We have seen, that, according to M. Muret, the probability of life, or the age to which half the born live, was, in the extraordinary parish of Leyzin, as high as 61 years. On the same authority, it appears that in nine other parishes of the Alps it was as high as 47; in 41 parishes of the Pays de Vaud and Jura 42; in 12 corn parishes 40; in 18 parishes among the great vineyards 37, in one marshy parish 24. † From other authorities we learn, that in country villages and parishes, the age to which half of the born live is such, that the major part will probably live to marry. ‡ In the parish of Ackworth in Yorkshire, it appears from an exact account kept by Dr Lee of the ages at which all died there for 20 years, from 1747 to 1767, that half the inhabitants live to the age of 46 (Price, Vol. II. p. 35, 7th edit.); and if the same account had been kept in many of the other healthy parishes in England, where the yearly mortality, instead of being 1 in 47 as in Ackworth, was 1 in 60, 1 in 66, and even 1 in 75 (Vol. II. p. 224), half of the born would be found to have lived to above 50 or 55. In the whole of Sweden, where the annual mortality, at the time referred to by Dr Price, was greater than 1 in 35, it appears from his tables, that half of the born must have lived to above 33 (Vol. II. p. 413, 7th edit.); and in Great Britain generally, where the mortality at present, after making due allowance for the omissions in the deaths, appears to be less than 1 in 51, it cannot be doubted that there is scarcely a village in the country tolerably well situated, where half of the born do not live till above 40. In towns the case is very different. According to

\* See Malthus *On Population*, Chapters i. and ii. of Book II.

† *Memoires, &c. par la Société Economique de Berne*, 1766, Table VIII. p. 92 of the Tables. As these calculations seem all to have been made from mortuary registers, they are all too low, except where the population was absolutely stationary.

‡ Graunt's and Short's *Observations, &c.* referred to by Dr Price, Vol. II. pp. 41, 42, &c. 7th edit.

Population. the data collected by Dr Price, one half of the born died in London under three years of age; in Vienna and Stockholm under two; in Manchester under five; in Northampton under ten (Vol. II. p. 33); and although in most of these towns, particularly those in England, a great improvement has taken place in their healthiness of late years, yet still they will always fall far short of the healthiness of country situations.

The age to which half the born live appears, therefore, to vary in different countries and places, and under different circumstances, in the very extraordinary degree of from 3 to 60.\*

The mean age of death, or the expectation of life, must necessarily be more steady; yet it appears to vary from about 16 or 17 to 50.

In Stockholm, according to a table calculated by Dr Price, from the medium of three different enumerations in 1757, 1760, and 1763, the expectation of life for males at birth was 14.25, and for females 18.10. † Taken together, the expectation of life was a little above 16. In Vienna, as appears from another table, it was 16½. ‡ While, according to M. Muret, at Leyzin, the expectation of life at birth was, about the same period, 50 years. §

The annual mortality, which is different, both from the age to which half of the born live, and the mean age of death, is found to vary in different places and countries, from about 1 in 19 to about 1 in 70. In Stockholm, the annual mortality was but 1 in 19 (Price's *Observations*, Vol. II. p. 136); and in some of the villages in England, even at the time that Dr Price wrote, it was as low as 1 in 70 and 1 in 75.

The proportion of births to the population appears to vary in different countries and under different circumstances, from about 1 in 17 to 1 in 49. In New Spain, according to Humboldt, it was 1 in 17. In New Jersey, according to the rate of increase determined by the census taken in 1738 and seven years afterwards, the proportion of births must have been about 1 in 18. (Price, Vol. II. p. 50.) At present, as far as can be collected from scattered facts and inferences, the proportion of births in the whole of the United States is about 1 to 19. In the table for Prussia and Lithuania given by Sussmilch, it appears, that after the great plague of 1709 and 1710, and omitting the extraordinary year immediately subsequent, the proportion of births in the five years, ending with 1716, was 1 in less than 17. || While, according to M. Muret, in the parish of Leyzin, the proportion of births was only 1 in 49 of the population.

The number of subsisting marriages, which yields one annual birth, appears to vary from 12 to 4, and

the two extreme cases occur in what may be called the same country, and are both noticed by M. Muret; the one in the parish of Leyzin, which presents all the symptoms of the prudential check to population in the greatest excess, and where twelve subsisting marriages yield only one annual birth; and the other in the parish of St Cergue in the Jura, where marriage is encouraged by the habit of emigration, and four subsisting marriages are sufficient to yield one annual birth.

The proportion of the population under 16 years of age, to that above 16, seems to vary in different countries and places, and under different circumstances, from one-half to one-fourth. In the United States, it appears by the late census, that it is one-half; while in the canton of Berne it is not much more than one-fourth, and in the parish of Leyzin not more than one-fourth. ¶

The mortality under the age of 15 varies in different places and circumstances, from above two-thirds to one-fifth. It appears from a table of Dr Price, that in Stockholm, above two-thirds died under 15 (Vol. II. p. 418); while, according to M. Muret, the proportion of the deaths under the age of 15 was, in the whole of the Pays de Vaud, one-third, in many parishes of the Alps one-fourth, and the extraordinary parish of Leyzin only one-fifth. \*\*

Under these very great variations in the registers of different countries and places, and in the structure of their population, it is obvious that we might fall into the grossest possible errors, by applying the registers of one country to the population of another. Even if we could find a country which was near to a just mean between these opposite extremes, and the registers of which were kept with the greatest accuracy, we could not apply such registers to any other country with a view to any important inferences; unless we knew that the two countries nearly resembled each other, not only in one or two particulars, but in all the main points relating to the structure of their population and the character of the prevailing checks to it.

When attention was first directed to tables of mortality, with a view to Assurances on lives and survivorships, these tables were almost universally formed from the registers of towns and of the neighbouring villages influenced by them. Buffon, calculating the probability of life from the registers of three parishes in Paris, and twelve country parishes in the neighbourhood, collected by M. Dupré de St Maur, makes it appear, that half of the born died under eight years of age. The parishes in Paris seemed to be healthier than the villages in the neighbourhood, which was occasioned by the custom of sending the

Population. children from the city to be nursed in the country. Other calculations from the registers of Breslaw by Dr Halley, of London by Mr Simpson, and subsequently of Northampton, Warrington, Chester, Norwich, &c. by Dr Price and other writers, all concurred to convey the impression, that more than half of the born die under the age of puberty; and though Dr Price, in his two volumes of *Observations on Reverendary Payments*, takes frequent opportunities of dwelling upon the prodigious difference in the mortality of towns and of country situations, and produces abundance of evidence to show that, taken together, in the actual state of things, half of the born live much beyond the age of puberty; yet, among some persons who have not attended to the subject, the former impression seems still to have remained; and what is more strange, it has been lately asserted that this must happen from the constitution and course of human nature (Godwin's *Answer to Malthus*); which is going very much further than to say that it happens under the poverty, distress, and unhealthy occupations which are known to affect the mortality of a considerable body of people in all the nations with which we are acquainted.

The Constitution and Course of Human Nature only to be determined by Experience.

The constitution and course of human nature can only be determined by experience, and the analogies derived from it; and the kind of experience necessary to determine the point in question, is to be obtained only by a reference to registers which inform us of the ages at which the born have died. Now, from the evidence of registers of this kind which have been carefully kept in country parishes, it appears that the age to which half of the born live is much nearer to 40 than to the age of puberty. Even in Sweden, where the general mortality is unquestionably very great, owing to the poverty of the labouring classes, and the diseases brought upon them by bad and insufficient food during seasons of scarcity, the age to which half of the born live is, as before stated, above 33;\* in the whole of the Pays de Vaud it is 41; in many particular parishes 47, in a parish in England not so healthy as many others 47; and as the expectation of life appears, by the late returns from the parish registers of Great Britain, to be as high as in Switzerland, there is little reason to doubt, from the evidence of registers, that the age to which half of the born live in this country can fall but little short of what it is in the Pays de Vaud;—that is, it must be somewhere near 40. But it will hardly be contended that there is no premature mortality in Great Britain occasioned by the pressure of poverty, and the effect of large towns and unwholesome occupations. Consequently, unless we are prepared to say that agricultural employments, airy and moderately sized towns, cleanliness, healthy occupations, and prudence, are against the constitution and course of nature, as applied to reasonable beings, we must acknowledge, that if the constitution and course of nature were carefully observed, and the admoni-

tions which they give properly attended to, half of the born would, in healthy climates, live on an average to 45. Taking things, however, as they are, it is obvious that, according to the testimony of the best registers, more than half of the born might live to marry in most countries, even if the average age of marriage was so late as 30.

The immediate cause of the increase of population is the excess of the births above the deaths; and the rate of increase, or the period of doubling, depends upon the proportion which the excess of the births above the deaths bears to the population. Immediate Causes of the Increase of Population.

The excess of births is occasioned by, and proportioned to, three causes; 1st, The prolificness of the marriages. 2dly, The proportion of the born which lives to marry; and, 3dly, The earliness of these marriages compared with the expectation of life, or the shortness of a generation by marriage and birth, compared with the passing away of a generation by death.

In order that the full power of increase should be called into action, all these circumstances must be favourable. The marriages must be prolific, owing to their being contracted early; the proportion of the born living to marry must be great, owing both to the tendency to marriage, and the great proportion of births rising to the age of puberty; and the interval between the average age of marriage and the average age of death must be considerable, owing to the great healthiness of the country, and the expectation of life being high. Probably these three causes, each operating with the greatest known force, have never yet been found combined. Even in the United States, though the two first causes operate very powerfully, the expectation of life, and, consequently, the distance between the age of marriage and the average age of death is not so favourable as it might be. In general, however, the excess of births which each country can admit being very far short of the full power of increase, the causes above mentioned contribute to the required supply in very various proportions, according to the different circumstances and habits of each state.

It would be very desirable to know something of these proportions with a view to their influence on the happiness of society. Our main sources of information on this subject are registers of births, deaths, and marriages; but in order to draw just inferences from them, we must consider well what they imply. The following observations and rules modified from Mr Malthus's chapter on the fruitfulness of marriages may be useful for this purpose. Inferences to be drawn from Registers.

If we suppose a country where the population is stationary, where there are no emigrations, immigrations, or illegitimate children, and where the registers are accurate, then the proportion of the annual births to the annual marriages will accurately express both the number of children born to each marriage, including second and third marriages, and also the Proportion of Births to a Marriage.

\* We allude to the registers and tables referred to by Dr Price. Since his time the health of the country has increased, like most of the countries in Europe, and the proportions of both the births and deaths have decidedly diminished.

Population. proportion of the born which lives to marry once or oftener: while the annual mortality will accurately express the expectation of life.

But if the population be either increasing or decreasing, and the births, deaths, and marriages, increasing or decreasing in the same ratio, such a movement will necessarily disturb all the proportions; because the events which are contemporary in the registers are not contemporary in the order of nature.

In the first place, the births of any year cannot, in the order of nature, have come from the contemporary marriages, but must have been derived principally from the marriages of preceding years.

If we were to cut off a period of 30 years in the registers of any country some time ago, and inquire what was the number of births which had been produced by all the marriages included in the period cut off, it is evident, that, with the marriages at the beginning of the period will be arranged a number of births proceeding from marriages anterior to it; and at the end a number of births produced by the marriages included in the period, will be found arranged with the marriages of a succeeding period. Now, if we could subtract the former number, and add the latter, we should obtain exactly all the births produced by the marriages of the period, and thus ascertain the real prolifickness of marriages. If the population had been stationary, the number of births to be added would exactly equal the number to be subtracted, and the proportion of births to marriages, as found in the registers, would exactly represent the real prolifickness of marriages. But if the population be increasing, the number to be added would be greater than the number to be subtracted, and of course the proportion of births to marriages, as found in the registers, would always be too small to represent the true prolifickness of marriages. A contrary effect would take place in a decreasing population. The question, therefore, is, what we are to add, and what to subtract, when the births and deaths are not equal.

The average proportion of births to marriages in Europe, as taken from registers, is about 4 to 1. Let us suppose, for the sake of illustration, that each marriage yields four children, one every other year. In this case, wherever the period in the registers is begun, the marriages of the preceding eight years will only have produced half their births, and the other half will be arranged with the marriages within the period, and ought to be subtracted from them. In the same manner the marriages of the last eight years of the period will only have produced half their births, and the other half ought to be added. But half the births of any eight years may be considered as nearly equal to all the births of the succeeding  $3\frac{1}{4}$  years. In instances of the most rapid increase it will rather exceed the births of the next  $3\frac{1}{2}$  years, and in cases of slow increase, approach towards the births of the next 4 years. The mean, therefore, may be taken at  $3\frac{3}{4}$  years. Consequently, if we subtract the births of the first  $3\frac{1}{4}$  years, and add the births of the  $3\frac{3}{4}$  years subsequent to the period, we shall have a number of births nearly equal to the number of births produced by all the marriages in-

Population. cluded in the period, and, of course, the prolifickness of marriages. But, if the population of a country be increasing regularly, and the births, deaths, and marriages continue always to bear the same proportion to each other, and to the whole population, it is evident that all the births of any period will bear the same proportion to all the births of any other period of the same extent, taken a certain number of years later, as the births of any single year to the births of a single year, taken the same number of years later. And, consequently, to estimate the prolifickness of marriages, we have only to compare the marriages of the present, or any other year, or the mean of five years, with the births of a subsequent year, or the mean of five years, taken  $3\frac{3}{4}$  years later.

It has been supposed, in the present instance, that each marriage yields four births; but the proportion of births to marriages apparent in the registers of most of the countries of Europe, is 4 to 1, and, as the population of most of the countries of Europe is known to be increasing, the prolifickness of marriages must be greater than 4. If, allowing for this circumstance, we take the distance of 4 years instead of  $3\frac{3}{4}$  years, we shall still be sure of not erring in excess. And though undoubtedly the period which we take, whatever it may be, will not answer exactly in different countries, yet its application generally will not be so incorrect as we might at first imagine; because, in countries where the marriages are more prolific, the births generally follow at shorter intervals, and where they are less prolific at longer intervals; and, with different degrees of prolifickness, the length of the period might still remain the same.

Probably, however, the period here assumed, which is the one taken by Mr Malthus, is too short. If, as he says, there is reason to think, that, in almost all registers, the omissions in the births and deaths are greater than in the marriages, there ought to be a greater number of births to each marriage, in which case it would take a longer time to have them in; and if, further, it is probable that a birth every other year is too rapid a succession for those countries where the marriages are frequently late, it may be thought that the births at the distance of five years will more nearly represent the prolifickness of marriages than at the distance of 4 years. But this matter must be left to the judgment of the reader.

At all events, it will follow, from what has been said, that the more rapid is the increase of population, the more will the real prolifickness of marriages exceed the proportion of births to marriages in the registers.

The rule which has here been laid down attempts to estimate the prolifickness of marriages, taken as they occur; but this prolifickness should be carefully distinguished from the prolifickness of first marriages, and of married women, and still more from the natural prolifickness of women in general, taken at the most favourable age. It is probable that the natural prolifickness of women is nearly the same in most parts of the world; but the prolifickness of marriages is liable to be affected by a variety of circumstances peculiar to each country, and particularly by the number of second and third, and late marriages. In all countries the second and third marriages alone form

**Population.** a most important consideration, and materially influence the average proportions. According to Sussmilch, in all Pomerania from 1748 to 1756, both included, the number of persons who married were 56,956, and of these 10,586 were widows and widowers (*Gottliche Ordnung*, Vol. I. Tables, p. 98). According to Busching, in Prussia and Silesia for the year 1781, out of 29,308 persons who married, 4841 were widows and widowers (Malthus, Vol. II. p. 140); and, consequently, the proportion of marriages will be given full one-sixth too much. In estimating the prolifickness of married women, the number of illegitimate births would tend, though in a slight degree, to counterbalance the overplus of marriages; and as it is found that the number of widowers who marry again is greater than the number of widows, the whole of the correction should not, on this account, be applied; but, in estimating the proportion of the born which lives to marry, which is what we are now about to proceed to, the whole of this correction is always necessary.

**Proportion of the Born which lives to Marry.**

To find the proportion of the born which lives to marry from registers, we must consider that the marriages of any year can never be contemporary with the births from which they have resulted, but must always be at such a distance from them, as is equal to the average age of marriage.

If the population be increasing, the marriages of the present year have resulted from a smaller number of births, than the births of the present year; and, of course, the marriages compared with the contemporary births, will always be too few to represent the proportion of the born which lives to marry, and the contrary will take place if the population be decreasing; and to find this proportion, after having first made the proper correction for second and third marriages, we must compare the marriages of any year with the births of a previous year at the distance of the average age of marriage.\*

**Expectation of Life.**

The third principal object which it is desirable to attain, and of which some estimate may be formed from registers, is the expectation of life. It has before been stated, that, in a country where the births and deaths are equal, the rate of the annual mortality will express the expectation of life, or the average age of death. But, if the population be increasing, the actual population of any one year will be greater than would belong to the contemporary deaths, supposing the births equal to the deaths, and less than would belong to the contemporary births, supposing the deaths equal to the births. Consequently, if we divide the actual population by the number of contemporary deaths in an increasing country, the result will be too high to express the average age of death belonging to any given number of births. If we divide the actual population by the number of births, the result will be too low to express this average, or, in other words, to express the expectation of life. And, in order to approximate to the true proportion, we are directed by Dr Price (Vol. II. p.

39, 7th ed.), in the absence of better data, to divide the actual population by a mean between the proportions of deaths and births. Consequently, when we know the proportion of births to deaths in any country, and the proportions which they usually bear to the whole population, we may form some estimate of the expectation of life or the average age of death.

If we attend to these observations in drawing our inferences from registers, we shall generally be able to form an approximating estimate of the prolifickness of marriages, the proportion of the born living to marry, and the expectation of life, in different countries and places, and under different circumstances; or if we cannot do this satisfactorily, owing to the varying rate of increase, and the inaccuracy of the registers, we shall at least guard ourselves against drawing incorrect inferences from them in their present state, and reconcile many of the difficulties with which they appear to be accompanied.

Thus to estimate the prolifickness of marriages in England. The proportion of the marriages to the births, according to the parochial returns ending with 1820, was 100 to 369; adding  $\frac{1}{6}$  for the omissions in the births, or on the present occasion only  $\frac{1}{7}$ , in order to make full allowance for illegitimate births, the proportion of marriages to births will be as 100 to 422. These births, at the rate at which the population was increasing in England and Wales from 1810 to 1820, would, in about  $4\frac{1}{2}$  years, increase .07, which, added to 4.22, makes 4.51. Consequently, the prolifickness of marriages, taken as they occur, and including second and third marriages, would be 4.51. If we wish to estimate the prolifickness of married women, we must subtract from the marriages those which consist of widows who have married again. According to some tables of Sussmilch, this would be little less than one-sixth; according to others one-eighth. If we take one-seventh, and deduct it from the marriages, the proportion will be 1 to 5.26, that is, each married woman will have 5.26 births. But of these married women, some have married at above 45 years of age, and many more above 35, so that there can be little doubt that, if the births could be collected from all the marriages in which the age of the woman did not exceed 35, nor the age of the man 45, the births would appear to be nearly six; and this number would be still further increased if the average age of marriage for males was 22, and for females 20. These conclusions are fully confirmed by some accurate observations of M. Muret. At Vevey, where the proportion of marriages to births, in the registers, was as 10 to 39, he found that 375 mothers had had 2093 children born alive, by which it appears that each mother had produced 5.55 births. But these, M. Muret observes, were all mothers, which is not the case of all married women. Allowing, however, for the usual proportion of barren wives at Vevey, which was about 20 out of 478, it appears that the married women, one with another, must have had above 5.3

**Prolifickness of Marriages in England.**

\* It is a shorter and more obvious process to compare the marriages at once with the births of the earlier period, than with the deaths, as Mr Malthus has done.

Population. births. Yet this was in a town, where he intimates that the inhabitants do not enter into the marriage state at the time when nature calls them, nor when married always have as many children as they might have. It is evident, therefore, that the proportions of marriages to births, to be found in registers, require considerable and important corrections, in order to deduce from them just estimates of the prolifickness of marriages, the prolifickness of married women, and the prolifickness of women marrying at the most favourable age. The instance here given is sufficient to illustrate the mode in which the rule should be applied.

Proportion of the Born living to Marry in England.

If we wish to apply the rule for estimating the proportion of the born living to marry in England, we must first take the proportion of marriages to births in the registers. This proportion, as before stated, was, during the ten years ending with 1820, as 100 to 369; which, increased by one-sixth, the supposed omissions in the registers of births, will be as 100 to 430. But the marriages of the present year must have resulted, not from the births of the present year, but from the births at such an earlier period in the registers, as is equal to the average age of marriage. Suppose this age to be 28, then at the rate at which the population was increasing, the present marriages must have resulted from a number of births, equal to about two-thirds of the present number, so as to be to the present marriages in the proportion of 286 instead of 430 to 100. But of the 200 persons forming the 100 marriages, more than one-sixth have been married before. Deducting, therefore, one-sixth from the marriages, the proportion of the marriages to the births from which they have resulted, will be as 100 to 343; or out of 343 births, 200 have lived to be married once or oftener; from which it would appear, that on account of the late increase in the healthiness of the country, a greater proportion had lived to marry than when Mr Malthus last estimated it; which, together with a slight increase in the prolifickness of marriages apparent in the latter registers, may account for the more rapid increase of the population from 1810 to 1820. It should be recollected, however, that as the rate of increase which prevailed from 1810 to 1820 had by no means prevailed during the whole 28 years, the births, from which 200 persons had lived to marry in 1820, were decidedly more than 343.

It will be observed how very important the correction for second and third marriages is. Supposing each marriage to yield four births, and the births and deaths to be equal, it might at first be thought necessary, that in order to keep up the population, half of the born should live to marry; but if, on account of the second and third marriages, we subtract one-sixth from the marriages, and then compare them with the births, the proportion will be as 5 to 24; and it will appear, that instead of one-half, it will only be necessary that out of 24 births 10 should live to marry. Upon the same principle, if the births were to the marriages as 4 to 1, and exactly half of the born lived to marry, it might be supposed at first that the population would be stationary; but if we subtract one-sixth from the marriages, and then compare them with the births, it

Population. will be obvious that, on the supposition of half the born living to marry, the births at the earlier period in the registers, at the distance of the age of marriage, must be to the present births as 5 to 6, which would imply a moderate rate of increase.

To estimate the proportion of male births living to marry, we must subtract full one-fifth from the marriages; and according to this correction, if each marriage yielded four births, it would only be necessary that two male children out of five should live to marry, in order to keep up the population. It is necessary also, in estimating the proportion of male births living to marry, to make allowance for the greater number of males born.

The foregoing illustrations and remarks show the error of supposing that a country must be in a precarious state when the proportion of births to marriages in the registers is less than 4 to 1. If, indeed, this observation were just, the population of many countries in Europe would be in a precarious state, as in many countries the proportion is less than this. But it has been shown in what manner this proportion in the registers should be corrected, in order to make it a just representation of the prolifickness of marriages; and if a large part of the born live to marry, and the age of marriage be considerably earlier than the expectation of life, such a proportion in the registers is by no means inconsistent with a rapid increase of population.

In Russia, the proportion of births to marriages is less than 4 to 1. Yet on account of the large proportion of the born living to marry, the early age of marriage, and the high expectation of life, it is one of the countries in Europe which increases the fastest. In England, the population increases much more rapidly than in France; yet in England, the proportion of births to marriages in the registers, when allowance has been made for omissions, was, from 1800 to 1810, 4 to 1, while in France it was  $4\frac{1}{2}$  to 1. (Malthus, Vol. II. p. 161, 5th edit.)

In England, indeed, for the ten years from 1810 to 1821, the proportion of births to marriages seems slightly to have exceeded the former proportion, being about 4.22 to 1; but this excess has been accompanied by such a rapidity of increase as would double the population in less than 46 years; and comparing this rapid rate of increase with the slow increase of France, where the births were to the marriages as  $4\frac{1}{2}$  to 1, and in Sweden, when these proportions were as  $4\frac{1}{4}$  to 1—it follows that the two other causes of the excess of births above the deaths, besides the prolifickness of marriages, must have very great power, and that the proportion of births to marriages, as found in registers, when taken alone, is a most uncertain criterion of increase.

To apply the rule for estimating the average age of death, or the expectation of life in England, we must first ascertain from the registers the proportions which the births and deaths bear to the whole population. The annual average of the births for the ten years, from 1810 to 1821, was 325,506, of the deaths 200,999. Adding one-sixth to the births, and one-twelfth to the deaths, for the omission in the registers, the births will be 379,757, and the deaths 217,749. The population of England and

Expectation of Life in England.

Population. Wales, according to the last corrected accounts, was, in 1810, 10,502,500, in 1821, 12,218,500,\* the mean of which in 11,360,500. The average births and deaths, compared with the mean population, give  $\frac{1}{29.9}$  as the proportion of the births, and  $\frac{1}{52.17}$  as the proportion of the deaths; and, according to Dr Price, the mean between them, which, in this case, is 41, will give the expectation of life. This rule, however, is only a rough approximation, and, in the few cases, where sufficient data have been obtained in progressive countries for calculating the expectation of life more accurately, it has turned out to be much nearer to the annual mortality than to the mean here referred to. While, according to the more correct estimates before adverted to, the annual mortality might, with the same expectation of life, be in different countries 1 in 39.38, 1 in 41.97, or 1 in 41.09, according as the population was stationary, or progressive at various rates.

This appears in the table which Dr Price himself calculated for Sweden (Vol. II. p. 410, 7th edit.), founded on data which he considered as quite satisfactory. It also appears in the table for Sweden and Finland, subsequently calculated by Mr Milne from similar data, in his *Treatise on Annuities and Assurances*. (Vol. II. p. 569.) And further, in a table for Sweden and Finland, published in this *Supplement*, under the head of MORTALITY. We have also lately seen a calculation by Mr Milne, by which it appears that the difference between the annual mortality and the expectation of life goes on increasing with the rate of the increase of the population to a certain point, but afterwards, owing to the increasing proportion of young children included in the population, diminishes; and is less when the population doubles in twenty-five years, than when it doubles in fifty years. Thus, on the three different suppositions of a stationary population, a population doubling in fifty years, and a population doubling in twenty-five years (all subjected to the same law of mortality as that which prevailed in Sweden and Finland during the five years ended with 1805)—in the first case, both the expectation of life and the annual mortality would be 39.388, and, of course, the expectation of life would be the same in all the cases; but in the second case, the annual mortality would be 1 in 41.971; and in the third, 1 in 41.096. It would be difficult, however, or at least premature, without further data, to lay down a general rule, with a view to determine correctly the expectation of life at birth, in countries progressive at various rates. But from what has been stated, it may safely be concluded, that the expectation of life lies very much nearer the annual mortality, particularly in cases of very rapid increase, than to the mean proposed by Dr Price; and that both the expectation of life, and the age to which half of the born live, are, in most countries, and especially in England, at the present time, considerably higher than they have generally been estimated.

Population. It may be remarked here, in reference to England during the ten years, from 1810 to 1821, that the omissions assumed in the births and deaths do not give such proportions as to make the increase of population, from the excess of births above the deaths, answer to the increase determined by the two censuses,—an agreement which must necessarily take place if both the enumerations and the registers are accurate, and no external causes disturb the result. An addition of one-sixth to the births, and one-twelfth to the deaths, seemed to answer correctly for the interval from 1800 to 1810; but to produce the same coincidence under the more rapid increase of the subsequent ten years, either a greater allowance must be made for omissions in the births, or a less allowance for the omissions in the deaths. If we add one-fifth instead of one-sixth to the births, retaining one-twelfth for the deaths, the excess of births above deaths in the ten years will be 1,728,587; the excess according to the censuses being 1,716,000. If we add only one-thirtieth to the deaths, retaining one-sixth for the births, the excess will be 1,720,502, within 4502 of the excess, as shown by the censuses. Whereas, under the actual allowances which have been made for omissions, the excess will be only 1,620,800, leaving a difference of 95,200, and on the wrong side. On account of the almost incredible healthiness, considering our great towns and manufactories, which would be implied by supposing the deaths to be only deficient one-thirtieth, an increased omission in the births might be thought more probable; but it is believed, that since 1812 the omissions in the births have been diminished rather than increased; and under this uncertainty it has been thought better to leave the question as it stands at present, rather than attempt to determine it on insufficient data. It should always be remembered, however, that if the increase of population by the enumerations, is different from the increase of population by the registers, one or the other must be incorrect.

On the supposition that the omissions in the deaths were only one-thirtieth, the average mortality, compared with the average population, would be 1 in 54.7; and the proportion of births, with the addition of one-sixth, being, as before stated, 1 in 29.9, the expectation of life, according to Dr Price's rule, would be 42.3. On the other supposition, of an omission of one-fifth of the births, and one-twelfth in the deaths, the births would be 1 in 29, and the deaths 1 in 52.17, and the expectation of life would be 40.58.

It appears, then, that when the population of a country is progressive, it would be erroneous to estimate its healthiness by the proportion which the annual mortality bears to the whole population. Healthiness must be measured by the expectation of life; and if, with the same expectation of life, the annual mortality is affected by the rate of increase, it is obvious that the healthiness of different countries may be different, with the same rate of annual mortality.

Expectation of Life at Birth and Annual Mortality, not the same when the Population is Progressive.

\* *Preliminary Observations to Population Abstracts*, p. 32.

Population.  
Mortuary  
Registers  
fallacious.

But while it is evidently necessary that we should be cautious in inferring, that a country is healthy just in proportion to the smallness of its annual mortality, we should be still more cautious in inferring that it is unhealthy at all the ages under puberty, on account of the number which appear to die in mortuary registers under that age. Here, as in the preceding case, but in a much greater degree, the excess of the births above the deaths has a powerful effect, but exactly in the opposite direction. When we compare the annual mortality of an increasing country with its actual population, we compare with it a number of deaths which may be said, properly speaking, to belong to an earlier and smaller number of births, and must necessarily represent the country as more healthy than it really is. On the other hand, when in a mortuary register, we compare the deaths under puberty with those above, if the population be increasing, we evidently compare the deaths belonging to a much greater number of births than those which have furnished the deaths above the age of puberty; and, consequently, these proportions must represent the country as much less healthy than it really is.\* According to the mortuary registers of Sweden for 21 years, from 1755 to 1776, more than half of the deaths were under 15, but it was by no means true that half of the *born* died under 15.† In the tables of mortality for Sweden during the same period, constructed by Dr Price, it appears that half of the born lived to above 33 years. ‡

In the same manner, in drawing inferences from an abstract of the mortuary registers of the principal cities in America, Baltimore, Boston, New York, and Philadelphia, given by Dr Seybert (*Statistical Annals*, p. 48), we must take care not to conclude that the proportions of the deaths which take place under 20 years of age, represent the proportions of any given number of births in these cities which die under 20. As, on account of the excess of the births above the deaths, all the early ages of the population are more numerous in proportion than the other, there will necessarily be a greater proportion of the deaths at these ages, than would naturally belong to a given number of births, if each infant born were traced to the age of its death.

In the present case, the abstract is only for a year, and no safe conclusions, therefore, can be drawn from it; but so far as it goes, as even notwithstanding the increase of population, these mortuary registers show that considerably less than half of the deaths take place under twenty (on an average only about 45½ per cent.), it would appear, that in the early ages of life, even the towns of America are more healthy than the whole of Sweden from 1755 to 1776. It should, however, be considered, that though the towns in America may be increasing fast

by procreation, they are increasing still faster by the influx of inhabitants from the country; and as these inhabitants generally come to the towns after the age of sixteen, this accession diminishes the proportion of persons in the earlier ages of life so much, that there is probably a larger proportion of mortality at these ages in the country than in the towns.

One of the most interesting and useful points of view in which registers can be considered, is in the proofs which they afford of the varying prevalence of the prudential check to marriage and population in different countries and places. It has been not an uncommon opinion, and has even been strongly expressed of late years, although the subject has been much better understood than formerly, that the labouring classes of people, under the circumstances in which they are placed, cannot reasonably be expected to attend to prudential considerations in entering upon the marriage state. But that this opinion does them great injustice, is not only obvious to common observation, by which we can scarcely fail to see that numbers delay marriage beyond the period when the passions most strongly prompt to it, but is proved by the registers of different countries, which clearly show, either that a considerable number of persons of a marriageable age never marry, or that they marry comparatively late, and that their marriages are consequently less prolific than if they had married earlier. As the prudential restraint on marriage may show itself in either of these ways, it may prevail nearly in the same degree with a different proportion of marriages to the whole population. But on the supposition of the same natural prolificness in the women of most countries, the smallness of the proportion of births will generally indicate with tolerable correctness the degree in which the prudential check to population prevails, whether arising principally from late, and consequently unprolific marriages, or from a large proportion of the population dying unmarried.

Referring then to the different proportions of births in different countries as the best criterion of the different degrees in which the prudential restraint on marriage operates, it will be recollected, that these proportions vary from about 1 in 36 to about 1 in 19, or even 17, in different countries, and in a much greater degree in different parishes or districts:

A particular parish in the Alps has already been mentioned, where the births were only a forty-ninth part of the population; and it appears by the late returns of the parish registers of England and Wales, that the births in the county of Monmouth are only 1 in 47, and in Brecon, 1 in 53; || which, after making ample allowance for omissions, would show the prevalence of the prudential restraint on marriage in a high degree.

If in any country all were to marry at 20 or 21,

Population.  
Criterion of  
the Prevalence of  
Prudential  
Restraint.

\* In the first case, the effect is, in a considerable degree, counteracted by the large proportion of children under four years old, which a rapid increase occasions. In the second case, the effect has no such drawback.

† Price's *Observations*, Vol. II. p. 405. 7th edit.

‡ *Ibid.* Table XLV. Vol. II. p. 413.

VOL. VI. PART I.

|| *Preliminary Observations*, p. 27.

Population. the proportion of the births would probably be more than 1 in 19; and this result would be still more certain if the resources of the country could not support an accelerated rate of increase, than if the means of subsistence were in the greatest abundance, and the demand for labour as effectual as it has ever been in the United States. On the latter supposition, taking the births at one-nineteenth, and the expectation of life the same as it is in England, the effect would be to occasion a most rapid increase of population; and the period of doubling, instead of being about 46 or 48 years, would be less than in America. On the other hand, if the resources of the country could not support a more rapid increase than that which has taken place in England and Wales during the ten years previous to the census of 1821, the effect would be a great diminution in the expectation of life. If the births were 1 in 19 instead of 1 in nearly 30, the same rate of increase would take place as at present, if the annual mortality were increased to about 1 in  $26\frac{1}{2}$ ; and in that case, the expectation of life would be reduced in the proportion of from 41, or, as is more probable, from above 45 to less than 26.\* This is the kind of effect which must inevitably follow the absence of the prudential check to marriage and population; and it cannot be doubted, that a considerable part of the premature mortality which is found to take place in all parts of the world is occasioned by it. The laws of nature, in application to man as a reasonable being, show no tendency to destroy half of the human race under the age of puberty. This is only done in very particular situations, or when the constant admonitions which these laws give to mankind are obstinately neglected.

Objection to the principle of Population arising from the great Mortality it must occasion.

It has been said, that a tendency in mankind to increase at such a rate as would double the population in 25 years, and, if it had full scope, would fill the habitable globe with people in a comparatively short period, cannot be the law of nature; as the very different rate of increase which is actually found to take place, must imply such an excessive degree of mortality and destruction of life as to be quite irreconcilable with actual facts and appearances. But the peculiar advantage of a law of increase in a geometrical progression is, that, though its power be absolutely immense, if it be left unchecked, yet, when this becomes impossible, it may be restrained by a comparatively moderate force. It can never, of course, happen, that any considerable part of that prodigious increase which might be produced by an uninterrupted geometrical progression should exist, and then be destroyed. The laws of nature which make food necessary to the life of man, as well as of plants and animals, prevent the continued existence of an excess which cannot be supported, and thus either discourage the production of such an excess,

or destroy it in the bud, in such a way as to make it scarcely perceptible to a careless observer. It has been seen, that, in some countries of Europe, where the actual progress of the population is slower than in many others, as in Switzerland and Norway, for instance, the mortality is considerably less. Here, then, the necessity of a greater check to the natural progress of population produces no increase of mortality. And it appears, farther, that even the degree of mortality which in each year would be sufficient to destroy that excess of births which would naturally be produced if all married young, and all could be supported, might take place, and often does take place in particular situations, and yet is very little noticed. About the middle of last century, the mortality in Stockholm and London was about 1 in 19, and 1 in 20. This is a degree of mortality which would probably keep the births on a level with the deaths, even though all married at twenty. And yet numbers resorted both to Stockholm and London from choice; the greater part probably not aware that, by so doing, they would shorten their own lives and those of their children; and the rest thinking that the difference was not worth attending to, or was at least balanced by the advantages of society and employment which the town presented. There is nothing, therefore, in the actual state of the mortality observed to take place in different countries and situations, which, in the slightest degree, contradicts the supposition of a natural tendency to increase quite as great as that which has been stated.

It has been further remarked, that as, in point of fact, it very rarely happens that mankind continue to increase in a geometrical progression of any kind, and only in a single instance in such a one as to double the population in 25 years, it is useless and absurd to lay any stress upon tendencies which never for any length of time together produce their natural effects. But it might really as well be said, that we are not to estimate the natural rate of increase in wheat or sheep; as it is quite certain that their natural tendency to increase has never practically continued to develop itself for so long a time together, as that of mankind. Both as a physical, and even economical question, it is curious and desirable to know the natural law of increase which prevails among the most important plants and animals. In the same view, it must be still more interesting to know the natural law of increase with respect to man. It may be said indeed, with truth, that the actual appearances all around us,—the varying rate of increase in different countries,—its very slow progress, or stationary state, in some, and its very rapid progress in others,—must be a mass of anomalies, and quite contrary to the analogies of all the rest of animated nature; if the natural tendency of mankind to increase be not, at the least, as great as that which is developed under the most favourable circum-

Objection that mere Tendencies are not to be considered.

\* If, as it has appeared, the expectation of life, though by no means the same, does not differ very much from the annual mortality, and the annual mortality in this country during the ten years from 1810 to 1820, after every abatement, appears to be not more than 1 in 51, the expectation of life cannot be less than 45, and is probably greater.

Population. stances, while in all others it is kept down by the varying difficulties which the state of the soil, and other obstacles oppose to it. But the question, as it applies to man, assumes at once a tenfold importance, in reference to the moral and political effects which must result from those checks to increase, the existence and operation of which, in some form or other, no human exertions can by possibility prevent. A field is here opened for the most interesting inquiries which can engage the friends of human happiness.

But, as a preliminary to these inquiries, it is obvious that we must know the degree of force to be overcome, and the varying character of the checks which, in the different countries of the world, are practically found to overcome it; and, for this purpose, the first step must be an endeavour to ascertain the natural law of population, or the rate at which mankind would increase under the fewest known obstacles. Nor can this tendency to increase ever safely be lost sight of in the subsequent inquiries, which have for their object the improvement of the moral condition of man in society.

The existence of a tendency in mankind to increase, if unchecked, beyond the possibility of an adequate supply of food in a limited territory, must at once determine the question as to the natural right of the poor to full support in a state of society where the law of property is recognized. The question, therefore, resolves itself chiefly into a question relating to the necessity of those laws which establish and protect private property. It has been usual to consider the right of the strongest as the law of nature among mankind as well as among brutes; yet, in so doing, we at once give up the peculiar and distinctive superiority of man as a reasonable being, and class him with the beasts of the field. In the same language it may be said that the cultivation of the earth is not natural to man. It certainly is not to man, considered merely as an animal without reason. But to a reasonable being, able to look forward to consequences, the laws of nature dictate the cultivation of the earth, both as the means of affording better support to the individual, and of increasing the supplies required for increasing numbers; the dictates of those laws of nature being thus evidently calculated to promote the general good, and increase the mass of human happiness. It is precisely in the same way, and in order to attain the same object, that the laws of nature dictate to man the establishment of property and the absolute necessity of some power in the society capable of protecting it. So strongly have the laws of nature spoken this language to mankind, and so fully has the force of it been felt, that nothing seems to be thought so absolutely intolerable to reasonable beings as the prevalence in the same society of the right of the strongest; and the history of all ages shows that if men see no other way of putting an end to it, than by establishing arbitrary power in an individual, there is scarcely any degree of tyranny, oppression, and cruelty which they will not submit to from some single person and his satellites, rather than be at the mercy of the first stronger man who may wish to possess himself of the fruit of their labour. The consequence of this universal and deep-

ly-seated feeling, inevitably produced by the laws of Population. nature, as applied to reasonable beings, is that the almost certain consequence of anarchy is despotism.

Allowing, then, distinctly, that the right of property is the creature of positive law, yet this law is so early and so imperiously forced on the attention of mankind, that if it cannot be called a natural law, it must be considered as the most natural as well as the most necessary of all positive laws; and the foundation of this pre-eminence is, its obvious tendency to promote the general good, and the obvious tendency of the absence of it to degrade mankind to the rank of brutes.

As property is the result of positive law, and the ground on which the law which establishes it rests, is the promotion of the public good and the increase of human happiness, it follows, that it may be modified by the same authority by which it was enacted, with a view to the more complete attainment of the objects which it has in view. It may be said, indeed, that every tax for the use of the government, and every country or parish rate is a modification of this kind. But there is no modification of the law of property having still for its object the increase of human happiness, which must not be defeated by the concession of a right of full support to all that might be born. It may be safely said, therefore, that the concession of such a right, and a right of property are absolutely incompatible, and cannot exist together.

To what extent assistance may be given even by law to the poorer classes of society when in distress, without defeating the great object of the law of property, is essentially a different question. It depends mainly upon the feelings and habits of the labouring classes of society, and can only be determined by experience. If it be generally considered as so discreditable to receive parochial relief, that great exertions are made to avoid it, and few or none marry with a certain prospect of being obliged to have recourse to it, there is no doubt that those who were really in distress might be adequately assisted, with little danger of a constantly increasing proportion of paupers; and in that case a great good would be attained without any proportionate evil to counterbalance it. But if, from the numbers of the dependent poor, the discredit of receiving relief is so diminished as to be practically disregarded, so that many marry with the almost certain prospect of becoming paupers, and the proportion of their numbers to the whole population is in consequence continually increasing; it is certain that the partial good attained must be much more than counterbalanced by the general deterioration in the condition of the great mass of the society, and the prospect of its daily growing worse: so that, though from the inadequate relief which is in many cases granted, the manner in which it is conceded, and other counteracting causes, the operation of poor-laws such as they exist in England might be very different from the effects of a full concession of the right, and a complete fulfilment of the duties resulting from it; yet such a state of things ought to give the most serious alarm to every friend to the happiness of society, and every effort consistent with justice and humanity ought to be made to remedy it.

Right of the  
Poor to full  
Support con-  
sidered.

Population. But whatever steps may be taken on this subject, it will be allowed, that with any prospect of legislating for the poor with success, it is necessary to be fully aware of the natural tendency of the labouring classes of society to increase beyond the demand for their labour, or the means of their adequate support, and the effect of this tendency to throw the greatest difficulties in the way of permanently improving their condition.

It would lead far beyond the limits which must be prescribed to this article, to notice all the various objections which have been made by different writers to the principles which have been here explained. Those which contain in them the slightest degree of plausibility have been answered by Mr Malthus in various parts of the late editions of his work, and particularly in the appendix to the fifth edition, to which we refer the reader. We will only, therefore, further notice the objection which has been made by some persons on religious grounds; for, as it is certainly of great importance that the answer which has been given to it should be kept in mind, we cannot refuse a place to a condensed statement of it at the end of this article.

Religious  
Objection  
considered.

It has been thought that a tendency in mankind to increase, beyond the greatest possible increase of food which could be produced in a limited space, impeaches the goodness of the Deity, and is inconsistent with the letter and spirit of the Scriptures. If this objection were well founded, it would certainly be the most serious one which has been brought forwards; but the answer to it appears to be quite satisfactory, and it may be compressed into a very small compass.

*First*, It appears that the evils arising from the principle of population are exactly of the same kind as the evils arising from the excessive or irregular gratification of the human passions in general, and may equally be avoided by moral restraint. Consequently there can be no more reason to conclude, from the existence of these evils, that the principle of increase is too strong, than to conclude, from the existence of the vices arising from the human passions, that these passions are all too strong, and require diminution or extinction, instead of regulation and direction.

*Secondly*, It is almost universally acknowledged, that both the letter and spirit of revelation represent this world as a state of moral discipline and probation. But a state of moral discipline and probation cannot be a state of unmixed happiness, as it necessarily implies difficulties to be overcome, and temptations to be resisted. Now, in the whole range of the laws of nature, not one can be pointed out which so especially accords with this scriptural view of the state of man on earth; as it gives rise to a greater variety of situations and exertions than any other, and marks, in a more general and stronger manner, and nationally, as well as individually, the different effects of virtue and vice, of the proper government of the passions, and the culpable indulgence of them. It follows, then, that the principle of population, instead of being inconsistent with Revelation, must be

considered as affording strong additional proofs of its truth. Population.

*Lastly*, It will be acknowledged, that in a state of probation, those laws seem best to accord with the views of a benevolent Creator, which, while they furnish the difficulties and temptations which form the essence of such a state, are of such a nature as to reward those who overcome them with happiness in this life as well as in the next. But the law of population answers particularly to this description. Each individual has the power of avoiding the evil consequences to himself and society resulting from it, by the practice of a virtue dictated to him by the light of nature, and sanctioned by revealed religion. And, as there can be no question that this virtue tends greatly to improve the condition, and increase the comforts both of the individuals who practise it, and through them of the whole society, the ways of God to man with regard to this great law are completely vindicated.

Subjoined are two Tables which may assist the reader in calculating the rate of increase in different countries, under different circumstances, and from different data. The first is the table calculated by Euler, and printed in Mr Malthus's work, at the end of his chapter on the *Fruitfulness of Marriage*; and the second has been calculated by Mr Bridge of Cambridge, well known as an able mathematician, and most useful elementary writer.

The first is to be used when it is wished to estimate the rate of increase by the proportions of the births to the deaths, and of these to the whole population. The yearly increase of people, independently of immigration, is the yearly excess of the births above the deaths, and the yearly rate of increase is measured by the proportion which this excess bears to the whole population. The fraction expressing the deaths must therefore be subtracted from the fraction expressing the births; and the remainder will be the fraction expressing the yearly rate of increase; opposite to which will be found the number of years in which the population will double itself, supposing the yearly rate of increase to continue the same for a sufficient length of time.

The second table is to be used when it is wished to know the period of doubling, resulting from a given *per centage* increase in ten years, determined by enumeration. An estimate of population from births and deaths is always liable to much uncertainty on account of the varying proportions which they bear to the population. The only remedy for this uncertainty is a census; and as the useful custom of taking a census of the population every ten years has latterly prevailed in some countries, the second table is constructed to show the period of doubling, or general rate of increase, which results from any given *per centage* increase in ten years. The first column represents the *per centage* increase in ten years determined by two enumerations; and the second column the number of years in which the population will double itself, supposing it to proceed at the same rate. (o. o. o.)

Porson.

**PORSON (RICHARD)**, the greatest of the verbal critics and classical scholars of modern times, born 25th December 1759, was the son of Mr Huggin Porson, parish clerk of East Ruston, near North Walsham, in Norfolk.

His father taught him, in his childhood, to practise all the common rules of arithmetic by memory only; and, before he was nine years old, he had learned to extract the cube root in this manner. He employed, at the same time, for teaching him to read and write, the method which has since been generally introduced in the schools of mutual instruction, making him draw the letters with chalk or on sand: and the neatness and accuracy of his handwriting, for which he was distinguished through life, may be considered as bearing ample testimony to his father's ingenuity and success.

At the age of nine he was sent to a village school, kept by a Mr Summers; but his father still made him repeat by heart in the evening the whole of the lessons of the day, and there seems to be sufficient evidence for considering this practice of exercising the memory continually, in very early life, as the best, if not the only method of cultivating, if not of producing great talent: for though a strong memory by no means constitutes talent, yet its possession is almost a necessary condition for the successful exertion of talent in general, and, indeed, it is very possible that the other faculties of the mind may be strengthened by the early cultivation of this one. It is remarkable that Wallis, who was as deservedly celebrated in his day as Porson, for his unerring sagacity, had also a singular facility of retaining numbers and calculations in his memory, but without having taken any particular pains to acquire the habit. Mr Hewitt, the vicar of the parish of East Ruston, hearing of young Porson's uncommon capacity, undertook to instruct both him and his brother Thomas in classical literature; and when he was about fifteen, Mr Norris, a wealthy and respectable gentleman of the neighbourhood, having ascertained the truth of the reports that he heard of him, resolved to be at the expense of sending him to Eton. Without this assistance, it would have been impossible for Porson to have acquired great excellence in any intellectual pursuit; for his father's situation in life was not such as to exempt his son even from the subordinate occupations of the country. He went out gleaning, in the autumn, with a Horace in his pocket; and he had learned by experience to appreciate the mechanical labours of Penelope, before he was much acquainted with the wisdom and wanderings of Ulysses.

At Eton, his talents procured him the friendship and admiration of the seniors among his schoolfellows, and, upon the unfortunate death of his first patron, Mr Norris, he found a number of liberal contributors, who stepped forward to supply the deficiency; but by far the most active of them was Sir George Baker, then President of the Royal College of Physicians; a man as much distinguished by his own classical taste and acquirements, as by his laudable disposition to cherish learning in others. He received the boy into his house for a vacation, and undertook, at the request of a relation of Mr Norris,

Porson.

the disagreeable task of receiving, in small sums, as much as was sufficient to purchase an income of L. 80 a year, for a few years, in the short annuities, which served, with great economy, to enable him to remain at Eton. This favour appears to have been too great to be properly acknowledged, or perhaps even duly appreciated, by its object, who only after many years paid Sir George the tardy compliment of a dedication, not, however, of an edition, but of a handsome copy of a single play of Euripides. In his own opinion, Porson learned little at Eton besides the quantity of syllables, being able to repeat by heart before he went there the principal part of the authors that he had to read; that is, almost the whole of Horace and Virgil, and the *Iliad*, and many parts of Cicero, Livy, and the *Odyssey*. A story is accordingly told of his book having been changed by one of his schoolfellows in joke, when he was going up to a lesson in Horace, and of his having read and translated what was required of him, without at all betraying the change to the master. At the same time, the emulation of a public school must have been a great advantage to him, as affording him a motive for exertion in his exercises, whether they were to be called his own, or to be written for other boys. It was a copy of Toup's Longinus, presented to him as a reward for a good exercise, that first gave him a decided inclination for the pursuit of critical researches; but he always considered Bentley and Dawes as his great masters in criticism.

In 1777 he was sent to Trinity College, Cambridge, and at first he began to apply more particularly to the mathematics, which had been the favourite study of his boyhood, and in which, as he himself remarked, his proficiency first brought him into a certain degree of public notice. He was, however, soon diverted from the pursuit, although he attained a place among the *senior optimes* of his year. But he was in fact more calculated for classical than for mathematical excellence; his memory would have been in a great measure thrown away, if he had been employed in abstract calculations; and his inventive powers do not appear to have been at all of the same class with his retentive faculties; although certainly in the mechanical pursuit of the fashionable methods of modern analysis, which are intended, like steam engines, to overcome all difficulties by the inanimate forces of mere patience and perseverance, he was capable of filling as distinguished a place as any living algebraist. The classical prize medal, and the university scholarship, he obtained without difficulty, as matters of course. The exercise, which he exhibited upon the examination for the scholarship, is the well known translation of an epitaph into Greek iambics; which, although not free from some inaccuracies in the use of the tenses, is still a very remarkable production, when it is considered as having been completed in less than an hour, with the help of Morell's *Thesaurus* only, and never afterwards corrected.

He obtained a fellowship of Trinity College in 1781, and took his degree of Master of Arts in 1785; but not thinking it right to subscribe the Articles of the Church of England, he could not enter into orders, and he was therefore unavoidably de-

Porson.

prived of his fellowship in 1791, having no dependence left for his subsistence through life, but his abilities and acquirements. His friends, however, did not abandon him on this urgent occasion, and in order to keep him out of actual want, a private subscription was set on foot, to which Mr Cracherode was one of the principal contributors, and by which enough was raised to purchase him an annuity of about L. 100 a year for life. A small addition was made to his income, about two years after, by his election to the Greek Professorship at Cambridge, with a salary of only L. 40 a year. The situation, however, gave him the option of at least doubling his whole receipts, by the delivery of an annual course of lectures in the university; and it was supposed that he would have made this exertion, if he had not been discouraged by the difficulty of obtaining rooms in his college, where it would have been his wish to reside.

He married, in 1795, Mrs Lunan, a sister of the late Mr Perry, well known as the editor of the *Morning Chronicle*, but he had the misfortune to lose his wife two years afterwards. Mr Perry continued to be his greatest friend through life, and was so far his best benefactor, as he knew how to oblige him essentially, without the appearance of doing him a favour. Porson had sometimes chambers in the Temple, and sometimes he lodged at the *Morning Chronicle* office: frequently also he was a visitor at Mr Perry's house at Merton, where he had the misfortune to leave several of his books, at the time of a fire, which destroyed them all, and among them some letters of Rhunkenius, with whom he had begun a correspondence in 1783, and who had communicated to him some valuable fragments of Æschylus, besides his manuscript copy of the lexicon of Photius, which had cost him ten months labour. He used indeed to say that this fire had destroyed the fruits of twenty years of his life; but he had the resolution to complete a second copy of the Photius, which is now in the library of Trinity College. His fondness for the mechanical employment of his pen has been regretted by some of his biographers, as having tempted him to waste much of his most valuable time on a trifling amusement: but in fact, his mode of writing Greek was fully as much calculated for expedition as for beauty; and those, who have not been in the habit of correcting mutilated passages of manuscripts, can form no estimate of the immense advantage that is obtained, by the complete sifting of every letter, which the mind involuntarily performs, while the hand is occupied in tracing it: so that, if the correction of Photius was really worth the labour of two years of Porson's life, it would have been scarcely possible to employ the greater part of those years more advantageously, than by copying him twice over. Mr Weston, in speaking of "his matchless penmanship," has observed, not very intelligibly, that "here, indeed, he thought himself surpassed by" another person "not in the stroke, but the sweep, of his letters:" what Porson really said on this subject was, that, with respect to "command of hand," that person had the advantage, but he preferred the *model* on which his own hand was formed.

Porson.

His writing was, in fact, more like that of a scholar, while the method explained in Mr Hodgkin's *Calligraphia* exhibits more the appearance of the work of a writing master; holding, however, a middle place between the neatness of Porson, and the wonderful accuracy of the country schoolmaster who made the fac simile of the Oxford Pindar in the British Museum.

Upon the establishment of the London Institution, his friends obtained for him the very desirable appointment of principal librarian, with a salary of L. 200 a year, and apartments in the house of the Institution, which was then in the Old Jewry; but although the arrangement was highly honourable to all parties, the librarianship was little more than a sinecure. Porson was, however, in the habit of attending in his place when the reading room was open, and of communicating, very readily, all the literary information that was required, by those who consulted him respecting the object of their researches. Had the inhabitants of Finsbury Square and its neighbourhood been more disposed to classical studies, and had the librarian of the Institution survived, to witness its completion and prosperity, his sphere of utility would, without doubt, have been greatly extended.

But it must ever be lamented that Porson's habits of life had unfortunately been such as to lay a foundation for a multitude of diseases; he suffered much from asthma throughout the year 1808; his memory began to fail him a little; and in the autumn he had some symptoms of intermittent fever. On Monday the 19th of September he had an apoplectic attack in the street, and he was carried to a neighbouring poor house in a state of insensibility: the next day an advertisement appeared in one of the papers, relating the accident, and describing some manuscripts which were found in his pocket, consisting of Greek fragments and algebraical characters: his friends at the London Institution immediately went in quest of him: he was afterwards well enough to appear in the library, and to receive a visit there from Dr Adam Clarke: but his speech was impaired, and his faculties evidently imperfect; he survived only through the week, and died in his 49th year, on Sunday the 25th of September 1808, at midnight.

He was buried at Cambridge, in Trinity College Chapel, near the grave of Bentley, and the monument of Newton. He founded by will an annual prize, to be given to the best Greek translation from an English dramatic author: and several specimens of the successful pieces have been published from time to time in the *Classical Journal*. His books were sold by auction, and many of them found purchasers at high prices, especially such as were enriched with any of his manuscript notes in their margins; but more than two hundred of these, which appeared to be the most valuable, were withheld from the sale, and were afterwards purchased, together with the whole of his manuscript papers, by the Society of Trinity College, for the sum of a thousand guineas. He left a sister, married to Siday Hawes, Esq. of Coltishall, Norfolk. His brother Thomas kept a boarding-school at Fakenham, and died, without issue, in 1792: his

Porson. second brother Henry was a farmer in Essex, and died young, leaving three children. His father had lived to 74, his mother to 57.

The principal works of Porson are his *Letters to Travis*, his four plays of Euripides with their prefaces, and the manuscript copy of Photius: the rest, though somewhat voluminous, are chiefly miscellaneous annotations on detached passages of a multitude of ancient authors. We find nothing in the nature of theory, or of the discovery of general laws, except some canons, which he has laid down, chiefly as having been used by the Greek tragedians in the construction of their verses. These are chiefly contained in the preface to the *Heuba*, together with its supplement. 1. The first is, that when a tragic iambic ends with a trisyllable, or a cretic, this word must be preceded either by a short syllable, or by a monosyllable. For example, an ancient tragedian would not have written the line "Εχχοι δε μήπος' εἰς ἀπεικτοῦ σώματος; though it might have been unexceptionable in a comedy. It seems to have been about the year 1790 that Porson first made this observation; he certainly did not attend to it in his own serious translation of the *Epitaph on Alexis*: but it was mentioned, in 1791, by one of Porson's intimate friends, in a moment of conviviality, while he was somewhat characteristically attempting to fill his glass out of an empty bottle; and the author of this article observed in answer, that it would certainly sound better, on such an occasion as then occurred, to say, Πᾶν ἐκπέπικας οὐδ' ἔνεστι κόπταβος, than οὐ λέλειπται κόπταβος. 2. The second canon is, that an anapaest is only admissible in a tragic iambic, as constituting the first foot, except in some cases of proper names: this indeed had been cursorily hinted by Dawes. 3. The same critic had also remarked, that the Attic poets never lengthen a short vowel before a mute or aspirate, followed by a liquid, or a middle consonant followed by *g*; and Porson more amply confirmed the observation as very generally, though not universally correct. On the other hand, Dawes had cursorily observed that Homer, and the other ancient epic poets, generally lengthened the vowel in such cases, and Porson's great rival, Hermann, has more fully established this distinction, as affording a good criterion of antiquity. 4. There are also some original remarks of Porson on the caesura, in iambics, and trochaics, and anapaests: he showed that the scenic poets do not elide the final iota, and that the tragedians do not employ the preposition *περί* before a vowel; and some other general laws, of greater importance than these, may probably be found in some of his publications, which it will now be necessary to enumerate in the order of time.

1. His first attempts, as an author, consisted of some anonymous articles in Dr Maty's *Review*, beginning with a part of Schutz's *Æschylus*, June 1783, *Tracts* ii. Brunck's *Aristophanes*, July 1783, *Tracts* iii.; *Mus. Crit.* II. 113; written in a day. In Latin, by Schäfer, *Class. Journ.* V. 136. Weston's *Hermesianax*, April 1784, *Tracts* iv. Huntingford's *Apology for his Menostrophics*, August 1784, *Tracts* v. *Account of the Learned Pig*, April 1785,

*Tracts* vi. Note, with letters of Le Clerc and Bentley, April 1786, *Tracts* vii.

2. He added some *Notes* to an edition of Xenophon's *Anabasis*, published by Nicholson, at Cambridge. 4to and 8vo. 1786. They are addressed *Lectori si quis erit*.

3. *Three Panegyric Epistles to Sir John Hawkins*, *Gent. Mag.* Aug. Sept. Oct. 1787. *Tracts* ix.

4. *Notes on Toup's Emendationes in Saidam*. 8vo. Oxf. 1790. Written in 1787.

5. *Letters on the Three Witnesses*, *Gent. Mag.* Oct. Dec. 1788. Feb. April, May, June, Aug. 1789. Feb. 1790. The last reprinted, *Tracts* xix.; most of the others in the collection of *Letters to Mr Archdeacon Travis*, in answer to his defence of the *Three Heavenly Witnesses*, 8vo. Lond. 1790. These letters are generally considered, by critics of all parties, as finally decisive of a question, which had often been agitated before, but never so learnedly argued, nor so satisfactorily discussed in all its bearings.

6. In the *Monthly Review*, Robertson's *Essay on the Parian Chronicle*, Jan. 1789, *Tracts* xiii.; satisfactorily answering the principal part of the objections alleged against the authenticity of that monument. Edwards's edition of the work attributed to Plutarch, on *Education*, July 1793, *Tracts* xxi. Payne Knight's *Greek Alphabet*, Jan. 1794, *Tracts* xxiii. Pybus's *Sovereign*, Dec. 1800; an article affording a good specimen of his talent for humour.

7. He is supposed to have written some *Remarks* on an *Essay upon the Transfiguration*, but never expressly acknowledged them. *Tracts* xv.

8. He added a few short *Notes* to the London edition of Heyne's *Virgil*, 8vo. 1793; for which he made an agreement with the bookseller to correct the press: but he complained that his corrections were disregarded; and in fact several hundred errors, of no great importance, were suffered to disfigure it.

9. He corrected the Greek text of *Æschylus* for the Glasgow editions, the folio of 1795, and the two volumes octavo, printed in 1794, but only published London, 1806. The folio is said to have appeared surreptitiously. There are more than two hundred original corrections, and a further number of passages pointed out as corrupt.

10. In the *Morning Chronicle* he published, at different times, a variety of spirited articles of a temporary nature. One of the most amusing was the *Nursery Song* in Greek iambics, 13th April 1796; called *A Fragment of Sophocles*, and signed "S. England," in ridicule of Ireland's pretended discoveries.

11. *Imitations of Horace*. *Spirit of the Public Journals*, 1797. *Class. Journ.* IV. 97.

12. The first four plays of Euripides appeared separately at different periods. *The Hecuba*, 8vo. London, 1797, Cambridge, 1802, with a Supplement and additional notes; which were also published separately, London, 1808. *Orestes*, London, 1798, 1811. *Phoenissæ*, London, 1799, 1811. *Medea*, Cambridge, 1801; London, 1812. *The four together*, London, 1822.

13. *Collation of the Harleian manuscript of the*

*Odyssey for the Grenville Homer*, 4to. Oxford, 1800; with some short notes. Reprinted, *Class. Jour.* IX.

14. Of the *Review of Wakefield's Lucretius*, in the *British Critic* for May 1801, the principal part appears to be Porson's.

15. *A Letter signed J. N. Dawes*, *Monthly Mag.* Dec. 1802; on some Greek constructions; admitting also an inaccuracy of his own with respect to a hiatus, pointed out by Mr C. Falconer.

16. *A Letter to Professor Dalzel*, dated Sept. 1803; *Mus. Crit.* I. p. 326; in answer to some remarks published in the Professor's *Collectanea Majora*; with an Epigram respecting Hermann in Greek and in English.

17. *Herodotus*, Edinburgh, 1806. Porson corrected the press for the first volume.

18. *Supplement to some Indices*, *Tracts* xxxvi.

19. It is well known that Porson bestowed considerable pains on the restoration of the text of the *Rosetta Stone*: his *Supplements* were added to the plates engraved by the Society of Antiquaries: they also appear among his *Tracts*, xxxvii. In Dr Clarke's *Greek Marbles*, 8vo. Cambridge, 1809, we find a translation of this inscription, communicated to the editor by Porson, and printed from "a corrected copy in his own beautiful hand writing:" but we may here venture to apply Porson's favourite remark on the facility of transposition, and to read, "a copy corrected in his own writing," that is, on the margin of Mr Gough's translation, as published in *Duane's Coins*: for the whole is very negligently performed; and it is not a little remarkable that this translation, which was at least approved by Porson, is decidedly less accurate than the Latin translation of Heyne, as appears from the investigation of the enchorial inscription, published in the sixth number of the *Museum Criticum*.

20. A variety of Porson's fugitive and miscellaneous pieces have reappeared at different times in the *Classical Journal*. *Authors cited by the Scholiast on Plato*, II. 619, *Tracts* xxxviii. *The Epitaph*, III. 233; more correctly than in the *Tracts*, but still with a gross error in the punctuation of the last line, which stands, in a manuscript copy of his own, Τῆς θνήσκου, ὃ δὲ πάχιστα πάσχοι οἱ γὰροί; this reading, though not very elegant, is at least more defensible, than to make πάσχειν alone signify to die, and a phrase to end with ὃ δὲ! A *Charade* in Latin, VII. 248. Some *Notes on Æschylus*, VII. 456, VIII. 15, 181, X. 114. *A property of the lines* employed in the 47th proposition of the first book of *Euclid*, p. 401. *Notes on Apollonius Rhodius*, XVIII. 370.

21. *Adversaria*, 8vo. Cambridge, 1812. Consisting of *Notes* on the Greek Poets, selected from his manuscripts, and arranged by Professor Monk and C. J. Bloomfield, M. A. The first article is an interesting *Lecture on Euripides*, delivered upon his appointment to the Greek Professorship: it is followed by a few miscellaneous observations, and by a large collection of *Notes* on Athenæus, on Euripides, on the *Fragments of the Tragic and Comic Poets*, on Stobæus, and on a variety of poets of miscellaneous descriptions. The volume was reprinted at Amsterdam, without any alteration, but the sale of

the foreign edition has never been permitted in Great Britain.

22. *Tracts and Miscellaneous Criticisms*, collected and arranged by the Rev. T. Kidd, M. A. 8vo. London, 1815. Besides the articles already noticed as reprinted in this volume, there are a few *Notes* on *Dawes's Miscellanea Critica*, not before published, No. xli. Some supplementary pages of *Simplicius and Cebes*, reprinted by Porson, for the use of his friends, as restored by Schweighäuser: the want of this leaf of the manuscript of *Simplicius* had given rise to the mistaken assertion that Xenophon was proclaimed a public benefactor at the Olympic Games, on occasion of the return of the ten thousand. There are also some miscellaneous *Notes* on Athenæus, Menander, and Philemon, Aristides, Pausanias, and the lexicographers, and some *Indices* of authors quoted by Scholiasts.

23. *Notæ in Aristophanem*, quibus Plutum comœdiam adjecit P. P. Dobree, 8vo. Cambridge, 1820.

24. *Gaisford Lectiones Platonicae*. Accedunt R. Porsoni *Notæ ad Pausaniam*, 8vo. Oxford, 1820.

25. *Photii Lexicon*, 8vo. Cambridge, 1822.

To attempt to form a just estimate of the merit of such a man as Porson, without servilely following the dictates of common fame, or blindly adopting the opinions of others, is a task of no small difficulty, even to one who had the advantage of his personal acquaintance for the last twenty years of his life. But it may safely be conceded to common fame and to partial friendship, that he was one of the greatest men, and the very greatest critic, of his own or of any other age. "Nothing came amiss," says Mr Weston, "to his memory. He would set a child right in his twopenny fable book, repeat the whole of the moral tale of the *Dean of Badajoz*, a page of Athenæus on cups, or of Eustathius on Homer, even though he did every thing to impair his mental faculties." It cannot, however, be denied, that the talents, and even the industry, that he possessed, might have made him a much greater man, had they been employed in some other department of human intellect. He might *probably* have been as great a statesman or as great a general as he was a scholar, and in these capacities his acquirements would have affected the interests of a much greater multitude of his fellow creatures, than can ever be benefited by the fruits of his erudition; and he might *possibly* have gained more popularity as an orator or a poet, than his refined investigations of grammar and prosody could ever procure him, although it is not by any means certain that his fancy and invention could have been rendered by any cultivation at all comparable to his memory and acuteness. But as far as regards the possession of a combination of the faculties which he did cultivate, he appears to have been decidedly the most successful of any man on record in the same department. On the other hand, it must be admitted that the subjects of his pursuits were in their nature incapable of raising a man to the first rank among the permanent benefactors of the human race; and, if we calmly consider the ultimate objects of prosody and metre, it will appear almost unfair to allow the discoverer of the prosodical rules,

Porson.

adopted by the ancient poets in their melodramas and choruses, to rank so very high among the luminaries of an age, and yet to look down, with so much contempt as we are accustomed to do, on the character of a modern *Dieu de la danse*, notwithstanding that he thought himself the third great man of his day, with Voltaire and the King of Prussia, for having given soul and sentiment to the measures and movements of the choric representations of the present times. Among the talents of Porson, however, which were so far superior to the importance of the objects on which they were employed, we ought not, perhaps, to consider his remarkable strength of memory as the most to be envied, since many persons who have been possessed of singular and almost miraculous, not to say morbid, memories, have been but little distinguished by any other faculty; and it appears to be possible that a memory may in itself be even too retentive for real practical utility, as if of too microscopic a nature; and it seems to be by a wise and benevolent, though by no means an obvious arrangement of a Creative Providence, that a certain degree of oblivion becomes a most useful instrument in the advancement of human knowledge, enabling us readily to look back on the prominent features only of various objects and occurrences, and to class them and reason upon them, by the help of this involuntary kind of abstraction and generalisation, with incomparably greater facility than we could do, if we retained the whole detail of what had been once but slightly impressed on our minds. It is thus, for example, in physic, that the experienced practitioner learns at length to despise the relation of individual symptoms, and particular cases, on which alone the empiric insists, and to feel the value of the Hippocratic system of "attending more to the prognostic than the diagnostic features of disease;" which, to a younger student, appears to be perfect imbecility. And it is perhaps for some similar reason that many persons, besides Barnes, "of happy memory," have had to wait long in darkness for "the day of judgment." But it must be repeated, that Porson's judgment and acuteness were really almost paramount to his memory, and with the addition of these faculties, his memory naturally rendered him capable of much that would have been impossible without it.

The respect that is justly due to classical learning has frequently been exaggerated in this country, partly, perhaps, on account of the awe which is naturally entertained, by an ingenuous mind, for its instructors in the earliest studies, by which it is advanced towards maturity: and classical learning having most wisely been placed by our ancestors the foremost, in the order of a liberal education, which is most commonly adopted in Great Britain, a personal as well as a general respect has been involuntarily paid to the characters of the individuals concerned, and to the dignity of all those who are engaged in similar occupations; besides that, the means being, by a most frequent inattention of the human mind, confounded with the end for which they are sought, the words and syllables, and the phrases and measures of the Greek and Latin authors have been often the almost frivolous occupation of a valuable life, instead of that of a few of the years of boyhood, which it

Porson.

was intended to devote to them, and which could not have been so well engaged in any other way. It is, however, wholly unjust to stigmatize the study of the classics, and of languages in general, as being confined to words instead of things: for it is utterly impossible that words can be learned, without the acquisition of a considerable degree of knowledge of the things to which they relate, and of the historical facts which they have been employed to express, and without an involuntary modelling of the mind to the elegance and elevation of sentiment, which pervade the works of those authors who are habitually put into the hands of boys in the course of their elementary studies: an acquirement which is of still greater value to the orator and the statesman, than the command of language, and facility of expression, and beauty of imagery, and power of reasoning, which he derives from a perfect familiarity with the great masters of antiquity. But granting all the respect that can possibly be claimed, for ancient literature, we cannot but lament that such a man as Porson should have lived and laboured for nearly half a century, and yet have left little or nothing to the world that was truly and originally his own.

After the full admission of the very high rank which is due to the comparative merits of Porson's talents and acquirements, it may be thought almost idle, if not invidious, to dwell on any trifling exceptions to their magnitude. But it is, in fact, of high importance to the progress of human knowledge to be aware of the degree in which the first of mankind are liable to error. The admission of the few errors of Newton himself is at least of as much importance to his followers in science, as the history of the progress of his real discoveries; and it is with reason that the detection of an error in such a man is considered as almost paramount to the establishment of a new fact. The English critics have been reproached, and not without some foundation, as paying too servile a deference to Porson's opinions, and it seems to have been very generally believed among them, that it was scarcely possible for him to commit an error or an oversight.

Although Porson was in many respects irregular, and often idle, or even intemperate, yet what he did perform as a critic may be allowed to leave a large balance, at the end of his life, in favour of his general industry, when compared with that of most of his countrymen. It has indeed been asserted, and perhaps with truth (*Classical Journal*, XXI.), that "with things Porson appears to have possessed but a very inconsiderable acquaintanc, and not a trace is to be found amidst his writings of that combination of universal encyclopaediacal knowledge with language learning, which is so abundantly found in the *Dissertation on Phalaris*, and the countless pages of Scaliger, Salmasius, and Casaubon." Certainly, however, neither Salmasius nor Casaubon, with all their learning, much less Scaliger, with all his industry and parade, nor even Bentley himself, with all his talent and acuteness, was at all comparable to Porson in his own department, that is, as a sound and accurate and refined Greek critic.

But it must be confessed, that at Cambridge, even although Porson had resolved to make the classics

Porson. his principal study, and although there had not yet been many instances of senior wranglers, who were also senior medallists, it was scarcely reputable for a man, with his undeniable abilities, to be only the twenty first of his year in mathematics. Among the literary objects, also, which afterwards engaged his attention, he might easily have found time for the study of some of the modern languages, and he might have derived essential benefit from it on many occasions of critical research. He had, indeed, read a good deal of French, but very little Italian: he had studied the Anglosaxon, but he knew nothing of the kindred dialects of the North of Europe, in which it is preserved almost entire; and he was wholly unacquainted with Oriental literature. He might have profited materially by some of these studies, in deriving from them a clearer conception of the distinctions of the tenses than he seems to have possessed, and he might have enlightened us in no small degree, with respect to the history of languages and of nations, by such etymological investigations, as his comprehensive mind, thus employed, would have rendered him peculiarly capable of pursuing with success.

It has been candidly and very truly admitted by a rival critic in Germany, that Porson committed fewer errors than almost any other person; but it is right to be aware that he has now and then committed some errors, even where he would have been expected to be the most correct. There is, for example, a very strange oversight in one of the criticisms contained in his early review of Weston's *Hermesiananax*, which implies a palpable blunder with respect to the gender of a participle, *Ζωρὸν μετροῦσα θυρὸν ποικιλοχρῆτος Δυσβιον ἐξ ὑέλου*, "the cup of purple glass, which measured the fragrant wine;" and even in a subsequent correction of the same passage, published in his *Adversaria*, he has changed the gender of an adjective in a way that is at least very unusual, if not wholly without example, *μετροῦν θυβεντα*. A mere omission, in a criticism on another author, would scarcely be called an error in an ordinary person; but in such a critic as Porson, it is very remarkable that he should have neglected to notice, in his catalogue of the *Errors of Le Clerc*, omitted by Bentley (*Adv.* p. 291), the grossest of all Le Clerc's blunders, which is the quotation of the word *Hypophauli*, or *semibarbarous*, from Pollux, with the translation *Sartagines*, or *frying pans*: while the real text of Pollux simply and plainly states that the *Teganismi*, or *fricassations*, in the *Hippocomus* of Menander, is a *semibarbarous* word. These instances, which have occurred in a very cursory perusal of some of Porson's works, would certainly not deserve to be noticed, in a general sketch of his character, any otherwise than as exceptions to his perfect infallibility.

It can scarcely be considered as an imperfection in the constitution of Porson's mind, that he wanted that amiable vanity, which is gratified by the approbation even of the most inconsiderable, and which delights to choose for its objects the most innocent and the most helpless of those who are casually present in society. It has been observed that he would neither give nor take praise; and when he was told

that somebody had called him a giant in literature, he remarked, that a man had no right to tell the height of that which he could not measure. In fact, having learned "to know how little can be known," it is not surprising that he found himself "without a second, and without a judge," and that he was unwilling to affect a community of sentiment, and an interchange of approbation with those whose acquirements and opinions he felt that he had a right to despise. It might have been wiser, in some instances, to conceal this feeling; but, on the other hand, he had perhaps occasion for something of the habit of retreating into his conscious dignity, from his deficiency in those general powers of ephemeral conversation, which are so valuable in mixed societies: for, with all his learning and all his memory, he was by no means prominent as a talker. He had neither the inclination nor the qualifications to be a fascinating story teller, or to become habitually a parasite at the tables of the affluent; but he was the delight of a limited circle of chosen friends, possessing talent enough to appreciate his merits, and to profit by the information that he afforded them.

There has not yet been a life of Porson that has collected all the particulars that would deserve to be recorded by a biographer, who undertook the task on an extensive scale; but of detached documents there is no deficiency. Mr Kidd has pointed out almost every work in which his name has been mentioned: the most material articles relating to him will be enumerated here.

PORTUGAL.—This kingdom, the origin of whose name is discussed in the *Encyclopædia*, had different limits assigned to it by the Romans, who possessed it under the name of Lusitania. Its northern boundary was the river Douro, whilst eastward it extended over a large part of Leon and Castile. Its line of demarcation passed from the bridge of Arzobispo to the eastward of Talavera, extended to Simanacas on the Douro, and included within its bounds the cities of Salamanca, Truxillo, Coria, Merida, and Avila, and the several intermediate towns and villages. When the northern tribes penetrated to the peninsula, and gained the mastery of it, Lusitania still retained the same name, and a

Portugal.

branch of the Suevi, having established themselves in it, made Braga the capital of their government. Though under the Moors, the names of many cities, towns, rivers, and mountains, received the nomenclature of that people, yet the whole country retained the Roman title till the more modern name of Portugal was bestowed upon it.

Limits and Extent.

The present kingdom of Portugal is bounded on the north by the Spanish province of Galicia, on the east by the several provinces of Leon, Estremadura, and Andalusia, and on the south and west by the Atlantic Ocean. It has the figure of a parallelogram, with its longest side from north to south; extending from 37° 3' to 42° 12' north latitude, and from 6° 15' to 8° 55' west longitude from Greenwich. Its extent is estimated, following the map of Lopez, at 3437 square leagues, or about 22,765,000 English acres. The divisions of Portugal, like those of most of the other kingdoms of Europe, have been derived rather from feudal possessions than from any other cause, and though they have produced great inequalities in their extent, in their relative and absolute population, and in their fertility and wealth, there is no reason to expect any alteration in them; they are as follows, according to Antillon, viz.

Provinces.	Population.	Extent in Square Leagues.	Extent in English Acres.	Number of Acres to Inhabitants.
Entré Duero e Minho	907.965	291	1,927,040	2 1/2
Tras los Montes -	318.665	455	3,007,760	9 1/2
La Beyra -	1,121.595	753	4,936,880	4
Estremadura -	826.680	823	5,450,880	4 1/2
Alemtejo -	380.480	883	5,848,320	15 1/2
Algarve - -	127.615	232	1,536,000	12

Population.

The population here given is the result of the last actual census, which was taken in the year 1798, by order of the late queen. The enumeration then made was of the number of families, which, being multiplied by five, gives the state of the population here expressed. Notwithstanding the desolating war which has since occurred, and which must, for a time, and within certain districts, have lessened the population, the best native authorities contend, that, during the last twenty years, the increase has been gradual, and that the number of inhabitants now is nearly equal to that census.

Portugal may then be considered a well peopled country; as compared with Spain, the density of population is as 3 to 2, and as compared with Scotland, which is of nearly the same extent, it is almost double. If the whole of Portugal were as thickly settled as the province of Entre Duero e Minho, the number of souls would amount to 10,700,000; whereas, if the whole had no greater density than that of Alemtejo, they would not exceed 1,480,000.

Portugal.

An ingenious writer, in comparing the present population of the kingdom with its state in the fifteenth century, remarks that, "in the provinces where commerce flourishes the inhabitants have increased; where they subsist by the fisheries they have diminished; and where both commerce and the fisheries exist, the increase has been only in proportion to the quantum of commerce."\*

The face of the country is generally mountainous, divided into ridges by deep chasms, through which rapid torrents rush, in the rainy seasons; but which, in times of drought, scarcely afford sufficient supplies of water for the wants of the inhabitants and their cattle. This irregular surface of the country is very unfavourable to intercourse between the different provinces. The expence of constructing roads and bridges in such a country is too great to be borne by its inhabitants. Hence, there is scarcely any conveyance either for goods or passengers by wheel carriages. Although, in the northern parts of the kingdom, there are some bridges of very ancient erection, yet in the south scarcely any are to be found. The roads, too, in the north are, in some few instances, tolerably good. The merchants of Oporto have constructed a road to Lamego for the conveyance of their wines, and are still extending it. A good road has been formed to Mafra, and the Government has been occupied in making one to Coimbra. In the southern provinces no such efforts have been made; but the road from Mertola to Beja, originally constructed by the Romans, has been recently repaired. At present none are likely to be commenced, so that the inconveniences of travelling are perhaps greater than in any other part of Europe.

Face of the Country and Roads.

The state of agriculture was till lately very bad; and though much of the soil is naturally fertile, and the climate highly favourable to the production of all the necessaries of life, yet Portugal did not raise more corn than was sufficient for one third of its annual consumption; and though animal food can scarcely be deemed an article of general sustenance, its own lands did not pasture cattle sufficient for the scanty demand of the inhabitants. When cultivated with care, the soil produces abundant crops of wheat, barley, maize, and rice; besides which, it yields hemp and flax of excellent quality. Some improvements in husbandry have, however, begun to appear. The cultivation of potatoes has been introduced, and, on the more elevated parts of the country, with great success. They have extended rapidly, and form already so large a part of the sustenance of the inhabitants, that the exportation of flour from the United States of America has nearly ceased; and the small quantity of corn now required is drawn from the northern parts of Europe, or from the Cape de Verd Islands.

Agriculture.

The attention of the Portuguese husbandmen is principally directed to the production of those articles which find their most ready vent in foreign countries, or which are raised with the least labour. Of the first sort is their wine, chiefly in the

\* *Memoirs Economiques de Academia Real das Sciencias de Lisboa*, Tom. I. p. 123.

**Portugal.** northern provinces. The quantity usually made is about 80,000 pipes of red, and 60,000 pipes of white. Of the former about one half is sent to England, about one eighth to the other parts of northern Europe, and the remainder to Brazil. Not more than one sixth part of the white wine is exported to all the countries of Europe; the rest is either sent to Brazil or is consumed at home; but, in general, the natives drink wine of a quality far inferior to any that could find a vent in foreign markets. The productions that require but little labour, such as chesnuts, almonds, oranges, lemons, and citrons, are profusely raised; and, with the onions and garlic, form no small proportion of the aliment of the inhabitants. Olive trees are plentiful, and the oil expressed from their fruit forms an important article of sustenance; and though not of a quality or flavour that is relished for the table in foreign countries, it is a considerable article of export; being used by the woollen manufacturers of England, Holland, and Germany, in their respective operations.

**Fisheries.** The sea coasts of Portugal abound with excellent fish, especially with Tunnys and Sardinias, and they, as well as the rivers, afford both occupation and food to a great portion of the inhabitants; but the supply from them is inadequate to the wants of the population, whose consumption of that kind of diet, from their adherence to the fasts prescribed by the Catholic religion, is very great; requiring an annual importation of salted fish, which is furnished by the English and Americans, from the banks of Newfoundland, and by the Swedes, Norwegians, and Dutch.

**Manufactures.** The manufactories of Portugal are in a very languid state. With the exception of the lower classes of people, who are clothed with their domestic manufactures, or with the skins of their sheep, nearly the whole of the nation may be said to be furnished with their apparel from England, Holland, and Germany. The few manufactures of Portugal are those of cotton, at Alcobaza and Tomar; of linens, at Guimarens, on the Ave; of glass, at Leyria; and of woollen cloths, at Guarda. The best goods that are made in the kingdom, as compared with those of other countries, are the cambrics, shirting and table linens, and sewing threads. In Lisbon are made some silks, hats, and silver and plated wares. A late most superb service of plate, presented to the Duke of Wellington, made wholly by natives, shows that they are not deficient in taste in the goldsmith's art.

**Minerals.** The mineral riches of Portugal have been much neglected. There are mines of tin which were formerly worked to considerable extent, and much profit, but are now abandoned. Besides these, there are veins of silver, iron, lead, and copper, none of which are wrought. The country abounds with most beautiful marbles, though many of the quarries are at so great a distance from water conveyance, and the roads are so bad, that they will not repay, in the present condition of the kingdom, the expences attendant on carrying them to a market.

**Commerce.** The emigration of the court to Brazil destroyed

that colonial monopoly which, till that event, was most rigidly maintained. Instead of being the point in which both the wants and the produce of the colonies met, and were exchanged, the imports have been confined to what the parent state has required for its consumption; and the exports have been restricted to the wines, oil, and fruits, which were sold to purchase the corn and other sustenance required to feed the people, and procure clothing from England and Holland. The sugar, cotton, and other productions of Brazil, are carried direct to the places of consumption; and from the same places the Brazilians obtain their supplies of European commodities, without the intervention of Portugal. Next to wine and fruits the chief export from Portugal is the bay salt, made from sea water, by natural evaporation, at St Ubes. The vessels which bring salted fish usually take a part of their returns in this article. Near five hundred vessels are annually loaded with salt, at St Ubes, and the quantity exported is about 100,000 tons. Of late years wool has been transported to England; in one year nearly one million pounds weight; but a tax laid on that commodity here has operated nearly to exclude that of a coarse quality from our markets.

The government of Portugal was a monarchy of the most absolute kind. The several Boards or Councils, which carried on the administration, had no check or even voice in the measures that were adopted, but obeyed the orders of the King implicitly; and it is generally understood, that in no Court did corruption and favoritism abound to an equal extent. The laws were a most incoherent mass, without fixed principles or regularity; and the administration of them, whether by superior or inferior judges, was perverted by bribery, so as to favour the purposes of oppression rather than of justice.

The religion of the kingdom is the Roman Catholic, of the most rigid, not to say of the most superstitious, description. The proportionate numbers of the clergy were greater than in any other country in Europe. There are three archbishops, thirteen bishops, and a prelate presiding over them, denominated the patriarch. The Inquisition was in full force, to check, in their earliest stages, the growth of any opinions that were thought to militate against the established faith. By some late regulations the number of the clergy has been reduced, and the Inquisition abolished.

Before the invasion by the armies of Buonaparte, the revenues of Portugal, including the sums drawn from Brazil, were calculated to amount to about 3,000,000 Sterling. At the same period, the land forces consisted of 30,000 men; and the marine comprised 20 sail of the line, besides frigates, corvettes, and sloops. During the war, resources were called forth which the nation never had imagined it possessed. Troops, notorious for indolence, want of discipline and filthiness, when placed under the command of British officers, became active, disciplined, and brave; and bore no inconsiderable share of the dangers and successful contests which liberated their own country, Spain,

**Finances and Military Strength.**

Portugal.

and ultimately the whole of Europe. When the Court emigrated to Brazil, where the marine of its ally was a better protection than any she could furnish, Portugal suffered her navy to dwindle, and she has now few large ships that are capable of warlike operations.

People and Language.

The inhabitants of Portugal are generally a robust, yet not an industrious people. They are enterprising and persevering, patient in adverse circumstances, excessively attached to their own religion and customs; and, though temporary circumstances may seem to indicate the contrary, they retain a high sense of loyalty to their monarch, and of submission to their spiritual superiors. The Portugese language is derived from the Latin, of which it contains a great proportion of words, though mixed with many others of Arabic origin. In the construction of its sentences, it very much resembles the Castilian; but the pronunciation of the syllables differs considerably; and there are many words introduced which are peculiar to itself, and whose derivation it is difficult to trace; though probably they are to be found among some of the tribes on the coast of Barbary.

Cities, Towns, and Ports.

Portugal contains twenty-two cities. The capital, Lisbon, on the north side of the Tagus, distinguished by its excellent harbour, by some superb buildings, its irregular surface, and disgustingly filthy streets, contains 260,000 inhabitants; Oporto contains about 65,000; Coimbra, 15,000; Evora, 12,000: the other cities are small, poor, and less populous. The remainder of the inhabitants occupy 647 towns and 4262 villages. The proportion of agricultural labourers to the whole population is so small, that, scanty as are their harvests, and favourable as the weather almost uniformly is for securing their fruits and corn, the labours of the field, in autumn, require numerous additional hands, which are furnished by the adjoining Spanish province of Galicia. The principal sea ports are Lisbon, Oporto, and St Ubes. Besides these, Viana, at the mouth of the river Lima, Aveiro, Sines, Serdao, Villa Nova, Faro, and Tavira, have harbours, but generally accessible only to small vessels; and, except Viana and Faro, they have scarcely any other than a mere coasting trade.

Recent History.

The *Encyclopædia* brings down the history of political events in Portugal to the conclusion of the Convention of Cintra in August 1808. Towards the close of that year, the armies which Spain had collected to oppose the invading forces of France being dispersed, Madrid having surrendered, and the British troops under Sir John Moore having been compelled to a precipitate retreat from the Peninsula; the invasion of Portugal was again resolved upon by the French with the fullest confidence of success.

Three armies were collected on the frontiers. One under Marshal Soult in Galicia, a second under General Lapisse at Salamanca, and a third on the banks of the Tagus under Marshal Victor. The only opposition which could be presented was to the last of these corps, by an assemblage of the fugitives of the Spanish army which General Cuesta was attempting to reorganize. Consternation and dismay spread

over the kingdom; the garrison and stores were withdrawn from the frontier fortress of Almeida; the forts and batteries on the Tagus were dismantled; and the British troops in the vicinity of Lisbon were concentrated as preparatory for instant embarkation. A war breaking out again, at this period, between Austria and France, induced Buonaparte to withdraw from Spain, and to take with him 15,000 of his best troops, which in some measure checked the rapid advance of his forces, and allowed an interval for preparation, which was sedulously improved in Portugal. General Beresford, who had acquired the confidence of the natives, was, at the suggestion of the British Government, appointed Marshal and Commander-in-Chief of the armies of Portugal. Twenty thousand of the Portuguese were taken into the pay of England, and British officers were nominated to the superior commissions in each battalion; by which means a general system of discipline and subordination was quickly established. Reinforcements of troops from England, augmenting the army to 17,000 men, had reached Lisbon, and confidence was in a great measure restored before a blow was struck.

Marshal Soult at length having dispersed the Spanish troops in Galicia, and thus secured that province, entered Portugal by the road of Chaves. He was slightly opposed by General Friere, at the head of a Portuguese army, who had intended to have retired, on his approach, to stronger ground nearer Oporto. In this design he was interrupted by the mutiny of a division of his troops, who, insisting on defending Chaves, were shut up in that town, and in a few days compelled to surrender. As Soult advanced, Friere would have retreated, but the rest of his army being without due subordination, were impatient to fight; and as he persisted in his prudent plans a mutiny arose, when, under the suspicion of treachery, the General and his Staff were massacred by the mutinous troops. They then demanded a British officer who would lead them to attack the enemy. Baron Eben, a German in the British service, took the command, and gratified their wishes by fighting the unsuccessful battle of Carvalho da Este, where, after some creditable efforts of individual bravery, the sabres of the enemy's cavalry took ample vengeance on them for the murder of their late Commander. Soult then invested Oporto, which had been strongly fortified, and was defended by 200 pieces of cannon, and a garrison of 20,000 men; but the same insubordination and want of confidence prevailed in the city as had produced the disasters in the field; and, after an ill conducted defence of three days, it was taken by assault on the 29th March. The French soldiers, on entering the town, made an indiscriminate slaughter of the inhabitants, and delivered themselves up to every species of plunder and licentiousness; and, though their Commander used efforts to repress their fury, he was unable to accomplish it before the sufferings had continued a whole day and night.

The day before the fall of Oporto, Victor had defeated the Spanish army commanded by Cuesta in the battle of Medellin. This event opened to the

Portugal. French an easy road to Lisbon. General Craddock, the British Commander, posted a corps of his army of 6000 men at Abrantes, assembled the main body of his troops at Leyria, and the Portuguese army at Thomar.

Such was the situation of affairs in Portugal when, on the 22d of April, Sir Arthur Wellesley landed at Lisbon to assume the chief command of the armies of England and Portugal.

The ill consequences of independent Commanders were visible in the movements of the French. The three armies of Soult, Victor, and Lapisse, which, if directed by one Chief, would long before this period have entered Lisbon in triumph, being disunited, and fearing to be separately committed, lost the precious moments for action in suspense, or petty movements. Soult remained nearly a month at Oporto, in expectation of intelligence from the other Commanders, without which he deemed it imprudent to move forward. In the meantime, the Portuguese troops had captured Chaves, and thus cut off his direct communication with Spain by that route. The movements of Lapisse and Victor were equally hesitating. Sir Arthur, on the other hand, being unfettered in his views, could act with decision and promptitude. On the tenth day from his landing, the British in Leyria, to the number of 16,000, began to move by Coimbra and Aveiro, for the recovery of Oporto; whilst 6000 Portuguese under Beresford marched to cross the Douro at Lamego, and cut off the enemy's retreat by Amarante; and the forces at Abrantes were left in that city to keep in check the army of Victor. The British from Leyria first met the enemy on the 10th May, on the banks of the Vouga, and, after a slight affair, drove them over the Douro. The floating bridge across that river was destroyed, and all the boats near Oporto were secured by the French on the right bank; thus the British General found himself separated from his antagonist by a rapid river, nearly 300 yards broad, without any means of effecting the passage across it. Sir Arthur then planned and successfully executed the boldest passage of a river that is to be found on military records. He detached a body of troops under General Murray to Avintas, five miles higher on the river, where, if boats could not be found, a ford would admit of the troops passing; and sent General Sherbrook with the Guards to the common ferry below the city; whilst from the Serra Convent, nearly opposite the town, he directed the passage in person. The stream was excessively rapid, and the heights on the right bank considerable. By the aid of some inhabitants, two boats were brought over from the enemy's side, and in them, protected by the fire of a brigade of light guns, three companies of the Buffs were ferried across. Soult, either despising the effort, or believing it to be merely a feint to draw his attention from the main object, did not oppose the landing, but gave time to General Paget, who commanded, to ascend the bank, and place the troops in a formidable attitude in a ruined building before he attacked them. He then brought up a considerable force, which was firmly resisted, and gained time for passing over several other battalions. General Paget was early wounded, and the command devolved on General Hill, who was warm-

ly engaged in contesting the post, when General Murray appeared in sight, marching on the enemy's left flank. The Guards were then pushed across, and the French precipitately retired into the city. Soult discovered that he had been out-manœuvred, and ordered the immediate retreat of his army; but the British were already in the town, and charging up the streets. The confusion and precipitancy with which the French fled was far greater than can be readily imagined, and their panic seemed to increase as they gained the open country. Never was the rout of an army more complete, when night put an end to the pursuit, and gave the enemy a few hours respite. Soult, finding the bridge at Amarante destroyed, abandoned all his artillery and wheel carriages, and leaving the high road, took the mountain track to Guimaraens. Thus freed from every incumbrance, the badness of the roads favoured his flight, and he gained a narrow pass on the shore near Salamonde, before Beresford's troops had reached the spot, as was projected, to intercept him. On the 18th he reached the frontier, and the pursuit closed, as more important affairs required attention to the south. Victor had joined with Lapisse, and forced the passage of the Tagus, at Alcantara; from whence they were advancing towards Lisbon at the time that the victorious army from Oporto reached that river early in June; when the enemy retired into Spain, and abandoned Portugal for the present.

When Buonaparte had compelled Austria to conclude a peace, he stood pledged to his people and to the world to conquer Portugal, and "to drive the British into the sea." His means for effecting those objects appeared unlimited; whilst the English nation, desponding at the general ill success of the war, and dissatisfied with the waste of their military strength in the Scheldt, were generally disposed to withdraw from the contest.

Early in March, however, the Parliament deciding with the administration to continue with vigour the defence of Portugal; the subsidiary force of that nation was increased to 30,000 men; and such of the British battalions as could be rendered effective after the effects of the climate of Walcheren, were sent out to reinforce the army. The French assembled an army of 72,000 men under Marshal Massena, in the vicinity of Salamanca, early in April; which could only be opposed by about 50,000; one-half composed of young Portuguese levies, yet untried in general action. The operations of the campaign commenced by the siege of the Spanish city of Ciudad Rodrigo, which, after a stout defence, capitulated on the 10th July. The road to Portugal was thus opened to the French, who entered it, and besieged Almeida. Owing to an explosion, by which all the powder in the garrison was destroyed, the Commander was compelled to surrender the latter end of August. The road by which Massena intended to force his way to Lisbon, soon became evident to the rival commander, and the united British and Portuguese armies were placed in such positions as were most likely to frustrate his intentions. The British Commander, during the whole progress of the enemy, had employed the abundant means at his disposal in constructing a secure asylum in which he

Portugal.

1810.

Portugal. could effectually make a head against the superior forces that were employed to drive him from the Peninsula, and to possess the capital of Portugal. Lisbon is situated on the extremity of an isthmus formed by the ocean and the river Tagus. Across this peninsula nature had drawn the outline of a strong defensive position, which the military art had been secretly but sedulously employed in rendering perfect. A track of country, thirty miles in extent from the mouth of the small river Tirandra to Alhandra, on the Tagus, was modelled into a field of battle; mountains were scarped perpendicularly, rivers dammed, and inundations formed. All roads that could favour the enemy were destroyed, and others made to facilitate the communications of the defenders; formidable works were erected to strengthen and support the weak parts; whilst numerous cannon, planted on inaccessible posts, commanded the different approaches to them, and gave an equality of defence to the whole position. Behind these defences the inhabitants of a district of nearly 2000 square miles were invited to retire with what of their substance they could convey, and were directed to destroy whatever could not be removed, that might afford support to the advancing army of Massena. Though these orders were but partially obeyed, yet, as far as they were executed, they contributed to the ultimate success of the defensive plan formed by Lord Wellington.

With this secure asylum in his rear, the British Commander could safely practise all the manœuvres which tended to retard the approach of his antagonist. Massena, after the capture of Almeida, pushed on with rapidity towards Coimbra, and meeting no opposition there, expected the British army was hastening to Lisbon to embark. He received a check at the mountains of Busaco, but having turned that position, the British slowly marched within the formidable lines so celebrated in military annals by the name of *Torres Vedras*. The day after the 9th of October Marquis Romano joined the British army with 6000 Spanish troops; and on the next day Massena first discovered the formidable works which covered his antagonists. "To judge," says an eye-witness, "from the instant halt he made, and from the retrograde movement which followed, as soon as it became dark, they struck him as much with dismay as astonishment, and three days elapsed before he again ventured to the same spot." After some slight efforts to ascertain the nature of the defences, the French remained a month without any movement, merely sending out strong parties to their rear to ascertain the nature and resources of the country, from which alone they could hope to draw sustenance. The irregular troops of Portugal pressed him on all sides, and contracted the limits from which supplies could be obtained; and a division of them captured the sick and wounded of the French to the number of 5000 men, which, in the haste of his progress, Massena had left at Coimbra.

On the 14th November the French army, to be nearer their supplies, retrograded towards Santarem and Thomar, where they fortified their position, and were followed by the British to Cartaxo, from whence they were ready to fall back on their lines, should

the enemy receive such reinforcements as to render it necessary. In this situation the two armies remained; the English receiving from Lisbon abundant supplies, which were sent by sea, and the French exhausting the country in their rear till scarcity produced disease, and rapidly thinned their ranks. Though reinforcements were sent to them, the desolate state of the country made them a burden, rather than an assistance to their coadjutors. After thus remaining in sight of each other till the 7th March 1810, a period of five inactive months, without a prospect of decisive action, the French were compelled to commence their retreat, just at the moment when the British had received a reinforcement of 7000 fresh troops. At the commencement of their retreat the loss in the French army since it had entered Portugal amounted to more than 30,000 men. Disgusting accumulations of filth, and remains of the most unhealthy kind of food, with the wretched and squalid appearance of most of the prisoners, and the neglected and unprovided state of the hospitals, sufficiently testified the miserable condition to which the invaders were reduced, and accounts for so prodigious a mortality beyond that inflicted by the sword. The sufferings and losses of the French, however, were nothing in comparison with those which their visitation had inflicted on Portugal and its inhabitants. A wide extent of country remained for five months with scarcely an inhabitant: every thing it contained was devoured by the enemy or destroyed by the season. In the space immediately bounding the positions of the two armies, which was not permanently occupied by either, the harvest perished in the ground, and the fruit fell rotten from the trees; flocks of innumerable small birds, as if drawn to the spot by instinct, fattened unmolested on the ungathered grapes; and latterly the very wolves, conscious of security, or rendered more daring by the absence of their accustomed prey, prowled about, masters of the territory, reluctantly giving way to the cavalry patrols which occasionally crossed their track.

