was not long before the dreadful news arrived at Plymouth. Alderman Tolcher and his son immediately went to sea, but found it impossible to do any thing with effect. Admiral West also, who then lay in Plymouth sound, sent a sloop properly armed, with a boat and an engine therein, which also carried out Mr Jessop the surveyor. This vessel arrived early in the day. Many attempts were made to play the engine, but the agitation of the sea prevented it from being employed with success. On the succeeding days the fire still continued, and about the 7th the destruction of the whole was completed.

"The man who has been mentioned already was named Henry Hall, of Stonehouse, near Plymouth, and though aged 94 years, being of a good constitution, was remarkably active, considering his time of life. He invariably told the surgeon who attended him, Mr Spry (now Dr Spry) of Plymouth, that if he would do any thing effectual to his recovery, he must relieve his stomach from the lead which he was sure was within him; and this he not only told Dr Spry, but all those about him, though in a very hoarse voice, and the same assertion he made to Mr Jessop.—The reality of the assertion seemed, however, then incredible to Dr Spry, who could scarcely suppose it possible than any human being could exist after receiving melted lead into the stomach; much less that he should afterwards be able to bear towing through the sea from the rock, and also the fatigue and inconvenience from the length of time he was in getting on shore before any remedies could be applied. The man, however, did not shew any symptons of being much worse or better until the sixth day after the accident, when he was thought to mend: he constantly took his medicines, and swallowed many things both liquid and solid, till the tenth or eleventh day; after which he suddenly grew worse; and on the twelfth, being seized with cold sweats and spasms, he soon after expired.

"His body was opened by Dr Spry, and in the stomach was found a solid piece of lead of a flat oval form, which weighed 7 ounces and 5 drachms. So extraordinary a circumstance appearing to deserve the notice of the philosophical world, an account of it was sent to the Royal Society, and printed in the 49th volume of their Transactions, p. 477.

"The light-house being thus demolished, the proprietors immediately turned their thoughts to the rebuilding of it. They had in it a term of near half a century, but some shares being settled by the marriage articles of one of the parties, some impediments arose which could not be overcome without the aid of parliament, which was soon obtained. To one of the partners, Robert Weston, Esq. the management of the business was committed,

---

(c) This benevolent gentleman caught a cold on this occasion which cost him his life.

Edystone.

committed, and he thought it requisite to apply to the earl of Macclesfield, then president of the Royal Society, to recommend a proper person to superintend the work. On communicating the object of his visit, Lord Macclesfield told him, that there was one of the Royal Society whom he would venture to recommend to the business; yet that the most material part of what he knew of him was, his having within the compass of the last seven years recommended himself to the Society by the communication of several mechanical inventions and improvements; and though he had at first made it his business to execute things in the instrument way (without having been bred to the trade), yet on account of the merit of his performances, he had been chosen a member of the Society, and that for about three years past, having found the business of a philosophical instrument-maker not likely to afford an adequate recompense, he had wholly applied himself to such branches of mechanics as were wanted by the proprietors; that he was then somewhere in the north of England, executing a work: and that as he had always satisfied his employers, he would not be likely to undertake what he could not perform.

“ The person thus described was Mr Smeaton, who was written to by Mr Benjamin Wilson the painter, laconically informing him, that he was the person fixed upon to rebuild the Edystone lighthouse. But this intimation conveying to his mind no more than a mere notice that he might, in common with others, deliver in proposals to repair it, not knowing then that it was entirely destroyed, it afforded but little satisfaction, and he returned only a cool answer. Mr Wilson's reply was still more laconic: That the demolition was total, and that as Nathan said unto David, ‘ Thou art the man.’

“ Mr Smeaton immediately divested himself of his engagements in the north, and arrived in London the 23d of February 1756, and had an interview next day with the principal proprietor. The mode of rebuilding then became the subject of their deliberations, which at length ended in a determination to rebuild it with stone.

“ On the 5th of April Mr Smeaton first set his foot on the Edystone rock. He immediately began to take his measures for proceeding on the work. He made all the necessary inquiries on the spot, and in the neighbourhood. He considered the nature and quality of the stone proper to be used, and from whence it might be obtained at the best and cheapest rates. He visited the quarries at Beare in Devonshire, and the isle of Portland, and from the latter of these places he at length determined to be supplied with his materials.

“ Having proceeded thus far, he returned to London, and had a meeting with the proprietors, who, for reasons highly honourable to them, confirmed their determination to rebuild with stone. He accordingly prepared his models and designs, which were approved by his employers, and directed to be exhibited to the lords of the Admiralty, and the masters of the Trinity house. To the former they were shewn; but the latter having fixed their time for viewing them at so distant a day as to hazard the progress of the work, he determined to set off for Plymouth without their inspection.

“ He arrived at Plymouth the 23d of July 1756, and immediately began his operations. He appointed his assistants, hired his men, settled their wages, and drew up rules for their conduct. He also hired a piece of ground for a work-yard. On the 3d of August they went off to the rock, and continued to work as long as the weather would permit. The next winter Mr Smeaton determined to continue at Plymouth, to go through a course of experiments on cements. On the 3d of June 1757, the works were resumed, and on the 12th the first stone was fixed. From this time the erection proceeded with regularity and dispatch, and with no other interruptions than what might be expected from the nature of the work, until the 9th of October 1759, when, after innumerable difficulties and dangers, a happy period was put to the undertaking, without the loss of life or limb to any one concerned in it, or accident by which the work could be said to be materially retarded.

“ It now remained only to wait for a storm to try the durability of the building. The hard weather of 1759, 1760, and 1761, appeared to make no impression. The year 1762 was ushered in by a tempest of the first magnitude, the rage of which was so great, that one of those who had been used to predict its downfal was heard to say, ‘ If the Edystone lighthouse is now standing, it will stand to the day of judgment;’ and in reality, from this time its existence has been so entirely laid out of men's minds, that whatever storms have happened since, no inquiry has ever been made concerning it. So confident was a very intelligent friend of Mr Smeaton's of its durability, that he wrote to him, that he might for ever rid himself of any uneasy thought of the house as to its danger from wind and sea.

“ The lighthouse is attended by three men, who receive 25l. a-year each, with an occasional absence in summer. Formerly there were only two, who watched alternately four hours and four hours; but one being taken ill, and dying, the necessity of an additional hand became apparent. In this dilemma, the living man found himself in an awkward situation. Being apprehensive if he tumbled the dead body into the sea, which was the only way in his power to dispose of it, he might be charged with murder, he was induced for some time to let the dead body lie, in hopes that the boat might be able to land, and relieve him from the distress he was in. By degrees the body became so offensive, that it was not in his power to get quit of it without help; for it was near a month before the attending boat could effect a landing; and then it was not without the greatest difficulty that it could be done, when they did land. To such a degree was the whole building filled with the stench of the corpse, that it was all they could do to get the dead body disposed of and thrown into the sea, and it was some time after that before the rooms could be freed from the noisome stench that was left.

“ It is said, that while two light-keepers only were employed, on some disgust they forbore to speak to each other. A person observing to one of them how happy they might live in their state of retirement, ‘ Yes,’ says the man, ‘ very comfortably, if we could have the use of our tongues; but it is now a full month since my partner and I have spoke to each other.’

“ To these anecdotes we shall add one more, and conclude. A shoemaker was carrying out to the lighthouse in order to be light-keeper. In their way, says the skipper to him, 'How happens it, friend Jacob, that you should choose to go out to be a light-keeper, when you can on shore (as I am told) earn half-a-crown and three shillings a-day in making leathern hose (leathern pipes so called); whereas the light-keeper's salary is but 25l. a-year, which is scarce ten shillings a-week.' Says the shoemaker, 'I go to be a light-keeper, because I don't like confinement.' After this answer had produced its share of merriment, he at last explained himself by saying, that he did not like to be confined to work.

"The whole time between the first stroke upon the rock and leaving the lighthouse complete, was three years nine weeks and three days; from the 5th of December 1755, to exhibiting the light October 1759, was three years ten months and sixteen days; and the whole time of working on the rock 111 days 10 hours (D)."

EEL. See MURÆNA, ICHTHYOLOGY *Index*.

EEL-Fishing. See BOBBING and SNIGGLING.

The silver eel may be catched with several sorts of baits, as powdered beef, garden worms, minnows, hens guts, fish garbage, &c. The most proper time for taking them is in the night, fastening your line to the bank sides, with your laying hook in the water: or a line may be thrown with good store of hooks, baited and plumbed, with a float to discover where the line lies, that they may be taken up in the morning.

Microscopic EELS. See ANIMALCULE, N° 8.

EELS in vinegar, are similar to those in sour paste. The taste of vinegar was formerly thought to be occasioned by the biting of these little animals, but that opinion has been long justly exploded. Mentzelius says, he has observed the actual transformation of these little creatures into flies.

EEL Spear, a forked instrument with three or four jagged teeth, used for catching eels: that with the four teeth is best, which they strike into the mud at the bottom of the river, and if it strike against any eels it never fails to bring them up.

EFFARE', or EFFRAYE', in *Heraldry*, a term applied to a beast rearing on its hind legs, as if it were frighted or provoked.

EFFECT, in a general sense, is that which results from, or is produced by, any cause. See CAUSE.

EFFEMINATE, womanish, unmanly, voluptuous.

EFFEMINATE (*effeminati*), according to the vulgate, are mentioned in several places of scripture. The word is there used to signify such as were consecrated to some profane god, and prostituted themselves in honour of him. The Hebrew word *hadesh*, translated *effeminatus*, properly signifies *consecrated*, and hence was attributed to those of either sex, who publicly prostituted themselves in honour of Baal and Astarte. Moses expressly forbids these irregularities among the Israelites; but the history of the Jews shows, that they were notwithstanding frequently practised. Levit. xxiii. 18.

EFFENDI, in the Turkish language, signifies *master:* and accordingly is a title very extensively applied; as to the mufti and emirs, to the priests of mosques, to men of learning, and of the law. The grand chancellor of the empire is called *reis effendi*.

EFFERVESCENCE, an intestine motion excited betwixt the parts of two bodies of different natures, when they reciprocally dissolve each other. Effervescences are commonly attended with bubbles, vapours, small jets of the liquid, and a hissing noise; and these phenomena are occasioned by the air which at that time disengages itself. Sometimes also they are accompanied with a great degree of heat, from the decomposition of some substances and the formation of new compounds.

Formerly the word *fermentation* was also applied to effervescences; but now that word is confined to the motion naturally excited in animal and vegetable matters, and from which new combinations among their principles take place.

EFFIGY, the portrait, figure, or exact representation of a person.

EFFIGY, is also used for the print or impression of a coin, representing the prince's head who struck it.

EFFIGY, *to execute or degrade in*, denotes the execution or degradation of a condemned contumacious criminal, who cannot be apprehended or seized. In France, they hang a picture on a gallows or gibbet, wherein is represented the criminal, with the quality or manner of the punishment: at the bottom is written the sentence of condemnation. Such persons as are sentenced to death are executed in effigy.

EFFLORESCENCE, among physicians, the same with exanthema. See EXANTHEMA.

EFFLORESCENCE, in *Chemistry*, denotes the formation of a kind of mealy powder on the surface of certain bodies. Efflorescence is occasioned either by decomposition or drying. The efflorescence which happens to cobalt and martial pyrites is of the first; and that observed on the crystals of soda, Glauber's salt, &c. of the latter kind. An efflorescence is sometimes also a species of crystallization; such as the beautiful vegetations which shoot up from different saline substances. See CRYSTALLIZATION.

EFFLORESCENTIA, in *Botany*, (from *effloresco* to bloom); the precise time of the year and month in which every plant shows its first flowers.

Some plants flower twice a-year, as is common between the tropics; others oftener, as the monthly rose. The former are called by botanists *biferæ;* the latter, *multiferæ*.

The time of flowering is determined by the degree of heat which each species requires. Mezereon and snowdrop produce their flowers in February; primrose, in the beginning of March; the greater number of plants, during the month of May; corn, and other grain, in the beginning of June; the vine, in the middle of the same month; several compound flowers, in the months of July and August; lastly, meadow-saffron flowers in the month of October, and announces the speedy approach of winter.

Grass of Parnassus always flowers about the time of cutting

(D) This account is extracted from a Narrative of the Building, and a Description of the Construction of the Edystone Lighthouse with stone. By John Smeaton, Civil Engineer, F. R. S.

cutting down the hay; and in Sweden, the different species of thistle, mountain lettuce, succory, and balsam, seldom flower till after the summer solstice: the countrymen even know, as by a kalendar, that the solstice is past when these plants begin to produce their flowers.

The temperature of the seasons has a great influence both in accelerating and retarding the flowering of plants. All plants are earlier in warm countries: hence such as are cultivated out of their native soil, never flower till the heat of the climate, or situation into which they are removed, is equal to that under the influence of which they produced flowers in their own country. For this reason, all exotics from warm climates are later in this country than many plants which it naturally produces.

In general, we may observe, that the plants of the coldest countries, and those produced on the mountains in all climates, being of equal temperature, flower about the same time, viz. during our spring in Europe.

Plants that grow betwixt the tropics, and those of temperate climates, flower during our summer.

Plants of temperate climates, situated under the same parallel of latitude with certain parts of Europe, but removed much farther to the west, such as Canada, Virginia, and Mississippi, do not produce flowers till autumn.

Plants of temperate climates in the opposite hemisphere to Europe, flower during our winter, which is the summer of these regions.

Linnæus and Adanson have given a sketch of the different times in which plants flower at Upsal and Paris.

EFFLUVIUM, in *Physiology*, a term much used by philosophers and physicians, to express the minute particles which exhale from most, if not all, terrestrial bodies, in form of sensible vapours.

EFFRONTES, in church history, a sect of heretics, in 1534, who scraped their forehead with a knife till it bled, and then poured oil into the wound. This ceremony served them instead of baptism. They are likewise said to have denied the divinity of the Holy Spirit.

EFFUSION, the pouring out of any liquid thing with some degree of force. In the ancient heathen sacrifices there were divers effusions of wine and other liquors, called *libations*.

Effusion, or **Fusion**, in *Astronomy*, denotes that part of the sign Aquarius, represented on celestial globes and planispheres, by the water issuing out of the urn of the water-bearer.

EFT, or **Water Lizard**. See Lacerta, Erpetology *Index*.

EGERIA, or **Ægeria**, a nymph held in great veneration by the Romans. She was courted by Numa Pompilius; and according to Ovid, she became his wife. This prince frequently visited her; and that he might introduce his laws and new regulations into the state, he solemnly declared before the Roman people, that they were previously sanctified and approved by the nymph Egeria. Ovid says, that Egeria was so disconsolate at the death of Numa, that she melted into tears, and was changed into a fountain by Diana. She is reckoned by many as a goddess who presided over the pregnancy of women; and some maintain that she is the same as Lucina.

EGG, in *Physiology*, a body formed in certain females, in which is contained an embryo or fœtus of the same species, under a cortical surface or shell. The exterior part of an egg is a shell; which in a hen, for instance, is a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined everywhere with a very thin but a pretty tough membrane, which dividing at, or very near the obtuse end of the egg, forms a small bag, where only air is contained. In new laid eggs this follicle appears very little, but becomes larger when the egg is kept.

Within this are contained the albumen or white, and the vitellus or yolk; each of which have their different virtues.

The albumen is a cold, viscous, white liquor in the egg, different in consistence in its different parts. It is observed, that there are two distinct albumens, each of which is enclosed in its proper membrane. Of these one is very thin and liquid: the other is more dense and viscous, and of a somewhat whiter colour; but, in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg is as sweet and free from corruption, during all the time of incubation, as it is in new laid eggs; as is also the vitellus. As the eggs of hens consist of two liquors separated one from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; so it is very probable that they are of different natures, and consequently appointed for different purposes.

When the vitellus grows warm with incubation, it becomes more humid, and like melting wax or fat; whence it takes up more space. For as the fœtus increases, the albumen insensibly wastes away and condenses: the vitellus, on the contrary, seems to lose little or nothing of its bulk when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed.