Many of the wretched inhabitants who had neglected the warning voice that invited them within the lines, passed the whole season of winter, exposed to its inclemencies, in the neighbouring woods or mountains, subsisting merely on roots and herbs; and on the advance of the allies, returned to their ruined homes with bodies emaciated from abstinence, and intellects impaired by long continued apprehension; among these were girls of 16, who, become idiots, resembled in person women of 50. At the departure of the French, in many districts neither a living animal nor an article of subsistence was to be found. The official account of the *Moniteur* correctly and unblushingly states, that "the towns and villages were deserted, the mills destroyed, the wine running in the gutters, the corn stalks burnt, the furniture broken; and not a horse, a mule, an ass, a cow, or even a goat, to be seen."

The retreat conducted by Massena exhibited great military talents, and every movement was made with such skill and celerity, that his active and indefatigable opponent could gain but few advantages over him. The rapid pursuit in a few days carried the

Portugal. allied armies farther than their supplies could reach them, and they were obliged to halt till provisions could overtake them. Massena availed himself of these circumstances to retire out of Portugal, after throwing supplies into the fortress of Almeida. The retreat of the French was conducted with so much ability, that its loss, both by the sword and in prisoners, did not exceed 5000 men; that of the allies being under 650. Having thus freely bestowed the tribute of praise justly due to the French as soldiers, it is but proper to notice their conduct as men, and to state, on the authority of an eye-witness, that the unnecessary cruelties and wanton devastation which marked every step of their retreat, were such as to cast a shade over their character which no military glory can efface, and to stamp them rather as sanguinary and unprincipled banditti, than as the organized warriors of a civilized state.

The French army was reinforced and refitted at Salamanca, returned to Portugal in the beginning of May, and made several movements and attacks, some of a very important nature, to prevent the British from capturing Almeida; but having been foiled in every attempt, they retired and left that fortress to its fate; the garrison of which evacuated it, and forced their way in a most spirited manner through the British army that surrounded them. With this operation the scene of war closed in Portugal; for though, during the sieges of Ciudad Rodrigo and Badajoz, and in the attempt made by Marmont, some parts of that kingdom were included in the theatre of hostilities, they never extended beyond the frontiers. The other events of this important war belong rather to the history of Spain and of France than to that of Portugal, though in all the operations the troops of that nation bore an active and conspicuous part.

After the dissolution of the government of Buonaparte, the troops of Portugal were marched to their own country; but before the proper measures for reducing their numbers were adopted, his return from Elba again set them in active movement, till the decisive battle of Waterloo once more permitted them to rest. The state of the country was, however, by no means tranquil. The absence of their Court in Brazil, the little influence enjoyed by the Regency, the calls for pecuniary aid from the Provinces, and especially the large army being still kept up, and its command continued in foreign hands, with the spirit of insubordination prevailing among the native officers, gave sufficient grounds to apprehend that convulsions must ensue. A conspiracy, of a very extensive nature, was timely discovered in the army, and its progress checked, but without the spirit which generated it being extirpated. This was strongly exhibited afterwards, when 10,000 men, who had been ordered to embark for Brazil, revolted, and showed such determination, that the Regency was compelled to yield to their wishes. Portugal felt that the order of nature was inverted, and the parent state become a dependent on her own colony. Conflicting claims between the Regency and the Commander of the Forces induced Lord Beresford to repair to Rio de Janeiro, to obtain fresh instructions, and probably additional authority from the King. In his

absence a revolution broke forth, which, giving to Portugal a new aspect, renders all accounts of its present condition doubtful, and leaves to conjecture what may be the result of the circumstances in which she is placed.

The first symptoms of this revolution were exhibited at Oporto, and the first movements were made on the 24th August 1820, in the 18th regiment, under the command of Don Bernardo de Castro e Sepulveda, in which he was supported by the other troops in that garrison, and, as is supposed, by the civil authorities of the city. A provincial Junta of 13 members was chosen by acclamation, who issued a proclamation to quiet the apprehensions of the British officers. Sepulveda was opposed by Count Amarante, the commander of the troops in the province Tras os Montes; but on marching towards him, in the end of August, that officer was forsaken by his troops, who joined the insurgents, and rendered it necessary for him to take refuge in Spain.

Sepulveda then advanced with his army towards Lisbon, and reached Coimbra, where the Junta of Oporto followed him and held their sittings. The Regency of the kingdom in Lisbon acted with indecision, or perhaps with treachery. On the 29th August, they issued a proclamation denouncing the transactions that had taken place at Oporto, and calling on the inhabitants and military to oppose their progress; and, on the 1st September, issued another, by which they directed the assembling of the Cortes of the kingdom according to its ancient institution. Before the period had arrived for the convocation of the assembly, an event occurred which wholly frustrated the plan projected by the Junta of Regency. It had been usual to celebrate, on the 15th September, the deliverance of Portugal from the French invaders. The Junta fearing to assemble, in the agitated state of the public mind, such a concourse of people as usually met on that day, resolved to omit the ceremony; but the troops, at the instigation of the native officers, paraded without orders, and, before they separated, deposed the Government, and installed a temporary Council to rule. The Junta of Oporto, who were at Coimbra, soon received intelligence of the occurrences in Lisbon, and reached the capital on the 1st October. Before any agreement between the two Juntas had been made, the arrival of Lord Beresford, from Brazil, in an English ship of the line, caused great consternation. The soldiers were known to be attached to him, his powers were presumed to be extensive, and the acclamations which the native officers had drawn forth from the troops could not be depended on. The two Juntas, agreeing in nothing else, united, however, to prevent his landing; and after some ineffectual efforts to open an intercourse, he departed for England. When left to themselves, divisions of the most embittered kind arose among the insurgents. The partizans of the Junta of Oporto were the most furious; and having placed at the head of the troops one of their own partizans, the Junta of Lisbon was surrounded on the 11th November, the meeting dissolved, and a proclamation issued declaring the adoption of the Spanish constitution. The ascendancy of this violent party was but short. Texeira, who had com-

Portugal  
||  
Gunpowder.

manded the troops, changed his views; and through his means the more moderate party were put in possession of power. By them the Cortes was convoked, and the Spanish constitution voted as far only as it should suit the circumstances of Portugal. The mode of election of one deputy to 30,000 inhabitants, as prescribed by the Spanish plan, was adopted; and when the assembly met, it was found that few men of wealth or family were chosen. The assembly assumed all power, uniting the executive, judicial, and legislative authority, in their own body. The King was induced to return from Brazil, but on his arrival found himself a mere cypher; every one in whom he had any confidence being carefully kept from his presence, and some of the ministers, who had accompanied him, being committed to prison. The Cortes have since occupied themselves in framing a constitution and a code of laws; but have made no such progress in either as can enable any certain judgment to be formed of what may be the result of their deliberations. In the meantime, the inhabitants of Brazil have established a government, in effect independent of Portugal, with the Prince Regent at its head. The troops that have been sent to that country have revolted to the Brazilians, and their officers being dismissed, have been sent back to Europe. The

state of the finances has so much deteriorated, that there is not money sufficient to pay even the troops, who are six months in arrear; and the civil officers and creditors of the state are in a still more lamentable situation. There is no power to put in execution the decrees that issue from the Cortes; and that body has not sufficient unity of mind to enact a series of laws consistent with themselves.

Portugal  
||  
Gunpowder.

Whether it was wise to attempt the establishment of a democracy, in a country where the priests of various kinds, the military, and the officers of the state, comprise one-fifth of the male population, it is not for us to determine; but so wretched was the previous condition of the Portuguese government, that it is scarcely possible the revolution can leave the country in a worse state than that which preceded it.

## G U N - P O W D E R .

History of  
Gunpowder.

THE invention of gunpowder is popularly ascribed to Barthold Schwartz, a German monk and alchemist, and the date of the discovery is further supposed to have been in 1320. The prior claims of our countryman, Roger Bacon, such as they are, are however unquestionable; as this substance is described in his writings about the year 1270; or eighty years before the time of the supposed discovery of Schwartz. But even Bacon has as little title to this invention as his supposed rival; nor, indeed, when we examine his own description of this then wonderful compound, do we perceive that he makes any claim to have been the discoverer. On the contrary, he quotes it as a well known substance, in common use all over the world for making squibs to amuse children. So pertinacious are vulgar errors. The passage in Bacon stands as follows: "Ex hoc ludicro puerili, quod fit in multis mundi partibus, scilicet, ut instrumenta facta ad quantitatem pollicis humani, ex violentia salis qui salpetræ vocatui, tam horribiles sonus nascitur." This is the description of a parchment cracker. "In ruptura tam modici pergameni, quod fortis tonitrum excedere rugitum et corruscationem maximam sui luminis jubar excedit." Thus the claim is shifted without difficulty from Bacon, and, as Dutens thinks he can show, is removed to Magnus Græcus, whose MS. he quotes, and from which he presumes that Bacon derived the invention; although, by his own showing, Bacon need not have consulted an obscure writing for an invention of general notoriety. The title of the MS. in question is as follows: "Incipit *Liber Ignium* a

Marco Græco perscriptus, cujus virtus et efficacius est ad comburendum hostes, tam in mari quam in terra;" so that even the military uses of gunpowder were then known. In the same MS. are contained directions for making a rocket, which we dare not quote on account of its length, but it is such as to prove that the nature of this firework was thoroughly understood. It is even remarkable that he recommends particularly the charcoal of willow wood, which we moderns have found by experience to be among the best for all the purposes of gunpowder.

Thus far, although we have not fixed the date of the invention, we have carried it, not only beyond Bacon, but even beyond this supposed predecessor; as he himself does not pretend to be the inventor, but the compiler, of a *Liber Ignium*; a treatise on pyrotechny. If, in attempting to ascend still higher, the evidence becomes more rare and more obscure, there are still insuperable facts to prove that its antiquity is far greater; however impossible it may be to approximate to the date of the invention, far less to assign that which seems buried among the obscurities of Oriental learning. The question of gunpowder, as applied to Artillery, is a separate one; but there is abundant reason to believe that this compound was not only used in some form or other as an explosive and combustible substance, but was even applied to military purposes; it may be in the shape of rockets or other fireworks, which, for objects of amusement at least, have been familiar to the Chinese beyond all record.

The earliest date to which we can refer the knowledge of gunpowder, in defect of a sufficiently re-

*Gunpowder.* mote acquaintance with Oriental History, is 355 A. C.; although, from the very nature of this evidence, it follows that it was then not only known to the eastern nations, but that it must have long been so; since, even at that early period, it was applied to warlike purposes. In the code of Hindoo laws, indeed, where it is mentioned, it is referred to a period which Oriental antiquaries have considered as coincident with the time of Moses. But the evidence to which we more particularly allude, is found in a passage of the Life of Apollonius Tyanæus by Philostratus; the purport of which is, that Alexander was unwilling to attack the Oxhydrææ, who lived between the Hyphasis and the Ganges, because they were under the care of the gods, and overthrew their enemies with thunder and lightning, which they shot from their walls. The same tale is told of the repulses experienced in this country by Hercules and Bacchus.

The next of these early dates, in which also our evidence is imperfect, is 212 A. C., but the establishment of the truth of the last would render this one more credible. In the defence of Syracuse by Archimedes, Vitruvius relates that one of his engines threw large stones with a great noise; a description which does not apply to any of the mechanical artillery of the ancients. On a notice so superficial, we must not, however, lay too much stress; and here ends all the information which we have yet procured respecting the earliest knowledge of gunpowder. It seems, however, to be so decidedly capable of being traced from the East, through the intervention of the Arabs, that there can be little doubt of its being an Oriental invention, and of its having been thence imported into Europe; and, indeed, the military use of rockets in the armies of India ascends to a period beyond record.

Of the earliest period at which it was known in China, we have, in defect of their own evidence, only the testimony of Uffano, an Italian author, who affirms that not only gunpowder, but ordnance, was in use in that nation in the year 85 A. D.; and that cannon were, in his day, remaining from the most ancient times, in some of the maritime provinces, made both of iron and brass. Hence some writers presume, that the Chinese communicated the invention to the Indians; while it has also been said, but on no sufficient authority, that they themselves received it from Tartary;—a nation respecting which we know little or nothing, and in which we should not be inclined to look for an early acquaintance with the arts. This, however, refers to a date so late as 917; so that, if there is any dependence to be placed on the Indian and Chinese hypothesis, the Tartars must themselves have borrowed the invention from those to whom they are said to have lent it.

There is after this a long blank; and the first author on the subject that we have discovered is in 1249, twenty years before the date of Bacon's narrative. This is an Arabic writer, in the Escorial collection, who is translated by Casiri. His description is such, that it may apply both to rockets and to shells. In the former case, it only proves the

*Gunpowder.* knowledge of the detonating compound; the latter, were it proved, would show that they were also acquainted with the use of ordnance; although it is not impossible but that such projectiles might have been thrown by mechanical artillery.

As the invention of gunpowder has been popularly attributed to Bacon and to Schwartz, so the use of ordnance has been referred to the time of the field of Cressy, or 1346. To pass over the Chinese hypothesis on this part of the subject, we shall find that cannon was known at least as early as 1312. This we derive from the source quoted by Casiri; from Arabian writers who describe the use of ordnance in 1312 and in 1323; while, if Barbour is to be trusted, Edward III. was also provided with some pieces of artillery in 1327; and Pere Daniel asserts that cannon was known to the French in 1338. We need not carry this discussion lower; though, in favour of the Oriental origin of this invention, we would still remark, that artillery was much in use in the Mediterranean when it was still little used elsewhere; as by the Venetians against Genoa, in 1380, and by Alphonso XI. in his wars against the Moors.

#### *Composition of Gunpowder.*

The present composition of the Chinese corresponds so nearly with our own, that the difference is nearly insensible; but whether it had arrived at that degree of perfection in their ancient periods, we have no means of knowing. Neither can we judge of its nature and power as known to the Arabs. But, in our own country, it was very late in arriving at its present state of perfection; nor do the various proportions given by one of our earliest writers on the subject, argue much in favour of their chemical knowledge, or turn for experiments. Peter Whitehorne, who wrote in 1573, gives numerous proportions, without seeming well aware of their respective values; and, respecting some of them, it is easy to see that they were scarcely fit for squibs, much less for the purpose of projecting shot. Such is nitre, sulphur, charcoal, equal parts; while, in the very opposite extreme, we have nitre 12 parts, sulphur and charcoal, of each 3 parts; and, still worse, nitre 27 to 3 of the other two ingredients; or nitre, 48 parts, with 7 of sulphur and 3 of charcoal. Here, such as these compositions are, want of experience can scarcely be pleaded, as they are not better than those given by Nyc, in 1580. In France also, the composition, at no very remote period, was nitre 50, sulphur 16, charcoal 34; from which it varied to, nitre 67, sulphur 13, charcoal 20, and to nitre 84, sulphur 8, charcoal 8: these differences being supposed necessary for the larger cannon, and the smaller progressively; the last being their musket powder.

But as we cannot afford space to describe the gradual progress of improvement in the composition of gunpowder, we shall now state the proportions at present in use in different nations. They do not materially differ from each other, although it is unquestionable that they are not all of equal power.

The proportions in the *commercial* gunpowder of England vary indefinitely, according to the views of the manufacturer respecting the markets, the price, and other matters. Cheapness being the leading object where it is only made for sale, and the nitre being the only expensive article, the proportion of this is diminished, and those of the other two ingredients increased. The worst is made for the Guinea trade, and, if we are not misinformed, that for the Canada trade is nearly as bad, while the next upwards in the scale is that sold to Turkey. We have never met any specimen in which there was less than 62 of nitre; but have reason to believe that some of the inferior kinds do not contain more than 50. For the use of miners it also is made with a low proportion of nitre; producing advantages in mining not intended by the makers, whose only object was to manufacture a cheap article. But the proportions of all the commercial powders are very inconstant, even when furnished *bona fide* to government, as it is impossible to prevent the workmen from purloining the nitre, and replacing it with the cheapest ingredients.

It is not for want of experiments if greater uniformity has not been attained in these compositions, and if all adhere to their own. Baptista Porta was one of the first who made accurate investigations on this subject; and, as long ago as 1515, he fixed on the proportions now used in France. Beaumé, some time ago, fixed on 80 of nitre, 5 of sulphur, and 15 of charcoal; and the opinions of Morveau, Chaptal, and Proust, are displayed in the preceding table. It is easy to account for these differences of opinion, when we recollect the numerous accessory circumstances which modify or vitiate the results obtained from practice. With the very same power it is scarcely possible to procure uniform ones, as is well known to Artillerists: and hence, from practice alone, unless with an enormous number of trials, no certain conclusions can be drawn. It will, indeed, appear,

that under various proportions, the effects may really be the same; because, as the force of powder depends partly on the quantity of gas generated, and partly on the heat to which it is raised, any deficiency on the one hand may be compensated by an increase on the other. Thus, as the greater quantity of gas is produced by the largest proportion of charcoal, the greater heat is caused by augmenting that of the sulphur. In all the trials that have been made in this country, no reason has been found for varying from the proportion 75 nitre, 10 sulphur, and 15 charcoal; and the same is used for arms of all calibres—the only difference for the respective arms being made in the sizes of the grains.

It is proper, on this subject, to state, that while the explosive power depends fundamentally on the quantity of gas that is permanently generated, that gas is almost entirely produced by the combustion of the charcoal; the nitre being the cause of that combustion, and furnishing one part of the generated gas from its decomposed acid, as it does the other by converting the charcoal into carbonic acid. Were nothing else required, therefore, to produce the effect, the best powder would consist of nitre and charcoal alone; as the sulphur consumes a considerable part of the oxygen of the nitric acid, without adding any thing to the permanently elastic gas. But as there are two other important elements in this problem, namely, the rapidity of the inflammation and the heat, the sulphur becomes an indispensable ingredient; while, by expanding the gas at the moment of explosion, it more than compensates for the diminution of permanent bulk which it causes. Perhaps, on this compound view of the subject, M. Beaumé's composition is really the best, abstractedly considered; as the nitre is sufficient to burn the whole of the sulphur and the charcoal also, and as both the degree of heat and the quantity of gas seem to be best balanced for the intended effect. But a composition of this accurate nature requires equal accuracy of mixture and manufacture; and as that is scarcely attainable on the great scale, it is found better so to increase the sulphur and charcoal as to insure the total decomposition of the nitre, this being further an object of economy.

Sportsmen, as well as Artillerists, ought to know that the fouling of their barrels after firing is in a direct ratio of the weakness and badness of their powder; and this effect is most completely obviated by using M. Beaumé's, or any similar mixture. Not only does the feebleness of such powder prevent the barrel from being swept clean at the explosion, but as the foulness consists chiefly in a mixture of the carbonat and sulphat of potash with charcoal, that becomes necessarily greatest wherever the nitre is reduced in quantity for the purpose of introducing the cheaper ingredients. The analysis of powder, at least as far as that ingredient is concerned, is so easily made, that every one who feels an interest in his success as a sportsman, should examine what he uses; as the very worst mixture can be rendered beautiful to the eye by a minute grain and a high polish.

The British Government use but one proportion for all services. As far as artillery and mus-

Gunpowder.

Gunpowder. ketry are concerned, we do not consider this as of much moment; or that any material object would be obtained by using different ones, proportioned to the respective calibres. But we consider that they commit a great error in adopting the same for the *mining* service; and that some of the failures caused in our wars, in attempting to blow up works or demolish bridges, have been produced by the very excellence of the powder,—by its too great strength, in short. To take the case of common blast-mining as a simple one, and to put the extreme case of all; if it be attempted to spring a rock by the powder of chlorate of potash, either the plug will be blown out, or a very narrow space round the mine will be broken. With the best musket or cannon powder the same effects, but in a less degree, follow. Here the miners' powder, which seldom contains as much as 60 *per cent.* of saltpetre, is effectual; and, what is more, it is rendered still more active by being damp from careless keeping, or from remaining some time in the mine before it is fired. Mathematicians will immediately see the solution of this apparent incongruity, by recollecting that the element of time is an ingredient in the problem. With too great a velocity the parts of the general mass nearest to the acting force are disintegrated; so that not only is the force expended in this act, but the gas thus escapes from the opening. With a power acting more slowly, the whole mass, or a much larger one at least than in the first case, is moved; and thus the rock is widely shaken, although not blown into the air. It will be found practically, that the further the fragments are dispersed, the less is the effect; and thus the mine which is most dangerous to the workmen, is also the least efficacious.

It is from this variation respecting the power of gunpowder, hitherto unattended to, from confounding impulse and pressure, to which at least it bears a certain relation, that so many different opinions have been entertained respecting the force of powder in particular cases. Hence also have arisen various projects for increasing its efficacy; among which quick-lime has been repeatedly recommended. In mining it does actually increase the effect, though not the force. It diminishes the force, on the contrary; and it is from that very cause that it is more effectual in mining or shaking a rock. The same object can be obtained by a mixture of sawdust; but it must also be remembered, that this will not happen unless good powder be used. Ordinary miners' powder will not often bear this kind of dilution. It is easy now to apply this principle to military mining, where the object is to produce as extensive a shock as possible. Mathematicians have calculated the globes of compression for certain charges; but it will be found that these will vary so much, according to the strength of the material, that the conclusions cannot be depended on. This is a very important problem, however; because the destruction of a work depends on the area of the base of the paraboloid, or whatever else the figure is, which the explosion produces. We dare not, however, enter further on this subject, as it would lead us beyond our limits.

*On the Choice and Examination of the Materials.*

Nitre, as it is imported from India, whence all

that is used in this country is procured, is mixed with much dirt and with some salts, consisting chiefly of the nitrats and muriats of lime, and of muriat of potash. As the deliquescent salts, in particular, are extremely injurious, from their property of attracting moisture, it is most important that the nitre to be used in gunpowder should be thoroughly refined. For this purpose rain water ought to be used if possible, and if not, such river or other waters as are found, on trial by the appropriate tests, to contain the least quantity of saline matters. The nitre is first boiled, and the grosser impurities separated by filtering through hempen bags, after which it is crystallized. After draining, one washing is sufficient to render the first crystallization sufficiently pure; but the subsequent ones require repeated solution and crystallization before all the foreign salts can be separated. We need not, however, dwell on this subject, and shall only add, that no nitre ought to be used unless it will stand the tests of nitrat of silver and of carbonate of potash, without exhibiting a precipitate.

It is held necessary that the nitre should be thoroughly dried; and, accordingly, much unnecessary labour is bestowed on this object, since it must be moistened in the mill when the composition is submitted to the rollers. The only real use in drying it is to enable the workman more easily to allot the true weight, which might equally well be done by an average and an experiment. We should scarcely have noticed this, but that the French manufacturers boast much of the superiority which they derive from reducing the nitre to minute crystals, by agitating the solution. In the royal mills it is further the practice to fuse the nitre into large cakes. By this method it is speedily dried, easily stored away, and protected from depredation. These advantages are held to be sufficient to compensate the expence; but it ought to be remembered that there is a degree of hazard in the process; as, if the salt should be overheated, it might be so far decomposed as to have a portion of potash united with it.

Sulphur, as it is received from Sicily, the great emporium of this commodity, is mixed with a considerable proportion of lime, while a portion of it is also combined with that substance, forming calcareous hepar, or sulphuret of lime. From this and the grosser accidental matters it is purified by melting; the sulphuret and the earth subsiding to the bottom of the mould, so as to admit of being mechanically separated. This residue, yielding no more pure sulphur by that process, is afterwards submitted to distillation. When the sublimed material is to be used, it requires previous washing, till it is entirely freed from the sulphuric acid adhering to it, and it may be tested for this purpose by means of the muriat of barytes. The fused sulphur, if doubted of, may be submitted to combustion, and the residue noted; but a little deficiency in the purity of this ingredient is of no moment.

With respect to the charcoal, there is considerably more nicety required than is generally imagined. The soft woods have been preferred from time immemorial; since even in the receipt of Magnus Græcus, formerly quoted, the willow is mentioned. The poplar and many others have been used abroad, but in this country those commonly adopted are the

**Gunpowder.** white willow and the alder. Even among these soft woods there is a considerable difference, as our own experiments have shown; and in them it was proved that the greatest explosive power, *cæteris paribus*, was produced by the wood of the *Rhamnus frangula*, commonly called black dogwood, as we shall show more particularly hereafter. The hard woods are invariably rejected, and with justice; though the reasons for this practice, which are derived from the presence of salts in these, are not the causes of their inferiority, certainly not the only ones. It is nevertheless true, that no wood which contains carbonat of potash, or other deliquescent salts, is fit for the purpose, and for the most obvious reasons; and this is the case in the oak, elm, fir, and other trees. But there is another reason for the badness of these kinds of charcoal, the cause of which is not so obvious, although it is evidently connected with their hardness. To us it appears to depend on the small proportion of hydrogen combined with the carbon in these charcoals, compared to that which exists in the produce of the softer woods. Even these can be reduced to the same state by overheating. Thus the hydrogen is dissipated, and the charcoal becomes so hard as to scratch steel, in which case, however obtained, it is always unfit for powder.

As this subject is yet obscure, from our imperfect acquaintance with the true nature of charcoal, and with the modifications of which it is susceptible, it becomes necessary to have recourse to experiment, for the purpose of determining, at any rate, the proximate cause of this difference in the explosive powers of the several kinds. Various trials have accordingly been made, as well by ourselves as by the French chemists; and, for brevity's sake, we add the most important results in the subjoined table. We are not informed of the process which was adopted by the French for measuring the gas; but in our own, we had recourse to the pneumatic apparatus, using it in the manner which is described in another part of this article for collecting the total produce of the combustion of gunpowder. The mixture, in the French experiments, consisted uniformly of 60 parts of nitre, and 12 of the charcoal submitted to trial. In our own they were varied, and the results taken from those in which the combustion of the charcoal was completed, and the quantity of gas greatest. As no more nitrous acid could be decomposed than there was coal present to burn the oxygen, it is plain that in these the results are correct.

	Prop. Parts.	Gas.	Solid Residue.
French Hemp stalks	- - -	62	12
Asphodel	- - -	62	20
Vine	- - -	64	20
Peartalks	- - -	62	21
Fir	- - -	66	30
Spindle tree ( <i>Euonymus Furo-peus</i> )	- - -	66	28
Chesnut	- - -	66	36
Hazel	- - -	66	33
Lamp black	- - -	54	44
Coak	- - -	54	45
Filbert	- - -	72	30

These results are such as to prove that there are important differences in the produce of gas; but, with regard to practice, they are of very little value, as few of the substances submitted to trial could be used. To admit of comparison between our own experiments and these, we shall reduce our proportions to the same standard, by taking our scale from the filbert at 72. We neglect the residue, knowing that it proves nothing, as the results are uncertain, in consequence of the irregular absorption of water, and partly from the impossibility of collecting the solid and the gaseous matters both from one charge.

	Gas.
Filbert	72
Oak	61, 63
Mahogany	58
Elm	62
Willow, <i>Salix alba</i>	76, 78
Alder	74, 76
Black dogwood, <i>Rhamnus frangula</i>	80, 82, 84
Oak bark	58
Animal charcoal	50, 46, 42, 40
Coak	52, 48
Lamp black	54, 52
Oak charcoal overheated	54, 56
Willow do.	59, 64, 66

The various results, and some others which we have thought it unnecessary to record, may, in a certain degree, depend on inaccuracies in the experiment; but in the greater number they arise from real differences in the charcoals from the same substance, produced, as we before insinuated, by overheating. This is apparent in the two cases above cited of oak and willow; but in some trials, the differences were even greater. Coak and animal charcoal are particularly liable to vary.

It is evident from the preceding table that the best charcoal for gunpowder must stand in the following order: Black dogwood, willow, alder, filbert. From the French tables, in which we do not, however, place much confidence, we may add, consecutively, hazel, and the spindle tree; but our own trials raise these to 70 at least, in the scale. Such, at present, are the results of these trials as to the best charcoal; but we are by no means satisfied that we have yet found out the best wood for this purpose. The experiments are laborious; yet we think the subject deserving of more attention than has yet been bestowed on it. With respect to coak and animal coal, they stand very low in the scale, as the over-hardened wood-coals do; and, in all cases, there is a direct relation between the produce of gas and the facility of combustion under ordinary circumstances.

To satisfy ourselves by trials of a more direct nature, and more applicable to practice, we chose a method derived from the flight of rockets, as less liable to disturbance from collateral causes than any practice with pieces of ordnance. The rockets were of compound dimensions, and were all made with the same proportions and driven by the same hand, so as to ensure all possible uniformity, the only variation being in the nature of the charcoal. The vertical

*Gunpowder.* elevations were taken by two quadrants at the same time, and all the flights that deviated from the perpendicular rejected. The mean vertical ascent of a great number of those, made with willow, alder, and dogwood, was 480 yards; but between these three coals, the differences were so great as to give various results, which may be represented by the following numbers:

Dogwood,	515, 550, 525
Willow,	470, 480, 490
Alder,	455, 460, 470

Greater accuracy is not attainable in this way, as may easily be conceived by those who know by how many collateral circumstances a rocket is influenced; but these trials are quite sufficient to justify the general inference made from the experiments in the pneumatic apparatus.

It has been held that the charcoal for gunpowder ought to be made in cylinders or retorts by distillation; and this expensive process is consequently universally adopted. It is doubtful if this is not a mistake of the *causa pro non causa*. Pit charcoal being made in coppice woods, is always the produce of oak, and it is probable that this wood, if charred in close vessels, would be even worse than it is now. There is more danger of overheating in the retort than in the pit, while the wood is not better burned; and hence, by a careless management of the process, even the charcoal of willow or alder may be rendered as bad as that of oak. Considering these various circumstances, charcoal requires to be submitted to three tests. It ought to act, as little as possible, mechanically, even on copper; it ought to exhibit no salts on being treated with boiling distilled water and tested; and it ought to be thoroughly burnt. The best test of this latter circumstance is its giving out no smoke when heated.

A new and economical method of distilling charcoal has recently been invented by Sir William Congreve. Subsequently, but without any knowledge of what had been done, as we understand, the same process was suggested in America by Dr Bollman, to whom we are indebted for the present cheap method of purifying pyrolignous acid, and rendering it a substitute for common vinegar. In this beautiful process the retorts or cylinders are ranged in a row, a gas pipe from each being conducted to the bottom of the next in succession. By means of a fire under the first alone, the distillation of the whole may be conducted together; the gas which issues from that one being sufficient to char the next, and so on in succession to the end of the chain. The acid is collected in this case, as in others, by means of a separate pipe arising from a lower point in the retort.

Before we dismiss this very important and somewhat neglected department of the gunpowder manufactory, we must point out a circumstance with respect to charcoal, that requires an attention which it has never yet experienced. This is the property which it possesses of absorbing and retaining water, and which we have ascertained to be different in the different kinds of wood; although we have had no opportunity of investigating fully that which is here

recommended to the attention of powder manufacturers. *Gunpowder.*

It is from this hygrometric power that gunpowder attracts moisture, even when the nitre has been perfectly purified: a circumstance which materially interferes with its rapidity of inflammation, and, consequently, with its strength. But as the various hygrometric powers of different charcoals have never yet been properly examined, we can communicate no information on this subject which is worth recording.

#### *On the Manufacture of Gunpowder.*

##### *Grinding.*

The first part of the process consists in pulverizing all the ingredients separately, after which, they are weighed and mixed in a general and rude manner before being submitted to the mill. In France, and in some other countries, a pestle engine is used, or a stamping-mill; but it is subject to more hazard and inconveniences than the grinding mill which is adopted in this country. This is formed on the model of the common bark mill, and with two rollers at different distances from the axis, so as to cover the whole bed. The weight of each roller is commonly about three tons, and they are generally made of limestone, although iron cylinders have been adopted in some works. The bed, which is surrounded by a wooden margin, is of the same materials, and the whole house is built of slight framed wood, to diminish the evils that might arise from a casual explosion. A wooden rake follows the rollers for the purpose of bringing the mixture under the cylinder; and the motion is communicated, either by water or by the power of horses.

The mixture being distributed on the stone, to the amount of 40 or 50 lbs. is moistened with distilled or rain water, but so as not to be wetted. It is barely sufficient to prevent the dust from flying. According to the velocity, the grinding is perfected in a space of time varying from three to seven hours, and it depends on the inspector to determine by trial for each velocity when the mixture is perfect. After that, time is a sufficient measure. The removal of the mill cake, as it is called, requires caution, as it is commonly at this time that the explosions take place. These, indeed, will generally be produced if the bed and cylinder should come into contact while they are moved round slowly, to enable the materials to be taken out; the friction, under so great a weight, even of the purest limestones, or of iron, being sufficient to inflame gunpowder. To prevent this risk, a thick piece of hide is carried before the cylinder as the powder is removed, and by this plan the contact is prevented.

##### *Pressing, Granulating, and Drying.*

The mill cake thus completed is gunpowder, and may be granulated. But it is yet not so firm as it can be rendered by further pressure; and that property is very essential to its durability in travelling. For this reason, it is further condensed by pressure, either in the common screw-press used by packers, or by means of Bramah's hydraulic engine. Thus it becomes indurated to a hardness equal to

*Gunpowder.* that of many stones, and its specific gravity is also increased. In the press, also, it is divided into cakes of an inch or more in thickness, that it may be the more easily broken into pieces for the Granulating Engine.

This machine consists of a number of sieves made of strong vellum, perforated by punched holes, and supplied with top and bottom covers, like those used by druggists. A platform, to which a horizontal circular motion is communicated by machinery, receives a number of these which are fixed in it. The lumps of the press-cake are introduced into each of these, together with a block of lignum vitæ or other hard wood, shaped somewhat like a Dutch cheese. During the rotatory motion, the lumps become thus broken into smaller fragments, which fall through the holes, together with the dust, into the receptacle below.

It remains to separate the grains according to the sizes that are required; and for military purposes, these are three; one for large ordnance, another for musketry, and a third for pistols. The powder generally used by sportsmen is of a still finer grain than the last. The separation is performed by means of wire gauze, or strong silk gauze, of different apertures; the sieves being commonly cylindrical and turned by the machinery. At the same time the dust is separated, and afterwards returned to the press.

The last operation is known by the name of Glazing, a term literally true in the case of sportsmen's shooting powder. But the real object of this operation is to take off all those acute angles from the grains, which would otherwise be ground off in travelling, and thus produce great inconveniences, by introducing dust into the casks. This process is performed, by causing the separate classes of grains to revolve in cylinders so constructed as only to let the dust through; and the mutual friction of the grains produces the desired effect. When it is required to give the powder a brilliant surface, as is the case with fine sportsmen's powder, the cylinder is lined with a woollen cloth; and sometimes, if a high polished gloss is desired, some black lead is introduced into it. But these are matters of mere ornament.

Although the powder thus completed appears dry to the feel as well as to the sight, it contains a considerable quantity of water. This must be separated by drying. In hot climates, exposure to the sun is sufficient, but in most cases, artificial heat is required. In France, a complex process was adopted by passing heated and dry air through a closed chamber, with the intention of diminishing the risk of explosion; but, with any moderate degree of care, it may be done in any manner. In some of the older works, the stove in use was a closed room with air holes above, heated by means of an iron cupola or large pot, to which a fire was applied outside of the building; the temperature being regulated by a thermometer fixed in the door and indicating the heat externally. In this room, the powder was exposed in flat trays round the circumference. Lately, the method by steam pipes has become generally adopted, and in this way, every possible security, real as well as imaginary, is obtained.

*Analysis of Gunpowder.*

*Gunpowder.*

It is often useful, and frequently indispensable, to analyse gunpowder. This process will, indeed, generally supersede the necessity of *proving* by the usual methods; as it is always certain that a specimen of gunpowder, well made, will produce the best proof. It is particularly convenient in the case of gunpowder purchased from merchants, or by contract; as, from the several causes which may easily be conjectured, such an article may be deficient in the quantity or in the quality of the saltpetre, or in both. It is useful, moreover, in the case of damaged powder, returned from military and naval service; as we can determine by these means, whether it has been wetted by rain or by sea water, or whether any portion of the nitre has been washed out. Powder thus damaged by fresh water only, and otherwise uninjured, may be committed to the mill and restored at a very trifling expence. If the saltpetre is diminished, it can thus also be restored; but, on the contrary, if the damage has been produced by sea water, it becomes necessary to destroy the powder for the purpose of extracting the nitre.

By washing the powder previously weighed in a filtre, with hot distilled water, the nitre is dissolved, and admits of being crystallized and weighed. The tests formerly mentioned, namely, nitrat of mercury and carbonat of potash, may then be used to determine its purity. Thus it may be ascertained whether, in a new sample, the nitre is in sufficient proportion, and whether it has been well purified, and in a damaged one, whether the injury has arisen from fresh or from salt water. It only remains to examine the proportions of the charcoal and sulphur; a task, however, which is less easy, but which is, at the same time, less necessary, as the manufacturers are under no great temptation to assume a wrong proportion of these, although the joint quantity of the whole may be in excess. This mixture, being dried and weighed, must be exposed to a moderate heat, as long as any sulphur can be sublimed. But, as the last portions are inseparable in this manner, it is necessary at length to have recourse to other means. Among those that have been tried, there is none more convenient than boiling, in a solution of pure alkali, by which a sulphuret is formed, and the weight of the dried charcoal thus completes the analysis.

*Analysis of Gunpowder after Explosion.*

To a certain extent, at least, an analysis of gunpowder, after explosion, is necessary for the purpose of procuring data whence its force may, *a priori*, be calculated. The rest is only matter of curiosity, and we have borrowed the determination from the experiments of the late Mr Cruikshank, a name known to chemists as that of the discoverer of carbonic oxide. As far as this analysis may differ from that of others, it must be recollected that the separation of mixed gases is not a very easy problem. The mere collection of the total gaseous products is easy; and had the same method been followed by Robins and others, less difficulty would have been found in their computations. Had Count Rumford,

*Gunpowder.* and a numerous party of speculators on this subject, adopted so simple an expedient, they would not have had recourse to the expansive force of steam, or of the air contained within the charge, for an explanation of the cause and nature of the force.

By ramming 100 grains of powder into a narrow metallic tube, furnished with a long handle, it is easily caused to burn under water; as the combustion is slow and safe when it is thus condensed; and this quantity is sufficient for any purpose of experiment. The tube being plunged under the water, with its mouth downwards under the bell glass of the pneumatic apparatus, the powder may be lighted without any loss. This is done by introducing, into that part of the tube above the charge, which is purposely left empty, a crooked wire heated to redness. After the hot wire and the tube in this position are immersed under the bell, the former is brought into contact with the charge. To prevent the water from absorbing any portion of the carbonic acid, sulphuric acid may be added to it, as well as many other matters too obvious to mention; or else it may be heated. Thus the gaseous product may be collected and examined at leisure, by the means which chemistry furnishes, and which our limits will not permit us to detail.

To collect the solid product, it is most convenient to use a glass vessel, on account of the certainty of obtaining the produce, which is, in great part, carried up in smoke, and adheres to the receptacle in which the powder is burnt. But we need not describe the numerous modes in which this object can be attained; only adding, that to diminish the hazard, the powder for this purpose may be wetted without affecting the results.

The following statement, then, contains the gaseous produce of 100 grains, made of the proportions 75 nitre, 10 sulphur, 115 charcoal; the measure and weight being both included. The temperature is reduced to 65, and the barometric pressure to 29.5.

The total gaseous produce measured 91 cubic inches, and the total weight 50 grains. Thus, about half the weight of the powder becomes converted into gas, and the remainder forms the solid produce:

	Grains.	Inches.
Azote - - - -	13.24	42
Carbonic acid - - - -	28.77	30
Carburetted hydrogen - - - -	2.70	9
Nitrous gas - - - -	3.25	6
Sulphuretted hydrogen - - - -	2.03	4
	49.99	91

The solid produce, however, appears in excess; possibly from being imperfectly dried: or else from some other unnoticed errors in the experiment. It is as follows:

	Grains.
Subcarbonat of potash - - - -	40
Sulphat of potash - - - -	11
Charcoal - - - -	3
Sulphur - - - -	0.5
	54.5

*Gunpowder.*

It is not difficult to account for these various products, and it is evident that the carbonic acid and the azote are the principal causes of the explosion. The decomposition of the acid, and the combustion of the charcoal, form the basis of the elastic force. It may be imagined that the hydrogen is the produce of contained water; but we consider that it is principally derived from the charcoal and from the sulphur. The two combinations which it forms are such as might be expected, and the nitrous gas requires no remark. Respecting the solid produce, the produce of the subcarbonat and sulphat of potash is a matter of course; and it is only necessary to point out the excess; of charcoal principally, of sulphur slightly. It is evident that more nitre would be required to consume them; but, as we formerly remarked, it is held expedient that there should be an excess in this way rather than in the other. We need not, however, dwell longer on this analysis; since, as far as the effects of gunpowder are concerned, it is the quantity, not the quality, of the produce that is an object of interest.

*On the Sizes and Forms of the Grains in Gunpowder.*

The variety in the effects of gunpowder, arising from differences in the sizes and forms of the grains, has been an object of much inquiry. The conditions of the problem are somewhat complicated. Within certain limits, which gunpowder made of nitre cannot exceed, rapidity of inflammation is essential to the production of a full effect. Not to inquire into other causes, without this property, a part of the charge is rendered useless by being blown out unburnt; an accident not uncommon on ordinary occasions. This may also happen from the form of the piece and that of the charge: it will occur in a long charge or in a short piece; or, most of all, when both are united. Hence variations in the effect of gunpowder, that are independent of its quality, and which will render computations, founded on that circumstance alone, deceptive. As we have not room to dwell on this subject as it deserves, we must refer our readers to Robins, and others who have written on it.

Now, this rapidity of inflammation may be attained, in some measure, in two ways: by intense heat, and by facility of transmission of the flame. But if a charge is considerable, no intensity of heat can compensate for the absence of the second condition. To put an extreme case. If the eight pound battering charge of a 24 pounder were a single grain, it requires little thought to perceive that the shot would have quitted the gun before the charge was half burnt. Hence, granulation is as necessary for ensuring the full effect as it is for con-

y y

Gunpowder. venience: and thus, also, we are led to the cause of the bad consequences of hard ramming: a charge very thoroughly rammed, and lighted at the anterior end, would burn like a fuse or a squib; if lighted by a touch hole, it will be blown out like a shot. Thus the rapidity of the inflammation is secured by multiplying as much as possible the intervals for the passage of the flame, or by diminishing the size of the grains. Yet there is a limit even to this; and as that can only be determined by experiment, it is from such trials that the grain for the smallest charges has been fixed. As the charge, however, increases in dimension, the volume of flame and the intensity of the heat produced admit of a grain of greater bulk, or one containing, in a given dimension, a smaller number of intervals. Much refinement on this subject being, however, unnecessary, one size is used for all ordnance; while an inferior size is made for muskets, and one still less for pistols: the powder manufactured for fowling pieces is also of the smallest size.

But there is a further element concerned in this question; and that is, the different specific gravities of the different sizes of powder, or, what is especially to the purpose here, the different spaces occupied by the different sizes. The same measure which contains 172 grains of the smallest, contains 180 of the medium, and 195 of the largest. If powder be measured instead of weighed, it is evident that there will be one-ninth more of the large than of the small grained in a given charge: if weighed, the larger will occupy about one-ninth less space. In either case the greater force will be excited by the large grained, presuming that the inflammation is perfect: when it is weighed, as is the correct practice, it will not be very difficult to calculate the difference; as the force of the expanding fluid is, in a certain inverse ratio, of the space in which it is confined.

To increase the rapidity of inflammation, the French have manufactured spherical powder. The details of the process are such as would exceed the limits allotted to this article; but the principle may be understood by saying, that it is similar to that used by confectioners in making comfits. Angular grains are rolled in machinery adapted to that purpose, in powder dust slightly moistened; and thus small globules are formed. This grain is less liable to wear in travelling, from the absence of angles; but it is, at the same time, more tender and less able to bear pressure than pressed powder. Nor do the French experiments, either by the *eprouvettes* or the tables of practice, prove its superiority; on the contrary, the average results of its comparison with ordinary powder are unfavourable; and this also was observed in our own trial. Hence, it has not been adopted in Britain.

#### *Proving of Gunpowder.*

To ascertain, by practical trials, the strength of gunpowder, is not merely a matter of curiosity, but of absolute necessity. As the force, in battering ordnance, and the range, in mortar and howitzer practice, is regulated by the quantity of the charge, it is obvious, that no regular practice in the field, or consistent results, will be obtained, unless the stand-

ard of strength in the powder is both known and Gunpowder. invariable. This is particularly the case with mortar practice against small works or redoubts, or against the enemy's trenches; and with howitzer practice against moving columns in the field. An invariable standard is, unfortunately, impossible; but it is always something to approximate to it. In military arrangements, a proof is also requisite, for the most obvious reasons, when powder is purchased from merchant manufacturers; not only that a minimum standard of strength may be fixed, but that, as far as is possible, the various qualities furnished may be reduced by mixture to an uniform standard.

It is usual, in the *first* place, among the workmen, as well as the merchants, to form a judgment of the quality of gunpowder by the aspect and firmness of the grain; and the latter, indeed, is a quality which is indispensable, if it is to be exposed to much land carriage. The nicety of tact required for this is, however, only to be attained by practice; as in all other species of sampling. The moisture is judged of by weighing, and by subsequent drying and comparison. The quantity of this is a question of profit and loss in the purchase. But it is more important to ascertain its hygrometrical powers, by exposure to moisture after drying. That is the best which gains least weight by this operation; nor, in any case, should the absorption of water amount to  $\frac{1}{4}$  per cent. It is also a common practice to try it by what is called *flashing*: but this only serves to show whether it has been thoroughly ground: if not, the charcoal will produce sparks.

The trial of force is made by *eprouvettes* of different constructions, or else by practice. The most common *eprouvette* is a short chamber, provided with a gun-lock, the orifice of which is closed by a cover, connected with a graduated and ratchet wheel and spring. The quantity of the wheel's revolution is the esteemed measure of the force. But often as this machine has been varied and improved, the results are so irregular, that it may fairly be considered as useless. Various other instruments for this purpose have been invented and tried; but, without figures, we could not render their constructions intelligible. Regnier's does not materially differ from the preceding in its principles; and the results are equally unsatisfactory. His hydrostatic one appears to be still worse. We may say the same of that described by Saint Remy, and of another recommended by the Chevalier D'Arcy; and, of the whole, we would remark that the leading fault is want of simplicity. In a case like the explosion of gunpowder, where so many disturbing forces are always at hand to vitiate the true results, we cannot be too careful in eliciting all unnecessary causes of disturbance. If there is any one class of machinery in which simplicity is indispensable, it is that which belongs to gunpowder, under any of its relations.

We, however, consider that, as an *eprouvette*, Dr Hutton's pendulum is as free from exception as any machine can be. The disturbing forces are nothing, or as little as possible; the charging and firing admits of great uniformity; and, on trial, the consistency of the results justifies the expectations

Gunpowder. formed from its simplicity. In this pendulum, the barrel is fixed upon the bob, and the force of the gunpowder is therefore measured, not, as in Robins's, by the impulse of a shot, but by the recoil. The indication of the extremity of the arc of vibration is made by a hand continuous with the pendulum rod, which moves an index furnished with a spring sufficiently strong to retain it at that point of a graduated arc, where it was left by the movement of the hand. The barrel used for this purpose is an inch in diameter, and is charged with two ounces of powder put in loosely, without wadding or ball. In this, as in all other cases of epreuves, the standard of strength is arbitrary; and, for service, is assumed from the best average of gunpowder manufactured by Government. The goodness of particular specimens is estimated by their agreement, or otherwise, with this standard.

Notwithstanding, however, the apparent accuracy of this method, artillery officers, both in France and England, are not satisfied with it as a method of proving powder for service. It is, perhaps, right, that practical men should, in a matter of so much importance, rely only on such a method of proof as agrees best with the particular objects for which the material is intended. Yet it should also be recollected, that all Robins's conclusions respecting the force of gunpowder were drawn from experiments made on his Ballistic pendulum, and that the much more accurate ones of Dr Hutton, on which we now rely, were the results of the practice with that pendulum which we have just described.

The method of proving, then, adopted both in France and England, consists in real practice from a mortar at short ranges. In France a mortar is used of which the diameter is 0,191 (metres), or nearly eight inches English, and that of the touch-hole somewhat less than two lines. The diameter of the ball is 0,1895 (metres), and the windage consequently is 0015. The weight of the ball is about 60 lbs. A troublesome verification of the diameter of the bore, of the vent, and of the shot, is made for each day's practice. The mortar is condemned when the diameter is enlarged to 0,192, or if that of the vent becomes 0005 more than it ought to be. A difference of windage, amounting to 0002 (metres) more than what is allowed, condemns the shot; or, as it may happen, the whole apparatus.

All these verifications are so tedious, and the wear of the mortar, the vent, and the shot, so rapid, that it becomes inconvenient or impossible to follow them so nicely in practice when there is much business. It is, therefore, found more convenient to make a standard trial for each day's proof, and to refer all the others to this one; instead of trying to preserve what becomes impossible in practice, an absolute and invariable range.

The English proof mortar, therefore, nearly corresponds with the French, it being of the eight-inch calibre, and of brass. The shot is turned and polished so as to be true, and to have at the commencement the least practicable windage. During the progress of use, as the windage increases from the wear both of the bore and of the shot, the range becomes contracted; a circumstance which also follows from

the enlargement of the vent; in consequence of which a greater proportion of the generated air escapes at that aperture. But, from the practice adopted with us, these variations are of no moment, till the range becomes contracted so as to render it expedient to replace the shot or the mortar, or both.

The quantity of powder that is used is four ounces, and the mortar being elevated to 45 degrees, the range is measured in each trial. If the standard range for the day is 225 yards, the powder that gives a range of only 200 is rejected. The chief precautions requisite to procure fair results in this comparative method, is to take care that the level of the platform and the elevation of the mortar are subject to no accidents; that the powder be fairly placed in the chamber; that the priming tube always reaches to the same depth within the charge; and that the mortar be brought to the same temperature at each experiment. For this purpose, it is to be cooled with water.

Musket powder is submitted to a different species of proof; founded on the same views of rendering the proof for each kind as nearly corresponding as possible with the purposes for which they are designed. A barrel fitted with a turned steel ball, and with as little windage as possible, is used for this purpose. The ball is discharged at the distance of a few yards only, against a compound butt, made of elm planks an inch thick, soaked in water, and separated at a short distance from each other. The extent of the penetration is the proof of the strength of the powder; and the trials in this case also are referred to a standard experiment made each day. Before concluding this subject, we must add, that trials are also made for the purpose of ascertaining the hygrometric property of the powder to be purchased or issued. This is done by exposing a quantity for a given time in a box perforated with holes, and in a damp room, and then submitting it to the same proof.

#### *Powder from Oxymuriat of Potash.*

To increase the strength of gunpowder has been a favourite project with inventors at all times; all of them forgetting that the same end can be attained, as far as it is attainable, by augmenting the charge; and that neither the one nor the other is practicable without an entire reformation of the whole system of artillery. Could the force of powder be increased one-half, for example, it would be necessary to condemn almost every gun in use; and not only every gun, but every carriage, breeching, ringbolt; nay, we might almost add, every ship in the service. And supposing a new species of ordnance invented to suit the new powder, it would require at least one-half as much more of weight in guns and mortars, the same in gun carriages; with additional strength in every object concerned about them. In the field, in the same manner, an increased number of horses would be required. This view presumes that the object is, what in fact it always has been with the herd of inventors on this subject, to gain additional force, or range. If the purpose is only that of being enabled to reduce the quantity, and thus diminish the bulk and trouble of transportation, it is so trifling an ob-

Gunpowder. ject as scarcely to be worth attaining. With regard to the main intention, or that of gaining greater range and force, it is only necessary to say that the powder is already too strong for the artillery.

As soon as the oxymuriat of potash was known, it became obvious that it would not only answer the same purpose as nitre, but, from its more energetic action, produce a more rapid combustion. It was first proposed and made by Mons. Berthollet in 1786; but an accident having happened from it at Essone, by which many people lost their lives, it was abandoned. The proportions used were 80 oxymuriat, 5 sulphur, and 15 charcoal. Afterwards they attempted to make a modified compound by using only a proportion of it with the nitre; but after various trials of this kind, the whole project was abandoned.

We have repeated Berthollet's method at different times, and on a very large scale, without accidents; but we consider that the proportion of oxymuriat is too large,—that it is at least larger than is necessary. A better proportion appears to be 75 oxymuriat, 5 sulphur, 20 charcoal. As this compound is very easily exploded by friction, it is necessary to be very cautious throughout the whole process; particularly in the granulations; nor is it safe to make more than one pound at a time. Of course, it may be mixed in wooden mortars, as it requires no large apparatus.

The great objection to its use is the facility with which it is inflamed by friction, or by a hard blow. The expence, indeed, would alone be an insuperable one, were there no other; as the price of this salt is more than twenty times that of nitre. It also corrodes the barrels very quickly. In fowling-pieces it is however of use; being the detonating priming of Forsyth's and of Manton's gun-locks. We may add, that very good powder may be made from this salt and charcoal alone, in the proportion of 80 to 20; but the grain is not very compact, and it is subject to all the same faults as the first.

The action of this powder on the shot in a charge is very capricious, and far from intelligible. In the French trials, it was found to give ranges sometimes double, and sometimes triple those of common powder, using the same weights. In various trials made in this country, the ranges were double in a majority of comparisons, when moderate charges were used. But, by increasing the charges beyond this, the ranges, instead of increasing in the same ratio, began to contract; double the quantity producing but a moderate increase in the range, and a third proportion making an addition still less than the preceding. This, however, agrees with Robins's experiments on common gunpowder; and he has accounted for it by what he calls the triple resistance; proving, as he thinks, that whenever the initial velocity exceeds 1142 feet in the second, a vacuum is formed behind the shot, which, by increasing the resistance before it, speedily reduces the velocity to what it would have been with a smaller charge. We need say no more respecting a compound, the use of which is not likely to be ever extended beyond its present application to the detonating gun-locks.

#### *Keeping and Restoration of Powder.*

Powder for service, whether for sea or land, is

kept in barrels, containing each one cwt. the size of Gunpowder. which is nearly that of a ten gallon cask, and they are hooped with copper. As it is difficult to keep dry casks water-tight, as indeed it was not thought necessary that they should be so, much powder was always rendered useless on service by wet. Lately copper linings have been very properly introduced, and the casks are now water-tight. As great quantities of powder always have been, however, and always must be, returned unserviceable; it is an important object to be able to restore it, or render it useful in the most economical manner.

Sometimes the grain is merely adhering, and can be shaken loose again; and this effect is not unfrequent even in magazines on shore. Such powder, when dried by restoring, appears sufficiently perfect; but it will be found that it is increased in bulk, and has become spongy and tender. On examination by the magnifying glass, it will also be perceived that the nitre is partially separated. Powder which has once undergone this change is deteriorated, yet is still fit for all ordinary purposes. It is not strong enough, however, to bear travelling; and, should it be required for that purpose, it ought to be remilled and granulated over again.

When the casks have been opened on service, before being returned, it is necessary to examine carefully whether they do not contain nails, or other foreign matters; an accident not uncommon. In such a case it is unsafe to commit them to the mill, and they must be reserved for extraction. When the powder has been so wetted as to be near into lumps, it is first necessary to examine, by the test of nitrate of mercury, whether the damage has been done by fresh or salt water. If by the latter, it must also be sent to the extracting house. If it has been very thoroughly wetted, even by fresh water, it will often be found that some of the saltpetre has been washed away. In this case it must be analyzed, so far at least as to determine the proportion of saltpetre wanting, which must be added to it in the mill. In the process of extracting, nothing more is necessary than to boil the powder in pure water, and to filter the solution through thick woollen bags. The crystals are purified exactly as in the case of rough nitre. This is a wasteful process, however, and *in all cases where it is possible, remilling is to be preferred.*

#### *On Accidental Explosions in Powder Manufactories.*

This is a subject which deserves far more attention than it has yet experienced; and we can only regret that our researches do not enable us to add more to the present suspicions as to the causes, than the little which follows. That want of sufficient care is the general source of these disasters is, however, certain; as certain merchants' mills have been celebrated for them, while in others, as well as in those belonging to the Government, they have been extremely rare. Such accidents may take place in any part of the works; but they are most frequent, as well as less injurious, when they happen in the mills; as the quantity of powder in these never exceeds 50 lbs. It ought at least to be an invariable rule to remove each charge to the pressing house as soon as it is completed.

Gunpowder. We already hinted at the cause of the explosions in the mills, when they happen at the time of removing the powder from beneath the stones. As stamping-mills are not used in this country, it may be thought superfluous to remark, that, in these cases, this accident sometimes happens from attempting to remove, by a mallet and chisel, the lumps of powder which adhere to the pestles. It is one of the inconveniences attached to that mode of grinding. But it is also proper to observe, that the mills are sometimes blown up while working; and, from some examinations which we have made, we have little doubt that this has arisen from fragments of the stones falling off, and being bruised together with the powder. We indeed consider metallic rollers as every way safer than stone ones; as they can only produce fire in case of friction in contact during the removal of the charge. If iron be held objectionable, it is easy to face them with a sheet of copper; but it is proper to recollect that, even thus, the chances of explosion from friction are not removed. It is a great mistake to suppose that the absolute hardness of any metal is indispensable to the production of explosion in gunpowder. A blow sufficiently powerful, or friction caused by sufficient weight and rapidity, will compensate for the absence of this, in very soft metals, as well as in many other substances, which do not readily give fire. Limestone we consider to be a very objectionable substance. Except that of Carrara, we know of none, either primary or secondary, that does not contain much silica; often, indeed, particles of quartz sand. In the secondary calcareous rocks it is universal; nor is even the finest white marble of Carrara always exempt; as is well known to statuaries. But the softness, even of the purest limestones, is no defence; as the friction between these is still more capable of setting fire to gunpowder than that of iron. The readiest way of putting these different substances to the test, is by experiments in fulminating silver (that of Howard): as the irritability of this substance enables us to ascertain the facts with a moderate and convenient force.

We know of no explosions in the stove, except in one noted instance, when it was pretty well ascertained to have been produced by a workman, who had determined on suicide in this manner. In the steam stove it can never happen from overheating; but as the floor must necessarily be dry when the workmen enter to remove the powder, instead of being wet, as it always is in the other houses, it requires additional care respecting the feet of the people employed. The only method that is quite safe, in all houses and magazines, is to oblige the workmen to labour barefooted. The heavy leather slippers in common use are far from safe; as, from not fitting well, they are frequently dragged along; in which way they may easily entangle particles of sand. It ought to be known to all powder makers, that the breaking of a fragment of quartz, or the sufficient friction of two grains between copper, or even wood, is capable of igniting gunpowder. This is more particularly the case when the finer charcoals are used; as it is this which is the susceptible ingredient.

Explosions in the pressing and granulating houses

have happened much too often, nor have the causes been ascertained. As there is a considerable quantity of powder always present here, these are of a very serious nature. It would be proper that these two buildings should always be separated, and, in the usual way, by a work of earth. The old granulating houses are far from safe, as the cranks and other parts of the moving machinery are contained within the house, which is always filled with the dust of the powder. It is trusting too much to the attention of persons, whom practice renders habitually careless, to expect that they will always keep the parts oiled. It is easy to remedy this evil by entirely separating the working machinery from the granulating engine, which may be suspended and steadied by ropes, so as to avoid all chance of friction.

In the pressing house there seem to be two sources of danger, both of which may be obviated. It is easy for powder to become entangled among the threads of the screw, and the consequence of this must be obvious. This would be remedied by adopting Bramah's press. We also think that the sudden condensation of air entangled among the fragments in the pressing box may be sufficient to produce fire. Whether this be the case or not, it will always be prudent to make the first pressure as slowly as possible, that the air may be allowed to escape.

We have observed three other causes for accident, though neither of them belong properly to the manufacturing houses. It is, nevertheless, very important that they should be generally known. Charcoal, in certain cases, is liable to take fire spontaneously, and that even in the lump. This is a case exactly analogous to the pyrophorus of Homberg; and it unquestionably arises from the same cause, namely, the presence of a portion of potassium. It is an accident which, we imagine, can only happen to charcoal made in retorts; as, in the pit method, the potassium could scarcely be expected to escape combustion. The precautions hence requisite, respecting the stowage of charcoal, and the place of the distilling houses, must be evident. When in a state of powder, and under pressure, it also has been known to inflame; and, possibly, from the same cause.

We are not aware that it is usual to keep many waggons and powder-cart tilts about powder magazines, but we do know that this has happened, and with the effect of producing fire. It ought to be generally known, for many other reasons, that fresh painted canvass, stowed close, is subject to spontaneous combustion.

Lastly, it has frequently been observed that fire was struck in closing up the powder barrels, as well on board ships as in magazines—an accident which was supposed impossible, since both copper hoops and hammers are exclusively used. We at length discovered that this accident had arisen from using cast rivets, in the surface of which the sand of the mould had become entangled. Hence the obvious necessity of using none but forged copper rivets, and since the adoption of these in the Government stores, this accident has been unknown.

Gunpowder.

*On the Force of Gunpowder when Fired.*

It remains to inquire, whether there are any means, *a priori*, of determining the explosive force of gunpowder, and of discovering what that is or ought to be. Many calculations have been made on this subject, and some of them, we need scarcely say, are deserving of great regard, although by no means in accordance with each other. Many, on the contrary, proceed on principles, so often gratuitous or false, as to be entitled to no consideration. When we consider the reputation of some of the authors of these speculations, and the real knowledge of the true cause of explosion which were then in existence, the history of these opinions, and thus of the deduced results, are not a little curious.

Lemery, Wolf, Papin, and some others, considered that the cause of the explosion was to be sought in the rarefaction of air contained in the interstices of the powder; forgetting, that in a rocket, which can contain none, the production of air was sufficient to communicate and maintain a considerable velocity during the whole time of the combustion. John Bernouilli imagined that this air contributed an eighth part of the force only, and that the remainder arose from water contained in the saltpetre. Muschenbroek, Stahl, Beaumé, and Macquer, again, considered the whole effect as produced by the conversion of the water of the nitre into steam; an error quite unpardonable in the two last chemists, who ought to have known that nitre contained little or no water of crystallization; and still more so in Count Rumford, who has followed them in this theory. Lombard, attempting to improve on it, adds to the expansion of steam that of the nitric acid. The Abbe Nollet allows the water but a share in the explosion. But not to enumerate more of these hypotheses, we shall only mention further, that of those who have attributed the expansive force to the conversion of latent into free, or radiant caloric, as they have thought fit to term it.

It would have been much more easy and correct to have put this question to the test of experiment, when the real cause would have immediately appeared. It was sufficiently unpardonable, in the greater number of these persons, not to have inquired what had been done before them; since Boyle, Hales, Hawksbee, and others, were aware that the combustion of gunpowder produced a permanently elastic fluid; although their mode of obtaining it in an exhausted receiver was not a very accurate one. Hawksbee found that one grain of powder, when fired in vacuo, produced a cubic inch of a permanently elastic fluid, and that the same result was obtained in air. Hence, though not acquainted with modern chemistry so as to be aware of the nature of the generated gas, he knew well that it could not have arisen from the expansion either of air or water contained in the powder. The inaccuracy of Count Rumford's views, and the extraordinary results of his numerous and laborious experiments, exceed, however, all that has been done on this, or perhaps on any subject in modern experimental philosophy.

The history of opinions respecting the explosive force of gunpowder, and all alike pretending to be

deduced from experiments, is scarcely less amusing than the hypotheses respecting the cause; although rendered much more marvellous by their extraordinary discrepancy. John Bernouilli considered the initial force as equal to 100 times the pressure of the atmosphere; while Daniel Bernouilli made it 10,000. Bracehus determines it at 450, D'Antone as lying between 1400 and 1900, and Ingenhouz at 2276. According to Dulacy it is 4000, by Amontons it is 5000, and by Lombard it is stated at 9215. After this there is a rapidly increasing estimate among other experimenters: Monsieur Le General de la Martilliere representing it at 43,600, Count Rumford at 54,750, and Monsieur Gay de Vernon, who outdoes all his competitors, stating it as making from 30,000 to 80,000.

Among the French, Gilot's experiments appear the only tolerably accurate ones; as he states the produce of 100 lb. of powder in gas to be 463 cubic feet. This, however, is considerably under the truth, at least in the present French powder, as well as in our own. Of course, this is not meant to represent the total force; but he has not given any statement of the increase of volume produced by the temperature on firing. The coincidence between Robins's and Gilot's results is, however, considerable; but the French philosopher is beyond the truth.

According to Robins, from experiments made in an exhausted receiver, the produce of gas from a given quantity of powder, bulk for bulk, is 236; or one cubic inch of powder produces 236 inches of elastic fluid at the mean temperature and pressure. If the powder be rammed into the smallest possible space, the produce is double, or 472 inches of air; as it may be condensed, by hard ramming, into half the space which it occupies when loose. But we must beware of assuming this as an element in the computation of the initial force, however true a representation it is of the fact, abstractedly considered. In practice, powder would produce no corresponding effect in this state, because the ball would have quitted the piece before it was half burnt. Now, Robins's experiments tally very nearly with our own, as formerly stated; the produce from rammed powder being about 520 on an average of trials, which, being reduced in the proper ratio for powder as it is fired, gives 260 instead of 236. It is not impossible but that our powder may have been superior to his.

Thus much for the permanent produce. But there is another important element required, before the expansive force of the powder at the time of firing can be determined, and the initial velocity calculated. This is the augmentation of bulk produced by the elevated temperature which results from the combustion. According to Robins, that is such as to render the pressure, or force of the generated fluid at the moment of explosion, equal to 1000 atmospheres. Dr Hutton, more justly, states this at 2000; a force far short of the imaginary ones which we have quoted above.

We should have proceeded to examine the experiments on which this determination was founded, and to compare the calculations with the results of

*Gunpowder.* practice. But our limits warn us that we must draw this article to a close; and we shall, therefore, refer our readers to the writings of Robins, Euler, and Hutton, on this subject, as alone deserving of attention. Yet we cannot conclude, without suggesting the only method,—a method yet untried, by which the true force of the explosion may be discovered *a priori*; or, at least, the real bulk of any given quantity of the generated gas, at the moment of inflammation, may be ascertained. It is a heat which cannot be conjectured, and to which no true approximation has been made by any method yet used.

By firing the given charge of gunpowder under a given quantity of water or mercury, it is easy to measure the temperature to which it is raised. Hence, recurring to the difference of capacity for heat between either of these substances and the generated gas, to their relative quantities, and to the law for the expansion of gaseous fluids by heat, as determined by Gay Lussac, the problem may be solved, for that case at least; as we are fully sensible that no rule truly applicable to all cases can be established, when the numerous variations to which, in practice, the conditions are liable, are considered.

*Life Preservers.*

P. P. P.

## L I F E P R E S E R V E R S .

ALTHOUGH it too frequently happens, that an accident, which materially endangers the life of an individual, deprives him, in the mean time, of that presence of mind which alone would enable him to take proper measures for his safety; yet to have meditated, in an interval of leisure, upon the best method of proceeding in case of emergency, must tend greatly to diminish the embarrassment and confusion that commonly accompany the accident, even if it should not be thought necessary to provide any particular apparatus for the purpose of escaping the danger. There are also many ways in which those who are not immediately involved in the disaster may contribute to the preservation of life, whether actuated by interest, or by humanity only; and the modes of relief will, therefore, be naturally divided into the *internal* and the *external*, whether relating to *fires* or to *shipwrecks*.

### SECT. I.—*Internal Fire Escapes.*

Whenever a family establishes itself in a residence not detached from others, it becomes of importance to ascertain what facilities the house affords for ascending to the roof, and for passing to those of the neighbouring houses. It is scarcely possible that a conflagration should extend at once to the contiguous houses on each side, before the inhabitants of the house in question have had time to escape. But in a detached house, if there are not two or more staircases remote from each other; and even in a house contiguous to others, when there is no facility of communicating by the roof, it becomes highly expedient to provide some *internal means* of escaping through the windows in case of fire; and to have *on every floor* a good strong rope, with a hook or a loop at the end, by which it may be fastened to a bed-post, so as to enable an active person to descend by its help out of the window, finding from time to time a partial footing in the inequalities of the wall. This process will be greatly facilitated by having the rope knotted at intervals of about a foot throughout its length; the knots being nearly as convenient as the blocks, or clips, that are sometimes made for the

purpose of retarding the descent, by holding them, and regulating the friction by the pressure of the hand\* (Plate CX. fig. 14); unless the clip be attached to a strong cross bar, on which a person may sit, while he regulates the position of the clip by its handles, and allows himself to descend with more or less velocity at pleasure. The arrangement for this purpose may be made by a roller, or pipe, sliding on the rope, and pushed down so as to open the handles of the clip and tighten its teeth, when the person holds by the roller and draws it down (Plate CX. fig. 13); and, on the contrary, the clip may be opened by pressing on the handles with the other hand, or with the thighs; or any other simple mode of regulating the clip may be adopted, provided that it be not liable to be misunderstood, or misapplied in a moment of confusion. After all, a rope ladder would perhaps be preferable, as not being liable to be deranged; it is often kept ready made in the shops; and in the absence of any other rope, a common bed cord will generally be found strong enough to support the weight even of a stout man; for a quarter inch rope may be safely trusted with two hundred weight, and ought, indeed, to support three times as much if new and good.

### SECT. II.—*External Means of Escape from Fire.*

The external means to be employed in cases of conflagration must be provided by the managers of fire offices, or by other public officers; and every ingenious workman, whom they may employ, will be able, at his leisure, to devise such apparatus as he can the most conveniently execute, and to give it a full trial in the absence of all danger; it will, therefore, only be advisable that he should compare for himself the particular inventions which have been suggested for this purpose, and that he should choose from among them such as he thinks most likely to do him credit; and he may, indeed, very possibly find means of improving on any of them.

1. In Leupold's *Theatrum Machinarium* (Plate LIV. LV.) we find the representation of a chair calculated to be drawn up or down by means of pulleys.

\* Emerson's *Mechanics*, fig. 228, 229; Leupold's *Theatrum Machinarium*, Plate LIV.

Life Preservers.

2. Mr Varcourt obtained, in 1761, the approbation of the Parisian Academy of Sciences for his invention of a hollow mast, fixed in a waggon, and supporting a stage, with the means of ascending and descending. (*Hist.* p. 158.) 3. In the beginning of the present century, a fire escape of Mr Audibert was approved by the Parisian Institute. (*M. Inst.* IV.) 4. A committee was also appointed for examining several similar inventions at the Lyceum of Arts, and a medal was awarded by it to Mr Daujon, for his apparatus, which consists of a platform carried on wheels, supported by three frames, with brass wires, on which boxes are made to slide up and down for the conveyance of persons or of furniture. (*Annales des Arts, Repertory* ii. I. p. 439.) 5. Mr Collins's invention of pipes raised by ropes, and affording a centre to a long lever, is described in the fourth volume of the *American Transactions*, and in the *Repertory*. (Vol. XV. p. 35.) 6. In the thirty first volume of the *Transactions of the Society of Arts* (for 1813, p. 244), we have an account of a fire escape invented by Mr Adam Young, for which he received a medal from the Society. It appears to constitute by far the most portable of ladders, consisting of cross bars or rounds, connected by ropes, and having their ends fitted together, so as to form a pole, which is readily elevated to the window; and the rounds being separated, and the hooks at the end properly fixed to the window frame, the whole forms itself into a very convenient ladder of a mixed structure. 7. The *thirty fourth* volume, for 1816 (p. 227), contains a description of Mr Braby's fire escape, consisting of a car made to slide on a strip of plank fixed to a pole, and governed by a rope, which is cased with iron, to protect it, in case of necessity, from the effect of the fire.

The modes of extinguishing fires are not precisely the objects of the present inquiry; but it deserves to be remarked, that the only rational principle on which the methods proposed have been founded, is that of cutting off the supply of air, either by a coat of water or steam, or by means of some chemical substance, capable of forming an impenetrable varnish, or glazing, on the surface of the combustible materials. A mixture of clay, with sulphate of iron and alum, has been proposed for this purpose, but its utility must obviously be extremely limited, and it must require to be applied with great address, so as to be brought into fusion exactly at the place where it is capable of protecting the substances not yet consumed.

#### SECT. III.—*Internal Means of Escape from Shipwreck.*

The means of escaping from shipwreck may be similarly divided into internal and external, or into the precautions to be taken by the ship's company, and the measures to be adopted by persons on shore. The internal means depend either on enabling the individuals to swim or float, or establishing a connexion with the shore by ropes; and of the former, we may first consider those which require no particular preparation before the occurrence of the accident that calls them into action, and which are therefore the most universally applicable.

Life Preservers.

Of such expedients the most effectual appear to be those which depend on the employment of empty water casks for assisting the ship's company to drift on shore. 1. A paper on the arrangement of water casks, to serve as floats in case of shipwreck, appears in the publications of the *Society for the Improvement of Naval Architecture*, dated in 1796. (Vol. II. i. p. 51.) 2. In 1818 Mr Grant of Bideford obtained a gold medal from the *Society of Arts*, for the invention of a life preserver, consisting of a 36 gallon cask, with some iron ballast fixed on a wooden bed, and lashed to the cask, and with ropes round it for the men to hold; and it was found that ten men were supported by it with convenience in tolerably smooth water, the bung of the cask being well secured by cork. (Vol. XXXVI. p. 63.) The ballast could be of very little use, and a cask simply tied round with a rope, like a common parcel, would probably answer the purpose equally well. It would, indeed, be prudent for every ship in a storm on a lee shore, to have a few of her casks well emptied and stopped, and tied in this manner, before the actual occurrence of imminent danger. 3. In the thirty seventh volume of the *Transactions of the Society* (p. 110), there is an account of Mr Cook's life raft, consisting of a square frame with canvas nailed across it, supported by a cask at each corner, for which the gold medal was voted to him. 4. It is followed by a description of Lieutenant *Rodger's life raft* (p. 112), which obtained a similar compliment. This raft has the advantage of requiring only such materials as are usually found on board of every ship; capstan bars, boat masts, yards, or any other spars of moderate dimensions, which are tied together so as to make a sort of waggon frame, with a large cask fixed on each side; it appears to afford a very convenient support to the men, but it can scarcely possess any great strength for resisting the force of the breakers.

Mr J. Bremner, a clergyman in the Orkneys, had received a medal from the Society in 1810, for his method of converting any ship's boat into a life boat, by putting into it three or four casks attached to the keel, which is to have a ring bolt fixed in it for receiving the ropes by which the casks are fastened; he gives particular directions for making all the necessary arrangements in the twenty eighth volume of the *Transactions* (p. 134); he particularly advises that no use should be made of the natural buoyancy of the cavity of the boat, but that the bottom should be perforated without hesitation, wherever the hole would afford any additional facility for fixing a rope. Captain *Manby's* jolly boat fitted as a life boat, "at the expense of three pounds," seems to be comprehended among those preparations which are to be made previously to the voyage.

The buckling a soldier's canteen on his breast, as an assistance to enable him to float, belongs to these temporary expedients, which may occasionally be employed with advantage. Tying a hat in a pocket handkerchief, and holding it as a float, has been recommended by Mr Lawson in the *Philosophical Magazine* (Vol. XX. p. 362); he advises that the crown of the hat should be held downwards, and observes that a stick may be employed, to enable us to use two or four hats at once; but this method can only

be adopted when the accident occurs in very still water.

The first and most obvious preparation for enabling a person to float, is the learning to swim. It is well known that swimming is scarcely ever sufficient to enable a seaman to reach the land from a ship that has been wrecked, without some assistance; and many have certainly been drowned from depending too much on their own strength; but for a momentary support, and to afford courage and presence of mind to seek for other aid, there is no question but that the faculty of swimming possesses an inestimable advantage. A boy generally learns to swim by the help of his schoolfellows, better than by any general rules, and more agreeably than in a school of natation; but it may be of some use to observe, that the act of diving to the bottom and reascending, in tolerably shallow water, is much more easily performed by a beginner, than that of simply supporting himself on the surface; and when he has thus acquired the feeling of the immediate effect of his arms in propelling and sustaining him, he soon finds out the means of employing his feet in their assistance. The art of swimming has, however, been systematically treated by Bächstrom, *Kunst zu Schwimmen*, 8vo. Berl. 1742; by Thévenot, *Art de Nager*, Paris, 1711; and by Bernardi, *Arte Ragionata del Nuoto*, 2 vols. 4to. Naples, 1794.

It is easy to convince ourselves, by trials in a warm bath, without reference to Robertson's experiments (*Phil. Trans.* 1757), that a substance possessing a very small degree of buoyancy is sufficient to enable the human body to float without effort. In fact, when the chest is fully expanded, the thinnest and most bony person will commonly float in sea water; but the effort of keeping the chest expanded is as fatiguing as any other muscular exertion; and when the chest collapses, the fattest people may be in danger of sinking unless they have learned to swim. Sir William Hamilton, indeed, tells us that in 1783, "a woman of Scilla, four months gone with child, was swept into the sea by the wave" accompanying the earthquake, "and was taken up alive, floating on her back at some distance, nine hours after; she had been used to swim; her anxiety and suffering, however, had arrived at so great a pitch, that just at the time that the boat which took her up appeared, she was trying to force her head under water to put a period to her miserable existence."

In China a frame of bamboo surrounding the person is used for a float, and the lightness and strength of this substance must make it extremely proper for the purpose; sometimes also a gourd is tied to a child, to secure its floating in case of accident. The inflated goat skins, used from time immemorial by the Arabs, or the seal skins employed by the Chilians, have the disadvantage of being easily punctured by a rock or a spar; an objection which is also more or less applicable to all substances containing air; for example, to the air jackets described in Leupold's *Theatrum Pontificium*, published about 1724. A float of a semicircular form was recommended by Ozanam, the author of the *Recreations*; and Bachstrom, in his *Art of Swimming*, proposed to float a troop of cavalry by fixing cork to the saddles. The

cork jacket of Gelacy is described in the *History of the Parisian Academy of Sciences for 1757*, and Lachapelle's *Scaphander*, which is considered an improvement on it, in the volume for 1765. In the year 1764, the attention of the British public was particularly called to the floating powers of cork, by some experiments which were made with cork jackets on the Thames, together with some comparative experiments on air jackets; and Dr Wilkinson, in the *Philosophical Transactions for 1765*, describes some experiments by which he ascertained that about a pound of cork was amply sufficient to enable a man of ordinary size and make to float without effort. It is almost superfluous to enumerate the multitude of trifling variations that have been made in the arrangements of cork jackets and air jackets, apparently for the purpose of exciting a momentary interest, though possibly from the best motives. Mr Bosquet advised a bag of cork shavings to be kept in readiness by each person: the *Seaman's Friend* was composed of two pieces of cork, united by straps; the *Collinetta* was a hollow vessel of copper, divided into cells; a "marine spencer" has been described by Mr Spencer, in the sixteenth volume of the *Philosophical Magazine*, consisting only of a number of old corks, arranged so as to form a girdle; and in 1806, Mr T. C. Daniell obtained a gold medal from the Society of Arts for the invention of an apparatus of water proof leather, surrounding the body, which, according to the testimonials he produced, had saved the lives of some persons who had been sailing in a pleasure boat on a river. In smooth water, it has been suggested that throwing a foot ball, with a small weight tied to it, to the person immersed, would often afford sufficient assistance; and with respect to floating, there is no doubt that any of the assistances which have been proposed would be sufficient, if they were at hand; but there is another object, to which it is necessary to attend, in cold, and even in temperate climates, that of supporting a temperature compatible with life and health, if the immersion is likely to be of long duration; and an additional provision of worsted stockings, jackets, and trowsers, will be almost as essential, in such cases, as the means of obtaining buoyancy.

For the second object which is desirable to a ship in distress, that of obtaining a safe communication with the shore, it has been usual of late years to rely principally on the humane exertions of persons who may be on the coast, and who may have made preparations for this purpose; and with this view, some instructions for properly co-operating in the measures to be adopted with Captain Manby's apparatus, have been liberally distributed to all ships when they received their papers from some of the British custom houses. There are, however, some simple expedients which may be adopted for this purpose by persons on board of the ship: for example, the making a kite with a pocket handkerchief stretched over a hoop, and causing it to carry a cord to the lee shore, by means of which a stronger line, and at last a hawser, may be drawn by persons standing on the beach. A line may also sometimes be carried on shore by a cask, allowed to drift before the wind; and a bag has been recommended to

Life Pre-  
servers.

be attached to such a cask or to a buoy, in order to act as a sail, and to insure its crossing the surf. Mr Cleghorn was also rewarded, in 1814, by the Society of Arts, for the invention of a buoyant line, having a heart of cork, to obviate the inconvenience which would arise from its sinking and being dragged on the stones under the breakers; but he observes, that in heavy storms there is generally a current along shore, which renders the method almost impracticable. (*Transactions*, XXXII. p. 181.) A Mr Wheatley assures us, in Captain Manby's *Essay*, that his own life, and that of eight other persons, were saved in 1791 by a lead line, which was carried on shore by a Newfoundland dog that he happened to have on board; when two good swimmers had been drowned in the attempt to swim on shore. It had occurred to Lieutenant Bell in 1791, that a rope might be thrown from a ship which had struck, by means of a mortar carrying a heavy shot, and upon the principle of the gun harpoon; and he showed the practicability of the suggestion by an actual experiment, in which a deep-sea line was carried to a distance of about 400 yards. (*Trans. Soc. Arts*, XXV. p. 136.) He recommended that every ship should be provided with a mortar capable of carrying such a shot, and observed, that it might be placed on a coil of rope to be fired, instead of a carriage. The line was to be coiled on handspikes, which were to be drawn out before the mortar was fired. In 1792 he received a premium of 50 guineas from the Society of Arts (*Transactions*, X. p. 204); and he obtained his promotion in the Ordnance as an acknowledgment of his merits. The shot was to weigh about 60 pounds or more, and the mortar five or six hundred weight. The experiments of the French artillery at Lafere were subsequent to those of Mr Bell, though they have sometimes been quoted as the first of the kind.

It has, however, generally been thought impracticable to manage a mortar with effect under the circumstances of actual shipwreck; and Mr Trengrouse has preferred a rocket, as more easily fired, and as having a smaller initial velocity than a shot, so that the rope would be less in danger of being broken by the impulse. He found that a rocket of 8 ounces carried a mackerel line 180 yards, and a pound rocket 212; and, in some experiments made under the inspection of the Society of Arts, a rocket, an inch and a quarter in diameter, carried a cord across the Serpentine River in Hyde Park. The musket is provided with a valve, to prevent the escape of the materials of the rocket, and it is to be fired with a little powder, without wadding. The whole apparatus is packed in a chest, containing from eight to twelve rockets, the musket, a life spencer, a chair, to traverse on a rope, a canvas bag, and a ball of wood to throw to a person swimming. Mr Trengrouse was complimented with a medal from the Society of Arts in 1820. (Vol. XXXVIII. p. 161.)

#### SECT. IV.—*External Means of Escape from Shipwreck.*

The means to be employed by persons on shore, in cases of shipwreck, depend either on projecting a line over the ship, or on the use of a life boat. Mr

Bell had cursorily observed, that a line might be carried over a ship from the shore by means of his mortar; but for the actual execution of this proposal, in a variety of cases, we are indebted to the meritorious exertions of Captain G. W. Manby, whose apparatus, according to the report of a Committee of the House of Commons, dated in March 1810, appears "to be admirably adapted to its purpose, and to have been attended with the fullest success in almost every instance." In consequence of this report, Captain Manby was thought worthy of a Parliamentary reward; and he afterwards published a description of his inventions under the title of *An Essay on the Preservation of Shipwrecked Persons*, 8vo. London, 1812. He had previously received a gold medal from the Society of Arts in 1808. (*Transactions*, XXVI. p. 209.) His success makes it expedient to extract from his *Essay* a detailed description of the apparatus, and it will be easy to make it somewhat more intelligible by a slight alteration of the order of arrangement.

P. 21. "The method of affixing a rope to a shot, for the purpose of effecting communication, when projected from a piece of ordnance over a stranded vessel, was at length succeeded in, by introducing a jagged piece of iron, with an eye at the top, into a shell, and securing it by filling the hollow sphere with boiling lead; and in another way, by drilling a hole through a solid ball, and passing a piece of iron, with an eye to it, as before described, to the bottom, where it should be well secured by rivetting." (Plate CX. fig. 24.)

"To produce the means of connecting a rope to a shot, and prevent its being burnt, and rendering it 'irresistible' to the powerful inflammation of gunpowder, was the labour of infinite time, and the number of experiments to accomplish it is beyond all possible conception. Chains in every variety of form and great strength breaking, proved that it required not only an elastic, but a closer connected body. At length, some stout platted hide, woven extremely close to the eye of the shot, about two feet in length beyond the muzzle of the piece, and with a loop at the end to receive the rope, happily effected it." (Plate CX. fig. 15.)

"This method is certainly desirable, as the rope may, immediately [as] it is required, be affixed to the loop, and applied in service. The form of the platted hide may likewise be woven by twisting it in the manner that the lashes of whips or ropes are spun; there is another method, by passing the rope through a case of leather, taking the greatest care that it is so well secured at the eye of the shot, as to leave no room for the SLIGHTEST PLAY, as is represented by the following BARBED SHOT." (Plate CX. fig. 19.)

"When the crews of the distressed vessel are incapable of availing themselves of the benefits arising from communication, they having previously lashed themselves in the rigging to prevent being swept away by the sea, which is repeatedly breaking over them, and when, from long fatigue and the severity of the storm (on which occasions it too frequently occurs), they totally lose the use of their limbs, and are rendered incapable of assisting themselves in

Life Pre-  
servers.

the slightest degree—the advantages of this shot are, that, on its being projected over the vessel, and the people of the shore hauling it in, it firmly secures itself on some part of the wreck or rigging, by which a boat can be hauled to the relief of the distressed objects; and by the counterbarbs it is rendered impossible [that it should] give up its hold, or slip, while that part of the wreck remains to which it has secured itself.

“Among the many that have been saved by this shot, the following are testimonials of a few of the cases:—We, the crew of the brig Nancy, of Sunderland, do hereby certify, that we were on board the said vessel when she was stranded on the beach of Yarmouth, on Friday morning, the 15th of December 1809, and compelled to secure ourselves in the rigging to prevent being swept away, the sea running so high over the vessel. And we do further declare and certify, that Captain Manby, firing a rope with a hooked shot, securely holding on the wreck, enabled a boat to be hauled from the shore over the surf to our relief, otherwise we must inevitably have perished.” This certificate is attested by six signatures.

P. 27.—“Facilitating communication is at all times of importance; but when the stranded vessel is in momentary danger of going to pieces, this point becomes a consideration of extreme urgency. I feel a persuasion that this particular service can only be carried into effect by a small and light piece of ordnance, the range of which is consequently very inconsiderable, when compared with that of a large and heavier piece, as it is weight alone that conveys the rope. In order, therefore, to increase the powers of a shot projected from a small mortar, its natural form must be varied, so as to give it additional ‘preponderance.’ The following shape, in the form of a pear, has been used with the greatest success, for by the increased weight, the shot’s momentum and power over the line is in consequence considerably augmented in its range; and when made to fit the piece as close as possible, a great increase of velocity is likewise produced from that decrease of windage. (Plate CX. fig. 11.)

“Portability in the construction of a piece of ordnance (as just described) is the very essence of this service; and communication with the stranded vessel or wreck may be effected with a cord, by which cord a rope can be conveyed, and by that rope a hawser or cable sent to the distressed vessel; for this purpose the following was constructed.” (Plate CX. fig. 18.)

P. 31.—“A person completely equipped with every necessary apparatus to effect communication with a vessel driven on a lee-shore . . . the horseman, fully equipped, travelled a mile and a half, the howitzer was dismounted, and the line projected 153 yards in six minutes.

“The application of a small piece of ordnance (Plate CX. fig. 21) likewise offers particular advantages, capable of being employed from a boat to go to the assistance of a vessel grounded on a bar when running for a harbour, the necessity of which repeatedly occurs, and was twice witnessed at Blake-

ney on the 10th of November 1810, when boats endeavoured to go to their relief, and were enabled to get out of the harbour on the ebb tide, within 20 yards of the vessel; but it was found impossible to approach them nearer. Had such boats been provided with a piece of this description, and the same firmly secured on a stout piece of plank, by the holes left at each corner of the iron bed, they might have projected a small rope, coiled in a crate or basket made to the form of the bow of the boat, and the persons in the boat, so provided, would not have remained the distressed spectators of the untimely end of their fellow creatures, without being able to afford them the smallest relief, although so little was then wanted for that desirable purpose.”

“Although advantages have been pointed out in the use of these small mortars, it is necessary to be kept in remembrance, that they are produced for particular services, as the nature of the coast, and circumstances attending the distressed vessel, will direct what piece is best adapted to the undertaking. To enable the mind to form a judgment what can be effected by other pieces, the following are the minutes of experiments made with a five and half inch brass mortar, stating the quantity of powder used, and distance the ropes were projected against a strong wind, at the angle of 17 degrees (elevation): weight of the mortar and bed about three hundred.

Ounces of Powder.	Yards of inch & half rope.	Yards of deep sea line.
4	134	148
6	159	182
8	184	215
10	207	249
12	235	290
14	250	310

“With a short eight inch mortar, the weight of which and bed was supposed to be about seven hundred; the angles of elevation uncertain.

Ounces of Powder.	Yards of deep sea line.	Yards of two inch patent Sunderland rope, capable of hauling the largest boat from a beach.
32	439	—
32	479	—
32	—	336

P. 15.—“Directions for using the apparatus.—When the rope (which should be pliant and well stretched) is brought on the beach or cliff opposite to the stranded vessel, the most even spot, and free from projecting stones, should be selected to lay it on, and great care be taken that no two parts of it whatever overlay or even touch each other, nor must it be laid in longer lengths than of two yards. But to project a small line or cord, it will be necessary, if it is required, to contract the faker to half a yard at most, to avoid the jerk received at the end of each right line. The best method, with such a

Life Pre-  
servers.

description of cord, is to lay it on the ground in the most short and irregular windings, to relieve it from this powerful impulse. To prove the effect of the impulse on a rope, if it is faked in lengths of ten or fifteen yards, it will break each time, as it then becomes a most powerful pendulum. These precautions are absolutely necessary to the success of the service.

"The following has, after various trials, been found a certain method of laying the rope, and placing it into compartments. (*French Faking*, Plate CX. fig. 1.)

"A particular attention to this mode will never fail with a good rope, when the impediments are removed that might otherwise obstruct its rapid flight. Its advantages are, that it will allow the eye rapidly (yet correctly, *just before firing*, which is absolutely necessary) to pass over the different compartments, and at once discover if any fake has been displaced by the storm, or by any other casualty or accident come in contact with another part, which would destroy its application by the rope breaking.

"It may likewise be coiled in the manner used in the whale fishery, *whale lair* (Plate CX. fig. 8); and in the following method, *chain faking* (Plate CX. fig. 5).

"It is, however, necessary to add, that great attention is required in laying it agreeably to the two latter methods, arising not only from the arm being liable to get under certain parts of the rope, and thereby displace it, but from the great anxiety of mind natural on these occasions, where the lives of fellow creatures are literally dependent on the correctness with which the rope is laid; it is, therefore, extremely difficult, in a moment of agitation, to determine whether any overlay has taken place, an error that would infallibly destroy every endeavour, and occasion even the fate of those whose lives we might be exerting ourselves to preserve. Could persons in the performance of this service be always collected, the two latter methods would have a decided advantage over the first mode of faking, they being laid in a much less space of time.

"As all these methods of laying the rope occupy time to place it with the care necessary; and as it has repeatedly happened that vessels, very soon after grounding, have gone to pieces, and all hands perished, it was necessary to produce a method of arranging the rope, so that it could be immediately projected as soon as it arrived at the spot; and none proved so effectual as when brought ready laid in a basket." (Plate CX. fig. 23.)

"In this case, the rope should be most carefully laid in alternate tiers or fakes, no part of it overlaying, and it should be well secured down, that in travelling it be not displaced. But, above all things, no mistake must happen in PLACING THE BASKET PROPERLY. For example, that the end of the basket, from which the shot hangs in the above plate, should be previously marked, as it is here represented, and must be placed towards the sea or wreck, that the rope be delivered freely, and without any chance of entanglement. It will be scarcely necessary to add, there will be several tiers of the rope when laid. The utmost care and attention are required in lay-

ing the rope in tiers with strict regularity, to prevent entanglement.

P. 36.—"The next is the application of the mortar. If the wind is sidewise to the shore, it must be pointed sufficiently to windward to allow for the slack of the rope lighting on the object, as the rope will, of course, be considerably borne to leeward by the effect of a strong wind, and by its being laid at a low elevation, insures the rope falling against the weathermost part of the rigging. While this service is performing, great care should be taken to keep the mortar dry; nor should it be loaded until every thing is ready; when that is done, it should be primed; but as it would be impossible to do it with loose powder in a storm, a tube is constructed in the simplest manner of common writing paper (the outer edge being cemented with a little gum) in this form. (Plate CX. fig. 2.) It is filled with meal gunpowder, made into paste with spirit of wine; when in a state of drying, run a needle through the centre, and take care the hole is left open, for, on the tube being inflamed, a stream of fire darts through the aperture with such force as to perforate the cartridge. The mortar should then instantly be fired, and in order to lessen a difficulty that has often occurred in performing this service, a pistol may be used, having a tin box over the lock, to exclude the effect of wind or rain on the priming; and the muzzle being cut [obliquely], dilates the inflammation, so as to require but little exactness in the direction of the aim.

"We will suppose the communication to be secured, although it is scarcely necessary to offer any other assistance than that of a rope, as the inventive genius of a sailor will supply every thing else, yet I could expect the people on shore to get a boat ready for meeting the vessel when driven on a beach; it is the promptest and most certain method of relief, as well as the most easy to be accomplished, for by hauling her off with the rope projected, the boat's head is kept to the waves, and not only insures safety by rising to the surge, but prevents her upsetting."

Again, p. 59.—"When the rope attached to the shot (not having barbs to it) is fired over the vessel and lodges, let it be secured by those on board, and made fast to some firm part of the rigging or wreck that they may haul off a boat by it; but should there not be any boat, then haul on board by the projected rope a larger one, and a tailed block, through which a smaller rope is rove. Let the large rope be made fast at the mast head, between the cap and the top of one of the lower masts, and the tailed block a little distance below it; but, if the masts should have been cut or carried away, then it must be made fast to the loftiest remaining part of the wreck. When this is done, there will be supplied from the shore a cot, hammock, netting, basket, hoop, or any of the numerous resources of seamen, which will run on the larger rope, and be worked by the people on shore. If a cot be used, the men may be so securely fastened to it, as to preclude all possibility of falling out, and then be brought from the wreck, one by one, in perfect safety."

P. 47.—"While communication is gaining, three

Life Pre-  
servers.

stakes should be driven into the ground in a triangular position, so as to meet close at the heads to support each other. As soon as communication has been effected by the crew of the vessel, and they have secured the line attached to the shot, made fast to these stakes, and the crew will haul on board by it a large rope and a tailed block, through which a smaller rope is to be rove, both ends of which (the smaller rope) are to be kept on shore. When they have secured these on board, and the larger rope is rove through the rollers, let a gun tackle purchase be lashed to it, then lash the purchase to the stakes. By the means of the purchase, the larger rope may be kept at a fit degree of tension; for, if care be taken to slacken the purchase as the ship rolls out to sea, the danger of the rope being broken will be guarded against; and on the other hand, if the purchase be gathered in as the ship rolls toward the shore, the slackness of the rope, which would prevent the cot traversing as it ought to do, and plunge it in the water more than it otherwise would, will be avoided." (Plate CX. fig. 9.)

P. 59.—"Supposing neither boat nor cot apparatus at hand, first cast off the shot from the projected rope, and with a close hitch, thus (Plate CX. fig. 17), let it be put over the head and shoulders of the person to be saved, bringing it close under each arm, drawing it tight, OBSERVING PARTICULARLY THE KNOT IS ON THE BRESTBONE; for, by having the knot in that position, on the people of the shore hauling the person from the wreck, he will naturally be on his back, consequently, the face will be uppermost to seize every moment for respiration, after each surf has passed over the body. If circumstances compel recourse to this method, care must be taken to free the rope from any part of the wreck, and to jump clear away; but should there be more than one on board, each man should make himself fast in the same way, above four feet from the other, and join hands, all attending to the same directions."

P. 61.—"For giving Relief to Vessels Stranded on a Lee shore in a Dark and Tempestuous Night. It will be requisite, first, to devise the means of discovering precisely where the distressed vessel lies, when the crew are not able to make their situation known by luminous signals; secondly, to produce a method of laying the mortar for the object, with as much accuracy as in the light; thirdly, to render the flight of the rope perfectly distinguishable to those who project it, and to the crew on board of the vessel, so that they cannot fail of seeing on what part of the rigging it lodges, and consequently have no difficulty in securing it."

"To attain the first object, a hollow ball was made to the size of the piece, composed of layers of pasted cartridge paper of the thickness of half an inch, having a lid on the top to contain a fuze (Plate CX. fig. 3), and it was then filled with about fifty luminous balls of star composition, and a sufficient quantity of gunpowder to burst the ball and inflame the stars. The fuze fixed in the ball was graduated, to set fire to the bursting powder at the height of 300 yards. Through the head of the fuze were drilled holes, at equal [distances], to pass through them strands of quick match, to prevent the

possibility from any accident of the match falling out, or from its not firing the fuze.

"On the stars being released they continued their splendour while falling, for near one minute, which allowed ample time to discover the situation of the distressed vessel.

"During the period of the light, a stand, with two upright sticks (painted white, to render them more discernible in the dark), was ready at hand, and pointed in a direct line to the vessel." (Plate CX. fig. 7.)

"A shell, affixed to the rope, having four holes in it, to receive a like number of fuzes (headed as before described), and filled with the fiercest and most glaring composition, which, when inflamed at the discharge of the piece, displayed so splendid an illumination of the rope, that its flight could not be mistaken." (Plate CX. fig. 22.)

P. 66.—"To get a Boat from a Beach over the Surf. The importance of going to the relief of ships in distress at a distance from the land, or for taking off pilots, was viewed as of the highest consequence by the Elder Brethren of the Trinity House, and offered to my particular attention by several distinguished characters. After numerous experiments to accomplish it in various ways, the mode following was most approved. About forty fathoms of two and a half inch rope, made fast to two moving anchors, was laid out parallel with the shore, at a distance beyond the sweep of the surf; to the centre of this rope was made fast a buoy of sufficient power to suspend the great rope, and prevent it from chafing on the sand, rock, or stones, as well as embedding, a circumstance that has rendered it impossible, on a sandy or shingly coast, to heave out an anchor with a rope to it from the shore. As this service should be performed in fair weather (to be prepared for the storm), it may be regulated with the greatest exactness, and should take place at the top of high water, that the upper part of the buoy may be at the full stretch of its power, and only seen at that time. (Plate CX. fig. 10.)

"Should the shore be extremely flat, it will be desirable to place another set at a sufficient distance beyond the first, to ensure the operation of this method in any state of the tide."

P. 71.—"The royal mortar being brought to the spot, is to be pointed in the direction for the buoy, and should be laid at a very low elevation, but such as to insure the range; for the more it is depressed, the less slack of rope there will be from the parabola formed in the shot's flight; the basket with the rope ready laid (having a barbed shot to it) is to be placed in the front of the mortar; on its being fired, instantly haul the slack of the rope in, to prevent the effect produced on it by a strong tide. Which being done, let the remainder be gently hauled in to insure the shot's grappling with the great rope; when that is caught and hooked, a power will be acquired fully adequate to the service. (Plate CX. fig. 16.)

"As a cast-iron anchor appears particularly adapted to this method, and would be much cheaper than hammered, the following is a plan of one which the Honourable the Navy Board approved, and allowed

Life Pre-  
servers.

Life Pre-  
servers.

me to cast at their expense, for the purpose of making the experiment." (Plate CX. fig. 20.)

P. 43.—"When a vessel is in that extreme and perilous situation, driven under a rugged and inaccessible cliff, and in danger of going soon to pieces, the most prompt method I should suggest is, by lowering to the crew a rope with stiff loops spliced into it, at the distance of a foot and a half from each loop, of sufficient size to contain the foot, by which they can ascend as a ladder. (Plate CX. fig. 6.)

"This rope ladder is capable of being projected; and one of an inch and half rope was thrown from a mortar 194 yards. It might also, from the simplicity of its structure, be extremely useful in escaping from a house on fire. By making one end fast to the leg of a bed or a table, the person would come down from the window in safety, and with much less difficulty, and quicker than with the common rope ladder, which is heavier and more unwieldy. It has great advantages when employed in saving shipwrecked men in situations just described, when, from extreme cold, and almost benumbed limbs, it would be impossible for them to climb up a rock, or ascend it even by the aid of a common rope. The holds, thus spliced in, will support both hands and feet."