The chick in the egg is first nourished by the albumen: and when this is consumed, by the vitellus, as with milk. If we compare the chalazæ to the extremities of an axis passing through the vitellus, which is of a spherical form, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg.

The yellowish white round spot, called *cicatricula*, is placed on the middle of the smaller portion of the yolk; and therefore, from what has been said in the last paragraph, must always appear on the superior part of the vitellus.

Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the small guts by a small duct.

Eggs differ very much according to the birds that lay them, as to their colour, form, bigness, age, and the different way of dressing them: those most used in food are hens eggs; of which, such as are new laid are best.

As to the preservation of eggs, it is observed that the egg is always quite full when it is first laid by the hen; but from that time it gradually becomes less and less so, to its decay: and however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute for the discernment of our eyes, the effect of which is a daily decrease of matter within the egg, from the time of its being laid; and the perspiration is much quicker in hot weather than in cold.

To preserve the egg fresh, there needs no more than to preserve it full, and stop its transpiration; the method of doing which is, by stopping up those pores with matter which is not soluble in watery fluids: and on this principle it is, that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresh for a long time, if they are carefully rubbed all over the shell: tallow, or mutton fat, is also good for this purpose.

Artificial Method of Hatching Eggs. See HATCHING.

EGINA. See ÆGINA.

EGINHART, secretary to the emperor Charles the Great, was a German. He is the most ancient historian of that nation, and wrote very eloquently for a man of the 9th century. It is said, that he insinuated himself so well into the favour of Imma, daughter to Charles the Great, that he obtained from her whatever he desired. Charles the Great, having found out the intrigue, did not do as Augustus, who is thought to have banished Ovid, because he believed him to be too much favoured by Julia; for he married the two lovers together, and gave them a fine estate in land.

EGLANTINE. See ROSA, BOTANY *Index*.

EGLON, a king of the Moabites, who oppressed the Israelites for 18 years (Judges iii. 12—14.). Calmet confounds this servitude of the Hebrews with that under Chusan-rishathaim, making it to subsist only eight years, from the year of the world 2591 to 2599; whereas this servitude under Eglon lasted 18 years, and commenced in the year of the world 2661, and 62 years after they had been delivered by Othniel from the subjection of Chusan-rishathaim.

EGRA, a town of Bohemia subject to the house of Austria. E. Long. 12. 30. N. Lat. 50. 21.

EGRET, in *Ornithology*, a species of ardea. See ARDEA, ORNITHOLOGY *Index*.

E G Y P T.

EGYPT, an extensive country of Africa, lying between 30° and 33° of east longitude, and between 21° and 31° of north latitude. It is bounded by the Mediterranean on the north; by the Red sea and isthmus of Suez, which divide it from Arabia, on the east; by Abyssinia or Ethiopia, on the south; and by the deserts of Barca and Nubia on the west; being 600 miles in length from north to south, and about 150 in extreme breadth from east to west.

1 Different names.

As a nation, the Egyptians may with justice lay claim to as high antiquity as any in the world. The country was most probably peopled by Mizraim the son of Ham and grandson of Noah. By its ancient inhabitants it was called *Chemia*, and is still called *Chemi* in the language of the *Copts* or native Egyptians; and this name it is supposed to have received from Ham the son of Noah. In scripture, we find it most generally named *Misraim;* though in the Psalms it is styled the *land of Ham.*—To us it is best known by the name *Egypt*, the etymology of which is more uncertain.—Some derive it from *Ægyptus*, a supposed king of the country; others say it signifies no more than "the land of the *Copts;*" *Aia* in Greek signifying a country, and *Æcoptos* being easily softened into *Ægyptus.*—The most probable opinion, however, seems to be, that it received its name from the blackness of its soil, and the dark colour both of its river and inhabitants: for such a blackish colour is by the Greeks called *ægyptios*, from *gyps*, and *ægyps*, "a vulture;" and by the Latins *subvulturius*. For the same reason, other names of a similar import have been given to this country by the Greeks; such as *Aeria* and *Melambolus:* the river itself was called *Melo* or *Melas;* by the Hebrews, *Shihor;* and by the Ethiopians, *Siris;* all of which signify "black."

Ancient Egypt is by some divided into two parts, the Upper and Lower Egypt: by others into three, the Upper Egypt, properly so called, or *Thebais;* the Middle Egypt, or *Heptanomes;* and the Lower Egypt, the best part of which was the *Delta*, or that space encompassed by the branches of the Nile. See THEBAIS, &c.

The Egyptians, like the Chinese, pretend to an excessive antiquity, pretending to have records for ten, twenty, or even fifty thousand years. Thus their history is so much involved in obscurity and fable, that for many ages it must be passed over in silence.—The first mortal king whom the Egyptians own to have reigned in that country, was *Menes* or *Menas*. At what time he reigned, it would be to very little purpose to inquire. He had been preceded, however, by a set of immortals, who it seems left him the kingdom in a very bad situation: for the whole country, except Thebais, was a morass; the people also were entirely destitute of religion, and every kind of knowledge which could render their life comfortable and happy. Menes diverted the course of the Nile, which before that time had washed the foot of a sandy mountain near the borders of Libya, built the city of Memphis, instructed his subjects, and did other things of a similar kind which are usually attributed to the founders of kingdoms.

2 Invade the she herds.

From the time of Menes, the Egyptian chronology is filled with a list of 330 kings, who reigned 1400 years, but did nothing worthy of notice.—The first distinct piece of history we find concerning Egypt, is the

the irruption of the *Shepherds*, by whom the country was subdued; but whether this revolution happened during the vast interval of indolence above mentioned, or before or after, cannot be known. The affair is thus related by Manetho. It happened, in the reign of Timaus king of Egypt, that God being displeased with the Egyptians, they suffered a great revolution; for a multitude of men, ignoble in their race, took courage, and, pouring from the east into Egypt, made war with the inhabitants; who submitted to them without resistance. The shepherds, however, behaved with the greatest cruelty; burnt the cities, threw down the temples of the gods; and put to death the inhabitants, carrying the women and children into captivity. This people came from Arabia, and were called *Hycsos*, or *king-shepherds*. They held Egypt in subjection for 259 years; at the end of which period, they were obliged by a king of Upper Egypt, named *Amosis*, or *Thethmosis*, to leave the country. This prince's father had, it seems, gained great advantages over them, and shut them up in a place called *Abaris*, or *Avaris*, containing 10,000 acres of land. Here they were closely besieged by Amosis, with an army of 400,000 men; but at last the king, finding himself unable to reduce them by force, proposed an agreement, which was readily accepted. In consequence of this agreement, the shepherds withdrew from Egypt with their families, to the number of 240,000; and, taking the way of the desert, entered Syria: but fearing the Assyrians, who were then very powerful, and masters of Asia, they entered the land of Judæa; and built there a city capable of holding so great a multitude, and called it *Jerusalem*.

According to Mr Bruce, the shepherds who invaded Egypt were no other than the inhabitants of Barabra. They were, he says, *carriers* to the Cushites, who lived farther to the south. The latter had built the many stately temples in Thebes and other cities of Egypt; though, according to him, they had no dwelling places but holes or caves in the rocks. Being a commercial people, they remained at home collecting and preparing their articles, which were dispersed by the *Barabers* or shepherds already mentioned. These, from the nature of their employment, lived in moveable habitations, as the Tartars do at this day. By the Hebrews, he tells us, they were called *phut*, but *shepherds* by every other people; and from the name *baraber*, the word *Barabra* is derived. By their employment, which was the dispersing the Arabian and African goods all over the continent, they had become a great and powerful people; and from their opposite dispositions and manners, became very frequently enemies to the Egyptians. To one Salatis our author ascribes the destruction of Thebes in Upper Egypt, so much celebrated by Homer for its magnificence. But this certainly cannot be the case; for Homer wrote long after the time of Joseph: and we find that even then the Egyptians had the shepherds in abhorrence, in all probability because they had been grievously oppressed by them. Mr Bruce counts three invasions of these people; the first that of Salatis already mentioned, who overthrew the first dynasty of Egyptian kings from Menes, and destroyed Thebes: the second was that of Sabacco or So; for according to him this was not the name of a single prince, but of a people, and signifies *shepherd;* and the third, after the building of Memphis, where 240,000 of them were besieged as above mentioned. But accounts of this kind are evidently inconsistent in the highest degree; for how is it possible that the *third* invasion, antecedent to the building of Jerusalem, could be posterior to the *second*, if the latter happened only in the days of Hezekiah?

In these early ages, however, it would seem that the kingdom of Egypt had been very powerful and its dominion very widely extended; since we find it said, that the *Bactrians* revolted from Osymandyas, another Egyptian king of very high antiquity, and of whose wealth the most marvellous accounts are given.

After an unknown interval of time from this monarch, reigned Sesostris. He was the first great warrior whose conquests are recorded with any degree of distinctness. In what age of the world he lived, is uncertain. Some chronologers, among whom is Sir Isaac Newton, are of opinion, that he is the Sesac or Shishak, who took Jerusalem in the reign of Rehoboam the son of Solomon. Others, however, place him much earlier; and Mr Whiston will have him to be the Pharaoh who refused to part with the Israelites, and was at last drowned in the Red sea. Mr Bryant endeavours to prove that no such person ever existed; but that in his history, as well as that of many ancient heroes, we have an abridgement of that of the Cushites or Babylonians, who spread themselves over great part of the then known world, and everywhere brought the people in subjection to them. His reign is reckoned the most extraordinary part of the Egyptian history; and the following seems to be the least fabulous account that can be got of it. The father of Sesostris was told in a dream, by the god Vulcan, that his son, who was then newly born, or perhaps still unborn, should be lord of the whole earth. His father, upon the credit of this vision, got together all the males in the land of Egypt that were born on the same day with Sesostris; appointed nurses and proper persons to take care of them, and had them treated like his own child; being persuaded that they who had been the constant companions of his youth would prove the most faithful ministers and soldiers. As they grew up, they were inured to laborious exercises; and, in particular, were never permitted to taste any food till they had performed a course of 180 furlongs, upwards of 22 of our miles. When the old king imagined they were sufficiently educated in the martial way he designed them to follow, they were sent by way of trial of their abilities against the Arabians. In this expedition Sesostris proved successful, and in the end subdued that people who had never before been conquered. He was sent to the westward, and conquered the greatest part of Africa; nor could he be stopped in his career till he arrived at the Atlantic ocean. Whilst he was on this expedition, his father died; and then Sesostris resolved to fulfil the prediction of Vulcan, by actually conquering the whole world. As he knew that this must take up a long time, he prepared for his journey in the best manner possible. The kingdom he divided into 36 provinces, and endeavoured to secure the affections of the people by gifts both of money and land. He forgave all who had been guilty of offences, and discharged the debts of all his soldiers. He then constituted his brother Armais the supreme regent; but forbade him to use the diadem, and commanded him to offer no injury to the queen or her children, and to abstain from the royal concubines. His army consisted of 600,000 foot, 24,000 horse, and 27,000 chariots. Besides these land forces, he had at sea two mighty fleets; one, according to Diodorus, of 400 sail. Of these fleets, one was designed to make conquests in the west, and the other in the east; and therefore the one was built on the Mediterranean, and the other on the Red sea. The first of these conquered Cyprus, the coast of Phœnicia, and several of the islands called *Cyclades*; the other conquered all the coasts of the Red sea; but its progress was stopped by shoals and difficult places which the navigators could not pass, so that he seems not to have made many conquests by sea.

With the land forces Sesostris marched against the Ethiopians and Troglodites; whom he overcame, and obliged them to pay him a tribute of gold, ebony, and ivory. From thence he proceeded as far as the promontory of Dira, which lay near the straits of Babelmandel, where he set up a pillar with an inscription in sacred characters. He then marched on to the country where cinnamon grows, or at least to some country where cinnamon at that time was brought, probably some place in India; and here he in like manner set up pillars, which were to be seen for many ages after. As to his farther conquests, it is agreed by almost all authors of antiquity, that he overran and pillaged the whole continent of Asia, and some part of Europe. He crossed the Ganges, and erected pillars on its banks; and from thence he is said to have marched eastward to the very extremity of the Asiatic continent. Returning from thence, he invaded the Scythians and Thracians; but all authors do not agree that he conquered them. Some even affirm, that he was overthrown by them with great slaughter, and obliged to abandon a great part of his booty and military stores. But whether he had good or bad success in these parts, it is a common opinion that he settled a colony in Colchis. Herodotus, however, who gives the most particular account of the conquests of this monarch, does not say whether the colony was designedly planted by Sesostris: or whether part of his army loitered behind the rest, and took up their residence in that region. From his own knowledge, he asserts, that the inhabitants of that country were undoubtedly of Egyptian descent. This was evident from the personal resemblance they bore to the Egyptians, who were swarthy complexioned and frizzle haired; but more especially from the conformity of their customs, particularly circumcision.

The utmost boundary of this mighty monarch's conquests, however, was in the country of Thrace; for beyond this country his pillars were nowhere to be seen. These pillars he was accustomed to set up in every country which he conquered, with the following inscription, or one to the same purpose: "Sesostris, king of kings, and lord of lords, subdued this country by the power of his arms." Besides these, he left also statues of himself; two of which, according to Herodotus, were to be seen in his time; the one on the road between Ephesus and Phocæa, and the other between Smyrna and Sardis: they were armed after the Ethiopian and Egyptian manner; holding a javelin in one hand and a bow in the other. Across the breast they had a line drawn from one shoulder to the other, with the following inscription: "This region I obtained by these my shoulders." They were mistaken for images of Memnon.

3 Return to Egypt.

The reasons given by Sesostris for his returning into Egypt from Thrace, and thus leaving the conquest of the world unfinished, were the want of provisions for his army, and the difficulty of the passes. Most probably, however, his return was hastened by the intelligence he received from the high priest of Egypt, concerning the rebellious proceedings of his brother; who, encouraged by his long absence, had assumed the diadem, violated the queen, and also the royal concubines. On receiving this news, Sesostris hastened from Thrace; and at the end of nine years came to Pelusium in Egypt, attended by an innumerable multitude of captives taken from many different nations, and loaded with the spoils of Asia. The treacherous brother met him at this city; and it is said, with very little probability, that Sesostris accepted of an invitation to an entertainment from him. At this he drank freely, together with the queen and the rest of the royal family. During the continuance of the entertainment, Armais caused a great quantity of dried reeds to be laid round the apartment where they were to sleep; and as soon as they were retired to rest set fire to the reeds. Sesostris perceiving the danger he was in, and that his guards, overcharged with liquor, were incapable of assisting him, rushed through the flames, and was followed by his wife and children. In thanksgiving for this wonderful deliverance, he made several donations to the gods, particularly to Vulcan the god of fire. He then took vengeance on his brother Armais, said to be the Danaus of the Greeks, who, being on this occasion driven out of Egypt, withdrew into Greece.

4 His great works.

Sesostris now laid aside all thoughts of war, and applied himself wholly to such works as might tend to the public good, and his own future reputation. In order to prevent the incursions of the Syrians and Arabians, he fortified the east side of Egypt with a wall which ran from Pelusium through the desert to Heliopolis, for 187½ miles. He raised also an incredible number of vast and lofty mounts of earth, to which he removed such towns as had before been situated too low, in order to secure them from the inundations of the Nile. All the way from Memphis to the sea he dug canals which branched out from the Nile; and not only made an easier communication between different places, but rendered the country in a great measure impassable to an enemy. He erected a temple in every city in Egypt, and dedicated it to the supreme deity of the place; but in the course of such a great undertaking as this necessarily must have been, he took care not to employ any of his Egyptian subjects. Thus he secured their affection, and employed the vast multitude of captives he had brought along with him; and to perpetuate the memory of a transaction so remarkable, he caused to be inscribed on all these temples, "No one native laboured hereon." In the city of Memphis, before the temple of Vulcan, he raised six gigantic statues, each of one stone. Two of them were 30 cubits high, representing himself and his wife; the other four were 20 cubits each, and represented his four

four sons. These he dedicated to Vulcan in memory of his above-mentioned deliverance. He raised also two obelisks of marble 120 cubits high, and charged them with inscriptions, denoting the greatness of his power, his revenues, &c.