The Report of the Committee of the House of Commons contains also a paper of instructions for the managers of Captain Manby's apparatus on shore, which are somewhat more minute than the directions published in his Essay. For example, p. 13,

"If the wind be sideways to the shore, the mortar must be pointed sufficiently to windwards to allow for the slack of the rope lighting on the object, as the rope will, of course, be borne considerably to leeward by the effect of a strong wind."

"The distance your judgment decides the vessel to be from the shore, should regulate the charge of powder as stated in the scale,—taking just a sufficient quantity to clear the object; an attention to this will be more certain of your effecting communication, and guarding against the danger of the rope breaking, or any other circumstance that might prevent the successful performance of the service. The elevation of 15 degrees is to be preferred, particularly if the wind is sideways, pointing the mortar sufficiently to windward, as the rope would then fall against the weathermost part of the rigging of the stranded vessel."

"When a vessel is driven on shore in the night, you will flash gunpowder as often as convenient on your way; this will animate the crew, and denote to them you are coming to their assistance. On getting to the spot where you have reason to suspect the vessel lies, as you are not able to discover her from the extreme darkness, and if the people on board cannot [make known] their situation by luminous signals or noises (which they will be directed to make if possible), you will lay the mortar at a very high elevation, and fire a light ball."

"Just before you fire (the rope) it would be advisable to let off a blue light to put the crew on their guard, to look out, and be ready to secure the rope. The service can be performed with a carronade."

In p. 15, Ch. IV. we have a copy of Directions to persons on board vessels stranded on a lee shore, proposed to be delivered to the masters at the custom house. It is observed, that even snapping a pistol, when the powder is wet, may sometimes afford a signal visible on shore, from the sparks of the steel alone. The other parts of the directions will be easily supplied by those who understand the principles of the proposed mode of relief.

The last description of the inventions to be considered with regard to the preservation of lives, in cases of shipwreck, is that of Life Boats which are of such a construction as to be incapable of sinking even when filled with water. The occasional adaptation of the common boats of the ship to such purposes, by means of empty casks, has been already considered. But the boats now in question are supposed to be kept on shore at proper stations, and manned by active persons, who are in the habit of exerting themselves for the relief of seamen in distress.

Mr Henry Greathead, of South Shields, received a gold medal and fifty guineas from the Society of Arts in 1802, and a Parliamentary reward of L. 1200, besides further remunerations from the Trinity House, and from Lloyd's Coffee-House, for his invention of a life boat, which is described in the *Transactions of the Society*, Vol. XX. p. 283. The length of this boat is thirty feet, its breadth ten, and its greatest depth about three, besides a general curvature which nearly doubles the depth, as reckoned from the ends; the convexity below being intended to give it a greater facility of turning, and a greater power of mounting on the waves without submersion of the bow, which would increase the resistance, though it would not sink the boat; the breadth is also continued further than usual fore and aft, in order to contribute to the same property. The gunwale projects some inches, and the sides below it are cased with pieces of cork, amounting in the whole to seven hundred weight, which are secured by plates of copper. There are ten short oars of fir, fixed on pins to the gunwales, and a longer oar for steering at each end, both ends of the boat being alike. It is painted white, in order to be more conspicuous, and a carriage is provided, for conveying it over land when required. The description is accompanied by documents of the preservation of two or three hundred men by the boats of South Shields and North Shields, which were built in 1789 and 1798 respectively.

Mr Christopher Wilson received a gold medal in 1807, for a life boat with air gunwales, which was tried at Newhaven, and was said to be lighter and more manageable than Mr Greathead's. (*Transactions*, XXV. 55.)

"Little is required," says Captain Manby, p. 73, "to establish the importance and advantages that will result from giving every boat the properties of a life boat, particularly when taken into consideration that it can be produced at a very trifling expense."

To illustrate the method of giving the properties of preservation to any boat, I have selected the representation of a man of war's jolly boat, fitted up

Life Pre-  
servers.

to make experiments thereon, by permission of the Honourable Commissioners of the Navy Board. (Plate CX. fig. 25.)

“To give it buoyancy, empty casks were well lashed and secured in it. For the advantage of keeping it in an upright position, launching from a flat shore, beaching, and to resist upsetting, it had billage boards of equal depth with the keel, and when a good sized piece of iron or lead was let into, or made fast to the keel, if any accident did upset the boat, it immediately regained its original posture. A stout projecting rope, with swellings upon it to increase its elasticity, surrounded the gunwale, served as a fender, and prevented it being stoved in lowering down, or when driven in contact with the vessel it might be going to relieve.

“The boat thus described had the plug out, and was filled with water until it ran over the gunwale, when a crew of four, with myself, tried it in every way, and found from the buoyant property of the casks, it kept the boat so much above the water's edge, that it was rowed with the greatest ease, and was capable of performing any service required.”

Mr J. Boyce, in 1814, obtained a medal for his life boat and safety buoy, consisting of hollow cylinders, made of canvas, painted and varnished, and connected with each other. It was tried on a river, and carried a man with safety (Vol. XXXII. p. 177); but surely it could not be trusted among breakers on a lee shore. In 1818, Mr Gabriel Bray obtained a silver medal for his invention of a boat filled with air boxes, under the seats and along the sides. (Vol. XXXV. p. 172.)

Captain Manby's proposal for throwing ropes from ship to ship in cases of accidents, may easily be understood from the methods which he employs for saving lives in shipwrecks. Mr Thomas Cook's *life buoy* is related to the same class of inventions; its object is to preserve the life of a person falling overboard in the night by means of a floating light; and it obtained him a gold medal from the Society of Arts in 1818. (*Transactions*, XXXVI. p. 121.) He observes that a ship may often have to run half a mile before she can get about, and lower a boat; so that it becomes highly desirable to afford a temporary support to the sufferer. The machine consists of two casks, with a pillar between them, carrying a composition of portfire, to be lighted by a lock when the accident happens, and to serve as a rendezvous to the man and the boat. He found that it might be lighted, and let down into the water in the short time of five seconds; being always kept suspended in a proper manner between the cabin windows at the stern of the ship. Mr Miller's safety poles for skaters, and Mr Prior's mode of preventing accidents in descending mines, are mentioned in the *Transactions of the Society of Arts*, Vols. XXXII. and XXXVI.; but they do not require more particular notice on the present occasion.

A sketch of the expedients which have been recommended for the preservation of mariners, published in a work entitled, *Shipwrecks and Disasters at Sea* (3 vols. 8vo. Edinb. 1822, Vol. III. p. 459), contains a few further historical details relating to some of the inventions which have been described.

(V. N.)

PRINCE OF WALES'S ISLAND, called also PULO PINANG, or BETEL NUT ISLAND, an island situated off the west coast of the Malay peninsula, from which it is separated by a narrow strait, about two miles broad, which forms the harbour, and affords excellent anchorage for the largest ships. There is also an inner harbour, where ships may receive every kind of repair that can be performed without going into dock. The principal entrance into the harbour is from the north-west; but there is also a fine channel to the southward.

This island is of an irregular four-sided figure; the north side being the longest, and the south the shortest. It is near five leagues in length, and is seven or eight miles in breadth. Throughout the centre of the island there is a range of lofty hills, decreasing in magnitude as they approach the south; and from these flow numerous fine streams, which supply the island abundantly with water.

The soil of this island is various, generally a light black mould, mixed with gravel, clay, and in many parts sandy. The whole island had been for ages covered with an immense forest, from which originated a fine vegetable mould, formed by the decayed leaves, which, as the woods were cleared, and the surface exposed to the weather, in a considerable degree disappeared; but the soil in the interior is still equal to any sort of cultivation. These forests produce excellent timber for ship building, and supply

masts of any dimensions; lower masts of one piece having been procured here for a 74 gun ship. Much of the north, and nearly the whole of the south and east sides of the island, are in a state of cultivation. The principal productions are pepper, betel-nut, betel-leaf, cocoa-nuts, coffee, sugar, paddy, ginger, yams, sweet potatoes, and a great variety of vegetables. The fruits are the mangosteen, rambosteen, pine apples, guavas, oranges, citrons, pomegranates, &c. The exotics raised here are cloves, nutmegs, cinnamon, pimento, kyapootee, colalava, and a number of other plants from the Moluccas and eastern isles. Pepper is the chief article of cultivation: the quantity raised in 1804 was calculated at two millions of pounds. The elastic gum vine (*Urceola elastica*) or American caout-chouc, is found in great plenty on Prince of Wales's Island. It is about the thickness of the arm, almost round, with a strong ash-coloured bark, much cracked and divided longitudinally, with points at small distances, that send out roots, but seldom branches. It creeps along the ground to the distance of more than 200 paces, and then ascends among the branches of high trees. The milky juice of the vine is drawn off by wounding the bark, or by cutting the vine in pieces. The best is procured from the oldest vines, which will yield two-thirds of their weight of gum. The chemical properties of this vegetable milk surprisingly resemble those of animal milk.

Prince of  
Wales's  
Island.

This island was originally granted to the East India Company by the King of Queda, at the request of Captain Francis Light, who had married his daughter. The Bengal government seeing the island so peculiarly adapted as a mercantile station for vessels from all the Malay ports, the Moluccas, Borneo, Celebes, and the Philippine islands, did not hesitate to accept the King of Queda's grant; conceiving that, by an establishment properly secured, the Bengal trade, with that of China, would be connected: and, from the conduct of the Dutch, it became necessary to have a port where the country ships might meet the eastern merchants, as well for the promotion of that valuable commerce, as to afford a windward station of refreshment and repair to the king's, the company's, and the country ships. A small detachment was accordingly sent from Calcutta, under the command of Captain Light, who took possession of the island in the name of his Britannic Majesty, and for the use of the East India Company, on the 12th of August 1786. He immediately commenced clearing the country, and began the construction of a small fort for the protection of the detachment against any attempts of the Malay powers, who might be instigated by the Dutch at Malacca, or induced, by the fickleness of their own disposition, to cut them off. Captain Light was authorized to receive such colonists as he might judge expedient; to allot such a portion of land to each family as circumstances would admit; and, as an encouragement to trade, the port was made free to all nations. In a very short space of time, numerous adventurers flocked to the settlement, some with the intention of remaining, others merely with a view of traffic. These finding a ready sale for their goods, and meeting with the merchandise they required in return, the commerce of the port rapidly increased: a town, called George Town, was marked out, and within the year there were upwards of sixty Chinese families living in it, besides great numbers of Malays, Buggesses, and other Eastern traders. The settlements continued in a progressive state of improvement, both in regard to its population and cultivation. In the year 1797, there were 6937 inhabitants on the island, exclusive of Europeans and the garrison; and in 1801, they had increased to 10,310, of which 1222 were slaves. In 1805, the inhabitants of all descriptions were estimated at 14,000, and have since been progressively increasing, and exhibit an uncommon diversity of races. Here are to be seen British, Dutch, Portuguese, Americans, Arabs, Parsees, Chinese, Chulias, Malays, Buggesses, Birmanians, Siamese, Javanese, &c. &c. The settlement having risen in importance, the company, in 1805, determined to constitute it a regular Government, subordinate only to the Governor-general of India; but, on account of the enormous expence incurred by the establishment, some modifications were made in it in 1808.

The fort, which is called Fort Cornwallis, is built on the north-east point of the island. It was originally badly constructed; and large sums have been spent upon it without completing it. It is incapable of defence, from its size and construction. In the fort are barracks for the military, the arsenal, maga-

zine, and military store-houses. The sea has of late years made encroachments on the north face of the fort, and along the esplanade, and for upwards of a mile in that direction. The town, called George Town by the English, and Panjang Panaique by the Malays, is of considerable extent. It is bounded on the north and east by the sea, on the south by a small river, and on the west by the high road. The streets, which cross each other at right angles, are spacious and airy; but having been at first merely lined out, without being either raised or drained, were frequently impassable after hard rain. This inconvenience has been removed, as the principal streets are now properly raised and drained; and the town has in consequence improved much in appearance and cleanliness. There is a large pier for landing and shipping goods, to which fresh water is conducted by pipes. Since the island has become the seat of government, considerable alterations have taken place in every department. A government house, a church, a jail, and several substantial bridges, have been built; the fortifications have been improved and strengthened, and the public roads repaired and widened. The markets are well supplied with fish of various kinds, and of excellent quality; poultry of all sorts, pork, grain of every description, and a great profusion of fine fruits and vegetables. The beef and veal are not of a good quality; sheep are imported from Bengal and the coast of Coromandel; goat mutton is procured from the Malay peninsula and Sumatra. Milk, bread, and butter, are very dear, and the first very scarce. Almost all the country ships bound to the eastward, particularly those for China, touch here, where they refresh and purchase such articles of trade as they have room for. The East India Company's ships bound to China touch also here, and load large quantities of tin, canes, rattans, sago, pepper, betel-nut, birds' nests, &c. for the China market, as also to serve for dunnage for their teas to Europe.

The imports from Europe, either directly or from the other Presidencies, are generally European manufactures in iron and steel; such as anchors, cutlery of all sorts, fire-arms, nails; also tin-ware, patent shot, sheet lead, sheet copper, iron in bars, boots and shoes, cables, canvas, cabinet-ware, cloths and cassimeres, glass-ware, hats, haberdashery, hosiery, musical and mathematical instruments, oilman's stores, painters' colours, plated-ware, watches, malt liquor, and European wines of all sorts. The value of the goods imported from England amounted in 1807 to L.76,000; in 1810, to L.38,253. Large quantities of Bengal and Madras piece-goods are imported for the Malay trade, and the consumption of the European residents. The other articles imported are opium, grain, tobacco, red wood, sandal wood, shark fins, myrrh, pepper, rice, betel-nut, benzoin, camphire, gold dust, elephants' teeth, &c. A great many of these commodities are re-exported to Sumatra, Ceylon, and the other Indian islands; also to China, to Bengal, and Coromandel. Long. of the north-east point, 100° 19'. E. ## PRINTING.

Printing.

THE article PRINTING, in the *Encyclopædia*, brings down the history of this invaluable art to the year 1790, and describes the presses and other implements in use at that period. In this article it is proposed —1. To give a short detail of the principal improvements which have since taken place; and 2. To give some account of Stereotype printing, a slight notice only of which is contained in the *Encyclopædia*.

Few of the mechanical arts seem to have made such rapid progress to perfection as that of printing. For centuries after the invention little seems to have been attempted in point of improvement, and nothing discovered of material use; indeed, in all the essentials of printing, many of the earlier productions of the press equal any thing that has since been produced. The printing-press, used in the infancy of the art, remained without improvement till about 1620, when William Jansen Bleaw, of Amsterdam, fabricated the press, which, till very lately, was in universal use; and till the beginning of the eighteenth century, and the establishment of the elder Caslon's letter-foundry, the printers of Britain imported nearly all their types from Holland.

William Caslon, to whom English typography is so much indebted, was originally an engraver of ornaments on gun-barrels, and was first employed to make punches for an Arabic New Testament in 1720. Under the patronage of Mr Bowyer, he, in 1722, cut the beautiful English letter which was used in printing Selden's works, 1726; and after improving the art of letter-founding, in all its parts, and carrying on an extensive business for nearly half a century, he died in 1766, leaving a son, by whom the foundry was carried on, and individuals instructed by him, who still further improved the art of letter-founding. The chief of these was Joseph Jackson, who cast a fount of letter for the Domesday Book, and furnished the types for the *Bible* published by Mr Macklin. Mr Jackson died in 1791. (Nichols's *Lit. Anec.* Vol. II. p. 355.)

Another individual, who acquired some celebrity in his attempt to improve English typography, was John Baskerville. Mr Baskerville was born at Wolverley, in the county of Worcester, in 1706. He was trained to no occupation, but in 1726 became a writing-master in Birmingham. He afterwards betook himself to the occupation of a japanner; and in 1750 turned his attention to printing. He manufactured his own paper, types, and ink; and his first attempt was a 4to edition of Virgil, printed in 1756. He obtained leave from the University of Cambridge to print a *Bible* in royal folio, and two editions of the *Book of Common Prayer*, in three sizes, for which permission he paid a premium to the Society. The *Bible* was printed in 1763. He also printed, in royal 4to, editions of Terence, Catullus, Lucretius, Sallust, and Florus. Mr Baskerville died in 1775, and his types, &c. not finding

purchasers in England, were sold to a Literary Society in Paris, for L. 3700. (Nichols's *Lit. Anec.* Vol. III. p. 450.)

Printing.

The exertions of Caslon and of Baskerville to improve the form of the types and render the letter-press more attractive, were not without their effect in introducing a taste for superior printing. Bodoni of Parma, Didot of Paris, and Bensley of London, successively called the public attention to specimens of typography, of an elegance till then unknown; and the grandsons of the first Caslon had the merit of producing specimens of types, which showed that even the form of the letters might be altered with advantage. Messrs Caslon and Catherwood published their specimens of these improved types in 1803: William Caslon junior began his improvements about the same period; and they were speedily followed by Messrs Fry and Steele, and all the other letter-founders in London. These improvements consisted chiefly in the hair-strokes of the letters being made finer, and the main body, or stalk, bolder. Many of the double or tied letters were also at this time discarded, such as the sh, ss, st; and the long s was finally exploded. The form of the letters was also improved, by rounding the terminations of several which formerly ended in acute angles; and the Italic types, in particular, were so much altered, as to present the appearance of beautiful writing.

When the taste for printing in better style began to gain ground, it was soon found that the common press was deficient in the necessary power to produce a sharp and beautiful impression of the types. Besides this want of power, which rendered the operation of printing a very severe one for the workmen, it had another palpable defect in its only printing half the sheet of paper at one pull. Many attempts were of course made by individuals to remedy these defects, and with various success. One of the first of these was an improvement of the French Press, which took its rise in France. It was a wooden press of the ordinary construction, except that the platen was formed of an iron plate instead of wood, and made sufficiently large to print the whole side of the sheet of paper at once. The under surface of this plate was covered with brass. The screw or spindle, instead of being turned by the bar or lever in the usual manner, was united by connecting rods with a strong lever placed at the side of the press, and it was worked by the man applying both hands to the lever to bring it down, nearly by the same action as working the lever of a common pump. But although additional power was thus procured, the exertion required from the workmen rendered this press unfit for general use.

In the year 1796, Thomas Prosser, of London, Mr Prosser's obtained a patent for an improvement of the printing-press. The chief feature of this invention was an attempt to increase the power by the addition of a spring between the cap and head to resist the

Printing. pressure upwards, and a similar one under the lower board or winter, to resist the pressure downwards. (*Repertory of Arts*, Vol. VIII. p. 368.)

Mr Row-  
orth's Press.

Another improvement adapted to the common press was made by Mr Roworth, a printer in London, which he is said to have found successful in a long course of practice. Instead of the screw, Mr Roworth substituted a plain vertical spindle, furnished with a bar, hose, &c. as in the common press: but the upper part, where the thread of the screw is usually cut, was a plain cylinder, fitted into a socket in the head of the press. Upon the upper end of the spindle, just beneath the head, a short cross arm is fixed, which acts against a circular inclined plane, fixed under the head of the press. On turning the bar or lever, this short arm, by its action on the inclined plane, causes the spindle to descend in the same manner as the screw; but with this advantage, that the inclined plane is formed so as to give a rapid descent to the spindle when the action first begins; and when the platen comes in contact with the tympan and types, and the pressure is begun, the plane has a very slight inclination, and a power which increases as the resistance increases. The inclined plane and cross arm of Mr Roworth's press are formed of hardened steel.

Mr Brown's  
Press.

In 1807, Mr John Brown, of London, obtained a patent "for improvements in the construction of a press for printing books and other articles, part of which may be applied to presses now in common use." Mr Brown's press is of iron; the pressure is produced by a screw, which is put in action by a bevel-wheel and pinion. The handle which gives motion to these is fixed on a spindle, or shaft, attached to the side of the press. Another handle which moves the bed with the types, likewise puts in motion two rollers or cylinders, covered with flannel or any other elastic substance, and this again with parchment or vellum, which rollers revolve and feed the types with ink. Mr Brown, from the specification of his patent, seems to consider this mode of inking the types as his chief improvement, and applies his invention to the common press by means of a fly-wheel or treadle, which puts in motion the two rollers or inking cylinders. (*Repertory of Arts*, Second Series, Vol. XIV. p. 368.)

The Stan-  
hope Press.

But the most successful improvement upon the printing-press was about this period made by the late Earl of Stanhope, whose genius for mechanics led him to turn his attention to this important machine. The Stanhope Press, as it is named from the inventor, is formed of iron, and prints the whole surface of the sheet of paper at once. The most important part of his Lordship's invention, however, consists in his having obtained, by a combination of levers, the requisite power for this purpose, without the excessive labour of the common press, where the lever or bar is fixed upon the axis of the screw. It consisted in applying a short lever upon the top of the screw of the press, and connecting it by a link with the extremity of another lever, which was fixed upon the top of a spindle or axis placed parallel to the screw. To the lower end of this spindle the handle or lever for working the press was attached; and the relative position of the levers was such, that

when the workman first pulls the handle towards him, the platen is moved or brought down with a considerable velocity; but on arriving at the point where the pressure is required, the levers have changed their position in such a manner as to operate upon the platen with a very slow motion, and a power immensely great. This principle has been employed, with certain modifications, in almost every description of printing press that has been brought forward since the date of Lord Stanhope's invention. (See Plate CXI. figs. 1, 2, 3, and *Description*, for the details.)

A Stanhope press of a new construction was afterwards invented by Augustus Frederick de Heine, of London, and a patent procured for it in 1810. The principle of this invention is the application of two sectors, or a sector and a cylinder, or a sector and a roller, to move one against the other by a single or compound lever. Mr de Heine's press is of iron, as the Stanhope press; the only material improvement being the substitution of a spiral or curved inclined plane in place of the screw. In turning the lever, the piston attached to the platen is depressed as by the common screw, but with this difference, that as the descent of the piston increases in velocity, the power increases in the same proportion. In the screw the descent is equal, and the power, of consequence, equal. The lever is fixed to a moveable spindle, and a regulating screw is fixed at the top. A discovery similar in many respects to this had been made, as formerly mentioned, by Mr Roworth, and adapted to the common press; but Mr de Heine had the merit of combining it with the iron frame and levers of Lord Stanhope's machine. (*Repertory of Arts*, Second Series, Vol. XVI. p. 321.)

Mr Peter Kier, of Camden Town, also made some improvements upon the construction of the Stanhope press, which have been considered as contributing much to the accurate performance and durability of the machine. A cylindrical hole is bored in the centre of the press, and into this a cylinder is accurately fitted, the platen being fixed on its lower end. To prevent the cylinder from turning round, a flat side is made to the cylinder, and a bar of iron is screwed across the two cheeks, which bears against the flat side of the cylinder. Another improvement is in the spindle to which the handle is fixed. This has a screw cut upon its lower end, which is fitted into a nut, and thus, when it is turned round, the spindle rises and falls a quantity equal to the descent of the main screw in the same period. By this means the connecting lever always draws in a horizontal direction. In the other presses one end remains at the level while the other descends, which occasions the joints to wear irregularly.

Mr Brooke, of London, about the same time applied the compound levers of the Stanhope press to the common press with much success; but as the wooden frame of the old press is not calculated to afford the same resistance as those constructed of iron, the power of these presses is, of course, much inferior. Mr Brooke's improvement, however, has been pretty universally adopted.

Mr Medhurst, of London, is also the inventor of a printing-press of great merit, from the simplicity of

Printing.

De Heine's  
Press.

hurst's Press.

Printing. its construction, and which has nearly the same advantage in point of power as that of Lord Stanhope. It is a common press in all its parts, but the platen is made the full size of the sheet, and instead of a screw a plain spindle is employed. On the lower part of the spindle, just above the bar or lever, a circular plate is fixed, which affords steps for the points of two iron rods which extend up to the head, and are there supported by their points entering sockets. When the platen is up, these rods stand in an inclined position; but when the spindle is turned by the lever, the circular plate in which the lower end of the rods rest turns round likewise, and the upper end remaining stationary, they come into a vertical position, in which motion the spindle and attached platen are forced to descend in the same manner as though a screw were employed. This motion seems to have every advantage of the Stanhope levers or Mr Roworth's press, without the friction of either; for the power increases as the resistance, and when the rods come nearly parallel to the spindle, or in a vertical position, it is immense.

Mr Ruthven's Press. In 1813, Mr John Ruthven, of Edinburgh, took out a patent for a printing-press, by which the necessary power is produced by a combination of levers alone. This ingenious mechanist, from being himself a printer, had long observed the defects of the common press, and set himself to remedy them; but finding this impracticable to the extent he wished, he at last succeeded in producing the printing-press which now goes by his name. Mr Ruthven's press differs from all those formerly invented, in the platen being movcable and the types stationary. The platen is the size of the sheet to be printed; there is no central pressure, the platen being drawn down by the two ends; and the resistance, being sustained against the under side of the table, affords complete security to all the parts. But the construction and appearance of this press will be best judged of by a reference to the plate. (See Plate CXII. figs. 4, 5, 6, and *Description*.)

Mr Ruthven makes these presses of all sizes, from a cubic foot to the largest newspaper size; and by an ingenious application of the same principle, has formed very useful machines for copying letters, printing from stone, &c.

Columbian Press. What is called the Columbian press is also formed to operate by a combination of levers, and is probably the most powerful of any of those constructed on this mechanical power. This press, which is now very generally introduced, was invented in 1814 by Mr George Clymer of Philadelphia. Its success in America induced the inventor to come to London in 1818, where he established a manufactory for its fabrication; and the trials it received there in some of the largest printing-offices, soon called the attention of the trade to this ingenious machine. A front and side view of it are given in Plate CXI. figs. 7, 8, from which its movement will be readily understood. The ornaments, which are formed upon the castings of the frame and levers, and which give this press so distinguished an appearance, are, however, omitted in the engraving, on account of the diminished scale of the figures.

Printing. Another press of American invention has been lately imported into this country by Mr David Barclay, who has obtained a patent for it. The power in this machine is produced by a wedge acting upon two cylinders, which again act upon inclined planes. The construction of this press is sufficiently simple, and it is said to work well, and with much ease to the workmen. (See Plate CXII. figs. 1, 2.)

Barclay's American Press.

As adapted to the improved presses which are capable of printing double sized sheets of paper, it may be farther mentioned, that Mr Thomas Curson Hansard of London invented dividing tympan, which, in the process of printing, cut such double sized sheets to the ordinary size. This invention was secured to him by patent dated the 1st of November 1817. (*Repertory of Arts*, Vol. XXXIII. Second Series, p. 257.)

These are the chief improvements which have been made in the construction of the printing-press within the last thirty years; and previous to that period little or nothing had been done to improve this useful machine. But not only was ingenuity successfully applied to increase the power, and lessen the labour required in working the common press, but attempts were made, and with more success than had been anticipated, to render manual labour in this department of printing almost unnecessary, by the invention of machinery.

Machine Printing.

The late Mr William Nicholson of London was, it is believed, the first who proposed the introduction of a machine for printing, which should supersede entirely the ordinary press. He obtained a patent, dated the 29th April 1790, "for a machine or instrument for printing on paper, linen, cotton, woolen, and other articles, in a more neat, cheap, and accurate manner than is effected by the machines now in use." A description of this machine, illustrated by figures, is inserted in the *Encyclopædia*; but as far as regards book printing, Mr Nicholson's invention was found impracticable, as it required the types to be so formed as to be fixed upon the surface of a cylinder. The ink was supplied by a cylinder or roller covered with soft skin, and stuffed with hair or wool, and the quantity was regulated by smaller cylinders, which acted so as to distribute it equally upon the larger one. This last part of Mr Nicholson's invention, however, or the idea of inking the types in printing by means of a roller, in place of the balls formerly used, has been since improved upon, and is now universally adopted.

Nicholson's Machine.

Another machine for printing was invented by Messrs Bacon and Donkin, for which they obtained a patent in the year 1813. This machine is so far different from Mr Nicholson's, that in place of the types being required to be cast so as to be arranged on the surface of a cylinder, they are firmly fixed in pages or galleys upon the surface of a revolving prism, having four, five, or any required number of sides. This prism is mounted in a frame so as to be capable of turning round on its axis, and is called the Printing Prism. Beneath this a revolving platen is mounted on an axis, the circumference of the platen being so formed, that it always keeps in con-

Bacon and Donkin's Machine.

Printing.

tact with the surface of the types or blocks upon the printing prism. The types being inked, and the machine put in motion, the paper to be printed passes between the prism and the platen, and thus receives the impression. The ink is applied to the types by means of a roller or cylinder with an elastic surface, which is formed so as to turn round in contact with the printing prism. But the structure of the machine will be best understood from the plate and accompanying *Description*. (See Plate CXIII.)

Shortly after the patent was procured, one of these machines was employed by the University of Cambridge for printing *Bibles* and *Prayer Books*; but its structure, though very ingenious, was too complicated, and too liable to derangement, to give any hopes of its being generally adopted; and the subsequent invention of a machine upon a different principle, and of which the moving power was steam, has rendered prior inventions of comparatively little value.

Bensley's  
Machine.

This ingenious application of machinery to the operation of printing was the invention of M. König, a native of Saxony, and a printer. M. König is said to have, many years ago, turned his attention to this subject, though his first efforts were bounded to give an accelerated motion to the common press. Failing in his applications to the most eminent of the continental printers, he came to London about 1804, and submitted his scheme to several printers of repute in that city. By most of these his proposals were coldly received; till fortunately he was introduced to Mr Bensley, senior, who, judging favourably of M. König's plans, entered into an arrangement with him for the purpose of carrying them into execution.

Mr G. Woodfall and Mr R. Taylor now joined the projectors; but the former having soon retired from the concern, the remaining gentlemen persevered in their experiments to fabricate a press which should have accelerated motion, and render the work of a man to ink the types unnecessary. After many experiments, however, and considerable expence, it was discovered that the attempt to improve the common press could never be attended with any great results, and attention was now turned to printing by means of a cylinder.

After some years of renewed experiments, a small machine was at last produced, which promised to be successful. The principle of this machine was, that the operation of printing was performed by the sheet of paper passing between a large cylinder, which gave the pressure, and the form of types. In place of balls used by hand, rollers, covered with leather, as in Mr Nicholson's invention, were substituted; under which the form of types passed its way to the printing cylinder. The action of this model now showed the practicability of extending the same principle to a more powerful machine; and on exhibiting it to Mr Walters, proprietor of the *Times* newspaper, and pointing out the further improvements which had suggested themselves, an agreement was entered into with that gentleman for the erection of two large machines for printing his journal. The machines were accordingly erected; and so secret had been the operations of the patentees, that the first intimation of their invention was given

to the public in the *Times* of Monday, the 28th of November 1814, the reader of which was told that he then held in his hand a newspaper printed by machinery and by the power of steam.

Printing.

The next step in the improvement of the machine was to fabricate one which should print both sides of the sheet at once; the first one erected being merely calculated to do this in succession, or one form of types after the other. A machine on this principle was accordingly erected for Messrs Bensley, complicated indeed, but not more so than might have been expected, from the difficulty of making the pages fall precisely on the back of one another. As the strained skins by which the ink was applied to the types were found unequal in their surface, the inking cylinders were now covered with an elastic preparation of glue and treacle, which has been found to answer completely. The patentees issued a prospectus, dated 18th March 1817, offering three different kinds of these machines at a high scale of prices; and besides the original purchase money, demanding a large annual premium. But the proposals were so extravagant, that they effectually operated to prevent their adoption by the trade.

Various individuals now turned their attention to the improvement and simplification of the machine, but with little success. At last, however, Mr Dryden, a judicious engineer, under the instructions of Messrs Applegath and Cowper, produced a machine similar in its capabilities to the one last mentioned, but much more simple in its construction. In the old machine it required upwards of 100 wheels to effect the purpose, which in this last improvement is performed by a tenth part of the number. Messrs Bensley's original machine, however, answered many useful purposes; and massive and complicated as it was, in comparison of the more recent improvement, they continued using it till the destruction of their establishment by fire in 1819. The fabricators of the present machine, however, had applied the inking apparatus invented by them to this machine, which, from its simplification, removed no less than forty wheels required to effect the same purpose by the old one. Even after the rebuilding of the premises, the machinery, which had been only partially deranged, was repaired, and worked for some time; but it has now given place to two machines erected on the improved plan, which appear indeed so simple in their operations, as apparently to be susceptible of but little further improvement.

The printing machine as now improved, besides being less cumbrous than that of M. König, produces work of better quality. The double or perfecting machine throws off 800 to 1000 sheets, printed on both sides, within the hour, and the single machine delivers 1500 or 1600 printed on one side. (*Literary Gazette*, No. 301.)

#### Inking Roller.

The old method of inking the types by balls, as described in the *Encyclopædia*, has been superseded by the use of elastic rollers, which fulfil the intention more completely, and with less labour to the workmen. The first idea of a roller for this

Inking  
Roller.

Printing. purpose seems to have occurred to Mr Nicholson ; this being a necessary part of the apparatus of the printing machine, for which he obtained a patent in 1790, and it has formed an appendage in every machine since proposed. At the first outset, the rollers were made of leather stuffed in the manner of a cushion ; but they were soon found to lose their elasticity and to grow hard, and by the unequal stuffing, to ink the types irregularly. A composition of glue and treacle spread upon canvas, which was used in some printing offices to cover the stuffed balls in place of skins or soft leather, was afterwards applied to a cylinder, and found not less admirably calculated for the operation of a machine, than for printing by manual labour at the ordinary press.

On the introduction of the inking roller, many devices were fallen upon to supply it regularly with ink. Of these it is scarcely necessary to give a detailed description in this place. An inking-table formed of a plate of cast iron, with a longitudinal trough or box at one end to contain the ink, seems best adapted to the purpose. A metal roller, in the centre of this trough, and of which a small part of the surface is exposed, turns in the centre of the trough of ink, and a steel bar along its upper surface, fixed by screws, regulates the quantity given out. The elastic roller, on being pushed up to the trough, receives a stripe of ink throughout its whole length, which is distributed equally over its surface, by rolling on the table before being applied to the types.

The roller is cast in a mould, upon a core of hard wood, which is mounted upon a light frame of iron, so as to revolve freely upon pivots, with two handles for the workmen to use it.

Mr Thomas Parkin of London has lately invented an apparatus to facilitate the operation of inking by composition rollers, which is said to be capable of being applied to most printing presses. Of this apparatus there is a sketch in Plate CXI. figs. 4, 5, and 6. But it has not yet been established for a sufficient length of time, to authorize a judgment to be formed of its superiority to the common mode of using the elastic roller.

STEREOTYPE PRINTING.

Stereotype printing (from στερεος, solid or entire, and τυπος a type) is the art of printing from solid plates instead of moveable types. Though printing from wooden blocks has been known for fifteen or sixteen centuries in China ; and although this was the first form in which books were printed at the invention of the art in Europe, yet the Chinese blocks, and other similar devices, are in reality only a species of engraving. The letters are cut in the block by the artist, and the impression is produced directly from it ; while in the formation of stereotype plates, a mould is first formed from the page of moveable types, and from this mould, a fac-simile of the original page is cast, from which the impressions are taken.

The history of stereotype printing has been hitherto involved in considerable obscurity ; and Hol-

land, France, and Scotland, have contested the merit of its discovery. The Dutch claimant was J. Vander Mey, father of the well known painter of that name, who resided at Leyden about the end of the sixteenth century. His pretensions were stated in the *Nieuw Algemein Konst en Letter Bode*, 1798, No. 232, in which it is asserted that the Dutch had been in possession of the art of printing with solid or fixed plates for above 100 years. With the assistance of Muller, the clergyman of the German congregation at Leyden, who superintended the correction, Vander Mey is said to have prepared and cast the plates for an edition of the *Bible*, which was printed in 4to, and the forms of which were in the possession of G. and J. Luchtman of Leyden. A folio edition was likewise prepared in the same manner with large margins, ornamented with figures, the forms of which were in the possession of Elwe, a bookseller at Amsterdam. Besides these, an English *New Testament*, Shaaf's *Syriac Dictionary*, 2 vols. 4to, and a small Greek *Testament*, were printed by Vander Mey in this manner ; but at his death the art of preparing solid blocks was said to have been lost, or not afterwards employed on account of the expence. (*Tilloch's Philosophical Magazine*. Vol. X. p. 275, 276.)

Such are the pretensions of the Dutch to the honour of the invention of printing by means of stereotype. But unfortunately for this claim, M. Camus, who published two papers on Polytype and Stereotype in the *Memoirs of the National Institute of France* (Vols. III. and V.), in his anxiety to do justice to the merits of a countryman of his own, was led to make some inquiries regarding the existence of Vander Mey's plates of the *Bible*. The result was, that he found these plates were still in existence, and in the possession of Messrs G. and J. Luchtman of Leyden ; the grandchildren of Samuel Luchtman, the bookseller, at whose expence it appears Vander Mey had originally prepared them. From a letter of these gentlemen to M. Renouard, a bookseller in Paris, dated 21th June 1801, accurately describing the plates of this *Bible*, it turns out that the forms of types have no analogy at all to modern stereotype plates, but are merely the pages of common moveable types, soldered together at the bottom : " c'est une reunion de caracteres ordinaires par le pied avec de la matiere fondue." (*Mém. de l'Instil.* Tom. V. p. 330.) The Dutch *Bible* in folio, we learn from the same authority, was at that time in the hands of Elwe the bookseller, and the Greek *New Testament* in the hands of Messrs Luchtman. The forms of the other works mentioned as having been prepared in this manner had been broken up and sold.

M. Camus having disposed of the pretensions of Vander Mey, his next object was to support the title of one Valleyre, a Paris printer, to the merit of the invention ; at least to the practice of printing from stereotype plates. In his first memoir (*Mém. de l'Inst.* Tom. III. p. 440), he claims the invention for the French ; 1st, Because, in a modern catalogue of the printers of Paris by Lottin, it is asserted, without any proof of the fact being adduced, that the calen-

Printing.

Printing.

dars at the beginning of church books were printed from solid plates towards the end of the seventeenth century. 2d, From the existence of a plate formed of copper, of which he has given an impression in his memoir, containing a page of such a calendar; and 3d, From the testimony of a compositor, who had been witness of the use of such plates in the office of Valleyre, prior to the year 1735. Two other pages of a similar calendar were in the possession of M. Herlian; but unfortunately, notwithstanding one of these contained the months of January and February, and another the months of November and December, the year to which they referred was not inserted; nor was M. Camus's industry sufficient to procure one of those church books printed by Valleyre to ascertain this fact, though, from their nature, it is reasonable to conclude the impressions must have been numerous.

It is scarcely necessary to make any remarks upon this claim of M. Camus for the invention being French. Lottin's catalogue is of no authority on the point; and the recollection of a nameless compositor, who must have been nearly eighty years of age, concerning a circumstance which happened sixty years before, is not more satisfactory. It seems, therefore, more than probable, that the plates of the calendar alluded to, which, if complete, would have only amounted to six very small 24mo pages, had been formed by some Parisian printer, who had heard of the invention of Ged, and attempted to imitate it; or, if they can be really proved to have been manufactured previous to 1735, the material, and the manner of their formation, were so different from his, and so nearly similar to the head and tail pieces fabricated by the Dutch founders for centuries before, that all claims to the invention of stereotype, as now practised, by Valleyre or his predecessors, must fall to the ground.

It may be mentioned that these plates of copper containing the calendar seem to have been cast, and that not very perfectly, from a mould formed of sand, clay, or some similar substance; precisely in the same manner that, till within these twenty years, the larger letters and vignettes used in printing were fabricated by the ordinary letter-founders, both on the Continent and in England. We have seen many of these antique decorations cast in type metal of the thickness of stereotype plate, and fastened to blocks of wood to raise them to the proper height; and though the transition from this to stereotype plates appears sufficiently obvious, yet it seems quite certain, that till our ingenious countryman, William Ged, attempted and perfected the process, in a manner that had not before been practised, the art of stereotype printing was unknown.

William Ged, the inventor of printing from plates in place of moveable types, and whose invention has formed the basis of all the subsequent attempts in the art, was a goldsmith in Edinburgh, in which profession he is said to have made many improve-

ments, which he liberally communicated to the other members of the trade. In the year 1725, happening to be in company with a printer, the conversation turned on the disadvantages which persons in that profession experienced from want of a letter-foundery; the printers at this time, both in Scotland and England, being chiefly supplied with types from Holland. Mr Ged's friend then showed him the types, both singly and put together in pages, and asked him if he could contrive a method to remedy that defect. "I answered" (says Mr Ged, in a narrative dictated by himself a short time before his death), "That I judged it more practicable for me to make plates from the composed pages than single types. To which he replied, that if such a thing could be done, an estate might be made by it. I desired he would give me a page for an experiment, which, after some days trial, I found practicable, and so continued for near two years improving on my invention, and making a great many experiments, several of which were expensive; but the more I practised, and the less chargeable materials I used, I was the more successful, till at last I brought it to bear, as that no distinction could be made between the impression from my plates, and that from the types."\*

Mr Ged's invention was now complete; and nothing but the want of capital hindered its being brought before the public in the most complete manner. To procure the necessary funds, he, therefore, in 1727, entered into a contract with a gentleman of Edinburgh, who, for a fourth share of the profits, agreed to advance the money that might be necessary for carrying on the work. But the jealousy of trade soon interrupted Mr Ged's progress; for his partner, consulting with a printer on the subject, was led to believe that his whole fortune would not be sufficient to complete the undertaking. This representation so intimidated the monied man, that in two years he had made no farther advance than L. 22; and so, says Mr Ged, "finding no appearance of success that way, I was glad of an opportunity by which I might expect better encouragement."

In July 1729, Mr Fenner, a London stationer, being in Edinburgh, and hearing of Mr Ged's project, made him proposals for carrying it on in London. He was, accordingly, induced to enter into a contract with that gentleman; obliging himself to share with him the profits of the proposed concern, on condition that he advanced the money that should be required. Mr Ged, accordingly, removed to London; but not finding that his partner Mr Fenner had provided the necessary accommodation and funds, Thomas James, a letter-founder, and his brother John James, an architect, were successively adopted into the copartnership; and some time afterwards, a privilege was obtained from the University of Cambridge, in the name of Fenner, for printing Bibles and Prayer Books on the new plan. This connection turned out unfortunately for Mr Ged;

\* See *Biographical Memoirs of William Ged; including a particular Account of his Progress in the Art of Block-Printing.* Nichols, London, 1781, p. 1.

Printing. for Thomas James, whose types were little calculated to do honour to their exertions, had, it is alleged, leagued with the King's Printers to defeat a measure which might eventually hurt their interests; and it seems to have been the object of Fenner, after acquiring sufficient knowledge of the art to carry it on without assistance, to drive Ged from the concern.

To accomplish their purposes, these persons are said to have engaged only such people, and procured only such types as were most likely to render the undertaking abortive; and the workmen themselves, averse to an invention which promised to lessen the demand for their labour, were not backward in lending their assistance to the same end. One of the workmen engaged in the business informed Mr Mores, that the compositors, when they corrected one fault, purposely made half a dozen more, and that the pressmen, when the masters were absent, broke the pages intentionally in aid of the compositors. The consequence was, that the Bible and Prayer Books printed in this manner were suppressed at the University; the plates were afterwards sent to the King's Printing-house, and from thence found their way to Mr Caslon's foundery. (*Memoirs of Ged*, p. 36.)

Disappointed in his prospects, and depressed by the ill-usage which he had experienced from all with whom he was connected in this unfortunate speculation, Mr Ged returned to Edinburgh. His friends in this city being anxious that a specimen of his art should be published, a subscription was opened for this purpose, and an edition of Sallust was finished in 1739, in 150 pages 12mo. We copy the title-page of this curious and interesting monument of Ged's ingenuity: "C. Crispi Sallustii Belli Catilinarii et Jugurthini Historiæ. Edinburgi, Gulielmus Ged, Aurifaber Edinensis, non Typis mobilibus, ut vulgo fieri solet, sed Tabellis seu Laminis fuis excudebat, M<sup>o</sup>CCXXXIX."

Even in getting this small work carried through the press Mr Ged met with difficulties, which it is painful to believe should have obstructed his progress. No compositor could be found to set up the types from which the plates were to be fabricated; and the whole of the work was composed by his son James, then a boy about twelve years of age. He had been put apprentice to a printer about a year before, and with the consent of his master, he was allowed to work at this task in the night time when all the workmen were absent.

What became of the plates of this volume is not well known. Mr Alexander Tilloch, the ingenious editor of the *Philosophical Magazine*, and the second inventor of the art of stereotype printing, relates, in a paper on the subject in the tenth volume of that work, that he was in possession of one of them. "This plate," says he, "I first saw in the hands of the deceased Mr John Murray, bookseller, in the year 1782, but do not now recollect the way in which he said it came into his possession. Having, about a year ago, applied to his successors in business, Messrs Murray and Highley, to request, if the plate could be found, that I might be allowed to take some impressions of it, they very politely insist-

ed on my acceptance of what they had used for years as a flat weight to lay upon papers at the end of the desk." (*Philosophical Magazine*, Vol. X. p. 273.) Philip Denis Pierres, an ingenious printer of Versailles, had, along with a copy of the book, the plate of page 44, so early as 1773. Its size, appearance, &c. is minutely described in the first memoir of M. Camus (*Mém. de l'Inst.* Tom. III. p. 445); and Pierres, we are given to understand, made many fruitless attempts to discover the mode by which it was produced.

Some years afterwards another work, which is less known, was undertaken and finished by Mr Ged. This was *The Life of God in the Soul of Man*, in a small writing pot 12mo. The imprint of this little volume, which is as well executed as books were generally at the time, is, "Newcastle: Printed and sold by John White, from plates made by William Ged, goldsmith in Edinburgh, 1742." Mr Tilloch was in possession of a copy of this volume; and in the *Philosophical Magazine* has given an impression of a page of Ged's Sallust, and specimens of his own and Mr Foulis's stereotype, in Greek and Roman letters. (Vol. X. p. 272.)

William Ged died at Edinburgh, in but indifferent circumstances, on the 19th of October 1749, after having invented, and dedicated the greater part of his life to the improvement of an art from which neither he nor his family were destined to receive any benefit. From the testimony of his daughter, however, it appears that advantageous terms had been repeatedly offered to him if he would remove to Holland, or sell his invention to the printers of that country; but that he uniformly rejected offers, the acceptance of which would have had the effect of giving an advantage to strangers over the artists of his own country. (*Memoirs of W. Ged*, p. 26.) His son, James Ged, whom the disappointments of the family had induced to join the rebel army in 1745, was seized at Carlisle and condemned; but through the interest of some of his father's friends, was pardoned and liberated in 1748. Notwithstanding the ill success his father had met with, he published proposals for reviving stereotype printing, dated at London, 29th May 1751; but these proposals having met with but little encouragement, he went to Jamaica, where he died in 1767. His younger brother, William Ged, had previously removed to the same island, where he died the year after his departure from England; and the name of Ged and the art of stereotype itself was soon forgotten.

Fifty years after the invention of stereotype by Mr Ged, Mr Tilloch was led to a similar discovery, without having, at the time, any knowledge whatever that another had preceded him in the invention. "The knowledge of this fact," says Mr Tilloch, "lessened the value of the discovery so much in my estimation, that I felt but little anxiety to be known as a second inventor; and, but for the persevering attempts of others to deprive Ged of the fame his memory so justly merits, and which he dearly earned, I might still have remained silent." (*Philosophical Magazine*, Vol. X. p. 268.)

Mr Tilloch having communicated his ideas upon the subject to Mr Foulis, printer to the University of

Printing.

Printing. Glasgow, where he then resided, that gentleman furnished him with a page of types ready set up for his first experiment. The success of this trial induced Mr Tilloch to make others; and after numberless experiments, in which he was assisted by Mr Foulis, he was at length able to produce plates, the impressions of which could not be distinguished from those taken from the types from which they were cast.

Mr Tilloch and Mr Foulis, who, as a practical printer, saw all the advantages which the art promised, now agreed to prosecute the business together, and, if possible, to bring it to perfection. In the mean time they accidentally learnt, that the art had been practised many years before by Mr Ged; and a biographical memoir of that ingenious man having been published soon after (in 1781) by Mr Nichols, they discovered that perseverance in the plan might be attended with difficulties which, till then, they had never contemplated. Notwithstanding, however, of the opposition which they were thus led to expect from prejudice and ignorance, Mr Tilloch and Mr Foulis persevered in their object, and took out patents for England and Scotland, dated 14th May 1784, to secure to themselves, for the usual term, the benefits of an invention which they considered as much their own as if nothing similar had been practised before.

Neither the ingenuity of Mr Tilloch, nor the public spirit of Mr Foulis, were, however, rewarded; for, owing to circumstances of a private nature, and after printing a few volumes in this way, the business was laid aside for a time; and Mr Tilloch's removal to London, and other avocations, prevented its being again resumed. The prejudices of the booksellers, besides, were so strong against books printed in this manner, that what volumes Messrs Tilloch and Foulis had completed were sold to the trade without any intimation of their being printed out of the common way. Their first attempts were confined to trifling popular books, such as *The Seven Champions of Christendom*, *The Twelve Cæsars*, &c. and a cheap edition of *The Economy of Human Life*. A Greek volume, however, Xenophon's *Anabasis*, was printed in 1783; and they had prepared plates for several small volumes of the English poets, which, however, were never put to press. (*Philosophical Magazine*, Vol. X. p. 275.)

The art of stereotype printing was thus twice invented and practised in Britain, by natives of Scotland, prior to any thing of the same kind being attempted, or brought to the same perfection, in any other country of Europe.

In the year 1784 Francis Ignatius-Joseph Hoffmann, a native of Alsace, established himself in France as the printer of a stereotype journal, and an improver of the art; but, from the testimony of M. Camus, it would appear that he was in the knowledge of what Ged had previously done, and perhaps also knew of the patent and productions of Messrs Tilloch and Foulis. Hoffmann's process is thus described by himself: "A page set up with moveable types in the usual manner, serves to make an impression in a soft fat earth mixed with plaster, and prepared with a gelatinous paste, formed of gum and potatoe-sediment. This impression became a matrix,

in which a composition of lead, pewter, and bismuth, when pressed in at the moment of cooling, gave a solid page, which bore in relief the characters that had served to form the matrix." Printing.

By this process Hoffmann printed many leaves of his *Polytype Journal*; and the work entitled *Les Recherches Historiques sur les Maures* by De Chénier, in 3 vols. 8vo, which appeared in 1787. Hoffmann and his son had also procured, in 1785, an extensive privilege for their new mode of printing, and some improvements which they had made in the art of engraving; but by a new order of council, in November 1787, the establishment was suppressed. (*Mém. de l'Inst.* Tom. III. p. 460.)

Hoffmann, thus deprived of his printing office (seemingly from having lent his art to the fabrication of prohibited books), turned his ingenuity to devise some method which should facilitate the ordinary mode of printing. He began with forming two kinds of punches to stamp the characters in his matrices; the first of single letters in the ordinary mode, and the second of the same letters combined into syllables of most frequent occurrence in the French language; such as *ais, etre, eurs, ment*, &c. Hoffmann denominated this invention the *Logotype* art. By this combination the case for the types consisted of no less than 370 boxes. He published a *Memoir* on the subject in 1792; and in the same year procured a patent for his invention for the period of 15 years. Hoffmann does not seem to have been aware that logotype had been proposed by Henry Johnson in 1778; and in France the same plan is said to have been invented by a lady in 1774. (See the Article LOGOGRAPHY in the *Encyclopædia*.)

The proceedings of Hoffmann attracted considerable notice in France; and some numbers of his *Polytype Journal* having fallen into the hands of Joseph Carez, a printer at Toul, he was struck with the advantages which it presented, and in 1785 began his operations. His first idea was, to take off the impression of the moveable types in plaster; but he afterwards adopted the plan of impressing the page in metal while at a certain heat; and this impression served him as a mould for casting with accuracy the fac-simile of the original page. In 1786 Carez executed by this process an edition of a church book in two large vols. 8vo, of more than a thousand pages each, twenty volumes of other descriptions, and afterwards a *Bible* in nonpareil characters, the execution of which is indeed very creditable to his ingenuity. (*Mém. de l'Inst.* Tom. III. p. 467.)

Other individuals, whom the attempts of Hoffmann excited to experiment, also made new discoveries in the art, or improved those already known; and all the departments of printing were afterwards improved by the artists called in to assist in the manufacture of *Assignats* at the period of the French Revolution, who were prompted to exertion, as M. Camus expresses it, "by a power which nothing could resist." Among the artists who assisted in the fabrication of *Assignats*, Firmin and Henry Didot, Louis Etienne Herhan, and Nicolas Marie Gatteaux, severally obtained patents for different modifications of stereotype printing in the year 1798.

From the specification in the patent of Herhan,

Printing. his mode of stereotyping seems to have been particularly ingenious. He invented moveable types, in which the letters, in place of being in relief, were sunk (*en creux*); and by merely setting up these types, or rather matrices, which were of copper, he was enabled to produce from them directly a stereotype plate, without the necessity of an intermediate moulding. Herhan printed specimens of this mode of stereotyping by moveable matrices of copper, which are extremely pretty. One is inserted in the *Memoirs of the Institute*, Vol. III. 510.

M. Poterat, many years afterwards, with a view to avoid the difficulty and expence of composing with matrices, suggested a plan by which the matrix of copper is soldered to the bottom of the types, which bear the characters in relief. But this plan is attended with an expence which more than counterbalances the proposed advantages.

Soon after their patents were obtained, Pierre Didot, the elder, Firmin Didot, his brother, and Louis Etienne Herhan, issued a prospectus for printing works in stereotype. An edition of Virgil in 18mo was published in the year 1798; and in spite of the clamours of those interested in opposing the scheme, Phædrus, and successively afterwards many splendid works, were given to the world, by which these individuals have rendered their names celebrated as improvers of the art of printing. (*Mém. de l'Inst.* Tom. III. p. 502.)

M. Camus thus describes the mode of stereotyping practised by Didot and Herhan; only concealing the composition of the metal of which the types used in stereotyping were formed, and that of the metal which formed the mould.

The types are cast in the ordinary mode, but of metal of a particular composition, and sufficiently hard to bear without injury the pressure required to stamp the metal matrix. After the page is composed, it is enclosed in a steel box, where it is compressed on all sides, and the surface made accurately plane. The page thus disposed serves for a punch. The metal plate intended for the matrix has two essential qualities, that of being able to receive a pure and distinct impression, and that of not being subject to any alteration, or commencing fusion, when by the action of a press it is brought into contact with the heated metal. The punch, or page of moveable types, is now placed above the matrix, and an equal pressure is made upon it by a machine, in some respects resembling that used in giving the impress to coin. The matrix is afterwards fixed in a frame, and is ready for the next operation, which the French founders consider as one of the most essential in the process. A table firmly fixed to the ground is provided, and at one side of this table two pieces of wood of convenient height are fixed, with a vertical groove or canal. A piece of wood furnished with a tongue, or feather, is formed to run in these grooves, so disposed as to act in the manner of the rammer used in sinking piles. At the lower part of this piece of wood, perpendicular to its axis, is fixed a

screw, and the box or frame which contains the matrix has in its back a female screw to correspond. The matrix is thus screwed firmly to the mass of wood, or rammer, with its face downwards. A drawer or tray of thick paper, or card, is now placed on the table below the descending matrix. This tray is filled with melted type metal, and when the metal is at the point of congelation, a peg disengages the rammer, which falls with its weight upon the metal, which congeals at the same moment. The matrix is now disengaged from the stereotype page by the blade of a knife, and the operation is completed if all the parts of the process have been well executed. \* The rammer is raised by a handle; and a thin slip of copper or brass round the matrix regulates the thickness of the plate. (*Mém. de l'Inst.* Tom. III. p. 492, 493, and 505, 506.)

Previous to this period, it may be mentioned, that Firmin Didot in 1796 prepared an edition of the *Logarithmic Tables* of Callet, much in the manner of Vander Mey's *Bible*. The displacement of a figure in works of this kind, from causes well known to printers, often occasions a serious error; and, with a view to prevent similar accidents, after the pages were composed in the usual manner, and finally corrected, the form of types was soldered at the bottom, by which all chance of a figure being displaced was completely prevented. (*Mém. de l'Inst.* Tom. III. p. 509.)

Towards the end of the year 1798, M. Bouvier, also one of the artists who were engaged in the fabrication of Assignats, stereotyped with considerable success, by a process different from that of Didot and Herhan. The metal of his plate was copper, and his mould was formed of argillaceous earth. M. Camus has given a specimen of a page cast in this way, which, however, does not seem so perfect as those fabricated by the other process. M. Bouvier, in extending his invention, applied it to many other purposes, one of which was adapting it to the printing of music. (*Mém. de l'Inst.* Tom. III. p. 509.)

The success of the French printers in stereotype printing naturally excited the attention of their brethren in England; and the next attempt to introduce the art into England was happily more successful than those which had been previously made. About the year 1800 Mr Wilson, a respectable printer in London, engaged with the late Earl of Stanhope, whose love for the mechanical arts is well known, for the purpose of bringing this mode of printing into general practice. His Lordship is said to have received his first instructions in the formation of stereotype plates from Mr Tilloch, the second inventor, and had afterwards the personal attendance of Mr Foulis for many months at his seat at Chevening, where his Lordship was initiated in the practical part of the operation.

After nearly two years spent in maturing the different processes connected with the operation, Mr Wilson announced to his friends that the ingenuity and perseverance of Earl Stanhope had overcome

\* This operation is termed *clichage*, from *clicher*, a word signifying to make fall perpendicularly, quickly, and with force, a matrix upon a metal in fusion.

Printing.

every difficulty,—that the various processes had been so contrived as to combine the most beautiful simplicity with the most desirable economy,—and that the public might look forward to the period when, by the application of this art to the manufacture of books, the prices of all standard works would be reduced at least thirty, and in many cases forty *per cent*.

In the year 1804 Mr Wilson offered, upon certain terms, the art of printing in stereotype to the University of Cambridge, for their adoption in the printing of *Bibles*, *Testaments*, and *Prayer Books*; but some differences between the syndics and the printer occasioned the contract to be dissolved. The plan, however, has been since adopted both at this university and that of Oxford; and thousands of *Bibles*, &c. are annually issued from their presses printed in stereotype. The art has also been gradually diffused, not only in the capital, but in other cities of the kingdom; and it was carried on to some extent in Edinburgh by the late Mr Charles Stewart, printer to the University, in the printing of school-books, for which, as insuring greater accuracy than the common mode, it is admirably adapted.

The mode of casting stereotype is sufficiently simple. A page of any work proposed to be stereotyped is set up in the usual manner, with the ordinary moveable types. From this page, when corrected, a mould in plaster, the basis of which is gypsum, is taken off, and from this mould an impression is cast in the ordinary type metal, from which the printing is made. Of course, the whole of a work to be stereotyped is set up by the compositor in distinct pages, from which casts are formed; and from these casts plates are procured from which impressions may be made, exactly the same in every particular as that from the moveable types originally set up. A stereotype plate is, therefore, nothing more than a fac-simile of the page from which it was taken; but the advantage in point of expence is, that a plate of stereotype does not require to be more than the seventh or eighth part of the thickness or height of the ordinary types.

In the selection of a proper substance for the moulds, and the management of the casting, the success of the operation chiefly consists. The head and tail pieces of the older printers were chiefly cast in moulds formed of clay or sand; Ged, Tilloch, and after them Hoffmann, used a composition, of which plaster of Paris was the chief ingredient; while Herhan, Didot, Carez, and others, procured their mould by impressing the types in a soft metal, or metal in the act of congelation. The substance required for this purpose must be of a nature so delicate when soft, as to be capable of receiving an impression from the finest lines, and when dry, must be capable of bearing without injury the action of the melted metal. Gypsum or plaster of Paris, when finely pulverized, and mixed with water, soon becomes hard, and will also bear any degree of heat. But gypsum contracts when exposed to heat, and is liable to warp; it is also difficult to expel the air and moisture which it absorbs and retains. The defects of the plaster of Paris are, therefore, to be counteracted by compounding it with other substances less absorbent; but whatever be added, must be capable of receiving and retaining a fine surface, so as to preserve a

perfect polish in the plate to be cast from it. The following simple expedient has been recommended as fully answering this purpose. A quantity of common whiting is dissolved in a tub of clean water, and made nearly of the consistence of what is generally used in white-washing. The plaster is mixed with this solution, which makes it contract but little from the heat, and renders it less liable to crack than when the plaster is employed alone.

In making the mould for the page to be cast, a frame of cast-iron is prepared, nearly half an inch wider and larger than the page or pages proposed to be cast, and nearly an inch deep. This frame determines the thickness and strength of the mould. Four cubic pieces of metal are now required, the height of which should be exactly four-fifths of the height of the types; as on the height of these the thickness of the stereotype plate depends. The page or pages, wedged up as usual in the chases or iron frames commonly used, are now to be laid upon the moulding table, and in the openings at the corners of the page are placed the four pieces of metal, on which the iron frame rests when laid over the page.

To prevent the adhesion of the plaster to the types it is necessary to oil over the surface of the page with a soft brush. Then a quantity of the white-wash is taken into a wooden bowl, and as much finely powdered gypsum added to it as will make it into a thin plaster. When reduced to an equal consistence, it is applied to the face of the types with a painter's brush, so as to fill every cavity; and the remainder is then poured in so as to fill the frame. When beginning to harden, the superfluous plaster is struck off with a straight metal rule, to smooth the back of the mould; and when sufficiently consolidated the mould is separated from the page, and dried in an oven.

The mould properly formed, the next process is the casting of the plate. For this purpose, the dried mould is put in a pan about two inches deep with the face upwards, and a small moveable screw is placed at each side or end of the pan, to fix the frame which contains the mould. The fluid metal (which is of the same composition as that used for ordinary types) is now applied to the mould in the pan, and carried to the oven, in which it should remain from one to two hours, to acquire an equal degree of heat; for, on the principle of equal temperature between the metal and moulds, the success of the operation materially depends; and unless the oven be kept sufficiently warm to raise the temperature of the mould to that of the fluid metal, the experiment cannot succeed.

After the plate has been cast, little imperfections are frequently discovered; such as that of the top of the e or similar letters, having been full of dust when the mould was taken. The workman now takes the plate, and after clearing it of all superfluous metal, pulls a proof, marks the defects, and proceeds to make the requisite alterations. If any letter or word chance to be damaged in the course of the operation, it is cut out, and a letter or word from moveable types of the same size, cut to the proper depth, is inserted in its place. When this is done, the plate is ready for the press. The pages are ar-

Printing.

Printing. ranged upon wooden blocks, and fastened down with slips of brass and a screw.

Such is the process of stereotyping, as usually practised; and such is its accuracy, that plates may be cast from copperplates as perfect as the engraving itself. Wood-cuts and ornaments of every kind may be cast in the same manner.

A patent for producing stereotype plates, in a manner different from that now described, was granted to Mr Augustus Applegath, of Surrey, printer, in April 1818. Mr Applegath's plan, however, is so similar to the process of Didot and Herhan, that it is not necessary to describe it. Both his mould and plates are procured by an impress on the semifluid metal in the act of congelation, in the manner originally practised by the French printers; and the instrument he has invented for stamping the impression is the same in principle, though a little different in form, as the *cliche* or stamping-machine of our continental neighbours. (*Repertory of Arts*, Vol. XXXVI. Second Series, p. 69.)

As connected with stereotype printing, it may be mentioned that Mr T. C. Hansard of London procured a patent, dated the 1st November 1817, for a species of stereotype plate risers, with holdfasts or claws, which are formed of metal, are moveable, and easily adapted to any size of plates or forms. These plate risers were intended to supersede the wooden blocks

upon which the plates were generally fixed. (*Repertory of Arts*, Vol. XXXIII. Second Series, p. 262.)

The advantages of stereotype printing are, saving in point of expence, and security against typographical errors. For works in great and general demand, such as the Greek and Roman classics, standard books in foreign languages, Bibles, Prayer Books, School-Books, &c. the saving in stereotyping is considerable. The expence of renewed composition in successive editions is thereby saved; and the additional capital expended in preparing the plates is, perhaps, more than compensated by the facility with which small editions of works can be printed without laying aside a stock of paper in warehouses to meet the gradual sale. But it is only in works of this description that stereotype can be profitably employed. For works of living authors, successively improved by corrections and additions, stereotype printing is quite unsuitable. Mr Wilson, the coadjutor of Lord Stanhope, in extending the practice of the art in England, stated, that the probable saving by stereotype to the public might be from 25 to 40 per cent.; but whatever may be the advantages in point of expence, its merit in point of accuracy is unquestionable. Dictionaries, classics, works on arithmetic and mathematics, once made accurate, may for ever be kept so with but little chance of error. (Q. Q. Q.)

## DESCRIPTION OF THE PLATES.\*

FIG. 1, Plate CXI. represents a side elevation of the improved *Stanhope Press*; fig. 2, a front view, and fig. 3, an horizontal plan; the same letters of reference being used upon all the figures. A A shows a strong cast-iron frame of the form represented in fig. 2. This frame is screwed down upon a piece of timber B, which has another timber C morticed into it, at right angles, forming a T frame, to serve as a base for the whole press. D D represent two horizontal rails, having channels formed along their upper surfaces, into which the two rails or ribs upon the underside of the carriage or table E E are adapted to slide. The carriage is put in motion by the action of the handle F and barrel W, which has three strong straps or belts passing round its circumference, as seen in fig. 2; the ends of the said belts being attached to the opposite ends of the carriage, in the manner of ordinary printing presses. The table E E is made perfectly flat upon its upper surface in order to receive the form of the types: *m* represents the tympan, which is jointed to the end of the table; it is composed of a light frame of wrought iron, and fitted up in the usual manner.

The rails D D upon which the carriage runs, are secured to the main frame A A by screw bolts *a a*; the outer extremities of the rails D are united together by cross bars, and supported by an arched frame *b* and upright pillar G, the foot of which is bolted down to the timber C. H H represent the platen, which is guided in its perpendicular motion by a slider, I, moving between angular ribs formed

within the opening of the main frame, as seen in fig. 2. The upper part *d* of the frame is considerably enlarged, and is perforated in the centre to receive a brass nut or female screw, through which the main screw of the press works. M shows an upright spindle, the lower end of which is formed with a pivot adapted to turn in a hole at the top of the arch of the main frame; the upper part of the spindle M works through a collar *c*, formed in a piece of metal, which projects from the main frame, and is secured by a screw, as seen in figs. 2 and 3. N represents the handle of the press: it is firmly attached to the lower parts of the spindle M, by passing through a cross hole in the said spindle, and having a nut on the opposite side to keep it in its place. Thus, when the handle is moved backwards or forwards it turns the spindle M round, and by the operation of the lever O, and connecting link P, the motion is communicated to the main screw, by the intervention of the arm or lever R fixed upon the top thereof. The platen is raised up and kept in contact with the end of the screw, by the operation of the balance weight S. The levers N O, and R, fig. 3, are represented in the positions they assume when at rest; but the dotted lines will serve to explain their positions when the power has been applied to the handle N; the motion in that case being limited by the broad part of the connecting link P coming to bear against a projecting rib formed upon the upper surface of the lever O; at which period the lever O and connecting

\* Owing to an oversight, some of the figures in Plates CXI. and CXII. have been reversed.

Printing.

link P will be nearly in one right line, and consequently exerting a very great power upon the lever R; which being nearly at right angles to the connecting link, is in a position to receive the greatest effect from the power applied to the handle N. The degree of pressure may be increased or diminished by the operation of the screw *p* at the end of the connecting link being disposed so as to admit of varying the effective length of the link.

*Mr Parkin's Inking Apparatus.*

Plate CXI. fig. 4, shows a side view of the apparatus, which was obliged to be placed vertically in the Plate for want of room. Fig. 5 shows an horizontal plan. A represents a square frame of metal which is mounted so as to slide freely backwards and forwards, being guided between a number of small rollers, *b*, the pivots of which turn in small standards attached to a fixed frame of cast iron, B, by screws and nuts so as to admit of raising or lowering any one of the rollers in order to adjust the position of the moving frame. I shows the inking roller, which is made of elastic composition, being supported upon pivots working in short pieces of metal which project from the cross bar *a* of the moving frame. The roller I receives its requisite supply of ink by passing over and rolling across the narrow table or metal plate T, as the moving frame is pushed in or drawn out by its handle H. The ink is distributed along the surface of the table T by means of a small furnishing roller F, being mounted in a carriage so as to be capable of rolling along the surface of the table T in a direction at right angles to the motion of the sliding frame A. The furnishing roller F is made of the elastic composition, and receives the ink upon its circumference, by coming into contact with the ink boxes or reservoirs 1 and 2, situated at each end of the table T. The boxes 1 and 2 contain a supply of ink which finds its way slowly through a fine wire grating forming the face of the boxes; and is taken off upon the circumference of the furnishing roller every time that the moving frame is drawn out or put in. The carriage of the furnishing roller moves upon small wheels along the surface of the lower rail C of the fixed frame, and the pivots of the furnishing roller are not inserted into round holes through the plates of its carriage, but have the liberty of sliding up and down a short distance in oblong holes; so that the circumference of the roller may always accommodate itself to the surface of the table T, along which it moves; the roller being kept down sufficiently by its own weight, in addition to the weight of several small metal rollers which are situated over the roller F, and adapted to bear upon it, for the purpose of distributing the ink more effectually upon its surface as it turns round. The traversing motion of the roller F, and its carriage along the table T, is effected in the following manner. The ends of the carriage have small catgut lines attached to them, which pass over pulleys *i i*, situated at the ends of the cross rail C; the catgut lines then return under the rail C and pass round small horizontal pulleys *k k*, fixed also to the lower rail, as shown in fig. 6, from whence they proceed to two pulleys *m*, one only of which is seen in the drawing fig. 4, being placed close together in one

frame, but so as to turn round quite independent of each other. The frame of the pulleys *m* is screwed to the fixed frame B, and the catgut lines pass up and over two pulleys *n* fixed in a frame in the same manner as the pulleys *m*. Both of the pulleys *n* are seen in the plan, fig. 5, where one of the catgut lines marked *o* is represented as attached directly to the cross bar *e* of the moving frame A; and the other catgut line *p* is conducted over a pulley *q*, which is mounted in a frame projecting from the fixed cross bar *t* of the frame B: the line *p* then returns and is attached to the cross bar *e* in the same manner as the line *o*. This apparatus is intended to be fixed behind the printing press (as represented by the dotted lines in fig. 7, Plate CXI.), in such position that the surface of the table T may be exactly on a level with the surface of the form of types to be inked; and so that the pressman may take hold of the handle H, and thereby move the frame A with its inking roller I across the types, to apply the ink and prepare them for printing.

*Columbian Press.*

A front view of this press is represented in fig. 7, Plate CXI., and a side elevation in fig. 8. A A shows the standards or main frame, of cast iron; they are united together at the bottom, but separate at the top; the main frame is supported upon four legs, *x x*. B B represent the rails or guides, upon which the carriage or table, C C, with its appendages of tympan, *z*, and frisket, *y*, is adapted to run, being moved backwards and forwards by the handle, E, and barrel, F, round which strong linen belts are passed, and affixed to braces *v, v*, at each end of the carriage, as in ordinary printing presses. D shows the platen, which is guided in its motion up and down by its square stem or pillar, *d*, being placed angleways, and sliding between pieces of metal, *a a*, which project from the main frame, A A. The pieces *a a* are furnished with adjusting screws and wedges for the purpose of tightening them up, and preventing any looseness in the platen. The stem *d* has a square plate, *e*, upon it at the part where it joins to the platen. The pressure is produced by a combination of levers situated at the upper part of the frame. G, H, I, shows the main lever, moving on a strong centre bolt at H, between a forked or divided part of the main frame; the end, I, of this lever also passes through an oblong opening formed between the bars, *h*, and projects some distance beyond the outside of the frame. The central part, G, of the main lever has a strong pivot or trunnion cast upon it, which projects out sufficiently on each side to enter into collars formed at the top of the stem, *d*, of the platen, being retained in their places by four screw bolts, two of which are seen at G in figure 7. *m, n, o*, shows the second lever, moving on a fixed centre pin in the main frame at *m*; it has the links *n I* jointed to it at the point *n*, one upon each side, as seen in figure 8: the uppermost ends of these links are also jointed on each side of the main lever at I. The point *o* of the second lever has the link or connecting-rod, *p*, jointed to it, whilst the opposite extremity of the connecting-rod is jointed to the lever or handle N, by which the pressman puts the system of levers into action.

Printing.

Printing. The handle N turns upon a fixed centre pin passing through projecting pieces of the main frame, as seen at *i i*; and the connecting-rod *p* is furnished with a double or universal joint, where it unites with the lever *o*, to admit of the oblique motion of the handle N, when it is pulled forwards to produce the pressure.

A counter-lever, *r, s, t*, is applied at the top of the press, moving upon a fulcrum at *s*; this lever has a balance weight clamped upon it by a screw at *r*, whilst the short end, *t*, of the lever is attached by a link to the end of the main lever at the end I. By this means the weight of the levers and platen is counterbalanced sufficiently to raise them up, when the handle N is left at liberty. The different levers in this press are so arranged, that the first motion which is communicated to the handle N brings the platen down quickly; but by the time that its under surface arrives upon the tympan, the second lever, *m, n*, is brought nearly in a line with the direction of the links *n I*, which causes them to draw down the end, I, of the main lever with great power; at the same time that the point, *o*, of the second lever is in the most favourable position to be operated upon powerfully by the connecting-rod proceeding from the handle N. When the impression is produced, two balance weights act in concert to return the handle N, and raise up the platen. The main frame A A of the press is strengthened by a cross bar situated behind the main lever, which bar serves to connect the top parts of the frame together, as shown by the dotted lines in fig. 7.

*Barclay's American Press.*

Fig. 1, Plate CXII. represents a side elevation of this press; fig. 2 is a back view; and fig. 3 a horizontal plan, representing the table or carriage as partly run in. The same letters of reference are used upon all the figures. A A represents the cheeks or iron frame of the press, being of a curved form, as seen in fig. 2, and supported upon cast iron legs, B B. C C shows the table to receive the form of types; it is composed of a cast iron plate turned and ground perfectly flat upon its upper surface, and strengthened by deep ribs on the underside, two of which ribs are made straight, and serve as guides to slide in grooves upon the upper edge of the rails D D, as seen in fig. 2, for running the carriage backwards and forwards. The carriage is moved by the handle E in the usual manner. G G represent strong brackets which are cast upon the main frame of the press, and serve to support the rails D D, at the part where the pressure is applied. The farther ends of the rails are united by a cross piece, H, seen in fig. 3, from which two small pillars, I, descend to the ground, to support the weight of the carriage when run out. K K shows the platen; it is guided so as to move steadily up and down by the metal frames or bars, L L, being screwed to its upper surface in such manner as to embrace the upper part of the main frame of the press, and slide between small projecting pieces, *c c*. The bars L L are furnished with spiral springs, which bear upon the top of the frame A A, and serve to balance the weight of the platen, keeping it always clear above the surface of the tympan, when the handle N of the press is left at liberty.

We shall now describe the manner in which the requisite pressure is effected in this press. R and S, figs. 1 and 2, represent two steel cylinders or rollers, having small projecting flanges on each end: the upper roller R, bears against the under surface of an inclined steel plate which is screwed to the projecting part T, of the main frame, and the under roller S, bears upon the upper surface of a similar inclined steel plate screwed upon the upper boss V, of the platen. In this situation a steel wedge is introduced between the rollers R and S, and this wedge is connected by a link W, with the lever or handle N, of the press, as shown in the plate, fig. 3. Now it is evident, that if the steel wedge is drawn forcibly between the rollers R and S, it will roll them along between the two inclined steel plates, and consequently force the plates asunder; and, since one of the inclined plates is fixed to the platen, and the other to the solid frame of the press, the platen will be forced down upon the types placed beneath it. The two small figures Y and Z, representing the rollers, &c. detached from the press, will serve to explain their operation. The rollers R and S, as also the inclined plates T V, and the wedge W, are made of steel, and hardened in the most perfect manner; otherwise, the immense pressure acting upon a mere line of contact upon their surfaces would indent them, and totally destroy their operation. The handle N, moves upon a fixed center of motion, at N, in the projecting part of the frame, Q Q, and the pressure is regulated by lengthening or shortening the connecting link W, which is furnished with a screw in the middle of its length for that purpose. The rails D D, upon which the carriage moves, are furnished with small square pieces of steel placed at regular distances.

*Ruthven's Press.*

Plate CXII. figures 4, 5, and 6. Fig. 4 on the Plate shows an horizontal plan of the press; fig. 5, a vertical section taken through the middle; and fig. 6, an end view. The same letters of reference are used on all the figures. A A represents the table or surface upon which the form of types is laid. This table is mounted upon a framing of cast iron, consisting of four upright legs, B, strengthened by diagonal braces C. Immediately beneath the table two levers, D E, D E, are situated, moving upon fixed centers or fulcrums, at D D. These levers are jointed to double hooks or clutches F F, so that when the ends, E, of the levers are depressed or drawn down by the links, *a* (communicating with a third lever G, H, I), the hooks F F are drawn down also, but with a slow motion. The fulcrum of the third lever is at G, and the point H is where the power is applied to actuate it by the connecting-rod K; the opposite end of which is jointed to a crank or short lever, situated upon an axis, L, which extends to the front of the press, and is furnished with a winch or handle N, for the pressman to move it by. M represents the platen. It has a strong metal bar, P, united to it by screws, *r r*, at the extremities of the bar P: strong iron bolts, *d d*, are secured by nuts upon their uppermost ends. These bolts have heads or projections formed at their lower ends, which are exactly fitted to the hooks or clutches, F F: by this means the

Printing.

Printing.

Printing. platen is connected occasionally with the levers D E, D E, and may be brought down upon the types by the pressman turning the winch, N, in the direction shown by the arrow in fig. 5.

By returning the winch N to its original position, the pressure is relieved, and the platen M may be removed from off the types. Thus, at the ends of the bar P, two springs *e e* are affixed, and in the ends of these springs small rollers or wheels are fitted to move freely upon these center pins. These wheels have grooves in their edges, adapted to run upon the angles of two rails R R, which extend on each side of the table A A, and project sufficiently behind the press to support the platen, when pushed back from off the types into the position shown in figures 4 and 6. The springs *e e* are so adjusted, that when the platen moves along upon the rails R R, its under surface will be raised up sufficiently above the tympan to allow it to come into its proper position, to produce the pressure; as shown by the dotted lines in fig. 6; or to go back into its original situation, without meeting with obstruction; but when the hooks F and bolts *d* are united, and the pressure brought on by turning the winch N, the springs yield and permit the platen to press upon the types. The platen in the model originally made by Mr Ruthven was contrived to be brought forward by a treddle; but in the presses since made, it is both brought forward and pushed back by the handle *n*. The centers of motion D D of the great levers, and of the lever G, as well as the pivots L of the winch N, are all supported in one frame, composed of two metal cheeks, which are situated beneath the table, and united thereto by screws, as shown by the dotted lines in the Plan, fig. 4. The lever G H is in the most favourable position to receive the action of the rod K, viz. perpendicular to it; and the lever G I is in a position to exert a greater power upon the links *a*, and levers D E, than when it is in the horizontal position; for when the pressman first takes the handle N, it acts with but little advantage as to power upon the levers, and, therefore, brings the platen down very quickly upon the tympan; but when the handle has arrived near the horizontal position, then the power it exerts to bring down the platen is immensely great. The tympan is jointed to one end of the table in the usual manner.

#### *Bacon and Donkin's Printing Machine.*

Plate CXIII. The machine represented in the Plate is furnished with a square prism, marked A, having four surfaces, upon which the types are fixed. The pivots at the ends of its axis are supported in bearings in the frames B B, and it is caused to revolve by a connection of wheelwork D E and F G, from the fly wheel and winch H. The types yield their impression upon the paper by means of the platen I, which is placed immediately beneath the printing prism. The circumference of the platen being formed, as shown at I in the section, fig. 3, applies itself in its revolution to the surface of the types. The ink is applied to the types by the cylinder K, placed above the prism. It is composed of a soft elastic substance upon a metallic cylinder or axis; and, that its surface may always apply to

the types, its spindle is fitted in the pieces L, which move upon an axis *n*, so as to allow the cylinder to rise and fall, and thereby accommodate itself to the prism. The inking cylinder receives its ink from a second cylinder M, which is called the Distributing Roller, having also an elastic surface, which is supplied with ink by a third roller N, made of metal, and turned as true and cylindrical as possible. The ink is deposited in quantity against this roller, upon a steel plate O, the edge of which being placed at a very small adjustable distance from the circumference, permits the roller, as it revolves, to carry down upon its surface a thin film of ink, which being taken off by the distributing roller, is applied to the surface of the inking cylinder, which, as before mentioned, inks the types.

The sheet of paper to be printed is introduced to the machine by placing it upon a blanket, which is extended upon a feeding board P, and drawn in at a proper time by having a small rail or ruler *a*, fig. 3, fixed to it; the ends of which are taken forwards by studs *b* attached to endless chains, extending from the wheels *e* (at the end of the platen seen in fig. 1), to other wheels *d*, which are supported in the frame of the feeding board. The wheels *e*, having teeth entering the links of the chains, cause them to traverse and draw the blanket and sheet of paper into the machine. The page or pages of types are composed in the usual manner in galleys, which galleys are attached by screw clamps to the sides of the printing prism, so as to be readily taken off. They are also furnished with adjusting screws to fix them exactly in their proper situations, as shown in the Front Elevation, fig. 1. The two wheels D E, which cause the prism and platen to accompany each other in their revolution, are formed, as shown in fig. 4, to correspond with the prism and platen: thus the upper wheel D, is a square with its angles rounded off, and the geometrical outline is exactly the same as that of the prism. The lower wheel E, is of the same shape as the platen, and its pitch line the exact shape of the surface thereof. These wheels being toothed must revolve together, so that no slipping or sliding can take place between the surfaces of the printing prism and platen at the point of contact.

To regulate the pressure upon the paper, the bearings in which the pivots of the platen are supported can be elevated by screws, and to prevent any derangement of the wheels, D and E, by such adjustment, universal joints are applied in their axes, as shown at R in fig. 1. The inking cylinder is turned round by a cog-wheel V upon the extremity of the axis of the prism, which is the same shape as the wheel D and shapes T. The wheel V communicates motion to a circular wheel W, fixed upon the end of the spindle of the inking cylinder. The wheel W gives motion to the distributing roller M, by a pinion *f*, and this again turns the ink roller N by a third pinion *g*, fixed upon the end of its axis *n*, which is supported upon bearings on the frame B B. The pieces L L, which support the pivots of the distributing roller and inking cylinder, are fitted upon the axis *n* of the ink roller, so as to rise and fall upon it as a center of motion. The steel plate *o* for regulating the supply of ink to the roller N, is supported by a bar

of metal extending across the fixed frame B B, and the ink is prevented from flowing off at the ends of plate *o*, by pieces of metal *p*, which enter a short distance into grooves formed round the ink roller N near its ends. The frame, supporting the feeding board P, is composed of two rails fitted upon round parts of the axis of the platen, and borne up at their outermost ends by a brace from the wood framing of the machine: these rails sustain the pivots of the wheels *d*, as shown at X in fig. 2. The feeding board has two ledges *c* formed along its sides to allow the rulers *a* of the blanket to slide freely upon, in their progress to the types; and the space left between the segments of the platen, as seen at 6 in the section, fig. 3, receives the ruler *a*.

*Bensley's Printing Machine.*

Fig. 1, Plate CXIV. represents a perspective view of a machine employed in Mr Bensley's printing office, which is moved by the power of a steam-engine. It is supposed to be in the act of printing, being attended by two boys, one of whom is occupied in laying on the blank sheets of paper, and the other in receiving the printed sheets as they quit the machine. Fig. 2 shows a longitudinal section of the machine, to explain the manner in which the paper passes through to receive the impression upon both sides, and also the means employed to apply the ink to the surface of the types. Though all the material motions of the machine are displayed, yet some of the minute parts, which produce the various movements, have been omitted, in consequence of the diminutive scale of the figures, which is only about one-third of an inch to a foot.

The supply of blank paper is laid upon a support or table, A, from whence the sheets are taken, one by one, by a boy standing upon an elevated platform, who lays them out upon the table B, which has a number of narrow linen tapes or girths passing across its surface. These tapes are formed into endless bands, which extend round the cylinders, or rollers C and D, in such a manner, that when the rollers are turned round, the motion of the tapes will carry the sheet of paper along with them, and deliver over the roller E, where it is seized between two systems of endless tapes, passing over a series of rollers to keep them extended. These endless tapes are so adapted, in number and position, as to fall between the pages of printing, and also on the outsides, or beyond the margin of the printing; they may, therefore, remain in contact with the sheet of paper on both sides during its whole passage through the machine; by which means the paper being once received or taken in between the two systems of endless tapes, it will be capable of continuing its motion along with the tapes, in order to bring it into a situation to be printed on both sides, without destroying the register (or coincidence of the pages on the opposite sides of the sheet). F and G represent the two main cylinders which effect the pressure upon the paper. They are mounted upon strong axes, which turn in stationary bearings affixed to the main frame of the machine. H and I are two intermediate cylinders situated upon axes between the main cylinders. Their use is

to effect the inversion of the sheet of paper, in order to print the opposite side.

We must now describe the manner in which the two systems of endless tapes before mentioned are arranged, to give a clear idea of the operation of the machine. We will suppose one system of tapes to commence at the upper part of the roller E, from whence they proceed in contact with the under portion of the circumference of the main cylinder F; they then pass over the upper portion of the intermediate cylinder H, and under the intermediate cylinder I, from whence they proceed to encompass a considerable portion of the main cylinder G; and by passing in contact with the rollers *a*, *b*, *c*, *d*, and *e*, they arrive again at the roller E, from whence they commenced; thereby forming one of the systems of endless tapes. The other system we will suppose to commence at the roller *h*. They are equal in their number to the tapes already described, and correspond with them also in their place upon the cylinders, so that the sheets of paper may be securely held between them. The second tapes descend from the roller *h* to the roller E, where they meet and coincide with the first system, in such a manner that the tapes proceed together under the main cylinder F, over the cylinder H, under the cylinder I, and round the main cylinder G, until they arrive at the roller *i*, where they separate; having remained thus far in actual contact, except at the places where the sheets of paper are held between them. From the roller *i* the tapes descend to the roller *k*, and by passing in contact with the rollers *m*, *n*, and *o*, they arrive at the roller *h*, from whence they commenced. Thus the two systems of endless tapes are established and arranged so as to be capable of circulating continually without interfering with each other. The cylinders F, G, H, and I, as also the roller E, are connected by toothed wheels, as represented in the perspective view, fig. 1, so as to cause their circumferences to move with one uniform velocity, and thereby prevent any sliding or shifting of the two systems of tapes over each other during their motion; as much of the perfection of the printing depends upon this circumstance. The separate forms of types for printing the two sides of the sheet are placed at a certain distance asunder upon one long carriage, which is represented in a detached state at fig. 3. This carriage, with the forms of type secured upon it, is adapted to move backwards and forwards upon steady guides or supports attached to the main frame of the machine; in such a position, that the surfaces of the types may be operated upon by the circumference of their respective cylinders F and G, to produce the impression as the carriage moves backwards and forwards. This reciprocating movement of the carriage is effected by a pinion fixed upon the end of a vertical spindle, K, fig. 2, engaging in the teeth of an endless rack, L L, which is connected by a system of levers with the type carriage in such a manner, that when the pinion is turned round, it engages at alternate periods in the teeth formed upon the opposite sides of the rack L L, and consequently on the opposite circumference of the pinion; thereby a continuous motion of the pinion communicates a reciprocating mo-

Printing.

Printing.

tion to the rack and carriage; the vertical spindle K is turned by a pair of bevelled wheels from the pinion P, fig. 1, which receives its motion by an intermediate wheel, Q, from the toothed wheel upon the end of the main cylinder G.

The mechanism for furnishing and distributing the ink upon the surfaces of the types in this machine is very ingeniously arranged, and performs its operation with great certainty. It is one of the most important points, and the most difficult to effect in printing machines. Two similar and complete systems of inking apparatus, one situated at each end of the machine, are adapted to ink their respective forms of types; we will therefore describe, by reference to the fig. 2, the inking apparatus situated at the right hand end of the machine. It consists of a cylindrical metal roller, N, which has a slow rotatory motion communicated to it by a catgut band passing round a small pulley upon the end of the axis of the main cylinder G. The roller N is adapted to carry down a thin film of ink upon its circumference, by turning in contact with a mass of ink disposed upon a horizontal plate of metal, the edge of which plate is ground straight, and fixed by screws *r r*, at a small adjustable distance from the surface of the said roller. O represents an elastic composition roller, which is mounted in a frame turning upon an axis, *p*, extending across the main frame of the machine. This roller is connected by cranked levers with a small eccentric circle fixed upon the end of the axis of the cylinder G (as seen in fig. 1), which causes it to move round the axis *p*, and remain for a short period in contact with the surface of the ink roller N (as seen by the position at the left hand end of the machine, fig. 2), thereby receiving a portion of ink upon its surface; it then descends and rests with its whole weight upon the surface of a flat metal plate or table, T, which is affixed to the type carriage, as seen in fig. 3; so that the reciprocating motion of the carriage causes the ink table T to receive ink upon its surface from the elastic roller O. In this situation, when the type carriage returns, the surface of the table T is obliged to pass under three small elastic rollers (seen at R), which are mounted upon pivots in a frame, with liberty of motion up and down, in order that the rollers may bear with their weight upon the surface of the table. The frame in which they are centered has also a slight end motion given to it by the inclined form of the end of the table T (as seen in fig. 3), bearing against a roller fixed upon the said frame. Thus the small composition rollers R operate in a very complete manner to equalize the supply of ink over the surface of the table T, and by the farther motion of the type carriage the ink table is caused to pass under four small elastic rollers (seen at S), which, in like manner, bear with their weight upon the surface of the table (but without end motion), and thereby take up the ink upon their circumferences. The type carriage then returns, for the table T to receive a new supply of ink, and by the form of types passing under the elastic rollers S, the letters become inked in a very perfect and uniform manner. Whilst the operation of inking the types is going on

at one end of the machine, the printing is performed at the other end on one of the sides of the sheet from the types last inked, and *vice versa*. The type carriage is caused to move steadily along with the circumferences of the cylinders F and G, by having racks Y Y formed on each side of the forms of types (as seen in fig. 3), which engage with sectors or portions of toothed wheels, *x x*, upon the ends of the said cylinders; at which part the surfaces of the cylinders are covered with a blanket or felt, to give elasticity, and cause them to press equally upon the paper, as in ordinary printing presses.

The machine is put in motion by a strap, *y y*, passing round a pulley, X, as seen in fig. 1, upon the axis of which pulley a pinion is fixed, engaging with the teeth of the large wheel upon the end of the main cylinder G. Thus the various cylinders, with their two systems of tapes, are caused to revolve with an uniform movement in the direction of the arrows (seen in fig. 2), whilst the type carriage travels alternately backwards and forwards upon its guides, as before mentioned. The operation of printing is performed as follows: The sheets of blank paper are laid one by one upon the table B, so as to bear upon the linen tapes which extend over its surface. In this situation the rollers C and D are caused to move a portion of a revolution, by the operation of a lever fixed upon the axis of the roller D, being acted upon by another lever fixed on the cog-wheel of the main cylinder F. This motion advances the sheet of paper sufficiently to enable it to be seized between the two systems of endless tapes at the point where they meet each other, or between the rollers *h* and E. As soon as the sheet of paper is carried clear off the table B, the rollers C and D are caused to turn back again to their original position, by the operation of a weight, W, and cord, *w*, as seen in fig. 2, ready to advance a second sheet of blank paper into the machine. The sheet of paper is carried along between the systems of tapes, and applies itself to the circumference of the main cylinder F, upon the blanket before mentioned; and by the continuous motion of the cylinder, the sheet of paper is pressed upon the surface of the form of types as they pass under the cylinder by the reciprocating motion of the carriage. By this means one of the sides of the sheet receives its impression at the same time the form of types situated at the opposite end of the carriage is receiving its ink, as before described. Now, by the continuous motion of the machine, the sheet of paper advances in company with the endless tapes round the intermediate cylinders H and I, until it applies itself to the blanket upon the surface of the main cylinder G; at which place it will be found in an inverted position, so that the printed side of the sheet is in contact with the blanket and the blank side of the sheet downwards, which, upon meeting with the other form of types at the proper instant, is pressed upon their surface sufficiently to produce the impression. Thus having arrived at the point *i*, where the two systems of tapes separate, the printed sheet is delivered upon the board Z, where it is received by a boy, and laid upon the pile.

## PRISONS AND PRISON DISCIPLINE.

**Prisons and Prison Discipline.** THE arrangements, necessary to adapt prisons to the ends for which they are designed, seem to require little more than the exercise of practical good sense; and yet the manner in which the practice of the world blunders on from one absurdity, and very often from one atrocity, to another, shows pretty distinctly, how little the public affairs of mankind have hitherto had the benefit of that practical faculty, or of any thing that resembles it.

**Ends of im-Prisonment.** Prisons have been applied to three purposes; 1st, That of safe custody; 2dly, That of punishment; 3dly, That of reformation.

It is very evident, that each of these purposes requires an arrangement of means peculiar to itself.

Though each requires a combination of means peculiar to itself, it does not follow that, of the means required for each, a portion may not be the same in all. Every body will acknowledge that this is the case.

The means of safe custody, for instance, are equally required for those who are imprisoned in order to be punished and those who are imprisoned in order that they may be reformed, as for those who are imprisoned to the sole end of being made present at a particular time and place.

The arrangements, then, for safe custody, form a basis, on which every combination of means for attaining any of the other ends of imprisonment must always be erected. Other means for the attainment of these ends are to be considered as accessories to those required for the first.

It is a corollary from this position, that the same house may, at one and the same time, be employed for all the three purposes. Those properties in the building which make it fittest, at the least expense, for safe custody, make it fittest also for the purposes either of punishment or of reformation. This will be rendered abundantly apparent in the sequel; and from the single circumstance, that the means of punishment and reformation are only additions to those of safe custody, it wants not much of its demonstration already. If the arrangements needed, for those who are to be punished, and those who are to be reformed, interfere not with one another, or with those needed on account of the persons in safe custody merely, the truth of the corollary is indisputable; for nobody will deny that, in point of economy, there must be very great advantage.

**Means of safe Custody.** I. We shall consider, first of all, what is the best combination of means for safe custody. Dungeons and fetters are the expedient of a barbarous age. And in respect of prisons, as of every thing which comes within the precincts of law, the expedients of a barbarous age are, with great industry, retained in those which are civilized; they are, indeed, not only retained with great industry, but preserved with a success which, if it were not experienced, would be altogether incredible. As the expedients of a bar-

**Prisons and Prison Discipline.** barous age are still preserved in many more of the arrangements for the purposes of law, so it is but of yesterday that the prisons of our forefathers have been regarded as fit for reform, or the means which in their ancestral wisdom those sages devised for attaining the ends of imprisonment were supposed capable of being altered for the better, by their less instructed sons.

It is at last, however, allowed, that inspection is a means for safe custody, which renders unnecessary all but very ordinary means of any other description. Thus, so long as a man is, and knows that he is, under the eyes of persons able and willing to prevent him, there is very little danger of his making an attempt, which he sees would be vain, to effect a breach in the wall, or force open the door, of his cell. Any great strength, therefore, in such wall or door, as well as fetters upon any part of his body, the object of which is to make provision against such attempts, are wholly unnecessary; since the attempts are sure of not being made, or of being instantly frustrated.

The plan of a prison, in which the power of inspection is rendered so complete, that the prisoner may be, and cannot know but that he is, under the eyes of his keepers, every moment of his time, and which we owe to General Bentham, so universally known for his mechanical genius, is described by his brother, in his work entitled *Panopticon, or Inspection House*; where also a system of management is delineated, and its principles are so perfectly expounded, and proved, that they who proceed in this road, with the principle of utility before them, can do little else than travel in his steps.

An idea of the contrivance may be conveyed in a few words. It is a circular building, of the width of a cell, and of any height; carried round a space, which remains vacant in the middle. The cells are all open inwards, having an iron grating instead of a wall, and, of course, are visible in every part to an eye properly placed in the vacant space. A narrow tower rises in the middle of that space, called the inspection tower, which serves for the residence of the keepers, and in which, by means of windows and blinds, they can see without being seen; the cells, by lights properly disposed, being capable of being rendered as visible by night as by day.

We have thus provision for safe custody; and along with it, five other important purposes are gained. First of all, there is great economy; the vast expense of thick, impenetrable walls, being rendered unnecessary. Secondly, All pretence for subjecting prisoners to the torture and degradation of irons is taken away. Thirdly, No misbehaviour of the prisoners can elude observation, and instant correction. Fourthly, No negligence, or corruption, or cruelty, on the part of the subordinate agents in the prison, can escape the view of their principals. And, Fifthly, No misconduct towards the prisoners, on the part

Prisons and  
Prison Dis-  
cipline.

of their principals, can remain unknown to the public, who may obtain a regulated admittance into the inspection tower, and regulated communication with the prisoners.

The persons who are liable to be in prison, for sure custody merely, are of three classes. First, Persons apprehended, and about to be put on their trial, for the commission of a crime. Secondly, Persons convicted of a crime, and about to receive their punishment; and, Thirdly, Debtors.

Under a good system of law, very little provision would need to be made for these cases. It is one of the essential properties of a good system of law to permit as little time as possible to intervene between the apprehension and trial, and between the conviction and punishment, of a person for a crime. There would never, therefore, be many such persons in any prison at a time. And under a good system of law, there never would be any body in a prison on account of debt.\* This is mentioned merely to show how little, under a good system of law, the apparatus and expense of a separate prison, for this set of cases, would be wanted.

These persons being inmates of a prison, for insuring their presence merely, the question is, What treatment they ought to receive?

Persons in prison before trial, and debtors, are persons of whom nothing is certainly known, but that they are unfortunate. They are, therefore, entitled to all the benevolence which is due to the unfortunate.

What is done for them in a prison must, however, be done at the expense of the community, that is, by sacrifices demanded of those who are not in prison; and those sacrifices ought, undoubtedly, to be the smallest possible. The question is, therefore, to be settled by a compromise between the principle of benevolence, and the principle of economy.

The principle of benevolence undoubtedly requires that the health of the prisoners should not be impaired; for this, importing the premature loss of life, is in reality the punishment of death, inflicted upon those to whom no punishment is due.

That health may not be impaired, three things are indispensable:—1. A wholesome apartment; 2. A sufficiency of wholesome food; 3. Sufficient clothing.

The principle of economy, with equal certainty, exacts, that all those should be of the cheapest possible kind.

All this is abundantly clear. It is equally clear that, with respect to those who are in prison for safe custody merely, the principle of benevolence requires, and the principle of economy does not forbid, that they should be free to use any indulgence, which costs nothing, or which they provide for themselves; and that no farther restraint should be placed upon their liberty than the custody of their persons, and the rule of economy, which prescribes

the limits and accommodations of the place, may demand.

Prisons and  
Prison Dis-  
cipline.

Few words will be necessary to show what is appropriate to the case of the man; who is in prison during the interval between his sentence and his punishment.

By the supposition, in this case, his punishment is something distinct from his imprisonment; because, if not, it is a case which comes under another head, namely, that of persons who are in prison for the sake of punishment; and will be fully considered in another part of this discourse.

If he is in prison for detention merely, his punishment, as meted out and fixed by the judge, being something wholly separate; every particle of hardship, imposed upon him, not necessary for his detention, is something without law, and contrary to law; is as much injustice and a crime, when inflicted upon him, as if inflicted upon any other member of the community. The same considerations, which, as we found above, ought to regulate the imprisonment of debtors, and persons in custody before trial, namely, the compromise between the principle of benevolence and the principle of economy; apply, without the smallest difference, to the case of persons who, during the interval between their sentence and its execution, are in prison for the mere purpose of preventing their escape.

We foresee a difficulty, or rather an objection, for there is really no difficulty in the case.

Persons come into prisons, who have been accustomed, in the preceding part of their lives, to all degrees of delicate and indulgent living; to whom, therefore, the hard fare prescribed by the principle of economy will occasion very different degrees of uneasiness.

Such persons, when in prison for safe custody merely (what is required when persons are in prison for punishment, or for reformation, will be seen hereafter), may be allowed to make use of any funds which they may possess for procuring to themselves all unexceptionable indulgences. They may be also allowed the exercise of any lucrative art, consistent with the nature of the prison, for procuring to themselves the means of such indulgences. This the principle of benevolence dictates, and there is nothing in the principle of economy which forbids it.

We shall be told, however, that there are persons, who have been accustomed to a delicate mode of living, and who come into prison without the command of any funds, or the knowledge of any art, by which they may soften the hardship of their lot: and we shall be asked what is the course which our philosophy recommends for the treatment of them? The course which it recommends is very clear. Such persons are paupers, and whatsoever treatment is fit for paupers of the description to which they belong, is fit also for them. If there are

\* If evident fraud were committed in contracting the debt, or if the property of others obtained by loan, had evidently been dishonestly spent, or dishonestly risked, such fraud, or dishonesty, being crimes, not a debt, might justly subject a man to imprisonment, or any other sort of due punishment.

Prisons and  
Prison Dis-  
cipline.

any funds, to which as paupers they can apply, the application should be open to them. If there are none, and there is no person to whose benevolence they can resort, the effects of such a destitute situation must be sustained, the same way in a prison, as they must be, when any person falls into it, out of a prison.

Means of  
Punish-  
ment.

II. Having stated what appears to us necessary for illustrating the principles which ought to regulate the imprisonment of those, in respect to whom safe custody is the end in view, we come, in the next place, to the case of those, in respect to whom, in addition to safe custody, punishment is to be effected through the same medium.

This subject we shall unfortunately be under the necessity of treating superficially; because, in order to explain it fully, we ought to have before us the whole doctrine of punishment; and, for this purpose, a development, too extensive for the present purpose, would be required.

This we may assume as an indisputable principle; that whatever punishment is to be inflicted, should be determined by the judge, and by him alone; that it should be determined by its adaptation to the crime; and that it should not be competent to those to whom the execution of the sentence of the judge is entrusted, either to go beyond the line which he has drawn, or to fall short of it.

We have already established, on what seemed sufficient reasons, that for persons confined, on account of safe custody merely, the cheapest accommodation, not importing injury to health, in respect to apartment, food, and clothing, should alone be provided at the public expense.

Unless in the case of those whom the judge might condemn to lose a portion of their health, as the punishment due to them, by the sufferings of an unwholesome prison, unwholesome food, or improper clothing, this accommodation ought to be afforded even to those who are placed in prisons for the sake of punishment. And if it should be thought that the loss of health never can be a proper punishment, if it has never been regarded as such even by savages, and is repudiated by every principle of reason, then it follows, that the accommodations which we have described in the former part of this discourse, as required in the case of prisoners detained for safe custody, are required in the case of prisoners of every description.

This is a basis, therefore, upon which every thing is to rest. In every rational system of prison management, this is an essential condition. We are now to see in what manner, upon this footing, punishment, by means of imprisonment, is to be effected.

One mode is sufficiently obvious and sufficiently known. The punishment may be rendered more or less severe by its duration. Want of liberty is, in almost all cases, a source of uneasiness; want of liberty, added to the denial of all pleasures of sense, can hardly ever fail to be a source of great uneasiness. A long imprisonment therefore, with the cheapest accommodation not importing injury to health, must be a severe punishment. This, it is

evident, may be graduated to more or less of severity, not only by degrees of time, but the use of such means as the prisoner might command for procuring accommodations and indulgences.

Prisons and  
Prison Dis-  
cipline.

To this imprisonment may be added solitude. But though we mention this, as a practicable addition to simple imprisonment, it is well known how little, unless for short periods, and on very particular occasions, it is to be recommended.

The modes, which lately have been most in repute, of adding to the severity of simple imprisonment for the purpose of punishment, have been two; 1st, Hard labour; and, 2dly, Bad prisons, and bad management in those prisons.

1. The species of labour which appears to have obtained the preference is that of treading in a wheel.

If a criminal in a prison is ever to be let out again, and to mix in society, it is desirable that nothing should be done, and least of all done on purpose, to make him a worse member of society than when he went in. There cannot be a worse quality of a punishment, than that it has a tendency to corrupt and deteriorate the individual on whom it is inflicted; unless, indeed, he is a prisoner for life; in that case, people of a certain temper might say, that making worse his disposition is a matter of little importance; and to them we have no time to make any reply.

Most of those persons who come into prison as criminals, are bad, because they have hated labour, and have had recourse to other means than their industry of attaining the supply of their wants and the gratification of their desires. People of industry, people who love labour, seldom become the criminal inmates of a prison.

One thing, however, is pretty certain, that men seldom become in love with their punishments. If the grand cause of the crimes which have brought a man to punishment is his not having a love but hatred of labour; to make labour his punishment, is only to make him hate it the more. If the more a man hates labour, the more he is likely to act as a bad member of society; to punish a man with labour, and then to turn him out upon society, is a course of legislation which savours not of the highest wisdom.

Besides, in treating labour as an instrument of punishment, call it *hard* labour, if you will, what sort of a lesson do you teach to the industrious and laborious class, who form the great body of your people? to those whose lot is labour, whose lot is hard labour, harder than any which it is in your power to impose? What compulsory labour is so hard as many species of voluntary labour?

As an instrument of reformation, labour, as we shall presently see, is invaluable. As an instrument of punishment, hardly any thing can be conceived more exceptionable. That which is the source of all that mankind enjoy, that which is the foundation of every virtue in the most numerous class of the community, would you stamp with ignominy and dishonour, by inflicting it as a punishment upon the worst and basest of your people? Is this your expedient for rendering it, what every wise legislator would wish to render it, honourable, and thence desirable?

There are other objections, perfectly decisive, against labour as a punishment. It operates with more inequality than almost any other instrument of punishment that ever has been invented. The same degree of labour would kill one man, that to another would be only a pastime. From this source we may apprehend the most horrid abuses, in the continuance of those tread-mills. We may be very sure, that the most atrocious cruelty will often be inflicted upon those who, with strength below the average standard, are placed in those penal engines; while, in the case of those whose strength is much above that standard, they will hardly operate as a punishment at all.

It is impossible that the judge can measure out this punishment; because the judge has not the means of ascertaining the relative strength of the parties who come before him. It must, therefore, be left to the jailor. The jailor, not the judge, will mete out and determine the degree of suffering which each individual is to undergo. The jailor, not the judge, is the man who adapts the punishment to the crime. Hence one of the stains which mark a careless and stupid legislation.

It is a far inferior, though still no inconsiderable proof of a blundering legislation, that the labour, if labour it must be, is not of such a sort as to be useful. The turning of a wheel, by human labour, when so many better means of turning it are possessed in abundance, is destitute of even this recommendation. It stands upon a similar footing with the contrivance of the jailor, whom Mr Bentham celebrates: "We are told somewhere," he says, "towards the close of Sully's *Memoirs*, that for some time after the decease of that great and honest minister, certain high mounts were to be seen at no great distance from his house. These mounts were so many monuments of his charity. The poor in his neighbourhood happened to have industry to spare, and the best employment he would find for it was, to remove dirt from the place where it lay to another where it was of no use. By the mere force of innate genius, and without having ever put himself to school to learn economy of a French minister, a plain English jailor, whom Howard met with, was seen practising this revived species of pyramid architecture in miniature. He had got a parcel of stones together at one end of his yard, and set the prisoners to bring them to the other: the task achieved, Now, says he, you may fetch them back again. Being asked what was the object of this industry, his answer was, 'To plague the prisoners.'"—In a note on this passage, Mr Bentham says, "I beg the jailor's pardon; what is above was from memory; his contrivance was the setting them to saw wood with a blunt saw, made blunt on purpose. The removers of mounts were a committee of justices."

2. Bad prisons, and bad management in these prisons, is a mode of punishment, the recommendation of which has lately been revived, after we might have hoped that, in this country at least, it was exploded for ever. The language of such recommendation has, on several recent occasions, been heard in Parliament; and an article on Prison Discipline, which

lately appeared in the *Edinburgh Review*, cannot be interpreted in any other sense. Even the Committee of the *Society for the Improvement of Prison Discipline* have not been able to withstand the force of what they may have supposed to be fashionable doctrine. In their *Fourth Report*, lately published, which we are sorry to say evinces more of good intention, than of enlightened views for its guidance, they say; "No charge can be more mistaken and unfounded, than that the plans recommended by this institution are calculated to introduce comfort into gaols. The committee are of opinion, and have always contended, that severe punishment must form the basis of an effective system of prison discipline;" thereby confounding two things, punishment, and prison discipline; which are totally distinct; and between which, it is of so much importance to preserve the distinction, that without it not a rational idea can be entertained about either.

No doubt crimes must be punished. Who needs instruction upon that head? But when the judge has prescribed, that, in a particular way, which he points out, a particular measure of pain shall be inflicted upon an individual; and when the individual is taken, and made to sustain the operations through which the pain is generated; what has this to do with the discipline of the prison? It is an act or series of acts, *sui generis*; acts not forming any part of the ordinary course of prison management; acts which would not have taken place, which ought not to have taken place, if the judge had not commanded them, and which were performed solely and exclusively in obedience to his commandment. This is the nature of punishment,—other punishment than this there ought to be none.

The Committee would make severe punishment the basis of prison discipline! What business have the Committee with punishment? The assigning of punishment the legislature have given to other and fitter hands; to those who take cognizance of the offence, and alone ought to measure the punishment. Saying they would make punishment the basis of prison discipline, what do they intend by this ill contrived expression? Do they mean, that their jailor shall hold the scales, and weigh out the proper quantity? If not, how are they to be understood? for if not the jailor but the judge is to weigh, and the jailor is to do nothing but punctually carry the prescription of the judge into execution, then is punishment, in no proper sense of the word, any part of prison discipline. It is a separate operation, performed on a particular occasion, because prescribed by the judge, and in the exact manner in which the judge has prescribed it. If it is, on the other hand, a part of prison discipline, then all the horrid consequences, inseparable from making the jailor the judge and meter of punishment, present themselves to the imagination; and he who can endure to look at them may dwell upon the picture of a prison, wherein the poor will not be more comfortable than at home, nor by the charms of imprisonment enticed to the commission of crimes.

Nothing can more clearly indicate that state of mind, which consists in confusion of ideas, than

Prisons and  
Prison Dis-  
cipline.

the vague language which we hear about the necessity of making prisons the seats of wretchedness, that crimes, they say, may not receive encouragement.

We have already seen, that, unless it is part of a man's punishment, expressly ordained, that he shall lose a portion of his health; that is, that his life shall be cut short; that is, that after a period of torture, he shall receive a capital punishment; a wholesome apartment, a sufficiency of wholesome food, proper clothing, all of the cheapest kind, must be provided for every body. When people talk about making prisons seats of wretchedness, do they mean something worse than this?

Many of them will no doubt answer; Yes, we mean hard labour in addition. We ask again, Do you mean hard labour, according to the prescription of the judge, or without the prescription of the judge? If according to the prescription of the judge, the case is the same with that which we have previously examined. This instrument of punishment is exceptionable, only because it is a bad instrument.

The whole matter evidently comes to this. If more wretchedness is desired than what is implied in confinement under the worst accommodation which the preservation of health admits, it must be meted out, either at the pleasure of the jailor, or the pleasure of the judge. The writer in the *Edinburgh Review*, and the Committee of the Society for the Improvement of Prison Discipline, speak as if they had never reflected upon the difference.

We do not mean to bestow a word upon that theory, which, for the prevention of offences, would make prisons scenes of wretchedness at the pleasure of the jailor.

The only question which can deserve a solution is, what mode of inflicting evil in a gaol can the judge make use of for best attaining the ends of punishment? The answer is not difficult. Unless, where that course of reformatory discipline, which we shall delineate under the next head, suffices; and we allow, that, though it may be made to involve no small degree of punishment, there are cases in which it would not suffice; it will certainly appear, that prisons are not the best instruments of punishment.

A single consideration suffices for the proof of this proposition. Punishment in a prison loses the grand requisite of a punishment, that of engendering the greatest quantity of terror in others, by the smallest quantity of suffering in the victim. The principal, perhaps the sole end of punishment, is to restrain by the example; because, with respect to the individual whom you have got, if you think society in any danger from him, you can keep him in sight, and no more is required. Yet, the language we hear about the tread-mill, and hear from the mouths of high persons, implies, that hardly any thing more is in their minds, than the effect upon the individual sufferers. "Nothing finer than the tread-mill; a fellow who has been in the tread-mill never comes back again." Be it so; but by your leave, this is a very insignificant part of the question.

The choice of expedients, for obtaining the punishment best adapted to the several cases for which a course of reformatory discipline does not suffice, belongs to another head of inquiry, and must, for the

present purpose, be regarded as determined. All that it is necessary for us to show here is, that a prison is not the proper scene for it, nor the instruments of a prison the proper instruments. To render a punishment the most efficacious in accomplishing the great end of punishment, it must be a punishment calculated to make the strongest impression upon the senses, and, through the senses, upon the imagination, of the public at large; more especially of that part of the public who lie under the strongest temptations to the commission of similar crimes. But the punishments inflicted in a prison are withdrawn from the senses of the public, and seem as if they were intended to make the smallest possible, not the greatest possible, impression upon the imaginations of those who are to be deterred from crime. They are defective, therefore, in the most essential quality of a punishment, and can always be supplied by better means of attaining the same end.

The proper idea of a prison is that of a place of custody, and that alone. This idea ought to be clearly, and distinctly, and steadily preserved in the mind, in all disquisitions respecting prison discipline. Punishment and reformatory discipline may be annexed to safe custody; and in as far as they consist of a series of operations, requiring time for their performance, it is essential to them. As reformatory discipline consists wholly in such a series, imprisonment is a necessary condition of it. Since many, also, of the best kinds of punishment are not such as can be executed all at once, but require a period of time, imprisonment is equally necessary for these punishments. But though you must have safe custody to enable you to execute certain punishments, and also to enable you to carry into effect a course of reformatory discipline, safe custody is not the same thing with punishment, nor the same thing with reformatory discipline; and no conclusions can be depended upon, in which ideas so distinct are confounded.

III. Having thus considered prisons, as instruments of safe custody, and as instruments of punishment; of two of the purposes to which they have been applied as means; it remains, that we consider them, as instruments of reformatory discipline, the third of the purposes to which they have been applied.

It is necessary, first of all, to state a clear idea of reformatory discipline.

When offences, against which it is necessary that society should have protection, are committed, it is desirable that the punishment of the offender should have three properties; 1st, That it should deter all other persons from committing a similar offence, which is its most important property. 2dly, That it should have the effect of deterring the man himself from a repetition of the offence. 3dly, That it should have the effect of removing his former bad habits, and planting useful habits in their stead. It is this last property which is sought to be communicated to his punishment by reformatory discipline.

As the creating and destroying of habits is the work of time, and as the restraint of safe custody, and restraint from all indulgences, except under certain conditions, are necessary to reformatory discipline, whatever punishment is involved in such protracted

Prisons and  
Prison Dis-  
cipline.Reformatory  
Discipline.

coercion, is a necessary part of reformatory discipline.

What is desired is, to create a habit of doing useful acts, in order to break the habit of doing hurtful acts. To accomplish this, means must be obtained of making the individual in question perform certain acts, and abstain from the performance of certain other acts.

The means to be employed for producing performance cannot be of more than two sorts; the pleasurable, and the painful. A man may be induced to perform certain acts, either by punishment, or reward. He may be made to abstain from performing certain acts by an additional means, by withholding the power of performing them.

The latter is the means chiefly applicable for preventing the performance of hurtful acts in prisons; not only crimes, but acts of intemperance, gaming, or any others, the tendency of which is towards crimes. As this is nearly the universal practice, the reasons of it must be so generally known, as not to need development.

The inquiry which chiefly calls for our attention is, What are the best means of producing the performance of those acts, the habit of performing which we desire to render so perfect, that it may be relied upon for the effect, even in a state of freedom?

The persons on whom reformatory discipline is intended to operate, belong to the class of those who depend upon their industry for their support. So nearly, at least, do they belong to this class exclusively, that the immaterial exceptions may, in this general inquiry, be omitted.

The necessary foundation, in the case of such persons, not only for all virtues, but for abstinence from crime, is the habit of performing some one of those series of acts, which are denominated lawful industry, and for which the performers obtain payment or reward.

Labour, therefore, in some of its useful branches, is to be regarded as the foundation of all reformatory discipline. But as the object of this discipline is to train the man to love, not to hate labour, we must not render the labour in such a case any part of his *punishment*. The labour must, for this important purpose, be a source of pleasure, not of pain.

The way in which labour becomes agreeable to men out of a prison, is the way in which it can be made agreeable to them in a prison; and there is no other. Advantages must accrue from the performing of it.

The way of attaching to it advantages the most intensely persuasive, in a reformatory prison or *Penitentiary*, is exceedingly obvious.

There it is easy to prevent the attaining of any pleasure, except through the medium of labour.

What is provided in the prison, according to the principles already explained, is lodging, food, and clothing, all of the very cheapest kind not producing injury to health. In the monotony of a prison, there is no one who will not intensely desire pleasure in addition to this.

In the sentence of a criminal, who is subjected to reformatory discipline, it may, and as often as the case requires, it ought, to be rendered a part, that

he shall not be permitted to make any additions to this hard fare from any source belonging either to himself or others, except his labour; but that what he earns by his labour he may, in a certain way, lay out to procure to himself better food, or any other indulgence (certain hurtful ones excepted) which he may desire. Few cases, indeed, will be found in which this simple contrivance will not produce steadiness of application.

We have now then attained what is of principal importance. For if we have got the inmates of a prison to labour steadily in some useful branch of industry, to look to labour as the great or only source of their enjoyments, and to form habits of so doing, sufficiently confirmed to be depended upon for governing their conduct in a state of freedom, we have prepared them for being useful members of society, and our purpose is accomplished.

Here, then, comes the question, By what arrangements, in detail, can the business of confining, maintaining, and setting offenders to work, be most advantageously performed?

In other words, In what hands should the government of Penitentiaries be placed, and under what rules should it be ordained for them to act?

It is an universal axiom in morals, that no security is equally to be depended upon for any desirable result, as the interest of those upon whom its accomplishment depends. If, in devolving upon a man the task of bringing about a particular end, we make it his interest to bring it about in the best possible manner, especially if we make it his interest in any high degree, we can hardly be disappointed in counting upon his most strenuous exertions. On the other hand, if he has no interest, or a very inconsiderable interest, in the end which he is entrusted to bring about; if little cognizance will be taken of his proceedings, whether good or bad; if to attend to the business would be exceedingly troublesome, to neglect it will produce little inconvenience; we may be very sure that, by a great majority of men, the business of the task devolved upon them will be very imperfectly performed. If they can make a profit out of oppression, or if, as is the case, to so great a degree in prisons, they can consult their ease by imposing additional and mischievous restraints upon the prisoners, their interests are strongly set against their duties, and ill conduct is still more perfectly secured.

This last, how deplorable soever the confession, is the state of management of all British prisons, with hardly any exception. There is a Jailor, who receives a salary and power; and is told to manage the prison well; and there is a number of Justices, that is, gentlemen of the neighbourhood, who obtain not a little power, and a great deal of praise, for undertaking to do certain public duties of a local nature, with little interest in doing them well, and no little interest in doing them in many respects exceedingly ill, who have the charge of looking after him. Varieties we cannot afford to particularize. This is the general description.

The management, then, of the prison, is the joint concern of the jailor and the justices, or magistrates, including sheriffs, who, jointly or severally, have no such interest, as can be expected generally to pro-

Prisons and  
Prison Dis-  
cipline.

Prisons and  
Prison Dis-  
cipline

duce any considerable effect, in any thing more than such a kind of management as will not excite attention and indignation by its badness. All the degrees of bad management, which are within those limits, having little or no interest to prevent, they have abundant interest to permit.

It is surely not necessary, that we should go far into the detail of this case, to show the causes which it places in operation, and their natural effects.

First of all, it is sufficiently evident, that the jailor has an interest in obtaining his salary, and other emoluments, with as little trouble to himself as possible.

It is not less evident, that the magistrates have an interest in getting the power and credit, attached to their office, with as little trouble to themselves as possible.

This is enough. The book of human nature is clear upon the subject. This principle, at uncontrolled work in a prison, is perfectly sufficient to generate all the evils which those abodes of misery can be made to contain.

It is undeniable, that so far as those, who thus have the superintendence of jailors, are disposed to consult their ease, and to perform negligently a troublesome duty, which they may perform well or ill, just as they please, so far they will be indisposed to listen to any complaints against the jailor. It saves them a good deal of trouble to confide in the jailor. They speedily come, therefore, to look upon confidence in the jailor, and to speak of it, as a good thing,—a duty. “Has not the jailor been most carefully and judiciously selected for his office, by wise and good men? (viz. ourselves). Would it not be an injury to a man of his character to distrust him? And to distrust him—for what?” For the complaints of prisoners. But prisoners are always complaining, always giving trouble. Jailors are a good set of men. Prisoners are a bad set of men; especially complaining prisoners. They are the very worst kind of men;—they are, therefore, to be silenced; and it is often very difficult to silence them; nothing but harsh measures will do it; when harsh measures, however, are absolutely necessary, it is the duty of jailors to use them, and the duty of magistrates to protect such men in the discharge of so important a duty.”

Such are the feelings and conclusions which are undeniably prompted, by the mere love of ease, in the bosoms of such men as English magistrates.

So far as the magistrates consult their ease (men generally do consult their ease when they have not a preponderating motive to the contrary), the jailor is at liberty to consult his ease.

In the jailor's consulting his ease, every thing that is horrid in a prison finds its producing cause.

What the jailor has chiefly to guard against is, the escape of his prisoners, because that is a result which cannot be hidden, and will not escape animadversion. But the love of ease prompts him to take the easiest means for this purpose; locking up in dungeons, loading with irons, and prohibiting communication from without: in other words, all the measures which are the most tormenting to the prisoner. If the prisoner, confiding in his ingenuity or his strength, makes any attempts to free himself from

this misery, by escaping, the disturbance which is thus given to the ease of the jailor, is a cause of pain, proportional to the love with which he cherishes his ease; this pain, excites resentment, resentment calls for vengeance, and the prisoner is cruelly punished. The demon despotism reigns in his most terrific form.

This is only one half of the evil. The servants of the jailor, the turnkeys, as they are called, and others who wait upon the prisoners, are as fond of their ease as the jailor is of his. If the jailor has not adequate motives to make him take care that the business of the prison is well done, he will repose the same confidence in his servants, which the magistrates so liberally exercise towards him. He will leave them to indulge their ease, as he could not do otherwise without disturbing his own.

From the servants of the prison indulging their ease, neglect of the prisoners is the immediate and unavoidable consequence. From neglect of prisoners, that is, of men placed in a situation destitute of all the means of helping themselves, all those evils, which, in another situation, could be produced only by the most direful oppression, immediately ensue.

Upon the servants of a gaol, cherishing their ease, and left by their superintendents to do so, every call of a prisoner for help, for relief from any annoyance, is felt as an injury, and resented as such. Cruelty speedily comes, as a co-operator with neglect, to fill up the measure of the prisoner's calamity.

The prisoner, finding himself destitute of all remedy, except he can prevail upon the people who approach him to remove some of the causes of the misery which he endures, has recourse to bribery, when he can possibly command the means; and then pillage, without limit and without mercy, is added to all the evils of this den of horrors.

If such are the consequences of entrusting the management of prisons to persons who have no interest, or not a sufficiency of interest, in good management, we have next to consider the important question, By what means a sufficiency of interest in good management can be created? We need not have any doubt, that if a sufficiency of good accrues to the managers from every particle of good management, and a sufficiency of evil from every particle of bad, we shall have as much as possible of the good, and as little as possible of the evil.

1. The grand object, as we have stated, of reformatory discipline is, to create habits of useful industry.

2. A second object is, to preserve the health of the prisoners, and impose upon them no suffering, not implied in the conditions of their confinement, or prescribed by the judge.

3. A third is, by moral and religious tuition, to generate and strengthen good dispositions.

4. A fourth is, to attain those ends at the smallest possible expense.

It is not difficult to give the manager or keeper of a reformatory prison or Penitentiary, a very strong interest in all these important results.

We have already seen, that the mode of giving to the prisoner a motive to labour, is, by giving him a share in the produce of his labour.

It is evident that an equally certain mode of giv-

Prisons and  
Prison Dis-  
cipline.

ing to the jailor a motive for obtaining as much of that labour as possible, that is, for doing all that depends upon him to make the prisoners labour as much as possible, and as productively as possible, is by giving him also a share in the produce of their labour.

It may be said, however, that if the jailor receives a share of the labour of the prisoners, he will have a motive for making them labour too much: labour may be so excessive as to equal the severest torture.

Effectual expedients, however, for the prevention of this evil, are easy and obvious. In the first place, it does not seem necessary that the labour should be in any degree compulsory. If a prisoner is, according to the rule above laid down with respect to the cheapest fare, confined to the coarsest kind of bread, and water, if he does not labour, but has it in his power to add to his enjoyments by labouring, more especially if he may labour in company, but if he will not labour, must remain in solitude, the cases will be exceedingly few in which compulsion will be needful; and these might, if it were deemed of sufficient importance, be specially provided for by the legislature.

If a man may work, or not work, as he pleases, and much or little as he pleases, there is no need of any farther security against excessive labour. If there were, it would be afforded by the interest which it is easy to give to the jailor in the health of the prisoner.

Giving to the jailor a share in the produce of the labour of a prisoner has two happy effects; not only that of giving him an interest in rendering the value of that produce as great as possible, but that, also, of giving him an interest in the health of the prisoner, because the produce of a man's labour is greater when he is in health than when he is not.

This may be increased by giving to the jailor, through a very obvious channel, an interest, and an interest to any amount, in the life of each prisoner. It being ascertained what is the proportion of persons of a similar age that die annually, when not confined in a prison, all that is necessary is, to entitle the jailor to a sum of money for each of the individuals above that proportion whom he preserves alive, and to make him forfeit a sum for each individual above that proportion who dies. This sum, it is evident, may be sufficiently high, to ensure, on the part of the jailor, a strong desire for the life, and thence a proper attention to the health of the prisoners.

Another particular in this case requires attention. It is obvious, that the motive of the prisoner to render the quantity or value of his labour the greatest, is, when the share which he enjoys of it is the greatest. It is equally obvious, that the motive of the jailor to promote the augmentation of this quantity or value is the greatest when his share is the greatest.

If the whole of the produce of the labour of each of the prisoners were left to be divided between himself and the jailor, the motives of the two parties, taken jointly, would be at the highest. And the question then would be, according to what proportion should the division be made?

The peculiar circumstances of this case permit the most decisive answer to be returned. No evil can accrue, and every good purpose is best gained, by allowing the jailor to take as much as he pleases. It being first established that he can employ no compulsory methods, that the prisoner must have as much of the coarsest fare and accommodation as he needs, whether he works or not, and that work can thus be obtained from him only by the operation of reward, it will be the interest of the jailor to make his reward sufficiently high to obtain from him all the work which he can perform, and, in his situation as a criminal, he ought, generally speaking, to receive no more. The propriety of this regulation, therefore, rests on conclusive evidence.

Here, however, an objection, worthy of attention, occurs. If the jailor receives so great a proportion of the produce of the labour of the prisoners, he may receive a much higher remuneration than the nature of his duties requires; and so far the public is deprived of a fund which ought to be available for the public service.

This observation is true; and the question is, in what manner can the separation of what is necessary in remuneration of the jailor, and what should be detached for the benefit of the public, be most advantageously made?

If the situation of the jailor affords more than an adequate reward, he will be willing to give something annually in order to retain that situation. And for measuring exactly what he ought to give, there is a sure and a well tried expedient: it is, to lay the thing open to competition.

By this expedient, a double advantage is gained: for both the public receives as great a share of the produce of the labour of the prison, as is compatible with the due remuneration of the jailor; and the jailor being entitled, in the first instance, to share the whole of the produce with the labourers, having both to pay what he owes to the government, and obtain his own remuneration out of his share, has a motive as strong as if the whole were his own, to render the produce as great as possible.

It will easily be seen that this contract between the public and the jailor, if sufficient securities can be taken for its being cancelled, as soon as misconduct on his part should render it desirable that it should be so, ought, for important reasons, to be concluded for a considerable number of years, or for his life. It is of importance that those individuals, who are to undergo the reformatory discipline, and who are unacquainted with any trade, should, especially if they are young, be taught the trade in which their labours can be turned to the greatest account: and, to make it the interest of the jailor to have them taught, it is evident that he must have the prospect of enjoying the benefit of their skilled labour for a sufficient length of time. This short illustration we hope will suggest to the reader sufficient reflections, for evidence on this point; and we must hasten to the remainder.

We have now shown, to how great an extent, upon the plan which we have thus briefly sketched, the interest of the jailor is rendered co-incident with the ends which are in view, and the most effectual

Prisons and  
Prison Dis-  
cipline.

Prisons and  
Prison Dis-  
cipline.Prisons and  
Prison Dis-  
cipline.

of all securities is obtained for the goodness of his management. We proceed to show what additional securities this plan enables us to provide.

Let us, first of all, attend to the power of inspection, which may be afforded in a degree altogether unparalleled. By the admirable properties of the building which we have recommended, not only is the conduct of the prisoners rendered wholly transparent to the jailor, but the conduct of the jailor may be rendered equally transparent to his inspectors. And as the central lodge, or tower of inspection, may be entered by any number, without giving the least disturbance to the prisoners, without their even knowing that any body is there, the public may be admitted on such terms, as to afford the full benefit of public inspection,—the most efficient of all inspections,—over the whole economy of the prison. By means of whispering tubes, oral communication might be permitted with the prisoners, at such times, and under such regulations, as would prevent it from interfering with the working hours, or other parts of the discipline, to all persons who might have a wish to hear if they had any complaints.

Another very simple expedient would make an important addition to the list of securities. It ought to be an obligation on the jailor to keep a book, in which all complaints of the prisoners should be entered, and, as often as they could write, signed with their names. Along with the complaint should be entered a statement of what had been done for removing the ground of the complaint, or of the reasons for doing nothing. And this book should be open to the perusal of the public, and should lie in a place convenient for the inspection of all the visitors of the prison.

A still more important and indispensable security would be, the obligation of the jailor to present, annually, to the principal court of justice, such as the Court of King's Bench in England, a report on the management and state of the prison during the preceding year, containing, with all other points of useful information, exact accounts of the receipts and disbursements; to verify these statements by his oath; to print and publish them at his own expense; and to answer, upon oath, all interrogatories, made to him, in open court, by the judge, or by any other person, how much soever the answer might tend to his own crimination; and this as often as the judge might call upon him for such a purpose. By this means, with the obvious security afforded for other still more important ends, so perfect a knowledge would be communicated of the gains of the jailor, and the mode of obtaining them, as would ensure an accurate bargain, rigidly proportioned to the amount of them, as often as the contract came to be renewed.

The last thing which we think it necessary to recommend in the shape of a security, would operate as a test of the efficacy of the management in its character of a reformatory discipline. The jailor should be held bound to pay a certain sum, varying in proportion to the length of time during which the prisoner had been subject to his discipline, for each

of the prisoners who, after liberation, should be convicted of a crime.

Connected with the important part of the subject relating to the labour of the prisoners, it is proper to bring to view the advantage of a subsidiary establishment for receiving and employing those who might be liberated from the prison. It is a well known ground of lamentation, that persons liberated from a prison, find often great difficulty in obtaining employment, and are constrained, by a kind of necessity, to betake themselves to their former evil courses, though with the inclination to have devoted themselves to honest industry, had the means not been denied them. The best mode of obviating this great evil would be, to have a subsidiary establishment, the architectural form the same as that of the prison, in which the jailor should be obliged to receive all persons who have been liberated from the prison, and who make application for admittance; and to employ them on the same terms as the prisoners, with the single exception of its being in their power to remove when they please, and to make, in respect to terms, all such stipulations with the jailor as may be for their mutual advantage.

The next part of the subject to which we proceed, is the plan according to which the prison shall be supplied with the articles which the prisoners are enabled by their labour to purchase.

As there are certain articles, such as intoxicating liquors, which ought to be altogether withheld, unless for special reason permitted, and as the jailor could not have a sufficient command over the articles conveyed into the prison, unless he had, in his own hands, the power of supply; as the intercourse, also, which would be created with strangers, if the prisoners were at liberty to purchase of whom they pleased, would be incompatible with the discipline of the prison, the power of supplying articles of purchase to the prisoners ought to be confined to the jailor.

If it be objected that the jailor would thus have the power of oppressing the prisoners, by selling bad articles, or good articles too dear, the answer is, That he could not. We have already seen, that in order to derive from the prisoners the greatest quantity of profit to himself, he must give to them a reward for their labour sufficient to make them labour to the most profitable account. But if he sells articles to them at more than the usual price, this is merely a reduction of the reward left to them for their labour: this he cannot reduce beyond a certain point, without reducing the amount of his profit; and any greater reward than up to this point, the nature of the case renders undesirable.

We have now then stated all that seems necessary to be said on the three great subjects; *1st*, Of the structure and form of the prison; *2dly*, The securities which may be applied for obtaining good conduct on the part of the jailor; and *3dly*, The first and principal part of reformatory discipline, namely, voluntary labour.

The remaining conditions of reformatory discipline will not require much explanation.

1. Separation, as far as concerns the sexes, and as

3 D.

far as concerns the good from the bad, is now so generally attended to as an object of importance, that the danger sometimes is of other things being too much overlooked in the comparison.

In a prison, such as we have described, in which, by means of moveable partitions, the cells may be enlarged or contracted at pleasure, and in which the prisoners are all under continual inspection, the power of separation, to any desired extent, is complete.

The two sexes, though inmates of the same prison, and simultaneously subject to the same inspection, may be as completely disjoined as if they were inhabitants of a different region. By a piece of canvas, and nothing more costly, extended in the form of a curtain, from the boundary on each side of the female cells, in the direction of a radius across the central area to the inspection lodge, the females would be as completely cut off from seeing, or being seen by the male prisoners, as if they were separated by seas and mountains; the same effect would be obtained as to hearing, by merely leaving a cell vacant between those of the males and females; and thus the space appropriated to each of the two sexes might, in the easiest manner, be diminished or enlarged, as their relative numbers might require.

A much more complete and desirable separation, than that which is aimed at, as the utmost in other prisons, is easily attainable in this. The ordinary separation of young offenders from old, of the greatly corrupted from those who are presumed to be less deeply infected, is still apt to leave associations too promiscuous, and too numerous, not to be unfavourable to the progress of reformation.

The prisoners should be put together in companies of twos, and threes, and fours, seldom more; each company occupying a separate cell. It would be the interest of the jailor to put them together in such assortments as would be most conducive to the quantity and value of work they could perform, and to the goodness of their behaviour; that is, to the most perfect operation of the reformatory discipline: and his experience of their dispositions and faculties would of course fit him beyond any one else for making the selection.

It will have been all along understood, that, to attain the ends of inspection and economy, the same rooms or cells which form the day and working rooms on our plan, form also the sleeping rooms. Not the smallest inconvenience from confusion of things in the apartment can thence be derived; because the hammocks, which would be more convenient than beds, could be stowed away in little compass during the day.

It is also to be particularly observed, that whatever degree of seclusion might either be indulged to the feelings of an individual, or might be deemed conducive to his mental improvement, might still, upon this plan, be easily secured; because, by means of screens, a portion of the cell might be formed into as many private apartments as might be desired; and where experience of good conduct had laid a foundation for confidence, periods of seclusion, even from the eye of the inspector, might be allowed.

2. Nothing of great importance to be mentioned in this summary sketch seems now to remain, except schooling, and religious instruction.

The Sunday is the appropriate period for both. Sunday-schools are found by experience to be sufficient for communicating to children the important arts of reading, writing, and accounts. It would be obligatory on the jailor to afford the means of instruction in these respects to every prisoner who might not have attained them; together with all other means, not incompatible with the case, of promoting their moral and intellectual improvement.

3. The religious services proper to the day, and such other devotional exercises as might be thought requisite on other days, would be conducted by the chaplain, the prison affording remarkable facilities for bringing all the prisoners into a situation conveniently to hear; and also, which would be a circumstance of great importance, bringing the public from without, to participate in the religious services of the prison, for whom temporary accommodation in the vacant central area might be provided, and to whom, by the charms of eloquence and music, and the power of curiosity, it would be the interest of the jailor, by letting the seats, to provide sufficient attraction.

It seems to be necessary, before concluding, to obviate an objection, which, though it has seldom been urged as a reason against reformatory discipline, is yet considered as requiring a great deduction to be made in the estimate formed of its advantages. The objection is, that, by affording the means of employment to prisoners, we take away those means from a corresponding number of persons who are not prisoners, and thus sacrifice the deserving to the worthless.

This objection is drawn from some of the conclusions of Political Economy. That which affords the means of employment to labour is capital; in other words, the means of subsistence to the labourer, the tools he works with, and the raw material on which he is employed. When labourers are too numerous for the means of employment, it is evident that, if any new ones are added to the number, you can give employment to them only by taking it away from the old ones. It is, therefore, said, that by giving employment to prisoners, we make an equal number of honest workmen paupers.

In this objection, however, as is generally the case with false reasoning, a part only of the essential circumstances, not the whole, is taken into the account. In the first place, with regard to the prisoners, one principal part of the capital which puts labour in motion, namely subsistence, is afforded to them of course, whether they labour or not.

In the next place, the objection proves too much; for, if it would be better, for the sake of affording employment to others, that the man should do nothing in prison, it would equally be better that he should have done nothing out of prison; better that we should have a portion of our population useless than productive. According to this doctrine, the proper rule, whenever population exceeds the demand for labour, and wages are low, would be to give subsistence to a portion of the people, on the condition of their abstaining from labour.

Thus much of the allegation is true, namely, that when to the subsistence, which you would have given at any rate, you add tools and raw mate-

||  
Prussia.

Prisons and  
Prison Dis-  
cipline  
||  
Prussia.

rials, you so far diminish the quantity of tools and raw materials which can be furnished to others. But, counting only this circumstance, another most important circumstance is left out of the computation. This deduction of tools and raw materials is made once for all. The productive labourer replaces the capital, which employs him, with a profit. Advance to him, for one year, the food and other articles which he needs, you never need to advance any thing more. What he produces in the course of the year, replaces the food and all other articles which he has used, with a profit. But if he has not laboured, he has produced nothing; you have to supply him, therefore, with the means of subsistence, not one year, but every year, from the produce of other men's labour. If he labours, you have to give him once, out of the general stock of means for the employment of labour, subsistence for a year, with tools and raw material, and you have no occasion to give him any more. If he is to be idle, you give him, it is true, only subsistence, without tools and raw material, the first year; but you have to give him subsistence, that is, so far to diminish the means of employing other men's labour, every year; whereas, if he is a productive labourer, for the advance which you make to him the first year, he not only exempts you from all farther deductions from the means of employing other men, but he every year adds to those means, by the whole amount of the profit made upon his labour. To make those persons, therefore, productive labourers, whom you must at any rate subsidise, is to increase, not to diminish the means of employing others.

As to another objection which is sometimes offered, that the commodities produced in a prison glut

the market, and injure other manufacturers, this is still more evidently founded upon the consideration of part of the determining circumstances, without consideration of the remainder. If it is meant to apply not to one class, or two classes of commodities, but to the mass of commodities in general, it may instantly be seen to be untrue. The men who become sellers of the articles produced in a prison, become buyers to the same amount. Whenever a man sells a greater amount of articles than before, he gets the means of buying an equally greater amount. He always brings as much of a new demand into the market as he brings of a new supply. If he introduces more of some one commodity than the market requires, and reduces the profits on producing it, capital leaves that employment till the inequality is redressed. If the number of people is the same, and the quantity of commodities is increased, it is a contradiction in terms, not to say that the circumstances of such a people are improved.

Having answered these objections, it does not occur to us that there is any thing more which in this outline it is necessary for us to add. The plan, both of construction and management, appears to us simple, and easy to be understood; and to offer securities for the attainment of the end, such as the imperfection of the human powers, seldom permit to be realized. In the delineation presented, the only merit we have to claim is that (if our endeavour has been successful) of adding perspicuity to compactness. There is not, we believe, an idea which did not originate with Mr Bentham, whose work ought to be the manual of all those who are concerned in this material department of public administration. (F. F.)

PRUSSIA.

WHEN the article under this head in the *Encyclopædia* was written, the kingdom of Prussia was reduced to a very low condition, and its boundaries contracted within a very narrow compass. Its capital and fortresses were in possession of the armies of France, and the whole country was considered merely as the highway to the future scenes of conquest which Buonaparte had planned. By a treaty of peace, which was merely nominal, since France fulfilled none of her part of the stipulations, the Prussian dominions were considerably curtailed, by the cession of many provinces to the powers that were allowed to exist, with an apparent sovereignty, under the control of the French chief. The reverse which the arms of France received in Russia led the Prussian monarch, who was, in reality, a prisoner in his capital, to break the chains by which he was bound, and turn the whole force of his state against his conqueror. During the lowest depression of his kingdom, though his army was reduced and his finances seized by his enemies, yet some part of the internal management of his affairs was left under the direction of his own ministers. As long as the French occupied his country, though the number of

his troops in actual service were but few, yet, by dismissing those who had been sufficiently drilled, and enlisting a constant succession of new recruits, when the proper period for exertion arrived, so great a proportion of the inhabitants had been taught the use of arms, that, from the general spirit of indignation which existed against France, and the simplicity of the system of recruiting which had been long established, no difficulty was found in raising, almost instantly, an army of numerous and moderately instructed soldiers. The French had, indeed, stripped the kingdom of arms, but the deficiency was supplied, with unexampled promptitude, from the arsenals of Great Britain; so that, within a few months after the retreat of the French from Moscow, the Prussian monarch was enabled to bring into the field an army of more than two hundred thousand men. The principal fortresses were garrisoned by the enemy, but the communication between them was completely cut off, as soon as the French had been compelled to abandon the fields of Prussia, and collect their forces in Saxony for the campaign of 1813. During that year the arms of Prussia, united to those of Russia and Sweden, at

Prussia. first, and subsequently with those of Austria, were splendidly victorious, and crowned a brilliant campaign by the decisive battle of Leipsic; by which Prussia and the whole of Germany were at length freed from that Gallic yoke which had pressed them down for the seven preceding years. The Congress which assembled in Vienna, after the conquest of France, had the difficult and dangerous task of assigning to the various powers who had contributed to that event the dominions which, by right of conquest, had fallen among them; and after various discussions, and it is reported, after altercations that threatened the renewal of hostilities, settled the state of Europe according to the divisions that now exist; and made such provision for extending the power of Prussia as was thought most conducive to the security of the balance of power on the continent.

Prussia has been gradually rising in importance in the scale of European politics, and has increased its dominions in the last hundred and thirty years by conquest and cessions, as well as by the augmentation of its territorial wealth and its population. On the death of Prince Frederick William in 1688, the number of Prussian subjects was 1,500,000; at the death of King Frederick in 1713, they were 1,620,000; at the death of Frederick William the First in 1740, they were 2,200,000; at the death of Frederick the Second in 1786, they were 5,800,000; at the death of Frederick William the Second in 1797, when the present king ascended the throne, they amounted to 8,700,000, and by the late acquisitions they have reached to 10,536,000. The divisions which Prussia received in 1815 were, from France,

the province of the Lower Rhine, and part of Juliers Cleve and Berg; from the kingdom of Westphalia (created for Jerome Buonaparte), the principality of Munster and part of Berg and Cleve; from the kingdom of Saxony, the ancient duchy of that name, and a part of Lausatia; and from Poland, the province of Posen, which had, indeed, been formerly added to this kingdom on the last division of that country.

Prussia has no intercourse betwixt its eastern and western provinces, without passing through the dominions of other princes. Hanover, to the north, is interposed between the eastern and western provinces of Prussia; and in the southward parts of it, the sovereigns of Brunswick, Waldeck, Hesse-Cassel, Hesse Darmstadt, Nassau, Saxe Weimar, and Saxe Gotha, intercept the direct communication. The boundaries of this kingdom are on the north, the Baltic Sea, and a small portion of the duchy of Mecklenburg; on the east, Russia and its dependant kingdom Poland; on the south-east Austria; on the south the kingdom of Saxony, and the Saxon duchies; on the south-west Bavaria and part of France; and on the west France and the kingdom of the Netherlands. In describing these boundaries, it is, however, necessary to remark, that some parts of the kingdom are small detached portions entirely insulated by the dominions of other powers, such as Neufchatel in Switzerland, Sulist in Saxony, and Rahnis in Saxe Weimar.

The great division of Prussia is into those provinces which are in Germany, which form a part of the Germanic Confederation, and maintain a stipulated number of troops for its defence; and of those states which have no connection with that alliance.

	Extent in British Statute Acres.	Number of Inhabitants.	Capitals.

Prussia.

Different Races and Languages

The people of this monarchy are of different races. The most numerous body are of German origin, divided by language and customs into the High and Low Germans. These together amount to 8,600,000, and, with the exception of the province of Posen, form everywhere the great majority. The Low German or *platt Deutsche* language is generally spoken in the countries between the Rhine and the Elbe, on the north side of the Hartz mountains, and prevails along the Baltic, through part of Brandenburg and Pomerania. In Silesia, in the southern part of Saxony, in the trans-Rhemish provinces, and in East Prussia, a dialect, or rather differing idioms of the High German tongue, are spoken; but all far removed from the pure language of Saxony, or, as it is called, *Der Meissnischen Dialect*. The Walloons in the vicinity of the forest of Ardennes, and the colonists descended from French refugees at the time of the revocation of the edict of Nantes, are now much mixed with the German inhabitants, but many of them have confused the two languages, and speak a kind of German-French-Patois. Among the higher classes in every part of the kingdom the pure High German language is spoken, generally with the peculiar idiom and pronunciation of Berlin; and that language is universally used in books, in the churches, in the courts of law, and in the more important transactions of commerce.

The Prussian subjects of Slavonian origin amount to about 1,750,000, and retain their original language. About 1,500,000 of these are usually denominated Poles, and are the inhabitants of parts of Posen, West Prussia, and Silesia. About 50,000 people in Lithuania have a peculiar language of their own. The *Wenden* or Vandals have also a different language from all the other subjects of Prussia. The whole number of them is about 225,000. They are settled, a few in the province of Brandenburg, the remainder in the province of Pomerania, and the districts of Leignitz and Kassubon in East Prussia. To these must be added the Jews, amounting to about 130,000 individuals, who are to be met with in every part of the Prussian territory, but principally in the province of Posen.

Religion.

The predominant religion in Prussia is the Protestant, now denominated the Evangelical Confession; comprehending Lutherans, Calvinists, Harnhuthers, or Moravians, and Hussites. The professors of it amounted in 1817 to 6,370,380 individuals; of whom more than 6,000,000 were, before the union, of the sects of the Lutheran persuasion. They form a large majority in the circles of Königsberg, Gumbinnen, Dantzic, Berlin, Potsdam, Frankfort, Stettin, Koslin, Stralsund, Breslaw, Reichenbach, Leignitz, Magdeburg, Merseburg, Erfurt, and Minden. The Catholics amounted at the same period to 4,023,513; and formed the majority in the districts of Marienwarder, Bromberg, Posen, Oppeln, Munster, Arensberg, Cologne, Dusseldorf, Cleves, Koblenz, Aachen, and Treves. The Mennonites, a species of Anabaptists, amount to about 15,000, and the Jews, as before stated, to about 130,000. These different parties are all equal in the eye of the law, have the same protection for their worship, and are

all alike eligible to every civil, judicial, and military office. Prussia.

The inhabitants are divided into classes. At the head of these the nobles are of two kinds practically, though not legally. The high nobility are the princes who were formerly petty Sovereigns on their own estates, but whose independence has merged in the general government; they amount to about fifty families. The lower nobility, consisting of about 200,000 individuals, have preferable claims to certain offices in the army, the state, and the church; but their privileges have been gradually contracting, and they are now in almost every point only equal to the burghers or citizens. The burgher class of inhabitants, including the military, amount to 2,900,000 individuals. The power of the guilds in the cities has been gradually diminished, and they are now scarcely obstacles, as they were formerly; here, and still are in other parts of Germany, to the exercise of industry and ingenuity in any profession which individuals may select for themselves. The inhabitants who enjoy personal rank are the civil officers of government, and the clergy; the former with their wives and children comprehend 170,000, and the latter about 50,000 individuals. The whole of the other people are the *Bauers* or peasants. They were formerly slaves, and were usually sold, as in Russia, with the estates to which they were attached; but their lot has been progressively ameliorated, and during the reign of the present king, the last vestiges of this barbarism have been totally abolished. The final extinction of personal slavery was not decreed till September 1811; and from the military events which speedily succeeded, it has not been practically destroyed till within the last four years. At present the peasantry, who amount to two-thirds of the whole population, are a species of copyholders with customary quitrents and herriots to the land owners; but they may purchase land, and become themselves proprietors; a benefit only recently conferred on them, and which those who are industrious and economical very eagerly avail themselves of.

As the cultivation of the soil is the employment of three-fourths of the inhabitants of the dominions of Prussia, it deserves the first notice in a description of the country. The greater part of the territory is a sandy soil, generally very level, and often covered with heaths. The woods of it are nearly one-fourth of the whole surface, and only certain portions near the rivers, or in particular situations, can be considered as fertile, or even grateful soils. The wants and the industry of the inhabitants, aided by a rigid parsimony, directed and stimulated by a paternal, though absolute government, have changed, in the course of the last century, the most sterile and unproductive kingdom of Europe into a territory which more than supplies the demands of its own inhabitants, and leaves a surplus quantity of corn in most years for provisioning other countries. Besides its corn, it exports to the neighbouring states vast quantities of fruits, whose cultivation was unknown in the kingdom, at the accession of Frederick the Great in 1740. In so extensive a territory there will necessarily be great inequalities in soil, in cul- Soil and Agricultural Productions.

Ranks of Society.

Prussia.

ture, and in productions. Many barren sandy plains are to be found, which are deemed to be more expensive to bring into cultivation than could be repaid by their productions. This is especially the case in the Churmark, in Lower Lausatia, and in some of the Westphalian provinces, where large spaces are occupied by heaths; such as the heaths of Minden, which extend over 10,000 acres, those of Lippstadt of 20,000, and the still larger ones of Senner and Fuhling. In East Prussia are several very extensive morasses, which require draining to render them productive. In the fruitful district of Magdeburg the bog of the Dromling covers more than 100,000 acres. A part of it, indeed, is in the Hanoverian, and a part of it in the Brunswick territory, which prevents the necessary drains from being executed, which would make it one of the most valuable tracts of land in that part of Germany.

The most fruitful corn land in the kingdom of Prussia is the vicinity of Tilsit, and some other districts of East Prussia, and the greater part of the province of Posen. In West Prussia the district of the Netze, the country round Marienburg, and that near Dantzic and Elbing, are excellent corn countries. In the Mark of Brandenburg only some districts, such as the Mark of Prignitz and the Uker-mark, are celebrated for the quantity and quality of their grain. In both Prussian and Swedish Pomerania, and especially on the island of Rugen, excellent corn is raised, as well as in some small portions of New Silesia. The soil is very favourable for all kinds of grains in the duchies of Saxony and Magdeburg, and in Thuringia, and in the principalities of Halberstadt and Quedlingburg. These divisions in favourable seasons may be considered as the real granaries from which the less fertile parts of Prussia draw their supplies of corn.

The western part of the Prussian dominions are far less productive in grain than the eastern. A few only of the Westphalian provinces are highly fruitful. The districts most eminent for corn are the vicinity of Minden and of Padderborn, the borders of the Soester, and circles of the Sieg and the Wupper. In the Rhenish provinces the neighbourhood of Julich, Bonn, Cologne, Coblenz, Kreusnach, Bacharach, and the banks of the Mense, are tolerably fertile. Though some parts of the kingdom are deficient, yet, on the whole, Prussia grows more corn than its consumption requires; and in favourable years the value of the surplus exported to other countries has amounted to from 1,800,000 to 2,000,000 florins, each florin estimated at two shillings Sterling. The principal grains of Prussia are wheat, rye, barley, and oats. The quantity of rye far exceeds that of every other kind of corn; it forms the principal aliment of the inhabitants, among whom wheat is seldom eaten in bread. Pease, both white and grey, are extensively raised, and especially that description of them known in England by the name of "Prussian blues." Beans of all varieties are cultivated in the soils on the borders of the rivers, that are suitable to their growth. Buck wheat is much sown in some parts, and forms an important part of the sustenance of the labouring classes. An article

for food is collected in Prussia, especially in Brandenburg, from the seeds of the grass called *Festuca fluitans*. It is manufactured into a substance called *Manna grits*, and is more agreeable to the taste, though employed for the same purposes, as oatmeal with us. The cultivation of potatoes has for many years past been gradually extending, and is become so great as to supply almost the sole aliment of a very great proportion of the labouring population.

The most productive branch of rural economy, next to corn, is that of breeding and fattening cattle. The practices in this branch are, however, of a very low description; and though the different races, especially of cows, are to be found in Prussia, yet so little attention has been paid by crossing them, to obtain the most perfect animals, that they are almost all very indifferent. The sheep generally are bad; but of late years great improvements have been made in their fleeces by the introduction of the Merino and Paduan rams. The fine woolled sheep now amount to 7,000,000, and supply the manufacturers with that raw material which used formerly to be furnished principally from Spain. The races of horses are not good, though great efforts have been made by the government to improve them, and establishments of stallions, for gratuitous propagation, are fixed in several parts of the kingdom. The breeding of swine is a very considerable employment; and the hams, bacon, and sausages made from them form a large proportion of the animal food of the inhabitants of the Prussian dominions.

The great deficiency in the rural economy of Prussia, as in most parts of the Continent, is the small portion of land appropriated to pasture. Hence the number of cattle maintained is small in proportion to its extent; and the effects of the deficiency of manure is to be found in the small increase on the different crops of grain. The average increase is stated to be six for one of wheat, five and three quarters for one of barley, four for one of rye, and four and a half for one of oats. The land of this kingdom is thus appropriated:

	English Acres.
Under the plough.....	29,224,741
In garden culture.....	295,302
Vineyards .....	36,908
Meadows and pasture .....	14,672,000
Woods, forests, and plantations	17,574,294
	61,803,245

The remaining 11,800,000 acres are either in lakes, ponds, rivers, canals, roads, the sites of cities, towns and villages, or of so bad a soil as not to be deemed worth cultivation.

Besides articles for food, the soil of Prussia produces many for commerce: the principal of these is flax, which is grown in every village, and almost by every peasant. Besides what is used by the growers for their own domestic manufactures, the quantity annually brought to the markets is calculated at 22,000,000 pounds. Two-thirds of this quantity is produced from Silesia alone. It is gene-

Prussia.

Appropriation of the Soil.

Productions furnished to Commerce from the Land.

Prussia. rally of a good quality, with a fine and long fibre, especially when raised from foreign seed. This change of seed is found so essential, that large quantities are annually brought from Russia; and the seed preserved at home is mostly used for making oil and oil cake, with the latter of which the oxen are fattened. Tobacco, madder, woad, safflower, and hops, have been much grown, especially during the continental restrictions of Buonaparte; and though the openings of foreign commerce have much discouraged their cultivation, they are still continued upon a small scale. Chicorium, or succory, as in other parts of Germany, is much used as a substitute for coffee; and though the peace has reduced the price of the latter article, the succory finds an extensive sale, and is still cultivated very largely in many districts. The wine made in Prussia before the acquisition of the Rhenish provinces was of a bad quality, and scarcely superior to vinegar; but these territories yield wine of good flavours and great strength: the annual quantity is calculated to vary from six to eight million gallons. The forests, amounting, as before stated, to nearly two-sevenths of the whole country, furnish timber for building and for exportation, fuel, tar, pitch, rosin, and potash, and are more valuable from the great facilities which the rivers and canals afford to internal navigation, by which their products can be easily conveyed to the borders of the sea.

Mines. The mines are by no means worked to the extent of which they are capable. Every province possesses iron, which is prepared in forges and blast-furnaces in their vicinity. They are principally worked with charcoal from the neighbouring forests, but in some few instances with fossil coal. Little or no iron is exported, as it can be made cheaper in countries that have more easy access to the ocean. The mines of rock salt, and the salt springs, are sufficiently worked to supply the consumption of their vicinity, but the provinces in the Baltic Sea find it more advantageous to draw their supplies from the mines of Cheshire. Coals are found in Silesia, Saxony, and Westphalia; but the mines are not extensively worked: the whole quantity raised not exceeding 330,000 chaldrons. From the unproductive state of the gold mines of Silesia, they ceased to be worked in 1798. The silver mines are those of Tarnowitz and Rudelstad, in Silesia, and of Mansfeld and Rothenburg, in Saxony. Their united produce does not at present exceed 160,000 ounces. The other minerals are copper, lead, cobalt, calamine, arsenic, alum, vitriol, and saltpetre; but they do not yield sufficient for the internal consumption. Amber is almost an exclusive production of Prussia. It is found in mines, as well as procured by the fishermen on the shores of the Baltic. It belongs to the crown, and is let to farm.

The capital, and annual produce of the land of Prussia has been calculated, by Professor Krug, from documents in the *Statistical Bureau*, at Berlin, as follows:

	Value of the Capital in Pounds Sterling.	Annual Income.
Ploughed land,..... L.	200,513,150	8,029,500
Pasture & grazing land,	77,890,150	2,614,566
Woodland,....	75,729,150	1,029,166
Gardens and vineyards,	11,591,650	440,483
Mines, .....	1,195,850	47,500
Fisheries on lakes & rivers,.....	2,964,775	118,592
Game (abundant in the markets),.....	2,642,290	105,291
	<b>372,527,015</b>	<b>12,376,128</b>
To these may be added the annual produce of the live stock, after deducting the amount of the supposed produce of the pasture land, .....		10,754,098
	<b>L. 23,130,226</b>	

According to the estimate of the same statistical writer, the live stock in the whole of the Prussian dominions, and their annual produce, was—

Species of Stock.	Numbers.	Produce.
Horses and foals,.....	1,661,800	0,355,000
Oxen, .....	1,255,000	
Cows,.....	2,355,900	10,140,010
Heifers and calves, ...	1,646,918	
Sheep and lambs, .....	11,230,000	1,663,450
Swine,.....	2,644,000	622,400
Goats, .....	181,000	7,441
Hives of bees,.....	521,000	356,090
Feathered tribes,.....		266,475
		<b>13,410,866</b>
From which is to be deducted the supposed annual proceeds of the meadow and pasture land,.....		2,614,566
Leaving the net produce of the stock,		<b>L. 10,796,300</b>

Prussia is a manufacturing country, though these branches of industry give employment to a far less portion of its inhabitants than the cultivation of the soil. The most natural manufacture is that of linen cloth, the raw material of which, and all the parts which contribute to its perfecting, are produced at home. It has been long established, and extensively spread. In Silesia, especially, the habit of spinning fine thread has given to the females a delicacy of tact, that is only excelled in some parts of the Netherlands. Besides, the common articles for personal and domestic use, the finest and most beautiful damask services for the table are made, which are generally preferred to all others, in the higher circles, through the whole of Europe. Before the late

Prussia.

war, the produce of the linen of Silesia, from 34,910 looms, amounted to L. 1,689,915 Sterling; of which L. 970,000 was destined for foreign consumption. In the western provinces, the linen cloth is principally made for home consumption. The number of looms in the whole kingdom, in 1816, was 207,870.

The increase of Merino sheep has given a great stimulus to the fine woollen manufactures, especially to those in the newly acquired provinces on the French frontiers, where some of the best superfine cloths that Europe can exhibit are made. In the late department of the Roer, or, as it is now denominated, the circle of Aachen, in the towns of Eupen, Aachen, Montjoie, Stolberg, and Montnedey, fine cloths and cassimeres are manufactured, which are estimated to amount to L. 1,500,000 Sterling, and afford employment to upwards of 50,000 workmen, as well as to every kind of machinery that has been invented in England, or in any other country. The cloths for the dress of the middle and lower classes are wholly made within the kingdom from their native wools.

Cotton goods have been made to a considerable extent. In some instances the yarn is spun in foreign countries, and the weaving, bleaching, and dyeing only, executed in Prussia; and as the raw material, a foreign article, cannot be rendered so cheap as in England, this branch of industry has much diminished since the general peace. The iron manufactures are more than sufficient for the domestic consumption, and furnish to the value of about L. 300,000 Sterling for exportation. There are three hundred paper-mills, which furnish the common kinds of paper in quantities sufficient for the consumption of the country; but the finer sorts are supplied either from England or France. Silk goods, and goods mixed either of silk and cotton, or silk and woollen, are chiefly made in the capital, in which, and in some other places, they give employment to about 20,000 looms. The various kinds of leather are made from skins produced at home, as far as they are found sufficient, and the deficiency is supplied from Buenos Ayres, through the intervention of England or Spain. Copper and brass wares, for all domestic purposes are made, partly from the copper and calamine of their own mines, but chiefly with copper furnished by other countries. The amount of these wares is estimated at about L. 200,000 Sterling. Tobacco, snuff, sugar, soap, candles, cabinet-ware, earthen-ware, porcelain, tin goods, and almost every article of common consumption, is made within the kingdom. As no wine is made in the eastern part of Prussia, the common beverage is either beer or brandy distilled from the native grains: the establishments for brewing and distilling are consequently very numerous, but none of them approach in magnitude to the larger concerns of a similar kind in England. The whole quantity of beer brewed is 4,243,100 casks, of 50 gallons each. The consumption of corn brandy is upwards of 8,000,000 gallons. In the larger cities, the letter-founders, printers, engravers, musical, optical, and mathematical instrument makers, gold and silver smiths, jewellers, watch-makers, and other similar artificers, are to be found as abundant and as skil-

ful as in the other countries on the Continent. The number of workmen, including masters, journeymen, and apprentices, exclusive of females and children, is estimated at 350,000, and the value of their productions, above the cost of the raw materials, is calculated to amount to L. 7,600,000 Sterling.

Few of the countries of Europe have been more Rivers. favoured by nature than Prussia, with streams that contribute to fertility and intercourse; and the labour of the inhabitants has been advantageously directed to several public works, which have facilitated the communication between the different rivers. As the slope of the whole Prussian dominions is towards the west and north, all the rivers that rise in, or pass through them, empty themselves either into the Baltic Sea or the German Ocean. The streams that merge in the first of these are the Niemen, which comes out of Russia, and becomes navigable at Schmaleninken: about ten miles below Tilsit it divides into two branches, which, through the Kurish Haff, empty themselves into the sea. During its short course through the Prussian territory, it receives, on its right side, the waters of the Scheschappe, and on its left those of the navigable river Jura. The Pregel is composed of the united streams of the Pisa, Ranit, Russe, Augerap, and Instar: after it assumes its name it receives the Deine near Tapiau, and the Alle near Wehlav; it becomes navigable near Gatterburg, and, passing Königsberg, discharges its streams by the Frish Haff into the Baltic. The Vistula, or, as it is better known on the Continent by the name of the Weisel or Weichsel, rises in the Austrian part of Silesia. It passes through Poland, where, at Cracow, it becomes navigable. On its entrance into the Prussian territories, it divides into two branches, the eastern of which takes the name of the Nogat, and joins the Baltic near Elbing; the western is again subdivided into two arms, one of which is lost in the Frishe Haff, and the other reaches the sea near Dantzic. Its course, after entering Prussia, is about 140 miles, and during its progress, it is augmented by the streams of the Ossa, the Brahe, and the Mottlaw. The Oder, rising in Moravia, enters the Prussian province of Silesia, soon after which, near Ratibor, it becomes navigable, and, after passing through Brandenburg and Pomerania, divides into two branches, and enters the great estuaries that communicate with the Baltic Sea, through the three mouths of Swine, Peene, and Divenow. Its course, in the Prussian states, is 370 miles, the general rate of its current is languid, and it is prevented from overflowing by embankments. It receives, near Oderberg, the waters of the Oppa, near Breslau, those of the Ohlau, near Groslogau, those of the Bartsch, near Neuzelle, those of the Neisse, and at Custrin, those of the Wartha. This last is the most valuable of all the secondary rivers of Prussia, because it affords the means of communication between the Oder and the Vistula. The rivers of Prussia which empty themselves into the German Ocean are the Elbe, coming from Bohemia. It is navigable at Muhlberg, where it enters this kingdom. It receives the Elster, near Wittenburg, the Muldau, near Dessau, the Saale, near Saalhorn, and the Havel, near Werben, soon

Prussia.

Prussia. } after which, in its passage to the ocean, it quits the Prussian dominions. The Weser enters but a small portion of the territory of this kingdom, though it forms the boundary on the eastern side of the Westphalian provinces, from Holtzminden to Carlshafen. The only part where both its banks are in Prussia, is near Minden, where it has forced its way through the range of mountains, and formed the celebrated passage, well known to the ancients as the Porta Westphalica. The Rhine enters the newly acquired provinces of Prussia, at Bingen, a little below Mentz, and quits them at Kerkerdom, above Nimeguen. It receives, within the Prussian territories, the streams of the Nahe, the Lahn, the Moselle, the Ahr, the Erft, the Roer, and the Lippe. The Ems, though it rises in the province of Westphalia, is a small stream, not navigable till it enters the kingdom of Hanover.

Canals. Most of the rivers of Prussia are so advantageously connected with each other, by means of navigable canals, that an uninterrupted intercourse is maintained by them from Halle and Magdeburg to Elbing; and the surrounding districts have the benefit of those facilities for exchanging their various productions. The Fredricksgraben canal, in East Prussia, is formed to avoid the dangerous navigation of the Kurische Haff, in the intercourse between Tilsit and Memel. The Bromberg canal joins the Netze and the Brahe, and by their means the Oder and the Vistula. It is the most expensive of all the Prussian canals, having, within eighteen miles, ten locks. The commerce on it furnishes freight to about 600 barges annually, each of 30 tons burden, besides smaller boats. The Finnow canal unites the Oder and the Havel, is about twenty miles long, and has on it about 4000 small, and from 1600 to 1700 large boats. The new Oder canal shortens the navigation of that river, and serves also for the purpose of draining the meadows through which it passes. The Plauen canal connects the Havel with the Elbe, and is the channel of intercourse betwixt Berlin and Hamburg. The Fredrick Williams canal unites the Oder and the Sprec. Besides these are others of less importance, viz. the Storkow, the Werbellin, the Klodnitz, the Saxon, and the Munster canals, all of which are of local benefit; and the Rhine canal, begun in 1809, but not yet completed.

Lakes. The lakes of Prussia, especially on the eastern portions of the kingdom, are numerous and extensive. On the coast of the Baltic, those lakes, usually denominated Haffs, to distinguish them from the bays, are of fresh water. The largest of them, the Kurische Haff, on the north-east part, extends over 700 square miles. The Frische Haff, near Pillau, is of 360 square miles. The Stettin Haff is of nearly the same extent. Besides the lakes on the shore, those in the interior of the country are stated to exceed 1000, many of them from ten to twenty miles in length. In East Prussia are 300, in West Prussia 160, and in the province of Brandenburg 680. Many parts of these lakes have been contracted by embankments, and the soil they covered gradually appropriated to agricultural purposes. At present

Prussia. } they supply vast quantities of fish, the right to take which is in many instances farmed at very high rates.

Climate. The climate may be generally described as temperate and healthy, though, from the great variety of situations, there are many exceptions. On the borders of the Baltic, the winters are severely cold, and the weather changeable, raw, and foggy. The greatest degree of cold, in the last century, was from the 21st to the 25th January 1795, when Reaumur's thermometer was at 24° below zero. The greatest heat of that century was in the following summer, when the same thermometer was at 36° above zero. The middle provinces of Posen, Brandenburg, Silesia, Saxony, and the whole western parts of the monarchy, possess a more mild and less variable climate, but very different in the several localities. The heat on the sandy plains of Brandenburg is, in summer, very oppressive, and the air, from the abundance of stagnant water, frequently unhealthy; whilst in the vicinity of the Hartz, the cool mountain breezes are enjoyed. The banks of the Rhine and Moselle are covered with verdure before the inhabitants of Riesengebirgs and of the Lithuanian heaths have laid aside the fur pelisses of the winter. Upper Silesia, and the mountainous parts, have a much rawer climate and a longer winter than Lower Silesia; but though the air is milder in the latter, from the great quantity of its water, it is not more healthy.

Foreign Commerce. The commerce of Prussia with foreign nations is much less than the extent of the country and the number of its inhabitants would lead us to expect. It is loaded with many restrictions, which, however necessary they may be deemed in a fiscal view, are vexatious and harassing. The commerce by land, by internal navigation, is principally with Austria and Russia, and with both those states the balance is unfavourable to Prussia. From Russia she draws hemp, corn, hides, tallow, and some other productions of the soil, and sends in return both linen and woollen cloths. From Austria she receives salt and wine, and has only linen yarn to send to that country. The provinces on the Rhine carry on very considerable traffic in wine and manufactured goods with the adjoining provinces in the kingdom of the Netherlands, and with several of the states of Germany.

As Prussia possesses no sea-ports, except on the Baltic, and as none of its harbours are calculated to receive ships of a great draft of water, or enjoy good entrances, there is very little commerce carried on beyond the limits of Europe. The shipping belonging to the different ports of Prussia, in 1817, consisted of 883 vessels, capable together of carrying 90,290 lasts of corn, or about 950,000 quarters. The greater part of their exports are conveyed by foreign ships, of which the British exceed in number those of all other nations together. Dantzic, once a Hans town, and the seat of extensive commerce, has much declined since it has become subject to Prussia, notwithstanding its favourable situation for exporting the productions raised on the banks of the Vistula and its tributary streams. It still, however, exports corn, wood, pot-ashes, linen,

Prussia. wool, wax, honey, horse-hair, and feathers; and imports colonial wares and some few manufactured goods. Königsberg exports corn, but the vessels to be loaded with it can approach no nearer than to Pillau. Elbing has lately increased by dividing the commerce with Dantzic, and the articles imported and exported are of the same description as constitute the trade of that city. Memel is, at present, the largest exporting city, and the corn, ship-timber and masts, pot and pearl-ashes, with flax-seed, are its chief commodities. Stettin has the greatest portion of the import trade, as, from its position on the Oder, it is best calculated to receive colonial produce, and forward it to the capital and to the centre of the kingdom. It is also the port in which the greater part of the vessels for the fisheries are equipped. Stralsund, though it enjoys a good harbour, has but little trade, from being destitute of water communication with the interior of the kingdom. The other ports of Prussia, Colberg, Rugenwalde, Stolpe, Barth, Swinemunde, and Wolgast, carry on some trade, and though not to a great extent, it is valuable, from being almost exclusively conducted in national vessels. The whole exports of Prussia, both by land and by sea, amount to about L. 4,500,000 Sterling; the whole of the imports to about L. 3,750,000; but in the latter is not included the products of their own oil and herring fisheries.

Government. The government of Prussia is an unlimited Monarchy; for though in some of the provinces, by ancient custom, the States still exist, they seldom assemble, and only for such inferior purposes as regulating the debts or expences of their respective provinces. They have no legislative powers, and scarcely even the right to make representations to the monarch. The crown is hereditary in the oldest member of the royal family, whether male or female. The sole executive and legislative power is vested in the king, and his authority is less restrained by the ancient privileges and usages of his subjects, than that of any other European monarch. The administration is vested in a council of state, consisting of members of the royal family, and of the ministers of foreign affairs, of the finances, of justice, of public instruction, of trade, of the public debt, of police, and of war. The State Chancellor is president of this council, and to him all the heads of the different departments are accountable, and make their weekly reports. He is uncontrollable by his colleagues, and directed solely by the king. In the details of the administration, through all the inferior departments, there is much simplicity, and a degree of economy in remunerating public services, which scarcely finds a parallel under any other government.

Revenues. The revenues of Prussia are derived from taxes on the land, on persons, on patents and licences, which are denominated direct contributions; and from an excise, or rather a custom duty, on foreign productions. A small sum is derived from stamped paper. In those provinces which were taken from the French empire, the taxes on land, on trades, on doors, and windows, as then established, are still

Prussia. continued, and will remain till the whole of these provinces are brought under the simple regulations established in the other dominions. More than one-fourth of the revenue of the monarchy is derived from the royal domains, and the hereditary rights or royalties, which are exercised over the mines, the salt springs, the game, the coinage, the posting and the postage, with some other branches. Though the higher branches of the administration appear to be benefited, by parsimony in the salaries, yet in the inferior department it appears to be injurious; as the petty officers, who are very numerous, are too poor to refuse bribes, and they are not deterred from the apprehension of dismissal from office, whose fair emoluments scarcely equal the wages of a day-labourer. As the revenue is returned to Berlin in a mass, from the different provinces, we give them in that form, rather than in the more detailed one of the several branches from which it is derived.

Before the reign of the father of the present king, Prussia had no public debt, but usually a sufficient accumulation of money to meet any emergency that might occur. The present king, on his accession, by economy and regularity, had reduced the debt which his predecessor had incurred, when the rupture with Buonaparte in 1806 drew forth all his resources, and, till the year 1815, the debt continued to increase. Since the restoration of general peace, due measures have been taken for the reduction of it. The floating debt has been reduced to less than L. 2,000,000 Sterling, and the funded debt amounts to about L. 24,000,000 Sterling; in which is included a loan of L. 6,000,000 from British subjects, and the debts assumed on the cessions of territory from Sweden, Denmark, and Saxony, amounting to L. 650,000 Sterling. Besides this national debt, many of the corporate bodies have borrowed considerable sums, which were presented to the government in the most critical periods, and which are in progress of being liquidated from their own incomes.

The expenditure of the government is upon a very low scale: no court can be less expensive than that of Berlin, and no monarch can be less attentive to his personal gratifications than the present king, who, like his predecessor Frederick II. appropriates but a small portion of his patrimonial income to his private purposes, devoting it principally to the ser-

Prussia.

before the high College of Justice in Berlin, whose decisions are final. The Prussian system of law is more simplified than most of those of feudal origin, and in its practice it is expeditious, economical, and uniform. The Police is under separate jurisdictions, and in the country, the *Landraths* resemble, in some measure, our petty sessions of justices of the peace. In the cities are peculiar Boards appointed, under whose direction the regulation of buildings, sewers, and the supplies of water and of food, are placed. The police has the superintendence of the examination of those who are licensed to practice the medical profession; of the assurance offices against losses by fire, and of the engines and other implements to prevent fires from extending. To this is added the keeping a watchful eye on all individuals who have no visible means of subsistence. In all the cities, the police is mildly and regularly administered, with more attention to the prevention than the punishment of crimes.

Education.

Few of the nations of Europe have, within the last two centuries, exceeded Prussia in the number and eminence of its men of learning, or in the various establishments for the promotion of science and literature that have been founded. In no other country is the instruction of the lower classes so sedulously provided for; and in none are there so few persons who are ignorant of the first rudiments of knowledge. With the exception of those provinces which formed a part of the French empire, where inattention to popular instruction prevailed to a great degree, and to which the system of Prussia is not yet extended, no village is without its school, in which reading, writing, and arithmetic, are taught, and moral and religious principles inculcated. Next to the village are burgher schools, where the pupils are taught the first elements of knowledge, and prepared for admission into institutions called *Gymnasiums*, similar to our great schools of Winchester, Eton, Westminster, and Edinburgh. In these, classical learning is pursued to a great extent, as preparatory to admission into the universities. The number of these *gymnasiums* is 105; some under the direction of the Protestants, others under that of the Catholics, and some few under a combined direction of both sects. They have, according to their extent, from four to twelve masters; and the pupils are divided into five or six classes; the lower of which differ but little in their pursuits from the burgher schools. In the larger and middle sized cities, schools are established for the instruction of the females, with which, in Silesia, are combined, among those of the lower class, the teaching the delicate art of lace-making. The universities, like those of the other parts of Germany, are either endowed, or the expences of the professors and libraries are defrayed by the government. The course of study is left much to the choice of the students, and is, therefore, too much influenced by the temporary popularity of particular professors. The means of instruction in every branch of science and literature is abundantly furnished; and, in spite of the want of discipline which generally prevails, the foundation is laid in them of those eminent acquirements in which the students have afterwards

Army.

The army of Prussia consists of regulars, and two kinds of militia, called the *Landwehr* and the *Landsturm*; the regulars are,

Guards.....	18,220 men.
Infantry of the line.....	112,140
Cavalry.....	19,232
Artillery and Engineers .....	15,408
	<hr/>
	165,000

The regular ranks are filled by a conscription, which compels every young man, as he arrives at 20 years of age, to serve for a limited period. If the conscript can purchase his arms and accoutrements, and pay a small sum, he may, at the end of one year, pass into the *landwehr*, which is composed of this class of men, and of all others between 25 and 40 years. In time of peace, the *landwehr* is exercised but one day in the year, but in war it becomes a disposable force, and is marched wherever its services may be deemed necessary. It amounts to 160,000 men, including cavalry, infantry, and artillery. The other militia force, the *landsturm*, is composed of all males capable of bearing arms above 40 years of age. This force is only called out in periods of great emergency, and then its duty is entirely domestic, being confined to guarding prisoners and maintaining internal tranquillity.

Administration of Law and Police.

Prussia enjoys a peculiar Code of Laws, founded by Frederick the Great, upon the ancient customs and usages of the people, and finally reduced to a more regular system in 1794. The magistracy, in the rural districts, is still a patrimonial right, vested in owners of particular estates; but the power formerly possessed by them has been contracted within narrower limits than formerly. The judgment of those lower courts is not final, except in very trifling cases, and an appeal may be made to the tribunals of the second instance, which are established in the several provinces, and to whom is attached the superintendence of the colleges for imparting legal knowledge to pupils. These tribunals of the second instance, or *Oberlandesgerichten*, have the duty of promulgating the laws, of watching over the interests of lunatics and minors, as well as of deciding processes. They are usually divided into two portions, one of which attends to the appeals from the inferior courts, and the other pronounces sentence on such civil and criminal cases as originate in them. In the provinces on the Rhine, the legal code of Napoleon is yet in force, but in a short period, the Prussian system is to be extended over those districts. From all the *Oberlandesgerichten* appeals may be brought

Prussia.

distinguished themselves in the various walks of science and literature. The universities are, Berlin, with 50 professors and 950 students; Breslau, 51 professors and 366 students; Geifswalde, 28 professors, 158 students; Halle, 51 professors, 500 students; Königsberg, 43 professors, 210 students; and Bonn, instituted in 1818, with 22 professors and 240 students. There are seminaries for the instruction of the village schoolmasters in fourteen of the cities; as well as theological academies for the Catholics, Lutherans, and Moravians, unconnected with the universities, where the clergy of the different parties receive the appropriate instruction to qualify them for the duties of their functions. Besides these are useful establishments for pupils in medicine, surgery, midwifery, the veterinary and military professions, rural economy, and for teaching the deaf and dumb, and the blind.

Libraries.

The collections of natural history, the philosophical and astronomical apparatus, and the public libraries, are upon a very liberal footing, and at the service of any individual who wishes to avail himself of their help. The libraries of Berlin, thus open to general use, contain more than 300,000 volumes; those of Breslau more than 100,000; Halle more than 50,000, and in the other cities are generally to be found large collections.

State of the Press.

The freedom of the press has been of late somewhat restrained, as far as relates to fugitive and periodical publications of the smaller class. All books must pass under Censors previous to publication; but works of science are allowed to pass with scarcely any inspection; and there is no restriction on bringing into Prussia any works published in any of the other states of Germany. The universities have an unlimited right of printing without a previous censure. Thus, with the exception of the political writings of the lowest character, the practical freedom of the press is enjoyed to a greater extent than in any other country except Great Britain. In the year 1819, the newspapers were, sixty-two government weekly papers, which contained little but domestic intelligence and advertisements; fifteen political papers, written by individuals, but with much reserve; and one literary journal.

Money.

The currency of Prussia consists of metallic and paper money, but the former is so much greater in amount, that the latter suffers no depreciation. The metallic money is estimated to amount to 30,000,000 *reichs thaleren*; the paper money, including that of a privileged company (*see Handlung obligationem*), does not amount to more than 5,000,000, and by means of a sinking fund, is gradually diminishing, and will soon be extinct. The money is coined in

Prussia.

Berlin, Breslau, and Dusseldorf. The gold coins are double, single, and half Frederick Williams d'ors, valued at 10d. 5d. and 2½d. *reichs thalern*. The silver coins are the thaler, half thaler, third, sixth, and twelfth of the thaler. The copper and mixed metal coins are groschen, sechser, drier, and pfennige. In the old provinces, accounts are kept in dollars (*thalern*), groschen, and pfennigen. Twelve pfennigen make a grosch, and twenty-four groschen a dollar. The value of the dollar in exchange with London varies from 3s. to 3s. 2d. In the other provinces, the accounts are kept in various denominations of money; but they are easily reduced into florins or gulden; three of which are equal to two dollars, and whose value in exchange with London is about two shillings.

Weights and Measures.

The legal long measure of Prussia is the Berlin ell of two feet, which contains 25⅜ Rhenish inches, or 296 French lines. In the distant provinces, a local measure of length prevails, which differs in each. The Prussian mile is 23,685 feet, or nearly the same as the German geographical mile, or one-fifteenth of a degree of latitude, being somewhat less than 4½ English miles. The land measure is the Magdeburgh morgen of 180 roods, each rood of 12 feet; the foot is about one-seventh longer than the English, thus a morgen is nearly two-thirds of an English acre. The dry measure is the Berlin scheffel of 2,758⅔ Parisian cubic inches, or nearly one bushel, one peck, and one gallon English measure. The liquid measures are more various than any other, and differ in every province; but as they are all legally reducible to Berlin measure, we give that, viz. a oxhoft is six eimer, an eimer two ankers, an anker thirty-two quarts, the quart two nöseln. The quart contains 58 Parisian cubic inches, or nearly one-ninth less than the English quart. The weights of commerce are the shipslast, containing 12 shipspounds. The shipspound contains 280 common pounds. The centner of 110 pounds is divided into light and heavy stones, having ten of the former and five of the latter. The pound is divided into two marks, the marks into sixteen loth, the loth into four quentchen, the quentchen into four pfennige.

## Q U A

Quakers.

QUAKERS.—Under this head, the *Encyclopædia* contains an account of the tenets of the Society of Friends, commonly called Quakers, extracted from a *Summary of the History, Doctrine, and Discipline* of that Society, published by authority. The article is prefaced with some observations on the character of George Fox, copied, seemingly, from the theological writings of the celebrated polemic, Charles Leslie, which appear to have given offence to the Society; as well on account of their alleged unfairness, as on account of the impropriety of reviving and circulating them in a work so generally referred to by all classes of the community. These observations have been accordingly subjected to some pointed animadversions in a piece entitled, *A Refutation of the more modern Misrepresentations of the Society of Friends*, written by Joseph Gurney Bevan; and as we have been requested to notice this piece, and have been also furnished with some additional strictures on the article in question, we think it right to take the present opportunity of stating the substance of the remarks, printed and manuscript, that have been laid before us in regard to it. It would be worse than uncourteous to refuse this satisfaction to a Society so highly respectable, so moderate in controversy, and which has so often distinguished itself by its generous and persevering efforts in the cause of truth and humanity.

The observations complained of, in regard to George Fox, the founder of this Society, are not merely such as tend to disparage his intellectual character, by representing him as a fanatic and enthusiast; representations of that kind Quakers are accustomed to, and can bear in silence; but they are such as represent him arrogating to himself a superhuman nature, and even blasphemously designating himself as “Christ,” and “the Son of God.” In support of these statements, reference is made in the *Encyclopædia* to three different pieces, all of which are quoted as undoubted productions of Fox. The first of them is entitled *The Battledoor for Teachers and Professors*, in the introduction to which, the writer says, “All languages are to me no more than dust, who was before

languages were;” the second, *News coming up out of the North sounding towards the South*, in which Fox is represented as saying of himself, “I am the same door that ever was: the same Christ yesterday, today, and for ever;” and the third, a *Letter to Cromwell*, in which Fox in like manner says of himself, “Him whom the world calls George Fox, who is the Son of God.”

With regard to the *Battledoor for Teachers and Professors*, it has been observed, first, that it is by no means correct to refer to it as being exclusively, or even chiefly written by Fox. On the contrary, it appears to have been compiled, with some assistance from him, by two of his friends; a circumstance wholly overlooked by the writer of the article in the *Encyclopædia*. It is thus mentioned by Fox, in that singular work, the *Journal of his Life*. “When I was prisoner in Lancaster Castle, the Book called the *Battledoor* came forth, which was written to show, that in all languages *thou* and *thee* is the proper and usual form of speech to a single person, and *you* to more than one. This was set forth in examples or instances taken out of the Scriptures, and out of books of instruction in about thirty languages. John Stubbs and Benjamin Furly took great pains in compiling it, which I put them upon; and some things I added to it.”\* Now, unless it could be shown, that the objectionable words quoted from this piece were “some of the things added” by Fox, there is evidently no reason for imputing them to him rather than to Stubbs or Furly. The author of the *Refutation* adds the following observations by way of apology for the passage, whether written by Fox, or by one of his coadjutors. “I have granted that the expression ‘all languages are to me no more than dust, who was before languages were,’ is liable to exception; but I think when we construe it by the context, the fairest way of interpreting that which is obscure in the writings of deceased authors, and of the difficulty ceases. It should be remembered that the main tenet, on which George Fox and his friends insisted, was the infinite superiority of the Spirit to the Letter. The learned of that day, as of other times, valuing themselves on their knowledge

Quakers.

\* The sequel of the passage is curious. “When it (the *Battledoor*) was finished, some of them were presented to the King and his Council, to the Bishops of Canterbury and London, and to the two Universities, one a-piece; and many bought of them. The King said, ‘It was the proper language of all nations.’ The Bishop of Canterbury, being asked what he thought of it, was so at a stand that he could not tell what to say to it. For it did so inform and convince people, that few afterwards were so rugged towards us for saying *Thou* and *Thee* to a single person, which before they were exceeding fierce against us for. For *Thou* and *Thee* was a sore cut to proud flesh, and them that sought self-honour; who, though they would say it to God and Christ, would not endure to have it said to themselves. So that we were often beat and abused, and sometimes in danger of our lives for using those words to some proud men, who would say, ‘What! you ill-bred clown, do you *Thou* me!’ as though there lay Christian breeding in saying *You* to one, which is contrary to their grammars and teaching books, by which they instructed their youth.”—*Journal*, p. 328. 3d edit. folio, London, 1765.

Quakers.

of languages, despised our Friends for their ignorance; these in return frequently decried human learning, to a degree in which, probably, they would not have slighted it, if they had not thought it to be set too much in competition with the knowledge of divine things, which they believed the soul to receive by immediate internal communication with the Mediator, Christ." "All languages are to me no more than dust, who was before languages were." (The writer immediately goes on,) "and am come'd before languages were, and am redeemed out of languages into the power where men shall agree; but this (meaning the *Battledoor*) is a whip and a rod (alluding to the correction of children) to all such who have degenerated through the pride and ambition from their natural tongues and languages, and all languages upon the earth is but natural, and makes none divine, but that which makes divine is the word, which was before languages and tongues were."—*Refutation*, p. 39, 40.

The most serious charge against Fox, that of assuming the name of the Saviour, and impiously designating himself as "the Son of God," in so far as it is founded upon his acknowledged piece, entitled, *News coming up out of the North*, appears to us to have been most unfairly made; and to require no other refutation but the simple inspection of the passage in which these words occur. We here copy it verbatim, with all its palpable defects of grammatical construction and punctuation: "Now to all dear ones, and dear hearts, I speak, the same seed, which is Christ, the same spirit takes upon it now as ever was, the same world is now as ever was, the same temptations, and the same Devils, and the same worship of the world, twining into another form and colour, but Jesus Christ is the way, the truth and life, he is the door that all must passe through, and he is the porter that opens it; I am the same door that ever was, the same Christ to day, yesterday and for ever."\* It is abundantly clear, as well from the context of this uncouth passage, as from the references to the gospels affixed to the words upon which the charge against Fox is made, that he is not here speaking in the first person, but copying certain expressions, used by Christ himself, in the texts referred to. We cannot conceive it possible for any rational person to entertain a doubt upon this point; and the

John 1. 1.

John 14. 6.

John 10. 3.

Luke 11. 34.

use which Leslie has made of the passage, can be viewed in no other light than as an instance of that blind zeal and gross unfairness which has often disfigured theological controversy.

The charge, in so far as it rests upon a *Letter to Cromwell*, does not admit of so direct a refutation. It is certain, that Fox, after being apprehended and brought to London, upon suspicion of being concerned in some plot, did address himself by letter to the Protector, with a view to satisfy him, that he was not a person at all likely to take arms against the government. Fox himself gives the *substance* of the letter, and some graphical details of the interview which followed it, in his *Journal*; † but the letter itself is not inserted; and it has never, it is said, appeared any where but in one of Leslie's pieces against the Quakers. It there appears, with an attestation of its authenticity, signed by two persons, who mention their having seen it delivered by Fox to the messenger who carried it to Cromwell. But the Society, notwithstanding, seem very unwilling to admit the genuineness of this letter and its attestations; at least, of the passage in which Fox designates himself as "the Son of God." ‡ It cannot, however, be denied, that the letter, as published by Leslie, corresponds pretty exactly with Fox's own account of its contents, given in that part of his *Journal* above referred to. But, granting that the words in question really made a part of it, we should be inclined to consider them rather as exemplifying some awkward elliptical reference to scripture, or as a specimen of the mystical jargon then prevalent, than as indicative of any intention in Fox to apply them literally to himself. Every page, almost, of his *Journal*, contains proofs of his ardent belief in the Divinity of Christ; and, whatever other fancies he may have entertained, it seems, therefore, quite absurd to speak of him as one who fancied himself possessed of the name or nature of the Saviour.

Penn and Barclay, the most generally respected names among the early Quakers, are alluded to in the article in the *Encyclopædia*, in a way which seems to imply, that their creed differed from, and was more rational than that of Fox, and that they did not altogether approve of his ministry. The information laid before us, however, bears, that there was a strict conformity in their tenets; that they

\* *Newes coming up out of the North sounding towards the South*, p. 15. 4to. Lond. 1655.

† "I spoke much to him (Cromwell) of truth; and a great deal of discourse I had with him about religion, wherein he carried himself very moderately. As I was turning, he caught me by the hand, and with tears in his eyes, said, 'Come again to my house; for if thou and I were but an hour of a day together, we should be nearer one to the other;' adding, that he wished me no more ill than he did to his own soul. I told him, 'If he did, he wronged his own soul; and admonished him to hearken to God's voice, that he might stand in his counsel, and obey it; and if he did so, that would keep him from hardness of heart; but if he did not hear God's voice, his heart would be hardened.' He said, It was true. Then I went out; and when Captain Drury came out after me, he told me his Lord Protector said, I was at liberty, and might go whither I would. Then I was brought into a great hall, where the Protector's gentlemen were to dine. I asked them, What they brought me thither for? They said, it was by the Protector's order, that I might dine with them. I bid them let the Protector know, I would not eat of his bread nor drink of his drink. When he heard this, he said, 'Now I see there is a people risen, that I cannot win either with gifts, honours, offices, or places; but all other sects and people I can.'" *Journal*, p. 127, 128.

County.

often preached them in conjunction, and in the most interesting circumstances, in perfect accordance; \* and that Fox was always held in the highest respect by both of his associates.

QUEEN'S COUNTY, a county in the province of Leinster, in Ireland, bounded by Kildare on the north, Carlow on the east, Kilkenny and Tipperary on the south, and King's County on the west; about 32 English miles long, and 25 broad, and containing about 600 square miles, or 384,000 English acres. It is divided into eight baronies and 50 parishes, the latter belonging to the Sees of Leighlin, Ossory, Kildare, and Killaloe. Portarlington, its principal town, on the northern side of the county, is situated in north latitude 53° 9' 30", and west longitude 7° 13'.

Excepting on the boundary with King's County, where the Sliebh-bloom mountains rise to a considerable height, this district is generally level; so much so, that, notwithstanding considerable tracts of bog, about three-fourths of the whole are said to be cultivated. The soil, though various, is for the most part fit for producing all the usual crops: and limestone for manure abounds in every townland. In the south-eastern quarter, near Carlow, coal, similar to that of Kilkenny, is wrought to a considerable extent; and iron ore, sandstone, marble, with marl, and a variety of clays, have been found in various parts. Besides a number of small streams, it has two considerable rivers, the Barrow and the Nore, which, having their source among the mountains on the west, flow, the former north-east and then south, and the latter south-east, until they meet at New Ross, in the county of Wexford, after which they are joined by the Suir from the west, and fall into the sea at Waterford Bay. Next to the Shannon these are the most considerable rivers in Ireland. The Barrow is navigable from New Ross upwards to Carlow and Athy, from which the communication is continued by a canal to Dublin. The Nore is also navigable for a few miles, but not in this county. After their junction at New Ross, there is water sufficient for large ships downwards to the sea. Queen's County, therefore, though an inland district, has the advantage of ready access by water both to the east and south coasts of Ireland.

Much of this county is divided into large estates, worth from L. 5000 to L. 15,000 a-year and upwards. Some of the most valuable, having been let on perpetual leases, afford a large income to the lessees. It is these lessees who form the middle class of gentry, with clear incomes of from L. 100 to L. 800 *per annum*, obtained from tenants to whom their lands are subset at rack-rent, and commonly in very

small farms. These leases are usually for 21 years and a life. The principal proprietors are the Marquis of Drogheda; Lords De Vesci, Ossory, Ashbrooke, Stanhope, Castlecoote, and Portarlington; Sir Charles Coote, Mr Parnel, Mr Strange, and Mr Wellesley Pole, now Lord Maryborough. Here and in King's County, Mr Wakefield observed some of the best farming in Ireland, with much more attention to a systematic course of cropping, and to keeping the land in good heart. Oxen and horses are used for the plough, the former generally preceding the latter. A good deal of cheese is made here for the Dublin market. In other respects the rural economy of this district does not differ materially from that of the Irish counties already described.

There is no large town in Queen's County. Maryborough, the county town, though pleasantly situated near the Barrow, is a place of no consideration. Portarlington, partly in King's County, noted for its schools, and for its being the residence of the smaller gentry, is the most extensive and populous. Mountmellick, Mountrath, Ballynakill, and Stradbally, are only villages. The manufactures are linen and coarse woollens, to no great extent; and its exports chiefly corn and other kinds of land produce.

In 1813 the number of inhabitants was 113,857; Population, in 1821 the number was 129,391, making an increase of 15,534.

The county sends two members to Parliament, and the town of Portarlington a third. Before the Union, this district had eight representatives in the Irish Parliament; two for each of the boroughs of Portarlington, Maryborough, and Ballynakill, and two for the county. The Irish language is still spoken in some parts, though the English is now more common. A few years ago, the wages of common labour were one shilling a-day for men and sixpence for women; their food is potatoes, their fuel turf or peat, and their clothing, excepting that of the females on holidays, the produce of their own domestic manufacture.

See the general works quoted under the former Irish counties, and Sir Charles Coote's *Agricultural Survey of Queen's County.* (A.)

QUESNAY (FRANÇOIS), a physician of considerable eminence, but who is chiefly known in the history of philosophy as a profound and ingenious inquirer into the constitution of society, and as the founder of the sect of the Economists.

The accounts of the life of this distinguished person—a life which, unlike that of most literary men—abounded in incident and adventure—are exceedingly meagre and contradictory.—Neither the place of his birth, nor the condition of his parents, is well ascertained; but the accounts apparently most enti-

\* In 1677, Penn, Barclay, Keith, and others, crossed over to Holland, where they preached, or discoursed together before numerous assemblages of the people.—“This being first-day, we had a very large meeting, there coming to it a great concourse of people of several opinions, Baptists, Seekers, Socinians, Brownists, and some of the Collegians. Robert Barclay, George Keith, William Penn, and I, did all severally declare the everlasting truth among them; opening the state of man in the fall, and shewing by what way man and woman may come into the restoration by Christ Jesus. The mystery of iniquity and the mystery of godliness were very plainly laid open, and the meeting ended quietly and well.” *Journal*, p. 502. 3d edit. fol. Lond. 1765.

Quesnay.

tled to credit state that he was born at the village of Ecquilly, in the Isle de France, in 1694; and that his father was either a common labourer, or a small proprietor, who cultivated his own little property.\* His humble origin is indeed evident from the fact mentioned by all his biographers, of his early education being almost entirely neglected, and of his being constantly occupied, until his fourteenth or sixteenth year, in the sports or labours of the fields, without having been either sent to school or taught to read. But though placed in such unfavourable circumstances, young Quesnay was imbued with an ardent love of knowledge, and with a strong desire to emerge from the painful and obscure life in which he had been brought up. The *Maison Rustique* of Liebaud was the first book that came into his hands; and he is said to have learned to read it by the assistance of a few lessons he received from a gardener of the village! The perusal of this book, which seems to have had a material influence on his future studies, awakened his latent powers, and stimulated him to make further efforts to extend his information. Having acquired a competent knowledge of his vernacular tongue, by the eager reading of such French books as came within his reach, he next applied himself to the study of the dead languages; and speedily attained, partly by the slender assistance of a self-dubbed surgeon of the village, but chiefly by his own extraordinary industry and sagacity, to a tolerable proficiency in Latin and Greek.

Quesnay now resolved, in opposition to the wishes of his parents, and especially of his mother, to devote himself to the profession of surgery, and received the rudiments of his instruction in that art from the village doctor who had assisted him in his philological studies. But the pupil very soon surpassed the master; and when the latter applied to be admitted into the *Maitrise*, or Corporation of Surgeons, he presented, as testimonials of his skill in his profession, and of his capacity to practise it with advantage, some Essays which Quesnay had written, and which were received with very great applause. Quesnay was not privy to this *ruse*; but soon after its occurrence he left his paternal village, and set out to prosecute his studies at Paris. We are not informed by what means he supported himself in that city, nor how long he remained there: while, however, his indefatigable industry and zeal enabled him to make great progress in his studies, his merit and modesty procured him several friends. Besides attending the prelections on the various branches of surgery, and the

different hospitals, he found leisure to devote some portion of his time to metaphysical researches, and the study of philosophy, for which the perusal of the *Recherche de la Verité* of Malebranche had given him a very decided taste. Nay, such was the almost unparalleled activity and vigour of his mind, that having accidentally met, during his stay in Paris, with the celebrated M. Cochin, of the Royal Academy of Painting, he put himself under his tuition; and we are told, that he profited so well by the few lessons he received as to be able not only to take remarkably good likenesses, but to design and engrave, with his own hand, the various bones of the human skeleton, in a manner which would not have disgraced the most skilful artists!

On finishing his studies at Paris, Quesnay formed the design of establishing himself as a surgeon in Mantes, a considerable town in his native province, and presented himself to the surgeons of its *Maitrise* for examination. But they refused, from jealousy of his talents, to admit him to trial. He was thus laid under the necessity of returning to Paris, where he passed his examinations with eclat; and received letters ordering him to be admitted into the *Maitrise* of Mantes in 1718.

Having established himself at Mantes, his reputation soon extended itself. He was employed by some of the first families in the neighbourhood, and, among others, by that of the Marshall de Noailles, Duc de Villeroy, who persuaded him to leave his residence in the country, and to accompany him to Paris as his surgeon, as nearly as we can collect in 1729 or 1730. An incident not long after occurred, which had the most material influence on his future prospects and life. Having accompanied the Duc de Villeroy to the house of the Comtesse d'Estades, Quesnay remained behind in the carriage while the Duc went in to visit that Lady, who, during the interview, was suddenly seized with an epileptic fit. The Duc called in Quesnay, who, on perceiving the nature of the attack, with singular presence of mind instantly ordered the Duc and the other attendants out of the room, and managed so well as to succeed in concealing the malady. The Comtesse was so much pleased with the dexterity and address of Quesnay, that she lost no time in recommending him to her all-powerful friend, Madame d'Estioles, afterwards Marquise de Pompadour, who made him her physician: and, besides obtaining for him apartments at Versailles, procured him, in 1737, the place of Surgeon in Ordinary to the King.†

\* It is stated in the *Eloge Historique* of Quesnay, in the *Memoires de l'Academie des Sciences* for 1774, that he was the son of an *avocat en Parlement*, who practised at Montfort, and that he was born at Merey. But it is difficult to suppose, had his father been in such a station, that his education would have been so entirely neglected. In the brief but interesting notice of Quesnay, given by Mr Crawford, in a note to the *Journal* of Madame du Hausset, femme-de-chambre de Madame de Pompadour, et *l'amie* de Quesnay, in the *Melanges d'Histoire et de Litterature* (p. 276), he is stated to have been the son of a labourer. This is also the statement in the *Encyclopedie Methodique*. According to the notice prefixed by Dupont to the *Eloge* of M. Gournay in the third volume of the *Œuvres de Turgot*, Quesnay was the son d'un *proprietaire cultivateur*.

† This incident is related by Mr Crawford, *Melanges*, p. 276, and is referred to by Marmontel.

Quesnay.