5 H leath.

The captives taken by Sesostris are said to have been treated with the greatest barbarity; so that at last they resolved at all events to deliver themselves from a servitude so intolerable. The Babylonians particularly were concerned in this revolt, and laid waste the country to some extent; but being offered a pardon and a place to dwell in, they were pacified, and built for themselves a city, which they called *Babylon*. Towards the conquered princes who waited on him with their tribute the Egyptian monarch behaved with unparalleled insolence. On certain occasions he is said to have unharnassed his horses, and, yoking kings together, made them draw his chariot. One day, however, observing one of the kings who drew his chariot to look back upon the wheels with great earnestness, he asked what made him look so attentively at them? The unhappy prince replied, "O king, the going round of the wheel puts me in mind of the vicissitudes of fortune: for as every part of the wheel is uppermost and lowermost by turns, so it is with men; who one day sit upon a throne, and on the next are reduced to the vilest degree of slavery." This answer brought the insulting conqueror to his senses; so that he gave over the practice, and thenceforth treated his captives with great humanity. At length this mighty monarch lost his sight, and laid violent hands on himself.

8 Egypt conquered by Sabbaco.

After the death of Sesostris, we meet with another chasm of an indeterminate length in the Egyptian history. It concludes with the reign of Amasis or Ammosis; who being a tyrant, his subjects joined Actisanes the king of Ethiopia to drive him out.—Thus Actisanes became master of the kingdom; and after his death follows another chasm in the history, during which the empire is said to have been in a state of anarchy for five generations.—This period brings us down to the times of the Trojan war. The reigning prince in Egypt was at that time called *Cetes*; by the Greeks, *Proteus*. The priests reported that he was a magician; and that he could assume any shape he pleased, even that of fire. This fable, as told by the Greeks, drew its origin from a custom among the Egyptians, perhaps introduced by Proteus. They were used to adorn and distinguish the heads of their kings with the representations of animals or vegetables, or even with burning incense, in order to strike the beholders with the greater awe. Whilst Proteus reigned, Paris or Alexander, the son of Priam king of Troy, was driven by a storm on the coast of Egypt, with Helen, whom he was carrying off from her husband. But when the Egyptian monarch heard of the breach of hospitality committed by Paris, he seized him, his mistress, and companions, with all the riches he had brought away with him from Greece. He detained Helen, with all the effects belonging to Menelaus her husband, promising to restore them to the injured party whenever they were demanded; but commanded Paris and his companions to depart out of his dominions in three days, on pain of being treated as enemies. In what manner Paris afterwards prevailed upon Proteus to restore his mistress, we are not told; neither do we know any thing further of the transactions of this prince's reign nor of his successors, except what has entirely the air of fable, till the days of Sabbaco the Ethiopian, who again conquered this kingdom. He began his reign with an act of great cruelty, causing the conquered prince to be burnt alive; nevertheless, he no sooner saw himself firmly established on the throne of Egypt, than he became a new man; so that he is highly extolled for his mercy, clemency, and wisdom. He is thought to have been the *So* mentioned in Scripture, and who entered into a league with Hoshea king of Israel against Shalmaneser king of Assyria. He is said to have been excited to the invasion of Egypt by a dream or vision, in which he was assured that he should hold that kingdom for fifty years. Accordingly, he conquered Egypt, as had been foretold; and at the expiration of the time above mentioned, he had another dream, in which the tutelar god of Thebes acquainted him, that he could no longer hold the kingdom of Egypt with safety and happiness, unless he massacred the priests as he passed through them with his guards. Being haunted with this vision, and at the same time abhorring to hold the kingdom on such terms, he sent for the priests, and acquainted them with what seemed to be the will of the gods. Upon this it was concluded, that it was the pleasure of the Deity that Sabbaco should remain no longer in Egypt; and therefore he immediately quitted that kingdom, and returned to Ethiopia.

9 Remarkable story of Sethon.

Of *Anysias*, who was Sabbaco's immediate successor, we have no particulars worth notice. After him reigned one Sethon, who was both king and priest of Vulcan. He gave himself up to religious contemplation; and not only neglected the military class, but deprived them of their lands. At this they were so much incensed, that they entered into an agreement not to bear arms under him; and in this state of affairs Sennacherib king of Assyria arrived before Pelusium with a mighty army. Sethon now applied to his soldiers, but in vain: they unanimously persisted in refusing to march under his banner. Being therefore destitute of all human aid, he applied to the god Vulcan, and requested him to deliver him from his enemies. Whilst he was yet in the temple of that god, it is said he fell into a deep sleep; during which he saw Vulcan standing at his side, and exhorting him to take courage. He promised, that if Sethon would but go out against the Assyrians, he should obtain a complete victory over them. Encouraged by this assurance, the king assembled a body of artificers, shop-keepers, and labourers; and, with this undisciplined rabble, marched towards Pelusium. He had no occasion, however, to fight; for the very night after his arrival at Pelusium, an innumerable multitude of field rats entering the enemies camp, gnawed to pieces the quivers, bowstrings, and shield straps. Next morning, when Sethon found the enemy disarmed, and on that account beginning to fly, he pursued them to a great distance, making a terrible slaughter. In memory of this extraordinary event, a statue of Sethon was erected in the temple of Vulcan, holding in one hand a rat, and delivering these words: "Whosoever beholdeth me, let him be pious."

Soon after the death of Sethon, the form of government in Egypt was totally changed. The kingdom was divided into twelve parts, over which as many of the

10 Reign of Psammitichus.

the chief nobility presided. This division, however, subsisted but for a short time. Psammitichus, one of the twelve, dethroned all the rest, 15 years after the division had been made. The history now begins to be divested of fable; and from this time may be accounted equally certain with that of any other nation. The vast conquests of Sesostris, were now no longer known; for Psammitichus possessed no more than the country of Egypt itself. It appears, indeed, that none of the successors of Sesostris, or even that monarch himself, had made use of any means to keep in subjection the countries he had once conquered. Perhaps, indeed, his design originally was rather to *pillage* than to conquer; and therefore, on his return, his vast empire vanished at once. Psammitichus, however, endeavoured to extend his dominions by making war on his neighbours; but by putting more confidence in foreign auxiliaries than in his own subjects, the latter were so much offended, that upwards of 200,000 fighting men emigrated in a body, and took up their residence in Ethiopia. To repair this loss, Psammitichus earnestly applied himself to the advancement of commerce; and opened his ports to all strangers, whom he greatly caressed, contrary to the cruel maxims of his predecessors, who refused to admit them into the country. He also laid siege to the city of Azotus in Syria, which held out for 29 years against the whole strength of the kingdom; from which we may gather, that, as a warrior, Psammitichus was by no means remarkable. He is reported to have been the first king of Egypt that drank wine. He also sent to discover the springs of the Nile; and is said to have attempted to discover the most ancient nation in the world by the following method. Having procured two newly born children, he caused them to be brought up in such a manner that they never heard a human voice. He imagined that these children would naturally speak the original language of mankind: therefore, when, at two years of age, they pronounced the Phrygian word *becos* (or some sound resembling it), which signifies bread, he concluded that the Phrygians were the most ancient people in the world.

11 Succeeded by Nechus.

Nechus, the son and successor of Psammitichus, is the *Pharaoh-Necho* of Scripture, and was a prince of an enterprising and warlike genius. In the beginning of his reign, he attempted to cut through the isthmus of Suez, between the Red sea and the Mediterranean; but, through the invincible obstacles which nature has thrown in the way of such undertakings, he was obliged to abandon the enterprize, after having lost 120,000 men in the attempt. After this he sent a ship, manned with some expert Phœnician mariners, on a voyage to explore the coast of Africa. Accordingly, they performed the voyage; sailed round the continent of Africa; and after three years returned to Egypt, where their relation was deemed incredible.

12 His wars with Josiah and Nebuchadnezzar.

The most remarkable wars in which this king was engaged are recorded in the sacred writings. He went out against the king of Assyria, by the divine command, as he himself told Josiah; but being opposed by the king of Judea, he defeated and killed him at Megiddo; after which he set up, in that country, King Jehoiakim, and imposed on him an annual tribute of 100 talents of silver and one talent of gold. He then proceeded against the king of Assyria; and weakened him so much, that the empire was soon after dissolved. Thus he became master of Syria and Phœnicia; but in a short time, Nebuchadnezzar king of Babylon came against him with a mighty army. The Egyptian monarch, not daunted by the formidable appearance of his antagonist, boldly ventured a battle; but was overthrown with prodigious slaughter, and Nebuchadnezzar became master of all the country to the very gates of Pelusium.

13 Apries a martial successfu prince.

The reign of Apries, the *Pharaoh Hophra* of Scripture, presents us with a new revolution in the Egyptian affairs. He is represented as a martial prince, and in the beginning of his reign very successful. He took by storm the rich city of Sidon; and having overcome the Cypriots and Phœnicians in a sea-fight, returned to Egypt laden with spoil. This success probably incited Zedekiah king of Judea to enter into an alliance with him against Nebuchadnezzar king of Babylon. The bad success of this alliance was foretold by the prophet Jeremiah; and accordingly it happened. For Nebuchadnezzar having sat down with his army before Jerusalem, Apries marched from Egypt with a design to relieve the city; but no sooner did he perceive the Babylonians approaching him, than he retreated as fast as he could, leaving the Jews exposed to the rage of their merciless enemies; who were thereupon treated as Jeremiah had foretold; and by this step Apries brought upon himself the vengeance denounced by the same prophet. The manner in which these predictions were fulfilled is as follows: The Cyreneans, a colony of Greeks, being greatly strengthened by a numerous supply of their countrymen under their third king *Battus* styled *the Happy*, and encouraged by the Pythian oracle, began to drive out their Libyan neighbours, and shared their possessions among themselves. Hereupon Andica king of Libya sent a submissive embassy to Apries, and implored his protection against the Cyreneans. Apries complied with his request, and sent a powerful army to his relief. The Egyptians were defeated with great slaughter; and those who returned complained that the army had been sent off by Apries in order to be destroyed, and that he might tyrannize without controul over the remainder of his subjects. This thought catching the attention of the giddy multitude, an almost universal defection ensued. Apries sent one Amasis, a particular friend, in whom he thought he could confide, to bring back his people to a sense of their duty. But by this friend he was betrayed; for Amasis, taking the opportunity of the present ferment, caused himself to be proclaimed king. Apries then despatched one Patarbemis, with orders to take Amasis, and bring him alive before him. This he found impossible, and therefore returned without his prisoner; at which the king was so enraged, that he commanded Patarbemis's nose and ears to be cut off. This piece of cruelty completed his ruin; for when the rest of the Egyptians who continued faithful to Apries beheld the inhuman mutilation of so worthy and noble a person as Patarbemis was, they to a man deserted Apries, and went over to Amasis.

14 Bad con quences his allia with Z kiah.

15 His sub revolt.

Both parties now prepared for war, the usurper having under his command the whole body of native Egyptians; and Apries only those Ionians, Carians, and other mercenaries whom he could engage in his service.

vice. The army of Apries amounted only to 30,000; but, though greatly inferior in number to the troops of his rival, as he well knew that the Greeks were much superior in valour, he did not doubt of victory. Nay, so far was Apries puffed up with this notion, that he did not believe it was in the power even of any *god* to deprive him of his kingdom. The two armies soon met, and drew up in order of battle near Memphis. A bloody engagement ensued; in which, though the army of Apries behaved with the greatest resolution, they were at last overpowered with numbers, and utterly defeated, the king himself being taken prisoner. Amasis now took possession of the throne without opposition. He confined Apries in one of his palaces, but treated him with great care and respect. The people, however, were implacable, and could not be satisfied while he enjoyed his life. Amasis, therefore, at last found himself obliged to deliver him into their hands. Thus the prediction received its final completion: Apries was delivered up to those *who sought his life;* and who no sooner had him in their power, than they strangled him, and laid his body in the sepulchre of his ancestors.

16 A ies defe d and t n pri- r by A sis.

17 E pt in- v d by N uchad- n ar.

During these intestine broils, which must have greatly weakened the kingdom, it is probable that Nebuchadnezzar invaded Egypt. He had been for 13 years before this employed in besieging Tyre, and at last had nothing but an empty city for his pains. To make himself some amends, therefore, he entered Egypt, miserably harassed the country, killed and carried away great numbers of the inhabitants, so that the country did not recover from the effects of this incursion for a long time after. In this expedition, however, he seems not to have aimed at any permanent conquest, but to have been induced to it merely by the love of plunder, and of this he carried with him an immense quantity to Babylon.

18 H py ad- m stra- t of A sis.

During the reign of Amasis, Egypt is said to have been perfectly happy, and to have contained 20,000 populous cities. That good order might be kept among such vast numbers of people, Amasis enacted a law, by which every Egyptian was bound once a-year to inform the governor of his province by what means he gained his livelihood; and if he failed of this, to put him to death. The same punishment he decreed to those who could not give a satisfactory account of themselves.

This monarch was a great favourer of the Greeks, and married a woman of Grecian extract. To many Greek cities, as well as particular persons, he made considerable presents. Besides these, he gave leave to the Greeks in general to come into Egypt, and settle either in the city of Naucratis, or carry on their trade upon the sea coasts; granting them also temples, and places where they might erect temples to their own deities. He received also a visit from Solon the celebrated Athenian lawgiver, and reduced the island of Cyprus under his subjection.

9 O ds C byses ki of P a.

This great prosperity, however, ended with the death of Amasis, or indeed before it. The Egyptian monarch had some how or other incensed Cambyses king of Persia. The cause of the quarrel is uncertain; but whatever it was, the Persian monarch vowed the destruction of Amasis. In the mean time *Phanes* of Halicarnassus, commander of the Grecian auxiliaries in the pay of Amasis, took some private disgust; and leaving Egypt, embarked for Persia. He was a wise and able general, perfectly well acquainted with every thing that related to Egypt; and had great credit with the Greeks in that country. Amasis was immediately sensible how great the loss of this man would be to him, and therefore sent after him a trusty eunuch with a swift galley. Phanes was accordingly overtaken in Lycia, but not brought back; for making his guard drunk, he continued his journey to Persia, and presented himself before Cambyses, as he was meditating the destruction of the Egyptian monarchy.

20 And Polycrates tyrant of Samos.

At this dangerous crisis also, the Egyptian monarch imprudently made Polycrates the tyrant of Samos his enemy. This man had been the most remarkable perhaps of any recorded in history, for an uninterrupted course of success, without the intervention of one single unfortunate event. Amasis, who was at this time in strict alliance with Polycrates, wrote him a letter, in which, after congratulating him on his prosperity, he told him that he was afraid lest his successes were too many, and he might be suddenly thrown down into the greatest misery. For this reason he advised him voluntarily to take away something from his own happiness; and to cast away that which would grieve him most if he was accidentally to lose it. Polycrates followed his advice, and threw into the sea a signet of inestimable value. This, however, did not answer the intended purpose. The signet happened to be swallowed by a fish, which was taken a few days afterwards, and thus was restored to Polycrates. Of this Amasis was no sooner informed, than, considering Polycrates as really *unhappy*, and already on the brink of destruction, he resolved to put an end to the friendship which subsisted between them. For this purpose he despatched a herald to Samos, commanding him to acquaint Polycrates, that he renounced his alliance, and all the obligations between them; that he might not mourn his misfortunes with the sorrow of a friend. Thus Amasis left Polycrates at liberty to act against him, if he chose to do so; and accordingly he offered to assist Cambyses with a fleet of ships in his Egyptian expedition.

Amasis had not, however, the misfortune to see the calamities of his country. He died about 525 years before Christ, after a reign of 44 years; and left the kingdom to his son Psammenitus, just as Cambyses was approaching the frontiers of the kingdom. The new prince was scarce seated on the throne, when the Persians appeared. Psammenitus drew together what forces he could, in order to prevent them from entering the kingdom. Cambyses, however, immediately laid siege to Pelusium, and made himself master of it by the following stratagem: he placed in the front of his army a great number of cats, dogs, and other animals that were deemed sacred by the Egyptians. He then attacked the city, and took it without opposition; the garrison, which consisted entirely of Egyptians, not daring to throw a dart or shoot an arrow against their enemies, lest they should kill some of the holy animals.

21 Egypt invaded by Cambyses.

22 Cruelty and defeat of the Egyptians.

Cambyses had scarce taken possession of the city, when Psammenitus advanced against him with a numerous army. But before the engagement, the Greeks who served under Psammenitus, to show their indignation

nation against their treacherous countryman Phanes, brought his children into the camp, killed them in the presence of their father and the two armies, and then drank their blood. The Persians enraged at so cruel a sight, fell upon the Egyptians with the utmost fury, put them to flight, and cut the greatest part of of them in pieces. Those who escaped fled to Memphis, where they were soon after guilty of a horrid outrage. Cambyses sent a herald to them in a ship from Mitylene: but no sooner did they see her come into the port, than they flocked down to the shore, destroyed the ship, and tore to pieces the herald and all the crew, afterwards carrying their mangled limbs into the city, in a kind of barbarous triumph. Not long after, they were obliged to surrender: and thus Psammenitus fell into the hands of his inveterate enemy, who was now enraged beyond measure at the cruelties exercised upon the children of Phanes, the herald, and the Mitylenean sailors.

23 Their dreadful punishment by Cambyses.

The rapid success of the Persians struck with such terror the Libyans, Cyreneans, Barcæans, and other dependents or allies of the Egyptian monarch, that they immediately submitted. Nothing now remained but to dispose of the captive king, and revenge on him and his subjects the cruelties which they had committed. This the merciless victor executed in the severest manner. On the 10th day after Memphis had been taken, Psammenitus and the chief of the Egyptian nobility were ignominiously sent into one of the suburbs of that city. The king being there seated in a proper place, saw his daughter coming along in the habit of a poor slave with a pitcher to fetch water from the river, and followed by the daughters of the greatest families in Egypt, all in the same miserable garb, with pitchers in their hands, drowned in tears, and loudly bemoaning their miserable situation. When the fathers saw their daughters in this distress, they burst into tears, all but Psammenitus, who only cast his eyes on the ground and kept them fixed there. After the young women, came the son of Psammenitus, with 2000 of the young nobility, all of them with bits in their mouths and halters round their necks, led to execution. This was done to expiate the murder of the Persian herald and the Mitylenean sailors; for Cambyses caused ten Egyptians of the first rank to be publicly executed for every one of those that had been slain. Psammenitus, however, observed the same conduct as before, keeping his eyes stedfastly fixed on the ground, though all the Egyptians around him made the loudest lamentations. A little after this he saw an intimate friend and companion, now advanced in years, who having been plundered of all he had, was begging his bread from door to door in the suburbs. As soon as he saw this man, Psammenitus wept bitterly; and calling out to him by his name, struck himself on the head as if he had been frantic. Of this the spies who had been set over him to observe his behaviour, gave immediate notice to Cambyses, who thereupon sent a messenger to inquire the cause of such immoderate grief. Psammenitus answered, That the calamities of his own family confounded him, and were too great to be lamented by any outward signs of grief; but the extreme distress of a bosom friend gave more room for reflection, and therefore extorted tears from him. With this answer Cambyses was so affected, that he sent orders to prevent the execution of the king's son; but these came too late, for the young prince had been put to death before any of the rest. Psammenitus himself was then sent for into the city, and restored to his liberty: and had he not showed a desire of revenge, might perhaps have been trusted with the government of Egypt: but being discovered hatching schemes against the government, he was seized, and condemned to drink bull's blood.

24 Egypt comes province the Pers and aft- wards the Gree empire.

The Egyptians were now reduced to the lowest degree of slavery. Their country became a province of the Persian empire: the body of Amasis their late king was taken out of his grave; and after being mangled in a shocking manner was finally burnt. But what seemed more grievous than all the rest, their god Apis was slain, and his priests ignominiously scourged; and this inspired the whole nation with such a hatred to the Persians, that they could never afterwards be reconciled to them. As long as the Persian empire subsisted, the Egyptians could never shake off their yoke. They frequently revolted indeed, but were always overthrown with prodigious loss. At last they submitted, without opposition, to Alexander the Great: after his death, Egypt again became a powerful kingdom, though since the conquest of it by Cambyses to the present time it hath never been governed but by foreign princes, agreeable to the prophecy of Ezekiel. "There shall be no more a prince of the land of Egypt."

25 Assigne Ptolem Lagus, assume title of king.

On the death of Alexander the Great, Egypt, together with Libya, and that part of Arabia which borders on Egypt, were assigned to Ptolemy Lagus as governor under Alexander's son by Roxana, who was but newly born. Nothing was farther from the intention of this governor, than to keep the provinces in trust for another. He did not, however, assume the title of *king*, till he perceived his authority so firmly established that it could not be shaken; and this did not happen till 19 years after the death of Alexander, when Antigonus and Demetrius had unsuccessfully attempted the conquest of Egypt.

From the time of his first establishment on the throne, Ptolemy, who had assumed the title of *Soter*, reigned 20 years; which added to the former 19, make up the 39 years which historians commonly allow him to have reigned alone.—In the 39th year of his reign, he made one of his sons, named *Philadelphus*, partner to the empire; declaring him his successor, to the prejudice of his eldest son named *Ceraunus*; being excited thereto by his violent love for *Berenice* Philadelphus's mother. When the succession was thus settled, Ceraunus immediately quitted the court; and fled at last into Syria, where he was received with open arms by Seleucus Nicator, whom he afterwards murdered.

The most remarkable transaction of this reign was the embellishing of the city of Alexandria, which Ptolemy made the capital of his new kingdom, and of which an account is given under the article ALEXANDRIA. About 284 years before Christ, died Ptolemy Soter, in the 41st year of his reign, and 84th of his age. He was the best prince of his race; and left behind him an example of prudence, justice, and clemency which few of his successors chose to follow. Besides the provinces originally assigned to him, he added to his empire those of Cœlo-Syria, Ethiopia, Pamphylia, Lycia, 26 S eeded b hila- d hus.

Lycia, Caria, and some of the Cyclades. His successor, Ptolemy Philadelphus, added nothing to the extent of the empire; nor did he perform any thing worthy of notice except embellishing further the city of Alexandria, and entering into an alliance with the Romans. In his time, one Magas the governor of Libya and Cyrene, revolted; and held these provinces as an independent prince, notwithstanding the utmost efforts of Ptolemy to reduce him. At last an accommodation took place; and a marriage was proposed between Berenice, the only daughter of Magas, and Ptolemy's eldest son. The young princess was to receive all her father's dominions by way of dowry, and thus they would again be brought under the dominion of Ptolemy's family. But before this treaty could be put in execution, Magas died; and then Apamea, the princess's mother, did all she could to prevent the match. This, however, she was not able to do; though her efforts for that purpose produced a destructive war of four years continuance with Antiochus Theus king of Syria, and the acting of a cruel tragedy in the family of the latter. See SYRIA.

27 emy rgetes a at con- q or.

About 246 years before Christ, Ptolemy Philadelphus died; and was succeeded by his eldest son Ptolemy, who had been married to Berenice the daughter of Magas, as above related. In the beginning of his reign, he found himself engaged in a war with Antiochus Theus king of Syria. From this he returned victorious, and brought with him 2500 statues and pictures, among which were many of the ancient Egyptian idols, which had been carried away by Cambyses into Persia. These were restored by Ptolemy to their ancient temples; in memory of which favour, the Egyptians gave him the surname of *Euergetes*, or the Beneficent. In this expedition he greatly enlarged his dominions, making himself master of all the countries that lie between Mount Taurus and the confines of India. An account of these conquests was given by himself, inscribed on a monument, to the following effect. "Ptolemy Euergetes, having received from his father the sovereignty of Egypt, Libya, Syria, Phœnice, Cyprus, Lycia, Caria, and the other Cyclades, assembled a mighty army of horse and foot, with a great fleet, and elephants, out of Trogloditia and Ethiopia; some of which had been taken by his father, and the rest by himself, and brought from thence, and trained up for war: with this great force he sailed into Asia; and having conquered all the provinces which lie on this side the Euphrates, Cilicia, Pamphylia, Ionia, the Hellespont, and Thrace, he crossed the river with all the forces of the conquered countries, and the kings of those nations, and reduced Mesopotamia, Babylonia, Susiana, Persia, Media, and all the country as far as Bactria."

On the king's return from this expedition, he passed through Jerusalem, where he offered many sacrifices to the God of Israel, and ever afterwards expressed a great favour for the Jewish nation. At this time, the Jews were tributaries to the Egyptian monarchs, and paid them annually 20 talents of silver. This tribute, however, Onias, who was then high priest, being of a very covetous disposition, had for a long time neglected to pay, so that the arrears amounted to a very large sum. Soon after his return, therefore, Ptolemy sent one of his courtiers named *Athenion* to demand the money, and desired him to acquaint the Jews that he would make war upon them in case of a refusal. A young man, however, named *Joseph*, nephew to Onias, not only found means to avert the king's anger, but even got himself chosen his receiver-general, and by his faithful discharge of that important trust, continued in high favour with Ptolemy as long as he lived.

Ptolemy Euergetes having at last concluded a peace with Seleucus the successor of Antiochus Theus king of Syria, attempted the enlargement of his dominions on the south side. In this he was attended with such success, that he made himself master of all the coasts of the Red sea, both on the Arabian and Ethiopian sides, quite down to the straits of Babelmandel. On his return he was met by ambassadors from the Achæans, imploring his assistance against the Etolians and Lacedæmonians. This the king readily promised them: but they having in the mean time engaged Antigonus king of Macedon to support them, Ptolemy was so much offended, that he sent powerful succours to Cleomenes king of Sparta; hoping, by that means, to humble both the Achæans and their new ally Antigonus. In this, however, he was disappointed; for Cleomenes, after having gained very considerable advantages over the enemy, was at last entirely defeated in the battle of Sellasia, and obliged to take refuge in Ptolemy's dominions. He was received by the Egyptian monarch with the greatest demonstrations of kindness; a yearly pension of 24 talents was assigned him, with a promise of restoring him to the Spartan throne; but before this could be accomplished, the king of Egypt died, in the 27th year of his reign, and was succeeded by his son Ptolemy Philopater.

28 Cleomenes king of Sparta takes refuge in Egypt.

Thus we have seen the Egyptian empire brought to a very great height of power; and had the succeeding monarchs been careful to preserve that strength of empire transmitted to them by Euergetes, it is very probable that Egypt might have been capable of holding the balance against Rome, and after the destruction of Carthage prevented that haughty city from becoming mistress of the world. But after the death of Ptolemy Euergetes, the Egyptian empire being governed only by weak or vicious monarchs, quickly declined, and from that time makes no conspicuous figure in history. Ptolemy Philopater began his reign with the murder of his brother; after which, giving himself up to all manner of licentiousness, the kingdom fell into a kind of anarchy. Cleomenes the Spartan king still resided at court; and being now unable to bear the dissolute manners which prevailed there, he pressed Philopater to give him the assistance he had promised for restoring him to the throne of Sparta. This he the rather insisted upon, because he had received advice that Antigonus king of Macedon was dead, that the Achæans were engaged in a war with the Etolians, and that the Lacedæmonians had joined the latter against the Achæans and Macedonians. Ptolemy, when afraid of his brother Magas, had indeed promised to assist the king of Sparta with a powerful fleet, hoping by this means to attach him to his own interest; but now when Magas was out of the way, it was determined by the king, or rather his ministers, that Cleomenes should not be assisted, nor even allowed to leave the kingdom; and this extravagant resolution produced the desperate attempt

29 Ptolemy Philopater a cruel tyrant.

tempt of Cleomenes, of which an account is given in the history of SPARTA.

Of the disorders which now ensued in the government, Antiochus king of Syria, surnamed *the Great*, took the advantage, and attempted to wrest from Ptolemy the provinces of Cœlo-Syria and Palestine. But in this he was finally disappointed; and might easily have been totally driven out of Syria, had not Ptolemy been too much taken up with his debaucheries to think of carrying on the war. The discontent occasioned by this piece of negligence soon produced a civil war in his dominions, and the whole kingdom continued in the utmost confusion till his death, which happened in the 17th year of his reign and 37th of his age.

30 Extraordinary story concerning the Jews.

During the reign of Philopater happened a very extraordinary event with regard to the Jews, which is mentioned in the Maccabees *. The king of Egypt, while on his Syrian expedition, had attempted to enter the temple of Jerusalem: but being hindered by the Jews, he was filled with the utmost rage against the whole nation. On his return to Alexandria, he resolved to make those who dwelt in that city feel the first effects of his vengeance. He began with publishing a decree, which he caused to be engraved on a pillar erected for that purpose at the gate of his palace, excluding all those who did not sacrifice to the gods worshipped by the king. By this means the Jews were debarred from suing to him for justice, or obtaining his protection when they happened to stand in need of it. By the favour of Alexander the Great, Ptolemy Soter, and Euergetes, the Jews enjoyed at Alexandria the same privileges with the Macedonians. In that metropolis the inhabitants were divided into three ranks or classes. In the first were the Macedonians, the original founders of the city, and along with them were enrolled the Jews; in the second were the mercenaries who had served under Alexander; and in the third the native Egyptians. Ptolemy now, to be revenged of the Jews, ordered, by another decree, that they should be degraded from the first rank, and enrolled among the native Egyptians. By the same decree it was enacted, that all of that nation should appear at an appointed time before the proper officers, in order to be enrolled among the common people; that at the time of their enrollment they should have the mark of an ivy leaf, the badge of Bacchus, impressed with a hot iron on their faces; that all who were thus marked should be made slaves; and, lastly, that if any one should stand out against this decree, he should be immediately put to death. That he might not, however, seem an enemy to the whole nation, he declared, that those who sacrificed to their gods should enjoy their former privileges, and remain in the same class. Yet, notwithstanding this tempting offer, 300 only out of many thousand Jews who lived in Alexandria could be prevailed upon to abandon their religion in order to save themselves from slavery.

The apostates were immediately excommunicated by their brethren: and this their enemies construed as done in opposition to the king's order; which threw the tyrant into such a rage, that he resolved to extirpate the whole nation, beginning with the Jews who lived in Alexandria and other cities of Egypt, and proceeding from thence to Judea and Jerusalem itself. In consequence of this cruel resolution, he commanded all the Jews that lived in any part of Egypt to be brought in chains to Alexandria, and there to be shut up in the Hippodrome, which was a very spacious place without the city, where the people used to assemble to see horse races and other public diversions. He then sent for Herman master of the elephants; and commanded him to have 500 of these animals ready against the next day, to let loose upon the Jews in the Hippodrome. But when the elephants were prepared for the execution, and the people were assembled in great crowds to see it, they were for that day disappointed by the king's absence. For, having been late up the night before with some of his debauched companions, he did not awake till the time for the show was over, and the spectators returned home. He therefore ordered one of his servants to call him early on the following day, that the people might not meet with a second disappointment. But when the person awaked him according to his order, the king was not yet returned to his senses; having withdrawn, exceedingly drunk, only a short time before. As he did not remember the order, he therefore fell into a violent passion, and threatened with death the servant who had awaked him; and this caused the show to be put off till the third day. At last the king came to the Hippodrome attended with a vast multitude of spectators; but when the elephants were let loose, instead of falling upon the Jews, they turned their rage against the spectators and soldiers, and destroyed great numbers of them. At the same time, some frightful appearances which were seen in the air so terrified the king, that he commanded the Jews to be immediately set at liberty, and restored them to their former privileges. No sooner were they delivered from this danger than they demanded leave to put to death such of their nation as had abandoned their religion; and this being granted, they despatched the apostates without excepting a single man.

31 Ptolemy Philomet taken pri soner by Antiochu

Philopater was succeeded by Ptolemy Epiphanes; and he, after a reign of 24 years, by Ptolemy Philometor. In the beginning of his reign, a war commenced with the king of Syria, who had seized on the provinces of Cœlo-Syria and Palestine in the preceding reign. In the course of this war, Philometor was either voluntarily delivered up to Antiochus, or taken prisoner. But however this was, the Alexandrians despairing of his ever being able to recover his liberty, raised to the throne his brother Ptolemy, who took the name of *Euergetes II.* but was afterwards called *Physcon* or "the great-bellied," on account of the prominent belly which by his gluttony and luxury he had acquired.