Quesnay was shortly after appointed Secretary to the Royal Academy of Surgery, established in 1731; and besides several articles on particular branches of surgery, he contributed the preface to the first volume of its *Memoires*; which has always been reckoned peculiarly valuable for its profound and discriminating observations on the respective uses of theory and observation in the physical sciences, and on the assistance which they reciprocally lend to each other.

Having from an early period been much subject to the gout, and becoming, in consequence, less able to discharge his duties as a surgeon, Quesnay took the degree of Doctor of Medicine in 1744; and was soon after appointed, through the influence of his patroness, to the important place of consulting physician to his Majesty. In this capacity he attended Louis in the campaigns of 1744 and 1745; and amid the distractions of a camp, collected and prepared the greater part of the materials for his *Traité de Fievres*, published in 1753.

His appointment to the situation of Physician to the King was preceded by the grant of letters of nobility, issued on occasion of the recovery of the Dauphin from the small-pox. Louis, who was much struck with the justice and solidity of Quesnay's remarks, and who familiarly called him *son penseur*, gave him, in allusion to this title, three pansy flowers (in French *pensées*), for his arms, with the motto *Propter cogitationem mentis*.

The leisure Quesnay now enjoyed, enabled him to prosecute his studies with greater assiduity. In 1747, he republished an enlarged edition, in 3 tomes. 12mo, of his *Essai Physique sur l'Economie Animale*, originally published in 1736; in 1748, he published an *Examen impartial des Contestations des Mediciens et des Chirurgiens de Paris*; in 1749, he published a *Memoire sur la Sagesse de l'Ancienne Legislation de la Chirurgie en France*, and two separate treatises, in 12mo, the one on *Suppuration*, and the other, *De la Gangrene*; in 1750, he republished his *Traité des Effets et de l'Usage de la Saignè*, written during his residence at Mantes, and originally published in 1730; and in 1753, he published his *Traité des Fievres Continues*, in 2 tomes 12mo.

These works have been all held in very high estimation; and an excellent judge has lately given it as his opinion, that "the *Traité de la Gangrene* is by far the most valuable publication which we yet possess upon this subject." Every page of this work, he adds, "is distinguished by the same talent for accurate observation, and perspicuous arrangement,

which are so remarkable in all the other writings of this celebrated author." (Dr Thomson's *Lectures on Inflammation*, p. 502.)

The *Traité des Fievres* was the last of Quesnay's professional works. He appears to have henceforth comparatively abandoned his medical studies. At no period, indeed, had he allowed them exclusively to occupy his attention, and he now devoted himself, in preference, to other and, if possible, still more interesting inquiries. He had always entertained a strong predilection for agricultural pursuits, the effect, perhaps, of his situation in early life; and this, combined with the speculative and metaphysical cast of his mind, seems to have led him to those peculiar notions respecting the paramount importance of agriculture as a source of wealth, and the constitution of society, which have rendered his name so justly celebrated in the history of economical science. The articles "*Fermier*" and "*Grains*" in the *Encyclopedie*, published in 1756 and 1757, contain the earliest development of his views on this subject. Both articles are written with great ability, and display an intimate acquaintance with the subject, considerable reading, and great powers of analysis. In the article "*Grains*" the distinction between the *produit total* and the *produit net*, between the productiveness of agriculture, and the unproductiveness of all other employments, the doctrine of the unrestricted freedom of commerce, and most of the other leading principles in the theory of the economists, are distinctly stated and illustrated with much ingenuity and talent. The *TABLEAU ECONOMIQUE*, and the *Maximes Generales du Gouvernement Economique*, annexed to it, under the title of *Extraits des Economies Royales, de M. de Sully*, were printed, by the express command of the King, at Versailles in 1758, with the following very remarkable epigraph for a work brought forth under such auspices, *Pauvres paysans, pauvre royaume; pauvre royaume, pauvre Souverain!* The maxims, which contain a short but comprehensive abstract of Quesnay's system, were reprinted, together with an analysis of the *Tableau*, and a selection from various articles contributed by Quesnay, in defence of his peculiar doctrines, to the *Journal d'Agriculture*, and the *Ephemerides du Citoyen*,\* in the collection of Quesnay's economical works, entitled *Physiocratie, ou Constitution Naturelle du Gouvernement le plus Avantageux au Genre Humain*, edited by his friend and scholar, Dupont, in 1767.

We have elsewhere entered at considerable length into an examination of the speculations of Quesnay and his followers, with respect to the constitution of po-

\* The *Ephemerides du Citoyen* was begun in 1767, and was, for a few months, conducted by the Abbé Baudeau, and then by Dupont. It was published monthly, and two numbers make a considerable duodecimo volume. The authors were all disciples of Quesnay, and zealous economists. Their discussions embraced only the moral and political sciences; many branches of which they have treated with much ability and acuteness. There is a valuable *Eloge* of Quesnay in one of the numbers for 1775, written by the Conte d'Albon. The following extract from the *approbation* given by the *Censeur* to the third number for 1770 is curious: "J'exhorte," says he, "de nouveau les auteurs de ce *Journal*, à résister à la tentation de critiquer—Le bonheur du citoyen tient à sa confiance—On peut et l'on doit quelquefois avertir en secret ceux qui sont proposés à l'administration. Mais on ne doit prêcher aux particuliers que leur propre réforme, et non celle de l'état."

Quesnay.

litical societies, and the sources of public wealth. (See the articles ECONOMISTS and POLITICAL ECONOMY.) That there is a good deal of error in them must be allowed; but this is far more than compensated by the many just, discriminating, and original views, and important discoveries, which they contain. Perhaps, however, the principal merit of Quesnay, and the sect of which he was the founder, does not consist so much in the discoveries they made, as in their having been the earliest philosophers who perceived that the institutions of society ought always to harmonize with the natural principles on which it is founded, or, as they termed it, with the *Ordre naturel et essentiel des Societes Politiques*. Economical science is defined by them to be, "*L'etude et la demonstration DES LOIX DE LA NATURE, relatives à la subsistence, et la multiplication du genre humain*. L'observation universelle de ces loix est l'interet commun et general de tous les hommes. La connaissance universelle de ces loix est donc le preliminaire indispensable, et le moyen necessaire du bonheur de tous." (*Ephemerides du Citoyen*, 1769, No. II. p. 13.) It is to be regretted that, in investigating these laws, they proceeded almost entirely on abstract and speculative principles, without sufficiently attending to the effects of particular institutions, and to the various phenomena manifested in the progress of society. But notwithstanding the defective mode in which the economists conducted their researches, they succeeded in establishing and elucidating many important principles; and there is certainly much more reason to wonder at the general correctness of their conclusions, than to feel surprised at the errors into which they fell. Quesnay and his disciples established, that society was formed for the purpose of securing the greatest possible advantage to its members; that the security of property and the freedom of industry were its essential bases; and that the proper business of the politician was not to interfere to regulate the pursuits of individuals, but to protect the equal rights and liberties of all, and to secure the utmost freedom of competition in all the departments of industry. And though it is undoubtedly true, that most of these principles had been pointed out by previous writers, Quesnay and his school have the unquestionable merit of being the *first* who showed their dependence on each other, who presented them in a *systematic and consentaneous form*, and who were thus enabled to give a scientific demonstration of the injustice and impolicy of such institutions as ignorance or mistaken views of national interest had established in opposition to them.

In our article on Political Economy we have shown the fallacy of Quesnay's opinion with respect to agriculture being the only source of wealth; and the experience of all ages sufficiently

proves that the *despotisme legal*, in the hands of an hereditary monarch, without *contreforces* of any kind, which he strangely supposed was the best of all possible governments, is about the very worst. \*

Notwithstanding his great age, and the sufferings he experienced from the almost incessant attacks of the gout, the activity of Quesnay's mind continued unimpaired. *Il a*, said one of his friends, *une tete de trente ans sur un corps de quatre-vingts*. He contributed, subsequently, to the publication of the *Physiocratie*, many acute and able articles to the *Ephemerides du Citoyen*; and continued wholly occupied with these studies and mathematics, to which he had latterly begun to pay considerable attention, till his death, which took place at Versailles, in December 1774, in the 80th year of his age.

Quesnay was a man of the most inflexible integrity; the nicest sense of honour; and the greatest prudence and discretion. Though highly esteemed by the King, and long resident at Court, he never intermixed in the intrigues of which it was the constant theatre. No one ever scrupled to express himself freely in his presence, nor was the confidence placed in him ever betrayed. "*Il recevoit chez lui des personnes de tous les partis, mais en petit nombre, et qui toutes avoient une grande confiance en lui. On y parloit tres hardiment de tout; et ce qui fait leur eloge et le sien, jamais on n'a rien repete.*" † To the utmost frankness and sincerity, he added the easy address and polished manners of a courtier and the intelligence of a philosopher. No man was ever less solicitous of distinguishing himself, or more careful to offend the self-esteem of others. His conversation was animated, without the least effort at brilliancy. So much, indeed, was he averse to every appearance of pretension, that he was in the habit of veiling the most profound remarks and observations, under the form of apologues, which generally referred to some subject connected with rural affairs, to which he was always particularly attached. He was most indulgent to the faults and errors of others, provided they were unalloyed by any taint of artifice or baseness, for which he never hesitated, whatever might be the rank of the party, to express the utmost contempt. Quesnay was truly a patriot and a philosopher. And we doubt much whether another instance can be produced of one who had lived so long in a profligate and luxurious Court, unsullied by its vices, and aloof from its contentions; and who preserved, to an extreme old age, all those generous and kindly feelings, with that unobtrusive but ardent zeal in the cause of humanity, and that love of speculation and profound inquiry, which distinguished his earlier years.

Quesnay, says Madame du Hausset, "*etoit un grand genie, suivant l'opinion de tous ceux qui*

\* We are at a loss to conjecture the grounds on which Mr Chalmers has presumed to affirm (*Biographical Dictionary*, Vol. XXV. Art. Quesnay), that the "economists abused their influence by circulating democratical principles!" It would be quite as correct to say, that Locke and his followers had abused their influence, by circulating *despotic* principles.

† *Journal de Madame du Hausset in the Melanges, &c.* p. 277. A striking instance of the confidence placed by the most opposite parties in Quesnay is given in the second volume of Marmontel's *Memoirs*.

l'avoit connu et de plus un homme fort gai. Il aimoit causer avec moi de la campagne; j'y avois été élevée, et il me faisoit parler des herbages de Normandie et du Poitou, de la richesse des fermiers, et de la maniere de cultiver. C'etoit le meilleur homme du monde, et la plus éloigné de la plus petite intrigue. Il estoit bien plus occupé à la cour de la meilleure maniere de cultiver la terre que de tout ce que s'y passoit." (*Melanges*, p. 343.)

"Tandis," says Marmontel, "que les orages se formoient et se dissipoient au-dessous de l'entresol de Quesnay, il griffonnoit ses axiomes et ses calculs d'économie rustique, aussi tranquille, aussi indifférent à ces mouvemens de la cour, que s'il en eût été à cent lieues de distance. Là bas, on décidoit de la paix, de la guerre, du choix des généraux, du renvoi des ministres; et nous, dans l'entresol, nous raisonnions d'agriculture; nous calculions le produit net, ou quelquefois nous dinions gaiement avec Diderot, d'Alembert, Duclos, Helvétius, Turgot, Buffon; et M.me de Pompadour, ne pouvant pas engager cette troupe de philosophes à descendre dans son salon, venoit elle-même les voir à table et causer avec eux."

Dr Smith was well acquainted with Quesnay. He frequently met with him during his residence at Paris in 1766; and while he bears the most honourable testimony to the "modesty and simplicity" of his character, he has pronounced his system to be, "with all its imperfections, the nearest approximation to the truth that has yet been published on the subject of Political Economy." (*Wealth of Nations*, Vol. III. p. 28.) So highly, indeed, was Dr Smith impressed with a sense of his merits, as a man and a philosopher, that it was his intention, had he not been prevented by Quesnay's death, to have inscribed to him the *Wealth of Nations*. (Mr Stewart's *Account of the Life and Writings of Dr Smith*.)

Quesnay had a son by his wife, to whom he was

united when at Mantes. He gave him an excellent education; and exhibited a striking proof of his disinterestedness, by constantly refusing to solicit for him any place or situation under government. This son ultimately settled in the country on an estate near Beauvoir. One of Quesnay's grandsons was appointed by Turgot to a place in the administration; and another entered the army, and acted as a captain of infantry at the battle of Jemappes.

No man was ever more esteemed by his friends than Quesnay, and none ever existed who was more ready to do all in his power to advance their interests. Mercier de la Riviere, the author of the work *Sur l'ordre Naturel et Essentiel des Sociétés Politiques*, and who had been *Intendant* at Martinique, seems to have occupied the chief place in his esteem, and was regarded by him as the only person in France who was qualified to conduct the administration of the Finances. He was also much attached to the Marquis de Mirabeau, Turgot, Dupont, the Abbé Baudeau, and the other leading economists, who willingly acknowledged him for their master, and enthusiastically exerted themselves to defend and propagate his doctrines. "The economists were in reality, and not merely in appearance, a sect of philosophers.

Secta fuit servare modum, finemque tueri  
Naturamque sequi, ritamque impendere vero,  
Nec sibi sed toto genitum se credere mundo.

They acted from honest zeal for the truth, and not from fashion, eccentric tastes, or the love of singularity; their sole object was to enlighten and improve mankind; and to them, among political inquirers, belongs the rare praise of having first pointed out the natural order of things, or the observed course of nature in the conduct of the world, as the example and guide of human policy." (s. s.)

R A D

Boundaries and Extent. RADNORSHIRE, an inland county of South Wales, bounded on the north by Montgomeryshire, on the west by the counties of Cardigan and Brecon, on the south-east by Herefordshire, and on the north-east by Shropshire. Its extremities from east to west are twenty miles, and from north to south twenty-four miles, as under. Its surface is computed to measure 426 square miles, or 272,640 English statute acres.

Population and Rental. The population in 1811 amounted to 20,900 souls, and in 1821 to 22,503, of whom 11,300 were males, and 11,203 females. The total sum charged to the property-tax in 1811, under the heads of rent of land and tithes, was, for the former, L. 88,250, and for the latter L. 9373. On comparing these numbers with the other returns of Great Britain, it appears that this county is the lowest in nu-

merical population, except the county of Rutland; although its annual rental is higher than either Anglesey or Merioneth.

This district of country continued under the jurisdiction of the Lords Marchers, until it obtained the privileges of a county by act of Henry VIII., and was divided into the hundreds of Radnor, Knighton, Painscastle, Rhayder, Colwyn, and Kevenleece. By the same act it was also empowered to return two members to Parliament, one for the county, and one for the contributory boroughs of Radnor, Rhayder, Knighton, Knuclas, and Kevenleece. The county is farther divided into parishes and townships. The former are fifty-two in number, and are all in the diocese of St David's, except five, which are included in the English diocese of Hereford. New Radnor, said to have been at one period the principal town

Radnorshire. is now a very poor village; it was an ancient borough

by prescription, and has also had charters granted by Queen Elizabeth, and by George II.

Face of the Country.

Two-thirds of the whole area of the county are supposed to be uninclosed, and uncultivated. An extensive mountainous tract, nearly in the centre, is usually called the Forest, though there is no reason to believe it was ever covered with trees. A part of this range still belongs to the Crown, although the forests of Radnor and Blathyagh have both been alienated, and are now held by Thomas Frankland Lewis, Esq. and Richard Price, Esq. as foresters. There is nothing remarkable in the circumstances or character of these mountains; the summit of which was ascertained, by Colonel Mudge, to be 2163 feet above the level of the sea. Within their limits is a torrent, called by a name, which, when translated, is "Water-break-its neck," that falls abruptly from a height of about 150 feet. The higher ranges produce only heath, but the sides and lower parts of the hills, which are less exposed to the winds, are entirely devoted to the pasturage of sheep and small horses. The north-western angle of the county is mountainous and uninclosed, and it was in the recesses of these wilds that the British monarch, Vortigern, retreated from the Saxons. On the eastern and southern districts, the valleys are wider and more fertile, and abound with small rivulets: the hills are less elevated, and are partially clothed with wood.

Soil and Climate.

The soil of this county is as varied in quality as its position is in elevation. A small portion of the southern angle is composed of the fertile red earth, which prevails in the adjoining counties of Brecon and Hereford. The mountains on the western side are chiefly of the primary slate rocks which abound in Wales; and the valleys between these and the forest have frequently a clayey substratum retentive of water. The forest, and the other subordinate hills connected with it, consist of a slaty rock, containing a portion of lime, which decomposes rapidly on exposure to the atmosphere. The valleys to the eastward of this range are chiefly of a fertile loamy soil, incumbent on an extremely absorbent gravel. The climate is wet and stormy, and the spring months are particularly cold and ungenial. It is, nevertheless, healthy: there are no peculiar or prevalent diseases, and the inhabitants are robust and long lived.

Rivers and Lakes.

The principal river is the Wye, which enters the county at Savan y Coed, and flows to the south till it divides it from Brecon. Its tributary streams are the Elan, the Ithon, the Edda, and the Mackwy. The river Terne flows on the eastern border, and continues its course by Ludlow to the Severn. The Lug and the Arrow, in the more central parts, form considerable streams before they enter the county of Hereford. There are some small lakes or pools requiring notice only as contributing to the beauty of the scenery. These are—Llyn, Llanbychllyn, Hendwell Pool, and Llyn-Gwyn. A cataract, at Rhayader, was formerly an object much visited by travellers; but the construction of a bridge has widened the channel, and deprived it of much of its remarkable character.

Agriculture.

The agriculture of the county is gradually improving. Irrigation has long been practised to a

considerable extent, and its effects on absorbent Radnorshire soils are found to be highly beneficial; but the process is not conducted in the most scientific manner. Lime is abundantly used as a manure, and is chiefly supplied from a valuable stratum of rock near Old Radnor. The ploughing was usually performed by two oxen and two horses; but oxen are now seldom used, and the plough with two horses is in gradual adoption. The implements of husbandry are, for the most part, in a rude form. Most of the farms consist of an equal portion of arable and of grass land. The latter is generally appropriated to the dairy, and the young cattle are reared on the more hilly and barren spots. About one-fifth of the county is under the plough, and one-tenth meadow: the remainder is generally used for sheep walks.

In the mountainous districts the cattle differ little from those which are common in the principality of Wales, but in the more fertile parts the Herefordshire breed prevails. The sheep are small, and when fattened, their mutton is excellent: the horses also are generally small, strong, and hardy.

There is little commerce carried on in this county, and the only manufactures are of flannels and coarse woollen cloths, which the inhabitants make for their own use. Cattle, sheep, horses, wool, butter, and, from the south-east districts, a surplus of grain, are sent annually to the markets of England. The county is not known to contain any valuable minerals. A lead mine has been opened and abandoned, and, in some places, an uncertain belief has prevailed of the existence of copper. Various mineral springs are known, and Llandrindad is a place of resort on account of the medicinal qualities of its saline sulphureous, and chalybeate wells. In several other parts are similar springs, the properties of which have not been accurately ascertained.

There are many vestiges of antiquity. The Abbey of Cwm Hir stood formerly in a singularly retired and romantic situation on the banks of a rivulet, which runs into the Wye. A small vestige remains of a castle at New Radnor, which was assailed and destroyed "by the irregular and wild Glendower," previous to the battle noticed by Shakespeare, in the first part of Henry IV., when Mortimer was taken prisoner. It was fought at Pilleth in this county. A Roman road, which reached from Chester to Caernarthen, traversed this county, entering its confines on the northern extremity, in the direction of Newtown, following the valley of the river Ithon, and crossing the Wye into Brecknockshire, near the town of Beulth. At Cwm, near Llandrindad, the remains of a Roman station, on this road, are still discernible.

The market towns, and their present population, are as follows: Presteign, 1387; Knighton, 1000; Rhayder, 647. The principal gentlemen's seats are—Slanage Park, Edward Rogers, Esq.; Maeslowgh, Walter Wilkins, Esq.; Harpton Court, T. Frankland Lewis, Esq.; Wellfield, D. Thomas, Esq.; Downton, Percival Lewis, Esq.; Pennybout Hall, J. C. Severn, Esq.; Cwm-Ellan, R. Peel, Esq.; and Noyadd, H. Powell Evans, Esq.

Railway.

**RAILWAY**, a species of road or carriage-way, in which the track of the carriage-wheels being laid with bars, or rails, of wood, stone, or metal, the carriage is more easily drawn along this smooth surface than over an ordinary road.

Wooden  
Railways.

Wooden railways are said to have been introduced at the Newcastle coal-mines so early as the year 1680, for transporting the coals from the mouth of the pits to the ships in the river Tyne. Even at that period, many of these mines employed each of them 400 or 500 carts in this traffic; it became, therefore, an object of manifest importance to reduce the great expence thereby incurred in the keeping up of horses, drivers, and roads; and the plan of wooden rails was the best, and, indeed, the only effectual method which could at that time have been devised for the purpose; for which also the situation was in other respects favourable, presenting in most cases an easy descent towards the river. These railways then were very generally introduced, and continued for a long period in use in this part of the kingdom. Slips of ground of the requisite breadth for the railway were marked out between the coal-pits and the river, and were either leased by the coal owners, or purchased of the different proprietors whose ground the proposed line of road intersected in its course. To obtain the most easy and regular descent, this line was varied in its direction to meet the inequalities of the ground; or, where these inequalities were inconsiderable, it was carried straight forward, and the regular slope made up by embankments and cutting. The ground being then smoothed and levelled as for an ordinary road, large logs of wood, termed *sleepers*, cut in lengths equal to the breadth of the road, were laid across it, and firmly bedded into it at short distances, to sustain and hold fast the rails, or slips of wood, on which the waggon-wheels were intended to run. These rails were made of beech, and were laid end to end, so as to form two continued lines of rail or wooden ridges, running parallel to each other, along each side of the road, crossing the large logs at each of their extremities, on which they rested as on so many foundations; and were also nailed, or otherwise secured, to keep each piece in its proper place. The waggons were of the usual construction, but of a large size, so as to contain several tons of coals, and set upon low wheels; the smoothness of the way rendering wheels of the ordinary size unnecessary. On these rails a single horse could readily draw three tons of coals from the pits to the river. Where any steep declivity occurred on the road, this was termed a *run*, or an inclined plane; and on it the descent of the waggons was retarded, and regulated by a species of brake, or crooked lever, termed a *convoy*, attached to the waggon and managed by the driver. The banks of the Tyne, near Newcastle, are remarkably steep on each side; but instead of forming inclined planes on them, the railway was here continued on a wooden stage, raised to the same height as the top bank of the river, and carried forward until it came perpendicularly over the river side, where a wooden platform, termed a *stait*, was erected for the convenience of delivering the coals; the waggons being emptied into a trough, or spout,

down which the coals descended either directly into the ships, or into the store below.

Railway.

Such was the construction of the original railways, in which we evidently perceive all the parts and members of the railway as it is formed at the present day; viz. the regular formed road, the rails, the sleepers, the low waggons, and the inclined plane. Their only defect consisted in the soft and decaying nature of the wood, the wear and tear of which caused such expence for repairs, as greatly limited their application; so that it was only the shortness of the distance, and the great extent of the traffic, which rendered their application at all beneficial. It was only about the year 1738 that they were attempted in the collieries of Whitehaven; and it does not appear that they were adopted in any other part of the kingdom. The use of iron, therefore, in place of wood, was an essential improvement in the construction of railways, and caused, indeed, a complete change in this, as it has done in every other branch of practical mechanics into which it has been introduced. Flat bars of iron were at first fastened on the top of the wooden rails; but after various unsuccessful attempts, the rails themselves were at last wholly composed of iron, cast in short bars, united at their extremities, and resting on sleepers, or square blocks of stone, disposed at short distances along each side of the road; and this construction having been once fairly reduced to practice, was not only adopted universally in place of wood, but soon led to new and more extensive applications. Iron railways were quickly introduced into all the coal and mining districts of the kingdom. They were employed on canals, in place of locks, to raise the barges on an inclined plane from a lower to a higher level; in some instances they were adopted in preference to the canal itself; and, on the whole, they now form an important auxiliary to inland navigation, pushing the channels of trade and intercourse into districts otherwise inaccessible, and even into the interior of the mines.

Iron Rail-  
ways.

The railways in Britain are so numerous, that it would exceed our limits to specify the particular lines. In the Newcastle coal district, on the river Wear, in the coal and mining districts of Yorkshire and Lancashire, as well as of Derbyshire and Staffordshire, there are numerous railways branching off from the navigable rivers and canals to the different mines. In Shropshire also, and in the great mining districts along the vale of the Severn, the use of railways is very general, and it was here that the inclined plane was first brought in aid of inland navigation. In Surrey, there is a railway of a considerable extent, termed the Surrey Railway, and this presents one of the few attempts that have been made to form public railways for general use. In the great mining districts on the west of the Severn, including South Wales, the rail or tram roads are very numerous; and here, owing to the steepness and impracticable nature of the ground, they have been of essential utility in supplying the place of canals. In the year 1791, there was scarcely a single railway in all South Wales, and in 1811, the completed railroads connected with canals, collieries, iron, and copper-works in the counties of Monmouth, Glamorgan, and Caer-

**Railway.** marthen, amounted to nearly 150 miles in length, exclusive of a great extent within the mines themselves; of which one company in Merthyr-Tydvil possessed 30 miles under ground. In Monmouthshire, the Sirhoway railway forms one of the first in point of magnitude which has hitherto been constructed. It extends from Pilgwellly, near Newport, to the Sirhoway and Tredagar iron-works, distant 23 miles, whence it is continued five miles farther to the Trevil lime-works, in Brecknockshire, along with a branch to the west, to the Rumney and Union Iron-works. This railway was made by the Monmouthshire Canal Company, under the authority of an act of Parliament. From Sirhoway, a branch proceeds eastwards to the Ebbwy works, and from thence down the course of the Ebbwy to Crumlin Bridge, whence it joins the canal from Newport; and from Sirhoway again, the Brinare railway is continued over the Black Mountain to the vale of the Uske at Brecon, and from thence to Hay on the river Wye. In Glamorganshire, the principal railways are the Cardiff and Merthyr-Tydvil, the Aberdare, and the Swansea railways. In Caermarthen-shire, the principal railway is that which extends from Caermarthen to the lime-works near Llande-bie, a distance of 15 miles.

From this account of the chief railways in England and Wales, it will appear that this species of inland carriage is principally applicable where trade is considerable and the length of conveyance short; and is chiefly useful, therefore, in transporting the mineral produce of the kingdom from the mines to the nearest land or water communication, whether sea, river, or canal. Attempts have been made to bring it into more general use, but without success; and it is only in particular circumstances that navigation, with the aid either of locks or inclined planes to surmount the elevations, will not present a more convenient medium for an extended trade. South Wales, however, presents an example, where the trade being great, and also chiefly descending, the country rugged, and the supply of water scanty, railways have been adopted with complete success; and have been found in some cases at least equal to canals in point of economy and dispatch. The Surrey railway, not having these advantages, has scarcely answered the expectations of its projectors, more especially the southern line from Croydon to Gadstone. It was at one time proposed to continue this railway to Portsmouth, but the plan was abandoned.

**Railways in Scotland.**

In Scotland there are various railways proceeding from the different mines throughout the kingdom. The principal one in point of magnitude is the Duke of Portland's railway, extending from the town of Kilmarnock to the harbour of Troon, a distance of nearly ten miles. Its chief object is the export of coal and lime, in which articles a great trade is carried on by means of the railway. In the coal and mining districts round Glasgow, there are numerous smaller railways, and also in the coal fields of Mid Lothian and Fife. Plans have been proposed for a public railway from Edinburgh to the different coal-works in the neighbourhood. An extensive railway was also at one time projected from Glasgow to

Berwick-upon-Tweed, but none of those schemes have been carried into effect.

**Railway.** **Construction of Railways.** The original wooden railways already mentioned are the model on which all the succeeding ones have been formed, and of which we shall now describe shortly the construction. In regard to the road itself, this should, in the first place, be formed in such a direction, and with such a declivity as may best suit the nature of the ground through which it passes, and of the trade to be carried on upon it. If the trade, for example, be all or chiefly in one direction, the road should obviously decline that way, so that the waggons, with their contents, may descend on this inclined plane as much as possible by their own gravity. The inclination should also be proportioned to the extent of the trade up the railway, so that the draught each way may be equal. If the exports and imports, therefore, be equal, the road should be on a level; and where the ground will not permit that declivity or level best suited to the trade, the line should be varied, and the inequalities made up, if it can be done at a moderate expence, so as to bring it as near as possible to the proper standard. If the inequalities are such as to render this impracticable, the only resource lies in inclined planes. Where the difference of level, for example, between the two extremities of the road is such as would render an equal declivity too steep, the road must then be carried, either on a level or with the due degree of slope, as far as practicable, and then lowered by an inclined plane; on which the waggons are let gently down by means of a brake, are dragged up by means of an additional power to that which draws them along the road, or at once let down and drawn up by means of a roller or pulley, the heavier preponderating over the lighter. In laying out a line of railway, therefore, as every situation presents peculiar circumstances, no general rule can be laid down, and the plan must be left to the skill and judgment of the engineer.

The line of railway being fixed on, the road is then properly formed, and of such a width as will be sufficient for containing the opposite rails, and for forming a foot-path on one side. The distance between the opposite rails varies from three feet to four and one half feet; some preferring a long and narrow waggon, and others a broad short one. Hence a breadth of from nine to twelve feet will be sufficient for a single road, and from fifteen to twenty for a double one. The next operation is the setting and firm bedding of the stone sleepers. These consist of solid blocks of stone, each of the weight of one or two cwt. Their shape is immaterial, provided their base be broad, and their upper surface present an even and solid basis for the rail. They are placed along each side of the road, about three feet distant from each other from centre to centre; the opposite ones being separated by the width between the opposite rails. The ground under them is beat down to form a firm foundation, or, if it be of a soft nature, is first laid with a coat of gravel or small metal, and this beaten under the stones; the situation of each stone being properly gauged both as to its distance from the adjoining ones, and as to the level or declivity of its upper surface, on which the rails are in-

Railway. tended to rest. The space between the sleepers is then filled up with gravel, metal, or other road materials, such as may consolidate into a hard and firm mass.

The next object is the construction of the iron rails; and on this point two very different plans have been adopted, each of which has its advocates, and is practised to a great extent. The one is termed the *flat rail*, or tram plate; the rails being laid on their side, and the waggon-wheels travelling over their broad and flat surface. The other is termed the *edge rail*; the rails being laid edgeways, and the wheels rolling on their upper surfaces. The flat rail, or tram plate, consists of a plate of cast-iron, about three feet long, from three to five inches broad, and from half an inch to an inch thick; extending from sleeper to sleeper, and having a flanche turn up or crest on the inside, from two and a half to four inches high. This rail bears on the sleepers at each end at least three inches, where the rails are cast about half an inch thicker than in the middle. As there is no intermediate bearing for the rail between the sleepers, except the surface of the road, the use of the flanche is not merely to prevent the waggon from being drawn off the road; it resists the transverse strain arising from the weight of the waggon; on this account it is often, and with great propriety, raised higher in the middle than at the sides, forming an arch of a circle; and, to strengthen the rail still farther, a similar flanche, arched inversely, is added below, as represented in Plate CXV. figs. 1, 2, 3. The weight of each rail is from forty to fifty pounds. To unite these rails into one continued line, they are merely laid to each other, end to end, all along each side of the road; being kept in their places, and at the same time made fast to the sleepers, by an iron spike driven through the extremity of each rail into a plug of oak fitted into a hole in the centre of each sleeper. This spike is about six inches long; it has no head, but the upper end of it forms an oblong square, about one inch broad, half an inch thick; and the hole in the rails, through which it passes, is formed by a rectangular notch, half an inch square, in the middle of the extremity of each rail; the opposite notches of each rail forming, when laid together, the complete oblong square of one inch by half an inch, and slightly dove-tailed from top to bottom, so as to fit exactly the tapering head of the spike, which is driven clear below the upper surface of the rail. Plate CXV. fig. 4, represents a section of a rail, with its sleeper and fastening. Wherever the rails cross any road, the space between them and on each side must be paved or causewayed to the level of the top of the flanches, that the carriages on the road may be enabled to pass clear over the rails. In single railways it is necessary to have places at certain intervals where the empty waggons, in returning, may get off the road to allow the loaded ones to pass. A place of this kind is termed a *turn-out*; and the waggons are directed into it by a moveable rail termed a *pointer*, fixed at the intersection between the principal rail and the turn-out, and turning on its extremity, so as to open the way into the turn-out, and shut that along the road. This contrivance is also used whenever one line of railway crosses an-

other. It is represented at Plate CXV. fig. 5, where, also, fig. 6 is a plan of the railway and of the turn-out.

The tram roads have been universally adopted in Wales, where they are preferred to any other species. They are also used in most parts of England. The Surrey railway is of this description, and was designed by Mr Jessop. In Scotland the Duke of Portland's railway, which, we believe, was planned by the same engineer, is of the same kind, and the rails nearly of the same dimensions. These flat railways have one advantage, in admitting waggons or carts of the ordinary construction, and this is particularly exemplified in the Troon railway. According to an account with which we have been favoured by Mr Wilson of Troon, "there are several kinds of waggons used upon the railway under certain restrictions; such as four-wheeled waggons with flat bottom and low shelmets for carrying stone, limestone, grain, timber, slates, &c. from the harbour to Kilmarnock, the mills," &c. "The common make of a cart is allowed to use the railway if the wheels are cylindrical, and there be no greater load on each pair than 28 cwt. A great deal is done with these carts in carrying timber, barks, grain, &c., as, with the same cart, they can carry these articles into and through the streets of the town."

The other railways in Scotland, however, are chiefly of the edge kind. In the principal collieries of the north of England, also, the flat rail has been almost entirely superseded by the edge rails, and the latter are now generally admitted to be decidedly superior in the ease of draught which they occasion; the edge of the bar presenting less friction, and being less liable to clog up with dust and mud, or to be obstructed with stones driven off the road upon the surface of the rails. The edge rail consists merely of a rectangular bar of cast-iron, three feet long, three or four inches broad, and from one-half inch to one inch thick; set in its edge between sleeper and sleeper, and bearing on the sleepers at its extremities. The upper side of the rail is flanché out to present a broader bearing surface for the wheels, and the under side is also cast thicker than the middle, for the sake of strength. But the greatest strength is evidently attained by casting the rail not rectangular, but deeper in the middle than at the ends, to resist better the transverse strain. The ends may be safely reduced nearly to one-third of the depth in the middle, and still be equally strong. To unite the rails together, and at the same time preserve them in their places, and in their upright position, and to bind them also to the sleepers, they are set in a cast-iron socket or chair, which is attached firmly to the sleeper. This socket embracing the extremities of the adjacent rails, which are here made to overlap a little; a pin is driven at once through the rails and through the socket, and binds the whole together. This is the general method of uniting the edge rails, but the shape and dimensions of the metal chair and of the overlap of the rails are varied according to the judgment and taste of the engineer. Plate CXV. fig. 7, represents a section of an edge railway with the sleepers and waggons, &c.;

Railway.

Railway. and figs. 8, 9, 10, is an enlarged section of a rail and sleepers with a plan. Since edge railways have come into more general use, an essential improvement has been made in their construction by the use of malleable iron, in place of cast-iron, in forming the rails. The advantage of malleable iron rails is, that they are less subject to breakage than cast-iron; a circumstance of importance in this case, where it is not easy to avoid those jolts and sudden shocks which cast-iron is least of all capable of withstanding, and though they should happen to give way, they are easily repaired. They can also be laid in greater lengths, and requiring therefore fewer joints; they can be bent with ease to the curvature of the road; when worn out they are of greater value; and lastly, their first cost is very little, if at all, greater than that of cast-iron rails. Malleable iron is, no doubt, less able to withstand exposure, decaying more readily under the influence of air and moisture; but hitherto this inconvenience has not been felt, and, on the whole, the malleable iron is now decidedly preferred. These rails are laid and joined in the same manner as the cast-iron, only in greater lengths. Malleable iron, we believe, was first introduced in railways by Mr George Grieve, at Sir John Hope's collieries, near Edinburgh, where it was first tried on the lighter work which is done under ground. The rails consisted of square bars one inch or one and one-fourth inch square, nine feet long, resting on one or two sleepers in the middle, and resting and made fast to sleepers at the extremities; a simple knee being formed on each end of the bar, and the two knees of each two adjacent rails jammed into one socket in the sleeper. The use of these rails was found so beneficial, that they have since entirely superseded the flat cast-iron rail in general use at the time of their invention. For heavier loads the rails are made deeper. We have been favoured with the following account of their construction by an engineer (Mr Neilson of Glasgow) who has formed several of the kind.

"One of them is on the property of the Earl of Glasgow, commencing at the Hurler extensive coal and lime-works, and extending to the Paisley canal, a distance of about two miles. It is formed of flat bar iron two and one-fourth inches deep, by nearly three-fourths of an inch thick, and the rail in lengths of nine feet, each rail being supported at every three feet by a sleeper and cast-iron chair. The joinings are formed by a cast-iron dovetailed socket suited to receive the jointed ends of the bar, and a dovetailed glut or key, by which means the several rails are joined as if into one continued bar."

An improvement has lately been made in the construction of malleable iron rails, which promises to be of essential utility. It consists in the use of bars, not rectangular, but of a wedge form, or swelled out on the upper edge. In the rectangular bar there is evidently a waste of metal on the under surface, which, not requiring to be of the same thickness as where the waggon-wheel is to roll, may be evidently reduced with advantage, if it can be done easily. The bar may then be made deeper, and broader at the top than before, so as with the same quantity of metal to be equally strong, and present a much

broader bearing surface for the wheel. This has been accomplished by Mr Birkinshaw of the Bedlington Iron-works, who has obtained a patent for these broad topped rails. The peculiar shape is given them in the rolling of the metal, by means of grooves cut in the rollers, corresponding with the requisite breadth, and depth, and curvature of the proposed rail. Mr B. recommends his rails to be of 18 feet in length. We have seen one of these patent rails at Sir John Hope's colliery; and it certainly forms the most perfect iron rail which has hitherto been contrived; combining very simply and ingeniously in its form the qualities of lightness, strength, and durability. It is twelve feet long, two inches broad along the top, about half an inch along the bottom, and still thinner between. It rests on sleepers at every three feet, and at those places the rail is two inches deep, while in the middle point between the sleepers it is three inches deep. Fig. 11 is a longitudinal section of this rail, and figs. 12 and 13 are transverse sections at the sleepers, and at the middle point between each sleeper. All these inequalities, we believe, are produced on the metal by means of the rollers; and this circumstance is well deserving of attention, as it may obviously be applied not merely to the formation of railways, but to a variety of other purposes in the arts. The moulding and shaping of the metal in this manner is quite a new attempt in the iron manufacture, and it is not easy to say how far such an invention may yet be carried by the skill of British artists.

The waggons used on railways are of various sizes, but of nearly the same general shape, and all set on four wheels from two to three feet diameter. They are made to carry from 20 to 50 cwt. exclusive of the waggon itself, which weighs from 12 to 15 cwt. The axles of the fore and hind wheels are fixed three feet asunder or more, so that the rail is never loaded with more than one-fourth of the waggon at once. According to Mr Wilson, "The size of the coal waggons of Kilmarnock colliery are, on an average, mean length 80 inches, mean breadth 45 inches, and depth 30 inches. Each contains 40 bushels, equal to 32 cwt. of fine coal, and 35 cwt. of blind or malting coal. The weight of the waggon, exclusive of the coal, is 13 cwt. Each waggon, including two pair of wheels and axles, costs from about L. 13 to L. 15, and are mostly lined with sheet iron." In Sir John Hope's railway the waggons are also nearly of the above dimensions. In the Sirhoway railway each waggon carries two and one-half tons.

In regard to the expence of constructing a railway, this will depend greatly on the ease or difficulties to be met with in forming the road, and making up the inequalities to the required slope. The above railway described by Mr Neilson cost only L. 660 per mile; but where there are considerable embankments to form, bridges to build, and deep cuttings, the expence may rise to L. 4000 and L. 5000 per mile. The usual rate of tonnage on coals, &c. conveyed on railways is 2d. per ton per mile.

An important consideration regards the work done, or capable of being performed on a railway. On this point, however, the accounts from different railways are various; the performance depending on

Railway. many circumstances little attended to in the general estimate of work; such as the quality of the horses, the state of the road, the greater or less declivity of the rails, and various other circumstances. More exact observations or experiments are therefore wanting to form correct notions on this subject; but in the mean time, we shall state such facts as have been noticed by different observers. The most exact experiments were made by Joseph Wilkes, Esq. of Measham in Derbyshire. The result is, that one horse, value L.20, on a railway declining at the rate of one foot perpendicular to 115 in the length of the road, "drew 21 carriages or waggons, laden with coals and timber, amounting in the whole to 35 tons, overcoming the *vis inertiae* repeatedly with great ease." This performance appears, no doubt, enormous; but was evidently owing not so much to the diminution of friction by the railway as to the great declivity; circumstances whose effect must be distinguished in order to obtain any general rule for future works. It is well known that, on any inclined road or plane, every carriage has a tendency to descend of itself, and with a force in proportion to its own weight, exactly as the height of the plane is to its length. In the above example, therefore, the carriages, independent of any external force of traction, would have been urged by their own gravity with a force of 115th of their weight, and equal, therefore, to 680 lbs. But as it will not be too low an estimate to assume 150 lbs. as the working draught of a horse, hence the waggons would descend by their mere weight as if they had been dragged on a level way by at least four horses. If, then, to this 680 lbs. we add 150 for the action of the horse, the sum, or 830 lbs. will be equal to the power necessary to overcome the friction and inertia of these waggons, and which appears by division to amount to  $\frac{1}{94}$ th of their whole weight; so that, if the railway had been level, the horse would only have drawn  $6\frac{1}{4}$ th tons. Carriages on an ordinary road require  $\frac{1}{12}$ th or  $\frac{1}{15}$ th of their actual weight to draw them along; so that, on a railway, the ease of draught is six times greater than on a common road. The same horse, Mr Wilkes observes, drew up the acclivity five tons with ease. Here the weight of the waggon, or its 115th part, would act against the horse, which would not only have to overcome their friction and inertia, but to drag also this additional load upwards. But  $\frac{1}{94} + \frac{1}{115}$  of 5 tons = 216 lbs., the force of traction, which was evidently a strained effort. The same horse drew three tons up an acclivity of 1 in 20. Here  $\frac{1}{94} + \frac{1}{20}$  of 3 tons, = 407 lbs., a power of traction which few horses could exert, and none could sustain for any length of time. The other experiments of Mr Wilkes agree nearly with the above. Mr Outram, Engineer, observes, that, with a declivity of 1 in 108, the waggons will almost descend of themselves, so that the horse has only to pull a little at his load. This would make the friction and inertia nearly  $\frac{1}{108}$ th of the weight, and the draught of a horse nearly  $6\frac{1}{2}$ th tons. Mr Telford observes, that in a railway, with a declivity of 1 in 98, a horse will readily take down waggons containing from 12 to 15 tons, and bring back the same with

four tons in them. The total load, in the first case, would be about 18 tons, and in the second 8 tons. Here the waggons being urged with  $\frac{1}{98}$ th of their weight; this makes the friction and inertia equal to  $\frac{1}{70}$ th of the weight, and the draught of a horse on a level way only  $4\frac{1}{2}$ th tons. In the Troon railway, the declivity is about 1 in 660; and, according to Mr Wilson's account, some horses take down two and some three waggons each, containing 33 cwt. of coal, and weighing itself 13 cwt., travelling at the rate of three miles an hour. The total load here may be averaged at 115 cwt.; and, the waggons being used with  $\frac{1}{880}$  of their weight, this makes the friction and inertia  $\frac{1}{75}$ th of the weight, very nearly equal to the last. We have been favoured by Mr Grieve with the following particulars regarding Sir John Hope's railway, which is of the edge kind. It is on a level; and one horse draws five loaded waggons, each containing 30 cwt. of coals, and weighing, unloaded, 12 cwt. equal in all to 210 cwt. or  $10\frac{1}{2}$  tons; travelling at the rate of four miles an hour, deducting stoppages. This makes the friction 150th of the load. This performance is beyond any that we have yet stated, and shows decidedly the ease of draught of the edge rail. Previous to the formation of this railway, it required eight horses for the work which is now done with one. On the whole, then, it may be concluded, that on a level tram road, making allowance for the weight of the waggon, one horse will be required for every four tons of coals, or other articles conveyed; and on an edge railway, one horse will be required for every seven tons. On an ordinary canal, one horse, with a boat, will be sufficient for every 30 tons. But the first cost of a canal is three or four times greater than that of a railway; so that, in some cases, it may become a question, whether a railway might not be adopted with advantage.

On some of the railways near Newcastle, the waggons are drawn by means of a steam-engine working in a waggon by itself, the wheels of which are driven by the engine, and acting on a rack laid along the railway, impel forward both the engine and the attached waggons: in some cases the wheels of the waggon operate without rail work, by the mere friction between them and the railway. The steam-engines employed for this purpose are of the high pressure kind; these requiring no condensing apparatus. But this application of steam has not yet arrived at such perfection as to have brought it into general use. (R. R. R.)

REFRACTION (DOUBLE). See ADDENDUM to this Volume.

RENFREWESHIRE, a county in Scotland, lying between  $55^{\circ} 41'$  and  $55^{\circ} 48'$  north latitude, and between  $4^{\circ} 15'$  and  $4^{\circ} 53'$  west longitude; is bounded on the west and north by the Frith of Clyde (excepting that a small tract opposite the town of Renfrew is situated on the north bank of the Clyde), and it has Lanarkshire on the east and Ayrshire on the south. From east to west it extends about 26 miles, and from north to south from nine to 13; and has an area of nearly 241 square miles, or 154,182 English acres. It comprehends 21 parishes, besides a small Divisions.

Renfrew-  
shire.

portion of some others, the churches of which are situated in the adjoining counties. Two of the parishes, Eaglesham and Cathcart, belong to the presbytery of Glasgow, and the other nineteen compose the presbytery of Paisley. Notwithstanding its moderate extent, its manufactures and commerce render it one of the most important in Scotland.

Surface.

About two-thirds of this district, comprising the western and south-eastern sides, are hilly, the medium elevation being from 500 to 600 feet; Misty-law, the highest hill, is about 1240 feet, and two others may be about 1000. This division is, in general, kept in pasture, for which it is better adapted, by the nature of its surface, than for tillage; though, as it has a free light soil, which readily absorbs water, it is seldom injured by moisture. The cultivated land lies on the north and north-east, and in the centre of the county, on both sides of the Black Cart. Of this, however, the greater part is not level, but consists of low detached hills, among which there is a good deal of natural wood in the state of coppice, and many winding rivulets, which give variety to the landscape. Much of this tract has a close subsoil of small stones and coarse clay, almost impenetrable to water, though there are here many flat holms of great fertility. It is only between Paisley and the Clyde that the country sinks down to a plain, the extent of which does not exceed 12,000 acres. Here the soil is generally a deep rich loam, of a dark brown colour, sometimes of the nature of what is called *carse clay*; and much of it seems to have been formed by the deposition of vegetable mould from the higher grounds. Moss prevails in the first and last divisions, but is not found in the second or middle one, where the soil is pretty uniform.

Climate.

Like the other western counties of Scotland, Renfrewshire has a moist climate, with frequent rains; and the prevailing wind is from the south-west. At Largs, a village in Ayrshire, near the western extremity of this county, the yearly quantity of rain, in 1809 and 1810, was  $38\frac{2}{3}$  inches; at Glasgow, near the eastern extremity, for 30 years, from 1761 to 1790, it was 29.65 inches.

Rivers.

The principal rivers are the Clyde, the White Cart, the Black Cart, and the Gryfe. The first, which only flows along the boundaries of this county, is by far the most considerable and important. The White Cart, which rises in Lanarkshire, enters Renfrewshire from the south; and, flowing west towards Paisley, and then north, receives the united streams of the Black Cart and the Gryfe at Inchinnan, and joins the Clyde about six miles below Glasgow. By means of a short cut, a little above Inchinnan, the White Cart has been rendered navigable from Paisley to the Clyde. The Black Cart from the south-west, and the Gryfe from the west, meet at Walkinshaw, about two miles above their confluence with the White Cart. These streams are chiefly deserving of notice for their being employed in giving motion to the cotton and other mills seated along their course. Several other and smaller ones have been applied in the same manner in various parts of the county; a steady

supply of water being secured by means of reservoirs, some of which are of the size and appearance of considerable lakes; or by enlarging the natural lakes themselves, of which there are many. Of these last, Castlesemple loch, in the middle of the southern boundary, from whence the Black Cart takes its rise, extending over about 200 acres, is the most considerable. These streams and lakes abound in the usual kinds of fish; but the salmon fishery on the Clyde, so far as it belongs to this county, is not of great value, seldom affording a rent of more than L. 200 a-year.

Renfrew-  
shire.

Lakes.

Minerals.

The minerals of this county are of great importance, constituting the main source of its manufactures and commerce; but we can only advert to them very generally. Coal, limestone, and sandstone, are wrought at Neilston, one of the parishes of the hilly district; and both coal and lime have been found in the flat district near Renfrew; but it is in the middle division that mines are wrought to the greatest extent. Of coal there are generally about 12 different works carried on; of which the most extensive and valuable are at Polmadie, on the north-east boundary, at Hurler, three miles south-east from Paisley, and at Quareltown, south-east from the Bridge of Johnston, on the Black Cart, near the centre of the county. The coal at this latter place consists of five contiguous strata; the thickness of the whole, measured at right angles to their surface, is upwards of 50 feet; but as, in some places, the seam forms a considerable angle with the horizon, the thickness of the whole in these places, measured vertically, is about 15 fathoms. In consequence of this great depth, it is wrought in floors or storeys. Limestone abounds in various parts, and is commonly wrought at eight different quarries. Ironstone in beds and balls is very generally diffused throughout this middle division of the county. Considerable quantities of pyrites are found in the stratum of coal at Hurler and Househill, and manufactured into sulphate of iron or green vitriol. Alum is obtained at Hurler, from the decomposed schistus, which forms one of the strata of its coal mines. Excellent freestone, lying near the surface, is wrought near Paisley and at other places.

The valuation of the lands of Renfrewshire is L. 69,172, 1s. Scots; but in 1811 the real rent of the lands was L. 127,068, 15s. 9d. and of the houses, L. 106,238, 7s. 2d. Sterling. In 1795 the land rent was only about L. 67,000, so that it must have nearly doubled in fifteen or sixteen years. The land-estate property in 1811 was divided into 328 estates; of which 300 were under the valuation of L. 500 Scots, and only six above L. 2000 Scots. Nearly half the valuation belonged to estates held under entail, and by corporations, which were not, therefore, allowed to be brought to market. The number of freeholders entitled to vote in the election of a member for the county was 77; but it appears that more than half this number voted on rights of superiority only, and not as owners of estates. There are about 30 seats of noblemen and gentlemen, besides villas belonging to merchants and tradesmen. The county is well covered with woods and plantations. The

Renfrew-  
shire. copse-woods, which are cut every 30 years, used to bring from L. 25 to L. 30 an acre.

Agriculture. Renfrewshire does not rank high as an agricultural district. Farms are generally small, seldom exceeding 100 acres on the arable land, and 400 or 500 acres on the hills; and the houses and other accommodations of the farmers are proportionally inferior to those of their brethren in most other parts of the lowlands of Scotland. The average rent *per* English acre, in 1811, would be about 15s., varying from 2s. or 3s. to L. 4 or L. 5; partly owing to situation, but still more to the different degrees of the natural fertility of the soil. Garden grounds let at from L. 8 to L. 10, and, in one instance near Greenock, as high as L. 40 the English acre. The University of Glasgow have right to the tithes of several parishes near that city, for which they receive, in some instances, no more than 4s. *per* Scots acre, and in no case more than 15s. The most common period of leases here, as in other parts of Scotland, is 19 years; but many are now shorter, though, in that case, it is the practice to enter into a new lease, two or three years before the old one expires. About two-thirds of the arable land is almost always in grass, on which the stock chiefly kept is cows, whose milk is made into butter. There are few cheese dairies. The rotation of crops is in many instances objectionable, two or more corn crops being taken successively; clover and rye-grass are sown only for hay; and turnips, even upon the most suitable soils, are in very limited cultivation. A flock of Merino sheep, consisting of about 1000 or 1200, of the pure Paular breed, was sent into this county in 1810, by Colonel Downie of Paisley, who was then in Spain, some of which are still to be found on the farms of the proprietors. In other respects, the rural economy of Renfrewshire presents nothing particularly worthy of notice.

Merino  
Sheep.

Manufac-  
tures.

It is by its manufactures and commerce that this district has been long distinguished. Among its manufactures are cordage and sail-cloth, ship-building, and sugar-boiling, at Greenock and Port-Glasgow, with a variety of others subordinate to these; but Paisley and its environs have long been the seat of its principal establishments. The linen manufacture, in various forms, was carried on here more than a century ago, and continued to extend till superseded by that of cotton, about the year 1780. This last is now by far the most extensive manufacture in the county; and is conducted in all its various branches, from the spinning of the yarn to the finishing of the finest fancy goods. In 1810, the cotton yarn sold was said to amount to L. 630,000; and the capital employed in the buildings and machinery of the mills was estimated at L. 300,000. About 7000 looms were then employed in the weaving of muslins, besides 500 which were wrought by steam, and produced coarse cottons to the value of L. 125,000 yearly. Paisley was long distinguished for its silk manufacture, which is now inconsiderable; and that of thread, though still extensive, is said to be on the decline. Soap-making, tanneries, distilleries, breweries, and foundries, with a great many bleachfields and print-fields, furnish employment to a large portion of the inhabitants.

The principal towns are Paisley, Greenock, and Port-Glasgow. (See these Articles in the *Encyclopaedia*.) It is at these towns, or rather at the two last, that the foreign and coasting trade of the county, and the principal foreign trade, of Scotland, is carried on. Greenock and Port-Glasgow have an extensive trade with America and the West Indies, Ireland, and the west of England; and coastwise, and, by means of the Forth and Clyde Canal, with every part of Scotland. The canal proposed to be carried from Glasgow to Ardrossan, through Paisley and Johnstone, has been executed as far as Johnstone, eleven miles from Glasgow; and passing through several populous parts of Renfrewshire, affords great accommodation to the trade between Paisley and Glasgow. The herring and whale fisheries were once prosecuted to a greater extent than at present, though the former is still considerable; and the merchants of Greenock are extensively engaged in the Newfoundland and Nova Scotia fisheries. As Renfrewshire does not raise enough of grain for its consumption, a good deal of corn is usually imported from Ireland and Canada, as well as coastwise. The other imports are the raw materials of its manufactures, and the commodities required for the consumption of its inhabitants; and its exports, the produce of its manufactures, mines, and fisheries, and of its import trade from America and the West Indies.

Renfrew-  
shire.  
Towns.

Notwithstanding the extensive manufactures of Poor. this county, the great fluctuation in the wages of labour, and its dense population, which, in 1811, was at the rate of 384 *per* square mile, there are regular assessments for the poor only in two or three parishes. In the rest of the county, the poor are supplied by voluntary contributions, aided by assessments imposed when circumstances require them.

The county sends one member to Parliament; and its only royal burgh, Renfrew, a place containing about 1600 inhabitants, joins with Glasgow, Rutherglen, and Dumbarton, in the election of another for the Scottish burghs. Paisley and Greenock, notwithstanding their wealth and population, have no vote. The Sheriff Court is now held at Paisley; yet Renfrew is still considered the county town, where the quarter sessions are held, the head courts, and the meetings of the freeholders for the election of members of Parliament.

Representa-  
tion.

The population in 1754 was only 26,645; in 1801 it amounted to 78,056; in 1811 it was 92,596; to which, if there be added the number of registered seamen, about 5000, and of men serving in the navy, army, and militia at the latter period, it would appear that it had quadrupled within 57 years, a rate of increase unexampled in any other county of Scotland. In 1821 it was 112,175; of which 51,178 were males, and 60,997 were females. The families employed in agriculture were 2725; in trade and manufactures, 15,780; in other occupations of various kinds, 5472. The increase of the population from 1811 to 1821 was 19,579.

Population.

See the general works quoted under the former Scottish counties, and Wilson's *General View of the Agriculture, &c. of Renfrewshire.* (A.)

Rennie. RENNIE (JOHN, F.R.S.), Mechanist, Architect, and Civil Engineer, was born on the 7th June 1761, at Phantassie, in the parish of Prestonkirk, in the county of East Lothian. His father, a highly respectable farmer, died in 1766, leaving a widow and nine children, of whom John was the youngest. The first rudiments of his education were acquired at the village school; and as it frequently happens, that some trifling circumstance in early life gives a bent to the pursuits, and fixes the destinies, of the future man, so it fared with young Rennie. The school was situated on the opposite side of a brook, over which it was necessary to pass by means of a rustic bridge of stepping-stones; but when the freshes were out, the only alternative of crossing the stream was by means of a boat, which was kept at the workshop of Mr Andrew Meikle, an ingenious mechanic, well known in Scotland as the inventor of the threshing-machine, and many improvements in agricultural implements. In passing through this workshop, which stood on his family property, young Rennie's attention was forcibly drawn to the various operations that were in progress; and a great part of his leisure and holiday-time was passed therein. The sons of Mr Meikle, and the workmen, seeing the delight which he appeared to take in examining their labours, were in the habit of indulging him with their tools, and showing him their various uses. His evenings were chiefly employed in imitating those models which had particularly attracted his attention in the workshop; and it is known in the family, that, at little more than ten years of age, he had constructed the model of a windmill, a pile-engine, and a steam-engine. That of the pile-engine is still in existence, and is said to be remarkably well made.

Having continued at Preston school till twelve years of age, he had a quarrel about that time with his schoolmaster, whom he deemed incompetent to give him further instruction, and therefore entreated that he might be permitted to leave the school. But his active mind became restless; for the first time he felt the hours hang heavily on his hands; and having expressed a wish to be placed under his friend Mr Meikle, he employed himself with this ingenious mechanic for about two years: but his mind expanding with his growth, he began to feel that the progress of his intellectual faculties was likely to be retarded by a constant application to manual labour. He therefore at length determined to place himself under the tuition of Mr Gibson, an able teacher of mathematics at Dunbar; where he soon distinguished himself in so particular a manner, that Mr David Loch, General Inspector of the Fisheries in Scotland, in describing a visit which he paid to the school at Dunbar in 1778, notices the great proficiency displayed by young Rennie; prophesying that at no distant period he would prove an honour to his country.\* From this school, in less than two

years, he returned to Mr Meikle, with a mind well stored with every branch of mathematical and physical science which Mr Gibson could teach him. About this time, Mr Gibson being appointed master to the public academy of Perth, he earnestly recommended young Rennie to succeed him at Dunbar. But his views were of a more aspiring cast. As a matter of favour, he undertook the management of the school for about six weeks, when he returned to his family, occasionally visiting and assisting his friend Mr Meikle, but mostly improving himself in drawing and making models of machinery. His first essay in practical mechanics was the repairing of a corn-mill in his native village; and he erected two or three others, before he was eighteen years of age.

Resolved, however, that these mechanical occupations should not interfere with his studies, he laid his plans so that he should be able to proceed occasionally to Edinburgh, with a view of improving himself in physical science. He there attended the lectures of Professors Robison and Black, and formed that acquaintance with the former of these gentlemen, which was gradually raised into friendship, and which, perhaps, may be said to have laid the foundation of his future fortune; for by him he was introduced to Messrs Bolton and Watt of Soho near Birmingham. With these gentlemen he remained but a few months, for the purpose of receiving explanations respecting the plan of the Albion Mills, then erecting, the machinery of which he superintended. This exactly suited his views, for, conscious of his own powers, he deemed the Capital the proper theatre to try their strength, and in this he was not mistaken.

In proceeding from Edinburgh to Soho, he had taken the route by Carlisle, Lancaster, Liverpool, and Manchester, for the purpose of visiting the different mills and public works in those great commercial and manufacturing towns; and the remarks which he made on the bridge then building over the Lune at Lancaster, on the docks at Liverpool, and more particularly on the Bridgewater canal, are distinguished by great sagacity, and were of essential use to him afterwards. On leaving Soho, he again made a tour through the manufacturing districts of Leeds, Sheffield, Rotherham, and Newcastle.

For some time after he was settled in London, the Albion Mills, of which Bolton and Watt and Mr Wyatt were the projectors and leading proprietors, and who engaged him to superintend the execution of the mill-work, occupied a great share of his attention. Mr Watt, in his *Notes to Professor Robison's Account of the Steam-Engine*, says, That, "in the construction of the mill-work and machinery, they derived most valuable assistance from that able mechanic and engineer Mr John Rennie, then just entering into

\* Loch's *Essays on the Trade, Commerce, Manufactures, and Fisheries of Scotland*, Vol. III. p. 211.

Rennie. business, who assisted in placing them, and under whose direction they were executed." He also says, that the machinery, which used to be made of wood, was here made of cast-iron, in improved forms, and thinks that this was the commencement of that system of mill-work which has proved so beneficial to this country. In fact, Rennie's mills are the most perfect species of mechanism in that way that exist, distinguished by a precision of movement, and a harmony and proportion of parts that now serve as models throughout the empire. His water-mills are so accurately calculated, that every particle of water is effectively employed, and none of it lost, as in the common mode of constructing water-wheels. There is reason to believe that the difficulties which occurred at the Albion Mills with regard to the ebb and flow of the tides, and which required all the ingenuity of that extraordinary genius Mr Watt, first led Mr Rennie to the study of that branch of civil engineering connected with hydraulics and hydrodynamics, and in which he soon became so celebrated, as to have no rival after the death of Smeaton, in whose steps, he always used to say, he was proud to follow.

Our limited space will not permit us to enter upon even an enumeration of all his great works, much less to give any detailed account of them; we must therefore content ourselves by mentioning some of the most important designs and undertakings in his threefold capacity of mechanist, architect, and civil engineer; three branches of art so intimately blended, as scarcely to admit of a separation.

*First, as a Mechanist.*—Immediately after the completion of the Albion Mills, in 1786 or 1787, Mr Rennie's reputation was so firmly established in every thing connected with mill-work, that he found himself in a very extensive line of business. To him the planters of Jamaica and of the other West India islands applied for their sugar-mills, which he constructed in a manner so superior to the old ones, that he soon obtained almost a monopoly of these expensive works. The powder-mill at Tunbridge, the great flour-mill at Wandsworth, several saw-mills, the machinery for various breweries and distilleries, were mostly of his manufacture; and wherever his machinery was required to be impelled by steam, the incomparable engines of his friends Messrs Bolton and Watt supplied the moving power; but, contrary to what has been stated in some of the public journals, he never had the least concern in directing, contriving, or advising any one part or movement of the steam-engine. He also constructed those beautiful specimens of machinery, the rolling and triturating mills at the Mint on Tower-Hill, to which Bolton and Watt's engines give motion; and, at the time of his death, he was engaged in the construction of a rolling-mill, and similar machinery, for the intended mint at Calcutta.

As a bold and ingenious piece of mechanism, which may be considered as distinct from positive architecture, there is nothing in Europe that can bear a comparison with the Southwark Bridge. The three immense arches, the centre one of 240, and each side arch of 210 feet span, consist entirely of masses of cast-iron, of various forms and dimensions,

put together, on the same principle as a similar fabric of hewn stone; a method of employing iron, which may be considered to form a new epoch in the history of bridge building. Various sinister predictions were entertained against this light and beautiful bridge, which was to be rent in pieces by the expansive power of the first summer's heat, or, if it escaped that, by the contraction of the first winter's cold; but it has stood the test of many winters and summers, and appears not to feel either. Mr Rennie was applied to by the East India Company for the design of a cast-iron bridge to be thrown over the river Goomty at Lucknow, at the desire of the Nabob Vizier of Oude. It consisted of three arches of cast-iron, the centre arch ninety, and each of the other arches eighty feet span. The arches were cast, and a superintending engineer sent out with them, but on their arrival the Nabob, in one of those moments of caprice to which eastern despots, even in their impotency, are so liable, changed his mind, and would not allow it to be put up.

*Secondly, as an Architect.*—As there are few parts of civil engineering that do not occasionally require the aid of architecture, Rennie, at a very early stage of his progress, was called upon for a display of his skill in this line. Among his first undertakings in either line was that of the Lancaster Canal, which presented many difficulties, and, among others, that of carrying it by an aqueduct over the Lune, so as not to interrupt the navigation of the river. Being one of the largest fabrics of its kind in Europe, and of a pleasing design, it is an object that arrests the attention of strangers, and is very generally admired. The bridges of Leeds, Musselburgh, Kelso, Newton-Stewart, Boston, New Galloway, and a multitude of others, attest the architectural skill, the solidity, and, we may add, the good taste of Rennie; whilst a thousand smaller ones, with the various locks, wharf-walls, quays, embankments appertaining to canals, rivers, and harbours in every part of the United Kingdom, are so many proofs of his diversified talent, and his skill in adapting the means to the end. The Breakwater in Plymouth Sound can scarcely be called an architectural work, but it is constructed on true hydrodynamic principles, and so gigantic in its dimensions, and cyclopean in its structure, as equally to defy the force of the waves and the ravages of time. To Mr Whidby, who has zealously superintended the execution of this immortal work, now near its completion, the highest praise is also due; nor was the plan finally determined on without his advice and assistance.

But the architectural work which, above all others, will immortalize the name of Rennie, is the Waterloo Bridge, a structure which even foreigners admit has no parallel in Europe (and if not in Europe, certainly not in the whole world) for its magnitude, its beauty, and its solidity. That a fabric of this immensity, presenting a straight horizontal line, stretching over nine large arches, should not have altered more than a few inches, not five, in any one part, from that straight line, is an instance of firmness and

Rennie.

solidity utterly unknown, and almost incredible; \* but all Rennie's works have been constructed for posterity; he made nothing slight; nor would he engage in any undertaking where, from an ill-judging economy, a sufficiency of funds was not forthcoming to meet his views.

Another work, from a design of his, is now likely to be carried into execution, to which for some years past he had given his attention. It is that of a new stone bridge over the Thames, to replace that disgrace to the present age, the existing London Bridge. His design, which has been selected by a Committee of the House of Commons out of at least thirty that were offered, consists of a granite bridge of five arches, the centre one of 150 feet span, which will be the largest stone arch in the world constructed in modern times. The execution of this work will form a remarkable feature in the future history of the capital, for, of the five bridges which bestride the Thames within the precincts of London, three of them, and those beyond comparison the most magnificent, will have been built from the designs of one man;—a record which will throw a lustre on the name of Rennie, and be read with a feeling of pride by every, even the most distant, branch of the family.

*Thirdly, as a Civil Engineer.*—The first great attempt in this line of his profession was the survey and execution of the Crinan Canal, a work remarkable for the multitude of practical difficulties that occurred throughout the whole of this bold undertaking; it being necessary in many places to cut down through solid rock, to the depth of sixty feet; and it is rather remarkable, that the second undertaking, the Lancaster Canal, was also replete with difficulties, and called for the exercise of his skill as an architect, as we have seen in noticing the aqueduct over the Lune. But these two works established his reputation as a civil engineer, and his opinion and assistance were required from all quarters. His faculties were now called into full play, and they expanded with the demands made upon them. The rage for canals had pervaded every part of the kingdom, and scarcely any of these useful means of conveyance and communication was thought of without a previous consultation with Rennie; so that in a few years the surveys he was called upon to make were so numerous, that he knew the surface of England as it were by heart, and could tell at once, when a canal was projected, whereabouts the line of it ought to be carried. The following are some of the most important of those whose execution he personally attended: Aberdeen, Brechin, Grand Western, Kennet and Avon, Portsmouth, Birmingham, Worcester, besides many others.

But the resources of his mind were displayed in all their vigour in the plans and construction of those magnificent docks, which are at once an ornament to the capital, and of the utmost utility to commerce and navigation. Nor are these splendid and useful

works confined to the metropolis. The docks at Hull, Greenock, Leith, Liverpool, and Dublin, attest his skill; and the harbours of Queensferry, Berwick, Howth, Holyhead, Dunleary (now called Kingstown Harbour), Newhaven, and several others, owe their security and convenience to his labours.

But even those works, splendid as they are, must yield to what he has planned and executed in his Majesty's dock-yards at Portsmouth, Plymouth, Chatham, and Sheerness. The latter was a mere quicksand of forty feet deep, mixed with mud and the wrecks of old ships; the whole of which was excavated, and a magnificent basin constructed, with a beautiful surrounding wall of granite, with which three of the finest dry-docks in the universe communicate; and that important dock-yard, which may be said to command the mouths of the Thames and the Medway, from being an unhealthy and detestable place, and wholly inefficient for its purpose, is now, by being raised many feet, and laid out with skill and judgment, one of the most convenient in the kingdom. He also planned the new naval arsenal at Pembroke, which is considered as a perfect model for a building-yard. But his plan for the projected naval arsenal at Northfleet on the Thames was far superior to all in design; and on a scale so grand as to be capable of containing afloat two-thirds of the whole navy, with dry-docks and slips for repairing and building ships of all classes to the same extent; with all manner of storehouses, workshops, and manufactories of all such articles as were required for consumption in the navy. But the estimated sum of eight millions, which would probably have amounted to ten, induced the Government to pause, and it was finally deemed prudent to abandon the design altogether.

The late excellent architect and civil engineer, Mr Smeaton, was the first who used the diving-bell effectually for building with stone under water; but the machine he employed for that purpose was very defective, and could be used only in certain situations. But Rennie, by improvements in the instrument itself, and in the machinery by which its movements could be regulated, was enabled to carry on the finest masonry, and the foundations of sea-walls, piers, and quays, as well under water as above it. The repairing of the pier-head of Ramsgate Harbour was a remarkable instance of this kind. The violence of the waves, acting upon the bad quality of the stone, had so completely undermined it, that the stability of the whole pier began to be endangered. It was from ten to thirteen feet below the level of low-water, spring-tides; yet, by means of the improved diving-bell, and its apparatus, the pier-head was not only effectually secured, but rendered more solid and durable than it originally had been. In the harbour of Howth the diving-bell was of the utmost use; and it is remarkable enough, that the masons who have been for a little while accustomed to work under water prefer it, at least the Irish masons do,

\* The Bridge of Neuilly, which the vanity of the French has ranked as superior to that of Waterloo, actually sunk 23 inches.

Rennie. to working in the air; it being cooler in summer, and warmer in winter; though an increase of pay for submarine work is probably the real cause of preference.

The last effort of Rennie's genius, to which we shall advert, was the drainage of that vast tract of marsh land bordering upon the rivers Trent, Witham, New Welland, and Ouse, which for centuries past had baffled the skill of some of the ablest men in that department of civil engineering. Upon the same principles, he laid down a grand scheme for draining the whole of that immense district known by the name of the Bedford Level, which has in part been carried into execution by the completion of the Eau-brink Cut, near Lynn. The estimate he made for draining the whole amounted to L. 1,200,000.

Such are some of the grand undertakings which Rennie, during the last thirty years of his life, was either employed to project or to carry into execution, and which, on a rough estimate, collected from his valuable *Reports*, did not fall far short of forty millions Sterling; about twenty millions of which were expended under his own immediate superintendence. Indeed, few great works were carried on, either by the public or individuals, on which he was not either employed or consulted. His industry was very extraordinary. Fond of the society of his select friends, and of rational conversation, he never suffered amusement of any kind to interfere with his business, which seldom engaged less than twelve hours, and frequently fifteen in the day. His conversation was always amusing and instructive. He possessed a rich fund of anecdote, and, like his old friend James Watt, told a Scotch story admirably. As a travelling companion, he was highly entertaining; he knew every body on the road, and every body knew John Rennie. Of an ardent and anxious mind, and naturally impetuous, he was gifted with the most perfect self-control; and the irritation of the moment was seen but as a light summer's cloud, passing across his finely marked features, which were on so large a scale, though blended with much mildness as well as dignity, as to obtain for his noble bust by Chantrey, when exhibited in Somerset House, the name of *Jupiter Tonans*.

Were we to seek for a parallel to Rennie, the name of Smeaton would at once suggest itself. Their boyhood was employed precisely in the same manner, in making models of pumps and windmills, while their school-fellows were at play; their pursuits in manhood were similar, and their paramount success pretty nearly the same: but the spirit of speculation and improvement was but just springing up, when Smeaton finished his career, and when Rennie began his. He was, in fact, the successor of Smeaton. There was a strong characteristic likeness between Rennie and the late Mr Ramsden. The pursuits of the former embraced a wider sphere of action, but they both arrived at their proposed objects by the most simple and obvious, and, at the same time, most effectual means. They were both equally clear in their mode of communicating information to others; and it is sufficiently remarkable that, in their illustrations, both of them had recourse rarely to any other instrument than a two-foot rule, which each always carried in his

pocket. Many a time has the writer of this article derived instruction from the two-foot rules of John Rennie and Jesse Ramsden. They were both equally communicative, when they saw that information was desired; and nothing like professional jealousy, or selfish feelings, actuated either of these ingenious men, who, on the contrary, were always kind and condescending to the more humble artists of their respective professions. To foreigners, in particular, the loss of Rennie will be severely felt; for to those who visited England with the view of inspecting her arts and manufactures, he was always ready to afford every information, and all the facilities in his power.

Mr Rennie possessed considerable skill in bibliography, and being a zealous and liberal collector, he succeeded in forming a very valuable library; consisting of the best and rarest books in all the branches of science and art, of voyages and travels, and many curious books in the black-letter; while in his own department, it contained every work of the least merit, in whatever language it might be written. He had, besides, a good collection of mathematical and astronomical instruments, and frequently spoke of erecting an observatory, but did not live to carry his intention into execution. He had for some years laboured under a disease of the liver, which had apparently yielded to the usual treatment, but a relapse took place; and on the 16th October 1821, after a few days illness, he expired without a struggle, in the 60th year of his age.

Mr Rennie, in 1789, married Miss Mackintosh, who died in 1806, leaving a family of seven young children, six of whom are now living. The two eldest, George and John, are successfully following the profession, and promise to tread in the footsteps of their late father.

Sixteen mourning coaches, filled with his friends, mostly men of eminence in the arts, sciences, or literature, followed his hearse to St Paul's, where his remains were interred near those of Sir Christopher Wren. A plain granite slab covers his grave, on which is the following appropriate inscription:

Here lie the mortal remains of  
JOHN RENNIE,

Civil Engineer,

F. R. S. L. & E. F. A. S. &c. &c.

Born at Phantassie, in East Lothian, 7th June 1761;  
deceased in London 4th Oct. 1821.

**ROADMAKING.** There are few departments of practical mechanics in which every individual, at some period or other of his life, is more immediately interested than in the management of roads and pavements. The mechanical theory of the motions of wheel carriages, and of the nature of the frictions and resistances that they have to overcome, as relating to the ultimate objects for which roads are constructed, may naturally constitute the first section of an essay on this subject; the second will naturally comprehend the best arrangement of the means for attaining those objects, by the form and construction of such roads and pavements as appear to be the most eligible under various circumstances; and the third may be devoted to some historical illustrations of the principal roads which exist, or which have existed, in various parts of the world.

#### SECTION I.—*Of the Objects of Roads.*

The grand object of all modern roads is the accommodation of wheel carriages. The construction of foot paths and of bridle roads is so simple as to require very little separate consideration: except that, in cities and towns, the convenience of the inhabitants requires that some pains should be taken to avoid dust, and has generally been a reason for employing pavements in preference to gravel roads, which might in some other respects be more eligible.

For facilitating the motion of carriages, the most essential requisite is to have the road as smooth, and as hard, and as level as possible. The wheels of carriages are principally useful in diminishing the friction of the materials; a dray sliding without wheels, even on a rail road of greased and polished iron, would have to overcome a friction as much greater than that of the wheel on its axle, as the diameter of the wheel is greater than that of the axle. The wheels assist us also in drawing a carriage over an obstacle; for the path which the axis of the wheel describes is always smoother and less abrupt than the surface of a rough road, on which the wheel rolls, and so much the smoother as the wheel is larger, since the portions of larger circles, which constitute the path in question, are less curved than those of smaller ones.

But in all common cases of roads not extremely hard, by far the greater part of the resistance, actually exhibited by a road to the motion of a carriage, is that which depends on the continual displacement of a portion of the materials from their inelasticity, which causes them to exert a continual pressure on the fore part of the wheel, without rising behind it to propel it forwards by its reaction, as an elastic substance would do. Hence, in a soft sand, although the axles of the wheels may move in a direction perfectly horizontal, the draught becomes extremely heavy. The more the wheel sinks, the greater is the resistance, and if we suppose the degree of elasticity of the materials, and their immediate resistance at different depths, to be known, we may calculate the whole effect of their action on the wheel, and the force that is required to displace them, in the progressive motion of the carriage. Thus, if the materials were perfectly inelastic, acting only on the preceding half of the immersed portion of the wheel,

and their immediate pressure or resistance were simply proportional to the depth, like that of fluids, or that of elastic substances compressed, the horizontal resistance would be to the weight nearly as two fifths of the length of the part immersed at once, in the newly formed rut, to the diameter of the wheel; or, on a still more probable supposition respecting the greater resistance of the more deeply seated parts of the rut, about half as much as this, or as about one fifth of the length of the part immersed in the rut to the diameter. Thus, if a coach or wagon, weighing sixty hundred weight, supported by wheels four feet in diameter, formed a new rut, an inch deep, in a smooth road, the length of the part immersed being about fourteen inches, the resistance would be about  $\frac{1}{7}$ th of the weight, upon the lowest supposition that is at all admissible, and more probably about one ninth, or from six to seven hundred weight at least; and if the rut were two inches deep, the resistance would be half as much more. But, on any supposition, the increased height, and even the increased breadth of the wheel, is calculated to diminish the resistance, by diminishing the depth of the part immersed: thus, if a wheel were made four times as high, the length of the part immersed, considering the road as an imperfect fluid, would be doubled, and the resistance would be diminished, theoretically speaking, to about half of its former magnitude; and if the breadth were increased from one to eight, the length of the part immersed would be diminished to about a half, and the resistance would in this case also be reduced to a half.

In soft and boggy soils, as well as in sandy roads, this consideration is of great importance; and the wheels employed for removing heavy weights, in such cases, ought to be as high and as broad as possible consistently with sufficient lightness and economy. But whether a broad, and, at the same time, a low roller, possesses any advantages above a narrow coach wheel, is a matter much more questionable; it must be remembered that a narrow wheel may often run between stones, where a broader would have to pass over them; and there appears to be no theoretical reason for preferring a low roller, except with respect to a single pair of wheels, as affording a more convenient attachment for the shafts in a moderate inclination, which is both more favourable to the exertion of the horses, and more effective in overcoming the friction; since it has been demonstrated that the angle affording the most advantageous line of draught is exactly the same as the inclination of a plane along which the carriage would just begin to descend by its own weight on the same kind of surface. In fact, however, there is no necessity for fixing the axletree precisely in the line of draught; and the principal reason for having the fore wheels lower than the others is for the convenience of turning the carriage more abruptly. A very accurate practical roadmaker has observed, that a good road never suffers from narrow wheels with moderate weights not in rapid motion, but that it is equally worn by the rapid driving of heavy stage coaches, and by the slow grinding of the conical rollers of overloaded, broad-wheeled waggons.

Such being the operation of the wheels of car-

riages on sandy or on rough roads, it is easy to perceive how much the hardness and smoothness of the surface must facilitate the draught; it is obvious also that the same qualities must be equally conducive to the durability of the road, since the inequalities will always cause the carriage to fall on it with a certain impetus after being elevated by the irregularities, and the same shock which strains the carriage will also tend to wear away the road still more where it is lowest; and, on the other hand, the resistance of the soft materials before the wheel will tend to tear up the road, as it causes the wheel to thrust them before it.

It happens not very uncommonly that the interests of the traveller and the postmaster are somewhat at variance with respect to the qualities of a road. The French postillion keeps to the rough pavement as long as the aching limbs of the ladies in the carriage will allow them to be silent, except when, in going down hill, he saves himself the trouble of locking the wheel, by bringing it to the soft edge of the ditch or kennel; and the horses of the Parisian cabriolets, in their excursions to the suburbs, have sagacity enough to incline always to the pavement, when their drivers allow them to have a will of their own; while a single horseman, on the contrary, more commonly finds his steed on the gravel road, if he happens to leave him to his own direction. In Great Britain the roads are commonly managed by commissioners, who have no community of interest with the innkeepers; on the Continent they are universally under the immediate direction of the different governments, who also appoint the postmasters, while the carriages are almost as uniformly the property of particular individuals, who have no immediate influence on the management of the roads; and this diversity may perhaps explain, in some measure, the different systems of roadmaking which prevail on the opposite sides of the Channel. But it may be said of roads as of governments, "that which is best administered is best;" whether a very smooth pavement not too slippery, or a very hard gravel road not worn into great inequalities.

#### SECT. II.—Of the Mechanical Formation of Roads.

The only strongly marked division of the different kinds of roads depends on their being paved or gravelled; but each of these classes admits of considerable diversity in the principles on which the road is constructed. The theory of pavement appears to be extremely simple; the stones, however, may be either small or large; the former being understood to be employed without previous preparation of their shape, as in the inferior kind of work which is called "pitching" in the west of England; the latter being more or less cut to fit each other, whether in the form of thick rough blocks, not very remote from cubes, or of flat and smooth flagstones: in the cities of Great Britain the former are commonly used for horse pavements, and the latter for foot passengers; but in Florence the whole breadth of the streets is paved with flagstones placed diagonally, and in Naples the surfaces are nearly as smooth; in both these cases it is necessary to roughen the stones frequent-

ly with chisels wherever there is a hill or a bridge, in order to prevent the horses slipping, but in both cities the horses from habit are sufficiently sure-footed, even when running with some rapidity. In Milan both kinds of pavements are mixed in the same streets; the smooth in two double lines, for the wheels of carriages coming and going, and the rougher in the intermediate parts, for the feet of the horses, as in the British railroads. But in none of these cities is there much heavy traffic to wear these well arranged surfaces into such inequalities as would probably soon be observed in the streets of London, if they were so delicately formed; although, until this deterioration actually took place, the locomotion would be luxurious both for the horses and for the passengers, and only ruinous to the coachmakers. The Romans used large and heavy blocks for their roads, cutting them on the spot into such forms as enabled them to be best adjusted to those of the neighbouring stones, though seldom exactly rectangular in their surfaces; and even at Pompeii, where the ruts are worn half through the depth of the blocks, the bottom remains tolerably even, in a longitudinal direction, at least as much so as would be required for carts and other carriages of business.

Our more particular object, however, at present, is the consideration of gravel roads rather than of pavements; the word gravel being here understood to mean in general all stone broken small, whether by nature or by art. The improvement of such roads has long been a subject of great interest with the agricultural and commercial inhabitants of Great Britain. It was soon after the year 1700 that a part of the charge of repairing roads was taken off the respective parishes through which they pass, and levied on the general traveller by means of turnpike-gates; but it was for many years a complaint that the roads were little, if at all, fundamentally improved by the expenditure of the money so raised. This complaint is very energetically advanced in *A Dissertation concerning the present State of the High Roads of England, especially of those near London, wherein is proposed a new Method of repairing and maintaining them*; read before the Royal Society in the Winter of 1736-7, by Robert Phillips, and printed in a small separate volume. The author's great object is to recommend washing the roads by a constant stream if possible, and at any rate, washing the materials of which they are composed; in this respect, notwithstanding the existence of single roads so situated that the effects of water upon them have been very beneficially introduced, his plans for the universal employment of water have been altogether superseded by later experience; but he remonstrates, with great propriety, against the practice, which has, however, continued to prevail so generally even of late years, of laying down large heaps of unprepared gravel, to be gradually consolidated into a harder mass, at the expense of the intolerable labour of the poor animals that are obliged to grind it down. As an illustration of the good effect of water, he mentions that even the sediment deposited by it at the bottom of Fleetditch, which was supposed to be a soft mud, and to require removal when the ditch was

Road-  
making.

filled up, proved in fact to be a hard gravelly substance, which afterwards afforded an excellent foundation for the roads and buildings supported by it.

The attention of the public has been more lately directed to the subject of roads and carriages by several essays which appeared in the *Communications of the Board of Agriculture*; they principally belong to the names of Beatson, Wright, Jessop, Hall, Wilkes, Erskine, Ellis, Cumming, Whetley, Amos, and Booth: the most remarkable are Mr Wilkes's *Remarks on the Advantages of Concave Roads*; Mr Ellis's *on Washing Roads*; Mr Wilkes's *on Railways*; and Mr Cumming's *on Wheel Carriages*; showing particularly the disadvantage of broad conical wheels, and the historical progress of the practice of bending the line of the axes.

But all these improvements, whether real or imaginary, have of late been in a great measure superseded by the ingenuity and success of Mr Loudon Macadam, a gentleman whose practice is in general principally to be applauded for its obvious simplicity and economy, though he has also had the merit of discovering that the simplest and cheapest methods, in particular cases, especially in that of boggy soils, are also the most scientific and the most effectual. The practical observations, which are to be here inserted, cannot therefore be so well expressed in any other form, as in that of an abstract of Mr Macadam's own directions.

Mr Macadam's leading "principles are" (*Remarks*, p. 37), "that a road ought to be considered as an artificial flooring, forming a strong, smooth, solid surface, at once capable of carrying great weights, and over which carriages may pass without meeting any impediment."

He proceeds to give directions for repairing an old road and for making a new one, in the form of a communication to a Committee appointed by the House of Commons, in the year 1819, with some subsequent corrections.

No additional materials, he observes, are to be brought upon a road, unless in any part of it there be not a quantity of clean stone equal to ten inches in thickness.

The stone already in the road, supposing it to have been made in the usual manner, is to be loosened and broken, so that no piece may exceed six ounces in weight; the road is then to be laid as flat as possible, leaving only a fall of three inches from the middle to the sides, when the road is thirty feet wide. The stones, thus loosened, are to be dragged to the side by a strong heavy rake, with teeth two inches and a half in length, and there broken; but the stones are never to be broken on the road itself.

When the great stones have been removed, and none are left exceeding six ounces in weight, the surface is to be made smooth by a rake, which will also settle the remaining materials into a better consistence, bringing up the stone, and letting the dirt fall down into its place.

The road being so prepared, the stone that has been broken by the side is then to be carefully spread over it; this operation requires very particular attention, and the future quality of the road will greatly depend on the manner in which it is per-

formed; the stone must not be laid on in shovels full, but scattered over the surface, one shovel full following another, and being spread over a considerable space.

Only a small part of the length of the road should be *lifted* in this manner at once; that is, about two or three yards; five men in a gang should be employed to *lift* it all across, two continually digging up and raking off the large stones, and preparing the road for receiving them again, and the other three breaking them at the side of the road. It may, however, happen, that the surveyor may see cause to distribute the labour in a proportion somewhat different.

The only proper method of breaking stones, in general, both for effect and for economy, is in a sitting posture. The stones are to be placed in small heaps, and women, boys, and old men past hard labour, may sit down and break them with small hammers into pieces not exceeding *six ounces* in weight. When the heavy work of a quarry can be performed by men, and the lighter by their wives and children, the stone can be obtained by contract for two thirds of the former prices, although the stones were then left four times as large. It has also been recommended by Mr Macadam and others (p. 35), that the largest stone employed should not exceed the measure of an inch in its greatest dimensions, or in other words, that it should be capable of being contained in a sphere of about an inch in diameter, which would seldom weigh more than a single ounce.

In some cases, it would be unprofitable to lift and relay a road, even if the materials should have been originally too large; for example, the road betwixt Bath and Cirencester was made of large stones, but so friable, that in lifting they would have fallen into sand; in this case, Mr Macadam merely had the higher parts cut down, and replaced when sifted (p. 107), and the surface kept smooth, until those materials were gradually worn out; and they were afterwards replaced by stone of a better quality, properly prepared. At Egham, it was necessary to remove the whole road, in order to separate the small portion of valuable materials from the mass of soft matter in which they were enveloped, and which was carried away, at a considerable expense, before a good road could be made. But although freestone is by no means calculated to make a durable road, yet, by judicious management, it may be made to form a very good road as long as it lasts. (p. 103.)

Whenever new stone is to be laid on a road already consolidated, the hardened surface is to be loosened with a pick, in order to enable the fresh materials to unite with the old.

A new road, however well it may have been made, will always receive the impressions of the carriage wheels until it is hardened; a careful person must, therefore, attend the road for some time, in order to rake in the tracks made by the wheels; that is, as long as any loose materials are left that can be so employed.

It is always superfluous, and generally injurious, to add to the broken stone any mixture of earth, clay, chalk, or any other matter, that will imbibe water, and be affected by frost; or to lay any thing

Road-  
making.

Road-making.

whatever on the clean stone for the purpose of binding it; for good stone, well broken, will always combine by its own roughness into a solid substance, with a smooth surface, that will not be affected by the vicissitudes of weather, or disfigured by the action of wheels, which, as they pass over it without a jolt, will consequently be incapable of doing it any considerable injury.

The experience of the year 1820 strongly confirmed the inutility and inconvenience of employing chalk with the stone. In January, when a hard frost was succeeded by a sudden thaw, a great number of roads broke up, and the wheels of the carriages penetrated into the original soil; in particular it was observed, that all the roads, of which chalk was a component part, became nearly impassable; and even roads made over chalky soils gave way in most places. But not one of the roads, that had been thoroughly made after these directions, was observed to give way. (p. 44, 46.)

The TOOLS required for lifting roads are, 1. Strong picks, but short from the handle to the point. 2. Small hammers, weighing about a pound, with a face the size of a shilling, well steened, and with a short handle. 3. Rakes, with wooden heads, ten inches in length, and with iron teeth, about two and a-half inches long, and very strong, for raking out the large stones when the road is broken up, and for keeping it smooth after it has been finished, and while it is consolidating. 4. Very light broad mouthed shovels, to spread the broken stones, and to form the road.

The whole EXPENSE of lifting and newly forming a rough road, to the depth of four inches, has generally been from a penny to twopence *per square yard*, being more or less, according to the quantity of stone to be broken. With proper tools, and by proper arrangements, stone may be broken for tenpence or a shilling *per ton*, including, in some cases, the value of the stone itself. A very material advantage of Mr Macadam's method is the introduction of a much greater proportion of human labour, instead of the work of horses: formerly one fourth of the whole expense was paid, in the district of Bristol, for men's labour, and three fourths for that of horses: now, on the contrary, one fourth only is paid for horses' labour, and the other three to men, women, and children.

Mr Macadam argues very strongly against the old opinion, of the necessity of placing a quantity of large stones, as a foundation, to carry the road over a wet subsoil. He says, that whatever be the nature of the soil, if it be previously "made quite dry," and a covering impenetrable to rain placed over it, the thickness of the covering needs only to depend on its own capability of becoming impervious. Large stones, he says, will constantly work up by the agitation of the traffic on the road, and leave vacancies for the reception of water; and the only way of keeping the stones in their places, is to have them of a uniform size. A rocky bottom causes a road to wear out much the faster [acting, probably, as a lower millstone in facilitating the operation of grinding]. "It is a known fact, that a road lasts much longer over a morass, than when made over rock.

Road-making.

In the neighbourhood of Bridgewater, for example, the materials consumed on a rocky road, when compared with those which are required for a similar road made over the naked surface of the soil, are in the proportion of seven to five."

In the summer of 1819, upon some new roads made in Scotland, more than three feet of materials, of various dimensions, were laid down; and more than two thirds of them, according to our author, were worse than wasted. In such an arrangement, the water generally penetrates to the bottom of the trench made to receive the road, and remains there to do mischief upon every change of weather.

To prevent such inconveniences, it is necessary in wet soils, either to make drains, to lower ground, or to raise the road above the general level, instead of making a trench to receive the stones; and from the penetration of rain the solidity of the road itself must protect it. A well made road, not quite four inches in thickness, was found to have kept the earth below it dry in the parish of Ashton near Bristol: but six, eight, or ten inches of materials are generally required to make a firm road; being laid on in successive layers of about two inches in thickness, all well broken, well cleaned, and well sized. Sometimes, indeed, a much greater depth of stone than this is required: in a road, for example, which has lately been made from Lewes to East Bourn, entirely upon Mr Macadam's principles, as much as three feet of materials was required in many parts before the road could be sufficiently consolidated; it has, however, ultimately been made excellent, though at an expense of not much less than a thousand pounds a mile.

Mr Macadam maintains that the quantity of stone required for paving is fully sufficient to make an excellent gravel road in any part of the world; and in almost every case, materials equally good can be obtained for roads at a still cheaper rate; commonly, indeed, at one tenth of the expense of pavements. It is, however, in steep ascents that pavements are most objectionable; at the north end of Blackfriars' Bridge, more horses are said to fall and receive injury than at any other place in the kingdom. In the suburbs of Bristol the pavements have lately been converted into roads with great success. It is probable that neither the inhabitants of these suburbs nor their housemaids were much consulted on the occasion, although justice seems to require that the pedestrian order should not be altogether sacrificed to the equestrian without their consent; but, in fact, the inhabitants of these *ci-devant* streets are said to be well satisfied with the change; and we seem in danger, from the opposition of contending theories, of having all the streets of our cities dug up, and many of our country roads, on the other hand, encumbered with pavements. Mr Macadam has received a new encouragement from Parliament to the amount of L. 4000, and not Charing Cross, indeed, but St James's Square, is going to be Macadamised without delay.

We find some further confirmations and illustrations of Mr Macadam's principles and precepts in the *Report* of the former Committee of the House of Commons as reprinted in his *Remarks*.

Road-  
making.

This gentleman, it seems, arrived from America in the year 1783, at the time that many new roads were making in Scotland (p. 97); he was then appointed a commissioner of the roads, and studied the subject in that capacity there; he has since resided chiefly in Bristol, and was induced to take charge of the roads of that district as a surveyor in 1816; because it was only in that situation that he could carry his principles into practice, and make the necessary experiments for establishing them. He observed in his travels, that the mixture of clay and chalk, with the materials of roads, was the almost universal cause of their failure; and he convinced himself that, by a proper application of materials, a good road might be made in every country. His improvements have been very generally adopted in the west and the south of England; and principally under his own direction or under that of his family. They had superintended more than 300 miles of road, and twice as many more had been improved by their advice and influence. Sober, active, and well informed subsurveyors he considers as the most important of all materials for a good road; and among the extrinsic arrangements which are often required, he thinks the union of different trusts into a single one the most likely to be generally beneficial.

The operation of washing gravel Mr Macadam has not found eligible, because it is more expensive than screening or sifting, and less effectual; for about London the common gravel is not capable of being cleaned by any ordinary washing, though the Thames gravel, where it can be procured, is generally clean and serviceable. Coarse gravel broken, he says, is preferable to fine, as it consolidates more perfectly into a single mass. The old practice of putting a heap of unprepared gravel along the middle of the road, and letting it work its own way gradually to the sides, he thinks every way reprehensible.

The objection to a very convex road is, that travellers only use the middle of it, which is, therefore, worn into three furrows by the string of horses, and by the wheels; if the road is flatter, it becomes worn more equally. Ditches, he observes, only require to be so deep that the surface of the water in them may be a few inches below the level of the road; the farmer often makes them dangerously deep on account of the value of the mould that is dug out of them. Mr Macadam would prefer a bog to any other foundation for a road, provided that it would allow a man to walk over it; and he justly observes, that the resistance to the motion of a carriage would not be materially affected by the foundation, if the road were well made. From Bridgewater to Cross, a part of the road shakes when a carriage passes over it; yet the consumption of materials is less there than on the limestone rock in the neighbourhood. He does not use any faggots in such cases, nor any stones larger than six ounces in weight; and these never sink in the bog, but unite into one mass like a piece of timber, which rests on it. He makes such a road generally at three different times: and he always prefers working in weather not very dry. The surveyors are direct-

ed to carry a pair of scales and a six ounce weight in their pockets, as a check upon the workmen.

Road-  
making.

Mr Macadam has generally found reason to approve the usual regulations respecting carriage-wheels: but he thinks broad wheels less advantageous to roads than is commonly supposed. He suggests that the tolls might always be fairly made proportional to the exact number of horses employed; except that the waggoners should be encouraged to harness them in pairs rather than in a line. The conical form of broad wheels he thinks very injurious.

Clean flints from the sea side are among the best materials for roads, and might often be procured cheap by canals: granite chippings also, brought as ballast, are excellent; and when the middle of the road has been well made with good stones, the sides may often be left for a few feet less abundantly provided with them, as they are naturally much less exposed to wear.

Of the other evidence produced to the Committee of the House of Commons, there is much that gives us valuable information respecting the economy of horses and carriages in general, and some that deserves to be noticed, as affording partial exceptions to the universal adoption of the system introduced by Mr Macadam.

Mr Waterhouse observes (p. 85), that stage coach horses generally last about four years in the neighbourhood of London, and about six in remoter parts. He agrees with Mr Macadam, that a very slight convexity is better for a road than a greater: that roads in wet situations often require underdraining; and that the gravel near London is too often used without being sufficiently cleaned. Mr Horne's horses generally wear out in about three years. The "light" coaches, with their loads, generally weigh about two tons and a half; the coach one, the passengers one, and the luggage a half; the Uxbridge road, he says, is generally heavy, because it lies lower than the neighbouring land, and is not sufficiently drained. Mr Eames reports, that the Guildford road is so much improved by the introduction of flints instead of gravel, that sixteen miles are as easily performed on it by his horses as twelve were before the alteration. Mr Farey explains the principle upon which some of the roads about London are watered in winter; it is in order to soften the tenacious mud, that is formed upon the surface; to prevent its adhering to the carriage wheels, and to enable it to be scraped off with ease. He says that about Whitechapel it has been found very advantageous for the heavy traffic, to have the middle of the road paved; and he thinks that two lines of pavement, one on each side, would be preferable to a single one, in order that the waggoners might walk at the sides of the road, leaving the middle for lighter carriages. He would have a road 55 feet wide, elevated about 12 inches in the middle. Broad wheels, he thinks, are seldom so flat as to bear on their whole surface at once, being commonly rather conoidal than conical; so that they differ less in their effect from narrower wheels than is commonly supposed. Mr Walker adheres to the old opinion, that in soft soils a road ought to be founded on bushes or "bavins;" that is, where they can be ex-

pected to remain always wet, so as not to be liable to a very speedy decay. He observes, that if a road does not possess some considerable convexity at first, it will wear concave, and collect mud; the elevation, he thinks, should be about  $\frac{1}{30}$ th of the breadth. Mr Telford informs the committee (p. 188) that the declivity of the Welsh roads was formerly in many places one inch in ten; and in some one in eight, and even one in six; but that the modern road scarcely ever rises above an inch in thirty; and that the utmost ascent in the whole line is one in seventeen, for about two hundred yards. With respect to the weight of the stones, he agrees with Mr Macadam, that they ought not to exceed six or eight ounces; and that gravel is best cleaned by riddling it repeatedly, and leaving it to dry in the intervals.

### SECT. III.—Of the Roads of different Ages and Countries.

The Romans appear to have been beyond comparison the greatest roadmakers of the ancient or the modern world. The story told by Montaigne (III. vi. p. 206) of a road in Peru, from Quito to Cusco, 300 leagues long, and 25 paces broad, made of stones 10 feet square, with a running stream and a row of trees on each side, seems to have been considerably exaggerated; and it is not very clear whether the stones he mentions were used for the road or for the houses of entertainment built at intervals by its side; nor have the "rocks cut through" and "mountains levelled" been very particularly noticed by more recent travellers in that country. In Italy only, the Romans are said to have made more than 14,000 miles of road, which was generally executed with great care and labour; and many of their roads still remain as the foundation of the most favourite routes of Italian travellers. The more than Roman despot of modern times was as much a Roman in his road-making as in the selfish character of his general policy; and in proportion to the duration of his dynasty, he performed more than all the Appii and Flaminii of antiquity. Whatever his merits may have been, the beneficial effects of his measures remain, and those who have profited by his improvements have no right to criticize his motives with too great severity.

Of the great roads diverging from the gates of ancient Rome, about twelve have been enumerated by antiquaries, and twelve more branched off from these at a small distance from the city; eighteen others commenced in different parts of Italy, and in the whole there are at least fifty, which have been distinguished by appropriate names, without including the military roads through the distant provinces; such, for example, as in England were distinguished by the name of streets, of which many traces yet remain in different parts of the country.

Directly to the sea the Romans travelled by the Ostian road; along its shores to the north west by the Aurelian, and to the south east by the Appian. Next within the Aurelian was the Flaminian, then the Salarian, the Nomentanian, the Tiburtine, the Praenestine, the Latican, and the Latin; and then the Appian, which was the most ancient of all, having been made as far as Capua, in the 442d year of the city, accompanied to a considerable distance by

an aqueduct. The Aurelian road was made in the year 512; the Flaminian about 533.

I. The *Flaminian* road still affords the great northern approach to Rome by the Porta del Popolo; it led to Foligno, Aneona, and Rimini, and was continued by the *Emilian* to Bologna, and thence to Aquilegia, near Venice; the present mountain route from Bologna to Rome is still facilitated by the remains of the ancient structures. Besides the *Emilian* road, the Flaminian was also connected with the *Cassian*, leading to Modena; the *Claudian* to Arezzo, Florence, and Lucca; there were also six other branches of less note, each named after its founder.

II. III. The *Salarian* and the *Nomentanian* roads lay to the east of the Flaminian; the former, from the Porta Salaria, led through the country of the Sabines by Rieti to Hadria; the latter from the Porta Sant' Agnese went north eastwards to Nomentum.

IV. The *Tiburtine* road led from the Porta Tiburtina, now San Lorenzo, to Tivoli, with a branch on the right called the *Gabian*. The large blocks which were employed to form this road, near the town of Tivoli, in ascending from the river, are still in their ancient places; they are accurately fitted together, and present a surface sufficiently smooth, after having been in use for about two thousand years.

V. VI. VII. The three next in order all met at Anagnia, 24 miles beyond Praeneste or Palestrina. The *Praenestine*, from the Esquiline gate, now called Porta Maggiore, on account of the magnitude of the ruins of the aqueduct of Clodius, with which it is incorporated, led by Aquinum to Praeneste; the *Latican* led from the same gate, more to the right, by way of Beneventum; and the *Latin* road, from the Porta Latina, went first to Compitum; and from Anagnia proceeded to join the Appian near Capua.

VIII. The *Appian* road is as well known from the minute description of Horace's progress, in his journey to Brundisium, as from the eagerness with which a modern traveller reckons the stages that he has completed, on his way to Naples, without a visit from the banditti that infest it. The original extent of this road, from the Colosseum to Capua, was 142 Roman miles; and it was continued 238 miles further to Brundisium by Julius Cæsar. It was constructed with large stones, or rather rocks, joined together with great care; and it is said to have had a foot pavement two feet wide on each side, besides the agger, or principal mass of stones in the middle, and the two marginal parts, which were probably unpaved.

IX. The *Ostian* road led from the Porta di San Paolo, near the Tiber, in a straight line to the mouth of that river.

X. The *Aurelian*, from the Porta Aurelia, a gate which was near the Moles Adriani, or Castle of Sant' Angelo, led by Laurentum to Centumcellae, or Civita Vecchia, to Genoa, and thence by Susa, across the Montcenis, as far as Arles in Provence. This seems to have been the oldest passage into the Gauls; it was improved by Pompey the Great under the name of the *Strata Romana*. Several other passages over the Alps are also particularised in the *Itinerary* of Antonine on the roads from Milan to

Road-making.

Road-  
making.

Arles; from Milan to Vienne in Dauphiné, either by the Grecian or by the Cottian Alps: the former north, the latter south of Montcenis; from Milan to Strasburg; and from Milan to Mentz.

XI. XII. The *Triumphal* road began from the Capitol, and went over the Tiber into the country beyond the present site of the Vatican. We may consider as the last of the twelve great roads, originating from Rome, the *Collatine*, leading due north from the Porta Pinciana on the Monte Pincio.

Among the less remarkable roads about the metropolis of the ancient world were also the Campanian, the new and the old Valerian, both leading by Tivoli to the Adriatic; the Tusculan, the Alban, the Ardeatine, on the right of the Appian; the Laurentine, a little more to the right, Pliny's villa being mentioned as accessible from either of these last; the Portuensis, from the Porta Portuense Trasteverina, leading to Ostia; and the Aurelia Nova, beginning from the Porta Janiculi, now Porta San Pancrazio, and leading towards Civita Vecchia.

Whether on the foundations of the ancient roads, or in any new lines that have been prepared in modern times by the magnificence of the Pontiffs or of the Princes, the great roads of Italy are at present almost universally well made and well repaired. In Lombardy, indeed, and throughout the immense plain that extends from the Alps to the Apennines, they are quite as good, in summer at least, as in England. The cross roads of Italy are, however, greatly neglected; for it is in fact almost exclusively in Great Britain that private and individual exertion supersedes the necessity of public munificence. The intercourse of Italy with the rest of Europe has been greatly facilitated by the improvements made in the two great passages over the Alps by the authority of Bonaparte. The more useful of these improvements are probably those which have been effected on the southern side of Montcenis, since they enable the traveller to pass with little danger or difficulty at all seasons of the year; the more magnificent are the works at the Simplon, which, however, are not completely secure from the danger of *avalanches*, whenever fresh snow is lying on the ground. The Apennine portion of the Aurelian road has also been greatly improved by some still more recent operations, so that carriages may now pass with comparative ease and safety from Lucca to Genoa; though, for one stage, near Sestri, it is not thought advisable for the travellers to retain their seats within them.

The general declivity of the new road over Montcenis is 1 inch in 15 or 20; and it is never greater, in the steepest part, that is, in the fourth and fifth turns that wind up over Lanslebourg, than 1 in 12.\* The road over the Simplon was executed jointly by the French and Italians, under the government of Bonaparte, from 1801 to 1805. The greatest declivity is 1 inch in 29; so that an English stage coachman might trot his horses up almost the whole way. The longest gallery or tunnel is about 500 feet underground.

The roads in France are generally rough in their original formation, and still rougher from want of care in repairing them, as the traveller feels to his cost in passing over the primitive mountains in the south of that country, where the roads are certainly very different from those which are made by Macadam across a bog; although some of the more recent French and Flemish pavements, as long as they remain unimpaired, are truly excellent: the new pavement between Cologne and Brussels, for example, is far more perfect than some of the unpaved parts of the continuation of the same line of road to Calais, although the civil postmasters are in the habit of congratulating their English guests on the "fine gravel road" they will have to pass over. In Germany they have few pavements, and the roads, except in sandy countries, are generally kept, or keep themselves, in good repair; that is, in the south and the west of Germany. Mr Cripps informs us, that the great roads in Sweden are beautiful; they are very slightly convex, and made of granite broken to the size of a walnut. The Irish roads, according to Mr Edgeworth, are generally better than the English; the Scotch, Macadam thinks worse, though the materials are better; but in many parts of Scotland the roads appear to be more than sufficiently good for the commerce of the country.

(A. L.)

ROBISON (JOHN), a distinguished Professor of Natural Philosophy, born, in 1739, at Boghall, in the parish of Baldernoek, and in the county of Stirling, was a younger son of John Robison, Esq. who

Road-  
making  
||  
Robison.

\* Derrien, *Notice Historique et Descriptive sur la Route de Montcenis*.

Robison.

had formerly been a merchant at Glasgow, and had retired to live in considerable affluence on his estate at Boghall, not far from that city.

He was of a family sufficiently respectable to enable his son at a subsequent period to prove himself, to the satisfaction of the Court of St Petersburg, a gentleman born. As a younger brother, that son was originally intended for the church, and went at an early age, according to the custom of Scotland, in 1750, to enter as a student of humanity in the University of Glasgow; so that he was initiated almost in the rudiments of Latin and Greek literature under the able instruction of Dr Moore, the well known professor of Greek; and he acquired such a knowledge of these languages as served to constitute him a correct classical scholar through life. He pursued his studies with so much attention, as to obtain the approbation of his teachers, and the admiration of his contemporaries, who were delighted with the originality and ingenuity of his conversation, though he did not himself reflect with perfect satisfaction upon the degree of application which he had exerted in his academical education. He took a degree of Master of Arts in 1756, having studied mathematics under Dr Robert Simson, and moral philosophy under Dr Adam Smith. The example of so correct and rigid a follower of the ancient methods of demonstration, as Dr Simson, must unquestionably have exercised considerable influence on his yet unformed taste in mathematics; but he seems to have had a natural preference, either from the constitution of his mind, or from some previously acquired habits of thinking, for the geometrical method; for we are informed that "he first attracted the regard of Dr Simson by owning his dislike of algebra, and by returning a neat geometrical solution of a problem which had been given out to the class in an algebraical form; with this mode of solution the professor was delighted, though the pupil candidly acknowledged that it had been adopted only because he could not solve the problem in the manner required of the class."

He had imbibed, in the course of his studies, an insuperable aversion to the pursuit of his original objects in the church; not certainly from any want of religious feeling, or from a dislike to the kind of life that was intended for him, but probably from some difficulties that had occurred to him respecting particular points of doctrine or of practice. He was therefore compelled to provide himself with some other occupation; and he readily accepted the offers of some of his friends in 1758, to recommend him to Dr Blair, a prebendary of Westminster, who had formed a scheme for sending Prince Edward, the young Duke of York, to complete his professional education at sea, in company with a son of Admiral Knowles; and Mr Robison was to have instructed his Royal Highness in mathematics and navigation. He was much disappointed, on his arrival in London, to find that the expedition had never been seriously intended; and he readily accepted an engagement to attend young Knowles as a private tutor, when he went as a midshipman on board of the Neptune of 90 guns, with Admiral Saunders, who had the command of a force intended to co-operate with General Wolfe in the reduction of Quebec; and

Robison.

upon the appointment of his friend as a lieutenant on board of the Royal William, Robison was himself rated as a midshipman in that ship.

The fleet arrived on the coast of America in April 1759; in May they got up the river, and Mr Robison was one of a party of 100 seamen draughted from the Royal William into the Admiral's ship, under the command of Lieutenant Knowles: in this capacity he had an opportunity of seeing considerable service, and of making some surveys of the river and of the neighbouring country, an employment for which he was perfectly qualified, both as a geometer and as a draughtsman. He also remarked the effect of the Aurora Borealis on the compass, which had been noticed by Mairan and Wargentin some years before, but which was then not commonly known. After the battle, which was signalised by the victory and death of the gallant Wolfe, the Royal William sailed with his body to Europe, and arrived at Spithead in November. The next year she was sent to cruise off Cape Finisterre, but in six months she was obliged to return home, from having the greater part of the men disabled by the scurvy.

He used to consider the two years that he spent on board of the Royal William as the happiest of his life; and no inconsiderable part of his gratification was derived from the study of seamanship as he saw it practised under the auspices of Captain Hugh Pigot. He did not, however, acquire any firm attachment to the mode of life which he had temporarily adopted; he was rather disposed to resume his academical pursuits, and he had overcome his earlier objections to the ecclesiastical profession. He could not, however, refuse the friendly invitation of Admiral Knowles to come and live with him in the country, and to assist him in some important experiments which he was making upon mechanical and nautical subjects.

In the month of February 1762, Lieutenant Knowles was appointed to the Peregrine sloop, of 20 guns, and Mr Robison accompanied him with the hope of becoming a purser. He visited Lisbon and several other parts of Portugal; but he found a cruise in a small ship much less convenient and agreeable than in a large one, and, fortunately for himself and for mankind, he finally quitted the Peregrine and the naval service in June, and returned to live with Admiral Knowles; who soon after recommended him as a proper person to take charge of Harrison's timekeeper, which had been completed by the labour of 35 years, after many unsuccessful experiments, and which was now sent out by desire of the Board of Longitude to the West Indies, under the care of young Harrison and of Mr Robison. The rate of the chronometer was ascertained at Portsmouth the 6th November 1762, and it indicated, at Port Royal in Jamaica, a difference of time amounting to  $5^h 2^m 47'$ , which is only four seconds less than the true longitude. After a few days, the observers had a prompt opportunity of returning home by the Merlin sloop, which was sent to Europe with despatches. The voyage was most disastrous with respect to wind and weather, and at last the ship took fire; but she arrived safe at Portsmouth in March, and on the 2d of April the watch gave

Robison.  $11^{\text{h}} 58^{\text{m}} 6\frac{1}{2}'$ , instead of  $12^{\text{h}}$ , for the time of mean noon, so that the error, after six months, was only  $1^{\text{m}} 53\frac{1}{2}'$ , amounting to no more than about 20 miles of distance.

Mr Robison received, upon his return, the afflicting intelligence of the total loss of the *Peregrine*, which had foundered at sea with her commander and the whole of the ship's company. He was also greatly disappointed in the failure of some hopes which had been held out to him from the Admiralty and the Board of Longitude; though in fact there is little reason for the public to regret that he was not gratified with the purser'ship, which he claimed as the reward of his services. He was indeed afterwards actually made a purser by Lord Sandwich, in 1763; but he then declined accepting the appointment. His biographers very naturally complain of the neglect of those Boards which ought to have recompensed him; but certainly the Board of Longitude had no power whatever, and probably not much influence, in the appointment of a purser; and after all, the delay of a year or two was nothing very uncommon in the navy.

He had now no other resource than to return to Glasgow, and to resume his academical pursuits with renewed energy. It was from this time that he dated his serious application to his studies; he became extremely intimate with Dr Reid and Dr Alexander Wilson, and he had the advantage of being a witness of two of the greatest steps in the improvement of physical science that have been made in modern times, Dr Black's experimental theory of heat, and Mr Watt's invention of a new steam-engine. Dr Black was the first that determined the quantity of heat required for the conversion of ice into water; Mr Watt, who was settled as a mathematical instrument-maker at Glasgow, had been employed in repairing a working model of Newcomen's engine for one of the professors of the university, and it was the difficulty of supplying this model with steam that suggested to Mr Watt the eligibility of having a separate condenser, and that led him, in conjunction with Dr Black, to a knowledge of the quantity of heat consumed in evaporation.

Amid the enthusiasm which is always inspired by the progress of scientific discovery, and of practical improvement, Mr Robison found every encouragement and every facility for the pursuit of his favourite objects. He was recommended by Dr Black, upon his removal to Edinburgh in 1766, as his successor in the lectureship of chemistry, though without the appointment of a professor. He took charge, also, of the education of Mr Macdowal of Garthland, and of Mr Charles Knowles, afterwards Sir Charles. Admiral Knowles was soon after recommended by the British government to the Empress of Russia, in order to effect a reformation in her navy, having been employed on a similar service in Portugal almost fifty years before; he had always been a firm friend to Mr Robison, and now engaged him on this mission, with a salary of L. 250 a year; and they proceeded together to St Petersburg in December 1770. Being hospitably entertained on their way by the Prince Bishop of Liege, whom they found to constitute, with his chapter and all his servants, a

Robison. lodge of freemasons, Mr Robison was easily persuaded to become one of that fraternity; in a few days he was made an apprentice, and by degrees attained the rank of Scotch master, as he has himself related in his publication upon the subject. He continued nearly two years at St Petersburg, still acting in the capacity of private secretary to Sir Charles, who was appointed president of the Board of Admiralty, much to the advantage of the Russian navy, though his improvements were frequently retarded by the prejudices of the native officers. Mr Robison was then appointed inspector general of the corps of marine cadets at Cronstadt, with a double salary, and with the rank of Lieutenant Colonel. His duty was to receive the report of about forty teachers and professors, respecting the studies of 400 young noblemen, who were their pupils, and to class them according to his judgment of their merits; but he had himself nothing to teach, nor could he have had much occasion for "lecturing fluently in the Russian language," though he was introduced by his friend Kutusoff to the Grand Duke Paul as a proficient in that language; but to the Empress he was not personally known. At Petersburg he could have lived without regretting his country, in the society of such men as Euler and Alpinus, admired by the Russians, and beloved by the British; but Cronstadt in winter was deplorably melancholy; and he was induced, without much difficulty, in 1773, to make some little pecuniary sacrifice in accepting the professorship of Natural Philosophy at Edinburgh, which had become vacant by the death of Dr Russell, and to which he had been recommended by Dr Robertson, then Principal of the University. His determination was not disapproved by the Russian government, who granted him a pension of about L. 80 a year for life; but it was only paid as long as three or four young men, who had accompanied him as pupils, continued to reside at Edinburgh; some discontent having been expressed because he did not keep up a correspondence with the Academy on the improvement of maritime education.

He arrived at Edinburgh in September 1774; he married soon after, and continued to reside in that city for the remaining thirty years of his life, paying only an annual visit to his native place, where he possessed a part of his paternal estate; not being solicitous to extend it, although "he did not diminish it otherwise than as it had been diminished before," that is, in making provision for younger children. His predecessor had been very judicious and successful as a lecturer, though not a mathematician of the highest order; he had himself more practical knowledge and experience in mechanics, and was better acquainted with the foreign mathematicians, who had naturally fallen under his notice during his residence on the Continent. His lectures were considered by most of his pupils as somewhat too difficult to be followed; a complaint which, if it did not depend on their own want of preparatory information, arose perhaps rather more from the hasty manner of his enunciation, than from the abstruseness of his matter. "The singular facility of his own apprehension," says Professor Playfair, "made him judge too favourably of the same power in others."

Robison. To understand his lectures completely was, on account of the rapidity, and the uniform flow of his discourse, not a very easy task, even for men tolerably familiar with the subject. On this account, his lectures were less popular than might have been expected from such a combination of talents as the author of them possessed." This inconvenience was increased "by the small number of experiments he introduced, and a view that he took of Natural Philosophy, which left but a very subordinate place for them to occupy. An experiment, he would very truly observe, does not establish a general proposition, and never can do more than prove a particular fact:" but he seems to have carried this principle to some little excess: it is, in fact, the *illustration*, and not the *proof*, of general principles that is the object of a public exhibition of experiments; and it is very doubtful whether Archimedes, or Newton, or Leibnitz, or Euler, would have been very successful as *showmen*. With respect, however, to "accuracy of definition, to clearness, brevity, and elegance of demonstration, and even to neatness and precision in experiments," Professor Robison was very successful; his course extended "to every branch of physics and of mixed mathematics," and entered so fully into the detail of each particular division of the subjects, that "a more perfect system of academical instruction is not easily to be imagined:" nothing, in short, was wanting, but so much previous knowledge of mathematics in his pupils as he thought he had a right to expect, though his expectations were too rarely fulfilled.

The Philosophical Society of Edinburgh had been almost suffered to sink into oblivion after the publication of the third volume of its *Essays*, in 1756. Professor Robison became a member of it soon after his return from Russia, and was chosen Secretary of the new Society upon its formation by Royal charter, in 1783, when it incorporated with itself the whole of the surviving members of the former Society. In 1798, he received the compliment of a degree of Doctor of Laws from the University of New Jersey; and a similar honour was paid him at Glasgow the year after. In 1800 he was elected, as successor to Dr Black, on the list of the Foreign Members of the Royal Academy of Sciences of St Petersburg.

He was attacked, in 1785, by a severe disorder, from which he was never afterwards wholly free, though it produced little inconvenience besides pain, with some depression of spirits, which was, however, attributed rather to the closeness of his application than to the immediate effect of the disease, which was a glandular induration. For many years he was obliged to obtain the assistance of substitutes in the delivery of his lectures; but towards the end of his life he was able again to perform the duties of the professorship in person. He continued his literary labours with little intermission, and was most happy in the care and attention of his wife and children, whose virtues he found the best alleviation of his suf-

ferings. He took a slight cold, after giving a lecture, on the 28th of January 1805, and died on the 30th.

Robison.

1. It was comparatively late in life that Professor Robison assumed the character of an author, having communicated to the Royal Society of Edinburgh, in 1785, a paper on the *Determination of the Orbit and Motion of the Georgium Sidus*, which was published in the *Edinburgh Transactions*, Vol. I. He had observed the opposition of the planet, in 1786, with an equatorial telescope only, and he had computed the elements of its orbit with greater accuracy than any other astronomer had then done; although his suspicion of the effect of such a planet on the motions of Jupiter and Saturn has not been confirmed by later investigations, the irregularities of these planets, on the contrary, having been otherwise explained.

2. A second paper, published in the same collection, Vol. II. p. 82, relates to *The Motion of Light*, as affected by refracting or reflecting substances which are themselves in motion: the author corrects some errors of Boscovich, who had miscalculated the effect of a water telescope; but he seems to agree with Dr Wilson in the suggestion of another experiment of a similar nature, which, to say the least, is wholly superfluous.

3. The most important, beyond all comparison, of Professor Robison's scientific publications, are the articles which he communicated from time to time to the *third* edition of the *Encyclopædia Britannica*, and to its *Supplement*. It was under the care of Mr Colin Macfarquhar that the twelve first volumes of that edition of this work were published;\* and upon his death, in 1793, the task of continuing it was committed to Dr Gleig, to whom Professor Robison became a most essential co-operator, and from that time "the work ceased to be a mere compilation." The first of his contributions, according to Professor Playfair, was the Article OPTICS, but he probably only revised and enlarged that article; it was followed by PHILOSOPHY, which he wrote jointly with Dr Gleig; by PHYSICS, PNEUMATICS, PRECESSION, PROJECTILES, PUMPS, RESISTANCE, RIVERS, ROOF, ROPE-MAKING, ROTATION, SEAMANSHIP, SIGNAL, SOUND, SPECIFIC GRAVITY, STATICS, STEAM, STEAM ENGINE, STEELYARD, STRENGTH, TELESCOPE, TIDE, TRUMPET, VARIATION, and WATERWORKS; and in the *Supplement*, by ARCH, ASTRONOMY, BOSCOVICH, CARPENTRY, CENTRE, DYNAMICS, ELECTRICITY, IMPULSION, INVOLUTION, MACHINERY, MAGNETISM, MECHANICS, PERCUSSION, PIANOFORTE, POSITION, TEMPERAMENT, THUNDER, TRUMPET, TSCHIRNHAUS, and WATCHWORK. Notwithstanding some degree of prolixity and want of arrangement, which could scarcely be avoided in the preparation of original articles for such a mode of publication, the whole of them, taken together, undeniably exhibit a more complete view of the modern improvements of physical science than had ever before

\* The third edition of the *Encyclopædia Britannica* consisted of eighteen volumes; the *Supplement* to it of two volumes.

Robison.

been in the possession of the British public; and display such a combination of acquired knowledge with original power of reasoning, as has fallen to the lot of a few only of the most favoured of mankind.

4. It is not altogether with so high approbation that his friends and his biographers have mentioned a work, of a nature rather political than philosophical, entitled *Proofs of a Conspiracy against all the Religions and Governments of Europe*, 8vo. Ed. 1797; though it went through several editions. The principal part of the book consists of the history of the *Illuminati* and the *German Union*, whom he considers as having become the chief agents in a plot first formed by the Freemasons, at the suggestion of some ex-jesuit, who proposed for their model the internal economy of the order which he had quitted; and whatever foundation this outline may have had in truth, there is no doubt that the manner, in which Professor Robison has filled it up, betrays a degree of credulity, extremely remarkable in a person used to calm reasoning and philosophical demonstration. For example, in the admission of a story told by an anonymous German author, that the minister Turgot was the protector of a society that met at Baron d'Holbach's, for the purpose of examining the brains of *living children*, in order to discover the principle of vitality. He does not accuse the English Freemasons of having participated in the conspiracy; but he considers the Continental lodges as having been universally implicated in it.

5. After the death of Dr Black in 1799, he undertook to superintend the publication of his *Lectures on Chemistry*, which appeared in 1803. 2 vols. 4. And he executed this task, which was rather laborious than difficult, with equal zeal and ability. He endeavoured to reduce to their just estimate the comparative pretensions of the French and British chemists, though he is somewhat puritanically severe in criticizing the literal meaning of the compliments paid to Black by Lavoisier, on which he founds a charge of insincerity.

6. His last publication was the first volume of a series which was to form a complete system, entitled *Elements of Mechanical Philosophy*, 8. Ed. 1804. It comprehended only *Dynamics* and *Astronomy*; and it never became very popular: it was too difficult for the many, who wished for general and philosophical notions only, and not sufficiently precise and demonstrative for the few, who wanted practical and numerical results. In attempting to combine the separate merits of the *Exposition du Systeme du Monde*, and of the *Mécanique Céleste*, the author sacrificed both the popular simplicity of the former, and the mathematical perfection of the latter. A few inaccuracies, which ought not to escape the attention of the reader of the work, have been pointed out in the *Imperial Review* for March 1805; a journal long since discontinued.

7. The contents of the volume last mentioned, together with some manuscripts intended to have formed part of a second, and the greater part of the articles furnished by Professor Robison to the *Encyclopædia*, were collected into a *System of Mechanical Philosophy, with Notes*, by David Brewster, LL.D. 4 vols. 8. Ed. 1822; a spirited book-

seller in London having undertaken the risk of the publication. 1. The first volume begins with the articles DYNAMICS, PROJECTILES, CORPUSCULAR FORCES, CAPILLARY ATTRACTION, BOSCOVICH'S THEORY, and ROTATION, all as remodelled for the *Elements*: then follow STRENGTH OF MATERIALS, CARPENTRY, ROOF, CONSTRUCTION OF ARCHES, CONSTRUCTION OF CENTRES. 2. The article STEAM-ENGINE is enriched with notes and an appendix, by the late Mr Watt; the next is MACHINERY; then RESISTANCE OF FLUIDS, RIVERS, WATERWORKS, PUMPS. 3. ASTRONOMY, TELESCOPE, PNEUMATICS. 4. ELECTRICITY, MAGNETISM, VARIATION, TEMPERAMENT, TRUMPET, WATCHWORK, and SEAMANSHIP. The notes are not numerous, and the editor's principal labour has been to retrench some passages that appeared to him superfluous, when the papers were to stand as parts of such a collection.

"Although Dr Robison's name," says Dr Brewster in his preface, "cannot be associated with the great discoveries of the century which he adorned, yet the memory of his talents and his virtues will be long cherished by his country. Imbued with the genuine spirit of the philosophy which he taught, he was one of the warmest patrons of genius wherever it was found. His mind was nobly elevated above the mean jealousies of rival ambition, and his love of science and of justice was too ardent to allow him either to depreciate the labours of others, or to transfer them to himself. To these great qualities as a philosopher, Dr Robison added all the more estimable endowments of domestic and of social life. His friendship was at all times generous and sincere. His piety was ardent and unostentatious. His patriotism was of the most pure and exalted character; and, like the immortal Newton, whose memory he cherished with a peculiar reverence, he was pre-eminently entitled to the high distinction of a Christian, patriot, and philosopher." His person was handsome, and his physiognomy prepossessing; and he appears to have been endowed with an extraordinary combination of talents, even exclusively of those which were called into immediate activity in his professional pursuits; for he was a good linguist, an excellent draughtsman, and an accomplished musician: his conversation was always energetic and interesting, and sometimes even poetical; and his liberality of sentiment was only limited by his regard for what he considered as the best interests of mankind.

A short account of his life was published in 1802, by a contributor to the *Philosophical Magazine*, who, among other inaccuracies, thought himself at liberty to assert that he was an admirer of the algebraical form of representation, in preference to the geometrical. His friend, Dr Gleig, stepped forwards soon after to correct these mistakes, in the *Antijacobin Review* for 1802, and his letter was copied into the *Philosophical Magazine*. He asserts, from his own knowledge, that even yet Professor Robison "delights much more in geometry than in any of the modes of algebra, assigning, as the reason of his preference, that in the longest demonstration, the geometrician has al-

Robison  
||  
Romance.

ways clear and adequate ideas, which the most expert algebraist can very seldom have." It may perhaps be asserted, on the other hand, that the same reasoning would lead us always to employ actual multiplication or division, in preference to the use of logarithms or of a sliding rule; and that the whole of the magic of calculation depends on the abstraction of the results from the numerous and separately unimportant steps by which they are obtained: but the having once seen those steps clearly is certainly of great importance to the process of reasoning, even when the memory no longer retains them; and no mathematician of correct taste can study the ancient geometricians without admiring the elegance and precision of their method, even amidst the pedantry which too frequently envelopes their expressions, and without being grateful for their punctuality in collecting their results into the very convenient form of distinct propositions, and in making such references from each proposition to the foundations on which it depends, as to enable him readily to trace back their steps to the most elementary principles; which is scarcely possible in any of the works of the most modern school of analysis. Professor Robison, however,

seems rarely to have cultivated the higher mathematics for their own sake only, or any further than as they could be applied to the study of the phenomena of nature, or to the practice of the combinations of art; in fact, without some such limitation, there would be no track to guide us in the pathless regions of quantity and number, and their endless relations and functions. But besides the utility of the pure mathematics, as a branch of early education, in exercising and fortifying the powers of the mind, it is impossible to foresee with certainty *how much* of mathematics may be wanted by the natural philosopher in any given investigation; and Professor Robison, as well as many others of his countrymen, would certainly have been the better for the possession of *a little more*, as the author of the criticisms in the *Imperial Review* has already had occasion to remark.

## R O M A N C E.

Definition  
and origin of  
the word  
Romance.

DR JOHNSON has defined Romance, in its primary sense, to be "a military fable of the middle ages; a tale of wild adventures in love and chivalry." But although this definition expresses correctly the ordinary idea of the word, it is not sufficiently comprehensive to answer our present purpose. A composition may be a legitimate romance, yet neither refer to love nor chivalry—to war nor to the middle ages. The "wild adventures" is almost the only absolutely essential ingredient in Johnson's definition. We would be rather inclined to describe a *Romance* as "a fictitious narrative in prose or verse; the interest of which turns upon marvellous and uncommon incidents;" being thus opposed to the kindred term *Novel*, which Johnson has described as "a smooth tale, generally of love;" but which we would rather define as "a fictitious narrative, differing from the romance, because accommodated to the ordinary train of human events, and the modern state of society." Assuming these definitions, it is evident, from the nature of the distinction adopted, that there may exist compositions which it is difficult to assign precisely or exclusively to the one class or other; and which, in fact, partake of the nature of both. But the distinction will be found broad enough to answer all general and useful purposes.

The word Romance, in its original meaning, was

far from corresponding with the definition now assigned. On the contrary, it signified merely one or other of the popular dialects of Europe, founded (as almost all these dialects were) upon the Roman tongue, that is, upon the Latin. The name of romance was indiscriminately given to the Italian, to the Spanish, even (in one remarkable instance at least)\* to the English language. But it was especially applied to the compound language of France; in which the Gothic dialect of the Franks, the Celtic of the ancient Gauls, and the classical Latin, formed the ingredients. Thus Robert De Brunne:

"All is calde geste Inglis,  
That en this language spoken is—  
Frankis speech is caled *Romance*,  
So sayis clerkis and men of France."

At a period so early as 1150, it plainly appears that the Romance Language was distinguished from the Latin, and that translations were made from the one into the other; for an ancient romance on the subject of Alexander, quoted by Fauchet, says it was written by a learned clerk,

"Qui de *Latin* la trest, et en *Roman* la mit."

The most noted romances of the middle ages were usually composed in the romance or French lan-

\* This curious passage was detected by the industry of Ritson in *Giraldus Cambrensis*, "*Ab aqua illa optima, que Scottice vocata est FROTH; Brittanice, WEIRD; Romane vero Scotie-Wattre.*" Here the various names assigned to the Frith of Forth are given in the Gaelic or Earse, the British or Welsh; and the phrase *Roman* is applied to the ordinary language of England. But it would be difficult to show another instance of the English language being termed Roman or Romance.

Romance.

guage, which was, in a peculiar degree, the speech of love and chivalry; and those which are written in English always affect to refer to some French original, which usually, at least, if not in all instances, must be supposed to have a real existence. Hence the frequent recurrence of the phrase,

“As in romance we read;”

Or,

“Right as the romaunt us tells;”

and equivalent phrases, well known to all who have at any time perused such compositions. Thus, very naturally, though, undoubtedly, by slow degrees, the very name of romaunt, or romance, came to be transferred from the language itself to that peculiar style of composition in which it was so much employed, and which so commonly referred to it. How early, a transference so natural took place, we have no exact means of knowing; but the best authority assures us, that the word was used in its modern sense so early as the reign of Edward III. Chaucer, unable to sleep during the night, informs us, that, in order to pass the time,

“Upon my bed I sate upright;  
A ROMANCE, and he me it took  
To read and drive the night away.”

The book described as a romance contained, as we are informed,

“————— Fables  
That clerkis had, in old time,  
And other poets, put in rhyme.”

And the author tells us, a little lower,

“This book ne spake but of such things,  
Of Queens' lives and of Kings.”

The volume proves to be no other than Ovid's *Metamorphosis*; and Chaucer, by applying to it the name of romance, sufficiently establishes that the word was, in his time, correctly employed under the modern acceptance.

Having thus accounted for the derivation of the word, our investigation divides itself into three principal branches, though of unequal extent. In the FIRST of these we propose to inquire into the general History and Origin of this peculiar species of composition, and particularly of Romances relating to European Chivalry, which necessarily form the most interesting object of our inquiry; and in the SECOND, to give some brief account of the History of the Romance of Chivalry in the different states of Europe. THIRDLY, We propose to notice cursorily the various kinds of Romantic Composition by which the ancient romances of chivalry were followed and superseded, and with these notices to conclude the article.

General History of Romance.

I. In the views taken by Hurd, Percy, and other older authorities, of the origin and history of romantic fiction, their attentions were so exclusively fixed upon the romance of chivalry alone, that they seem to have forgotten that, however interesting and peculiar, it formed only one species of a very nu-

merous and extensive genus. The progress of romance, in fact, keeps pace with that of society, which cannot long exist, even in the simplest state, without exhibiting some specimens of this attractive style of composition. It is not meant by this assertion, that in early ages such narratives were invented, in the character of mere fictions, devised to pass away the leisure of those who have time enough to read and attend to them. On the contrary, romance and real history have the same common origin. It is the aim of the former to maintain as long as possible the mask of veracity; and indeed the traditional memorials of all earlier ages partake in such a varied and doubtful degree of the qualities essential to those opposite lines of composition, that they form a mixed class between them; and may be termed either romantic histories, or historical romances, according to the proportion in which their truth is debased by fiction, or their fiction mingled with truth.

A moment's glance at the origin of society will satisfy the reader why this can hardly be otherwise. The father of an isolated family, destined one day to rise from thence into a nation, may, indeed, narrate to his descendants the circumstances which detached him from the society of his brethren, and drove him to form a solitary settlement in the wilderness, with no other deviation from truth, on the part of the narrator, than arises from the infidelity of memory, or the exaggerations of vanity. But when the tale of the patriarch is related by his children, and again by his descendants of the third and fourth generation, the facts it contains are apt to assume a very different aspect. The vanity of the tribe augments the simple annals from one cause—the love of the marvellous, so natural to the human mind, contributes its means of sophistication from another—while, sometimes, the king and the priest find their interest in casting a holy and sacred gloom and mystery over the early period in which their power arose. And thus altered and sophisticated from so many different motives, the real adventures of the founder of the tribe bear as little proportion to the legend recited among his children, as the famous hut of Loretto bears to the highly ornamented church with which superstition has surrounded and enshrouded it. Thus the definition which we have given of Romance as a fictitious narrative turning upon the marvellous or the supernatural, might, in a large sense, be said to embrace

————— quicquid Græcia mendax  
Audet in historia,

or, in fine, the mythological and fabulous history of all early nations.

It is also important to remark, that poetry, or rather verse—rhythm at least of some sort or other, is originally selected as the best vehicle for these traditional histories. Its principal recommendation is probably the greater facility with which metrical narratives are retained in the memory—a point of the last consequence, until the art of writing is generally introduced; since the construction of the verse itself forms an artificial association with the sense, the one of which seldom fails to recal the other to recollection. But the medium of verse, at first adopted

Romance. merely to aid the memory, becomes soon valuable on account of its other qualities. The march or measure of the stanza is gratifying to the ear, and, like a natural strain of melody, can be restrained or accelerated, so as to correspond with the tone of feeling which the words convey; while the recurrence of the necessary measure rhythm, or rhyme, is perpetually gratifying the hearer by a sense of difficulty overcome. Verse being thus adopted as the vehicle of traditional history, there needs but the existence of a single man of genius, in order to carry the composition a step higher in the scale of literature than that of which we are treating. In proportion to the skill which he attains in his art, the fancy and ingenuity of the artist himself are excited; the simple narrative transmitted to him by ruder rhymers is increased in length; is decorated with the graces of language, amplified in detail, and rendered interesting by description; until the brief and barren original bears as little resemblance to the finished piece, as the *Iliad* of Homer to the evanescent traditions, out of which the blind bard wove his tale of Troy Divine. Hence the opinion expressed by the ingenious Percy, and assented to by Ritson himself. When about to present to his readers an excellent analysis of the old romance of *Lybius Disconius*, and making several remarks on the artificial management of the story, the Bishop observes, that "if an Epic poem may be defined a fable related by a poet to excite admiration and inspire virtue, by representing the action of some one hero favoured by Heaven, who executes a great design in spite of all the obstacles that oppose him, I know not why we should withhold the name of *Epic Poem* from the piece which I am about to analyse."\*

Yet although this levelling proposition has been laid down by Percy, and assented to by Ritson (writers who have few opinions in common), and although, upon so general a view of the subject, the *Iliad*, or even the *Odyssey*, of Homer might be degraded into the class of romances, as *Le Beau Deconnu* is elevated into that of epic poems, there lies in ordinary speech, and in common sense, as wide a distinction between these two classes of composition, as there is betwixt the rude mystery or morality of the middle ages, and the regular drama by which these were succeeded. Where the art and the ornaments of the poet chiefly attract our attention—where each part of the narrative bears a due proportion to the others, and the whole draws gradually towards a final and satisfactory conclusion—where the characters are sketched with force, and sustained with precision—where the narrative is enlivened and adorned with so much, and no more, of poetical ornament and description, as may adorn, without impeding its progress—where this art and taste is displayed, supported, at the same time, by a sufficient tone of genius, and art of composition, the work produced must be termed an *Epic Poem*, and the author may claim his seat upon the high and honoured seat occupied by Homer,

Romance. Virgil, and Milton. On the other hand, when a story languishes in tedious and minute details, and relies for the interest which it proposes to excite, rather upon the wild excursions of an unbridled fancy, than upon the skill of the poet—when the supernatural and the extraordinary are relied upon exclusively as the supports of the interest, the author, though his production may be distinguished by occasional flashes of genius, and though it may be interesting to the historian, as containing some minute fragments of real events, and still more so to the antiquary, from the light which it throws upon ancient manners, is still no more than a humble Romancer, and his work must rank amongst those rude ornaments of a dark age, which are at present the subject of our consideration. Betwixt the extremes of the two classes of composition, there must, no doubt, exist many works, which partake in some degree of the character of both; and after having assigned most of them each to their proper class, according as they are distinguished by regularity of composition and poetical talent, or, on the contrary, by extravagance of imagination, and irregularity of detail, there may still remain some, in which these properties are so equally balanced, that it may be difficult to say to which class they belong. But although this may be the case in a very few instances, our taste and habits readily acknowledge as complete and absolute a difference betwixt the *Epopœia* and *Romance*, as can exist betwixt two distinct species of the same generic class.

We have said of romance, that it first appears in the form of metrical history, professes to be a narrative of real facts, and is, indeed, nearly allied to such history as an early state of society affords; which is always exaggerated by the prejudices and partialities of the tribe to which it belongs, as well as deeply marked by their idolatry and superstition. These it becomes the trade of the romancers still more to exaggerate, until the thread of truth can scarce be discerned in the web of fable which involves it; and we are compelled to renounce all hope of deriving serious or authentic information from the materials upon which the compounders of fiction have been so long at work, from one generation to another, that they have at length obliterated the very shadow of reality or even probability.

The view we have given of the origin of romance will be found to agree with the facts which the researches of so many active investigators of this curious subject have been able to ascertain. It is found, for example, and we will produce instances in viewing the progress of romance in particular countries, that the earliest productions of this sort, known to exist, are short narrations or ballads, which were probably sung on solemn or festival occasions, recording the deeds and praises of some famed champion of the tribe and country, or perhaps the history of some remarkable victory or signal defeat, calculated to interest the audience by the associations

\* *Reliques of Ancient English Poetry*, III. xxvii. fixed to *Telemachus*.

Romance.

which the song awakens. These poems, of which very few can now be supposed to exist, are not without flashes of genius, but brief, rude, and often obscure, from real antiquity or affected sublimity of diction. The song on the battle of Brunanburgh, preserved in the *Saxon Chronicle*, is a genuine and curious example of this aboriginal style of poetry.

Temporal and Spiritual Romances.

Even at this early period, \* there may be observed a distinction betwixt what may be called the *Temporal* and *Spiritual* romances; the first destined to the celebration of worldly glory,—the second to recording the deaths of martyrs and the miracles of saints; both which themes unquestionably met with an almost equally favourable reception from their hearers. But although most nations possess, in their early species of literature, specimens of both kinds of romance, the proportion of each, as was naturally to have been expected, differs according as the genius of the people amongst whom they occur leaned towards devotion or military enterprise. Thus, of the Saxon specimens of poetry, which manuscripts still afford us, a very large proportion is devotional, amongst which are several examples of the spiritual romance, but very few, indeed, of those respecting warfare or chivalry. On the other hand, the Norman language, though rich in examples of both kinds of romances, is particularly abundant in that which relates to battle and warlike adventure. The Christian Saxons had become comparatively pacific, while the Normans were certainly accounted the most martial people in Europe.

However different the spiritual romance may be from the temporal in scope and tendency, the nature of the two compositions did not otherwise greatly differ. The structure of verse and style of composition was the same; and the induction, even when the most serious subject was undertaken, exactly resembled that with which minstrels introduced their idle tales, and often contained allusions to them. Warton quotes a poem on the Passions, which begins,

I hereth one lutele tale, that Ich eu wille telle,  
As wi vyndeth hit invrite in the godspelle,  
Nuz hit nouht of Carlemeyne ne of the Duzpere,  
Ac of Criste's thruuryngc, &c.

The temporal romances, on the other hand, often commenced by such invocations of the Deity, as would only have been in place when a much more solemn subject was to be agitated. The exordium of the Romance of *Ferumbras* may serve as an example of a custom almost universal:

God in glorie of mightis moost  
That all things made in sapience,  
By virtue of Word and Holy Gooste,  
Giving to men great excellence, &c.

The distresses and dangers which the knight endured for the sake of obtaining earthly fame and his mistress's favour, the saint or martyr was exposed to for the purpose of securing his rank in heaven, and

the favour of some beloved and peculiar patron saint. If the earthly champion is in peril from monsters, dragons, and enchantments, the spiritual hero is represented as liable to the constant assaults of the whole invisible world, headed by the ancient dragon himself. If the knight is succoured at need by some favouring fairy or protecting genius, the saint is under the protection not only of the whole heavenly host, but of some one divine patron or patroness who is his especial auxiliary. Lastly, the conclusion of the romance, which usually assigns to the champion a fair realm, an abundant succession, and a train of happy years, consigns to the martyr his fane and altar upon earth, and in heaven his seat among saints and angels, and his share in a blessed eternity. It remains but to say, that the style and language of these two classes do not greatly differ, and that the composers of both employ the same structure of rhythm and of language, and draw their ideas and their incidents from similar sources; so that, having noticed the existence of the spiritual romance, it is unnecessary for the present to prosecute this subject farther.

Another early and natural division of these works of fiction seems to have arranged them into *Serious* and *Comical*. The former were by far the most numerous, and examples of the latter are in most countries comparatively rare. Such a class, however, existed, as proper romances, even if we hold the comic romance distinct from the *Contes* and *Fabliaux* of the French, and from such jocular English narratives as the *Wife Lapt in Moril's Skin*, *The Friar and the Boy*, and similar humorous tales; of which the reader will find many examples in Ritson's *Ancient English Poetry*, and in other collections. The scene of these *gestes* being laid in low, or at least in ordinary life, they approach in their nature more nearly to the class of novels, and may perhaps be considered as the earliest specimens of that kind of composition. But the proper comic romance was that in which the high terms and knightly adventures of chivalry were burlesqued, by ascribing them to clowns or others of a low and mean degree. They formed, as it were, a parody on the serious romance, to which they bore the same proportion as the anti-masque, studiously filled with grotesque, absurd, and extravagant characters, "entering," as the stage direction usually informs us, "to a confused music," bore to the masque itself, where all was dignified, noble, stately, and harmonious.

An excellent example of the comic romance is the *Tournament of Tottenham*, printed in Percy's *Reliques*, in which a number of clowns are introduced practising one of these warlike games, which were the exclusive prerogative of the warlike and noble. They are represented making vows to the swan, the peacock, and the ladies; riding a tilt on their clumsy cart horses, and encountering each other with ploughshares and flails; while their defensive armour consisted of great wooden bowls and troughs, by way of helmets

\* The religious romances of *Barlaam* and *Jehosaphat* were composed by John of Damascus in the eighth century.

Romance— and cuirasses. The learned editor seems to have thought this singular composition was like Don Quixote, with which he compares it, a premeditated effort of satire, written to expose the grave and fantastic manners of the serious romance. This is considering the matter too deeply, and ascribing to the author a more critical purpose than he was probably capable of conceiving. It is more natural to suppose that his only ambition was to raise a laugh, by ascribing to the vulgar the manners and exercises of the noble and valiant; as in the well known farce of *High Life Below Stairs*, the ridicule is not directed against the manners described, but against the menials who affect those that are only befitting their superiors. The *Hunting of the Hare*, published in the collection formed by the late industrious and accurate Mr Weber, is a comic romance of the same order. A yeoman informs the inhabitants of a country hamlet that he has found a hare sitting, and invites them to come to course her. They attend, accordingly, with all the curs and mastiffs of their village, and the unsportsmanlike manner in which the inexperienced huntsmen and their irregular pack conduct themselves, forms the interest of the piece. It can hardly be supposed the satire is directed against the sport of hunting itself; since the whole ridicule arises out of the want of the necessary knowledge of its rules, incident to the ignorance and inexperience of the clowns who undertook to practise an art peculiar to gentlemen. The ancient poetry of Scotland furnishes several examples of this ludicrous style of romantic composition; as the *Tournament at the Drum*, and the *Justing of Watson and Barbour*, by Sir David Lindsay. It is probable that these mock encounters were sometimes acted in earnest; at least King James I. is accused of witnessing such practical jests; "sometimes presenting David Droman and Archie Armstrong, the king's fool, on the back of other fools, to tilt at one another till they fell together by the ears."—(Sir Antony Weldon's *Court of King James*.)

Classical Romances. In hastily noticing the various divisions of the romance, we have in some degree delayed our promised account of its rise and progress; an inquiry which we mean chiefly to confine to the romance of the middle ages. For, although it be true that this species of composition is common to almost all nations, and that even if we deem the *Iliad* and *Odyssey* compositions too dignified by the strain of poetry in which they are composed to bear the name of metrical romances; yet we have the pastoral romance of *Daphnis and Chloe*, and the historical romance of *Theagenes and Churiclea*, which are sufficiently accurate specimens of that style of composition to which it is probable the *Milesian fables* and the romances of Antonius Diogenes, described by Photius, could they be recovered, would also be found to belong. It is impossible to avoid noticing that the Sybarites, whose luxurious habits seem to have been intellectual, as well as sensual, were peculiarly addicted to the perusal of the Milesian fables; from which we may conclude that they were not of that severe kind which inspired high thoughts and martial virtues. But there would be little advantage derived from extending our researches into the ages of classical antiquity respecting a class of compositions which,

Romance— though they existed then, as in almost every stage of society, were neither so numerous nor of such high repute as to constitute any considerable portion of their literature.

Want of space also may entitle us to dismiss the consideration of the Oriental romances, unless in so far as in the course of the middle ages they came to furnish materials for enlarging and varying the character of the romances of knight-errantry. That they existed early, and were highly esteemed both among the Persians and Arabians, has never been disputed; and the most interesting light has been lately thrown on the subject by the publication of *Anitar*, one of the most ancient, as well as most rational, if we may use the phrase, of the Oriental fictions. The Persian romance of the *Shah-Nameh* is well known to Europeans by name, and by copious extracts; and the love-tale of *Mejnoun and Leilah* is also familiar to our ears, if not to our recollections. Many of the fictions in the extraordinary collection of the *Arabian Tales* approach strictly to the character of romances of chivalry; although in general they must be allowed to exceed the more tame northern fictions in dauntless vivacity of invention, and in their more strong tendency to the marvellous. Several specimens of the comic romance are also to be found mingled with those which are serious; and we have the best and most positive authority that the recital of these seductive fictions is at this moment an amusement as fascinating and general among the people of the East, as the perusal of printed romances and novels among the European public. But a minute investigation into this particular species of romance would lead us from our present field, already sufficiently extensive for the limits to which our plan confines it.

Romances of Chivalry. The European Romance, wherever it arises, and in whatsoever country it begins to be cultivated, had its origin in some part of the real or fabulous history of that country; and of this we will produce, in the sequel, abundant proofs. But the simple tale of tradition had not passed through many mouths, ere some one, to indulge his own propensity for the wonderful, or to secure by novelty the attention of his audience, augments the meagre chronicle with his own apocryphal inventions. Skirmishes are magnified into great battles; the champion of a remote age is exaggerated into a sort of demi-god; and the enemies whom he encountered and subdued are multiplied in number, and magnified in strength, in order to add dignity to his successes against them. Chaunted to rythmical numbers, the songs which celebrate the early valour of the fathers of the tribe become its war-cry in battle, and men march to conflict hymning the praises and the deeds of some real or supposed precursor who had marshalled their fathers in the path of victory. No reader can have forgotten that when the decisive battle of Hastings commenced, a Norman minstrel, Taillefer, advanced on horseback before the invading host, and gave the signal for onset, by singing the *Song of Roland*, that renowned nephew of Charlemagne, of whom romance speaks so much, and history so little; and whose fall, with the chivalry of Charles the Great in the pass of Roncesvalles, has given rise to such clouds of ro-

Romance.

mantic fiction, that its very name has been for ever associated with it. The remarkable passage has been often quoted from the *Brut of Wace*, an Anglo-Norman metrical chronicle.

Taillefer, qui moult bien chantont  
Sur un cheval gi tost alont,  
Devant le Duc alont chantant  
De Karlemaigne et de Rollant,  
Et d'Oliver et des vassals,  
Qui morurent en Rençevals.

Which may be thus rendered,

Taillefer, who sung both well and loud,  
Came mounted on a courser proud;  
Before the Duke the minstrel sprung,  
And loud of Charles and Roland sung,  
Of Oliver and champions mo,  
Who died at fatal Ronçevaux.

This champion possessed the sleight-of-hand of the juggler, as well as the art of the minstrel. He tossed up his sword in the air, and caught it again as he galloped to the charge, and showed other feats of dexterity. Taillefer slew two Saxon warriors of distinction, and was himself killed by a third. Ritson, with less than his usual severe accuracy, supposed that Taillefer sung some part of a long metrical romance upon Roland and his history; but the words *chanson*, *cantilena*, and *song*, by which the composition is usually described, seems rather to apply to a brief ballad or national song; which is also more consonant with our ideas of the time and place where it was chaunted.

But neither with these romantic and metrical chronicles did the mind long remain satisfied; more details were demanded, and were liberally added by the invention of those who undertook to cater for the public taste in such matters. The same names of kings and champions, which had first caught the national ear, were still retained, in order to secure attention, and the same assertions of authenticity, and of reference to real history, were stoutly made both in the commencement and in the course of the narrative. Each nation, as will presently be seen, came to adopt to itself a cycle of heroes like those of the *Iliad*; a sort of common property to all minstrels who chose to make use of them, under the condition always that the general character ascribed to each individual hero was preserved with some degree of consistency. Thus, in the romances of *The Round Table*, Gawain is uniformly represented as courteous; Kay as rude and boastful; Mordred as treacherous; and Sir Launcelot as a true though a sinful lover, and in all other respects a model of chivalry. Amid the Paladins of Charlemagne, whose cycle may be considered as peculiarly the property of French in opposition to Norman-Anglo romance, Gan, or Ganelon of Mayence, is represented as uniformly faithless, and engaged in intrigues for the destruction of Christianity; Roland as brave, unsuspecting, devotedly loyal, and somewhat simple in his disposition; Renaud, or Rinaldo, is painted with all the properties of a borderer, valiant, alert, ingenious, rapacious, and unscrupulous. The same con-

Romance.

ventional distinctions may be traced in the history of the Nibelung, which has supplied matter for so many Teutonic adventurers. Meister Hildebrand, Etzel, Theodorick, and the champion Hogan, as well as Chrimhelda and the females introduced, have the same individuality of character, which is ascribed, in Homer's immortal writings, to the wise Ulysses, the brave but relentless Achilles, his more gentle friend Patroclus, Sarpedon, the favourite of the gods, and Hector, the protector of mankind. It was not permitted to the invention of a Greek poet to make Ajax a dwarf, or Teucer a giant, Thersites a hero, or Diomedes a coward; and it seems to have been under similar restrictions respecting consistency that the ancient romancers exercised their ingenuity upon the materials supplied them by their predecessors. But, in other respects, the whole store of romantic history and tradition was free to all as a joint stock in trade, on which each had a right to draw as suited his particular purposes. He was at liberty not only to select a hero out of known and established names which had been the theme of others, but to imagine a new personage of his own pure fancy, and combine him with the heroes of Arthur's Table or Charlemagne's Court, in the way which best suited his fancy. He was permitted to excite new wars against those bulwarks of Christendom, invade them with fresh and innumerable hosts of Saracens, reduce them to the last extremity, drive them from their thrones, and lead them into captivity, and again to relieve their persons, and restore their sovereignty, by events and agents totally unknown in their former story.

In the characters thus assigned to the individual characters of romantic fiction, it is possible there might be some slight foundation in remote tradition, as there were also probably some real grounds for the existence of such persons, and perhaps for a very few of the leading circumstances attributed to them. But these realities only exist as the few grains of wheat in the bushel of chaff, incapable of being winnowed out, or cleared from the mass of fiction with which each new romancer had in his turn overwhelmed them. So that romance, though certainly deriving its first original from the pure font of History, is supplied, during the course of a very few generations, with so many tributes from the Imagination, that at length the very name comes to be used to distinguish works of pure fiction.

When so popular a department of poetry has attained this decided character, it becomes time to inquire who were the composers of these numerous, lengthened, and once admired narratives which are called metrical romances, and from whence they drew their authority. Both these subjects of discussion have been the source of great controversy among antiquarians; a class of men who, be it said with their forgiveness, are apt to be both positive and polemical upon the very points which are least susceptible of proof, and which are least valuable if the truth could be ascertained; and which, therefore, we would gladly have seen handled with more diffidence, and better temper in proportion to their uncertainty.

The late venerable Dr Percy, Bishop of Dromore, The Minstrels.

Romance. led the way unwarily to this dire controversy, by ascribing the composition of our ancient heroic songs and metrical legends, in rather too liberal language, to the minstrels, that class of men by whom they were generally recited. This excellent person, to whose memory the lovers of our ancient lyre must always remain so deeply indebted, did not, on publishing his work nearly fifty years ago, see the rigid necessity of observing the utmost and most accurate precision either in his transcripts or his definitions. The study which he wished to introduce was a new one—it was his object to place it before the public in an engaging and interesting form; and, in consideration of his having obtained this important point, we ought to make every allowance, not only for slight inaccuracies, but for some hasty conclusions, and even exaggerations, with which he was induced to garnish his labour of love. He defined the minstrels, to whose labours he chiefly ascribed the metrical compositions on which he desired to fix the attention of the public, as “an order of men in the middle ages, who subsisted by the arts of poetry and music, and sung to the harp verses composed by themselves or others.”\* In a very learned and elegant essay upon the text thus announced, the reverend Prelate in a great measure supported the definition which he had laid down; although it may be thought that, in the first editions at least, he has been anxious to view the profession of the minstrels on their fairest and most brilliant side; and to assign to them a higher station in society than a general review of all the passages connected with them will permit us to give to a class of persons who either lived a vagrant life, dependent on the precarious taste of the public for a hard-earned maintenance, or, at best, were retained as a part of the menial retinue of some haughty baron, and in a great measure identified with his musical band.

The late acute, industrious, and ingenious Mr Joseph Ritson, whose severe accuracy was connected with an unhappy eagerness and irritability of temper, took advantage of the exaggerations occasionally to be found in the Bishop's *Account of Ancient Minstrelsy*, and assailed him with terms which may be termed any thing but courteous. Without finding an excuse either in the novelty of the studies in which Percy had led the way, or in the vivacity of imagination which he did not himself share, he proceeded to arraign each trivial inaccuracy as a gross fraud, and every deduction which he considered to be erroneous as a wilful untruth, fit to be stigmatized with the broadest appellation by which falsehood can be distinguished. Yet there is so little room for this extreme loss of temper, that, upon a recent perusal of both these ingenious essays, we were surprised to find that the reverend Editor of the *Reliques*, and accurate Antiquary, have differed so very little as, in essential facts, they appear to have done. Quotations are, indeed, made by both with no sparing hand, and hot arguments; and, on one side

Romance. at least, hard words are unsparingly employed; while, as is said to happen in theological polemics, the contest grows warmer in proportion as the ground concerning which it is carried on is narrower and more insignificant. In reality, their systems do not essentially differ.

Ritson is chiefly offended at the sweeping conclusion in which Percy states the minstrels as subsisting by the arts of poetry and music, and reciting to the harp verses composed by themselves and others. He shows very successfully that this definition is considerably too extensive, and that the term minstrel comprehended, of old, not merely those who recited to the harp or other instrument romances and ballads, but others who were distinguished by their skill in instrumental music only; and, moreover, that jugglers, sleight-of-hand performers, dancers, tumblers, and such like subordinate artists who were introduced to help away the tedious hours in an ancient feudal castle, were also comprehended under the general term of minstrel. But although he distinctly proves that Percy's definition applied only to one class of the persons termed minstrels, those namely who sung or recited verses, and in many cases of their own composition; the bishop's position remains unassailable, in so far as relates to one general class, and these the most distinguished during the middle ages. All minstrels did not use the harp, and recite or compose romantic poetry; but it cannot be denied that such was the occupation of the most eminent of the order. This Ritson has rather admitted than denied; and the number of quotations which his industry has brought together, rendered such an admission inevitable.

Indeed, the slightest acquaintance with ancient romances of the metrical class, shows us that they were composed for the express purpose of being recited, or, more properly, chaunted to some simple tune or cadence for the amusement of a large audience. Our ancestors, as they were circumscribed in knowledge, were also more limited in conversation than their enlightened descendants; and it seems probable, that, in their public festivals, there was great advantage found in the presence of a minstrel who should recite some popular composition on their favourite subjects of love and war, to prevent those pauses of conversation which sometimes fall heavily on a company, even of the present accomplished age, and to supply an agreeable train of ideas to those guests who had none of their own. It is, therefore, almost constantly insinuated, that the romance was to be chaunted or recited to a large and festive society, and in some part or other of the piece, generally at the opening, there is a request of attention on the part of the performer; and hence, the perpetual “Lythe and listen lordings free,” which in those, or equivalent words, forms the introduction to so many romances. As, for example, in the old poem of *Guy and Colbrand*, the minstrel speaks of his own occupation:

\* *Essay on Ancient Minstrels in England*, prefixed to the first volume of Bishop Percy's *Reliques*.

Romance.

"When meat and drink is great plentye,  
Then lords and ladyes still will be,  
And sit and solace lythe.  
Then it is time for mee to speake,  
Of kern knights and kempes greate,  
Such carping for to kythe."

Chaucer, also, in his Ryme of Sir Thopas, assigns to the minstrels of his hero's household the same duty of reciting romances of spiritual or secular heroes, for the good knight's pastime while arming himself for battle:

"Do cum," he sayed, "my minestrales,  
And jestours for to tellen tales  
Anon in min arming,  
Of romaunces that ben reales,  
Of popes and of cardinales,  
And eke of love-longing."

Not to multiply quotations, we will only add one of some importance, which must have escaped Ritson's researches; for his editorial integrity was such, as rendered him incapable of suppressing evidence on either side of the question. In the old romance or legend of *Truc Thomas and the Queen of Elfland*, Thomas the Rhymer, himself a minstrel, is gifted by the Queen of the Faery with the faculties of music and song. The answer of Thomas is not only conclusive as to the minstrel's custom of recitation, but shows that it was esteemed the highest branch of his profession, and superior as such to mere instrumental music:

"To harp and carp Thomas wheresover ye gon,  
Thomas take the these with the" —  
"Harping," he said, "ken I non,  
For tong is chefe of Mynstralse."\*

We, therefore, arrive at the legitimate conclusion, that although, under the general term minstrels, were comprehended many who probably entertained the public only with instrumental performances, with ribald tales, with jugglery, or farcical representations, yet one class amongst them, and that a numerous one, made poetical recitation their chief, if not their exclusive occupation. The memory of these men were, in the general case, the depository of the pieces which they recited; and hence, although many of their romances still survive, very many more have doubtless fallen into oblivion.

That the minstrels were also the authors of many of these poems, and that they altered and enlarged others, is a matter which can scarce be doubted, when it is proved that they were the ordinary reciters of them. It was as natural for a minstrel to become a poet or composer of romances, as for a player to be a dramatic author, or a musician a

composer of music. Whosoever, among a class, whose trade it was to recite poetry, felt the least degree of taste or enthusiasm in a profession so peculiarly calculated to inspire it, must, from that very impulse, have become an original author, or translator at least; thus giving novelty to his recitations, and acquiring additional profit and fame. Bishop Percy, therefore, states the case fairly in the following passage: "It can hardly be expected that we should be able to produce regular and unbroken annals of the minstrel art and its professors, or have sufficient information, whether every minstrel or bard composed himself, or only repeated, the songs he chaunted. Some probably did the one and some the other; and it would have been wonderful, indeed, if men, whose peculiar profession it was, and who devoted their time and talents to entertain their hearers with poetical compositions, were peculiarly deprived of all poetical genius themselves, and had been under a physical incapacity of composing those common popular rhymes, which were the usual subjects of their recitation."† While, however, we acquiesce in the proposition, that the minstrels composed many, perhaps the greater part of the metrical romances which they sung, it is evident they were frequently assisted in the task by others who, though not belonging to this profession, were prompted by leisure and inclination to enter upon the literary or poetical department as amateurs. These very often belonged to the clerical profession, amongst whom relaxation of discipline, abundance of spare time, and impatience of the routine of ceremonious duties often led individuals into worse occupations than the listening to or composing metrical romances. It was in vain that both the poems and the minstrels who recited them were, by statute, debarred from entering the more rigid monasteries. Both found their way frequently to the refectory, and were made more welcome than brethren of their own profession; as we may learn from a memorable *Gest*, in which two poor travelling priests, who had been received into a monastery with acclamation, under the mistaken idea of their being minstrels, are turned out in disgrace, when it is discovered that they were indeed capable of furnishing spiritual instruction, but understood none of the entertaining arts with which the hospitality of their convent might have been repaid by itinerant bards.

Nay, besides a truant disposition to a forbidden task, many of the grave authors may have alleged, in their own defence, that the connection between history and romance was not in their day entirely dissolved. Some eminent men exercised themselves in both kinds of composition; as, for example,

\* Jamieson's *Popular Ballads*, Vol. II. p. 27.

† *Essay on the Ancient Minstrels*, p. 30.

Another authority of ancient date, the *Chronicle* of Bertrand Guesclin, distinctly attributes the most renowned romances to the composition of the minstrels by whom they were sung. As the passage will be afterwards more fully quoted, we must here only say, that after enumerating Arthur, Lancelot, Godfrey, Roland, and other champions, he sums up his account of them as being the heroes

"De quoi cils minestriers font les nobles romans."

Romance. Maitre Wace, a canon of Caen, in Normandy, who, besides the metrical chronicle of *Le Brut*, containing the earliest history of England, and other historical legends, wrote, in 1155, the *Roman de Chevalier de Lyon*, probably the same translated under the title of *Ywain and Gawain*. Lambert li Cors, and Benoit de Saint-Maur, seem both to have been of the clerical order; and, perhaps, Chretien de Troyes, a most voluminous author of romance, was of the same profession. Indeed, the extreme length of many romances being much greater than any minstrel could undertake to sing at one or even many sittings, may induce us to refer them to men of a more sedentary occupation than those wandering poets. The religious romances were, in all probability, the works of such churchmen as might wish to reconcile an agreeable occupation with their religious profession. All which circumstances must be received as exceptions from the general proposition, that the romances in metre were the composition of the minstrels by whom they were recited or sung, though they must still leave Percy's proposition to a certain extent unimpeached.

Romance. Boromhe, a harper and a musician,—and without resorting to the questionable authenticity of Ossian, several instances of the same kind might be produced in the Highlands.

But, in process of time, when the classes of society come to assume their usual gradation with respect to each other, the rank of professional poets is uniformly found to sink gradually in the scale, along with that of all others whose trade it is to contribute to the amusement of society. The mere professional poet, like the player or the musician, becomes the companion and soother only of idle and convivial hours; his presence would be unbecoming on occasions of gravity and importance; and his art is accounted at best an amusing but useless luxury. Although the intellectual pleasure derived from poetry or from the exhibition of the drama be of a different and much higher class than that derived from the accordance of sounds, or from the exhibition of feats of dexterity; still it will be found that the opinions and often the laws of society, while individuals of these classes are cherished and held in the highest estimation, has degraded the professions themselves among the idle, dissolute, and useless appendages of society. Although it may be accounted ungrateful in mankind thus to reward the instruments of their highest enjoyments, yet some justification is usually to be drawn from the manners of the classes who were thus lowered in public opinion. It must be remembered, that, as professors of this joyous science, as it was called, the minstrels stood in direct opposition to the more severe part of the Catholics, and to the monks in particular, whose vows bound them to practise virtues of the ascetic order, and to look upon every thing as profane which was connected with mere worldly pleasure. The manners of the minstrels themselves gave but too much room for clerical censure. They were the usual assistants at scenes, not merely of conviviality, but of licence; and as the companions and encouragers of revelling and excess, they became contemptible in the eyes, not only of the aged and the serious, but of the libertine himself, when his debauch palled on his recollection. The minstrels, no doubt, like their brethren of the stage, sought an apology in the corrupted taste and manners of their audience, with which they were obliged to comply, under the true but melancholy condition that

—they who live to please must please to live.

But this very necessity, rendered more degrading by their increasing numbers and decreasing reputation, only accelerated the total downfall of their order, and the general discredit and neglect into which they had fallen. The statute of the 39th Queen Elizabeth, passed at the close of the sixteenth century, ranks those dishonoured sons of song among rogues and vagabonds, and appoints them to be punished as such; and the occupation, though a vestige of it was long retained in the habits of travelling ballad-singers and musicians, sunk into total neglect and contempt. Of this we shall have to speak hereafter; our business being at present with those ro-

Condition of the Minstrels. To explain the history of Romance, it is necessary to digress a little further concerning the condition of the minstrels by whom these compositions were often made, and, generally speaking, preserved and recited. And here, it must be confessed, the venerable Prelate has, perhaps, suffered his love of antiquity, and his desire to ennoble the productions of the middle ages a little to overcolour the importance and respectability of the minstrel tribe; although his opponent Ritson has, on the other hand, seized on all circumstances and inferences which could be adduced to prove the degradation of the minstrel character, without attending to the particulars by which these depreciating circumstances were qualified. In fact, neither of these excellent antiquarians has cast a general or philosophical glance on the necessary condition of a set of men who were by profession the instruments of the pleasure of others during a period of society such as was presented in the middle ages.

In a very early period of society, ere the division of ranks had been generally adopted, and while each tribe may be yet considered as one great family, and the nation as an union of such independent tribes, the poetical art, so nearly allied to that of oratory or persuasion, is found to ascertain to its professors a very high rank. Poets are the historians and often the priests of the tribe. Their command of language, then in its infancy, excites not merely pleasure but enthusiasm and admiration. When separated into a distinct class, as was the case with the Celtic Bards, and, perhaps, with the Skalds of Scandinavia, they rank high in the scale of society, and we not only find Kings and Nobles listening to them with admiration, but emulous of their art, and desirous to be enrolled among their numbers. Several of the most renowned northern Kings and Champions valued themselves as much upon their powers of poetry as on their martial exploits; and of the Welsh Princes, the Irish Kings, and the Highland Chiefs of Scotland very many practised the arts of poetry and music. Llward Hen was a Prince of the Cymraig,—Brian,

Romance.

mances, which, while still in the zenith of their reputation, were the means by which the minstrels, at least the better and higher class among them, recommended themselves to the favour of their noble patrons, and of the audiences whom they addressed.

It may be presumed, that, although the class of minstrels, like all who merely depend upon gratifying the public, carried in their very occupation the evils which first infected, and finally altogether depraved their reputation; yet, in the earlier ages, their duties were more honourably estimated, and some attempts were made to introduce into their motley body the character of a regular establishment, subjected to discipline and subordination. Several individuals, both of France and England, bore the title of King of Minstrels, and were invested probably with some authority over the others. The Serjeant of Minstrels is also mentioned; and Edward IV. seems to have attempted to form a Guild or exclusive Corporation of Minstrels. John of Gaunt, at an earlier period, established (between jest and earnest, perhaps) a Court Baron of Minstrels, to be held at Tilbury. There is no reason, however, to suppose that the influence of their establishments went far in restraining the licence of a body of artists so unruly as well as numerous.

It is not, indeed, surprising that individuals, whose talents in the arts of music or of the stage rise to the highest order, should, in a special degree, attain the regard and affection of the powerful, acquire wealth, and rise to consideration; for, in such professions, very high prizes are assigned to pre-eminent excellence; while ordinary or inferior practisers of the same art may be said to draw in the lottery something more than a mere blank. Garrick, in his chariot, and whose company was courted for his wit and talent, was, after all, by profession, the same with the unfortunate Stroller, whom the British laws condemn as a vagabond, and to whose dead body other countries refuse even the last rites of Christianity. In the same manner it is easy to suppose that, when in compliance with the taste of their age, monarchs entertained their domestic minstrels,\* those persons might be admitted to the most flattering intimacy with their royal masters; sleep within the royal

chamber, † amass considerable fortunes, found hospitals, ‡ and receive rewards singularly over-proportioned to the perquisites of the graver professions; § and even practise in company with their royal masters the pleasing arts of poetry and music, which all are so desirous of attaining; || whilst, at the same time, those who ranked lower in the same profession were struggling with difficulty to gain a precarious subsistence, and incurring all the disgrace usually attached to a vagabond life and a dubious character. In the fine arts, particularly, excellence is demanded, and mere mediocrity is held contemptible; and, while the favour with which the former is loaded, sometimes seems disproportioned to the utility of the art itself, nothing can exceed the scorn poured out on those who expose themselves by undertaking arts which they are unable to practise with success. Self-conceit, however, love of an idle life, and a variety of combined motives, never fail to recruit the lower orders of such idle professions with individuals by whose performances, and often by their private characters, the art which they have rashly adopted can only be discredited without any corresponding advantage to themselves. It is not, therefore, surprising that, while such distinguished examples of the contrary appeared amongst individuals, the whole body of minstrels, with the romances which they composed and sung, should be reprobated by graver historians in such severe terms as often occur in the monkish chronicles of the day.

Respecting the style of their composition, Du Cange inform us, that the minstrels sometimes devoted their strains to flatter the great, and sing the praises of those Princes by whom they were protected; while he owns, at the same time, that they often recommended to their hearers the path of virtue and nobleness, and pointed out the pursuits by which the heroes of romance had rendered themselves renowned in song. ¶ He quotes from the romance of *Bertrand Guesclin*, the injunction on those who would rise to fame in arms to copy the valiant acts of the Paladins of Charles, and the Knights of the Round Table, narrated in romances; and it cannot be denied, that those high tales, in which the vir-

Romance.

Character and Style of the Romances of Chivalry.

\* Berdic (*Regis Jocolator*), the jogleur or minstrel of William the Conqueror, had, as appears from the Domesday record, three vills and five caracates of land in Gloucestershire without rent. Henry I. had a minstrel called Galfrid who received an annuity from the abbey of Hide.

† A minstrel of Edward I., during that prince's expedition to the Holy Land, slept within his tent, and came to his assistance when an attempt was made to assassinate him.

‡ The Priory and Hospital of Saint Bartholomew, in London, was founded in the reign of Henry I. by Royer or Raber, a minstrel of that prince.

§ In 1441, the monks of Maxlock, near Coventry, paid a donation of four shillings to the minstrels of Lord Clinton for songs, harping, and other exhibitions, while, to a doctor who preached before the community in the same year, they assigned only sixpence.

|| The noted anecdote of Blondel and his royal master, Richard Cœur de Lion, will occur to every reader.

¶ *MINISTELLI dicti præsertim Scurræ, mimi, jocolatores, quos etiamnum vulgo Menestreux vel Menestriers, appellamus.*—Porro ejusmodi scurrarum erat Principes non suis duntaxat ludicris oblectare, sed et eorum aures variis avorum, adeoque ipsorum Principum laudibus, non sine assentatione, cum cantilenis et musicis instrumentis, demulcere.—Interdum etiam virorum insignium et heroum gesta, aut explicata et jucunda narratione commemorabant, aut suavi vocis inflectione, fidibusque decantabant, quo sic dominorum, cæterorumque qui his intererant ludicris, nobilium animos ad virtutem capessendam et summorum virorum

Romance. tues of generosity, bravery, devotion to his mistress, and zeal for the Catholic religion, were carried to the greatest height of romantic perfection in the character of the hero, united with the scenes passing around them, were of the highest importance in affecting the character of the age. The fabulous knights of romance were so completely identified with those of real history, that graver historians quote the actions of the former in illustration of, and as a corollary to, the real events which they narrate.\* The virtues recommended in romance were, however, only of that overstrained and extravagant cast which consisted with the spirit of chivalry. Great bodily strength, and perfection in all martial exercises, was the universal accomplishment inalienable from the character of the hero, and which each romancer had it in his power to confer. It was also easily in the composer's power to devise dangers, and to free his hero from them by the exertion of valour equally extravagant. But it was more difficult to frame a story which should illustrate the manners as well as the feats of chivalry; or to devise the means of evincing that devotion to duty, and that disinterested desire to sacrifice all to faith and honour;—that noble spirit of achievement which laboured for others more than itself—which form, perhaps, the fairest side of the system under which the noble youths of the middle ages were trained up. The sentiments of chivalry, as we have explained in our article on that subject, were founded on the most pure and honourable principles, but unfortunately carried into hyperbole and extravagance; until their religion approached to fanaticism, their valour to frenzy, their ideas of honour to absurdity, their spirit of enterprise to extravagance, and their respect for the female sex to a sort of idolatry. All those extravagant feelings, which really existed in the society of the middle ages, were magnified and exaggerated by the writers and reciters of romance; and these given as resemblances of actual manners became, in their turn, the glass by which the youth of the age dressed themselves; while the spirit of chivalry and of romance thus gradually threw light upon and enhanced each other.

The romances, therefore, exhibited the same system of manners which existed in the nobles of the age. The character of a true son of chivalry was

Romance. raised to such a pitch of ideal and impossible perfection, that those who emulated such renown were usually contented to stop far short of the mark. The most adventurous and unshaken valour, a mind capable of the highest flights of romantic generosity, a heart which was devoted to the will of some fair idol, on whom his deeds were to reflect glory, and whose love was to reward all his toils,—these were attributes which all aspired to exhibit who sought to rank high in the annals of chivalry; and such were the virtues which the minstrels celebrated. But, like the temper of a tamed lion, the fierce and dissolute temper of the age often showed itself through the fair varnish of this artificial system of manners. The valour of the hero was often stained by acts of cruelty, or freaks of rash desperation; his courtesy and munificence became solemn foppery and wild profusion; his love to his lady often demanded and received a requital inconsistent with the honour of the object; and those who affected to found their attachment on the purest and most delicate metaphysical principles, carried on their actual intercourse with a licence altogether inconsistent with their sublime pretensions. Such were the real manners of the middle ages, and we find them so depicted in these ancient legends.

So high was the national excitation in consequence of the romantic atmosphere in which they seemed to breathe, that the knights and squires of the fourteenth and fifteenth centuries imitated the wildest and most extravagant enterprises of the heroes of romance; and, like them, took on themselves the most extraordinary adventures to show their own gallantry, and do most honour to the ladies of their hearts. The females of rank, erected into a species of goddesses in public, and often degraded as much below their proper dignity in more private intercourse, equalled in their extravagances the youth of the other sex. A singular picture is given by Knyghton of the damsels errant who attended upon the solemn festivals of chivalry, in quest, it may reasonably be supposed, of such adventures as are very likely to be met with by such females as think proper to seek them. "These tournaments are attended by many ladies of the first rank and greatest beauty, but not always of the most untainted reputation. These ladies are dressed in party-coloured tunics,

\* Barbour, the Scottish historian, censures a Highland chief, when, in commending the prowess of Bruce in battle, he likened him to the Celtic hero, Fin Mac Coul, and says, he might in more mannerly fashion have compared him to Gaudifer, a champion celebrated in the romance of Alexander.

Romance.

one-half of one colour, and the other half of another; their lirrripes, or tippets, are very short; their caps remarkably little, and wrapt about their heads with cords; their girdles and pouches are ornamented with gold and silver; and they wear short swords, called *daggers*, before them, a little below their navels; they are mounted on the finest horses, with the richest furniture. Thus equipped, they ride from place to place in quest of tournaments, by which they dissipate their fortunes, and sometimes ruin their reputation."—(Knyghton, quoted in Henry's *History*, Vol. VIII. p. 402.)

The minstrels, or those who aided them in the composition of the romances, which it was their profession to recite, roused to rivalry by the unceasing demand for their compositions, endeavoured emulously to render them more attractive by subjects of new and varied interest, or by marvellous incidents which their predecessors were strangers to. Much labour has been bestowed, somewhat unprofitably, in endeavouring to ascertain the sources from which they drew the embellishments of their tales, when the hearers began to be tired of the unvaried recital of battle and tournament which had satisfied the simplicity of a former age. Percy has contended for the Northern *Sagas* as the unquestionable origin of the romance of the middle ages; Warton conceived that the *Oriental fables*, borrowed by those minstrels who visited Spain, or who in great numbers attended the crusades, gave the principal distinctive colouring to those remarkable compositions; and a later system, patronised by later authors, has derived them, in a great measure, from the fragments of classical superstition, which continued to be preserved after the fall of the Roman Empire. All those systems seem to be inaccurate, in so far as they have been adopted, exclusively of each other, and of the general proposition, That fables of a nature similar to the romances of chivalry, modified according to manners and state of society, must necessarily be invented in every part of the world, for the same reason that grass grows upon the surface of the soil in every climate and in every country. "In reality," says Mr Southey, who has treated this subject with his usual ability, "mythological and romantic tales are current among all savages of whom we have any full account; for man has his intellectual as well as his bodily appetites, and these things are the food of his imagination and faith. They are found wherever there is language and discourse of reason, in other words, wherever there is man. And in similar stages of civilization, or states of society, the fictions of different people will bear a corresponding resemblance, notwithstanding the difference of time and scene."\*

To this it may be added, that the usual appearances and productions of nature offer to the fancy, in every part of the world, the same means of diversifying fictitious narrative by the introduction of prodigies. If in any romance we encounter the description of an elephant, we may reasonably con-

clude that a phenomenon, unknown in Europe, must have been borrowed from the east; but whosoever has seen a serpent and a bird, may easily aggravate the terrors of the former by conferring on a fictitious monster the wings of the latter; and whoever has seen or heard of a wolf, or lion, and an eagle, may, by a similar exertion of invention, imagine a griffin or hippogriff. It is imputing great poverty to the human imagination, to suppose that the *speciosa miracula*, which are found to exist in different parts of the world, must necessarily be derived from some common source; and perhaps we should not err more grossly in supposing that the various kinds of boats, skiffs, and rafts, upon which men have dared the ocean on so many various shores, have been all originally derived from the vessel of the Argonauts.

On the other hand, there are various romantic incidents and inventions of a nature so peculiar, that we may boldly, and at once, refer them to some particular and special origin. The tale of *Flora and Blanche fleur*, for example, could only be invented in the east, where the scene is laid, and the manners of which are observed with some accuracy. That of *Orfeo and Herodius*, on the contrary, is the classical history of Orpheus and Euridice, with the Gothic machinery of the Elves or Fairies, substituted for the infernal regions. But notwithstanding these and many other instances in which the subjects or leading incidents of romance can be distinctly traced to British or Armorican traditions, to the tales and history of Classic Antiquity, to the wild fables and rich imagery of Arabia, or to those darker and sterner themes which were first treated of by the Skalds of the north, it would be assuming greatly too much upon such grounds, to ascribe the derivation of romantic fiction, exclusively to any one of these sources. In fact, the foundation of these fables lies deep in human nature, and the superstructures have been imitated from various authorities by those who, living by the pleasure which their lays of chivalry afforded to their audience, were especially anxious to recommend them by novelty of every kind; and were undoubtedly highly gratified when the report of travellers, or pilgrims, or perhaps their own intercourse with minstrels of other nations, enabled them to vary their usual narrations with circumstances yet unheard in Bower and Hall. Romance, therefore, was like a compound metal, derived from various mines, in which one metal or other was alternately predominant; and viewed in this light, the ingenious labours of those learned antiquaries, who have endeavoured to seek the origin of this style of fiction in one of these sources alone, to the exclusion of all others, seem as vain as that of travellers affecting to trace the proper head of the Nile to various different springs, all of which are allowed to be accessory to form the full majesty of his current.

As the fashion of all things pass away, the metrical romances began gradually to decline in public estimation, probably on account of the depreciated charac-

\* Preface to Southey's edition of the *Morte D'Arthur*, Vol. II. Lond. 1817.

Romance. ter of the minstrels by whom they were recited. Tradition, says Ritson, is an alchemy, which converts gold into lead; and there is little doubt, that, in passing from mouth to mouth, and from age to age, the most approved metrical romances became gradually corrupted by the defect of memory of some reciters and the interpolations of others; since few comparatively can be supposed to have had recourse to the manuscripts in which some have been preserved. Neither were the reciters in the latter, as in the former times, supplied with new compositions of interest and merit. The composition of the metrical romance was gradually abandoned to persons of an inferior class. The art of stringing together in loose verse a number of unconnected adventures, was too easy not to be practised by many who only succeeded to such a degree as was discreditable to the art, by showing that mere mediocrity was sufficient to practise it. And the licentious character, as well as the great number of those who, under the various names of glee-men, minstrels, and the like, traversed the country, and subsisted by this idle trade, brought themselves and their occupation into still greater contempt and disregard. With them, the long recitations formerly made at the tables of the great, were gradually banished into more vulgar society.

But though the form of those narratives underwent a change of fashion, the appetite for the fictions themselves continued as ardent as ever; and the Prose Romances which succeeded, and finally superseded those composed in verse, had a large and permanent share of popularity. This was, no doubt, in a great degree owing to the important invention of printing, which has so much contributed to alter the destinies of the world. The metrical romances, though in some instances sent to the press, were not very fit to be published in this form. The dull amplifications which passed well enough in the course of a half-heard recitation, became intolerable when subjected to the eye; and the public taste gradually growing more fastidious as the language became more copious, and the system of manners more complicated, graces of style and variety of sentiment were demanded instead of a naked and unadorned tale of wonders. The authors of the prose romance endeavoured, to the best of their skill, to satisfy this newly awakened and more refined taste. They used, indeed, the same sources of romantic history which had been resorted to by their metrical predecessors; and Arthur, Charlemagne, and all their chivalry, were as much celebrated in prose as ever they had been in poetic narrative. But the new candidates for public favour pretended to have recourse to sources of authentic information, to which their metrical predecessors had no access. They refer almost always to Latin and sometimes to Greek originals, which certainly had no existence; and there is little doubt that the venerable names of the alleged authors are invented, as well as the supposed originals from which they are said to have translated their narratives. The following account of the discovery of *La tres elegante delieieux mellifue et tres plaisante hystoire du tres Noble Roy Perceforest* (printed at Paris in 1528 by Galliot du Pré), may serve to show that modern authors were not the first who invented the popular mode of introducing their works to

Romance. the world as the contents of a newly discovered manuscript. In the abridgment to which we are limited, we can give but a faint picture of the minuteness with which the author announces his pretended discovery, and which forms an admirable example of the lie with a circumstance. In the year 1286, Count William of Hainault had, it is averred, crossed the seas in order to be present at the nuptials of Edward, and in the course of a tour through Britain, was hospitably entertained at an abbey situated on the banks of the Humber, and termed, it seems, Burtimer, because founded by a certain Burtimericus; a monarch of whom our annals are silent, but who had gained, in that place, a victory over the heathens of Germany. Here a cabinet, which was inclosed in a private recess, had been lately discovered within the massive walls of an ancient tower, and was found to contain a Grecian manuscript, along with a royal crown. The abbot had sent the latter to King Edward, and the Count of Hainault with difficulty obtained possession of the manuscript. He had it rendered from Greek into Latin by a monk of the abbey of Saint Landelain, and from that language it is said to have been translated into French by the author, who gives it to the world in honour of the Blessed Virgin, and for the edification of nobleness and chivalry.

By such details, the authors of the prose romances endeavoured to obtain for their works a credit for authenticity which had been denied to the rythmical legends. But in this particular they did great injustice to their contemned predecessors, whose reputations they murdered in order to rob them with impunity. Whatever fragments or shadowings of true history may yet remain hidden under the mass of accumulated fable, which had been heaped on them during successive ages, must undoubtedly be sought in the metrical romances; and according to the view of the subject which we have already given, the more the works approach in point of antiquity to the period where the story is laid, the more are we likely to find those historical traditions in something approaching to an authentic state. But those who wrote under the imaginary names of Rusticien de Puise, Robert de Borron, and the like, usually seized upon the subject of some old minstrel; and, recomposing the whole narrative after their own fashion, with additional characters and adventures, totally obliterated in that operation any shades which remained of the original, and probably authentic tradition, which was the original source of the elaborate fiction. Amplification was especially employed by the prose romancers, who, having once got hold of a subject, seem never to have parted with it until their power of invention was completely exhausted. The metrical romances, in some instances, indeed, ran to great length, but were much exceeded in that particular by the folios which were written on the same or similar topics by their prose successors. Probably the latter judiciously reflected that a book which addresses itself only to the eyes, may be laid aside when it becomes tiresome to the reader; whereas it may not always have been so easy to stop the minstrel in the full career of his metrical declamation.

Who, then, the reader may be disposed to inquire,

Romance.

can have been the real authors of those prolix works, who, shrouding themselves under borrowed names, derived no renown from their labours, if successful, and who, certainly, in the infant state of the press, were not rewarded with any emolument? This question cannot, perhaps, be very satisfactorily answered; but we may reasonably suspect that the long hours of leisure which the cloister permitted to its votaries, were often passed away in this manner; and the conjecture is rendered more probable, when it is observed that matters are introduced into those works which have an especial connection with sacred history, and with the traditions of the church. Thus, in the curious romance of *Huon de Bourdeau*, a sort of second part is added to that delightful history, in which the hero visits the terrestrial paradise, encounters the first murderer Cain, in the performance of his penance, with more matter to the same purpose, not likely to occur to the imagination of a layman; besides, that the laity of the period were, in general, too busy and too ignorant to engage in literary tasks of any kind. The mystical portion of the romance of the *Round Table* seems derived from the same source. It may also be mentioned, that the audacious and sometimes blasphemous assertions, which claimed for these fictions the credit due even to the inspired writings themselves, were likely to originate amongst Roman Catholic churchmen, who were but too familiar with such forgeries for the purpose of authenticating the legends of their superstition. One almost incredible instance of this impious species of imposture occurs in the history of the *Saint Graal*, which curious mixture of mysticism and chivalry is ascribed by the uncaring and unblushing writer to the Second Person of the Trinity.

Churchmen, however, were by no means the only authors of these legends, although the *Sires Clercs*, as they were sometimes termed, who were accounted the chronicles of the times in which they lived, were usually in orders; and although it appears that it was upon them that the commands of the sovereigns whom they served often imposed the task of producing new romances under the usual disguise of ancient chronicles translated from the learned languages, or otherwise collected from the ruins of antiquity. As education became improved, and knowledge began to be more generally diffused, individuals among the laity, and those of no mean rank, began to feel the necessity, as it may be called, of putting into a permanent form the "thick-coming fancies" which gleam amongst the imagination of men of genius. Sir Thomas Malony, who compiled the *Morte D'Arthur* from French originals, was a person of honour and worship; and Lord Berners, the excellent translator of Froissart, and author of a romance called *The Chevalier de la Cygne*, is an illustrious example that a nobleman of high estimation did not think his time misemployed on this species of composition. Some literary fame must therefore have attended these efforts; and perhaps less eminent authors might, in the later ages, receive some pecuniary advantages. The translator of *Perceforest*, formerly mentioned, who appears to have been an Englishman or Fleming, in his address to the warlike

and invincibility of France, holds the language of a professional author, who expected some advantage besides that of pleasing those whom he addressed; and who expresses proportional gratitude for the favourable reception of his former feeble attempts to please them. It is possible, therefore, that the publishers, these lions of literature, had begun already to admit the authors into some share of their earnings. Other printers, like the venerable Caxton, compiled themselves, or translated from other languages, the romances which they sent to the press; thus uniting in their own persons the three separate departments of author, printer, and publisher.

The prose romance did not, in the general conduct of the story, where digressions are heaped on digressions, without the least respect to the principal narrative, greatly differ from that of their metrical predecessors, being, to the full, as tedious and unartificial; nay, more so in proportion as the new romances were longer than the old. In the transference from verse to prose, and the amplification which the scenes underwent in the process, many strong, forcible, and energetic touches of the original author have been weakened, or altogether lost; and the reader misses with regret some of the redeeming bursts of rude poetry which, in the metrical romance, makes amends for many hundred lines of bald and rude versification. But, on the other hand, the prose romances were written for a more advanced stage of society, and by authors whose language was much more copious, and who certainly belonged to a more educated class than the ancient minstrels. Men were no longer satisfied with hearing of hard battles and direful wounds; they demanded, at the hand of those who professed to entertain them, some insight into nature, or at least into manners; some description of external scenery, and a greater regard to probability both in respect of the characters which are introduced, and the events which are narrated. These new demands the prose romances endeavoured to supply to the best of their power. There was some attention shown to relieve their story, by the introduction of new characters, and to illustrate these personages by characteristic dialogue. The lovers conversed with each other in the terms of metaphysical gallantry, which were used in real life; and from being a mere rhapsody of warlike feats, the romance began to assume the nobler and more artificial form of a picture of manners. It is in the prose folios of *Lancelot du Lac*, *Perceforest*, and others, that antiquarians find recorded the most exact accounts of fights, tournaments, feasts, and other magnificent displays of chivalric splendour; and as they descend into more minute description than the historians of the time thought worthy of their pains, they are a mine from which the painful student may extract much valuable information. This, however, is not the full extent of their merit. These ancient books, amid many pages of dull repetition and uninteresting dialect, and notwithstanding the languor of an inartificial, protracted, and confused story, exhibit from time to time passages of deep interest, and situations of much novelty, as well as specimens of spirited and masculine writing. The general reader, who dreads the labour of winnowing out these

Romance.

Romance. valuable passages from the sterile chaff through which they are scattered, will receive an excellent idea of the beauties and defects of the romance from Tressan's *Corps d'Extraits de Romans de Chevalrie*, from Mr Ellis's *Specimens of Early English Romances*, and Mr Dunlop's *History of Fiction*.

These works continued to furnish the amusement of the most polished courts in Europe so long as the manners and habits of chivalry continued to animate them. Even the sagacious Catherine of Medicis considered the romance of *Perceforest* as the work best qualified to form the manners and amuse the leisure of a young prince; since she impressed on Charles IX. the necessity of studying it with attention. But by degrees the progress of new opinions in religion, the promulgation of a stricter code of morality, together with the important and animating discussions which began to be carried on by means of the press, diverted the public attention from these antiquated legends. The Protestants of England, and the Huguenots of France, were rigorous in their censure of books of chivalry, in proportion as they had been patronized formerly under the Catholic system; perhaps because they helped to arrest men's thoughts from more serious subjects of occupation. The learned Ascham thus inveighs against the romance of *Morte D'Arthur*, and at the same time acquaints us with its having passed out of fashion: "In our forefathers' tyme, when papistrie, as a standyng poole, covered and overflowed all *Englande*, fewe bookes were read in our tongue, sayvng certaine bookes of chevalrie, as they said for pastime and pleasure; which, as some say, were made in monasteries by idle monks, or wanton chanons. As for example, *La Morte D'Arthur*, the whole pleasure of which booke standeth in two speciall poyntes, in open manslaughter, and bold bawdrye: in which booke they counted the noblest knightes that do kill most men without any quarrell, and commit fowlest adulteries by sutlest shiftes; as Sir *Launcelote*, with the wife of King *Arthur* his master; Sir *Tristram*, with the wife of King *Marke* his uncle; Sir *Lamerocke*, with the wife of King *Lote*, that was his own aunt. This is good stuffe for wise men to laughe at, or honest men to take pleasure at: yet I know, when God's Bible was banished the court, and *La Morte D'Arthur* received into the prince's chamber."\*

The brave and religious La Noue is not more favourable to the perusal of romances than the learned Ascham; attributing to the public taste for these compositions the decay of morality among the French nobility. "The ancient fables whose reliques doe yet remaine, namely, *Lancelot of the Lake*, *Pierceforest*, *Tristram*, *Giron the Courteous*, and such others, doe beare witness of this olde vanitie; herewith were men fed for the space of 500 yeeres, untill our language growing more polished, and our mindes more ticklish, they were driven to invent some nouelties wherewith to delight us. Thus came y<sup>c</sup> bookes of *Amadis* into

Romance. light among us in this last age. But to say y<sup>c</sup> truth, *Spaine* bred thē, and *France* new clothed thē in gay garments. In y<sup>c</sup> daies of *Henrie the Second* did they beare chiefest sway, and I think if any man would then have reproved thē, he should have bene spit at, because they were of themselves playfellows and maintainers to a great sort of persons; whereof some, after they had learned to amize in speech, their teeth watered, so desirous were they even to taste of some small morsels of the delicacies therein most livelie and naturally represented."† The gallant Marechal proceeds at considerable length to refute the arguments of those who contended that these books were intended as a spur to the practice of arms and honourable exercises amongst youth, and labours hard to show that they teach dishonest practices both in love and in arms. It is impossible to suppress a smile when we find such an author as La Noue denouncing the introduction of spells, witchcrafts, and enchantments into these volumes, not because such themes are absurd and nonsensical, but because the representing such beneficent enchanters as Alquife and Urganda is, in fact, a vindication of those who traffic with the powers of darkness; and that those who love to read about sorceries and enchantments become, by degrees, familiarized with those devilish mysteries, and may at length be induced to have recourse to them in good earnest.

The romances of chivalry did not, however, sink into disrepute under the stern rebuke of religious puritans or severe moralists, but became gradually neglected as the customs of chivalry itself fell into disregard; when, of course, the books which breathed its spirit, and were written under its influence, ceased to produce any impression on the public mind, and, superseded by better models of composition, and overwhelmed with the ridicule of Cervantes, sunk by degrees into utter contempt and oblivion.

Other works of amusement, of the same general class, succeeded the proper romance of chivalry. Of these we shall take some notice hereafter; since we must here close our general view of the history of romance, and proceed briefly to give some account of those peculiar to the various European nations.

II. We can here but briefly touch upon a subject of great interest and curiosity, the peculiar character and tone, namely, which the romance of chivalry received from the manners and early history of the nations among whom it is found to exist; and the corresponding question, in what degree each appears to have borrowed from other countries the themes of their own minstrels, or to have made use of materials common to the whole.

Scandinavia, as was to be expected, may be safely considered as the richest country in Europe in ancient tales corresponding with the character of romance; sometimes composed entirely in poetry or rythm, sometimes in prose, and much more frequent-

\* Works of Roger Ascham, p. 254. 4to edition.

† *The Politicke and Militarie Discourses* of the Lord De La Nowe, pp. 87, 88. Quarto, Lond. 1587.

Romance.

ly in a mixture of prose, narrative, and lyrical effusions. Their well-known Skalds or bards held a high rank in their courts and councils. The character of a good poet was scarce second to that of a gallant leader, and many of the most celebrated champions ambitiously endeavoured to unite both in their own persons. Their earlier Sagas or tales approach to the credit of real history, and were unquestionably meant as such, though, as usual at an early period, debased by the intermixture of those *speciosa miracula* which the love of the wonderful early introduces into the annals of an infant country. There are, however, very many of the sagas, indeed by far the greater number of those now known to exist, which must be considered as falling rather under the class of fictitious than of real narratives; and which, therefore, belong to our present subject of inquiry. The *Omeyinger Saga*, the *Heimskringla*, the *Saga of Olaf Triggwason*, the *Eirbyggja Saga*, and several others, may be considered as historical; whilst the numerous narratives referring to the history of the Nibilungen and Volsungen are as imaginary as the romances which treat of King Arthur and of Charlemagne. These singular compositions, short, abrupt, and concise in expression, full of bold and even extravagant metaphor, exhibiting many passages of forceful and rapid description, hold a character of their own; and while they remind us of the indomitable courage and patient endurance of the hardy Scandinavians, at once the honour, and the terror of Europe, rise far above the tedious and creeping style which characterised the minstrel efforts of their successors, whether in France or England. In the pine forests also, and the frozen mountains of the north, there were nursed, amid the reliques of expiring paganism, many traditions of a character more wild and terrible than the fables of classical superstition; and these the gloomy imagination of the skalds failed not to transfer to their romantic tales. The late spirit of inquiry which has been so widely spread through Germany, has already begun to throw much light on this neglected storehouse of romantic lore, which is worthy of much more attention than has yet been bestowed upon it in Britain. It must, however, be remarked, that although the north possesses champions and romances of its own, unknown to southern song, yet, in a later age, the inhabitants of these countries borrowed from the French minstrels some of their most popular subjects; and hence we find sagas on the subject of Sir Tristrem, Sir Percival, Sir Ywain, and others, the well-known themes of French and English romance. These, however, must necessarily be considered later in date, as well as far inferior in interest, to the sagas of genuine northern birth. Mr Ritson has indeed quoted their existence as depreciating the pretensions of the northern nations to the possession of poems of high antiquity of their own native growth. Had he been acquainted with the *Norman-Kiempe-Datur*, a large folio, printed at Stockholm in 1737, he would have been satisfied, that out of the numerous collection of legends respecting the achievements of Gothic champions, far the greater part are of genuine Norse origin; and although having many features in common with the romances of southern

chivalry, are, in other marked particulars, distinctly divided from that class of fictitious composition. Romance.

The country of Germany, lying contiguous to France, and constantly engaged in friendly and hostile intercourse with that great seat of romantic fiction, became, of course, an early partaker in the stores which it afforded. The Minnesingers of the Holy Empire were a race no less cherished than the Troubadours of Provence, or the Minstrels of Normandy; and no less active in availing themselves of their indigenous traditions, or importing those of other countries, in order to add to their stock of romantic fiction. Godfred of Strasburgh composed many thousand lines upon the popular subject of Sir Tristram; and others have been equally copious, both as translators and as original authors, upon various subjects connected with French romance; but Germany possessed materials, partly borrowed from Scandinavia, partly peculiar to her own traditional history, as well as to that of the Roman empire, which they applied to the construction of a cycle of heroes as famous in Teutonic song as those of Arthur and of Charlemagne in France and Britain.

As in all other cases of the kind, a real conqueror, the fame of whose exploits survived in tradition, was adopted as the central object, around whom were to be assembled a set of champions, and with whose history was to be interwoven the various feats of courage which they performed, and the adventures which they underwent. Theodorick King of the Goths, called in these romantic legends Diderick of Bern (*i. e.* Verona), was selected for this purpose by the German Minnesingers. Amongst the principal personages introduced are Ezzel, King of the Huns, who is no other than the celebrated Attila; and Gunter, King of Burgundy, who is identified with a Guntachar of history who really held that kingdom. The good knight Wolfram de Eschenbach seems to have been the first who assembled the scattered traditions and minstrel tales concerning these sovereigns into one large volume of German verse, entitled *Helden-Buch*, or the Book of Heroes. In this the author has availed himself of the unlimited licence of a romancer; and has connected with the history of Diderick and his chivalry a number of detached legends which had certainly a separate and independent existence. Such is the tale of *Sigurd the Horny*, which has the appearance of having originally been a Norse Saga. An analysis of this singular piece was published by Mr Weber, in a work entitled *Illustrations of Northern Antiquities, from the earlier Teutonic and Scandinavian Romances*; and the subject has been fully illustrated by the publications of the learned Von der Hagen in Germany, and those of the Honourable William Herbert.