32 and Phys con raise to the throne.

He was scarce seated on the throne, however, when Antiochus Epiphanes, returning into Egypt, drove out Physcon, and restored the whole kingdom except Pelusium, to Philometor. His design was to kindle a war betwixt the two brothers, so that he might have an opportunity of seizing the kingdom for himself. For this reason he kept to himself the city of Pelusium; which being the key of Egypt, he might at his pleasure re-enter the country. But Philometer, apprised of his design, invited his brother Physcon to an accommodation; which was happily effected by their sister Cleopatra. In virtue of this agreement, the brothers were to reign jointly, and to oppose to the utmost of their power Antiochus, whom they considered as a common

---

* Lib. iii. 2. 3, 4, 5.

common enemy. On this the king of Syria invaded Egypt with a mighty army, but was prevented by the Romans from conquering it.

3
Difference between the two brothers decided by the Roman senate.

The two brothers were no sooner freed from the apprehensions of a foreign enemy than they began to quarrel with each other. Their differences soon came to such a height, that the Roman senate interposed. But before the ambassadors employed to inquire into the merits of the cause could arrive in Egypt, Physcon had driven Philometor from the throne, and obliged him to quit the kingdom. On this the dethroned prince fled to Rome, where he appeared meanly dressed, and without attendants. He was very kindly received by the senate; who were so well satisfied of the injustice done him, that they immediately decreed his restoration. He was reconducted accordingly; and on the arrival of the ambassadors in Egypt, an accommodation between the two brothers was negotiated. By this agreement, Physcon was put in possession of Libya and Cyrene, and Philometor of all Egypt and the island of Cyprus; each of them being declared independent of the other in the dominion allotted to them. The treaty, as usual, was confirmed with oaths and sacrifices, and was broken almost as soon as made. Physcon was dissatisfied with his share of the dominions; and therefore sent ambassadors to Rome, desiring that the island of Cyprus might be added to his other possessions. This could not be obtained by the ambassadors; and therefore Physcon went to Rome in person. His demand was evidently unjust; but the Romans, considering that it was their interest to weaken the power of Egypt as much as possible, without further ceremony adjudged the island to him.

4
Island of Cyprus adjudged to Physcon.

Physcon set out from Rome with two ambassadors; and arriving in Greece on his way to Cyprus, he raised there a great number of mercenaries, with a design to sail immediately to that island and conquer it. But the Roman ambassadors telling him, that they were commanded to put him in possession of it by fair means and not by force, he dismissed his army, and returned to Libya, while one of the ambassadors proceeded to Alexandria. Their design was to bring the two brothers to an interview on the frontiers of their dominions, and there to settle matters in an amicable manner. But the ambassador who went to Alexandria, found Philometor very averse from compliance with the decree of the senate. He put off the ambassador so long, that Physcon sent the other also to Alexandria, hoping that the joint persuasions of the two would induce Philometor to comply. But the king, after entertaining them at an immense charge for 40 days, at last plainly refused to submit, and told the ambassadors that he was resolved to adhere to the first treaty. With this answer the Roman ambassadors departed, and were followed by others from the two brothers. The senate, however, not only confirmed their decree in favour of Physcon, but renounced their alliance with Philometor, and commanded his ambassador to leave the city in five days.

5
Philometor refuses to comply.

6
Rebellion against Physcon.

In the mean time, the inhabitants of Cyrene having heard unfavourable accounts of Physcon's behaviour during the short time he reigned in Alexandria, conceived so strong an aversion against him, that they resolved to keep him out of their country by force of arms. On receiving intelligence of this resolution, Physcon dropped all thoughts of Cyprus for the present; and hastened with all his forces to Cyrene, where he soon got the better of his rebellious subjects, and established himself in the kingdom. His vicious and tyrannical conduct, however, soon estranged from him the minds of his subjects, in such a manner, that some of them entering into a conspiracy against him, fell upon him one night as he was returning to his palace, wounded him in several places, and left him for dead on the spot. This he laid to the charge of his brother Philometor; and as soon as he was recovered, took another voyage to Rome. Here he made his complaints to the senate, and showed them the scars of his wounds, accusing his brother of having employed the assassins from whom he received them. Though Philometor was known to be a man of a most humane and mild disposition, and therefore very unlikely to have been concerned in so black an attempt; yet the senate, being offended at his refusing to submit to their decree concerning the island of Cyprus, hearkened to this false accusation; and carried their prejudices so far, that they not only refused to hear what his ambassadors had to say, but ordered them immediately to depart from the city. At the same time, they appointed five commissioners to conduct Physcon to Cyprus, and put him in possession of that island, enjoining all their allies in those parts to supply him with forces for that purpose.

Physcon having by this means got together an army which seemed to him to be sufficient for the accomplishment of his design, landed in Cyprus; but being there encountered by Philometor in person, he was entirely defeated, and obliged to shelter himself in a city called *Lapitho*. Here he was closely besieged, and at last obliged to surrender. Every one now expected that Physcon would have been treated as he deserved; but his brother, instead of punishing, restored him to the government of Libya and Cyrene, adding some other territories instead of the island of Cyprus, and promising him his daughter in marriage. Thus an end was put to the war between the two brothers; for the Romans were ashamed any longer to oppose a prince who had given such a signal instance of his justice and clemency.

37
He is defeated and taken prisoner by Philometor.

On his return to Alexandria, Philometor appointed one Archias governor of Cyprus. But he, soon after the king's departure, agreed with Demetrius king of Syria, to betray the island to him for 500 talents. The treachery was discovered before it took effect; and the traitor, to avoid the punishment due to his crime, laid violent hands on himself. Ptolemy being offended with Demetrius for this attempt on Cyprus, joined Attalus king of Pergamus, and Ariarathes king of Cappadocia, in setting up a pretender to the crown of Syria. This was Alexander Balas; to whom he even gave his daughter Cleopatra in marriage, after he had placed him on the throne of Syria. But he, notwithstanding these and many other favours, being suspected of having entered into a plot against his benefactor, Ptolemy became his greatest enemy; and marching against him, routed his army in the neighbourhood of Antioch. He did not, however, long enjoy his victory; for he died in a few days after the engagement, of the wounds he had received.

38
Death of Philometor.

On the death of Philometor, Cleopatra the queen designed to secure the throne for her son. But some of

39 Monstrous wickedness of Physcon.

40 He is driven out.

of the principal nobility declaring for Physcon, a civil war was about to ensue, when matters were compromised on condition that Physcon should marry Cleopatra, that he should reign jointly with her during his life, and declare her son by Philometor heir to the crown. These terms were no sooner agreed upon than Physcon married Cleopatra, and, on the very day of the nuptials, murdered her son in her arms. This was only a prelude to the cruelties which he afterwards practised on his subjects. He was no sooner seated on the throne, than he put to death all those who had shown any concern for the murder of the young prince. He then wreaked his fury on the Jews, whom he treated more like slaves than subjects, on account of their having favoured the cause of Cleopatra. His own people were treated with little more ceremony. Numbers of them were every day put to death for the smallest faults, and often for no fault at all, but merely to gratify his inhuman temper. His cruelty towards the Alexandrians is particularly mentioned under the article ALEXANDRIA. In a short time, being wearied of his queen, who was also his sister, he divorced her; and married her daughter, who was also called *Cleopatra*, and whom he had previously ravished. In short, his behaviour was so exceedingly wicked, that it soon became quite intolerable to his subjects; and he was obliged to fly to the island of Cyprus with his new queen, and *Memphitis*, a son he had by her mother.

41 Murders his son.

On the flight of the king, the divorced queen was placed on the throne by the Alexandrians; but Physcon, fearing lest a son whom he had left behind should be appointed king, sent for him into Cyprus, and caused him to be assassinated as soon as he landed. This provoked the people against him to such a degree, that they pulled down and dashed to pieces all the statues which had been erected to him at Alexandria. This the tyrant supposed to have been done at the instigation of the queen, and therefore resolved to revenge it on her by killing his own son whom he had by her. He therefore, without the least remorse, caused the young prince's throat to be cut; and having put his mangled limbs into a box, sent them as a present to his mother Cleopatra. The messenger with whom this box was sent, was one of his guards. He was ordered to wait till the queen's birthday, which approached, and was to be celebrated with extraordinary pomp; and in the midst of the general rejoicing, he was to deliver the present.

42 Physcon restored.

The horror and detestation occasioned by this unexampled piece of cruelty cannot be expressed. An army was soon raised, and the command of it given to one *Marsyas*, whom the queen had appointed general, and enjoined to take all the necessary steps for the defence of the country. On the other hand, Physcon having hired a numerous body of mercenaries, sent them, under the command of one *Hegelochus*, against the Egyptians. The two armies met on the frontiers of Egypt, on which a bloody battle ensued; but at last the Egyptians were entirely defeated, and Marsyas was taken prisoner. Every one expected that the captive general would have been put to death with the severest torments; but Physcon, perceiving that his cruelties only exasperated the people, resolved to try whether he could regain their affections by lenity; and therefore pardoned Marsyas, and set him at liberty.—Cleopatra, in the mean time, being greatly distressed by this overthrow, demanded assistance from Demetrius king of Syria, who had married her eldest daughter by Philometor, promising him the crown of Egypt for his reward. Demetrius accepted the proposal without hesitation, marched with all his forces into Egypt, and there laid siege to Pelusium. But he being no less hated in Syria than Physcon was in Egypt, the people of Antioch, taking advantage of his absence, revolted against him, and were joined by most of the other cities in Syria. Thus Demetrius was obliged to return; and Cleopatra, being now in no condition to oppose Physcon, fled to Ptolemais, where her daughter the queen of Syria at that time resided. Physcon was then restored to the throne of Egypt, which he enjoyed without further molestation till his death; which happened at Alexandria, in the 29th year of his reign and 67th of his age.

43 Ptolemy Lathyrus driven out, and Alexander set up.

To Physcon succeeded Ptolemy Lathyrus, about 122 years before Christ; but he had not reigned long, before his mother, finding that he would not be entirely governed by her, by false surmises stirred up the Alexandrians, who drove him from the throne, and placed on it his youngest brother Alexander. Lathyrus after this was obliged to content himself with the government of Cyprus, which he was permitted to enjoy in quiet. Ptolemy Alexander, in the mean time, finding he was to have only the shadow of sovereignty, and that his mother Cleopatra was to have all the power, stole away privately from Alexandria. The queen used every artifice to bring him back, as well knowing that the Alexandrians would never suffer her to reign alone. At last her son yielded to her entreaties; but soon after, understanding that she had hired assassins to despatch him, he caused her to be murdered.

44 Lathyrus restored.

The death of the queen was no sooner known to the Alexandrians, than, disdaining to be commanded by a parricide, they drove out Alexander, and recalled Lathyrus.—The deposed prince for some time led a rambling life in the island of Cos; but having got together some ships, he, the next year, attempted to return into Egypt. But being met by *Tyrrhus*, Lathyrus's admiral, he was defeated, and obliged to fly to Myra in Lycia. From Myra he steered his course towards Cyprus, hoping that the inhabitants would place him on the throne, instead of his brother. But *Chareas*, another of Lathyrus's admirals, coming up with him while he was ready to land, an engagement ensued, in which Alexander's fleet was dispersed, and he himself killed.

45 Cyrenaic bequeath to the R mans.

During these disturbances, *Apion* king of Cyrenaica, the son of Ptolemy Physcon by a concubine, having maintained peace and tranquillity in his dominions during a reign of 21 years, died, and by his will left his kingdom to the Romans; and thus the Egyptian empire was considerably reduced and circumscribed.

46 City of Thebes ruined.

Lathyrus being now delivered from all competitors, turned his arms against the city of Thebes, which had revolted from him. The king marched in person against the rebels; and, having defeated them in a pitched battle, laid close siege to their city. The inhabitants defended themselves with great resolution for three years. At last, however, they were obliged to submit, and the city was given up to be plundered by the soldiery. They left everywhere the most melancholy

choly monuments of their avarice and cruelty; so that Thebes, which till that time had been one of the most wealthy cities of Egypt, was now reduced so low that it never afterwards made any figure.

47
Aander IIcceeds Lyrus.

About 76 years before Christ, Ptolemy Lathyrus was succeeded by Alexander II. He was the son of the Ptolemy Alexander, for whom Lathyrus had been driven out; and had met with many adventures. He was first sent by Cleopatra into the island of Cos, with a great sum of money, and all her jewels; as thinking that would be the safest place where they could be kept. When Mithridates king of Pontus made himself master of that island, the inhabitants delivered up to him the young Egyptian prince, together with all the treasures. Mithridates gave him an education suitable to his birth; but he, not thinking himself safe with a prince who had shed the blood of his own children, fled to the camp of Sylla the Roman dictator, who was then making war in Asia. From that time he lived in the family of the Roman general, till news was brought to Rome of the death of Lathyrus. Sylla then sent him to Egypt to take possession of the throne. But, before his arrival, the Alexandrians had chosen Cleopatra for the sovereign. To compromise matters, however, it was agreed, that Ptolemy should marry her, and take her for his partner in the throne. This was accordingly done; and 19 days after marriage, the unhappy queen was murdered by her husband, who for 15 years afterwards showed himself such a monster of wickedness, that a general insurrection at last ensued among his subjects, and he was obliged to fly to Pompey the Great, who was then carrying on the war against Mithridates king of Pontus. But Pompey refusing to concern himself in the matter, he retired to the city of Tyre, where he died some months after.

8
Mties Clbatra, annur-detier.

9
Les his kiom to Ro-ma

When he was forced to shut himself up in the city of Tyre, Alexander had sent ambassadors to Rome, in order to influence the senate in his favour. But, dying before the negotiation was finished, he made over by his last will all his rights to the Roman people, declaring them heirs to his kingdom: not out of any affection to the republic; but with a view to raise disputes between the Romans and his rival Auletes, whom the Egyptians had placed on the throne. The will was brought to Rome, where it occasioned warm debates. Some were for taking immediate possession of the kingdom. Others thought that no notice should be taken of such a will, because Alexander had no right to dispose of his dominions in prejudice of his successor, and to exclude from the crown those who were of the royal family of Egypt. Cicero represented, that such a notorious imposition would debase the majesty of the Roman people, and involve them in endless wars and disputes; that the fruitful fields of Egypt would be a strong temptation to the avarice of the people, who would insist on their being divided among them; and lastly, that by this means the bloody quarrels about the Agrarian laws would be revived. These reasons had some weight with the senate; but what chiefly prevented them from seizing on Egypt at this time was, that they had lately taken possession of the kingdom of Bithynia in virtue of the will of Nicomedes, and of Cyrene and Libya by the will of Apion. They thought, therefore, that if they should, on the like pretence, take possession of the kingdom of Egypt, this might too much expose their design of setting up a kind of universal monarchy, and occasion a formidable combination against them.

50
Character of Auletes the new king.

Auletes, who was now raised to the throne by the Egyptians, is said to have surpassed all the kings that went before him in the effeminacy of his manners. The name *Auletes*, which signifies the *flute-player*, was given him because he piqued himself on his skill in performing upon that instrument, and was not ashamed even to contend for the prize in the public games. He took great pleasure in imitating the manners of the Bacchanals; dancing in a female dress, and in the same measures that they used during the solemnities of their god Bacchus; and hence he had the surname of the *New Dionysius* or *Bacchus*. As his title to the crown was disputable (he being only the son of a concubine), the first care of Auletes was to get himself acknowledged by the Romans, and declared their ally. This was obtained by applying to Julius Cæsar, who was at this time consul, and immensely in debt. Cæsar being glad of such an opportunity of raising money, made the king of Egypt pay pretty dear for his alliance. Six thousand talents, a sum equal to 1,162,500l. sterling, were paid partly to Cæsar himself, and partly to Pompey, whose interest was necessary for obtaining the consent of the people. Though the revenues of Egypt amounted to twice this sum, yet Auletes found it impossible for him to raise it without severely taxing his subjects. This occasioned a general discontent; and while the people were almost ready to take up arms, a most unjust decree passed at Rome for seizing the island of Cyprus. When the Alexandrians heard of the intentions of the republic, they pressed Auletes to demand that island as an ancient appendage of Egypt; and, in case of a refusal, to declare war against that haughty and imperious people, who, they now saw, though too late, aimed at nothing less than the sovereignty of the world. With this request the king refused to comply; upon which his subjects, already provoked beyond measure at the taxes with which they were loaded, flew to arms, and surrounded the palace. The king had the good luck to escape their fury, and immediately leaving Alexandria, set sail for Rome.