It is here only necessary to say, that Theodorick, like Charlemagne and Arthur, is considered in the romance as a monarch more celebrated for the valorous achievements of the brotherhood of chivalry whom he has drawn around him than for his own, though neither deficient in strength or courage. His principal followers have each their discriminatory and peculiar attributes. Meister Hildebrand, the Nestor of the band, is, like the Maugis of Charle-

Romance. magne's heroes, a magician as well as a champion. Hogan, or Hagan, begot betwixt a mortal and a sea-goblin, is the fierce Achilles of the confederation. It is the uniform custom of the romancers to conclude by a general and overwhelming catastrophe, which destroys the whole ring of chivalry whose feats they had commemorated. The ruin which Roncesvalles brought to the Paladins of Charlemagne, and the fatal battle of Camlan to the Knights of the Round Table, fell upon the warriors of Diderick through the revengeful treachery of Crimhilda, the wife of Ezzel; who, in revenge for the death of her first husband, and in her inordinate desire to possess the treasures of the Niflunga or Burgundians, brought destruction on all these celebrated champions. Mr Weber observes that these German fictions differ from the romances of French chivalry, in the greater ferocity and less refinement of sentiment ascribed to the heroes; and also in their employing to a great extent the machinery of the Duerger, or Dwarfs, a subterranean people to whom the *Helden-Buch* ascribes much strength and subtilty, as well as profound skill in the magic art; and who seem, to a certain extent, the predecessors of the European fairy.

Italy, so long the seat of classical learning, and where that learning was first revived, seems never to have strongly embraced the taste for the Gothic romance. They received, indeed, the forms and institutions of chivalry, but the Italians seem to have been in a considerable degree strangers to its spirit, nor to have become deeply enamoured of its literature. There is an old romance of chivalry proper to Italy, called *Guerino the Wretched*, but we doubt if even this be of indigenous growth. Indeed, when they did adopt from the French the fashionable tales of Charlemagne and his Paladins, they did not attract the attention of the classical Italians, until Boiardo, Berni, Pulci, and, above all, the divine Ariosto, condescended to use them as the basis of their well-known romantic poems; and thus the fictitious narratives originally composed in metre, and after rewritten in prose, were anew decorated with the honours of verse. The romantic poets of Italy did not even disdain to imitate the rambling, diffuse, and episodic style proper to the old romance; and Ariosto, in particular, although he torments the reader's attention by digressing from one adventure to another, delights us, upon frequent perusals, by the extreme ingenuity with which he gathers up the broken ends of his narrative, and finally weaves them all handsomely together in the same piece. But the merits and faults of romantic poetry form themselves the fruitful subject of a long essay. We here only notice the origin of those celebrated works, as a species of composition arising out of the old romance, though surpassing it in regularity, as well as in all the beauties of style and diction.

With Spain the idea of romance was particularly connected; and the associations which are formed upon perusing the immortal work of Cervantes, induce us for a long time to believe that the country of Don Quixote must be the very cradle of romantic fiction. Yet, if we speak of priority of date, Spain

Romance. was among the last nations in Europe with whom romance became popular. It was not indeed possible that, among a people speaking so noble and poetical a language, engaged in constant wars, which called forth at once their courage and their genius, there should not exist many historical and romantic ballads descriptive of their rencounters with the Moors. But their native poets seem to have been too much engaged with the events of their own age, or of that which had just preceded them, to permit of their seeking subjects in the regions of pure fiction; and we have not heard of a Spanish metrical romance, unless the poems describing the adventures of the Cid, should be supposed to have any affinity to that class of composition. The Peninsula, however, though late in adopting the prevailing taste for romantic fiction, gave origin to one particular class, which was at least as popular as any which had preceded it. *Amadis de Gaul*, the production, it would seem, of Vasco de Lobeira, a Portuguese knight, who lived in the fourteenth century, gave a new turn to the tales of chivalry; and threw into the shade the French prose romances, which, until the appearance of this distinguished work, had been the most popular in Europe.

The author of *Amadis*, in order, perhaps, to facilitate the other changes which he introduced, and to avoid rushing against preconceived ideas of events or character, laid aside the worn-out features of Arthur and Charlemagne, and imagined to himself a new dynasty both of sovereigns and of heroes, to whom he ascribed a style of manners much more refined, and sentiments much more artificial, than had occurred to the authors of *Perceval* or *Perceforest*. Lobeira had also taste enough to perceive, that some unity of design would be a great improvement on the old romance, where one adventure is strung to another with little connection from the beginning to the end of the volume; which thus concludes, not because the plot was winded up, but because the author's invention, or the printer's patience, was exhausted. In the work of the Portuguese author, on the contrary, he proposes a certain end, to advance or retard which all the incidents of the work have direct reference. This is the marriage of Amadis with Oriana, against which a thousand difficulties are raised by rivals, giants, sorcerers, and all the race of evil powers unfavourable to chivalry; whilst these obstacles are removed by the valour of the hero, and constancy of the heroine, succoured on their part by those friendly sages, and blameless sorceresses, whose intervention gave so much alarm to the tender-conscience De la Noue. Lobeira also displayed considerable attention to the pleasure which arises from the contrast of character; and to relieve that of Amadis, who is the very essence of cliivalrous constancy, he has introduced Don Galaor, his brother, a gay libertine in love, whose adventures form a contrast with those of his more serious brother. Above all, the *Amadis* displays an attention to the style and conversation of the piece, which, although its effects are now exaggerated and ridiculous, was doubtless at the time considered as the pitch of elegance; and here were, for the first time, introduced those hyper-

Italian Romance.

Spanish and Portuguese Romance.

Romance.

bolical compliments, and that inflated and complicated structure of language, the sense of which walks as in a masquerade.

The *Amadis* at first consisted only of four books, and in that limited shape may be considered as a very well conducted story; but additions were speedily made which extended the number to twenty-four; containing the history of Amadis subsequent to his obtaining possession of Oriana, and down to his death, as also of his numerous descendants. The theme was not yet exhausted; for, as the ancient romancers, when they commenced a new work, chose for their hero some newly invented Paladin of Charlemagne, or knight of King Arthur, so did their successors adopt a new descendant of the family of Amadis, whose genealogy was thus multiplied to a prodigious degree. For an account of *Esplandian*, *Florimond of Greece*, *Palmerin of England*, and the other romances of this class, the reader must be referred to the valuable labours of Mr Southey, who has abridged both *Amadis* and *Palmerin* with the most accurate attention to the style and manners of the original. The books of *Amadis* became so very popular, as to supersede the elder romances almost entirely, even at the court of France, where, according to La Noue, already quoted, they were introduced about the reign of Henry II. It was against the extravagance of these fictions in character, and in style, that the satire of Cervantes was chiefly directed; and almost all the library of Don Quixote belongs to this class of romances, which, no doubt, his adventures contributed much to put out of fashion.

French Romance.

In every point of view, France must be considered as the country in which chivalry and romance flourished in the highest perfection; and the originals of almost all the early romances, whether in prose or verse, whether relating to the history of Arthur or of Charlemagne, are to be found in the French language; and other countries possess only translations from thence. This will not be so surprising when it is recollected, that these earlier romances were written, not only for the use of the French, but of the English themselves, amongst whom French was the prevailing language during the reigns of the Anglo-Norman monarchs. Indeed, it has been ingeniously supposed, and not without much apparent probability, that the fame of Arthur was taken by the French minstrels for the foundation of their stories in honour of the English kings, who reigned over the supposed dominions of that British hero; while, on the other hand, the minstrels who repaired to the coast of France, celebrated the prowesses of Charlemagne and his twelve peers as a subject more gratifying to those who sat upon his throne. It is, perhaps, some objection to this ingenious history, that, as we have already seen, the battle of Hastings was opened by a minstrel, who sung the war-song of Roland, the nephew of Charlemagne; so that the Norman duke brought with him to England the tales that are supposed, at a much later date, to have been revived to soothe the national pride of the French minstrels.

How the French minstrels came by the traditional reliques concerning Arthur and Merlin, on which they wrought so long and so largely, must,

we fear, always remain uncertain. From the Saxons we may conclude they had them not; for the Saxons were the very enemies against whom Arthur employed his good sword excalibar, that is to say, if there was such a man, or such a weapon. We know, indeed, that the British, like all the branches of the Celtic race, were much attached to poetry and music, which the numerous reliques of ancient poetry in Wales, Ireland, and the Highlands of Scotland, sufficiently evince. Arthur, a name famous among them, with some traditions concerning the sage Merlin, may have floated either in Armorica, or among the half-British of the borders of Scotland, and of Cumberland; and thus preserved, may have reached the ear of the Norman minstrels, either in their newly conquered dominions, or through their neighbours of Brittany. A theme of this sort once discovered, and found acceptable to the popular ear, gave rise, of course, to a thousand imitations; and gradually drew around it a cloud of fiction which, embellished by such poetry as the minstrels could produce, arranged itself by degrees into a system of fabulous history, as the congregated vapours touched by the setting sun, assume the form of battlements and towers. We know that the history of Sir Tristram, first versified by Thomas the Rymer of Ercildoune, was derived from Welsh traditions, though told by a Saxon poet. In fact, it may be easily supposed, that the romancers of that early period were more eager to acquire popular subjects than delicately scrupulous of borrowing from their neighbours; and when the foundation-stone was once laid, each subsequent minstrel brought his contribution to the building. The idea of an association of knights assembled around one mighty sovereign, was so flattering to all the ruling princes of Europe, that almost all of them endeavoured to put themselves at the head of some similar institution. The historical foundation of this huge superstructure is almost imperceptible. Mr Turner has shown that the evidence rather inclines to prove the actual existence of King Arthur; and the names of Gawain, his nephew, and of Genuera, his faithful spouse, of Mordred, and Merlin, was preserved by Welsh tradition. To the same source may be referred the loves of Tristrem and Ysolde, which, although a separate story, has become, in the later romances, amalgamated with that of Arthur. But there can be little doubt that all beyond the bare names of the heroes owes its existence to the imagination of the romancers.

It might be thought that the romances referring to the feats of Charlemagne ought to contain more historical truth than those concerning Arthur; since the former relate to a well-known monarch and conqueror, the latter to a personage of a very doubtful and shadowy existence. But the romances concerning both are equally fabulous. Charles had, indeed, an officer named Roland, who was slain with other nobles in the field of Roncesvalles, fighting, not against the Saracens or Spaniards, but against the Gascons. This is the only point upon which the real history of Charlemagne coincides with that invented for him by romancers. Roland was Prefect of Bretagne, and his memory was long preserved in the war-song which bore his name. A fabulous chronicler, calling himself

Romance. Turpin, compiled, in or about the eleventh century, a romantic history of Charlemagne; but it may be doubted whether, in some instances, he has not availed himself of the fictions already devised by the early romancers, while to those who succeeded them his annals afforded matter for new figments. The personal character of Charlemagne has suffered considerably in the hands of the romantic authors, although they exaggerated his power and his victories. He is represented as fond of flattery, irritable in his temper, ungrateful for the services rendered him by his most worthy Paladins, and a perpetual dupe to the treacherous artifices of Count Gan, or Ganelon, of Mayence; a renegade to whom the romancers impute the defeat at Roncesvalles, and all the other misfortunes of the reign of Charles. This unfavourable view of the Prince, although it may bear some features of royalty, neither resembles the real character of the conqueror of the Saxons and Lombards, nor can be easily reconciled with the idea, that he was introduced to flatter the personal vanity of the princes of the Valois race, by a portrait of their great predecessor.

The circumstance, that Roland was a lieutenant of Brittany, and the certainty that Marie borrowed from that country the incidents out of which she composed her lays, seems to fortify the theory, that the French minstrels obtained from that country much of their most valuable materials; and that, after all that has been said and supposed, the history of Arthur probably reached them through the same channel.

The Latin writers of the middle ages afforded the French romancers the themes of these metrical legends which they have composed on subjects of classical fame.

The honour of the prose romances of chivalry, exclusive always of the books of Amadis, belongs entirely to the French, and the curious volumes which are now the object of so much research amongst collectors, are almost universally printed at Paris.

English Romance. England, so often conquered, yet fated to receive an accession of strength from each new subjugation, cannot boast much of ancient literature of any kind; and, in the department of which we treat, was totally inferior to France. The Saxons had, no doubt, romances (taking the word in its general acceptance); and Mr Turner, to whose researches we are so much indebted, has given us the abridgment of one entitled *Cædmon*, in which the hero, whose adventures are told much after the manner of the ancient Norse Sagas, encounters, defeats, and finally slays an evil being called Grendel, who, except in his being subject to death, seems a creature of a supernatural description. But the literature of the Saxons was destroyed by the success of William the Conqueror, and the Norman knights and barons, among whom England was in a great measure divided, sought amusement, not in the lays of the vanquished, but in those composed in their own language. In this point of view, England, as a country, may lay claim to many of the French romances, which were written, indeed, in that language, but for the benefit of the court and nobles of England, by whom French was still spoken. When the two lan-

Romance. guages began to assimilate together, and to form the mixed dialect termed the Anglo-Norman, we have good authority for saying that it was easily applied to the purpose of romantic fiction, and recited in the presence of the nobility.

Robert de la Brunne, who composed his *History of England* about this time, has this remarkable passage, which we give, along with the commentary of the Editor of *Sir Tristrem*, as it is peculiarly illustrative of the subject we are inquiring into.

Als thai haf wryten and sayd  
 Haf I alle in myn Inglis layd,  
 In symple speche as I couthe,  
 That is lightest in manne's mouthe.  
 I made nocht for no disours,  
 Ne for no seggours, no harpours,  
 Bot for the luf of symple men,  
 That strange Inglis cannot ken;  
 For many it ere that strange Inglis,  
 In ryme wate never what it is;  
 And bot thai wist what it mente,  
 Ellis methought it were alle schente.  
 I made it not for to be praysed,  
 Bot at the lewed men were aysed.  
 If it were made in ryme couwee,  
 Or in strangere, or enterlacé,  
 That rede Inglis it ere inowe  
 That couthe not have copped a kowe.  
 That outhur in cowee or in baston,  
 Sum suld haf ben fordon;  
 So that fele men that it herde  
 Suld not witte howe that it ferde.  
*I see in song, in sedgeyng tale,  
 Of Erceldoune and of Kendale,  
 Non tham sayis as thai thaim wroght,  
 And in ther saying it semes nocht,  
 That may thou here in Sir Tristrem,  
 Over gestes it has the steem,  
 Over all that is or was,  
 If men it sayd as made Thomas;  
 Bot I here it no man so say,  
 That of some copple som is away.  
 So thare fayre saying here beforene,  
 Is thare travaile nere forlorne;  
 Thai sayd it for pride and nobleye,  
 That were not suylike as thei.  
 And alle that thai willed overwhere,  
 Alle that ilke will now forfare.  
 Thai sayd it in so quaint Inglis,  
 That many wate not what it is.  
 Therfore heuyed welle the more  
 In strange ryme to travayle sore  
 And my wit was oure thynne;  
 So strange speche to travayle in;  
 And forsoth I couth nocht  
 So strange Inglis as thai wroght,  
 And men besoght me many a tyme  
 To turne it bot in light ryme.  
 Thai seyde if I in strange ryme it turn,  
 To here it many on suld skorne;  
 For in it ere names fulle selcouthe,  
 That ere not used now in mouthe.  
 And therfore, for the commonalte,  
 That blythely wild listen to me,  
 On light lange I it began,  
 For luf of the lewed man.*

"This passage requires some commentary, as the sense has been generally mistaken. Robert de Brunne does not mean, as has been supposed, that the minstrels who repeated Thomas's romance of *Sir Tristrem*, disguised the meaning by putting it into 'quainte Inglis;' but, on the contrary, that Kendal and Thomas of Erceldoune did themselves use such 'quainte Inglis,' that those who repeated the

Romance, story were unable to understand it, or to make it intelligible to their hearers. Above all, he complains that, by writing an intricate and complicated stanza, as 'ryme cowee, strangere, or entrelacé,' it was difficult for the *diseurs* to recollect the poem; and of *Sir Tristrem*, in particular, he avers, that he never heard a perfect recital, because of some one 'cople' or stanza, a part was always omitted. Hence he argues at length, that he himself, writing not for the minstrel or harper, nor to acquire personal fame, but solely to instruct the ignorant in the history of their country, does well in chusing a simple structure of verse, which they can retain correctly on their memory, and a style which is popular and easily understood. Besides which, he hints at the ridicule he might draw on his poem, should he introduce the uncouth names of his personages into a courtly or refined strain of verse. They were

Great names, but hard in verse to stand.

While he arrogates praise to himself for his choice, he excuses Thomas of Erceldoune and Kendale for using a more ambitious and ornate kind of poetry. They wrote for pride (fame) and for nobles, not such as these my ignorant hearers.\*

If the editor of *Sir Tristrem* be correct in his commentary, there existed in the time of Thomas de Brunne minstrels or poets who composed English poetry to be recited in the presence of the great, and who, for that purpose, used a singularly difficult stanza, which was very apt to be mutilated in recitation. *Sir Tristrem*, even as it now exists, shows likewise that considerable art was resorted to in constructing the stanza, and has, from beginning to end, a concise, quaint, abstract turn of expression, more like the Saxon poetry than the simple, bold, and diffuse details of the French minstrel. Besides *Sir Tristrem*, there remain, we conceive, two other examples of "gestes written in quaint Inglis" composed, namely, according to fixed and complicated rules of verse, and with much attention to the language, though the effect produced is far from pleasing. They are both of Scottish origin, which may be explained, by recollecting that in the Saxon provinces of Scotland, as well as at the court, Norman was never used; and therefore it is probable that the English language was more cultivated in that country at an early period than in England itself, where it was for a long time superseded by that of the conquerors. These romances, entitled *Sir Gawain*, and *Sir Gologras*, and *Sir Galeran of Galloway*, have all the appearance of being original compositions, and display considerable poetical effort. But the uncouth use of words dragged in for the sake of alliteration, and used in secondary and oblique meanings, renders them extremely harsh in construction, as well as obscure in meaning.

In England it would seem that the difficulties pointed out by De la Brunne threw out of fashion this ornate kind of composition; and the English minstrels had no readier resource than translating from

Romance, the French, who supplied their language at the same time with the phrases of chivalry which did not exist in English. These compositions presented many facilities to the minstrel. He could, if possessed of the slightest invention, add to them at pleasure, and they might as easily be abridged when memory failed, or occasion required. Accordingly, translations from the French fill up the list of English romance. They are generally written in short lines rhyming together; though often, by way of variety, the third and sixth lines are made to rhyme together, and the poem is thus divided into stanzas of three couplets each. In almost all of these legends, reference is made to "the romance," that is, some composition in the French language, as to the original authority. Nay, which is very singular, tales where the subjects seem to be of English growth, seem to have yet existed in French ere they were translated into the language of the country to which the heroes belonged. This seems to have been the case with *Hornchild*, with *Guy of Warwick*, with *Bevis of Hampton*, all of which appear to belong originally to England; yet are their earliest histories found in the French language, or at least the vernacular versions refer to such for their authority. Even the romance of *Richard*, England's own *Cœur de Lion*, has perpetual references to the French original from which it was translated. It must naturally be supposed that these translations were inferior to the originals, and whether it was owing to this cause, or that the composition of these rhymes was attended with too much facility, and so fell into the hands of very inferior composers, it is certain, and is proved by the highest authority, that of Chaucer himself, that even in his time they had fallen into great contempt. The *Rime of Sir Thopas*, which that poet introduces as a parody, undoubtedly, of the rythmical romances of the age, is interrupted by mine host Harry Bailly with the strongest and most energetic expressions of total and absolute contempt. But though the minstrels were censured by De la Brunne for lack of skill and memory, and the poems which they recited were branded as "draffy rhymings," by the far more formidable censure of Chaucer, their acceptance with the public in general must have been favourable, since, besides many unpublished volumes, the two publications of Ritson and Weber bear evidence of their popularity. Some original compositions doubtless occur among so many translations, but they are not numerous, and few have been preserved. The poem of *Sir Eger* and *Sir Greme*, which seems of Scottish origin, has no French original; nor has any been discovered either of the *Squire of Low Degree*, *Sir Eglamour*, *Sir Pleindamour*, or some others. But the French derivation of the two last names renders it probable that such may exist.

The minstrels and their compositions seem to have fallen into utter contempt about the time of Henry VIII. There is a piteous picture of their condition in the person of Richard Sheale, which it is impossible to read without compassion, if we con-

\* *Sir Tristrem*, Introduction, pp. lxi. lxii. lxiii. lxiv. lxxv. Edin. 1804.

Romance. sider that he was the preserver at least, if not the author, of the celebrated heroic ballad of *Chevy Chase*, at which Sir Philip Sidney's heart was wont to beat as at the sound of a trumpet. This luckless minstrel had been robbed on Dunsmore Heath, and, shame to tell, he was unable to persuade the public that a son of the muses had ever been possessed of the twenty pounds which he averred he had lost. The account he gives of the effect upon his spirits is melancholy, and yet ridiculous enough.

After my robbery my memory was so decayde,  
That I colde neather syng nor talke, my wytt wer so dismayde.  
My audacitie was gone, and all my myrry tawke,  
Ther ys sum heare have sene me as myrry as a hawke ;  
But nowe I am so trublyde with phansis in my mynde,  
That I cannot play the myrry knave, aecordyng to my kynd.  
Yet to tak thought, I perseve, ys not the next waye  
To bring me out of det, my ereditors to paye.  
I may well say that I hade but well hape,  
For to lose about threscore pounde at a clape.  
The losse of my mony did not greve me so sore,  
But the talke of the pyple dyde greve me moch mor.  
Sum sayde I was not robde, I was but a lyeng knave.  
Yt was not possyble for a mynstrell so much mony to have ;  
In dede, to say the truthe, that ys ryght well knowene,  
That I never had so moche mony of myn owene,  
But I had frendds in London, whos namys I can declare,  
That at all tymes wold lende me eclds. worth of ware,  
And sum agayn such frendship I founde,  
That thei wold lend me in mony nyn or tene pownde.  
The occasion why I cam in dete I shall make relacion,  
My wyff in dede ys a sylk woman be her occupation,  
And lynen cloths most chefly was her greatyste trayd,  
And at faris and merkytts she solde sale-ware that she made ;  
As shertts, smockys, partlytts, hede clothes, and othar thingss,  
As sylk thredd, and eggyns, skirrts, bandds, and stringss.

From *The Chant of Richard Sheale*,  
*British Bibliographer*, No. XIII. p. 101.

Elsewhere, Sheale hints that he had trusted to his harp, and to the well known poverty attached to those who used that instrument, to bear him safe through Dunsmore Heath. At length the order of English minstrels was formally put down by the act 39th of Queen Elizabeth, classing them with sturdy beggars and vagabonds ; in which disgraceful fellowship they only existed in the capacity of fiddlers, who accompanied their instrument with their voice. Such a character is introduced in the play of *Monsieur Thomas*, as the "poor fiddler who says his songs." The metrical romances which they recited also fell into disrepute, though some of the more popular, sadly abridged and adulterated, continued to be published in *chap. books*, as they are called. About fifty or sixty years since, a person acquired the nickname of *Rosewal and Lilian* from singing that romance about the streets of Edinburgh, which is probably the very last instance of the proper minstrel craft.

If the metrical romances of England can boast of few original compositions, they can show yet fewer examples of the prose romance. Sir Thomas Malory, indeed, compiled, from various French authorities, his celebrated *Morte d'Arthur*, indisputably the best prose romance the language can boast. There is also *Arthur of Little Britain* ; and the Lord Berners compiled the romance of the *Knight of the Swan*. The books of *Amadis* were likewise translated into English ; but it may be doubted whether the country in general ever took that deep interest

Romance. in the perusal of these records of love and honour with which they were greeted in France. Their number was fewer ; and the attention paid to them in a country where great political questions began to be agitated was much less than when the feudal system still continued in its full vigour.

III. We should now say something on those various kinds of romantic fictions which succeeded to the romance of chivalry. But we can only notice briefly works which have long slumbered in oblivion, and which certainly are not worthy to have their slumbers disturbed.

Even in the time of Cervantes, the pastoral romance, founded upon the *Diana* of George of Manté Mayer, was prevailing to such an extent as made it worthy of his satire. It was, indeed, a system still more remote from common sense and reality than that of chivalry itself. For the maxims of chivalry, high-strained and absurd as they are, did actually influence living beings, and even the fate of kingdoms. If *Amadis de Gaule* was a fiction, the Chevalier Bayard was a real person. But the existence of an Arcadia, a pastoral region, in which a certain fantastic sort of personages, desperately in love, and thinking of nothing else but their mistresses, played upon pipes, and wrote sonnets from morning to night, yet were supposed all the while to be tending their flocks, was too monstrously absurd to be long credited or tolerated.

A numerous, and once most popular, class of Heroic Romances, was that entitled the *Heroic Romance of the Seventeenth Century*.

If the ancient *Romance of Chivalry* has a right to be called the parent of those select and beautiful fictions which the genius of the Italian poets has enriched with such peculiar charms, another of its direct descendants, *The Heroic Romance of the Seventeenth Century*, is, with few exceptions, the most dull and tedious species of composition that ever obtained temporary popularity. The old romance of Heliodorus, entitled *Theagenes and Churiclea*, supplied, perhaps, the earliest model of this style of composition ; but it was from the romances of chivalry that it derives its most peculiar characteristics. A man of a fantastic imagination, Honoré d'Urfé, led the way in this style of composition. Being willing to record certain love intrigues of a complicated nature which had taken place in his own family, and amongst his friends, he imagined to himself a species of Arcadia on the banks of the Lignon, who live for love and for love alone. There are two principal stories, said to represent the family history of D'Urfé and his brother, with about thirty episodes, in which the gallantries and intrigues of Henry IV.'s court are presented under borrowed names. Considered by itself, this is but an example of the pastoral romance ; but it was so popular that three celebrated French authors, Gomberville, Calprenede, and Madame Scuderi, seized the pen, and composed in emulation many interminable folios of heroic romance. In these insipid performances, a conventional character, and a set of family manners and features, are ascribed to the heroes and heroines, although selected from dis-

Romance  
||  
Roscommon.

tant ages and various quarters of the world. The heroines are, without exception, models of beauty and perfection; and, so well persuaded of it themselves, that to approach them with the most humble declaration of love is a crime sufficient to deserve the penalty of banishment from their presence; and it is well if it is softened to the audacious lover, by permission, or command to live, without which, absence and death are accounted synonymous. On the other hand, the heroes, whatsoever kingdoms they have to govern, or other earthly duties to perform, live through these folios for love alone; and the most extraordinary revolutions which can agitate the world are ascribed to the charms of a Mandana or a Statira acting upon the crazy understanding of their lovers. Nothing can be so uninteresting as the frigid extravagance with which these lovers express their passion; or, in their own phrase, nothing can be more freezing than their flames, more creeping than their flights of passion.

Yet the line of metaphysical gallantry which they exhibited had its fashion, and a long one, both in France and England. In the latter country they continued to be read by our grandmothers during the Augustan age of English, and while Addison was amusing the world with its wit, and Pope by its poetry. The fashion did not decay till about the reign of George I.; and even more lately, Mrs Lennox, patronized by Dr Johnson, wrote a very good imitation of Cervantes, entitled, *The Female Quixote*, which had those works for its basis. They are now totally forgotten.

Romance  
||  
Ross-shire.

The modern romance, so ennobled by the productions of so many master hands, would require a long disquisition. But we can here only name that style of composition in which De Foe rendered fiction more impressive than truth itself, and Swift could render plausible even the grossest impossibilities.

(N. N.)

Situation  
and Bound-  
aries.

ROSCOMMON, a county in the province of Connaught in Ireland, bounded on the north by Sligo and Leitrim; on the east by the river Shannon, which separates it from Longford and Westmeath; on the south by Galway; and on the west by Mayo. It is of a very irregular form, extending about 60 miles from north to south, at both which extremities its breadth is greatly contracted; from east to west its greatest extent is about 37 miles; and it contains 869 square miles, or 556,847 English acres, divided into six baronies and 56 parishes. Of these parishes, 50 belong to the see of Elphin, and the rest to those of Tuam, Clonfert, and Ardagh. Roscommon, the county town, situated near its centre, is in north latitude  $53^{\circ} 35'$ , west longitude  $8^{\circ} 8'$ , about 89 English miles W. N. W. of Dublin.

Extent and  
Divisions.

Surface.

This is for the most part a flat country; in some places sprinkled with rocks, in many interrupted by extensive bogs; but having few hills, except in its northern quarter, where the Curlew Mountains form its boundary with Sligo. In this quarter, at Arigna, coal and iron-works were carried on a few years ago, but afterwards discontinued. The soil is for the most part rich, incumbent upon limestone, and adapted to either tillage or grazing. The rivers are the Shannon and the Suck. The Shannon flows along the eastern boundary for about 60 miles, and is there navigable for small vessels. In its course it forms several fine lakes, of which the most considerable are Loughs Ree, Baffin, and Allen. The Suck, in like manner, separates this county from Galway on the south and west. Both flow south, and almost parallel to each other, till the Suck, turning to the east, joins the Shannon a little to the north of Clonfert. There are several other lakes, the largest of which is Lough Key, on the north side, distinguished for its beautiful scenery of wooded islands and surrounding groves.

Estates.

Here, as in most parts of Ireland, the estates were once very large; but they have been broken down in some instances, by the granting of leases in perpe-

tuity; a practice which has given rise to a class of landholders, interposed between a few great proprietors on the one hand, and a numerous body of cultivators on the other.

Roscommon is chiefly a grazing county, and feeds some of the best long-horned cattle and long-woolled sheep in Ireland, but there are few dairies. During the late war its fine green pastures, under this management, afforded a very ample rent, and tillage was therefore conducted on a small scale; but the plough has been more in request since the peace, both here and in other parts of Ireland; and the soil of such rich grazing lands requiring nothing more than the common operations of tillage to yield large crops, the growth of corn throughout Ireland has been greatly increased. Yet within these few years agriculture was here in a very backward state. "In Roscommon," says Mr Wakefield, "I heard of horses being yoked to the plough by the tail, but I had not an opportunity of seeing this curious practice. I was, however, assured by Dean French, that it is still common with two-year-old colts in the spring." Potatoes, oats, and flax, are the principal crops.

There are no large towns here. The principal are, Boyle, Roscommon, the county town, Stokes-town, and Elphin, the birth-place of Oliver Goldsmith; none of which are so considerable as to be represented in Parliament; though Roscommon, Boyle, and Tulsk, the latter a wretched village, had each two representatives in the Irish Parliament. The county itself, in which the Catholic interest predominates, sends two members to the Parliament of the United Kingdom. In 1791 the population was estimated to be 86,000, nearly all Catholics; and by the census of 1821 the number is 207,777. The English and Irish languages are spoken in most parts of the county with equal facility.—See the general works quoted under the former Irish counties. (A.)

ROSS-SHIRE, one of the northern counties of Scotland, situated between  $57^{\circ} 8'$  and  $57^{\circ} 59'$  north

Situation  
and Bound-  
aries.

Ross-shire. latitude, and between 4° and 5° 46' west longitude from Greenwich. Including the small county of Cromarty, which consists for the most part of detached tracts surrounded by Ross-shire, the boundaries are the sea on the east and west, the county of Sutherland on the north, and Inverness-shire on the south. On the east are the Friths of Dornoch, Cromarty, and Moray, arms of the sea which run up into the interior; the latter, the most considerable, washing its south-eastern extremity. The west coast is still more indented with similar, though smaller, inlets, here called lochs; of which the largest are the Great and Little Loch Broom, Loch Groinard, Loch Ewe, Gareloch, where there has long been a regularly productive cod-fishery, Loch Terridon, Lochs Kisserne and Carron, and Loch Duich. From north to south Ross-shire extends about 56 miles, and from east to west somewhat more than 70; having an area, according to the latest authorities, of 2129 square miles, or 1,362,560 English acres, without including the island of Lewis, one of the Hebrides belonging to this county, or the space occupied by the county of Cromarty. In the *Agricultural Survey* by Sir George Mackenzie, its extent is computed to be greater by about half a million of acres. Ross and Cromarty contain 33 parishes, of which seven are on the west coast, and four in the island of Lewis. One parish lies within the bounds of the synod of Glenelg, and all the rest in that of Ross. Many of these parishes are very large, but the ministers are assisted in their duties by missionaries maintained by the Royal bounty, and the Society for Propagating Christian Knowledge.

Surface. In the *Encyclopædia* will be found a pretty full description of this extensive district, to which we must refer, and shall notice here only such circumstances as may be necessary to give a general view of its present condition. Excepting a narrow tract on the sea-coast on the east, where the soil and climate are not unfavourable to cultivation, the general character of Ross-shire is that of a rugged mountainous country, interspersed with narrow glens, fresh water lakes, and mountain streams, with here and there fringes of natural wood, and plantations of some extent, and a few gentlemen's seats; but, upon the whole, it is a wild and desolate region, upon which a great deal of rain falls in summer, and snow in winter, the latter lying among the recesses of some of the mountains all the year. Including the woodlands, only about 9 acres in 100 are supposed to be susceptible of cultivation.

Estates. The landed property of Ross-shire, valued in the cess-books at L. 75,043, 10s. 3d. Scots, consisted, in 1811, of 85 estates, of which 50 were under the valuation of L. 500 Scots each, 25 above L. 500, and below L. 2000, and 10 above L. 2000; from which it would appear that they are generally of great extent; the medium size being upwards of 16,000 English acres. But their value is far from being in proportion; the real rent of the lands in that year having been L. 91,089, 18s. 8d., and of the houses L. 2798, 1s. 4d. Sterling; the former affording a mean rental for each estate of not quite L. 1072, or about 1s. 4d. *per* acre. The principal seats are Brahan Castle, Stewart Mackenzie; Tulloch Castle, Davidson; Fowlis

Castle, Monro, Bart.; Coul, Mackenzie, Bart.; Novar House, Munro, Bart.; Invergordon Castle, Macleod; Balnagowan, Ross, Bart.; Tarbat House, Hay Mackenzie; Geanies House, Macleod; Conan House, Hector Mackenzie, Bart.; Roschaugh, Roderick Mackenzie, Bart.; Cromarty House, Ross; and Lochalsh, Innes, Bart.

The occupation of this district in an agricultural view, and the system of management which prevails among the tenantry, do not differ materially from what we have already described under Inverness-shire and the other Highland counties of Scotland. The native farmers hold a few acres of arable land, with grazings commonly contiguous, but in some cases at a distance;—raise oats, bear or big, and potatoes; and keep a great many cattle and horses, which are always stunted in their growth for want of food, and in severe winters many of them perish. Except in seed-time and harvest, and while they are preparing peat for their winter's fuel, the tenants spend much of their time in idleness, or in the practice of illicit distillation among their hills, though in some parts, particularly on the west coast, also in fishing; and their labour, and that of their cattle, is, generally speaking, irregular and unproductive. Several of the proprietors, however, and some farmers brought hither from other counties, conduct their farming operations upon the most approved system; and upon the east coast all the crops grown in Scotland may be seen under excellent cultivation. Sheep-farming, too, notwithstanding the opposition of the small tenants, has been introduced into this as well as most of the other Highland counties. Leases for nineteen years have become common here as in other parts of Scotland.

Towns. The towns are Dingwall, at the bottom of the Frith of Cromarty, Fortrose, Tain, on the south coast of Dornoch Frith; all royal burghs, but very small places, and situated on the east side of the county. On the west, the only place of any consideration is the village of Ullapool, on the banks of Loch Broom, built within these thirty years by the British Society for extending the Fisheries, &c. at an expence of upwards of L. 20,000. But the herring-fishery on this coast, always precarious, having failed for several years in succession, the inhabitants have been often reduced to great distress, and notwithstanding every encouragement, many have abandoned it. It remains to be seen whether the recent repeal of the salt duties may not lead to a more spirited and successful prosecution of the fisheries, so much to be desired for the employment and subsistence of the people of this and other parts of the Highlands, who are by far too numerous to be employed beneficially in agriculture. Even the loch-fishings, hitherto much neglected, might be rendered a valuable resource in this respect.

There is scarcely any thing in Ross-shire that deserves the name of a manufacture, except one of a somewhat peculiar description, and which may be worth notice for that reason. We allude to the practice of obtaining tar, so necessary for the sheep-stocks of the county, and other purposes, from the roots and trunks of the fir-trees found in the mosses. These mosses, which are of great extent here, as

well as in many other parts of Scotland, so generally abundant in such materials, that Sir George Mackenzie thinks that more tar might be thus procured than would suffice for home consumption. From these roots the Russians extract considerable quantities of turpentine by a very simple and unexpensive process, described by Dr Howison in a recent communication to the Highland Society of Scotland.

Ross-shire, which has about 90 freeholders, sends one member to Parliament; and in the elections for the Scottish burghs, Dingwall and Tain are associated with Dornoch, Wick, and Kirkwall, and Fortrose with Forres, Nairn, and Inverness. The jurisdiction of one sheriff extends over this and the shire of Cromarty; and his substitutes hold their courts at Tain, Dingwall, and Fortrose, for the mainland of the county, and at Stornoway, in Lewis, for the islands politically attached to it. The population of the two counties of Ross and Cromarty, according to the census of 1801, was 52,291; in 1811 it amounted to 60,853; and in 1821 to 68,828, of which 32,324 were males, and 36,504 were females. The families employed in agriculture were 7947; in trade and manufactures 3356; in other occupations of various kinds 3203. The increase of population from 1811 to 1821 was 13,485.

See the general works quoted under the former Scottish counties, and Sir George Mackenzie's *General View of the Agriculture of the Counties of Ross and Cromarty*. Also the article CROMARTY in this Supplement. (A.)

ROXBURGHSHIRE, a county in Scotland, on its south-eastern extremity, where it meets with England, situated between 55° 6' and 55° 43' north latitude, and between 2° 12' and 3° 7' west longitude from Greenwich. It is sometimes called Teviotdale, from its principal river the Teviot, but improperly, as it also includes a tract called Liddesdale on the south-west, which is unconnected with the Teviot. Its boundaries are Berwickshire, from which it is separated in part by the river Tweed, on the north; Selkirkshire and Dumfries-shire on the west, and south-west; and the English counties of Cumberland and Northumberland on the south-east and east. Between Berwickshire and Selkirkshire, a small tract touches the county of Mid-Lothian; on the south, between Dumfries-shire and Cumberland, the county terminates almost in a point; on the west it surrounds small portions of Selkirkshire in some places, and in others projects into that county; and it has the Cheviot hills on the east; the outline being exceedingly irregular on all sides. According to the latest authorities, its area is 715 square miles, or 457,600 English acres; containing 30 entire parishes, and part of other four, which properly belong to the counties adjoining. For the purposes of justice and police, it is divided into the four districts of Kelso and Jedburgh on the east, and Melrose and Hawick on the west. In an agricultural view, it may be considered as divided into arable land and hilly pasture; the pasture land, estimated at about  $\frac{2}{3}$ ths of the whole, occupying the eastern, southern, and western quarters, and surrounding, in a circular form, the arable, which lies on the north and north-east sides of the county.

Except upon the banks of the streams, which are commonly of no great width, there is very little level or flat land in this district; and, compared with the high grounds in other parts of Scotland, hardly any part of it can be said to be mountainous. The cultivated districts are beautifully diversified with narrow valleys, each traversed by its own rivulet, often fringed with wood, and bounded by gentle acclivities; and the hills in pasture are, with few exceptions, clothed in verdure to their very summits. On the confines of Northumberland, the most elevated quarter, the hills seldom reach the height of 2000 feet, but there are many from that height down to 800 or 1000 feet. The most considerable are Minto and the Eildon hills, both in the arable division; and Dunion, Ruberslaw, Wisp, Hownam Law, Milenwood-Fell, Carter-Fell, and Chillhill, in the pastoral districts. Most of them having a conical form, insulated at their base by streamlets, and not rising in a continuous range, present very conspicuous objects, and at a distance seem higher than they are found to be when approached. The beauties of the natural scenery have, over all the lower grounds, been heightened and improved by the wealth and industry of its inhabitants; all this division abounding in gentlemen's seats, comfortable, and sometimes elegant farm-houses; the fields inclosed with hedges of thorn, and belts of wood, and many spots covered with young trees. On the skirts of the hills, too, cultivation has made considerable progress of late, as much, perhaps, as could be expected in the natural circumstances of the country; but the interior of the pastoral district is in general naked, without trees or fences, and very thinly inhabited.

The prevailing soil of the arable land, and over most of the hills, is what is called a sandy loam, though of different qualities, excellently adapted to the turnip culture. Tracts of a clayey or more heavy soil, however, occupy a considerable space, especially on the north-west. Clay is also found on the north, near the Tweed, where it is rich and fertile. Moss, marsh, and heath, occur in the south-west, and occasionally in other quarters; but altogether they cover but a small proportion of the surface.

No district in Britain is better supplied with streams, though it has only two that deserve the name of rivers, the Tweed and the Teviot. The Tweed, which crosses the north part of the county, and for part of its course forms the boundary with Berwickshire, enters it from Selkirkshire, on the north-west, and leaves it below Redden on the north-east; carrying with it nearly all the waters that pass through, or have their source in, this district. Its banks, especially near Kelso, where it is crossed by an elegant bridge, built about 20 years ago, are perhaps equal in richness and beauty to those of any river of the same extent in Britain. The Teviot more properly belongs to this county; rising and terminating within its bounds. It has its source in the south-west extremity, near the confines of Dumfries-shire, and flowing north-east almost through the middle of the district, joins the Tweed, in which its name is lost, a little above the town of Kelso. From Hawick downwards it is a considerable stream, and,

Roxburgh-  
shire.  
Surface.

Roxburgh-  
shire.

like the Tweed, flows through a very fertile and well cultivated country. The principal rivulets that fall into the Teviot from the south are Allen, Slittrick, Rule, Jed, Oxnam, and Kale; and from the north and west, Borthwick and Ale. The Liddel and Hermitage, which run on the south-west, and whose united streams retain the name of Liddel, from which this tract is called Liddesdale, soon leave Roxburghshire; and after forming the boundary between Dumfries-shire and Cumberland, fall into the Esk above Longtown. The other streams are the Etterick, which joins the Tweed from the south-west as it enters this county; another Allen and the Leader, which fall into the same river from the north; and the Eden, which, after an easterly course, partly on the boundary with Berwickshire, enters the Tweed on the north-east, a little before it leaves the county. The Beaumont also rises here among the Cheviot hills on the east, but after a short course, passes by Kirketholm, and enters Northumberland. Of the smaller streams, the Ale, Jed, Rule, and Hermitage, are distinguished for their natural scenery; to which we may add the Liddel, celebrated by the late Dr Armstrong, a native of Liddesdale. Tweed is the only river frequented by salmon, except at the time of spawning, when they are found in most of the other streams. Trout abounds in the Ale, Rule, Jed, and Kale, and there are a few small lakes which contain perch and pike.

Minerals.

Roxburghshire is not rich in minerals. Coal has been found on the Carter Hill, near the borders of Northumberland, and in the southern extremity of Liddesdale. It is worked at the latter place, but this is too remote to render it of much value to the inhabitants of this county, who are chiefly supplied with coal from Northumberland. Limestone, which abounds in various parts, is not wrought to any extent, owing to the want of coal. There are excellent sandstone quarries at Sprouston on the Tweed, and marl in several parishes, particularly at Eckford, on the Teviot, and Ednam, near the Tweed. But the use of marl as a manure is confined to a narrow circle around the places where it is found; lime, of which a much smaller quantity answers the purpose, being most in request; and the lime is almost all like the coal brought from Northumberland, from 20 to 30 miles distant from many parts of the arable district.

Valuation  
and Rental.

The valued rent of Roxburghshire is L. 314,663, 6s. 4d. Scots, being next to Fife and Perth, the highest in Scotland; and the real rent of the lands, in 1811, was L. 230,663, 9s. 9d. Sterling, and of the houses L. 11,508, 6s. 3d. It is one of the few counties where the rent in Sterling falls below the valuation in Scots money; a circumstance which is certainly not owing to the want of improvements to sustain rent, nor to the present rents being too low; but to the mistaken vanity of its land owners, whose rent-rolls at the time of the valuation are understood to have been stated too high. Of this valuation, which in 1811 was divided among 349 estates, about one-third belongs to lands held under entail, and more than two-thirds to families of the name of Kerr, Scott, Elliot, and Douglas. The principal proprietors are the Dukes of Roxburgh and Buccleuch,

Estates.

Roxburgh-  
shire.

and the Marquises of Lothian and Tweeddale; but there are 33 estates in all that have a valued rent of upwards of L. 2000 Scots each; and 55 more are from L. 500 to L. 2000. Yet moderate and small properties are very numerous; the remaining 261 estates being under L. 500 Scots. Several of these exceeding a valuation of L. 400 Scots, and held of the Crown, have been acquired by professional farmers, who have thus become freeholders, and enjoy a share of political influence. Among the seats in the county, which are too numerous to be mentioned here, the most splendid is Fleurs, the mansion of the Duke of Roxburgh, beautifully seated at the confluence of the Tweed and Teviot, near Kelso.

Farms.

Roxburghshire is divided, for the most part, into larger farms, if we except a few sheep farms in the Highlands, than any other county in Scotland; many of them, consisting of land partly arable and partly pasture, being from 1000 to 3000 acres; and several of these, in some instances, are in the occupation of one tenant. Farms altogether arable, containing from 500 to 1000 acres, are not uncommon. The capital and knowledge required for conducting concerns so extensive entitle such men to suitable accommodations in their houses and farm-offices, many of which are accordingly laid out and constructed in a superior style. Most of the farm servants are married and live in houses apart, set down together in some convenient quarter of the farm, each having a small garden attached. It is the practice here, as in other parts of the lowlands of Scotland, to pay most of their wages in the produce of the farm, and not in money; every married ploughman, or *hind*, getting a certain quantity of corn, a cow kept, and some land allowed for potatoes, and often also for flax: he is also commonly allowed to keep a pig and a few hens. Whatever may be the fluctuation of the markets, these labourers are thus always provided with the necessaries of life; and the sale of the butter made from their cow, with its calf, and the eggs of their poultry, and, if the family be not large, a part of their corn, supplies them with the other articles they need; while they fatten their pigs, and work up the flax for the use of their families. No class of men of their rank are to be compared with these hinds for propriety of conduct and frugality; and few of the labouring classes any where are so comfortable and contented with their condition. The practice of paying wages in kind is not, it must be admitted, free from objections; a little pilfering is sometimes detected on the one hand, and a hard master, on the other, may be willing to pay in produce of an inferior quality; but after all, the long experience that has been had of this system over five or six of the principal agricultural counties of Scotland, and the north of England, warrants us in asserting that it works well for both parties, and might have some effect in keeping down poor rates if it prevailed more generally among our southern neighbours.

On the best soils, the rotation of crops is very simple, corn being taken every second year with a green crop intervening; but, in general, the land does not admit of such constant tillage, and two-fifths, or a half, is commonly in pasture from seeds. Un-  
Rotation of  
Crops.

Roxburgh-  
shire.

der a six years' course, the most profitable on rather weak soils, and in a district where there are no large towns to furnish manure, the rotation from pasture is oats, turnips, barley or wheat, clover and rye-grass, partly cut for hay the first year, but chiefly pastured with sheep, and then continued in pasture two years longer. Under this system the crops are almost always good, and the land, instead of being exhausted, is kept in a state of progressive improvement. Though little of the soil be naturally adapted to wheat, yet this grain is now raised to a great extent on all the better descriptions of sandy loam; generally after turnips eaten on the ground by sheep, which, by their treading, give consistency to the soil, as well as leave it greatly enriched by their manure. Only a small part is under beans, somewhat more under pease; barley has in many instances been superseded by wheat; so that wheat and oats are the principal crops of grain; while, whatever be the number of acres in corn, nearly half the quantity is allotted to turnips, and the other half to clover and rye-grass. Potatoes occupy but a very small part of every farm; and flax, where raised at all, is only in small patches for the use of the farm servants. The turnip crop, however, has been lately attacked with a disease which has already begun to make some alteration in the system, leading to the more extensive culture of potatoes, and also of cabbages. This disease, which has been long known in England, but which was a stranger in this and other parts of Scotland 10 or 12 years ago, popularly known by the name of *fingers and toes*, converts the bulb of the turnip, when one has been allowed to form, into a shapeless and morbid mass which no animal will eat, and becomes putrid, and disappears altogether on the first approach of frost. It often prevails over extensive fields, while others adjoining escape; and it seems to make no difference whether the land be fresh from pasture or has been long in tillage.

Sheep and  
Cattle.

The pastoral district of this county is occupied with an excellent breed of sheep called *the Cheviot*, from the general name of the hills on which they feed; for an account of which breed we must refer to the Article AGRICULTURE in this *Supplement*. On the arable farms, the short-horned cattle and Leicester sheep, neither of them, however, always in a pure state, form the principal stock; and, as so large a proportion of even the arable land is always in grass, the number of both is very great. By means of turnips, most of the disposable stock, whether of cattle or sheep, are carried forward till they are ready for the butcher; when the far greater part is sent to the weekly market of Morpeth in Northumberland, for the consumption of Newcastle and other towns in the north of England.

The progress which agriculture has made in this district has not been favoured by its situation in respect to markets. It has no large towns, and comparatively a small population. Most of the corn, as well as live stock, must, therefore, be carried out of the county; and Berwick-upon-Tweed, the nearest seaport, is upwards of 30 miles from much of its corn lands.

Towns and  
Manufactures.

The towns are Kelso, Jedburgh, Hawick, and Mel-

rose; and of the villages the most considerable are Yetholm and Kirkyetholm, near its eastern boundary. Kelso, pleasantly situated on the north bank of the Tweed, is a well built, cleanly, and cheerful place, containing near 5000 inhabitants, the capital of this and the adjoining county of Berwick. Some branches of the leather and woollen manufacture, and that of thread, have been long carried on here, with a considerable brewery. Jedburgh, the county town, situated on the rivulet Jed, in the interior, though a place of note formerly, has been long stationary, if not declining. Hawick, which stands on the Teviot, at the point where it is joined by the Slit-trick, is a more thriving place, and has manufactures of carpeting, stockings, and other sorts of woollen goods. Melrose, near the south bank of the Tweed, about 10 miles west from Kelso, is no otherwise distinguished than for its abbey. (See MELROSE in the *Encyclopædia*.) The two Yetholms are worthy of notice for their fairs, at which a great part of the cattle, sheep, and wool, of the county are sold; and Kirkyetholm for being the residence of gypsies, and their principal colony in Scotland. Roxburgh, which gives its name to the county, and whose castle was of such importance in the wars between England and Scotland, has long since ceased to exist, and has left no trace of its former consequence. At Jedburgh, Kelso, Melrose, and the village of Gattonside, there are some valuable orchards, particularly at Jedburgh and Melrose, where some very old trees which belonged to their abbeys are still remarkably prolific.

Antiquities

This county, placed on the borders of the two kingdoms, the scene of frequent warfare and depredation, presents the ruins of a great many castles and towers, and other remains of an early age. It was also distinguished for its religious buildings, of which there are still magnificent remains at Kelso and Jedburgh, as well as at Melrose.

Roxburghshire, which has about 140 freeholders, sends one member to Parliament; and Jedburgh, its only royal burgh, joins with Lauder, Haddington, Dunbar, and North Berwick, in electing another for the Scottish burghs. This is one of the few Scottish counties in which there are regular assessments for the poor; and, not many years ago, it presented the still greater anomaly of a Scottish clergyman drawing tithes in kind. Among the eminent men to whom this district has given birth are Thomson, Armstrong, Lord Kames, Elliot, the brave defender of Gibraltar, Leyden, Park, the African traveller, and William Dawson, the father of the improved agriculture of Scotland.

Eminent  
Men.

The population, according to the census of 1801, was 33,682; in 1811 it amounted to 37,230; and in 1821 to 40,892, of which 19,408 were males, and 21,484 were females. The families employed in agriculture were 3613; in trade and manufactures 2822; in all other occupations 2204. The increase of population from 1811 to 1821 was 7210.

Population

See the general works quoted under the former Scottish counties, and Douglas' *General View of the Agriculture of Roxburghshire*. (A.)

RUMFORD (COUNT). See THOMPSON (SIR BENJAMIN).

RUSH (BENJAMIN), a celebrated American physician, born, 5th January 1745, near Bristol in Pennsylvania, was descended from a family who were originally Quakers, and who had accompanied Penn, in 1683, to his infant colony.

He lost his father at an early age, and having been first placed by his mother at a school kept by the Rev. S. Finley, he proceeded to finish his classical education at the College of Princeton, and there took a degree of Bachelor of Arts before he was sixteen. He then determined to make the profession of physic the pursuit of his life, and went to study it, first under the care of Dr Redman of Philadelphia, and then at Edinburgh, where he was created a Doctor of Physic in 1768. At the time of his return from Europe, a new school of medicine was about to be founded in Philadelphia, and he became Professor of chemistry immediately upon his arrival. In 1776, he began to take an active part, with the rest of his countrymen, in the political struggle of the day, and he was chosen a member of Congress for the state of Pennsylvania; in 1777 he was appointed Surgeon General to the army, and not long after became Physician General: he also contributed his best efforts to the improvement of the internal government of the state which he represented. But he soon withdrew his attention from political affairs, in order to devote it exclusively to medical and literary subjects, and he continued to be actively engaged in the practice of physic for the remainder of his life.

In 1776 he married Miss Julia Stockton of New Jersey. He had by her thirteen children, nine of whom survived him in respectability and prosperity. In 1791, when the two medical colleges of Philadelphia were incorporated into a single university, he was appointed Professor of the Institutes of Medicine, and of Clinical Practice. In 1793, he greatly distinguished himself by the new and apparently successful modes of practice that he introduced in the epidemic yellow fever, which was then causing great mortality throughout the United States; and which, shortly before his death, he was induced to believe not contagious, but derived from some general causes independent of the previous existence of the disease. He died on the 13th of April 1813, after an illness of five days, of a typhous fever, with some pulmonary symptoms. He had for a considerable part of his life been threatened with consumption, but had combated its attacks with unusual success. The number of his writings is considerable in proportion to their bulk; the times and the state of society in which he lived being such as to produce rather hasty and spirited than highly finished compositions.

1. His inaugural dissertation was entitled *De Concoctione ciborum in ventriculo*, and contained an explanation of the opinions relating to digestion, which he had learned from Dr Cullen. Edin. 1768.

2. *Account of the Effects of the Stramonium*. Amer. Phil. Trans. I. 1770.

3. *On the Utility of Wort in ill-conditioned Ulcers*. Med. Obs. Inq. IV. 1770; addressed to Dr Huck.

4. *Inquiry into the Natural History of Medicine among the Indians of North America*, an anniversary oration delivered in 1774.

VOL. VI. PART II.

5. *Remarks on Bilious Fevers*, addressed to Dr Huck. Med. Obs. Inq. V.

6. *Account of the Influence of the Revolution on the Human Body: with Observations on the Diseases of Military Hospitals*.

7. *Inquiry into the Cause of the Increase of Bilious and Intermittent Fevers in Pennsylvania*. Am. Trans. II.

8. *Observations on Tetanus*.

9. *Inquiry into the Influence of Physical Causes upon the Moral Faculty*.

10. *Remarks on the Effects of Ardent Spirits upon the Body and Mind*.

11. *Inquiry into the Causes and Cure of Pulmonary Consumption*, in his *Medical Inquiries and Observations*, I. Phil. 1788. His grand object, in the cure of consumption, is to recommend exercise, and every thing which will enable the patient to take exercise; anticipating a practice which has become somewhat fashionable in England of late years, from its frequent success as a temporary palliative. The subject is continued in the second volume of the *Inquiries*, published in 1793; and bleeding is very strongly recommended in the earlier and only curable stages. Consumption, he observes, is common in America, though scrofula scarcely ever occurs; and it has sometimes been known to be clearly communicated by infection to the negroes belonging to a family, who had, of course, no consanguinity that could account for a similarity of constitution. Five volumes, in the whole, of this collection appeared from 1788 to 1798; a second edition was published, in four volumes 8vo, 1804; a third in 1803, revised and enlarged, with a continuation of the *Histories of the Yellow Fever from 1793 to 1809; a Defence of Bloodletting, as a Remedy for certain Diseases; A View of the State of Medicine in Philadelphia; An Inquiry into the Sources of the usual Forms of Summer and Autumnal Diseases in the United States; and the recantation of his opinion of the contagious nature of the yellow fever already mentioned*.

26. *Inquiry into the Cause and Cure of the Cholera Infantum.* 1797.

27. *Observations on Cynanche Trachealis.* 1797.

28. *Introductory Lectures.* 1801. Ed. 2. 1811; with ten new introductory lectures, and two lectures on the Pleasures of the Senses and of the Mind.

29. In 1809, he published the works of Sydenham and of Cleghorn, with *Notes*, and in 1810 those of Pringle and Hilary.

30. *On Diseases of the Mind.* 8. 1812; an elaborate work, which had long been impatiently expected.

31. *A Letter on Hydrophobia.* 1813; addressed to Dr Hosack, and containing additional reasons for believing the seat of the disease to be chiefly in the blood vessels; an opinion which, in all probability, has at least tended to shorten the sufferings of several individuals on whom the experiment of profuse depletion has been tried.

Dr Rush's numerous publications obtained him many marks of respect from his contemporaries, and procured him admission, as an honorary member, into the most distinguished literary and philosophical societies of Europe. His name was familiar to the medical world as the Sydenham of America; his accurate observations and correct discrimination of epidemic diseases well entitled him to this distinction; while, in the original energy of his reasoning, he far excelled his prototype. His literary and professional character, indeed, appears to have been greatly influenced by the moral and political sentiments which were prevalent in his day. A love of innovation led him to that proud defiance of established authority which is just as likely to be pernicious as to be salutary. The study of the learned languages he depreciated, in one of his early essays, as unfit for a republican education; and this was the first step to the true Jacobin doctrine, that it was unrepugnant and aristocratical to have received any education whatever. In physic, his rejection of the prejudices of antiquity was somewhat more consistent with moderation, and the reform that he attempted was occasionally more successful than his literary speculations; nor can it be denied that there are a multitude of original suggestions in his works, which may very probably be found capable of affording valuable hints to the lovers of medical experiments.

## R U S S I A N E M P I R E.

THE Article RUSSIA in the *Encyclopædia* appears to have been drawn up with attention, and, as far as it was founded on the documents collected by Mr Tooke, with accuracy; but the changes that have taken place, and the additional information that has been communicated, render it necessary to give some account, in this place, of the present state of the empire. The principal changes in Europe have arisen from the possession of Finland, and the erection of Poland into a kingdom under the control of Russia. In Asia, some additions of territory have been gained from Persia and Tartary. In America, settlements have been established on the north-west coast of that continent, and claims have been made to some extensive tracts of country which are supposed to conflict with the rights of Great Britain, of the United States of America, or of Spain.

### GENERAL VIEW OF THE RUSSIAN EMPIRE.

The Russian dominions, including Poland, form a connected territory, extending from the frontiers of Germany and Prussia eastward to the sea which divides America from Asia, and beyond that, on the continent of America, to an extent hitherto undefined, and which is likely to become the subject of discussion with the other powers established in that division of the globe. Its most western point is in longitude 18° 6', and its most eastern in 202° 26' east from London. Its northern and southern boundaries have deep indentations; the extreme points of the former are in 78° north latitude, and of the latter 39° 50'. The extent of this empire has been calculated by different writers with considerable variations. Some have included the mountains of Caucasus, others the whole of the Caspian Sea; whilst some, again, have omitted the

Russian Empire.

Russian Empire.

one and not the other. The comparative results of the several calculations, and the modes by which they have been conducted, lead to the conclusion, that an extent of 7,350,000 English square miles, or 4,704,000,000 acres, is the nearest approximation to accuracy. The whole of China is not equal to two-thirds of Russia; and the Roman Empire, at the period of its greatest extension, did not comprehend more than one-fourth of the territory now subject to that power.\* The extent of the European portion of her dominions is only calculated at about one-fifth part of the whole.

Taking the account of the population, as stated before, to have been in the year 1806 - 41,253,483  
 And inferring an annual increase by excess of births over deaths at 500,000 from 1806 to 1822, being 16 years,  
 or - - - - - 8,000,000  
 And for acquired territory, viz.  
 in 1807, Bialystock, - - - 219,050  
 1809, Finland, - - - 1,101,898  
 1812, Caucasus provinces, - 120,000  
 — Moldaw and Bessarabia, 310,000  
 1815, The portion of Poland, 3,472,500

We estimate the inhabitants of this empire - - - - - 54,476,981

This vast population consists of several distinct races, which have been classed and calculated by several different writers under the following heads: ||

1st, *Sclavonians*. These, comprehending the inhabitants of Russia, Poland, Lithuania, and Cour-land, are estimated at 44,930,000. Different Races.

2d, *Fins*. These consist of the chief residents of Finland, Livonia, Lapland, and some other tribes, which together amount to about 2,360,000.

3d, *Tartars*. They comprehend several tribes, and a great number of subdivisions of tribes. The Tartars proper are divided into fourteen different branches; the Noggiers into six; besides which are the Kirgusiens, the Aralians, the Chewensens, the Bucharens, the Bashirs, the Teleutes, and the Jakutes, who are taken together at 1,800,000.

4th, *The Caucasians*, which comprehend the Ischerkessens, the Awcheses, the Lesghies, the Ossets, and Kistenses, estimated at 1,300,000.

5th, *Monguls*. Under this head are comprehended the Monguls proper, the Calmucks, the Buritens, and the Kuriles, supposed to amount to 350,000 only.

6th, *The Mandshurs*, in two branches, viz. Tungusens and Lamutes, whose numbers do not exceed 80,000.

7th, *Polar People*, comprehending Samoiedes, Korjacks, Ostjacks, Kamschats, and some smaller tribes, whose whole numbers are not more than 300,000.

8th, *The Colonists*. These include the various foreigners established in the empire with peculiar rights. The Jews amount to about 500,000; the Germans to 250,000; and the other Europeans and Asiatics to about 750,000; making together, under this head, 1,500,000.

The comparative religious classes in the Russian dominions have been recently stated as follow:

Population. The increase of population in Russia appears to have been equal to that of any other European country. The accounts were very imperfectly kept before the year 1796, as neither the females nor the privileged classes were noticed. By estimates, founded upon the return of taxable males, the inhabitants were calculated to have been, in 1723, 11,736,676; in 1743, 13,653,191; in 1763, 17,886,139; and in 1783, 25,482,214.

The *Memoirs* of the Academy of Petersburg give the population of the following years till 1805, thus:

Year.	Population.
In 1800 .....	33,159,860
1801 .....	34,043,357
1802 .....	34,893,828
1803 .....	35,134,177
1804 .....	36,043,483

In these accounts, the inhabitants of Moscow and Petersburg, the military and their families, and the wandering tribes, amounting to 2,900,000 persons, were not included. With the addition of those classes, the result of the calculation gave, as the whole number of inhabitants, 41,253,483.

The following Table is formed from the reports published by the Synod (which, however, includes only the members of the Orthodox Greek church), and shows the rate of the progressive increase of the population, as far as relates to that most numerous proportion of the people.

	1806.	1810.	1816.	1820.
Marriages	299,057	320,389	329,683	317,805†
Births	1,361,286	1,374,926	1,457,606	1,570,399‡
Deaths	818,585	903,380	820,333	917,680§
Deaths of Persons above 100 years old	293	350	689	807

\* See Kraft, *Sur la Surface Geometrique de la Russie*. *Novis Act. Petersb.* T. I. p. 389—400.

† It appears that the marriages in 1820 were fewer by 22,470 than in the year 1819.

‡ The births of 1820 exceeded those of 1819 by 48,265.

§ The deaths of 1820 were fewer than those of 1819 by 1429.

## RUSSIAN EMPIRE.

Russian Empire.	Orthodox Greek Church,	40,351,000	
	Catholics and United Greeks,	5,990,000	
	Lutherans,	2,400,000	
	Reformed or Calvinists,	82,800	
	Armenians,	63,000	
	Hernhuters,	9,200	
	Mennonites,	6,000	
	Christians,		48,902,000
	Mahomedans,		3,100,000
	Jews,		500,000
	Worshippers of the Grand Lama,		300,000
	Schamans or Heathens,		600,000
			<hr/> 53,402,000

The people of Great and Little Russia, the Cossacks, the Greeks, Arnauts, Walachians, Moldavians, and Bulgarians, adhere to the Greek church. The Catholics are chiefly in Poland and Lithuania, and among the colonists. The Lutherans are to be found mostly in Finland, Courland, and Esthonia, and among the German colonists. The Armenians are mostly in the southern part of the Asiatic division of Russia, in the vicinity of Astrachan. The Calvinists, Hernhuters, Mennonites, are all colonists, except a few in Poland. Tartary contains chiefly Mahomedans. Schamanism or idolatry is practised by the Samoiedes and other Polar tribes.

All religious sects, whether Christians or others, enjoy equal civil rights; and the same protection in the exercise of their various modes of devotion. The predominant party, the Greek church, possess about 70,000 places of worship, which are served by about 160,000 secular clergy. There are 480 monasteries, and 156 nunneries, under the direction of the regular clergy. The whole are governed by a Consistory, of which the Emperor is perpetual president, and which is divided into three departments; and these again into thirty-six sections or dioceses. The learning of the inferior clergy is very inconsiderable; many of them can merely repeat by rote a few established prayers, can scarcely read, and much less write. They are allowed to marry once, but not after becoming widowers. Their sons must all be devoted to the ecclesiastical profession. They are generally paid small stipends by the government; but some few of them enjoy landed property attached to their benefices. A few men of learning are to be found among the higher ranks of the clergy; but their number and acquirements have never been very distinguished.

The Catholic church, governed by a Consistory, comprehends one archbishopric, six bishoprics, and about forty religious establishments belonging to the several orders of Benedictines, Franciscans, Carmelites, Bernardines, and Trinitarians.

The Lutherans, established in Finland, in Courland, and Livonia, are under the superintendence of their respective Consistories, each of which has a bishop as their president.

The other religious Christian denominations are rather voluntary associations, recognized by the state, than, properly speaking, established ecclesiastical communities.

Few of the Mahomedans are very rigid in their

adherence to the regulations of their prophet. They have colleges for education; several mullahs, and two muftis. The mufti of Ufa enjoys a stipend of 1500 roubles from the crown, and has two mullahs in Casan. The mufti of Taurus has joined with him a cadî, an effendi, and five ulemas, who regulate religious affairs, and administer the laws in that province.

The worshippers of the Grand Lama have their principal religious establishment at Darsan, in the province of Udinsk. Their priests are numerous, and, in the province of Irkurzk alone, are said to be near 300, where they are very successful in making converts among the wandering tribes.

The inhabitants of Russia are divided into the following classes or ranks; for though all offices are equally open to every description of subjects, yet exclusive privileges are enjoyed by some numerous bodies.

The Nobles in Russia, though distinguished by the several titles of prince, count, or baron, are all upon an equal footing, and enjoy equal privileges. Their persons and lands are freed from taxation; they are exempted from the recruiting ballot; and are not subject to bodily penalties. These exemptions are, however, more apparent than real; for though their lands and persons are not taxable, yet a capitation tax, at the will of the government, may be imposed on their slaves, who form the most valuable part of their possessions. Though not in person compelled to serve in the army, yet they are bound to furnish from their slaves a number of recruits in proportion to the demands of the service. In some of the more recently acquired provinces, such as Livonia, Esthonia, and in Poland, the nobles have, or rather exercise other privileges, extending even to the power of life and death, over their vassals; but these powers arise from custom and general acquiescence much more than from the existing law.

The Clergy are exempt from taxation, and from corporal punishment; which privileges are extended to each eldest son, who must, however, though his father is excused, take the risk of being called upon for military service.

The Citizens are divided into three guilds or classes, according to the amount of capital they possess; and have some most whimsical privileges proportioned to their rank. Those of the first rank, with a capital of from 10,000 to 50,000 roubles, may carry on home or foreign trade; may be owners of ships; may drive a carriage with two horses; and are exempt from corporal punishment. The members of the second guild, possessing a capital of from 5000 to 10,000 roubles, can only carry on home trade, but enjoy all the other rights of the first guild. The members of the third guild must enjoy a capital between 1000 and 5000 roubles; they may carry on retail trades, be proprietors of barges and boats, keep taverns, and drive one horse, though not in a coach; but are not exempt from corporal punishments. Besides these there are the foreign and designated citizens. In this class is comprehended each person who has twice served any civic office; learned men and artists who can produce

Russian Empire.

Nobles.

Clergy.

Citizens.

Russian Empire.

academic testimonials ; bankers who possess capitals from 100,000 to 200,000 roubles ; wholesale dealers, that keep no shops, and shipowners, that use the sea. These may harness two or four horses to a coach ; may possess country houses and gardens ; may own ships ; and are exempt from bodily penalties. None of the trading classes are exempt from the military conscription ; but they are allowed to procure substitutes.

Peasants.

The next class is that of the Peasants or free inhabitants of the country. In this rank are included, 1st, The ancient race of proprietors who cultivate their own lands, but do not enjoy the right of possessing slaves. The males of this description amount to about 1,150,000. 2d, The Tartars, the Bashirs, and several other races, less numerous, to the south of Siberia, who are all proprietors of the lands they cultivate. 3d, The peasants of Finland. Since the acquisition of New Finland, the privileges enjoyed by the peasants of that country, under the Swedish government, have been continued and confirmed to them ; and the same rights granted to those of Old Finland, where all are now either proprietors or renters. 4th, The colonists, consisting of foreign families of agriculturists, who are proprietors of the lands they cultivate, and whose number is about 65,000. 5th, The military colonists. These are soldiers who, after having served a prescribed period, have had land given to them, and a capital sufficient to cultivate it, in the southern provinces. And lastly, The free cultivators, a new class, founded by the present Emperor in 1803. They comprehend several villages, which have been liberated as an experiment. The number of individuals in 1810 was 13,757, since which period they have rapidly increased, and are said now to be near 20,000.

Serfs.

The class next below these is that of the Serfs. They are chiefly peasants on the Crown lands, or of the province of Livonia. The first of these, the Crown peasants, amount to near 12,000,000, some of whom labour in the fields, the others in the mines and manufactories. The lot of this class seems to be placed on the confines betwixt liberty and slavery. They may rise to the rank of citizens, they may acquire property, they enjoy the protec-

tion of the laws ; and, under some restrictions, may quit their residences to obtain employment for a limited time ; but they are liable to be hired to the service of the mines, or to be sold. Although the Empress Catherine rarely gave these peasants away as presents to favourites, and the present Emperor has never done so, yet there is no legal security against the practice ; and consequently their condition is scarcely less precarious than it was formerly. The peasants of Livonia, amounting to about 560,000, were slaves until the year 1804, when they first obtained the rights of serfs. They are now subject to some peculiar claims, but those claims are fixed, and they cannot be removed from the soil without their own consent.

The last and most numerous class is that of the Slaves. These amounted, in 1782, to 6,678,000 males, and at present are estimated to include 23,000,000 persons. They are in law considered as *things*, not as persons ; may be bought, sold, or exchanged, with no more restrictions than are enacted in dealing for cattle ; and have no other protection against their masters than what is created by a regard to their pecuniary interest. They belong to the nobles, or to such civil or military officers as have acquired the right of possessing them. They are divided into agricultural, mining, manufacturing, or domestic slaves, and have their condition only improved when drawn for military service.

The accounts of the agricultural and manufacturing productions of Russia are fully detailed in the article of the *Encyclopædia* already mentioned. They have undergone very few alterations in their nature since that article was written ; and, consequently, only that their amount has increased with the increase of population and the extension of territory, no other notice seems here to be required beyond the value of the imports and exports at different periods.

The following Table exhibits a view of the Imports into, and Exports from, the whole of the Russian dominions, by sea and by land, in bank assignation roubles, estimated at four francs each, at several periods :

Year.	Imports.	Exports.	Together.	Value in Pounds Sterling.
1797	36,980,111	54,601,368	91,581,479	15,263,570
1802	56,330,094	63,277,759	119,607,853	19,934,642
1803	55,557,675	67,148,643	122,706,318	20,451,053
1805	55,529,118	72,434,095	127,963,213	21,277,152
1819	167,599,003	210,589,310	378,188,310	66,531,235

The chief exports are corn, hemp, tallow, flax, flax-seed, iron, furs, linen goods, live cattle, timber, and potash. The principal imports are cotton and woollen goods, wines, dyers' drugs, raw silk, cotton wool, tea, sugar, coffee, salt, silk goods, fruit, and foreign silver coin.

Government.

The Government of Russia is an absolute hereditary monarchy, in which the Emperor is the sole framer of the laws ; but, as in other absolute

monarchies, the exercise of power is tempered and somewhat moderated by the rights and privileges to which many bodies in different provinces have, by long established usage, such claims as would be dangerous to the monarch to infringe. In the administration of the government, there is an uniformity preserved throughout all the several provinces, and in the different branches into which the executive power is divided. The Emperor, through

Russian Empire.

Russian Empire.

the directing senate, issues his ukases or laws to the Governors of the several provinces; which laws are executed by a Board, divided into sections, of which they are presidents. Besides the civil, there is a military governor in each department, to whom alone the affairs of the army are intrusted. There are deviations from this regularity of system among some tribes of Cossacks, who are ruled by their hereditary chiefs, and among the ruder classes. The ministers are appointed to different branches, denominated Foreign Affairs, War, Marine, Interior, Instruction, Finance, Justice, Police, Agriculture, and Ecclesiastical.

Law.

The Civil and Criminal codes of Russia are very imperfect, notwithstanding the efforts directed towards its improvement by the Empress Catherine, and the more practical, but unfinished attempt of the present Emperor. In the cities, two burgo-masters and four counsellors; and in the country, one justice, with two noble and two plebeian proprietors, form tribunals of the first instance. From these, appeals may be made to higher courts in the several provinces; and from them again to the supreme tribunals at St Petersburg or Moscow. Among the less civilized people, great deviations from this system are still indulged; and their chiefs exercise an hereditary power in civil as well as in criminal matters, over their several tribes. A kind of Court of Conscience exists in most places, which hears verbal complaints; acts as arbiters in differences about smaller matters; and exercises power in behalf of minors and imbeciles.

Finances.

The Finances of the Russian empire are not submitted to general inspection with the same freedom, nor with the same accuracy, as is now practised by most other governments. The great depreciation experienced in the paper currency creates some difficulty in ascertaining the amount of the income, expenditure, and national debt. Besides the payments in money, so many personal services and other benefits are derived to the crown, that the bare produce of the taxes falls considerably short of the effective revenue which is extracted by the government. The chief taxes are the capitation-tax of two roubles from each peasant, and five from each burgher; the property-tax of  $1\frac{3}{4}$  per cent. on the capital of the traders; and the duties on the importation of foreign goods. The other material sources of revenue are, the monopoly of distilled corn spirits; the profits of the coinage, of postage, and of stamped paper; and the sale of wood from the annual cuttings of the royal forests. These several branches have been estimated to have afforded, in the year 1820, about thirteen or fourteen millions Sterling, including the kingdom of Poland. The expences of the state, for many years, exceeded the income; and thus the public debt has been constantly increasing; but, it is said, the revenue now equals, or rather exceeds the expenditure. The national debt is supposed to amount to 1,000,000,000 roubles, or about L. 160,000,000 Sterling. One-half of this is believed to consist in the government paper roubles, which have been issued at a gradually increasing depreciation. The other half, or funded debt, is principally owing to foreigners, and the

interest is paid to them in silver money. This state of debt, for so extensive and so numerous peopled a country, may not appear very heavy; but in Russia, there is only paper money in circulation, and the constant drain to pay the interest of the debt in the precious metals, makes the difficulty of returning to a metallic currency almost insurmountable. The project of a sinking fund was adopted in 1817, but it has hitherto made but a slight progress in redeeming the debt, or in diminishing the quantity of circulating paper; which is not at the present period worth one-fourth of its nominal value.

The increase of the Russian army has far exceeded what has been experienced in either the territory, the population, or the revenue of the empire.

Czar Peter I. in 1687 had of regular troops	10,000
Emperor Peter I. in 1724 .....	108,350
Empress Elizabeth in 1747 .....	162,750
Empress Catherine in 1771 .....	198,107
————— in 1786 .....	263,662
Emperor Paul in 1800 .....	368,715
Emperor Alexander in 1805 .....	428,287
————— in 1820 .....	989,117

At the last of these periods the land force was composed of the following descriptions of troops:

	Men.
189 regiments and 565 battalions infantry	613,722
76 regiments and 563 squadrons cavalry	118,141
30 battalions artillery.....	47,088
Extra corps .....	27,632
Irregular troops (horse and foot).....	105,534
Garrison troops .....	77,000
	<hr/>
	989,117

Besides this prodigious force, a national guard, or militia, is organised in all parts of the empire, except in Siberia and the two northern European provinces. The expence of this vast force is very small; the articles for their equipment, provisioning, and arming, being of the cheapest and coarsest kind; and as the recruits are procured by ballot, and the pay of officers and men is low, the whole expence of the establishment is only 20,000,000 roubles, or about L. 3,000,000 Sterling. The institutions for military education are fully commensurate to the extent of the force. In the Cadets-house at Petersburg are 1000 youths; and the whole number in the empire, under appropriate instruction for the military profession, amount to nearly 3000.

The navy of Russia has been neglected; and although the present force is equal to what existed in 1813, yet its character is much inferior, as many of the ships are become old. Very little timber of the best quality is to be found in the Russian territory; but every other article, required for a navy, is abundantly and cheaply supplied from domestic sources.

The fleet consists of 32 ships of the line, 18 frigates, 6 cutters, 7 brigs, 25 floating batteries, 121 gun-boats, and numerous armed small craft. This force is divided between the Baltic, the Caspian, and the Black Seas. The whole number of officers,

Russian Empire.

Naval Force.

European Russia.

seamen, and marines, with which the fleet is manned, is about 32,000, who are obtained by ballot from the seafaring people of the maritime provinces. The naval ports are at Cronstadt, Revel, Sweaborg, and Rotschensalm, on the Baltic; at Archangel, on the White Sea; at Nikolajew, Sewastopol, Taganrog, and Cherson, on the Black Sea; and at Astrachan, on the Caspian.

Having thus given a view of the general condition and circumstances of the Russian empire, in those respects in which alterations have taken place since the article in the *Encyclopædia* was written; we may now proceed to a more particular description of its members and divisions.

EUROPEAN RUSSIA, INCLUDING THE DEPENDENT KINGDOM OF POLAND.

The grand division of European Russia is into six provinces, viz.

Names.	Extent in Square Miles.	Population.
East Sea Province .....	192,064	3,857,107
Great Russia .....	938,929	21,330,279
Little Russia .....	88,256	6,124,585
South or New Russia ...	192,362	2,550,700
West Russia.....	139,712	8,480,022
Poland .....	46,741	2,732,324

It thus appears, that in the whole of European Russia, the density of the population is somewhat less than  $2\frac{1}{4}$  persons to each square mile, or nearly one person to 282 English statute acres.

The East Sea province is divided into the following governments, viz.

Names.	Extent in Square Miles.	Population.
Petersburg .....	18,090	808,512
Finland .....	134,444	1,346,139
Esthonia .....	6,890	396,032
Livonia .....	20,110	737,734
Courland .....	9,544	568,690

The inhabitants in this province are nearly one to twenty acres of land. The principal cities in the government of Petersburg are, Petersburg, one of the capitals of the empire, with 300,000 inhabitants; Kronstadt, with 35,000; Narva, with 3800. In Finland are Helsingfors, with 8000 inhabitants; Abo, with 11,300; Uleaborg, with 3350; and Wiborg, with 3200. The chief city of Esthonia is Revel, with 15,000 inhabitants. The cities of Livonia are Riga, with 30,000; Dorpat, with 6000; and Pernau, with 2500. The only city of note, in Courland, is Mitau, containing 12,000 inhabitants. No other places than those here noticed, in the East Sea province, contain so many as 2000 inhabitants.

The province of Great Russia is divided into 19 governments, whose names, extent, and population, are as follows:

European Russia.

Names.	Extent in Square Miles.	Population.
Moscow .....	10,500	1,289,823
Smolensko .....	22,088	1,297,055
Pskow, or Pleskow.....	22,293	783,945
Novogorod .....	54,997	960,000
Olonez .....	80,789	352,904
Archangel .....	346,133	162,666
Wologda .....	163,712	802,178
Kostroma .....	38,570	1,422,700
Nishegorod .....	20,501	1,349,508
Wolodimir .....	18,669	1,306,046
Tula .....	11,904	1,093,721
Kaluga .....	12,736	1,159,600
Twer .....	24,213	1,233,358
Jaroslaw .....	14,528	1,022,991
Kurst .....	14,954	1,611,109

Riäsan .....	14,553	1,270,291
Tambow .....	22,869	1,391,400
Woronesh.....	32,487	1,436,357

The inhabitants in this province are nearly one to twenty-four acres of land. The chief cities in the government of Moscow are, first, Moscow, one of the capitals of the empire, nearly the whole of which was destroyed by the fire in 1812, when the French troops were in possession of it. It has been since rebuilt in a great part, as far as regards the dwellings of individuals, but many of the public edifices are yet unfinished. There are now rebuilt upwards of 200 churches, more than 9000 houses, and between 6000 and 7000 booths. The number of inhabitants in the summer of 1820 was about 200,000; and in the following winter, when the nobles, with their numerous establishments of domestics and slaves, took up their residence in the city, they are said to have been increased to about 50,000. The city of Kolomna contains 5809 inhabitants, Serpuchow 5540, Wereja 5941, and Moshaisk 3944; all the others have less than 3000 inhabitants. In the government of Smolensko, the city of that name contains about 12,000 persons, Weasma 1150. Pleskow contains 10,000, and Toropez 12,000 inhabitants. Novogorod has 10,000, and Storaja Russa 5250 persons. In the government of Olonez the city of Petrosawodsh has 3285, and Kargapol 3032. The only city in the government of Archangel is of that name, and contains 8000 souls. The population of the city of Wologda amounts to 10,529, and of Oustjug to 12,000. Kostroma contains 8000, Galitzkaja 3300, and Galitsch 6000 inhabitants. Nishegorod has 12,000, and Arsamas 8000 persons. No place in the government of Wolodimir contains 2000 persons; the capital of the same name has only 1500. Tula or Toola, the chief city of the government of that name, has 30,000 inhabitants, Bjeleu 7000, and Obajew 3200. The city of Kaluga contains 25,000 souls, Borowsk 6000, and Koselsk 3500. In the government of Twer, the city of that name contains about 20,000 people, Stariza 3500, Ostaschkow 6207, Torshok 15,000, Wolotschok 3500, Kalasin 3521, Kashin 3513, and Beshezsk 3120. In Jaroslaw, the city of the name has a po-

European Russia.

pulation of 24,000, Uglitsch 7000, and Rostow 6000. The government of Kurst contains the city of that name, with 20,000 inhabitants, Rylsk with 6000, Sudsha with 7000, Bielgorod with 8000, Korotsha with 4000, and Obojan with 5500. The city of Orel has 20,000 inhabitants, Minsk 6000, Bolchow 14,000, Briansk 5000, Trubtochwsk 3500, Siawsk 5,000 Liwny 6000, and Jelez 8000. The city of Riasan, in the government of that name, contains 5000 souls, Soraisk 4500, and Kasimow 10,000. The government of Tombow contains Tombow, with 15,000 souls, Hoslow with 8000, Lebedjan with 3500, Lipesk with 6400, Kirsanow with 4500, Morshansk with 5500, Shazh with 6500, Temnikow with 4500, and Jelatma with 5800. Woronesh has no city of more than 3000 souls, except the capital of the same name, which contains about 15,000.

The province of Little Russia, composed chiefly of the Ukraine, or the country of the Cossacks, the best peopled of the whole empire, is now divided into four governments, viz.

Names.	Extent in Square Miles.	Population.
Kiew.....	17,557	1,353,800
Slobodsk Ukraine .....	21,717	1,471,000
Tschernigow .....	22,983	1,378,500
Pultowa .....	16,810	1,933,000

The inhabitants are about one to eight acres of land. The city of Kiew, or Kiow, contains about 40,000 inhabitants; the population of no other place in the government reaches beyond 3000. Charkow contains 15,000, Sumy 15,000, Bielopolje 9000, Lebidjan 8970, Achtyrka 12,788, Bogoduchow 6749, Walkj 9286, Smijew 5000, and Isjum 4248 inhabitants. The smaller towns in Slobodsk Ukraine are numerous. In the government of Tschernigow, the city of that name contains 10,000, Neskin 16,000, Gluchow 9000, Nowgorod 8000, Starodub 4000, and Mglin 5077 inhabitants. Pultowa has 10,000, Mirgorod 7437, Lubni 6000, Pereaslavl 6000, Solontonscha 5500, and Krementschuk 8000 inhabitants; besides which, the smaller towns and villages in the government of Pultowa are well peopled.

The province of South Russia, a great part of which has been added to the empire in the course of the eighteenth, and the first ten years of the nineteenth century, is divided into five governments, viz.

Names.	Extent in Square Miles.	Population.
Catherinoslaw .....	29,757	944,994
Cherson .....	25,728	523,600
Taurida .....	43,562	437,428
Bessarabia .....	13,711	310,000
Land of the Don Cossacks.....	77,034	398,103

The inhabitants are about one to forty-nine acres of land. The city of Catherinoslaw contains about 5000 inhabitants; none of the other places more than

2000; and only two reach to that number. The towns in the government of Cherson are almost wholly of very recent foundation. The capital of that name contains 5000 inhabitants, Nicolajew (founded in 1789) 9000, and Jelisawetgrad 12,000. The greater part of the inhabitants of Taurida are of the Tartar race, and of the Mahomedan religion. The population of the cities has been very fluctuating since this district first came under the Russian government. Kaffa or Feodosia, formerly the seat of the Genoese trade, with the countries around the Black Sea, and then stated to have had a population of 40,000, when visited by Dr Clarke, had only 50 families; but in 1820 had increased to more than 4000 persons. Simferopol, a frontier garrison city, has 20,000 inhabitants, of various nations and religions. Baktshisarai contains 5777 persons, mostly Tartars, and Koslow 4410 of the same description. Bessarabia was formerly a part of Moldavia. Akerman, a strongly fortified place, has a population of about 10,000. Ismail, celebrated for its siege, and once containing 40,000 people, is still in ruins, and nearly without inhabitants. The only city among the Don Cossacks is Ischerkask, in a very unhealthy situation, but containing a population of 15,000.

West Russia comprehends those provinces of Poland and Lithuania which have been formed into a component part of the Russian empire. They have been divided into eight governments, viz.

Names.	Extent in Square Miles.	Population.
Wilna .....	23,061	1,328,100
Grodno .....	11,434	842,500
Minsh .....	14,140	914,686
Witebesk .....	23,424	1,135,100
Mohileu .....	19,584	963,400
Wolhynia.....	29,739	1,464,000
Podolia .....	20,224	1,606,400
Bialystock .....	3,370	219,050

The inhabitants are about one to eleven acres of land. The chief cities and their population are, in Wilna, Wilna with 25,000, of whom 12,000 are Jews, and Kieydani, with 5000 inhabitants. In Grodno, the city of that name, with 5000, and Slonem 6000. In Minsh 6000, in Slusk and in Pinsk 4000. In Witebesk, the city of that name, 15,000, Welisk 4700, Dunaburg 4000, and Polozk 3200. The city of Mohileu has 16,000. The cities of Wolhynia are Berdyczeu with 10,000, Zaslow with 4500, Staro Constantino with 4200, Ostrog with 4500, Rowno with 3270, Waldimer with 3126, and Dubno with 5635 inhabitants. In Podolia are the cities of Kamenetz, with 5650 inhabitants, and Mohileu with 7000. The city of Bialystock contains 3350 inhabitants; and no other place of that government 2000.

The ancient kingdom of Poland has, by successive divisions, been reduced to a small territory, when compared with its former extent. A description of the Duchy of Posen, a part of it, is to be found in this work, under the head of Prussia. Galicia is united to Austria; part is included in the present province of West Russia; and a very small portion, con-

European  
Russia.

taining the city of Cracow, and the surrounding district, is formed into an independent republic. The part now called the kingdom of Poland is, properly speaking, a Russian viceroyalty. It has, indeed, been permitted to retain some of its ancient forms and institutions; but it is effectively, at present, a mere province of the Russian empire, and in that view we must now consider it.

The grand divisions are into eight Waywodeships, and these are again subdivided into Obwodeships.

Name of Waywodeship.	Extent in Square Miles.	Population in 1819.	Capitals and their Inhabitants.
Massovia ...	6858	481,000	Warsaw 98,000
Kalitch.....	6862	512,000	Kalitch 7,310
Cracow .....	4500	445,000	Kielce 5,000
Sandomir...	5982	432,000	Radom 1,500
Lublin .....	6657	490,000	Lublin 10,300
Polachia ....	4864	286,000	Siedlec 2,145
Augustow	6870	335,000	Suwalki 3,000
Plock .....	6635	364,000	Plock 6,000

The inhabitants are one to about nine acres of land.

Poland is generally a level country, but towards the south is more undulating, and some of the hills rise to the height of 2000 feet above the level of the sea. It is well supplied with running streams. To the north of the Vistula and the Bug, the soil is for the most part sandy, but generally fertile. In the south, the soil is a rich vegetable mould, intermixed with marshes and morasses. The climate is colder in the winter than in the same latitude in Germany and France. The productions are, corn of all kinds, hemp, flax, hops, tobacco, wood, fruit, cattle, abundance of game, river fish, honey, and wax. The minerals are copper, lead, iron, and calamine. There is much marble, alabaster, and limestone; and in some parts salt, sulphur, saltpetre, and coal. The manufacturing labour is chiefly destined to provide clothing, and the most homely articles for domestic use. The Jews are the chief traders, manufacturers, and innkeepers; and their dwellings, in the towns and villages, are far better than those of the clergy, or even the lower nobility.

The inhabitants have increased at an extraordinary rate since the return of tranquillity. The difference between the year 1815 and 1819 appears to be 708,400 individuals, many of whom are German colonists. The number of Jews in 1819 was 212,944. All religious professions enjoy equal rights. The Roman Catholic is the predominant sect; their hierarchy consists of an archbishop and five bishops. There is a Unitarian bishop of the Greek ritual, who presides over 200 churches. The Lutherans are about 150,000, who have a consistory and superintendent. The Calvinists are about 6000. Besides these are several smaller Christian sects, and more than 100 families of Mahomedans. The nobility are very numerous, comprehending more than 60,000 families. They are distinguished by different titles, but have none of the privileges of rank, unless they possess property. Many of them are

European  
Russia.

very poor, but about 100 enjoy very extensive estates. Some restrictions in the use of titles have been recently introduced, which prevent those from assuming them who do not possess a graduated specific amount of income according to the title. Professors of the universities of ten years standing, civil and military officers of the same length of service, and such burghers as make useful discoveries, may be now admitted into the ranks of nobility. The burghers have some civil rights granted in addition to those formerly enjoyed. The peasants have, however, been most benefited by the divisions that have been made of Poland. Under the ancient system, this numerous class of persons had neither property nor rights; and their common proverb, "We have nothing but what we drink," is sufficiently descriptive of their low condition, and their habitual intemperance. They have now acquired personal freedom, and the right of holding landed property. To this extension of freedom may, in some measure, be attributed the recent increase of inhabitants; as many of the German emigrants would not have availed themselves of the greater fertility of the Polish soil, whilst the old slavish degradation of the peasants was continued.

The present constitution of Poland is a limited monarchy. The Emperor nominates the King, who has the sole executive power. The legislature is divided into two chambers. The upper, or senate, consists of thirty members, nominated for life by the king; of whom ten are bishops, or clergy (approved by the Pope), ten are Waywodes, and the other ten Castellans, or Magnates. The lower house consists of sixty members, who must have attained 40 years. They are chosen for nine years, but every third year the retirement of one-third of them is determined by lot. They are elected by the provincial assemblies of the nobles, where there are at least 600 qualified electors. A commissioner is appointed for civil affairs, another for criminal matters, and a third for finances. These three persons, with the ministers who sit in the assembly, not by election, but of right, are the only members permitted to speak, and all the others give their votes in silence. The assemblies are convened every other year, and sit only fourteen days to dispatch such business as is laid before them. They have no power to initiate a law, nor the right to exercise any inquisitorial functions. The assent of the upper chamber is not indispensable for promulgating a new law, if it be approved by the lower chamber, on the recommendation of the king.

The Poles had formerly few or no written laws; but in the year 1257, Boleslau the Fifth introduced the use of the law-book of Magdeburg, which has been continued ever since as the compendium of civil and criminal law. The local courts consist of the landowners; the next higher court extends over each Waywodeship, and from them there is a court of general appeal. A new code of laws has been drawn up, but is not yet in practice.

The income of Poland is about L. 850,000 Sterling, derived from a hearth and capitation-tax; from stamps, customs, lotteries, and posting. The civil list is about L. 170,000; one-half of which arises from the

Constitution  
of Govern-  
ment.

Finances.

Classes of  
Inhabitants.

Asiatic  
Russia.

national domains, the other is taken from the public treasury. The debts of the state, including old and new, amount to 200,000 Polish gulden. The expenses are not accurately known, as no budget has yet been made public since the introduction of the new constitution, and the accession of the Russian Imperial family.

Army.

The army consists of 30,000 infantry and 20,000 cavalry, of whom the royal guards form a body of 12,000; but the military organization is not yet completed. Every Pole, without exception of rank or religion, is, by the law, a soldier from the age of twenty to thirty; but, in practice, numerous exceptions to the general rule are allowed. The muskets are supplied from a manufactory at Kouskie, but the cannon, as well as cloths for uniforms, must be drawn from other countries. There is a scarcity of gunpowder, although saltpetre is abundant. \*

## ASIATIC RUSSIA.

The dominion of Russia comprehends the whole of Northern Asia, and extends from longitude 37° 14' to 190° 22' east from London; and from latitude 38° 58' to 78° 2' north. This vast dominion is calculated to be spread over  $\frac{27}{100}$ ths of the land of the globe, and to be rather more than one-third of the surface of the whole of the continental portions of it.

Face of the  
Country.

The eastern division of the Asiatic Russian territory, from the river Jenisy, or Yenesii, has, on its southern and eastern parts, vast mountain ranges; and on its interior there are several chains that run to the Arctic Ocean in vast masses. It is covered with woods, large lakes, or extensive elevated plains, and terminates, towards the shores of the Frozen Ocean, in vast fields of eternal ice. The division to the westward has, indeed, some ranges of mountains, especially the Altaian chain on the south, the Ural range on the west, and the ridge of Caucasus on the south-west, with their various projecting branches; but taken as a whole, it may be described as a vast level plain, partially watered, but by its climate and soil, ill adapted for the increase or the comfort of human beings. The soil to the westward of the Ural mountains is generally very fertile, and produces abundant returns of corn, but to the eastward it is barren, cold, and scarcely exhibits any symptoms of vegetation.

Steppes.

Although Russia in Asia is in part surrounded by, and in some parts covered with mountains, yet there are several barren plains of great extent, usually denominated *Steppes*. The most remarkable of these are, the Kirgissch Steppe, between the Irtish and the Orenburg boundary line. It is a very dry and barren district, with some lakes, whose water is saline. The few rivers have copious streams in the spring from the melted snows, but in summer become dried up. The Wolgau Kalmuck Steppe, between the Ural and the Wolga, extending from the Caspian Sea to Samara, is of the same description. The Kuman Steppe, extending from the Caspian

Sea to the Don and the Wolga, resembles a lake recently dried up; being formed of a mixture of sand and clay with an undulating surface, intermixed with salt lakes, and utterly destitute of vegetation. The other steppes, with slight varieties of character, are that of Terek, between the rivers Terek and Kuma, touching on the Caspian Sea; of Kuban, extending from Kuban to the Manitsch and the lake of Bolschei; of Jettish to the eastward of the Ural; of Ischim on both sides the river of that name, between Tobol and the Irtish; and the Baraba, between the Irtish and the Ob. To these may be added the Arctic plain, between the 67th degree of latitude and the Frozen Ocean, whose whole surface is little more than morasses, mixed with rocks, and bound up by frost betwixt ten and eleven months in the year. These extensive plains are sometimes passed by the wandering tribes, who find subsistence on the less sterile spots which are to be met with on the banks of the rivers that bound them.

Asiatic  
Russia.

The rivers of Asiatic Russia that empty themselves into the Arctic Sea, are among the most considerable of the ancient world. The most remarkable of these are, 1st, The Ob, whose course is 2800 miles in length, during which it receives the great rivers, the Tom, the Kek, the Irtish (which, before the junction, runs 2500 miles, and takes into its stream the waters of the Ischim, the Tobol, and many other rivers), the Tyda, and all their tributary streams. 2d, The Yenesii, or Jenisy, which has a course of 2000 miles, with fewer sinuosities than are usually observed in other great rivers. It receives the waters of fourteen large streams and all their tributary collections. 3d, The Piasana, whose course is 300 miles. 4th, The Taimurskoe, a short stream issuing from a lake of the same name, in latitude 70°. 5th, The Khatanga, which empties itself into the bay of Khatangaskoi, on the Frozen Ocean. 6th, The Anabara, an Arctic stream. 7th, The Olenk, whose waters only become considerable after entering the Arctic circle. 8th, The Lena, one of the largest of the Asiatic Russian rivers. It rises in the Backal mountains to the north of China, in latitude 52° 30', and empties itself into the ocean in latitude 70° 40', and longitude 164° 26', after receiving the waters of fourteen large rivers and their numerous tributary streams. 9th, The Omoloi. 10th, The Jana. 11th, The Indigirka. 12th, The Alazeja. 13th, Kolyma. 14th, The Tchauna; and, 15th, The Amgonia. The streams whose courses have been traced to fall into the sea of Kamtschatka, between Asia and America, are the Anadyr, the Katirka, the Kamtschatka, the Penshena, the Tilcha, the Ischiga, the Tauna, the Okhota, the Uda, the Argun, and the Shilka. The Black Sea receives from Russian Asia the great rivers Kooban and Rioni, with their tributary waters, and several smaller streams which arise on the western sides of the mountains of Caucasus. The rivers which discharge themselves into the Caspian Sea are, 1st, The Wolga, which comes

\* The best recent works on Poland are, *Guide du Voyageur en Pologne*, Varsovie, 1820; *Polen Staatsveränderungen und Letztere Verwaltung*, von F. Jäkel, Wien, 1819.

Asiatic  
Russia.

out of the centre of European Russia, and forms the principal means of internal water communication between the European and Asiatic portions of the empire. Its course is upwards of 2500 miles in length, during the progress of which it receives the streams of fourteen large, and of a vast number of smaller rivers. 2d, The Kuma, rising in the northern Caucasus. 3d, The Teret, a mountain torrent, nearly dry in summer. 4th, The Akhracan. 5th, The Sulach, both rivers only abundant in the spring, and nearly dry in summer. 6th, The Kur, a stream formed by a union of several others in Armenia and Georgia, and navigable from Teflis. 7th, The Ural, rising in the Uralian range of mountains, and forming a course of nearly 1400 miles, during which it receives the waters of six large, and numerous smaller rivers. 8th, The Jemba, a river coming from the north, and running about 450 miles.

Lakes.

The lakes in Russian Asia are very numerous, and some of them very extensive. One of the largest is the Baikil in Siberia, between latitude 52° and 55°, and longitude 104° 26', and 109° 56', extending over 11,180 square miles. Its water is clear and bright, the depth varies from 18 to 480 feet. It is covered with ice from the middle of December till April. The river Angara, which runs to the Jenisy, issues from it. It receives the waters of several streams which come either from the Chinese territory or its vicinity. The lakes next in extent are the Tchani and the Piasenskoe, both in the government of Tomsk. Almost every province has one or more lakes, several of which are of salt water, on whose banks a natural crystallization prepares culinary salt for the use of the inhabitants.

Agricultural  
Products.

The agriculture necessarily varies both in its practices and its productions in countries so extensive as those we are sketching. By an harvest table before us, it appears that the winter corn (wheat and rye) does not yield, on an average, more than three and a half for one grain that is sowed; and the summer corn (barley and oats) not much more than two and a half for one. The increase of production seems to be about as progressive as the increase of population. By a return of the whole produce of the harvest of 1808, it appears that the whole quantity raised was 43,424,966 tschetwerts on 29,854,622 quarters; from which, if two-sevenths be allowed for seed, there will remain for subsistence 21,324,760 quarters. Taking the whole population at 10,164,000, and allowing for 1,164,000 who eat no bread, there will have been about 18 bushels of corn for each individual. In many parts the goats and sheep, and in some the oxen, furnish food for the inhabitants; whilst aid for the subsistence of others is afforded from the fish of the seas, lakes, and rivers.

The mines of Russian Asia are by far more productive than those of any other portion of the em-

pire; as from them is extracted the whole of the gold, silver, and lead, nine-tenths of the copper, and eleven-twelfths of the iron which is brought into use. By the latest returns the whole produce was as follows:

Asiatic  
Russia.

Gold,	17,940 ounces.
Silver,	540,000 ounces.
Copper,	3,360 tons.*
Lead,	900 tons.
Bar-iron,	1,680,000 tons.
Vitriol,	5,184 tons.
Rock Salt,	14,675 quintals.