51
Is acknowledged by the Romans.

52
Is driven from the throne, and flies to Rome.

In his way to that city, he landed on the island of Rhodes, where the famous Cato at that time was, being on his way to Cyprus, to put the unjust decree of the senate into execution. Auletes, desirous to confer with a man of his prudence, immediately sent to acquaint him with his arrival. He imagined, that, upon this notice, Cato would immediately come and wait upon him; but the proud Roman told the messenger, that if the king of Egypt had any thing to say to Cato, he might, if he thought proper, come to his house. Accordingly the king went to pay him a visit; but was received with very little ceremony by Cato, who did not even vouchsafe to rise out of his seat when he came into his presence. When Auletes had laid his affairs before this haughty republican, he was blamed by him for leaving Egypt, the richest kingdom in the world, in order to expose himself, as he said, to the indignities he would meet with at Rome. There Cato told him, that nothing was in request but wealth and grandeur. All the riches of Egypt, he said, would not be

53
Cato's advice to him.

sufficient to satisfy the avarice of the leading men in Rome. He therefore advised him to return to Egypt; and strive, by a more equitable conduct, to regain the affections of his people. He even offered to reconduct him thither, and employ his good offices in his behalf. But though Ptolemy was sensible of the propriety of this advice, the friends he had with him dissuaded him from following it, and accordingly he set out for Rome.

54
Infamous conduct of Auletes.

On his arrival in this metropolis, the king found, to his great concern, that Cæsar, in whom he placed his greatest confidence, was then in Gaul. He was received, however, by Pompey with great kindness. He assigned him an apartment in his own house, and omitted nothing that lay in his power to serve him. But, notwithstanding the protection of so powerful a man, Auletes was forced to go from house to house like a private person, soliciting the votes of the senators. After he had spent immense treasures in procuring a strong party in the city, he was at last permitted to lay his complaints before the senate; and at the same time there arrived an embassy from the Alexandrians, consisting of 100 citizens, to acquaint the senate with the reason of their revolt.

55
Berenice raised to the throne of Egypt.

When Auletes first set out for Rome, the Alexandrians, not knowing what was become of him, placed on the throne his daughter Berenice; and sent an embassy into Syria to Antiochus Asiaticus, inviting him into Egypt to marry the queen, and reign in partnership with her. Antiochus was dead before the arrival of the ambassadors; upon which the same proposal was made to his brother Seleucus, who readily accepted it. This Seleucus is described by Strabo as monstrously deformed in body, and still more so in mind. The Egyptians nicknamed him *Cybiosactes*, or *the Scullion:* a name which seemed more fit for him than any other. He was scarce settled on the throne, when he gave a signal instance of his sordid and avaricious temper. Ptolemy the first had caused the body of Alexander the Great to be deposited in a coffin of massy gold. This the king seized upon; and by that means provoked his wife Berenice to such a degree, that she caused him to be murdered. She then married one Archelaus, high priest of Comana in Pontus, who pretended to be the son of Mithridates the Great; but was, in fact, only the son of that monarch's general.

56
She marries Seleucus, and murders him.

57
Marries Archelaus.

Auletes was not a little alarmed on hearing of these transactions, especially when the ambassadors arrived, which he feared would overturn all the schemes he had laboured so much to bring about. The embassy was headed by one Dion, a celebrated Academic philosopher who had many powerful friends at Rome. But Ptolemy found means to get both him and most of his followers assassinated; and this intimidated the rest to such a degree, that they durst not execute their commission, or, for some time, even demand justice for the murder of their colleagues.

58
Auletes murders the Egyptian ambassadors.

The report of so many murders, however, at last spread a general alarm. Auletes, sure of the protection of Pompey, did not scruple to own himself the perpetrator of them. Nay, though an action was commenced against one Ascitius, an assassin, who had stabbed Dion the chief of the embassy above mentioned, and the crime was fully proved; yet he was acquitted by the venal judges, who had all been bribed by Ptolemy. In a short time, the senate passed a decree, by which it was enacted, that the king of Egypt should be restored by force of arms. All the great men in Rome were ambitious of this commission; which, they well knew, would be attended with immense profit. Their contests on this occasion took up a considerable time; and at last a prophecy of the Sybil was found out, which forbade the assisting an Egyptian monarch with an army. Ptolemy, therefore, wearied out with so long a delay, retired from Rome, where he had made himself generally odious, to the temple of Diana at Ephesus, there to wait the decision of his fate. Here he remained a considerable time: but as he saw that the senate came to no resolution, though he had solicited them by letters so to do; at last, by Pompey's advice, he applied to Gabinius the proconsul of Syria. This Gabinius was a man of a most infamous character, and ready to undertake any thing for money. Therefore, though it was contrary to an express law for any governor to go out of his province without positive orders from the senate and people of Rome, yet Gabinius ventured to transgress this law, upon condition of being well paid for his pains. As a recompense for his trouble, however, he demanded 10,000 talents; that is, 1,937,500l. sterling. Ptolemy, glad to be restored on any terms, agreed to pay the above-mentioned sum; but Gabinius would not stir till he had received one half of it. This obliged the king to borrow it from a Roman knight named *Caius Rabirius Posthumius;* Pompey interposing his credit and authority for the payment of the capital and interest.

59
His restora
tion de-
creed by th

60
Gabinius
undertake
to restore
him for a
great sum.

Gabinius now set out for Egypt, attended by the famous Mark Antony, who at this time served in the army under him. He was met by Archelaus, who since the departure of Auletes had reigned in Egypt jointly with Berenice, at the head of a numerous army. The Egyptians were utterly defeated, and Archelaus taken prisoner in the first engagement. Thus Gabinius might have put an end to the war at once: but his avarice prompted him to dismiss Archelaus on his paying a considerable ransom; after which, pretending that he had made his escape, fresh sums were demanded from Ptolemy for defraying the expences of the war. For these sums Ptolemy was again obliged to apply to Rabirius, who lent him what money he wanted at a very high interest. At last, however, Archelaus was defeated and killed, and thus Ptolemy again became master of all Egypt.

No sooner was Auletes firmly settled on the throne, than he put to death his daughter Berenice, and oppressed his people with the most cruel exactions, in order to procure the money he had been obliged to borrow while in a state of exile. These oppressions and exactions the cowardly Egyptians bore with great patience, being intimidated by the garrison which Gabinius had left in Alexandria. But neither the fear of the Romans, nor the authority of Ptolemy, could make them put up an affront offered to their religion. A Roman soldier happened to kill a cat, which was an animal held sacred and even worshipped by the Egyptians; and no sooner was this supposed sacrilege known, than the Alexandrians made a general insurrection, and gathering together in crowds, made their way through

through the Roman guards, dragged the soldier out of his house, and, in spite of all opposition, tore him in pieces.

63 In atitude of uletes.

Notwithstanding the heavy taxes, however, which Ptolemy laid on his people, it doth not appear that he had any design of paying his debts. Rabirius, who, as we have already observed, had lent him immense sums, finding that the king affected delays, took a voyage to Egypt, in order to expostulate with him in person. Ptolemy paid very little regard to his expostulations; but excused himself on account of the bad state of his finances. For this reason he offered to make Rabirius collector general of his revenues, that he might in that employment pay himself. The unfortunate creditor accepted the employment for fear of losing his debt. But Ptolemy soon after, upon some frivolous pretence or other, caused him and all his servants to be closely confined. This base conduct exasperated Pompey as much as Rabirius; for the former had been in a manner security for the debt, as the money had been lent at his request, and the business transacted at a country house of his near Alba. However, as Rabirius had reason to fear the worst, he took the first opportunity of making his escape, glad to get off with life from his cruel and faithless debtor. To complete his misfortunes, he was prosecuted at Rome as soon as he returned, 1. For having enabled Ptolemy to corrupt the senate with sums lent him for that purpose. 2. For having debased and dishonoured the character of a Roman knight, by farming the revenues, and becoming the servant of a foreign prince. 3. For having been an accomplice with Gabinius, and sharing with him the 10,000 talents which that proconsul had received for his Egyptian expedition. By the eloquence of Cicero he was acquitted; and one of the best orations to be found in the writings of that author was composed on this occasion. Gabinius was also prosecuted; and, as Cicero spoke against him, he very narrowly escaped death. He was, however, condemned to perpetual banishment, after having been stripped of all he was worth. He lived in exile till the time of the civil wars, when he was recalled by Cæsar, in whose service he lost his life.

4 L es his ch en to th re of th o- ma

Auletes enjoyed the throne of Egypt about four years after his re-establishment; and at his death left his children, a son and two daughters, under the tuition of the Roman people. The name of the son was *Ptolemy*, those of the daughters were *Cleopatra* and *Arsinoe*. This was the Cleopatra who afterwards became so famous, and had so great a share in the civil wars of Rome. As the transactions of the present reign, however, are so closely connected with the affairs of Rome, that they cannot be well understood without knowing the situation of the Romans at that time, we refer for an account of them to the *History of Rome*.

St of E- gy ll its con est by the iph of C wan.

With Cleopatra ended the family of Ptolemy Lagus, the founder of the Grecian empire in Egypt, after it had held that country in subjection for the space of 294 years. From this time Egypt became a province of the Roman empire, and continued subject to the emperors of Rome or Constantinople. In the year 642, it was conquered by the Arabs under Amru Ebn al As, one of the generals of the caliph Omar. In the year 889, an independent government was set up in this kingdom by Ahmed Ebn Tolun, who rebelled against Al Mokhadi caliph of Bagdad. It continued to be governed by him and his successors for 27 years, when it was again reduced by Al Moctasi caliph of Bagdad. In about 30 years after, we find it again an independent state, being joined with Syria under Mahomet Ebn Taj, who had been appointed governor of these provinces. This government, however, was also but short-lived; for in the year 968 it was conquered by Jawhar, one of the generals of Moez Ledinillah, the Fatemite caliph of Cairwan in Barbary. See BARBARY, N° 34.

66 Moez takes possession of his new kingdom.

No sooner was Moez informed of the success of his general, than he prepared with all expedition to go and take possession of his new conquest. Accordingly he ordered all the vast quantities of gold which he and his predecessors had amassed, to be cast into ingots, of the size and figure of the millstones used in hand-mills, and conveyed on camels backs into Egypt. To shew that he was fully determined to abandon his dominions in Barbary, and to make Egypt the residence of himself and his successors, he caused the remains of the three former princes of his race to be removed from Cairwan in Barbary, and to be deposited in a stately mosque erected for that purpose in the city of Cairo in Egypt. This was a most effectual method to induce his successors to reside in Egypt also, as it was become an established custom and duty among those princes frequently to pay their respectful visits to the tombs of their ancestors.

67 Will not suffer prayers to be said for the caliph of Bagdad.

To establish himself the more effectually in his new dominions, Moez suppressed the usual prayers made in the mosques for the caliphs of Bagdad, and substituted his own name in their stead. This was complied with not only in Egypt and Syria, but even throughout all Arabia, the city of Mecca alone excepted. The consequence was, a schism in the Mahommedan faith, which continued upwards of 200 years, and was attended with continual anathemas, and sometimes destructive wars between the caliphs of Bagdad and of Egypt.—Having fully established himself in his kingdom, he died in the 45th year of his age, three years after he had left his dominions in Barbary; and was succeeded by his son Abu Al Mansur Barar, surnamed Aziz Billah.

68 Unsuccessful expedition into Syria.

The new caliph succeeded to the throne at the age of 21; and committed the management of affairs entirely to the care of Jawhar, his father's long-experienced general and prime minister. In 978, he sent this famous warrior to drive out Al Aftekin, the emir of Damascus. The Egyptian general accordingly formed the siege of that place; but at the end of two months was obliged to raise it, on the approach of an army of Karmatians under the command of Al Hakem. As Jawhar was not strong enough to venture an engagement with these Karmatians, it was impossible for him to hinder them from effecting a junction with the forces of Al Aftekin. He therefore retreated, or rather fled, towards Egypt with the utmost expedition; but being overtaken by the two confederate armies, he was soon reduced to the last extremity. He was, however, permitted to resume his march, on condition that he passed under Al Aftekin's sword and Al Hakem's lance; and to this disgraceful condition Jawhar found himself obliged to submit. On his arrival in Egypt, he he immediately advised Al Aziz to undertake an expedition in person into the east, against the combined army of Turks, Karmatians, and Damascenes, under the command of Al Aftekin and Al Hakem. The caliph followed his advice; and advancing against his enemies, overthrew them with great slaughter. Al Aftekin himself escaped out of the battle; but was afterwards taken and brought to Al Aziz, who made him his chamberlain, and treated him with great kindness. Jawhar, in the mean time, was disgraced on account of his bad success: and in his disgrace he continued till his death, which happened in the year of our Lord 990, and of the Hegira 381.

69 Aleppo desieged without success.

This year Al Aziz having received advice of the death of Saado'dawla prince of Aleppo, sent a formidable army under the command of a general named *Manjubekin*, to reduce that place. Lulu, who had been appointed guardian to Saado'dawla's son, finding himself pressed by the Egyptians, who carried on the siege with great vigour, demanded assistance from the Greek emperor. Accordingly, he ordered a body of troops to advance to Lulu's relief. Manjubekin, being informed of their approach, immediately raised the siege, and advanced to give them battle. An obstinate engagement ensued, in which the Greeks were at last overthrown with great slaughter. After this victory, Manjubekin pushed on the siege of Aleppo very briskly; but finding the place capable of defending itself much longer than he at first imagined, and his provisions beginning to fail, he raised the siege. The caliph upon this sent him a very threatening letter, and commanded him to return before Aleppo. He did so; and continued the siege for 13 months; during all which time it was defended by Lulu with incredible bravery. At last, the Egyptians hearing that a numerous army of Greeks was on their way to relieve the city, they raised the siege, and fled with the utmost precipitation. The Greeks then took and plundered some of the cities which Al Aziz possessed in Syria; and Manjubekin made the best of his way to Damascus, where he set up for himself. Al Aziz being informed of this revolt, marched in person against him with a considerable army; but being taken ill by the way, he expired, in the 21st year of his reign and 42d of his age.

Al Aziz was succeeded by his son Abu Al Mansur, surnamed Al Hakem; who, being only 11 years of age, was put under the tuition of a eunuch of approved integrity.

70 Strange madness of the caliph Al Hakem.

This reign is remarkable for nothing so much as the madness with which the caliph was seized in the latter part of it. This manifested itself first by his issuing many preposterous edicts; but at length grew to such a height, that he fancied himself a god, and found no fewer than 16,000 persons who owned him as such. These were mostly the Dararians, a new sect sprung up about this time, who were so called from their chief, Mohammed Ebn Ishmael, surnamed Darari. He is supposed to have inspired the mad caliph with this impious notion; and, as Darari set up for a second Moses, he did not scruple to assert that Al Hakem was the great Creator of the universe. For this reason, a zealous Turk stabbed him in the caliph's chariot. His death was followed by a three days uproar in the city of Cairo; during which, Darari's house was pulled down, and many of his followers massacred. The sect, however, did not expire with its author. He left behind him a disciple named Hamza, who, being encouraged by the mad caliph, spread it far and wide through his dominions. This was quickly followed by an abrogation of all the Mahommedan fasts, festivals, and pilgrimages, the grand one to Mecca in particular; so that the zealous Mahometans were now greatly alarmed, as justly supposing that Al Hakem designed entirely to suppress the worship of the true God, and introduce his own in its place. From this apprehension, however, they were delivered by the death of the caliph; who was assassinated, by a contrivance of his own sister, in the year 1020.

Al Hakem was succeeded by his son Al Thaher, who reigned 15 years; and left the throne to a son under seven years of age, named Al Mostanser Billah.—In the year 1041, a revolt happened in Syria; but Al Mostanser having sent a powerful army into that country, under the command of *Anushtekin*, he not only reduced the rebels, but considerably enlarged the Egyptian dominions in Syria.

71 Al Mosta ser attempts th conquest Bagdad.

In 1054, a Turk named Al Bassasiri, having quarrelled with the vizir of Al Kayem caliph of Bagdad, fled to Egypt, and put himself under the protection of Al Mostanser. The latter, imagining this would be a favourable opportunity for enlarging his dominions, and perhaps seizing on the city of Bagdad, supplied Bassasiri with money and troops. By this assistance, he was enabled to possess himself of Arabian Irak, and ravaged that province to the very gates of Bagdad. On this, Al Kayem wrote to Togrol Beg, or Tangrolipix, the Turkish sultan, who possessed very extensive dominions in the east, to come to his assistance. The sultan immediately complied with this request, and soon arrived at Bagdad with a formidable army and 18 elephants. Of this Bassasiri gave notice to Al Mostanser, and entreated him to exert himself further for his support against so powerful an enemy. This was accordingly done, but nothing worthy of notice happened till the year 1058. At this time Bassasiri having found means to excite Ibrahim the sultan's brother to a revolt, Togrol Beg was obliged to employ all his force against him. This gave Bassasiri an opportunity of seizing on the city of Bagdad itself; and the unfortunate caliph, according to some, was taken prisoner, or, according to others, fled out of the city. Bassasiri, on his entry, caused Al Mostanser to be immediately proclaimed caliph in all quarters of the city. Al Kayem's vizir he caused to be led on a camel through the streets of Bagdad, dressed in a woollen gown, with a high red bonnet, and leathern collar about his neck; a man lashing him all the way behind. Then being sewed up in a bull's hide, with the horns placed over his head, and hung upon hooks, he was beaten without ceasing till he died. The imperial palace was plundered, and the caliph himself detained a close prisoner

72 Caliph of Bagdad sisted by Togrol Beg.

73 Bagdad taken.

74 The ca restored

This success was but short-lived; for, in 1059, Togrol Beg defeated his brother Ibrahim, took him prisoner, and strangled him with a bow string. He then marched to Bagdad, which Bassasiri thought proper to abandon at his approach. Here the caliph Al Kayem was delivered up by Mahras, the governor of a city called *Haditha*, who had the charge of him. The caliph

caliph was immediately restored to his dignity; which Bassasiri no sooner understood, than he again advanced towards the city. Against him Togrol Beg sent a part of his army under some of his generals, while he himself followed with the rest. A battle ensued, in which the army of Bassasiri was defeated, and he himself killed. His head was brought to Togrol Beg, who caused it to be brought on a pike through the streets of Bagdad.

5 De ne of he gyp- a mpire.

Thus the hopes of Al Mostanser were entirely frustrated; and from this period we may date the declension of the Egyptian empire under the caliphs. They had made themselves masters of almost all Syria; but no sooner was Bassasiri's bad success known, than the younger part of the citizens of Aleppo revolted, and set up Mahmud Azzo'dawla, who immediately laid siege to the citadel. Al Mostanser sent a powerful army against him, which Azzo'dawla entirely defeated, and took the general himself prisoner; and soon after this he made himself master both of the city and citadel, with all their dependencies. In his new dominions he behaved with the greatest cruelty, destroying every thing with fire and sword, and making frequent incursions into the neighbouring provinces, which he treated in the same manner.

6 Ter le fa- min nd lag

This disaster was soon followed by others still more terrible. In 1066, a famine raged over all Egypt and Syria, with such fury, that dogs and cats were sold for four or five Egyptian dinars each, and other provisions in proportion. Multitudes of people died in Cairo for want of food. Nay, so great was the scarcity, that the vizir had but one servant left who was able to attend him to the caliph's palace, and to whom he gave the care of his horse when he alighted at the gate. But at his return, he was surprised to find that the horse had been carried off, killed and eaten by the famished people. Of this he complained to the caliph; who caused three of them who had carried off the horse to be hanged. Next day, however, he was still more surprised to hear, that all the flesh had been picked off the bones of the three unhappy criminals, so that nothing but the skeletons were left. And to such a degree of misery were the inhabitants, not only in Cairo but through all Egypt, reduced, that the carcases of those who died were sold for food at a great price, instead of being buried. All this time the caliph showed the greatest kindness and beneficence towards his unhappy subjects; insomuch that of 10,000 horses, mules, and camels, which he had in his stables when the famine began, he had only three left when it was removed.

nva d by he ks.

The famine was followed by a plague; and this by an invasion of the Turks under Abu Ali Al Hasan Naserod'dawla, the very general who had been sent against the rebel Azzo'dawla and defeated by him. He began with besieging the caliph in his own palace; and the unhappy prince, being in no condition to make resistance, was obliged to buy himself off at the expence of every thing valuable that was left in his exhausted capital and treasury. This, however, did not hinder those merciless plunderers from ravaging all the Lower Egypt from Cairo to Alexandria, and committing the most horrid cruelties through that whole tract.—This happened in the years 1067 and 1068; and in 1069 and 1070, there happened two other revolts in Syria: so that this country was now almost entirely lost.

78 Jerusalem taken.

In 1095 died the caliph Al Mostanser, having reigned 60 years; and was succeeded by his son Abul Kasem, surnamed Al Mostali. The most remarkable transaction of this prince's reign, was his taking the city of Jerusalem from the Turks in 1098; but this success was only of short duration; for it was the same year taken by the crusaders.

79 A revolution in the kingdom.

From this time to the year 1164, the Egyptian history affords little else than an account of the intestine broils and contests between the vizirs or prime ministers, who were now become so powerful, that they had in a great measure stripped the caliphs of their civil power, and left them nothing but a shadow of spiritual dignity. These contests at last gave occasion to a revolution, by which the race of Fatemite caliphs was totally extinguished. This revolution was accomplished in the following manner. One *Shawer*, having overcome all his competitors, became vizir to Al Aded, the eleventh caliph of Egypt. He had not been long in possession of this office, when Al Dargam, an officer of rank, endeavoured to deprive him of it. Both parties quickly had recourse to arms; and a battle ensued, in which Shawer was defeated, and obliged to fly to Nuroddin prince of Syria, by whom he was graciously received, and who promised to reinstate him in his office of vizir. As an inducement to Nuroddin to assist him more powerfully, Shawer told him that the crusaders had landed in Egypt, and made a considerable progress in the conquest of it. He promised also that, in case he was reinstated in his office, he would pay Nuroddin annually the third part of the revenues of Egypt; and would, besides, defray the whole expence of the expedition.

As Nuroddin bore an implacable hatred to the Christians, he readily undertook an expedition against them, for which he was to be so well paid. He therefore sent an army into Egypt under the command of Shawer and a general named *Asadoddin*. Dargam, in the mean time, had cut off so many generals whom he imagined favourable to Shawer's interest, that he thereby weakened the military force of the kingdom, and in a great measure deprived himself of the power of resistance. He was therefore easily overthrown by Asadoddin, and Shawer reinstated in the office of vizir. The faithless minister, however, no sooner saw himself firmly established in his office, than he refused to fulfil his engagements to Nuroddin by paying the stipulated sums. Upon this, Asadoddin seized Pelusium and some other cities. Shawer then entered into an alliance with the crusaders, and Asadoddin was besieged by their combined forces in Pelusium. Nuroddin, however, having invaded the Christian dominions in Syria, and taken a strong fortress called *Harem*, Shawer and his confederates thought proper to hearken to some terms of accommodation, and Asadoddin was permitted to depart for Syria.

In the mean time, Nuroddin, having subdued the greatest part of Syria and Mesopotamia, resolved to make Shawer feel the weight of his resentment on account of his perfidious conduct. He therefore sent back Asadoddin into Egypt with a sufficient force, to compel Shawer to fulfil his engagements: but this

the

the vizir took care to do before the arrival of Asadoddin; and thus, for the present, avoided the danger. It was not long, however, before he gave Nuroddin fresh occasion to send this general against him. That prince had now driven the crusaders almost entirely out of Syria, but was greatly alarmed at their progress in Egypt; and consequently offended at the alliance which Shawer had concluded with them, and which he still persisted in observing. This treaty was also thought to be contrived on purpose to prevent Shawer from being able to fulfil his promise to Nuroddin, of sending him annually a third of the revenues of Egypt. Nuroddin therefore again despatched Asadoddin into Egypt, in the year 1166, with a sufficient force, and attended by the famous Salahaddin, or Saladin, his own nephew. They entered the kingdom without opposition, and totally defeated Shawer and the crusaders. They next made themselves masters of Alexandria; and, after that, overran all the Upper Egypt. Saladin was left with a considerable garrison in Alexandria; but Asadoddin was no sooner gone, than the crusaders laid siege to that city. This at last obliged Asadoddin to return to its relief. The great losses he had sustained in this expedition probably occasioned his agreeing to a treaty with Shawer, by which he engaged to retire out of Egypt, upon being paid a sum of money.

Asadoddin was no sooner gone, than Shawer entered into a fresh treaty with the Franks. By this new alliance he was to attack Nuroddin in his own dominions, as he was at that time engaged in quelling some revolters, which would effectually prevent his sending any more forces into Egypt. This treaty so provoked the Syrian prince, that he resolved to suspend his other conquests for some time, and exert his whole strength in the conquest of Egypt.

80
Conquests of the crusaders.

By this time the crusaders had reduced Pelusium, and made a considerable progress in the kingdom, as well as in some other countries, through the divisions which reigned among the Mahometan princes. In such places as they conquered, they put almost every body to the sword; Christians as well as Mahometans; selling their prisoners for slaves, and giving up the towns to be plundered by the soldiers. From Pelusium they marched to Cairo; which was then in no posture of defence, and in the utmost confusion, by reason of the divisions which reigned in it. Shawer, therefore, as soon as he heard of their approach, caused the ancient quarter called *Mesr* to be set on fire, and the inhabitants to retire into the other parts. He also prevailed upon the caliph to solicit the assistance of Nuroddin; which the latter was indeed pretty much inclined of himself to grant, as it gave him the fairest opportunity he could have wished for, both of driving the crusaders out of Egypt, and of seizing the kingdom to himself. For this purpose he had already raised an army of 60,000 horse under his general Asadoddin; and on the receipt of Al Aded's message, gave them orders to set out immediately. The crusaders were now arrived at Cairo; and had so closely besieged that place, that neither Shawer nor the caliph knew any thing of the approach of the Moslem army which was hastening to their relief. The vizir, therefore, finding it impossible to hold out long against the enemy, had recourse to his old subterfuge of treaties and high promises. He sent the enemy 100,000 dinars, and promised them 900,000 more, if they would raise the siege; which they, dreading the approach of Asadoddin, very readily accepted.

81
They are repulsed by the army of Nuroddin prince of Damascu

The army of Nuroddin now approached the capital by hasty marches, and were everywhere received with the greatest demonstrations of joy. Asadoddin, on his arrival at Cairo, was invited by Al Aded to the royal palace, where he was entertained in the most magnificent manner, and received several presents; nor were Saladin and the other principal officers less magnificently treated. Shawer also, conscious of his perfidious conduct, was no les assiduous in attending punctually upon him. But having invited the general and some others to an entertainment, he had formed a scheme of having them seized and murdered. The plot, however, being discovered, Shawer himself had his head cut off, and Asadoddin was made vizir in his stead. He did not, however, long enjoy his new dignity; for he died two months and five days after his instalment, being succeeded in his office of vizir by his nephew Saladin.

82
Saladin becomes vizi of Egypt.

The new vizir was the youngest of all the grandees who aspired to that office, but had already given some signal proofs of his valour and conduct. What determined the caliph to prefer him to all the rest is not known; but it is certain that some of them were highly displeased with his promotion, and even publicly declared that they would not obey him. In order to gain these to his interest, therefore, Saladin found it necessary to distribute among them part of the vast treasures left by his uncle; by which means he soon governed Egypt without controul, as had been customary with the vizirs for some time before. Soon after his being installed into the office of vizir, he gave a total defeat to the negroes who guarded the royal palace, and had opposed his election; by which means, and a strong garrison he had placed in the castle of Cairo, his power became firmly established. Though he had not the least intention of continuing in his allegiance to Nuroddin, he did not think it prudent at first to declare himself. He sent for his father, however, and the rest of his family, who were in Nuroddin's dominions, in order, as he said, to make them partakers of his grandeur and happiness. Nuroddin did not think proper to deny this request; though, being already jealous of the great power of Saladin, he insisted that his family should consider him only as one of his generals in Egypt.

A good understanding subsisted between Nuroddin and Saladin for some time, which did not a little contribute to raise the credit of the latter with the Egyptians. In 1169, Nuroddin sent him orders to omit the name of Al Aded, the caliph of Egypt, in the public prayers, and substitute that of the caliph of Bagdad in its place. This was at any rate a dangerous attempt; as it might very readily produce a revolt in favour of Al Aded: or if it did not, it gave Saladin an opportunity of engrossing even that small remnant of power which was left to the caliph. Al Aded, however, was not sensible of his disgrace; for he was on his deathbed, and past recovery, when Nuroddin's orders were executed. After his death, Saladin seized on all his wealth and valuable effects; which consisted of jewels of prodigious size, sumptuous furniture, a library containing

83
Seizes effects the ca

containing 100,000 volumes, &c. His family he caused to be closely confined in the most private and retired part of the palace; and either manumitted his slaves, or kept them for himself, or disposed of them to others.

spi to e own.

Saladin was now arrived at the highest pitch of wealth, power, and grandeur. He was, however, obliged to behave with great circumspection with regard to Nuroddin: who still continued to treat him as his vassal, and would not suffer him to dispute the least of his commands. He relied for advice chiefly on his father Ayub; who was a consummate politician, and very ambitious of seeing his son raised to the throne of Egypt. He therefore advised Saladin to continue stedfast in his resolutions; and, whilst he amused Nuroddin with feigned submissions, to take every method in his power to secure himself in the possession of so valuable a kingdom. Nuroddin himself, however, was too great a master in the art of dissimulation to be easily imposed on by others; and therefore, though he pretended to be well pleased with Saladin's conduct, he was all this time raising a powerful army, with which he was fully determined to invade Egypt the following year. But while he meditated this expedition, he was seized with a quinsy at the castle of Damascus, which put an end to his life, in the year 1173.

ubd A- bia elix.

Saladin, though now freed from the apprehensions of such a formidable enemy, dared not venture to assume the title of *Sovereign*, while he saw the successor of Nuroddin at the head of a very powerful army, and no less desirous than able to dispossess him. For this reason his first care was to secure to himself an asylum, in case he should be obliged to leave Egypt altogether. For this purpose he chose the kingdom of Nubia; but having despatched his brother Malek Turanshah thither, at the head of a considerable army, the latter was so much struck with the sterility and desolate appearance of the country, that he returned without attempting any thing. Saladin then sent his brother into Arabia Felix, in order to subdue that country, which had been for some time held by Abdalnabi an Arabian prince. Malek entered the country without opposition; and having brought Abdalnabi to a general action, entirely defeated him, took him prisoner, and threw him into irons. He then overran and reduced under subjection to Saladin great part of the country, taking no fewer than 80 castles or fortresses of considerable strength.

ssu e t of ltal

After this good fortune, Saladin, now sure of a convenient place of refuge in case of any misfortune, assumed the title of *Sultan* or sovereign of Egypt; and was acknowledged as such by the greater part of the states. The zeal of the Egyptians for the Fatemite caliphs, however, soon produced a rebellion. One *Al Kanz*, or *Kanzanaddowla*, governor of a city in Upper Egypt, assembled a great army of blacks, or rather swarthy natives; and marching directly into the lower country, was there joined by great numbers of other Egyptians. Against them Saladin despatched his brother Malek, who soon defeated and entirely dispersed them. This, however, did not prevent another insurrection under an impostor, who pretended to be David the son of Al Aded the last Fatemite caliph, and had collected a body of 100,000 men. But before these had time to do any great damage, they were surprised by the sultan's forces, and entirely defeated. Above 300 were publicly hanged, and a vast number perished in the field, insomuch that it was thought scarce a fourth part of the whole body escaped.

About this time Saladin gained a considerable advantage over the crusaders, commanded by William II. king of Sicily. That prince had invaded Egypt with a numerous fleet and army, with which he laid close siege to Alexandria both by sea and land. Saladin, however, marched to the relief of the city with such surprising expedition, that the crusaders were seized with a sudden panic, and fled with the utmost precipitation, leaving all their military engines, stores, and baggage behind.

87 Saladin made sovereign of Damascus.

In the year 1175, the inhabitants of Damascus begged of Saladin to accept the sovereignty of that city and its dependencies; being jealous of the minister, who had the tuition of the reigning prince, and who governed all with an absolute sway. The application was no sooner made, than the sultan set out with the utmost celerity to Damascus, at the head of a chosen detachment of 700 horse. Having settled his affairs in that city, he appointed his brother Saif Al Islam governor of it; and set out for Hems, to which he immediately laid siege. Having made himself master of this place, he then proceeded to Hamah. The city very soon surrendered, but the citadel held out for some time. Saladin pretended that he accepted the sovereignty of Damascus and the other places he had conquered, only as deputy to Al Malek Al Saleh, the successor of Nuroddin, and who was then under age; and that he was desirous of sending Azzoddin, who commanded in the citadel, with a letter to Aleppo, where the young prince resided. This so pleased Azzoddin, that he took the oath of fidelity to Saladin, and immediately set out with the sultan's letter. He had not, however, been long at Aleppo before he was by the minister's orders thrown into prison; upon which his brother, who had been appointed governor of the citadel of Hamah in his absence, delivered it up to Saladin without further ceremony. The sultan then marched to Aleppo, with a design to reduce it: but, being vigorously repulsed in several attacks, he was at last obliged to abandon the enterprise. At the same time, Kamschlegin, Al Malek's minister or vizir, hired the chief of the Batanists, or Assassins *, to murder him. Several attempts were made in consequence of this application; but all of them, happily for Saladin, miscarried.

After raising the siege of Aleppo, Saladin returned to Hems, which place the crusaders had invested. On his approach, however, they thought proper to retire; after which, the sultan made himself master of the strong castle belonging to that place, which before he had not been able to reduce. This was soon followed by the reduction of Baalbec: and these rapid conquests so alarmed the ministers of Al Malek, that, entering into a combination with some of the neighbouring princes, they raised a formidable army, with which they designed to crush the sultan at once. Saladin, fearing the event of a war, offered to cede Hems and Hamah to Al Malek, and govern Damascus only as his lieutenant: but these terms being rejected, a battle ensued; in which the allied army was utterly defeated, and the shattered remains of it shut up in the city of Aleppo. This produced a treaty, by which Saladin

88 Defeats his enemies.

* See *Assassin*.

Saladin was left master of all Syria, excepting only the city of Aleppo and the territory belonging to it.

89 Receives a terrible overthrow from the crusaders.

In 1176 Saladin returned from the conquest of Syria, and made his triumphal entry into Cairo. Here, having rested himself and his troops for some time, he began to encompass the city with a wall 29,000 cubits in length, but which he did not live to finish. Next year he led a very numerous army into Palestine against the crusaders. But here his usual good fortune failed him. His army was entirely defeated. Forty thousand of his men were left dead on the field; and the rest fled with so much precipitation, that, having no towns in the neighbourhood where they could shelter themselves, they traversed the vast desert between Palestine and Egypt, and scarce stopped till they reached the capital itself. The greatest part of the army by this means perished; and as no water was to be had in the desert above mentioned, almost all the beasts died of thirst before the fugitives arrived on the confines of Egypt. Saladin himself seemed to have been greatly intimidated; for in a letter to his brother Al Malek, he told him, that "he was more than once in the most imminent danger; and that God, as he apprehended, had delivered him from thence, in order to reserve him for the execution of some grand and important design."

In the year 1182, the sultan set out on an expedition to Syria, with a formidable army, amidst the acclamations and good wishes of the people. He was, however, repulsed with loss both before Aleppo and Al Mawsel, after having spent much time and labour in besieging these two important places.

90 The Christians receive a great defeat at sea.

In the mean time, a most powerful fleet of European ships appeared on the Red sea, which threatened the cities of Mecca and Medina with the utmost danger. The news of this armament no sooner reached Cairo, than Abu Becr, Saladin's brother, who had been left viceroy in the sultan's absence, caused another to be fitted out with all speed under the command of Lulu, a brave and experienced officer, who quickly came up with them, and a dreadful engagement ensued. The Christians were defeated after an obstinate resistance, and all the prisoners butchered in cold blood. This proved such a terrible blow to the Europeans, that they never more ventured on a like attempt.

91 Saladin's rapid conquests.

In 1183, Saladin continued to extend his conquests. The city of Amida in Mesopotamia surrendered to him in eight days; after which, being provoked by some violences committed by the prince of Aleppo, he resolved at all events to make himself master of that place. He was now attended with better success than formerly; for as his army was very numerous, and he pushed on the siege with the utmost vigour, Amadoddin the prince capitulated, upon condition of being allowed to possess certain cities in Mesopotamia which had formerly belonged to him, and being ready to attend the sultan on whatever expedition he pleased. After the conquest of Aleppo, Saladin took three other cities, and then marched against his old enemies the crusaders. Having sent out a party to reconnoitre the enemy, they fell in with a considerable detachment of Christians; whom they easily defeated, taking about 100 prisoners, with the loss of only a single man on their side. The sultan, animated by this first instance of success, drew up his forces in order of battle, and advanced against the crusaders, who had assembled their whole army at Sepphoris in Galilee. On viewing the sultan's troops, however, and perceiving them to be greatly superior in strength to what they had at first apprehended, they thought proper to decline an engagement, nor could Saladin with all his skill force them to it. But though it was found impossible to bring the crusaders to a decisive engagement, Saladin found means to harass them greatly, and destroyed great numbers of their men. He carried off also many prisoners, dismantled three of their strongest cities, laid waste their territories, and concluded the campaign with taking another strong town.

92 Christians totally defeated.

For three years Saladin continued to gain ground on the crusaders, yet without any decisive advantage; but in 1187, the fortune of war was remarkably unfavourable to them. The Christians now found themselves obliged to venture a battle, by reason of the cruel ravages committed in their territories by Saladin, and by reason of the encroachments he daily made on them. Both armies therefore being resolved to exert their utmost efforts, a most fierce and bloody battle ensued. Night prevented victory from declaring on either side, and the fight was renewed with equal obstinacy next day. The victory was still left undecided; but the third day the sultan's men finding themselves surrounded by the enemy on all sides but one, and there also hemmed in by the river Jordan, so that there was no room to fly, fought like men in despair, and at last gained a most complete victory. Vast numbers of the Christians perished on the field. A large body found means to retire in safety to the top of a neighbouring hill covered with wood; but being surrounded by Saladin's troops, who set fire to the wood, they were all obliged to surrender at discretion. Some of them were butchered by their enemies as soon as they delivered themselves into their hands, and others thrown into irons. Among the latter were the king of Jerusalem himself, Arnold prince of Al Shawbec and Al Carac, the masters of the Templars and Hospitalers, with almost the whole body of the latter. So great was the consternation of the Christians on this occasion, that one of Saladin's men is said to have taken 30 of them prisoners, and tied them together with the cord of his tent, to prevent them from making their escape. The masters of the Templars and Hospitalers, with the knights acting under them, were no sooner brought into Saladin's presence, than he ordered them all to be cut in pieces. He called them *Assassins* or *Batanists*; and had been wont to pay 50 dinars for the head of every Templar or Hospitaler that was brought him. After the engagement, Saladin seated himself in a magnificent tent, placing the king of Jerusalem on his right hand, and Arnold prince of Al Shawbec and Al Carac on his left. Then he drank to the former, who was at that time ready to expire with thirst, and at the same time offered him a cup of snow water. This was thankfully received; and the king immediately drank to the prince of Al Carac, who sat near him. But here Saladin interrupted him with some warmth: "I will not (says he) suffer this cursed rogue to drink; as that, according to the laudable and generous custom of the Arabs, would secure to him his life." Then, turning

turning towards the prince, he reproached him with having undertaken the expedition while in alliance with himself, with having intercepted an Egyptian caravan in the time of profound peace, and massacring the people of which it was composed, &c. Notwithstanding all this, he told him, he would grant him his life, if he would embrace Mahometanism. This condition, however, was refused; and the sultan, with one stroke of his scimitar, cut off the prince's head. This greatly terrified the king of Jerusalem; but Saladin assured him he had nothing to fear, and that Arnold had brought on himself a violent death by his want of common honesty.

93 Further conquests.

The crusaders being thus totally defeated and dispersed, Saladin next laid siege to Tiberias, which capitulated in a short time. From thence he marched towards Acca or Ptolemais, which likewise surrendered after a short siege. Here he found 4000 Mahometan prisoners in chains, whom he immediately released. As the inhabitants enjoyed at present a very extensive trade, the place being full of merchants, he found there not only vast sums of money, but likewise a great variety of wares exceedingly valuable, all which he seized and applied to his own house. About the same time his brother Al Malec attacked and took a very strong fortress in the neighbourhood; after which the sultan divided his army into three bodies, that he might with the greater facility overrun the territories of the Christians. Thus, in very short time, he made himself master of Neapolis, Cæsarea, Sepphoris, and other cities in the neighbourhood of Ptolemais, where his soldiers found only women and children, the men having been all killed or taken prisoners. His next conquest was Joppa, which was taken by storm after a vigorous resistance. Every thing being then settled, and a distribution made of the spoils and captives, Saladin marched in person against Tebrien, a strong fortress in the neighbourhood of Sidon; which was taken by assault, after it had sustained a siege of six days. No sooner was he master of this place, than he ordered the fortress to be razed, and the garrison put to the sword. From Tebrien the victorious sultan proceeded to Sidon itself; which being deserted by its prince, surrendered almost on the first summons. Berytus was next invested, and surrendered in seven days. Among the prisoners Saladin found in this place the prince of a territory called *Hobeil*, who by way of ransom delivered up his dominions to him, and was of consequence released. About the same time, a Christian ship, in which was a nobleman of great courage and experience in war, arrived at the harbour of Ptolemais, not knowing that it was in the hands of Saladin. The governor might easily have secured the vessel; but neglecting the opportunity, she escaped to Tyre, where the above-mentioned nobleman, together with the prince of Hobeil, contributed not a little to retrieve the affairs of the Christians, and enable them to make a stand for four years after.

Jerusalem taken.

Saladin in the mean time went on with his conquests. Having made himself master of Ascalon after a siege of 14 days, he next invested Jerusalem. The garrison was numerous, and made an obstinate defence; but Saladin having at last made a breach in the walls by sapping, the besieged desired to capitulate. This was at first refused: upon which the Christian ambassador made the following speech: "If that be the case, know, O sultan, that we who are extremely numerous, and have been restrained from fighting like men in despair only by the hopes of an honourable capitulation, will kill all our wives and children, commit all our wealth and valuable effects to the flames, massacre 5000 prisoners now in our hands, leave not a single beast of burden or animal of any kind belonging to us alive, and level with the ground the rock you esteem sacred, together with the temple Al Aksa. After this we will sally out upon you in a body; and doubt not but we shall either cut to pieces a much greater number of you than we are, or force you to abandon the siege." This desperate speech had such an effect upon Saladin, that he immediately called a council of war, at which all the general officers declared, that it would be most proper to allow the Christians to depart unmolested. The sultan therefore allowed them to march out freely and securely with their wives, children, and effects; after which he received ten dinars from every man capable of paying that sum, five from every woman, and two from every young person under age. For the poor who were not able to pay any thing, the rest of the inhabitants raised the sum of 30,000 dinars.

Most of the inhabitants of Jerusalem were escorted by a detachment of Saladin's troops to Tyre; and soon after, he advanced with his army against that place. As the port was blocked up by a squadron of five men of war, Saladin imagined that he should easily become master of it. But in this he found himself mistaken. For, one morning by break of day, a Christian fleet fell upon his squadron, and entirely defeated it; nor did a single vessel escape their pursuit. A considerable number of the Mahometans threw themselves into the sea during the engagement; most of whom were drowned, though some few escaped. About the same time Saladin himself was vigorously repulsed by land; so that, after calling a council of war, it was thought proper to raise the siege.

In 1188, Saladin though his conquests were not so rapid and considerable as hitherto, continued still superior to his enemies. He reduced the city of Laodicea and some others, together with many strong castles; but met also with several repulses. At last he took the road to Antioch; and having reduced all the fortresses that lay in his way, many of which had been deemed impregnable, Bohemond prince of Antioch was so much intimidated, that he desired a truce for seven or eight months. This Saladin found himself obliged to comply with, on account of the prodigious fatigues his men had sustained, and because his auxiliaries now demanded leave to return home.

95 Crusaders retrieve their affairs.

All these heavy losses of the Christians, however, proved in some respects an advantage, as they were thus obliged to lay aside their animosities, which had originally proved the ruin of their affairs. Those who had defended Jerusalem, and most of the other fortresses taken by Saladin, having retreated to Tyre, formed there a very numerous body. This proved the means of preserving that city, and also of re-establishing their affairs for the present. For, having received powerful succours from Europe, they were enabled in 1189 to take the field with 30,000 foot and 2000 horse. Their first attempt was upon Alexandretta; from whence they dislodged a strong party of Mahometans, and made themselves

themselves masters of the place with very little loss. They next laid siege to Ptolemais; of which Saladin had no sooner received intelligence, than he marched to the relief of the place. After several skirmishes with various success, a general engagement ensued, in which Saladin was defeated with the loss of 10,000 men. This enabled the Christians to carry on the siege of Ptolemais with greater vigour; which place, however, they were not able to reduce for the space of two years.

This year the sultan was greatly alarmed by an account that the emperor of Germany was advancing to Constantinople with an army of 260,000 men, in order to assist the other crusaders. This prodigious armament, however, came to nothing. The multitude was so reduced with sickness, famine, and fatigue, that scarce 1000 of them reached the camp before Ptolemais. The siege of that city was continued, though with bad success on the part of the Christians. They were repulsed in all their attacks, their engines were burnt with naphtha, and the besieged always received supplies of provisions in spite of the utmost efforts of the besiegers; at the same time that a dreadful famine and pestilence raged in the Christian camp, which sometimes carried off 200 people a-day.

96 Richard I. of England arrives in Asia.

In 1191, the Christians received powerful succours from Europe. Philip II. of France, and Richard I. of England (from his great courage surnamed *Cœur de Lion*) arrived at the camp before Ptolemais. The latter was esteemed the bravest and most enterprising of all the generals the crusaders had; and the spirits of his soldiers were greatly elated by the thoughts of acting under such an experienced commander. Soon after his arrival, the English sunk a Mahometan ship of vast size, having on board 650 soldiers, a great quantity of arms and provisions, going from Berytus to Ptolemais. Of the soldiers and sailors who navigated this vessel, only a single person escaped; who being taken prisoner by the English, was despatched to the sultan with the news of the disaster. The besieged still defended themselves with the greatest resolution; and the king of England happening to fall sick, the operations of the besiegers were considerably delayed. On his recovery, however, the attacks were renewed with such fury, that the place was every moment in danger of being taken by assault. This induced them to send a letter to Saladin, informing him, that if they did not receive succours the very next day, they would be obliged to submit. As this town was the sultan's principal magazine of arms, he was greatly affected with the account of their distress, especially as he found it impossible to relieve them. The inhabitants, therefore, found themselves under a necessity of surrendering the place. One of the terms of the capitulation was, that the crusaders should receive a very considerable sum of money from Saladin, in consequence of their delivering up the Mahometan prisoners they had in their hands. This article Saladin refused to comply with; and, in consequence of his refusal, Richard caused 3000 of those unfortunate men to be slaughtered at once.

97 Defeats Saladin.