According to the work from which these statements are taken, † the culinary salt, annually prepared in Asiatic Russia, is 830,000 quintals.

The fishery is a considerable branch of industry, Fisheries, and furnishes articles for exportation. The crown &c. lets to farm its fishing on the Caspian Sea to some companies in Astrachan. The produce consists chiefly of the flesh and the roe of the sturgeon, and of the skins of seals. In 1815 there were employed 1847 boats, and 6688 men in this fishing. The Wolga and some other rivers yield prodigious quantities of excellent fish. The whole value of this object is estimated at 8,000,000 silver roubles, or more than L. 1,500,000 Sterling. The chase is a business of much importance, both on account of the food which it supplies for subsistence, of the peltry which furnishes for winter garments, as well as articles for an export trade. The productions of the forests not only supply the article of fuel which the severe climate requires, but furnish large quantities both for building and firing to other nations. Most of the forests belong to the crown: those of Asia, exclusive of Siberia, are calculated to cover 43,500,000 desjatines, or nearly 100,000,000 English statute acres.

The manufactures are very few, and very homely. The best article produced is the leather. Some linen is made of a coarse kind. In Casan and Astrachan there are establishments for making cotton, woollen, and silk goods, and for various kinds of hardware and glass. The breweries, but especially the distilleries, are more numerous than any other manufacturing objects. Making corn spirits is a royal monopoly, but in some of the Asiatic cities it is let to farm by the government. The chief commerce is internal between the several provinces whose productions are most different from each other. There is an increasing transit trade between China, India, and Europe, and custom-houses are established on the frontiers, at which the tolls are collected. We have no statements of the extent of this trade that are sufficiently accurate to create much confidence. The value of the goods, which in 1809 were manifested in the governments of Irtusk and Kiachta, on the Chinese

Manufactures  
and  
Commerce.

\* It appears from a recent intelligent work (Tooke *On High and Low Prices*, Part II.), that the exportation of copper from Russia, which before 1818 was trifling, in that year amounted to 155 tons; in 1819 1419; in 1820 4466; in 1821 5023; and in 1822 3545 tons.

† *Die Wichtigkeit des Russischen Bergbaus*, von Herman.

Asiatic  
Russia.

Divisions.

frontier, was 5,049,138 silver roubles, or about L. 840,000 Sterling, including both exports and imports.

The names and divisions, both military and political, of Russian Asia, are at present the following:

*Kingdom of Casan.*

	Governments.	Extent.	Population.	Capitals.
Kingdom of Casan.	Casan .....	22,272	1,138,804	Casan.
	Wiatka .....	47,381	1,265,900	Wiatka.
	Perm .....	127,017	1,232,474	Perm.
	Simbirsk ....	29,910	1,095,145	Simbirsk.
	Pensa.....	16,597	1,044,824	Pensa.

The city of Casan, about five miles from the Wolga, in north latitude  $55^{\circ} 47' 51''$ , and east longitude  $49^{\circ} 26' 41''$ , is an increasing place, with 25,000 inhabitants. In the governor and Archbishop have palaces, and there are some few other good stone buildings. A very wide-spreading conflagration destroyed many hundred houses in 1815, and the new buildings since erected on their site have much improved the appearance of the city, which is now half European and half Asiatic. The city of Wiatka, in latitude  $58^{\circ} 24'$ , and longitude  $50^{\circ} 48'$ , contains 12,000 inhabitants, employed in the trades of corn, tallow, and hemp, and in the manufacture of leather, soap, and some hardware. Most of its productions are conveyed by the Dwina to Archangel. Stobosk, in latitude  $58^{\circ} 30'$ , and longitude  $50^{\circ} 20'$ , has 6000 inhabitants, occupied as those of Wiatka. Perm, in latitude  $58^{\circ} 1' 13''$ , erected into a city in 1780, is built almost wholly of wood, and contains 6000 inhabitants, employed chiefly in trade arising from the copper mines. Soltikumsk, in latitude  $59^{\circ} 39'$ , and longitude  $56^{\circ} 50'$ , supports about 6000 people, chiefly by copper, tin, and gold manufactures. Irbit, in latitude  $57^{\circ} 35'$ , and longitude  $63^{\circ} 26'$ , contains 3600 inhabitants, who depend mainly on the great fairs which are held there, in which the productions of Europe and Asia are exchanged for each other. The sales in the fair have amounted to 6,287,000 roubles; of which 800,000 consisted of cloth, 1,400,000 of Chinese goods, 850,000 of peltry, 9000 of spices, 350,000 of sugar, and 350,000 of linen. Jekaterinburg, in latitude  $56^{\circ} 50' 15''$ , and longitude  $60^{\circ} 56'$ , contains 6000 inhabitants, who subsist on trades dependant on the mines, and arising also from its being on the high road to Siberia. Simbirsk, in latitude  $54^{\circ} 24'$ , and longitude  $49^{\circ} 55''$ , contains 15,000 persons, who find subsistence from several manufactures, from the fishery, and carrying trades on the Wolga, and from the corn, tallow, and hemp of the surrounding districts. Samara, in latitude  $53^{\circ} 53'$ , and longitude  $49^{\circ} 57'$ , contains 3500 inhabitants, who are employed in the fishery on the Wolga, and export by it large quantities of fresh and salted fish, and of caviare, or the roes of the sturgeon. The city of Pensa, in latitude  $53^{\circ} 30'$ , and longitude  $45^{\circ} 44'$ , contains 1697 private dwellings, of which only three are built of stone, and 10,000 inhabitants. There is a cathedral, five stone, and eight wooden churches, and several other public buildings. Its principal

trade consists in leather, linen, soap, and corn; part of which is conveyed to the different markets by land carriage, and part is sent by the small river Sura to the Wolga. Saransk, in latitude  $54^{\circ} 23'$ , and longitude  $44^{\circ} 41'$ , contains 6200 inhabitants.

Asiatic  
Russia.*Kingdom of Astrachan.*

	Governments.	Extent in Square Miles.	Population.	Capitals.
Kingdom of Astrachan.	Saratow ...	91,563	1,305,170	Saratow.
	Astrachan	83,178	200,000	Astrachan.
	Caucasus ...	33,813	130,000	Georgiewsk.
	Orenburg	120,021	1,044,000	Orenburg.

The city of Saratow, in latitude  $51^{\circ} 31' 28''$ , and longitude  $46^{\circ} 6'$ , contains 6500 inhabitants, whose chief dependence is on the produce of the fisheries on the Wolga, and the transit commerce between Eastern and Western Russia, carried on by means of that river. Molsk, in latitude  $52^{\circ} 4'$ , and longitude  $47^{\circ} 37'$ , on the right bank of the Wolga, has 5000 inhabitants; and trades on the river. Kusnezsk, in latitude  $53^{\circ} 7'$ , and longitude  $46^{\circ} 42'$ , has about 5000 inhabitants. Astrachan, in latitude  $46^{\circ} 21' 12''$ , and longitude  $48^{\circ} 8' 17''$ , is situated at the spot where the Wolga begins to form that delta by which, in various branches, it enters the Caspian Sea. It contains several public edifices for government, and for the various religious forms of worship which its Christian, Mahomedan, and Hindoo inhabitants follow. There is a naval arsenal, a seminary for Greek priests, several inferior seminaries for the different classes of the people, and an imperial botanic garden. The inhabitants are about 30,000, who manufacture silks, cottons, leather, soap, linen, and some other articles. The fisheries are considerable, and in 1815 employed 1847 vessels, with 6688 men. The gardens and vineyards are important objects, and produce much fruit, and tolerable wine and vinegar; which are conveyed by the Wolga to the interior of European Russia. Georgiewsk, or St George's, a fortified city, in latitude  $44^{\circ} 4'$ , and longitude  $42^{\circ} 47'$ , contains about 3000 inhabitants, some few of whom are citizens or merchants, but the greater part are Cossacks. Mosdok on the Terek, in latitude  $43^{\circ} 43' 46''$ , and longitude  $27^{\circ} 52' 51''$ , contains 4000 people, who trade by that river with the Caspian Sea. Kislan Cower, on the same river, in latitude  $43^{\circ} 51' 15''$ , and longitude  $46^{\circ} 20'$ , is a rapidly rising place, chiefly from the industry of the Armenians, with 10,000 inhabitants. The city of Orenburg is situated on the river Ural, in latitude  $51^{\circ} 46' 5''$ , and longitude  $55^{\circ} 10' 17''$ , and is the head quarters of the military power, and the seat of the provincial government; it is fortified, the streets paved, and has a good market-place in its centre. It contained in 1820 about 2900 houses, and rather more than 20,000 inhabitants. There are manufactures of cloth, linen, soap, and leather. The chief support of the population is derived from commerce. About half a mile from the city stands the exchange, a large mass of square building, containing 392 shops, in which the productions of Europe and Asia

Asiatic  
Russia.

are exchanged. The building has two gates, by one of which the Europeans enter, and by the other the Asiatics. The sales effected in this place amount to upwards of 1,000,000 roubles annually. The country round it is a complete waste. Ufa, in latitude  $54^{\circ} 42' 45''$ , and longitude  $55^{\circ} 59' 17''$ , has a population of 6000 inhabitants, of whom one-half are Tartars, who carry on considerable trade, and are employed in agriculture and breeding cattle. Troizk, in latitude  $54^{\circ} 10'$ , and longitude  $55^{\circ} 10' 17''$ , is, next to Orenburg, the most considerable trading place, and has like it an exchange, in which are 300 shops.

*Kingdom of Siberia.*

	Government.	Extent in Square Miles.	Population.	Capitals.
Kingdom of Siberia.	Tobolsk ...	532,501	887,186	Tobolsk
	Tomsk .....	1,289,056	500,000	Tomsk
	Irkuzk ....	2,655,660	575,000	Irkuzk

In this statement of the population, the numbers of the wandering tribes, who are very numerous, and some very small, is necessarily an estimate, and not the result of that census which has been taken of the settled inhabitants. The extent of land is thus near 1900 acres to each individual of the population. Each of the governments is divided into circles, in which the capital is denominated a city, though the number of its inhabitants, in many cases, scarcely equal those of the villages in more civilized countries.

The city of Tobolsk, in latitude  $58^{\circ} 12' 30''$ , and longitude  $68^{\circ} 31'$ , was founded, in 1587, at the junction of the rivers Tobolsk and Irtish; and contained, in 1820, 25,000 inhabitants, who are employed in the trade for domestic consumption, as well as in the transit trade between China and Europe. Since a great fire in 1784, which destroyed most of the houses, then built of wood, the buildings have been constructed of stone, and on much better plans than formerly. Tomsk, in latitude  $56^{\circ} 29' 39''$ , and longitude  $85^{\circ} 36' 23''$ , is situated on the navigable river of the same name, at its junction with the Uschaika, on the great road to China. It has few manufactures, but depends principally on transit trade, and on some great fairs, where much business is transacted. Kainsk, in latitude  $55^{\circ} 33'$ , and longitude  $78^{\circ} 40'$ , has 3500 inhabitants, and is the place of a great annual fair. Barnaul, in latitude  $53^{\circ} 20'$ , and longitude  $83^{\circ} 32' 32''$ , has 6000 inhabitants, who chiefly derive their subsistence from the mines in the surrounding district. Korjakow, on the Irtish, has 3500 inhabitants, chiefly employed in mining. Kusnezsk contains 3400, and Krašnoijarsk 3500 inhabitants, employed in mining, and in the transit trade with China. Irkuzk is the seat of the governor of the province, in latitude  $52^{\circ} 16' 41''$ , and longitude  $104^{\circ} 39' 17''$ . It contains 30,000 inhabitants, many of whom are Tartars or Chinese, and others, in their dress and manners, approach nearly to those people. It is the chief seat of the trade with China, and for that of furs, which are brought from the north-east coasts of Asia,

Asiatic  
Russia.

and the north-west shores of America. Okhozsk, in latitude  $59^{\circ} 20' 10''$ , and longitude  $143^{\circ} 18' 17''$ , is the easternmost city of the Russian dominion. It is the chief seat of the American Company, and there are many vessels built here for their trade. The inhabitants are between 2000 and 3000, mostly military men, agents of the company, or ship carpenters. The fishery is productive; but the attempts to grow corn have been hitherto unsuccessful. The other places, though many of them are denominated cities, are of small population. In the circle of Kamschatka, one of the divisions of the government of Irkuzk, there are two places denominated cities, Mishnii and Werchnoi; the former only with 300, and the latter with 200 inhabitants.

*Islands in the Polar and Eastern Oceans.*

In the Polar Ocean are the groups of New Siberia and of the Bear's Island. The first consists of four large and many smaller islands. They are covered with snow the greater part of the year; their surface is generally rocky, and on some of them are marks of volcanoes. They are chiefly remarkable for the bones and teeth of the mammoth, rhinoceros, buffalo, and other animals, which are found upon and beneath the surface of the ground. The search for this ivory first induced the Russians to visit these islands; and an expedition for exploring them was equipped in 1820, which had not returned when the last dispatches to the government were forwarded. These islands do not appear to be inhabited, though marks of human beings have been discovered by the Russians engaged in the fisheries. The Bear's Island group consists of six small islands, with several kinds of plants and shrubs on them, but no trees; although their shores are found to be covered with large drift wood. The southernmost point of these islands is in latitude  $69^{\circ} 5'$ , and they extend to latitude  $76^{\circ} 20'$ . Their longitude is between  $154^{\circ}$  and  $183^{\circ} 50'$  east.

In the Eastern Ocean the islands are thus classed:

1st, The islands of Gevosbewy and Nelken, in Behring's Straits, in latitude  $65^{\circ} 4'$ , with about 400 people.

2d, St Lawrence, latitude  $63^{\circ} 40'$ , and longitude  $190^{\circ} 26'$ , and three smaller islands on the south-east of it.

3d, St Mathew's, in latitude  $60^{\circ}$ , in the sea of Kamtschatka, consisting of three islands, one of which was named by some early British navigators Pinacle Island.

4th, The Prebelow Islands, in latitude  $57^{\circ}$ . Two of them have been named St Paul and St George. The former is about 28 miles long, and 20 broad, and both are well stocked with animals whose furs are valuable.

5th, The Aleutian Islands. This is a chain of islands extending from the peninsula of Kamtschatka to the American peninsula of Alaschka, between  $51^{\circ}$  and  $55^{\circ} 10'$  north latitude, and  $167^{\circ}$  and  $197^{\circ}$  east longitude. (See ALEUTIAN ISLANDS in this Supplement.)

6th, The Kurile Islands. This chain extends from north latitude  $43^{\circ} 48'$  to  $50^{\circ} 56'$ , and from longitude  $145^{\circ} 5'$  to  $156^{\circ} 30'$  east. They are evidently of vol-

American  
Russia.

canic origin. In some of them good water is found, but others are utterly destitute of it. The few inhabitants are of Japanese origin. Many of these islands have hitherto obtained no European names; but nineteen of the most considerable have been named by the Russians.

## Provinces of Caucasus.

Government.		Extent in Square Miles.	Popula- tion.	Capitals.
Provinces of Caucasus.	Grusia .. .. .	26,645	600,000	Teflis.
	Awchasa ....	5,077	56,000	Anakria.
	Tscherkessia	32,547	800,000	Waldikawkas.
	Daghestan ...	9,249	184,000	Derbent.
	Schirwan ...	9,493	120,000	Baku.

Thus it appears there is one human being to 645 acres of land.

Grusia is recently so denominated by the Russians from the river of that name, but is better known by the Asiatic name Curdistan, or the European name Georgia. It is subdivided into the provinces of Imeretus, Mingrelia, and Guria, and further divided into circles, or districts. The greater part of these provinces were wrested from Persia in the war which terminated in 1813; or the authority over the native princes was acquired at different periods. From having been long the seat of bloody and wasting hostilities, the country has become almost depopulated; but, under a settled government, such as it has now acquired, as much of the land is fertile, it has rapidly increased in population and cultivation, and many of the wandering tribes are gradually becoming stationary. The city of Teflis, in latitude  $41^{\circ} 28' 30''$ , and longitude  $44^{\circ} 23'$ , is the capital, containing 18,000 inhabitants, besides the Russian garrison. It is a place of considerable commerce with Turkey, and with Persia, and by the navigable river Kur, is connected with the Caspian Sea. Anakaria, though called a city by the Russians, is rather a military post than a civil or trading place. Waldikawkus is also a military station, considered as the key to the Caucasian provinces, and rapidly increasing. Derbent, in latitude  $42^{\circ} 5' 45''$ , and longitude  $47^{\circ} 45'$ , on the Caspian Sea, contains a population of 4000 persons, mostly Mahomedans, who are employed in manufactures of cotton, silk, carpets, and leather. The vineyards around the city produce excellent wine. Taxki, the capital of one of the ancient princes, or khans, in latitude  $42^{\circ} 59'$ , and longitude  $46^{\circ} 58'$ , contains 10,000 inhabitants, employed in making silk goods, and in agriculture. Baku is a Russian fortress of the first class. In it is the palace built by Shah Abbas. The harbour is the best on the Caspian Sea, from which wheat, maize, wine, silk, opium, salt, saltpetre, and naphtha, are exported.

## AMERICAN RUSSIA.

The claim of Russia to that dominion on the west coast of North America, which is now to be discussed by different powers, is founded on the right of prior discovery. In 1648, as the Russians assert, a

person named Deschneew sailed from the river Kalyma, and passed round Cape Shelatskoi to Kamtschatka. His account of this voyage was generally discredited in Europe, and scarcely engaged any attention in Russia itself; where no measures were taken to verify the narration till the year 1725, when Behrings was equipped for northern discovery, and, in 1723, succeeded in passing through the straits separating Asia from America, which have since borne his name. In that and the following year, with Tschirikoff and Spangberg, he reached the latitude  $67^{\circ} 18'$ , and next year explored the Kurile Islands. In 1730 and 1731, Gwodew and Krupischew made the land of America, in latitude  $66^{\circ}$ , and Behrings himself that part which lies in latitude  $58^{\circ} 28'$ . Captain Cook, in 1778, explored the whole of this coast, as high as latitude  $70^{\circ} 44'$ ; and has since been followed by the other English navigators Clarke, Vancouver, Dixon, Portlock, and Meares; by the Frenchman Peyrouse, and by the Russian Billings. These several officers have given names to the different capes, inlets, and rivers. The Russian government was desirous to appropriate to itself the beneficial trade in furs which this extensive district furnished. With this view the American Company was formed in 1799. It soon established its chief factory on the island Kodjah, and founded several smaller dependant branches along the American shore from latitude  $55^{\circ}$ , and even to Badoga, in latitude  $38^{\circ} 50'$ , in the vicinity of the Spanish settlements. It does not appear, by any accounts that have reached us, how far the government of Russia laid claim to the exclusive right of trading with those countries till the year 1822; when an Ukase was issued, asserting a right, not only to the whole coast from latitude  $51^{\circ}$  northwards, but to the seas which border them, to the extent of 100 leagues from the shores. Notice to this effect has been formally given to the British and United States' ships; and the trade hitherto carried on by them has been prohibited. The British claim the whole coast from latitude  $51^{\circ}$  to  $56^{\circ} 30'$ ; whilst the Americans have some pretensions to portions of it.

Without entering farther into the different views which may be entertained by the several claimants to the dominion of the countries, designated by us as New Albion, New Hanover, New Cornwall, and New Norfolk, we shall consider the territory of Russia as extending from  $56^{\circ} 30'$  to  $71^{\circ}$  north; and from the point of Alaska to Mackenzie's River from west to east; thus extending over  $14^{\circ} 30'$  of latitude, and  $27^{\circ} 40'$  of longitude. Unless we knew the trending of the land between Mackenzie's River and Behring's Straits, which will be ascertained if Captain Parry should succeed in the object of his present voyage, any estimate of its extent can only be an approximation to the truth. The medium calculation would make it extend over 512,000 square miles. The several Russian factories on this coast contain from 800 to 1000 people on the whole, who traffic with the Aborigines for peltry, and direct such of them as have been reduced to obedience, and a kind of civilization, as to the spots which they shall select for hunting. The furs collected here are nearly of the same description as are furnished from Hudson's

American  
Russia.

American Russia || Rutlandshire. Bay. The capital of the company, that conducts the whole Russian operations in America, amounts to 2,747,000 roubles; each share receives a dividend of 156 roubles; and the present value of their actions is 3700 roubles. The Emperor, as protector of the company, receives one-tenth of all the furs for his share. The factories of the company are in general only an assemblage of huts, defended by palisades, and just sufficiently strong to protect the property from any attacks that the tribes of Indians can make. The country, even close to them, remains in a state of nature, except at the southernmost of them, Bodago, in latitude 38° 20', where, under the guns of the fort, about 100 huts are erected, inhabited by Russians and natives, who cultivate corn, potatoes, turnips, and hemp.

The recent voyage of the Russian Captain Kotzebue has thrown much light on the geography of the north-west coast of America, and we hope for still

greater information from the present expedition under Captain Parry.

American Russia || Rutlandshire.

Boundaries, Extent, and Divisions.

RUTLANDSHIRE, an English county, nearly in the centre of the kingdom, and the smallest of all the divisions so denominated. It is bounded by Lincolnshire on the east and north-east, by Leicestershire on the north-west and west, and by Northamptonshire on the south. Its length, from north to south, is sixteen, and its breadth, from east to west, is twelve miles. The square contents are 200 miles, or 128,000 acres. It is divided into five hundreds, and contains two market towns, Uppingham and Okeham, and 49 parishes; being a greater number, in proportion to its extent, than any other county in the kingdom.

Political State.

It gives only one title at present, that of Duke, to the family of Manners; two former peerages, that of Ferrars of Oakham, and Noel of Exton, being extinct. Only two members are returned to the House of Commons from the county, and none from either of the towns. In judicial affairs, it is on the midland circuit of the judges; and in ecclesiastical matters it has formed, since the year 1541, a portion of the bishoprick of Peterborough.

Face of the Country.

The appearance of this small county is pleasing to the traveller. It is much diversified by ranges of moderate hills, running from east to west, in some parts well timbered. Between these ranges of hills the valleys, of about half a mile in breadth, are luxuriant and verdant. The principal vale, called Catmose, is in the centre of the county, having to the north a tract of table land, overlooking the well wooded plains of Leicester, Lincoln, and Nottinghamshire. The eastern part is more diversified; the southern division of it consisting of a beautiful valley, stretching towards Northamptonshire, and the western, bordering on Leicestershire, being abundantly wooded.

Soil and Climate.

The soil on the east and south-east parts is chiefly shallow, resting upon a basis of limestone, composed of clays and loams. The other parts consist principally of a tenacious but fertile loam; but the vale of Catmose enjoys a most fertile soil of good clay, or red loam, or a grateful mixture of both those earths. A peculiarity of the soil is a redness which

generally prevails, and which tinges all the waters of the country.

Mr Parkinson, surveyor for the Board of Agriculture, estimates the land of the county in the following manner, viz.

Pasture land .....	34,861 acres.
Arable land .....	42,536
Wastes .....	30
Woods .....	2,815
Meadows .....	9,356
Commons .....	693
Plantations .....	65
Lakes and ponds .....	44

The woods of this county were far more extensive in former ages than they are at present. The ancient forest of Leafield, and the chase of Beaumont, though now under the plough, once occupied a great portion of the surface. The climate is generally accounted peculiarly soft and healthy; and the elevation is of that medium kind which equally exempts it from the pernicious effects of moist exhalations and cold mountain fogs.

The agriculture, though it has partaken of some Agriculture. modern improvements, is not conducted, upon the whole, in the best manner. In some parts, the reprobated system of two corn crops succeeding a fallow is still continued. In other parts, after a fallow, barley is sown with clover; the clover is mowed two years, or sometimes fed the second year, and then, after one ploughing, the land is sown with wheat. In some cases, on the lighter lands, the four course system of turnips, barley, clover, and wheat, is followed. The wheat of Rutlandshire is highly valued for seed, and much in request in even very distant counties. Nearly two-thirds of the land are tithe free, and in all the late inclosures, provisions to that end have been inserted in the acts of Parliament for effecting them. The cows of Rutlandshire are remarkable for the richness of their milk, though they yield but a small quantity. The rich cheese, commonly known as Stilton, is chiefly

Rutland-  
shire  
||  
Salop.

made in the dairies of this county. As many oxen are brought from the more northern countries, and fattened in Rutlandshire, as are bred within it: the annual number of each is from 2700 to 3000. The sheep are more numerous in proportion than horned cattle. Mr Parkinson calculated them to be about 80,000; consisting of old and new Leicesters, of South-downs, and a few Lincolnshires. It has been remarked, that though the quality of the wool has increased in fineness, the diminution in the weight of the fleeces has of late years more than counterbalanced that advantage.

Rivers and  
Canal.

The small rivulets that water this district run into the two rivers, the Guash, or Wash, which passes through it, or the Walland, which forms its southern boundary. The latter river is navigable only to Stamford, on the confines of Rutlandshire; but is useful in opening a communication with the ocean. A canal has been constructed from Oakham to Mel-

ton Mowbray, by which a supply of coals has been drawn from the mines of Leicestershire.

Rutlandshire is neither a manufacturing nor a mineral district, but depends exclusively on its agriculture. By the returns in 1801, the inhabitants were 16,356; viz. 7978 males, and 8378 females; in 1811 the numbers were 16,380, viz. 7931 males, and 8449 females; in 1821 they were 18,487, viz. 9223 males, and 9264 females.

Rutland-  
shire  
||  
Salop.  
Population.

The residences of noblemen and gentlemen in this county hold nearly the same proportion as in the other divisions of England; the most remarkable are, Ayston, G. B. Breidnell, Esq.; Burley on the Hill, Earl of Winchelsea; Cotsmore House, Earl of Lonsdale; Exton, Colonel Noel; Lyndon, Thomas Barker, Esq.; Normanton, Sir Gilbert Heathcote; Ryall, Matthew Pierpoint, Esq.

See Parkinson's *Agricultural Survey*; and *Beauties of England and Wales*. (w. w.)

## S A L

Extent and  
Boundaries.

SALOP, or SHROPSHIRE, an inland county of England. It is bounded on the north by Cheshire, and the Welsh counties of Flint and Denbigh; on the west by the Welsh counties of Denbigh, Montgomery, and Radnor; on the south by Herefordshire and Worcestershire; and on the east by Staffordshire. It is of an oblong figure, extending from north to south, and contains a variety of projections and indentations. Its greatest length is about 46, and its greatest breadth 37 miles. Its superficial contents are 1341 square miles, or 854,240 statute acres.

Civil and  
Ecclesiastical  
Divisions.

This county is divided into fifteen districts, or hundreds, of which five are on the north-east side of the river Severn, three extend to both banks of that river, and the remainder are on its south-west side. The ecclesiastical divisions of the county are into the diocese of Lichfield and Coventry, extending over 114 churches,—of Hereford over 127,—of Worcester over 3,—and of St Asaph over 12;—besides which there are 6 in the peculiar jurisdiction of Bridgenorth, making in the whole 262 churches, of which 229 are parochial.

Population.

The population of this county has increased at a much less ratio, between the census of 1811 and that of 1821, than that of any other of the English or Welsh counties; the average increase of the kingdom being 16 *per cent.* and that of Shropshire only 5 *per cent.* By the latter enumeration, the number of individuals was 206,153; of whom 102,056 were males, and 104,097 females. The number of *families* were 41,636; of whom 18,414 were chiefly employed in agriculture, 17,485 in trade, manufactures, or handicraft, and 5737 were not comprised in either of those classes. The number of houses were 38,663 inhabited, 179 building, and 1012 uninhabited.

Face of the  
Country.

The face of the country is much diversified. On the western side it has the wild appearance of the adjoining principality of Wales. Throughout the

rest of the county the land is rather undulating, tolerably wooded, and with many beautiful rivulets meandering along the different valleys. The whole tract of country, from Wellington to the termination of the county between Oswestry and Chirk, exhibits the mild beauties of a fertile and cultivated district, inclosed by well formed hedges into fields, of dimensions well calculated for advantageous husbandry; and ornamented with several domains of noblemen and gentlemen, which present a most pleasing succession of pictures to the traveller.

That singular insulated mountain, the Wrekin, rising from a plain to the height of 1100 feet, exhibits its sugar-loaf form over the tops of the smaller elevations in its vicinity, and increases the interest of the scenery. In the southern division of the county, the Brown Clee Hill, and the Titterton Clee Hill, rise to greater elevations than the Wrekin, and produce much picturesque variety.

In a county of such extent, the soil must be very varied. On the eastern side, the valleys are flat and warm, and the soil generally of a sandy nature. In the middle part, the soil is more tenacious, and the bottoms of the wider valleys have frequently a stiff but rich clay. On the most western parts, the soil is very shallow, resting upon rocks of varied descriptions; and is better calculated for sheep pasture than for producing grain. There are some moor lands, but inclosures and drainage have considerably diminished their extent. A very great portion of the soil rests on a limestone subsoil; and almost the whole of the plains are easy to work with light ploughs, and two or three horses. The easterly winds generally prevail in the spring, and the westerly in autumn; the former are more remarkable for their regularity than the latter. The whole of the county enjoys a salubrious air; but on the hills, on the western side, the cold of winter is most intensely felt.

Soil and  
mate.

Salop.  
Rivers,  
Lakes, Ca-  
nals, and  
Railroads.

The chief river is the Severn, which runs through the whole extent of the county from north-west to south-east. It is navigable at all seasons to the Bristol Channel downwards, and in wet seasons upwards to Welshpool, in Montgomeryshire. The navigation is, however, at all times, impeded by many obstructions. In dry weather, the fords are only passable with difficulty, and in very wet weather the floods cover the banks, and extend so far over the level land on both sides, that the barges cannot be drawn up, from wanting a path on which the men who draw them can securely walk. It is one of the singularities of this navigation, that men are employed instead of horses, as on other rivers, to draw the vessels against the stream. Imperfect as this navigation is, it is, however, the chief source of the wealth of the country, as affording the means of conveying to good markets the various heavy productions which it yields. The fish found in the Severn, in its course through Shropshire, are salmon, pike, flounders, grayling, and eels. There are also some lampreys in the Shropshire part of the Severn, but they are less abundant than in the lower parts of the river. The principal tributary rivers are the Camlet, the Vyrnwey, the Tern, the Clun, the Ony, and the Teme. There are, besides, innumerable rivulets and streams, which adorn and fertilize the country. The lakes of Shropshire, though neither numerous nor extensive, form a variety in its landscapes rarely to be seen in the midland counties of England. Adjoining the town of Ellesmere is a beautiful lake of 116 acres, with some others smaller near it. On the western side of the county is Marton Pool, of 45 acres. On the north of the Severn are Fennymer, Llynclyspool, and Ancot; and at Shrawardine is a fine lake of 40 acres. That side of the county which most abounds in running streams has few or no lakes. The canals of this county, if not equal in extent to those in some others, yield to none in their construction, or the obstacles they have surmounted, or in the beneficial consequences by which they have been followed. The first canal was a private undertaking by a Mr Reynolds, completed in 1788, for the conveyance of his iron-stone and coals. It was a short canal, but a descent of seventy-three feet was conducted by a well contrived inclined plane, and double railroad, by means of which the loaded boat passing down drew up another with a load, nearly equal to one-third of its own weight. This contrivance was found to be applicable to similar purposes, upon a larger scale, and was speedily adopted by a company who, under the power of an act of Parliament, soon constructed the Shropshire Canal, which passes through the most considerable iron and coal works, till it reaches the Severn. The Ellesmere Canal is a most important undertaking, as by it a communication is opened between the Severn and all the great canals and rivers in the north of England. Bristol and Liverpool are thus become connected by inland navigation, and the rivers Severn, Dee, Mersey, Trent, and Humber, are united for the purposes of conveyance. In districts where the inequalities of the surface would not admit of canals, iron railways have been constructed, on which heavy goods are conveyed, in appropriate waggons, with a great saving in the expence of carriage.

VOL. VI. PART II.

Salop.  
Agriculture.

There are few counties in which the agricultural business is, on the whole, better conducted than Shropshire. The land is very well adapted for the turnip cultivation, and the large flocks of sheep which are commonly fed on that valuable root a great part of the year, supply abundance of manure for the due cultivation of the different kinds of grain. The most prevailing breed of sheep are the Southdown, but many of the New Leicesters are to be seen, and in the hilly parts of the county are many of the fine-woolled Welsh sheep. The meadows on the banks of the Severn, and on the flat lands contiguous to the smaller streams, afford pasturage for numerous cows, whose milk, when converted into cheese, is commonly sold under the denomination of Cheshire. The corn generally cultivated is either wheat, barley, oats, or pease, and the crops, on an average, equal in productiveness those of the best districts of the kingdom. Hops are grown in small quantities on that part of the county which adjoins to Herefordshire. Some small portions of land are appropriated to the growth of hemp and flax. The cultivation of potatoes has been very much extended of late years, and now furnishes a large proportion of the aliment of the labouring part of the population. The growth of hay, and the cultivation of artificial grasses, are more neglected than any other branch of rural economy. On the flat lands, the deposits from the overflowing of the streams sufficiently enriches them without any artificial manure; but from the embankments being neglected, the hay produced on such situations is liable to be much injured by the floods that frequently occur in summer.

A great portion of the wealth of this county consists in the mineral productions, which are most profusely found beneath its surface. The chief of these are lead, iron, limestone, freestone, pipe-clay, and coals. The lead is procured in considerable quantities chiefly from the mines of the Hope and Snailbeach. The matrix of the ore is crystallized quartz, sulphate and carbonate of barytes, and carbonate of lime. The iron ore is found contiguous to the coal, and frequently close to it. This is especially the case about Colebrook Dale, a division peculiarly rich in those minerals. This district is about eight miles long and two broad, on the banks of the Severn, on the western side of the Wrekin, and running parallel with it, from north-east to south-west. The whole, but especially the southern part of the coal district, is considerably above the plain of Shropshire, so that at one part the height is 500 feet above the Severn. The works of the Dale supply both ore and coal, as well as limestone, in great quantities; and every part of the process, from digging the ore to the completion of the manufacture, including the conversion of the coal into coke, is performed on the spot. Arthur Young, describing this part of the county, says, "Colebrook Dale is a winding glen, between two immense hills, which break into various forms, being all thickly covered, and forming most beautiful sheets of hanging woods. The noise of the forges, mills, furnaces, &c., with all their vast machinery; the flames bursting from the furnaces, with the burning coal, and the smoke of the limekilns, are altogether horribly

Salop.

sublime." A bridge of cast iron, the first, we believe, constructed in this kingdom, thrown over the Severn, gives to the whole scenery a most romantic appearance. Soon after it was ascertained that iron might be made with coals, reduced to the state of coke, as well as from wood, the operation of coking was begun here by Lord Dundonald, with a view to obtain the fossil tar in the course of the process. This operation led to the discovery of that gas, extracted from coal, whose brilliant light now serves to illuminate so many of our streets and public buildings. In this dale was discovered, in opening a coal mine, a copious spring of fossil tar. It yielded, at first, very plenteously, but the quantity diminished in a few years, and though it still runs, its produce is but of small amount. Though the iron-works in this dale were the first begun, on a large scale, they are by no means confined to it; for in many other parts of the county, they are carried on to an extent that is unequalled in any other country but Great Britain.

Manufactures and Trade.

Besides the process of separating the iron from its ore, and bringing it into the state of bar-iron and pig-iron, the other steps in the application of that mineral to general purposes are made within this county. The larger kind of iron goods, whether cast or wrought, are prepared, and most of the iron bridges which have been erected in different parts of the kingdom have been formed here into such a state as only to require to be put together in the places where they were destined to be ultimately fixed. Some of the largest establishments for making porcelain have been formed here, especially that for iron-stone china in Colebrook Dale, which has lowered the price of that beautiful commodity so as to bring it within the reach of a greater number of consumers than could formerly afford it. Manufactures of a coarser kind of earthenware, and of tobacco-pipes, are carried on at Broseley and other places. The raw materials of which these articles are formed are almost all found near the spots where they are converted to those useful and profitable purposes. The manufacture of cotton has been recently introduced into this county, and establishments formed at Coleham and some other places, which rival the largest factories in the county of Lancaster. Many branches of the linen trade have been long, though not extensively, carried on in the northern part of the county. Some of the coarser kinds of woollens are made in different districts; but none of the establishments for their fabrication are upon an extensive scale. The trade in Welsh flannels centres in a great degree in Shrewsbury. The merchants of that town repair to the markets of Welshpool and Oswestry, and make their purchases of the small country weavers, who bring their goods in an unfinished state; and the pieces are rendered fit for the markets to which they are destined by the Shrewsbury traders. A coarser kind of woollens, called Welsh webs, are prepared in the same manner, and are exported to the West Indies for clothing the negroes.

Shrewsbury.

Shrewsbury, the county town of Shropshire, from its vicinity to Wales, in which the towns are few, and from its distance from any other large town, has ever

been considered as a kind of provincial capital. It is situated on a circular peninsula, of considerable elevation, formed by the curvatures of the Severn. It presents, at every approach, a pleasing variety of views; and the noble sweep of the river, which seems to embrace it, heightens at every turn the charm of the scenery. The exterior ranges of houses command the rich and beautiful landscapes of the surrounding country. The stately spires of two venerable churches, and the massive towers of the castle, give that imposing grandeur to the whole which is commonly felt in contemplating the works of antiquity. The walks between the river and the town are finely shaded by an avenue of lofty trees, and furnish an agreeable promenade to the inhabitants. The interior of the town by no means corresponds with its external beauty. The streets are intricately dispersed, many of them steep and narrow, and all badly paved. They exhibit a strange contrast of ancient and modern buildings, and are as uncouth in their names as in their appearance. This town, as well as many other parts of the county, exhibits now many interesting remains of antiquity. Among these is the castle, placed on the narrow neck of land, by which the only entrance to the town can be gained without passing a bridge. The remains consist of the keep, a square building of 100 feet, connected with two towers; the walls of the inner court; and the great arch of the interior gate. The keep is the most perfect of the whole mass of building. The walls of this building are ten feet in thickness, and its beams of very large dimensions. It is stated to have been built by Roger de Montgomery, the Norman, as a feudal hold; but being forfeited to the crown in the reign of Henry I., was used as a royal fortress in subsequent periods, to check the incursions of the less civilized Welsh. The remains of the abbey, erected by the same founder as the castle, rewards the lover of antiquities for the inspection of them. The most perfect of the remains of this edifice is an octagonal structure six feet in diameter, usually called the Stone Pulpit, standing upon a portion of the ruined wall. It is crowned by an obtuse dome of stone-work at about eight feet from the base, supported on six narrow pointed arches rising on pillars. The ancient Church of St Chad, which fell down in 1788, presents an interesting group of ruins. That of St Mary, founded by Edgar, as well as St Alkmunds, founded by Queen Elfleda, daughter of Offa, King of Mercia, have received such alterations in more recent periods, that they exhibit the architectural taste of several successive ages. The charitable institutions of Shrewsbury, consisting of hospitals, infirmary, schools, and other establishments, rather exceed the proportion to be found in other places of equal population, and do much credit to the liberality of the natives.

Our limits do not admit of lengthened description of the numerous remains of ancient architecture which are still existing in this county. The most remarkable are Haugmond Abbey, about four miles from Shrewsbury; the walls of Wroxeter, of British and Roman construction; the Abbey of Buildwas, founded in 1135 by Roger, Bishop of Chester, for monks of the Cistercian order;

the Monastery of Wenlock, founded in 680, destroyed by the Danes, and afterwards re-established; the Roman Camp called the Walls at Quatford; the Castle of Ludlow, celebrated for its splendour in the reigns of Henry VIII. and of Elizabeth;—during the latter period the residence of the Sidneys, and in the reign of Charles I. immortalized as the place where Milton composed some of his works; Wannington Castle, near Oswestry, a house of strength before the Norman Conquest; Lilleshall Abbey, near Newport, with one of the most highly adorned Norman arches in the kingdom; and Boscobel House, with the oak in the grounds near it which served as a shelter to Charles II. when, after the battle of Worcester, he was closely pursued by the victorious party.

dominion possessed by the petty sovereigns; and divisions arising between different branches of the family, the other Saxon duchies were formed into independent states, leaving to the descendants of Bernard the sovereignty over the Margravate of Meissen, and that of Saxony in a contracted state; whilst the houses of Gotha, of Weimar, of Coburg, and some others, inherited the whole of the western parts, which Albert had seized. Meissen and the remaining part of Saxony was then formed into one independent state, on which the electoral dignity was conferred by the Emperor Charles V. because of the adverse conduct of the Elector of the house of Weimar, the oldest branch of the family, in the wars which arose from the reformation of Luther.

Representa-  
tion.

Shropshire returns to Parliament two members for the county, and two each for the boroughs of Shrewsbury, Ludlow, Wenlock, Bridgenorth, and Bishop's Castle.

From that period till the war of the French Revolution, though its territories had been occupied, and its capital taken by Frederick of Prussia, Saxony had experienced but little alteration. When France attacked Prussia in 1806, the Elector of Saxony took part with the latter power, but the reverse occasioned by the battle of Jena compelled him to join the conqueror. An alliance was formed between Buonaparte and the Elector, who, as the Empire of Germany was dissolved, and the electoral dignity annihilated, assumed, under the sanction of the Ruler of France, the rank and title of King. The newly created King maintained with good faith the alliance, which necessity had compelled him to form, till the overthrow of the French armies, in the decisive battle of Leipsic, occasioned in part by the defection of his troops; on which event he was taken prisoner by the allied sovereigns in that city, and his dominions placed under sequestration. When, at length, he was reinstated on his throne, nearly one-half of his subjects were forced to transfer their allegiance to the Prussian monarch, to whose kingdom was added the duchy of Saxony itself, comprising the most fertile part of his dominions.

Titles and  
Seats.

The titles of peers derived from the county are—Earl of Shrewsbury, and Barons Hill and Forrester. As there are fewer titles derived from this county, so the seats of peers are much fewer than in any other of the same extent. The most remarkable residences of noblemen and gentlemen are the following: Walcot Hall, Earl Powis; Hardwicke, Lord Hill; Ross Hall and Willey Park, Lord Forrester; Apley Park, Thomas Whitmore, M. P.; Dudmaston, William Whitmore, M. P.; Pitchford, Honourable C. C. C. Jenkinson, M. P.; Hodnett, Reginald Heber, M. P.; Hawkstone, Sir Richard Hill, Bart. M. P.; Kinlet Hall, W. C. Childe, Esq. M. P.; Stanley Hall, Sir T. Tyrwhit Jones, Bart.; Altingham, Lord Berwick; Manor House, Sir G. Jerningham, Bart.; Pradoc, Honourable Thomas Kenyon; Pentrepant Hall, Honourable F. West; Orlaton Hall, William Cludde, Esq.; Downton Castle, Richard Payne Knight, Esq.; Oakley Park, Honourable Robert Clive; Plowden Hall, Edward Plowden, Esq.; Audlim, Lady Cotton.

The kingdom of Saxony, in its present state, is a compact and connected territory. It extends from 28° 5' to 31° 13' east longitude, and from 50° 10' to 51° 31' north latitude. It is bounded on the north and north-east by Prussia; on the south-east and south by Austria; on the south-west by Bavaria; on the west by the principality of Reus and the duchy of Saxe Gotha, and on the north-west by Prussia. Its square extent is about 7150 miles, or 4,625,000 English acres.

By the census of 1821, the population of the towns was as follows: Shrewsbury, 21,695; Wenlock, 17,265; Wellington, 8390; Hales Owen, 8187; Ellesmere, 6056; Bridgenorth, 4345; Ludlow, 4820; Oswestry, 3910; Newport, 2343; Bishop's Castle, 1880.

See Plymley's *Survey of Shropshire*; Aikin's *Tour*; Telford's *Account of the Inland Navigation of Shropshire*; *Antiquities of Shrewsbury*, by the Rev. Hugh Owen; and *Beauties of England and Wales*. (w. w.)

It is divided into five circles or provinces, and these are subdivided into Amts or Baliwichs.

Origin and  
History of  
the King-  
dom.

SAXONY. The kingdom of Saxony has been formed out of the principality of the same name. The duchy from which the sovereign dignity arose was no part of the ancient duchy, but a Vandal province, which Albert, Margrave of Saltzwedel, seized and transmitted as an inheritance to his son Bernard. This Bernard received the ducal rank from the Emperor Frederick, usually distinguished by the name of Rothbar, or Redbeard; and his territories were spread out from the Weser to the Rhine, and from Westphalia to the borders of Bohemia. In these turbulent times power was necessary to preserve the

This state of the population is drawn from a census taken in 1817.

Face of the Country.

The northern part of the kingdom of Saxony is, for the most part, a level, or an undulating country; but on the south it is very mountainous. The mountains rise in three successive ridges, denominated the Vorgeberg, Mithelgeberg, and Hochgeberge; the southernmost of these, bordering on Bohemia, is the loftiest. The highest points of these mountains are those of the Fichtelberg, 3730 feet; Auersberg, 2931 feet; the Lausche, 2400 feet; and Hochwald, 2299 feet.

Saxon Switzerland.

A part of this mountainous district, betwixt Dresden and Bohemia, usually denominated Saxon Switzerland, has peculiar charms for the lovers of picturesque scenery. It is about 28 miles in length, and 23 in breadth, displaying deep chasms bordered by perpendicular rocks, some naked, and others clothed with every variety of trees. Rapid streams pour from declivities, forming cascades in some parts, and in others, in deep vales, meander through verdant meadows, without their issue or their egress being discoverable by the observer from the precipices which enclose such recesses, and from whence he can see no path by which the vales can be reached. Through this mass of mountains the river Elbe has worn itself a passage, by a most tortuous course, and washes the bases of rocks, in some parts of near one thousand feet perpendicular height, from whose summit that stream appears to the beholder as an insignificant rivulet. From the surface of this mountain plain rise the pinnacles of rocks, on which castles, in the feudal times, were erected, some of whose ruins add to the romantic grandeur of the prospect; whilst others, such as Koenigstein and Litherstein, have had applied to them all the arts of modern fortification, and are the most impregnable fortresses in the Saxon dominions. Koenigstein especially, though, from its great height, it appears to terminate in a point, has on its apex strong walls, surrounding buildings in which the treasures of the crown are secured in times of danger, with ground to yield potatoes enough to feed the garrison, as that vegetable grows there to perfection; though, from being 1400 feet high, the rigid cold of winter is most severely felt. This fortress, and that of Lillienstein on the opposite side of the Elbe, are considered to be the keys to Bohemia. Few spots in Europe create greater interest in the geologist, the botanist, or the lover of picturesque scenery, than this portion of the country so appropriately denominated Saxon Switzerland.

Rivers.

The principal river of Saxony, and that to which almost all the others contribute their streams, though not till it has left this kingdom, is the Elbe. It enters from Bohemia, and is navigable for barges through

the whole of its Saxon course. The other rivers are the Black Elster, which rises in Lusatia, and soon enters the Prussian territory; the Spree, which comes out of Bohemia, divides itself into two branches near Bautzen, and then passes into Prussia. These rivers fall into the Elbe on its right bank. On the left bank it receives the Moldau, which has two sources in Bohemia, and in Saxony unites with the Zwickau, and runs parallel to the Elbe till it joins that stream at Dessau. The White Elster rises in Voightland, with many curvatures, reaches the suburbs of the city of Leipsic, and, receiving there the small river Pleisse, falls into the Saale, and ultimately is lost in the Elbe, above Magdeburg. The only river that does not run to the Elbe is the Neisse, which rises in the eastern corner of the kingdom, and, passing into Silesia, at length is emptied into the Oder. There are no lakes in Saxony, nor any canals, except such as are used in the mining districts for conveying the ore to the mills.

Agriculture.

As compared with most parts of Germany, the agriculture of Saxony is much advanced. Wherever the soil is capable of cultivation, it is worked with diligence; and the more hilly and poorer soils have a good herbage, and yield pasture to numerous flocks and herds. The sides of the mountains towards the Elbe, from Pirna to Meissen, are covered with vines which yield both red and white wine; the former from the vicinity of Pilsnitz and Loschwitz, and the latter from Hoflasnitz, are the most valued; but the great portion of the Saxon wine is of a very indifferent quality. The best of them are produced from the vineyards belonging to the king; and though they are sold at the highest prices, it is very doubtful if the expences of cultivation, and the rent which might be obtained for the land, does not exceed what is produced by the sale of the wine.

The whole of Saxony is highly productive of fruit, and the care and skill exercised in its cultivation is amply rewarded. Great destruction to the fruit trees took place during the tremendous military conflicts of which the country was the theatre; but still the orchards and gardens are very extensive, and new trees, planted since the wasting warfare of 1813, are beginning to yield their products. The calamities which were injurious to the fruit trees have lessened the number of cattle of every description; in the year 1817, in many districts of the circle of Meissen, not a single head of cattle was to be found. The bee-hives were destroyed by the same events; and it will yet require some years before Saxony can, as in past periods, supply the neighbouring countries with meat, hides, honey, and wax. The sheep were better preserved than the other kinds of animals, being mostly driven to the mountainous districts. These have increased, and great attention having been paid to breeding them so as to produce the finest wools, they have succeeded to such an extent, that their fleeces are now superior to those of Spain, and furnish the chief agricultural article which is exported.

The arable land is chiefly cultivated on a three course system, consisting of a fallow, winter sown grain, and spring sown grain. In some cases there is a fallow crop of flax, hemp, or potatoes. The

**Saxony.** winter corn that succeeds is generally rye, and sometimes, though less extensively, wheat; the summer corn which follows is chiefly oats and sometimes barley. The greater part of the arable land is in common fields, held under a feudal tenure, over which the lord of the manor has the right of depasturing his flocks between the harvest and the next seed time. The farming occupations are generally very small, and the increase of grain through the whole kingdom is said not to average more than five for one. The culture of potatoes has been very much extended of late years, and forms almost exclusively the food of the labouring classes in the mountainous districts. Tobacco, hemp, flax, wood, hops, and chiccory, are grown in some parts of the kingdom, but neither of them to the extent which the consumption of the country requires. The woods of the kingdom, since the separation of its best portions, are insufficient to furnish the inhabitants with the necessary fuel; and though abundance of coal is found near Dresden, it is of so sulphureous a nature as to be deemed unwholesome, and is used only by those who are unable to pay the high price for wood which its scarcity has created.

**Minerals.** Saxony abounds in minerals, and though the veins, in general, are far from being of great thickness, the ore is tolerably rich; which, added to superior skill and economy in working the mines, and separating the metals, makes them very beneficial to the crown, to whom the greater portion of them belong. The mineralogical school of Freyberg has had a wonderful influence, not only in Saxony, but in all parts of the world, in increasing the knowledge and improving the practice of the operative labourers in the mining art. The annual produce of the silver mines is about 400,000 ounces; besides this, they yield copper, lead, tin, iron, sulphur, quicksilver, bismuth, arsenic, and coal. Gold is found in very small quantities.

**Manufactures.** In no part of the continent has manufacturing industry been carried to so great an extent, or occupied so large a proportion of the population, as in Saxony. Before the separation from it of the most productive agricultural provinces, it was calculated that two-fifths of the inhabitants were employed in manufactures; but since that unfortunate event, it is estimated that three-fifths are occupied in commerce and manufactures, and only two-fifths in agriculture. It is only by the extent of its manufactures that the country can be furnished with the means of paying for those articles of the first necessity, of which a sufficiency is not now produced within it. The provinces which supplied corn, fuel, and salt, have been ceded to Prussia, and those articles must be paid for by the sales of the minerals and manufactures. During the continuance of Buonaparte's continental system, the Saxon manufacturers enjoyed a most extensive trade, and the encouragement thus obtained gave an impulse which directed the efforts and the capital of the country towards their perfection; but the division of labour was not carried to such an extent, nor was the application of machinery so generally adopted, as to enable them to withstand the competition with the British goods, which peace introduced into many of those markets which they had

**Saxony.** before almost exclusively supplied. It would include almost the whole catalogue of European manufactures to enumerate all the respective kinds of goods made in Saxony. Woollens, linens, cottons, and silks for clothing; iron, brass, and copper wares; paper, leather, earthenware, hats, musical instruments, and turnery-ware; various chemical and dyeing preparations; clocks, watches, swords, guns, and pistols, are all comprehended in the list of Saxon manufactures.

**Commerce.** The commerce of a country, whose inhabitants are chiefly occupied in manufactures, and produce an insufficiency of food for their own consumption, must be extensive. The trade of Saxony chiefly centres in the city of Leipsic, from whence, at the time of the two annual fairs, the greater part of the manufactures are disposed of, and contracts are made for such foreign commodities as the supply of the country demands. As the fairs of Frankfort on the Maine precede, and those of Frankfort on the Oder follow, the fairs of Leipsic, some portion of the trade is carried on by those channels. The roads leading to Leipsic are generally good, and trains of waggons, loaded with goods, are to be seen proceeding to and from that place at all times; many of which come from Flanders, Holland, Hamburg, and Brunswick, on one side, and from Russia, Poland, and even Turkey, on the other. At the fairs of Leipsic, the new books printed in most parts of Germany are brought for publication. There the publishers meet and exchange the works of one part of the country, where the German language is spoken, with those of another. So extensive is this trade, that it is said the commissions on it to the brokers and merchants of Leipsic amount to more than 40,000 rix-dollars a year. The whole sales at the fairs in that city are estimated, including exports and imports, at about 20,000,000 rix-dollars, or more than L. 3,000,000 Sterling. Saxony disposes, in this way, of sheep's wool, fine woollen goods, linen and thread lace, yarn and worsted, ironmongery, cutlery and braziers, and books. It receives in return, corn, wine, salt, wood, and colonial wares. Although the river Elbe is navigable from the ocean to the interior of Saxony, it is only used for the conveyance of the heaviest goods, and for them but partially. It is found that the tolls on that river, with the risk of damage and of robbery, make it more advantageous to convey commodities by land than by water.

The government is a monarchy hereditary in the Saxon Albertine line, and in failure of that, on the Ernestine, or Saxe Weimar branch of the family. The monarchy may be called limited; but the limitations are of such a nature that the liberties of the people have been more secured by the mildness of the reigning family than by any restrictions that the states have or could exercise. The king enjoys the whole executive power, confirms pardons, bestows commissions, nominates the supreme judges, and enjoys the power of making peace and war, and of concluding all treaties. In making new laws, and in imposing new taxes, the states have the right to be consulted. According to the ancient constitution, which is still adhered to, the states are constituted of various ele-

Saxony  
||  
Scotland.

ments; and, in fact, are an amalgama of various corporations, each of which thinks only of its own peculiar interests, and contrives to cast the weight of all public burdens from the cities and the nobles, who are represented, to the country people who have no voices. The assembly consists, 1st, Of members chosen by the provincial representatives of the nobility; 2dly, Of the representatives of the prelates, who, before the Reformation, had seats; but who have since been chosen by the higher class of nobles in right of their possessing certain estates of which the prelates were deprived; and, 3dly, The university of Leipsic. These states represent only the circles of Meissen, Leipsic, Erzgebirge, and Voightland; for that of Lusatia has its own peculiar assembly of states, which differs but little from those of the other four, except that the members from the land possessors must have at least sixteen quarterings in their coats of arms. When the king pleases these states are convoked; but, as it has not been found necessary to impose new taxes, or to make great alterations in the laws, they have seldom been assembled, and their session has usually been very short. The administration is conducted by a Cabinet Council, under which, through the medium of the privy council, orders are communicated to the departments of Finance, War, Domains, Police, and Foreign Affairs.

Revenue,  
Taxes, and  
Debt.

The revenue at present amounts to about L.1,250,000 Sterling annually. This revenue is derived in a great degree from royal domains, possessed by the government by ancient grants from the imperial court, or obtained by having been mortgaged and foreclosed for non-payment, or purchased by the ancestors of the present monarch. The royalties belonging to the crown furnish also a considerable share of this revenue; they consist of the mines, the forests, the fisheries, and of interest on money lent. The direct taxes are on land, on trades, various excise duties, stamp taxes, and tolls on roads, rivers, and bridges; the greater part of which fall exclusively on those who have no voice in the states. The whole public debt, including the cash notes (*Kassenbillets*), which did amount to L.550,000, but are now reduced to L.450,000, and circulate as freely as cash, is somewhat less than L.4,000,000; the interest on which is regularly paid, and a portion of the principal is annually discharged. The credit of no government stands higher than that of Saxony,

and nearly the whole debt is due to its own subjects.

The regular army of Saxony at present is reduced to 10,000 men, including cavalry, infantry, and artillery. Since the year 1817, when the regulars were thus reduced, there has been a register kept of the single men between 18 and 31 years of age, who form a kind of militia, and from among whom the troops of the line are chosen; from this conscription, however, the privileged orders are exempt. There are military academies in Dresden for instructing both the cadets of the line and those of the artillery.

Although the royal family profess the Catholic religion, and are zealous in discharging its injunctions, the established faith is the Lutheran, and, until the year 1811, no person of any other sect was eligible to seats in the several corporations in the provincial or general assembly of the states. At that period all sects were placed on the same footing. The whole number of Catholics is about 40,000, some of whom are attached to the royal household; but most of them are found among the inhabitants of the province of Lusatia. The number of Protestants dissenting from the established church, including Moravians and Calvinists, is not supposed to exceed two thousand. The Lutheran church is regulated by four Consistories or Assemblies of divines; differing in the number of superintendents, but comprising together twenty-four of that order. The Catholics in Lusatia are regulated by the Abbot of Bautzen, on whom the Pope generally bestows the title of Bishop *in partibus infidelium*.

Education is well conducted in the university of Leipsic, and in the endowed classical schools of Meissen, Wurzen, and Grimma, as well as in several gymnasiums. The popular education is not so well managed as in the other Protestant German states; and some recent efforts to improve the system have not been attended with good practical results. The fine arts have been cultivated with considerable success; and both statuary and painting receive valuable assistance from the fine productions of both which the collections of Dresden contain.

## SCOTLAND.

THE history of Scotland as a separate kingdom having been treated at considerable length in the *Encyclopædia*, all that we propose here is, to supply what is wanting in the imperfect account there given of its STATISTICS; referring, however, to our county articles for local description and details, and confining ourselves, for the most part, to such general state-

ments as concern the industry, population, and resources of the nation at large.

### I.—GENERAL DESCRIPTION OF THE COUNTRY.

Scotland, the northern division of Great Britain, is situated between 54° 37' and 58° 42' north latitude, and between 1° 47' and 6° 7' west longitude,

Scotland. from Greenwich; having the sea on all sides, except the south, where it is separated from England partly by the Tweed, and other streams, and partly by a line supposed to be drawn along the high grounds in that quarter. Its greatest extent in the same longitude is from the Mull of Galloway, on the south, to Farouthead in Strathnaver, on the north, a distance of 275 miles; while its breadth from east to west varies from 36 to 147 miles; its area, calculated from Arrowsmith's map, being about 25,520 square miles of land, and 494 square miles of fresh water lakes. This is the extent of the Mainland only, exclusive of the islands on the west, called the HEBRIDES; and those of ORKNEY and ZETLAND on the north, which altogether are computed to extend over 4224 square miles. Including these islands, the northern limit of Scotland stretches beyond the 61st degree of latitude, and its longitude is between the meridian of London and 8° 18' west; and its area comprehends 30,238 square miles, of which the fresh water lakes occupy 638 square miles, or about one forty-eighth part of the whole. The outline on the sea-coast is exceedingly irregular, and of great extent, the sea penetrating to a great depth, both on its eastern and western sides. Of these arms of the sea the most considerable are the Friths of Forth and Tay, and the Moray Frith, on the east; and the Frith of Clyde and the bays of Glenluce and Wigton on the west and south-west: along the northern and north-western coasts there are a number of smaller inlets, called lóchs, which indent the country in all directions.

Face of the Country. With the exception of narrow tracts along its principal rivers, there is very little of the country flat or level, and not a large proportion of the whole that would be deemed productive land in more favoured regions. Every where, even in the south, and along the east and west coasts of what is called the *Lowlands*, the surface presents great variety; in some places, gently rising from the sea, and the banks of the principal rivers, and spreading out into considerable tracts of fertile land; and in others projecting into the ocean, the termination of those ridges which traverse the interior, and which, a few miles from the coast, sometimes ascend to the height of 2000 feet. In this quarter of Scotland, a tract of mountainous country, known by various names, stretches in a south-west direction from the Cheviot hills of Roxburghshire, on the borders of England, to the Irish Channel, sending off branches on both sides; while detached hills frequently occur over all the low country. These high grounds, however, are for the most part clothed in green, almost to their summits, and have little of that wild and desolate character which distinguishes many of the mountains of the Highlands. Northward from the isthmus formed by the Friths of Forth and Clyde, the low grounds form but a small proportion of the whole. Here, in latitude 57°, the Grampians extend from sea to sea, with a breadth of from 40 to 60 miles; and parallel to them, to the south, is another and lower chain, called the Sidlaw, Ochills, and Campsie hills. Between these two ranges lies the fertile valley of Strathmore. Farther north, cultivation is mostly confined to the sea-coast, the banks of the larger rivers, and the narrow glens between the mountains. On the north-

west, beyond the line of the Caledonian Canal, the country is, with few exceptions, singularly rugged and sterile, consisting of lofty mountains, either covered with heath, or presenting a mass of naked rocks, interrupted only by deep and dark ravines, lakes, and precipitous streamlets. Caithness, the north-eastern county of the Mainland of Scotland, is, nevertheless, generally low, but marshy and unproductive.

The elevation of the most considerable mountains of Scotland above the sea, with the counties in which they are situated, are stated as follows: (Playfair's *Scotland*, Vol. II. p. 341, and *General Report of Scotland*, App. Vol. I. p. 128).

Names.	Height in Feet.	Situation.
Benevis .....	4380	Inverness-shire
Benwyvis .....	4380	Ross-shire
Benmacdowie .....	4300	Aberdeenshire
Cairngorum .....	4060	Banffshire
Rona .....	3944	Zetland
Benlawers .....	3978	Perthshire
Schehaillon .....	3673	Ibid.
Hartfell .....	3302	Dumfries-shire
Benlomond .....	3262	Stirlingshire
Lowthers .....	3150	Lanarkshire
Goatfield .....	2950	Arran Isle
Hartfield .....	2800	Peebles-shire
Muirfoot Hills .....	1850	Edinburghshire
Ruberslaw .....	1419	Roxburghshire
Eildon Hill .....	1330	Ibid.
Soutra Hill .....	1000	Berwickshire
North Berwick Law .....	940	Haddingtonshire
Cockburn Law .....	900	Berwickshire
Arthur's Seat .....	822	Edinburghshire

To these heights we may add the site of the village of Leadhills, in Lanarkshire, 1564 feet above the sea. The land near this village is the highest cultivated land in Scotland. In Aberdeenshire the plough sometimes reaches the height of nearly 1300 feet. But with few exceptions, an elevation of 600 feet seems to be the limit to the tillage lands of Scotland. None of the Scottish mountains ascend to the line of perpetual congelation, yet snow may be found in some of their dark recesses, on which the sun never shines, all the year round.

The climate of Scotland, as might be expected, from its insular situation and high latitude, is cold, cloudy, and wet. This is its general character, as compared with the greater part of England; yet, even in the south of England, frost is sometimes more intense, and snow falls more copiously, than in Scotland; and on the west coast of that country the quantity of rain is also greater. Corn, however, and most of the fruits and vegetables common to both divisions of Great Britain, attain maturity nearly a month sooner in England than in Scotland; and some plants, such as hops, and a few others, cannot be profitably cultivated at all in the latter country. The range of the barometer is 2.82 inches, or from 30.92 to 28.10 inches; in the Orkneys it is somewhat more, or about 3 inches. The lowest yearly temperature is 41° 11', the highest 50° 32', and the annual average

Scotland. for all Scotland may be between  $45^{\circ}$  and  $47^{\circ}$ . Of rain the average is about 31 inches; and the difference between the east and west coasts, in this respect, has been estimated generally at one-fifth more on the latter than on the former. The number of fair days on the west coast is only 160, while on the east it is 230. The prevailing winds in both situations are from the westerly points; but on the east coast it blows from the easterly points for about a third of the year. Easterly winds generally prevail in March and April, and often in May and part of June; and not only check vegetation, but occasion various slight disorders among the inhabitants.

For the purpose of exhibiting the distribution of heat and of rain throughout the year, we give the following abstract from a register of the weather kept near Perth, for the year 1820. The temperature is probably not very different from the average temperature of Scotland, but the number of rainy days, and the quantity of rain, are both considerably less than on the western coast.

	Fair Days.	Rainy Days.	Quantity of Rain.	Mean Temperature.
January .....	21	10	1.321	30.4
February ...	24	5	1.198	39.1

For an account of the mineralogy, zoology, and botany, and also of the rivers, lakes, and forests, of Scotland, see SCOTLAND in the *Encyclopædia*, and the *Scottish counties* in this *Supplement*.

## II.—DIVISIONS.

Divisions. The most natural and obvious, as well as the most ancient, division of Scotland, is into the Lowlands and the Highlands; a distinction marked by the difference in the language and dress of the people as well as by the surface of the country; though the line of separation between the two is by no means well defined. The friths or arms of the sea, which entering the land on both sides, leave but a comparatively small extent of country between their extreme points, present limits more distinct; especially since the execution of the two canals, which, being carried along these isthmuses, connect the eastern and western seas. These are the Forth and Clyde Canal between the friths so called; and the Caledonian Canal, now (1823) nearly completed, which runs from the Moray Frith on the north-east to Linnhe

Loch on the south-west. The country to the south of the Forth and Clyde Canal has been called the southern division; that between the two canals the middle; and all to the north and north-west of the Caledonian Canal the northern division.

The divisions generally recognized are counties and parishes. Of the counties, the number is 33, most of which are again subdivided by local acts of Parliament into two or more districts in each, for the purposes of police and internal economy; and several of them comprise a variety of territorial divisions, founded on the natural circumstances of the country. Thus the county of Berwick is popularly divided into the three districts of the Merse, Lauderdale, and Lammermuir; Lanarkshire into the Upper, Middle, and Lower Wards; and, in the extensive Highland counties, the subdivisions are still more numerous. The number of parishes is at present 899, but liable to vary from annexations and disjunctions. Every country parish contains a church and burying-ground, with a *manse* or dwelling-house, and a few acres of land as a glebe, for the clergyman, who is always resident; and a school, with a schoolmaster's house and garden. In several of the towns one church has two ministers, so that the number of the clergy is greater than that of the parishes. In 1813, the parochial clergy amounted to 938, besides assistants and ministers of chapels of ease. An indefinite number of parishes form the ecclesiastical division, called a presbytery, and several presbyteries unite to compose a synod. We shall give the names and extent of these divisions under their proper head.

## III.—INTERNAL COMMUNICATION.

Until after the middle of last century there was scarcely any thing that deserved the name of a good road in Scotland. About the year 1732, indeed, Government began to open up the country by roads made by the military, hence called Military Roads, which extended in all about 800 miles; but these being confined for the most part to the Highlands, and intended only for military purposes, and formed with little or no regard to such ascents and descents as do not impede the passage of an army, were of little advantage to the more populous parts of the country. It is within the recollection of persons still alive, when corn, coals, and other heavy articles, were usually carried on the backs of horses, even in the southern counties of Scotland; the roads or rather the tracks being for the greater part of the year unfit for wheel-carriages. But so great a change has been made in this respect, particularly within the last forty years, that mail-coaches, and other carriages, now run day and night at the rate of from six to eight miles an hour through every part of the country, from the borders of England to Thurso in Caithness, the northern extremity of Great Britain.

The only funds formerly applicable to the making and the repairing of the roads in Scotland were what is called the *Statute-Labour*, or the labour of the occupiers of the land, for six days annually, on the roads passing through their respective parishes; and a small assessment imposed upon the proprietors.

Scotland. This labour, which has been converted into a payment in money, and also the sums raised by assessment on the proprietors, under the name of *road and bridge* money, are now applied to *bye-roads*, or such as communicate with the great turnpikes, or others calculated for the accommodation of the particular district in which the money is levied. Almost every county has procured an act of Parliament which fixes the rate of these assessments; but this varies in different counties, according to the circumstances of each.

The turnpike roads and bridges in the Lowlands have been made and are kept in repair by means of tolls exacted from those who use them, under the authority of private acts. The trustees named in these acts are commonly empowered to borrow money on the security of the funds to be received, by which means the work is executed more speedily, to the great advantage of the public. The expence of these roads depends so much upon local circumstances, that it has varied from L.1200 to L.100 per mile; but may be averaged at about L.400, the rate which the Highland roads, confessedly not so substantially made as the great roads in the Lowlands, have cost under the direction of the Parliamentary Commissioners. Of the road between Glasgow and Carlisle, conducted under the same superintendence, 39 miles, which was nearly finished in 1821, would cost, with its bridges, L.50,000, or L.1282 per mile. (*Ninth Report of the Commissioners for Highland Roads and Bridges.*)

In the Highlands, the nature of the country, and the state of the population, did not admit of the same system as in the Lowlands. The military roads had not only been made, but were kept in repair at the public expence, for which L.5000 a-year was usually granted by Parliament; but a great many new roads and bridges were required; and, in 1803, an act was passed, proceeding upon "A survey and report of the coasts, and central Highlands of Scotland," by which Parliament agreed to provide half the estimated expence of the necessary roads and bridges; the other half to be defrayed by the landed proprietors; and Commissioners were named to carry into effect the beneficent intentions of the Legislature. It appears from the Report just referred to, that, under this act, the Commissioners had, in 1821, expended, on 875 miles of road, and several large bridges, upwards of L.450,000, of which L.240,000 was granted by Parliament, and the rest defrayed by the counties through which the roads passed; and that L.100,000 more had been laid out by them on harbours, of which L.50,000 was paid out of the funds arising from the Forfeited Estates in Scotland, and the remainder was raised by the Burghs, and the contributions of individuals. If, to these sums, we add the amount of the losses sustained by the contractors, as stated in the Report, and the expence of the new roads made at the sole expence of the proprietors to communicate with the Parliamentary roads, together with the charges of repairs, the whole amount expended within these twenty years on the roads, bridges, and harbours of the Highlands of Scotland, may not be too high stated at a million Sterling. The Commissioners have under their charge both the maintaining of their own roads, and

VOL. VI. PART II.

part of the military roads; the extent of the whole in 1821 being 1183 miles; and about L.10,000 a-year, of which L.5000 is granted by Parliament, was considered to be necessary for this purpose, including all charges of management.

We have already mentioned the Forth and Clyde Canals and Caledonian Canals, as affording the means of communication between the east and west seas. A full account of the former has been given in the *Encyclopædia* (see CANAL), and of the latter in this *Supplement*. On the Caledonian Canal, now nearly completed, there had been expended, in May 1822, L.884,159, 12s. 1 $\frac{1}{2}$ d. (See *Nineteenth Report of the Commissioners on the Caledonian Canal.*) The other canals are the Crinan, cut across the peninsula of Kintyre at an expence of L.140,000; the Glasgow, Paisley, and Ardrossan Canal, of which only about a third part of the line, or 11 miles, is finished; a cut from the Forth and Clyde to Port-Dundas at Glasgow; the Monkland Canal, extending about 12 miles from Glasgow to the collieries in the parish of Monkland; a canal from the harbour of Aberdeen to Inverury, about 18 miles; and the Union Canal from Edinburgh to the Forth and Clyde near Falkirk. For a more particular account of these works, see the Scottish counties through which they pass in the *Encyclopædia*, and in this *Supplement*.

Railways have not yet been carried to any great extent in Scotland. They are employed for a short distance at some of the principal coal-works and others; but the most considerable is that which has been carried from Kilmarnock to the harbour of Troon in Ayrshire, a distance of 10 miles, at the expence of the Duke of Portland, the proprietor of extensive coal-fields in that quarter.

#### IV.—VALUED AND REAL RENT—PROPORTIONS OF LAND CULTIVATED AND UNCULTIVATED.

About the middle of the seventeenth century, the lands of Scotland were valued, with a view to ascertain what proportion of the land, and other taxes, should be paid by each county; and this valuation, called the *Valued Rent*, which had been undertaken under the authority of Cromwell, was afterwards established by an act of the Scottish Convention in 1667. It is still the rule by which the counties, and the estates of each county, are assessed for payment of the land-tax, and all local imposts on land. The Table subjoined to this section exhibits, among other things, the valued rent of each county, as it stood in 1674, and the amount of the whole, namely, L.3,804,221 Scots, or L.317,018, 8s. 4d. Sterling. In 1811 this valuation was divided as follows:

Description of the Estates.	Number of Proprietors.	Estates.
Large properties or estates above L. 2000 of valued rent . . . . .	396	
Middling properties or estates, from L. 2000 to L. 500 of valued rent . . . . .	1077	
Small properties or estates, under L. 500 of valued rent . . . . .	6181	
Estates belonging to corporate bodies . . . . .	144	
Total . . . . .	7798	

Scotland.

Tenures.

The land-rights of Scotland are still subjected to feudal tenures; and all the land is held either immediately or mediately of the Crown, as the paramount superior. The only distinction in regard to land-rights, which requires to be noticed here, is that between property which acknowledges no other superior than the Crown, and that which is held immediately of a subject; the right of voting in the election of the county representatives being vested in proprietors of the former class, while those of the latter, however large their estates, are wholly excluded. In general, to give a right to vote requires a freehold to the extent of L. 400 Scots of *valued rent*; but it is not necessary that the freeholder should have property in the soil to that amount; the mere feudal *superiority* of lands of that valuation, though seldom affording any income, is sufficient; for the lands themselves may, and in many cases do, belong to another. The number of voters in each county, at Michaelmas 1822, will be found in the table subjoined; but it varies, though not greatly, from year to year.

Rental.

The gross rental of the lands and houses of Scotland, according to the returns made under the late Property-tax act, for the year 1812, is exhibited in the same table. Of this, the rent of the *land* may amount to nearly five millions, which may not be far from the present revenue of the landed proprietors; for although many of the rents contracted for during the last years of the late war have been reduced since, yet others, upon the falling in of older leases, have been much advanced. As the common duration of the lease in Scotland is nineteen years, the average term of the current leases at any period must be between nine and ten years, so that half the leases current in the beginning of 1812 must have been entered into soon after the beginning of the century, and at such rents as would even now, considering the improvements that have been so generally made since, admit of some augmentation.

Leases.

This rent is paid by tenants; only a very small proportion being in the occupation of the proprietors themselves; and, with the exception of grazing lands near their seats, which are usually let for the season only, the tenants all hold on written leases for periods, varying from 12 or 15 to 21, and in some cases 38 years. These leases, with few exceptions, prohibit the tenant to sub-let his farm, either in whole or in part, without the consent of the proprietor; and upon the death of the tenant, the lease falls to his heir at law. Life leases were formerly very common, at least in those districts where the more improved system of agriculture had made little progress; but the extraordinary enhancement of prices during the late war had the effect of deterring landholders from letting out their estates for an indefinite, and, as it often proved, a very long term; and the practice, now almost obsolete, is not likely to be revived.

The rents are paid in money, and not, as in former times, in grain or other produce, or in services. Of late, since the great fall in the prices of land produce, it has become not uncommon to regulate the rent by the price of grain; the quantity and kinds of grain being fixed by the lease, and the rent, or the price of that grain, by the rates of the market; or more commonly by what is called the *Fiars*,

or prices struck yearly, for certain purposes, by a jury in all the counties of Scotland. In some parts of the Highlands, where the land is still in some instances let out again by the principal tenant in small portions, the sub-tenants are required to perform certain sorts of work for the superior tenant; and on the shores of the western and northern islands the tenant may be said to pay his rent chiefly in kelp or in fish; but all these exceptions bear but a small proportion to the whole rent of Scotland.

The main source from which rent is paid over the greater part of Scotland is live stock, principally cattle and sheep. Of the area, extending to 29,600 square miles, or 18,944,000 English acres, exclusive of lakes, little more than a fourth, or five millions of acres, are regularly or occasionally in cultivation; and about two-thirds even of this is employed in grazing and in raising crops for live stock, or is under fallow. According to the *General Report of Scotland*, drawn up for the Board of Agriculture, the extent yearly under corn, with beans and pease, is only 1,799,150 acres; of which 1,260,362 produce oats, 280,193 barley, and only 140,095 wheat; an estimate which is probably rather above the truth as to both oats and barley. The rest of the country, or nearly 14 millions of acres, is, after deducting about 900,000 acres, as the estimated extent of the natural and planted wood, still in a state of nature, and by far the greater part must always remain so. But much of this yields a valuable return under sheep, with a small proportion of cattle. For an account of these and the other kinds of live stock kept on the farms of Scotland, see AGRICULTURE in this *Supplement*.

It is little more than half a century since the management of tillage lands was conducted even in the Lothians and Border counties, according to the system which has now become pretty general over all the country. Previous to that period the mode of cultivation did not differ materially from that which, though falling into disuse, may still be met with in some of the Highland counties, and which we have described under these counties in this *Supplement*. Almost every where the practice was to take crops of grain successively, and then to leave the soil in a state of waste, till gradually invigorated again by time and the folding of the cattle. Such of the farmers as wished to learn better methods sought for this information in England, where agriculture was then in a much more advanced state than in Scotland; but in many parts of which it has long remained stationary, while that of Scotland has been always making some progress since, and within the last twenty-five years a very rapid progress. The crops cultivated (see AGRICULTURE in this *Supplement*) are now the same in both countries, with the exception of a few species, not of great importance, which the climate of Scotland does not bring to profitable maturity.

With regard to the capital invested in the agriculture of Scotland, and the amount of its yearly produce, of which little can be said with any great pretension to accuracy, we must refer to the Tables in the *General Report of Scotland*, Vol. III., which have been given in the last edition of the *Encyclopædia*.

Scotland.

Extent cultivated and uncultivated.

Value of Land Produce.

Scotland. Taking the rental, exclusive of mines, quarries, and river fisheries, at  $4\frac{1}{2}$  millions, and supposing that to be equal to one-third of the gross produce, a common estimate in most parts of Scotland, the amount of the latter would be  $13\frac{1}{2}$  millions; but as lands in their natural state, depastured with sheep, certainly do not yield three times the rent, perhaps it would be nearer the truth to estimate the total annual produce of the soil, exclusive of mines, &c. at twelve millions.

The least proportion of cultivated land is in the counties of Selkirk, Sutherland, and Orkney, being only about six acres in the hundred; the greatest in the county of Haddington, or East Lothian, where not quite a fourth remains uncultivated; and the average of all Scotland is 26.6 in the 100. Including mines,

quarries, and fisheries, the medium rent of the land may be a little more than 5s. an acre.

It is worthy of remark, that both the law and practice of Scotland are favourable to agricultural enterprise. Leases are almost universal, and of considerable duration. There is no tithe drawn; poor rates are unknown, except in a few districts, and where they do prevail, of a very trifling amount; and commons and common fields, for the division of which no act of Parliament is necessary, have, with very few exceptions, disappeared.

The titles of the columns in the following Table sufficiently indicate the contents of each. The rental for 1812 is the gross rental of the *Lands and Houses* as returned by the parties, or estimated by assessors acting under the Property-tax act.

V.—MINES AND FISHERIES.

Scotland is not deficient in the most useful minerals. It has coal, iron, lead, with excellent stones for building and paving, slate, limestone, and marble.

Its great coal-field, stretching across the country in a diagonal line from west to east, or from the Frith of Clyde at Dunbarton to St Andrews, in Fife, and Haddington, in East Lothian, is about 98 miles

\* The rental of this small county is included in that of Ross-shire, in which its lands are interspersed.

Scotland.

long, with an average breadth of 33 miles, and estimated to extend over 600,000 acres. Coal has also been found to the north, in the county of Sutherland, and in Dumfries-shire and Roxburghshire on the south; but owing to situation, or to its inferior quality, it is not worked in either quarter to any considerable extent. Hence, though at the present rate of working, it has been calculated that the great coal-field would last 3000 years, yet a large portion of the country is but indifferently supplied with this necessary of life in so cold a climate. In the Highlands and Isles, peat or turf is the most common fuel, and the only sort to which the lower classes have access; and in the south and south-west coasts are imported largely from Newcastle and Whitehaven, by sea, and from the borders of Northumberland by land carriage. On the other hand, Scotland exports to Ireland and other parts to a still greater amount, and some of her best kinds begin to find a ready market even in England. The Scotch coal differs from the English in its rising in large masses, which do not adhere or cake together in burning; and though it makes a more cheerful fire it is not so durable, and the common kinds leave more ashes than the English. Some of the fusing or caking coal is occasionally met with in the same pits with the other kind, but it bears a small proportion to the whole. The quantity consumed in the country is stated to be about two and a-half millions of tons, of which two millions are supposed to be required for domestic purposes, and the remainder for the iron and lime works and other manufactures; and the price which, in 1813, was averaged at the pit-mouth at 6s. 8d. the ton, may be less at present by 10 or 15 per cent. After paying all charges at the works, the coal owner's share of the price does not exceed 1s. a ton.

Iron.

Iron is very generally found, particularly in the coal districts, and is wrought to a considerable extent; though a great deal is still imported, chiefly from Wales. The greatest manufactory is near Falkirk, well known by the name of the Carron-works. A few years ago there were in all 21 blast furnaces in Scotland, producing about 33,000 tons annually, and giving employment to 7650 people.

Lead.

Lead, which occurs in many parts of Scotland, is wrought to the greatest extent at Leadhills and Wanlockhead, on the confines of the counties of Lanark and Dumfries, where between 3000 and 4000 tons are raised yearly. The number of people in these two villages, the most elevated in Scotland, employed in and supported by the labour of the mines, is about 2000. Other mines, upon a small scale, have been long worked in the isle of Isla, one of the Hebrides, and on the west coast. The produce of the whole has been estimated at L. 136,000, of which the proprietor has a sixth part, and the contractor, or lessee, who bears all the charges, the remainder. The silver obtained from the lead varying from six to seventeen ounces for every ton, is said to be worth about L. 10,000 a year, and is now extracted at home instead of being sent to Holland for that purpose, as was the practice till within the last thirty years.

Stone.

Granite, sandstone, basalt, and other stones, are so abundant, that in every district one or more kinds

is at hand for building, paving, inclosing, and other purposes; but it is only near large towns that the quarries afford any considerable rent to the owners. Those in the neighbourhood of Edinburgh, from which the freestone of the elegant buildings in the New Town is procured, rented at about L. 10,000 *per annum* more than twenty years ago. The most beautiful and durable species of freestone in the kingdom is that furnished by the quarries at Culello, in Fifeshire. Slate is wrought extensively at Easdale, Slate. one of the Hebrides, at Balachelish, in Argyleshire, and other places. Limestone, producing in all about Limestone. 12,000,000 of bushels of slacked lime, worth upwards of L. 350,000, is wrought in various parts, but chiefly in the neighbourhood of the coal-works. About 100,000 acres are supposed to be dressed every year with this important manure. Marble is found in the Marble. Hebrides, on the west coast of Argyleshire, and in Sutherland, but often blended with other minerals, which injure its appearance, and render it difficult to work. A pearl fishery on the Tay is said to have yielded L. 10,000 annually for a few years, but has produced little or nothing for more than half a century. Marl has a local value as a manure, but the quantity that must be applied to land is too great to admit of its being used at a distance from the spot where it is found.

Mineral waters, of various qualities, occur in many parts of Scotland. Those which have been long in most repute, and still maintain their character, are found at Moffat, in Dumfries-shire, and Pitcaithly, in Strathearn, in the county of Perth.

The fisheries form a very important article in the productive labour of Scotland; the annual value of the whole having been estimated, ten years ago, at near a million and a half Sterling. Since that time the herring fishery, which was then stated at half a million, has been progressively increasing; and the repeal of the duties on Scotch salt in the last session of Parliament (1822), must afford encouragement, especially to the small fishermen on the coast, who felt themselves so much annoyed by the excise regulations, to prosecute both that and the other fisheries to the utmost extent of the market; for as to the supply it is held to be inexhaustible. But, for a particular account of this great branch of national industry, we must refer to the Article FISHERIES in this *Supplement*, and also to the Article ORKNEY, where notice has been taken of a productive cod bank lately discovered in that quarter.

#### VI.—MANUFACTURES, COMMERCE, AND SHIPPING.

Since the Union with England, and more especially since the close of the American war of independence, Scotland has enjoyed a full share, in proportion to her wealth and population, of the manufactures and commerce of Great Britain. There is scarcely a single branch of either in which she does not participate, while in some articles, such as linen and spirits, she has long been in advance of England, and has one or two others almost peculiar to herself.

As several of the Tables given under this head in the Article ENGLAND, in this *Supplement*, embrace Scotland as well as England, for which, in some instances, it would be impracticable to exhibit separate articulate statements, we must refer the reader to that article,

Scotland. and confine ourselves at present to a general view of such branches belonging to Scotland as are common to both countries; giving some further notices of others which are more properly of a Scottish character.

Woollens. Of the manufactures, that of woollen, carried to so great an extent in England, has never made much progress in Scotland. A variety of articles, of a coarser description, are made for domestic consumption in country families; and a number of small establishments have been formed in different parts, where machinery is employed, and the several processes of the English manufacture, from the raw material to the finished fabric, are adopted with considerable success. But most of the wool grown in the country is still exported to England, and almost all classes of the people, at least in towns, use English broad cloth, flannels, and blankets, in preference to their native fabrics. Carpeting is made to some extent at Kilmarnock and a few other places; tartans in the county of Stirling; and Shetland has been long noted for its hosiery.

Cottons. The cotton manufacture, though not half a century old, has been much more successful. Its principal seat is in Lanarkshire and the western counties adjacent, where it is conducted in its various branches to such an extent, as to give employment to about 150,000 hands, of whom 90,000 are women and children. The value of the goods produced was estimated, in 1812, at near seven millions Sterling. In 1818, Glasgow and its neighbourhood furnished to the amount of more than five millions, about half of which was exported. For a particular account of this great branch of industry, see the Article COTTON MANUFACTURE in this Supplement.

Linens. Of the linen manufacture of Great Britain, Scotland has by far the greatest share. In 1727, a Board was established at Edinburgh under the authority of an act of Parliament (13th Geo. I.), for the regulation and encouragement of the linen and hempen manufactures. Since 1812, according to a Return made to Parliament (ordered to be printed 3d July 1823), this Board has had an income of about L. 8000 a year, of which it expended annually between L. 3000 and L. 4000 for this purpose, and in premiums to the growers of the raw materials. Among other regulations it was till lately required, that all the linen cloth made for sale should be stamped by officers appointed by the Board; but this regulation was abolished by the act of the 4th Geo. IV. cap. 40, passed in June 1823. The quantity and estimated value, every tenth year, from 1730 to 1810, are as follows:

After 1810, this branch seems to have declined. In 1811, the quantity stamped was less by about five millions of yards, and in 1812 it was further reduced by about two and a half millions. Since the peace it has participated in the fluctuation, to which almost all the other branches of our industry have been exposed, but has of late increased very much, and is now in a prosperous state.

Very little of the linen is of a fine quality; it consists chiefly of sheetings, osnaburghs, bagging, &c. the average price not exceeding 1s. a yard. The finer kinds are either made in private families or imported from Ireland. The counties of Aberdeen, Fife, and Forfar, carry this manufacture to the greatest extent, having about four-fifths of the whole. Machinery has been extensively employed since 1790, but it has not yet been found applicable to the finer qualities of yarn, which are still spun by hand.

The royal navy, during the late wars, was chiefly supplied with sail cloth from Scotland. In 1812, the whole quantity made for this purpose, for private shipping, and for exportation, was estimated at 6,750,000 yards, worth about L. 300,000. This article is not included in the returns made to the Board.

The total value of the linen and hempen manufactures of Scotland, about the end of the war, including the yarn exported to England, has been stated at L. 1,775,000; but with what was made for private use and not stamped, of which no accurate account can be given, the whole perhaps amounted to about two millions Sterling, and is now estimated at near three millions.

As very little flax, and scarcely any hemp, are grown in Scotland, the raw materials must be imported; the flax chiefly from Holland, and the hemp from Russia; the prices of which, during the latter years of the late war, bore a large proportion to the value of the manufacture.

In 1812, the imports of these articles into Scotland, and their value, were as follows:

	Quantity.			Value.		
	Tons.	cwt.	qrs. lb.	L.	s.	d.
Flax	6094	4	2 18	@ L.100	609,423	6 1 1/2
Hemp	2496	17	1 18	@ L.90	224,718	7 0 1/2
	8591	2	0 8	Amounting to	834,141	13 2

Since the peace, these prices have been greatly reduced, and the import of flax is almost doubled; but the export trade has increased in the same proportion, as appears from the following statement. (Customhouse Returns, 13th May, 1823.)

Years.		Total Yards.	Total Value.		
			L.	s.	d.
1730	Under 9d.	3,755,622 1/4	131,262	15	11 3/4

Scotland.

These are the exports of British linens, no separate account being kept of what are made in England and in Scotland; but by far the greater part is of Scotch manufacture.

The countries to which these exports were made in the years 1821 and 1822 are as follows: (*Parliamentary Paper*, ordered to be printed 22d May 1823.)

Countries.	1821.			1822.

Bounty on Linens.

A bounty is paid on the export of linen cloth according to its value; below 5d. the yard, a halfpenny; from 5d. to 6d., a penny; and from 6d. to 1s. 6d., one penny halfpenny. On linens above 1s. 6d. per yard there is no bounty. The bounty is allowed on English and Irish linens as well as Scotch.

Malt and Spirituous Liquors.

Malt liquors and spirits are made in great perfection in Scotland; and, notwithstanding the frequent alteration of the laws by which this manufacture is regulated, and a corresponding fluctuation in the trade itself, it has long formed a most important branch of the national industry. From 1786 to 1800, the quantity of malt made in Scotland varied from 1,500,000 to 2,000,000 of bushels yearly; the ordinary rate of duty being then 7 $\frac{7}{8}$ d. per bushel. In 1804, when the duty on malt made from barley was raised to 3s. 8 $\frac{3}{8}$ d., and from bear or bigg to 3s. 0 $\frac{1}{8}$ d., the number of bushels fell to 1,125,482, and never reached 1,500,000 while these duties remained in force. In 1817, 1818, and 1819, when the duty was 1s. 8 $\frac{1}{8}$ d., the quantity increased from 1,129,992 $\frac{5}{10}$  to 1,556,586 bushels. But in 1820, when it was raised to 3s. 6d., the number of bushels fell to 1,284,918 $\frac{3}{4}$ . In 1822, under new modifications of the duty, it was 1,347,432 bushels; and for the year ending 5th April 1823, the number had increased to 2,150,795 bushels; of which 1,816,691 $\frac{1}{2}$  were made from barley, and 334,103 $\frac{1}{2}$  from bear or bigg. No-

thing can afford a more striking proof of the unproductiveness, as well as the impolicy of a tax, when carried to an extreme. In 1792, the number of bushels was upwards of 2,000,000, and, at that rate, allowing for the increase of population, it should have been almost 3,000,000 in 1822, instead of being, as it actually was, less in 1822 than 1792 by one-third.

The quantity of beer and ale made in Scotland in 1822 was near 350,000 barrels, less by almost 3000 barrels than in 1792. The exports to England for the four years ending with 1820 was about 13,000 barrels yearly. Before 1801 it was seldom more than 500 barrels.

The duties and regulations affecting the Scotch distilleries have been so often altered, and even the principle itself according to which the duty is imposed, that it becomes difficult to exhibit an intelligible comparison between different periods without more explanation than our limits will permit. But some notion may be formed of their importance from the following account, which embraces three different rates of duty, and shows the influence of each on the quantity produced, and the revenue derived from it. The spirits are those made for home consumption only, not partly for the English market, and all made from grain or malt; no sugar or molasses being used in those years. (*Report on the Malt Duties of Scotland*, May 1821.)

*Scotland.* For the quantity of spirits made in Scotland for the English market, and exported to that country, see the Article ENGLAND in this Supplement.

Besides the spirits which pay duty, illicit distillation, carried on in most of the Highland counties, supplies not a small proportion of the home consumption; the produce, from its being generally of a finer quality, finding its way, in spite of the vigilance of the revenue officers, into every part of the country. But the act passed in July 1823 (4th Geo. IV. cap. 94), by which the duty on spirits is greatly reduced, will leave so small an advantage to the illicit distiller, that he will probably find it no longer for his interest to persist in a course which has been the cause of so many evils both in this country and in Ireland.

*Breweries and Distilleries.*

Breweries have been established in all the towns of Scotland, among which those of Edinburgh, Alloa, and a few others, are in high repute. The principal distilleries are in the Lothians and the counties of Stirling, Fife, and Clackmannan. The business of the maltster being rarely a separate one, is combined with that of the distiller and brewer, the malt being generally made at the works where it is to be used.

Of the other manufactures of Scotland we must confine ourselves to a very brief notice. We have already mentioned her iron-mines, and the quantity produced yearly; to which we may add, that there are about 50 founderies, where it is converted into a great variety of agricultural and domestic implements and machinery, of which the export to America, the West Indies, and the other British colonies, is considerable; but the finer branches of the iron manufacture, such as locks and hinges, cutlery, &c., are not carried to any great extent. The silk manufacture, about fifty years ago, was prosecuted to a considerable amount in Paisley, but is now of little importance. Among the other articles, we may mention paper, glass, soap, culinary salt, and leather, which, with many others, though not singly of much interest, afford employment to a great many hands, and produce altogether a large sum.

*Kelp.*

The simple process of burning sea-weed into kelp, and the value of the article, form an important branch, especially in the Western and Northern Isles. About 80,000 people, of all ages, it is calculated, are employed in or dependent on this rude manufacture. The kelp is made during the summer months by the same people who afterwards engage in the herring fishery. The quantity has been stated variously, but, in favourable seasons, may probably amount to 16,000 tons; the best of which, during the late war, when the price of barilla was very high, brought upwards of L. 20 per ton. But since the peace, the price has been so much reduced, that it will do little more than pay the expence of the labour required, which may average between L. 3 and L. 4 per ton. Some of the Highland proprietors draw the greater part of their income from their kelp shores, and it is by their labour in making the kelp that many of the small tenants are enabled to pay their rents.

*Commerce.*

The commerce of Scotland with the British colo-

nies, and with foreign countries, is included in that of Great Britain given in the Article ENGLAND in this Supplement. Scotland trades with the same countries as England, and the articles she exports are, for the most part, of the same description. From Leith, Dundee, Aberdeen, and a few other ports on the east coast, a considerable trade is carried on with Sweden, Russia, the shores of the Baltic, and Holland; but the principal part of her foreign and colonial trade centres in the Clyde, which is the great emporium of the trade with the West Indies and America, and also with Ireland.

*Scotland.*

The trade between Scotland and England must be to a large amount, but as that part of it which is carried on by land does not appear in the Custom-house books, it does not admit of being estimated with much accuracy. Scotland sends to England exclusively cattle, sheep, and wool, and home-made spirits, and a large proportion of her other exportable produce and manufactures, such as corn, kelp, salmon, linen goods, &c.

*Banks.*

Intimately connected with the trade are the banking establishments of the country, which are numerous, substantial, and liberal in their dealings. Three of them, having their head offices in Edinburgh, and a great many branches throughout the country, were established by charter; namely, the Bank of Scotland, the Royal Bank of Scotland, and the British Linen Company. These, with several private banks in Edinburgh, Glasgow, and other large towns, issue notes, receive deposits, discount inland bills at three or four months date, and pay and receive sums so low as L. 10 on cash accounts. On money deposited with them, and also on what is paid in on the cash accounts, they invariably allow interest, though at a less rate than they charge themselves. As there is no limitation as to the number of partners, the credit of the Scotch banks is above all suspicion; and even with such of them as have stopped payment, a thing which very rarely happens, the loss has fallen upon the partners—very seldom, and to a very small amount, upon the public. The circulating medium of the country is almost entirely composed of the notes of these banks.

*Shipping.*

The registered vessels belonging to Scotland, with the amount of their tonnage, and the number of men and boys usually employed in navigating them, on the 30th September 1820, 1821, and 1822, were as follows:

	Vessels.	Tons.	Men.
1820 .....	3133	288,770	20,470
1821 .....	3160	289,535	20,855
1822 .....	3071	276,931	19,831

The number of vessels, with the amount of their tonnage, built and registered in Scotland in the years ending 5th January 1821, 1822, and 1823, will give an idea of the extent to which ship-building is carried on; and to show that it has more than its proportional share of this trade, we subjoin the same account for England.

Scotland.

	1821.		1822.		1823.	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
England	461	54,014	399	46,296	442	43,212
Scotland	121	11,004	122	9,457	87	6,162

Steam-Boats.

The intercourse between the different parts of the United Kingdom has been greatly facilitated by the recent invention of Steam-Boats. On the east coast of Scotland, there is a cheap, speedy, and regular communication by this means between all the principal towns, and between Leith and London, and the intermediate ports in England, for the greater part of the year; and on the west coast, besides those which ply on the Clyde between Glasgow and Greenock, vessels of this description sail between Glasgow and Liverpool, and cross the Channel to Ireland. Hitherto, passengers have been the principal object, and the hours of departure and arrival are almost as regular as those of the mail-coaches. The voyage between Leith and London is often made in about fifty hours, and the ordinary rate of sailing on the Forth and Clyde is from eight to ten miles an hour.

VII.—EDUCATION—RELIGIOUS INSTRUCTION—THE POOR.

Parish-Schools.

By an act of the first Parliament of William and Mary, it was provided, that "there be a school and schoolmaster in every parish" of Scotland; the salary of the schoolmaster to be not under 100 merks, nor above 200. In 1803 the lowest salary was fixed by another act at 300 merks (L. 16, 13s. 4d.), and the highest at 400 (L. 22, 4s. 5d.), besides a dwelling-house of at least two apartments, and a quarter of an acre of ground for a garden. At all these schools, reading, writing, and arithmetic are taught, and at many of them the classics and the French language, with geography, and some branches of the mathematics. The fees paid by the scholars in the country parishes, in addition to the salary, vary from 1s. 6d. to 5s. the quarter; but the master is obliged to teach the children of the poor on the recommendation of the kirk-session, *gratis*. The school, and schoolmaster's house and garden, are provided by the parish by assessments on the land; and one half of the salary is payable by the proprietors, and the other half by their tenants. These schools are under the inspection of the presbytery in which they are situated, who visit and examine them yearly. So generally have the lower classes availed themselves of this primary source of instruction, that an adult male, a native of the Lowlands of Scotland, who is ignorant of the common rules of arithmetic, is very rarely to be met with; and there are but few females who have not been taught to write as well as to read. In the Highlands and Isles, however, where many of the parishes are of great extent, and the intercourse is obstructed by the nature of the country, the case is very different. In some of these, half the inhabitants cannot read, and from the same causes the means of religious instruction are scanty, and of difficult attainment.

Scotland.

The Society of Scotland for *Propagating Christian Knowledge*, and the Committee of the Church for applying the Royal bounty, have done much, in both respects, by means of missionaries, catechists, and schoolmasters. Every year at the meeting of the General Assembly, the Sovereign, through his representative, the Commissioner, presents to this Court an order for L. 2000, to be employed in these useful labours.

Besides the parish-schools, a great many private schools are supported by the fees of the pupils alone. Of these, there is one or more in all the towns and villages of Scotland; and in the principal towns are found academies, and other seminaries of a higher order, besides the universities of Edinburgh, Glasgow, Aberdeen, and St Andrews. (See these towns, and also SCOTLAND in the *Encyclopædia*, and EDINBURGH and GLASGOW in this *Supplement*.) Sunday schools, and those taught after the manner of Bell and Lancaster, are therefore less wanted here than in most other countries. Yet about 500 Sunday schools were reported to the General Assembly in 1818, and, including those of Edinburgh and Glasgow, the number of scholars was then upwards of 25,000.

The Church.

For a particular account of the Church establishment, we must refer to SCOTLAND in the *Encyclopædia*, and confine our notices here to its present state, in so far as it differs from its former. In 1818 the number of presbyteries and parishes which compose each of the synods were as follows:

No.	Synods.	Presbyteries.	Parishes.
1	Lothian and Tweeddale .....	7	104
2	Merse, or Berwick and Teviotdale .....	6	66
3	Dumfries .....	5	53
4	Galloway ... ..	3	37
5	Glasgow and Ayr .....	7	127
6	Perth and Stirling .....	5	78
7	Fife .....	4	66
8	Forfar and Mearns .....	6	75
9	Aberdeen .....	8	97
10	Moray .....	7	52
11	Ross .....	3	23
12	Sutherland and Caithness ...	3	23
13	Argyle .....	5	39
14	Glenelg .....	5	29
15	Orkney .....	4	30
		78	899

Stipends of the Clergy.

The stipends of the clergy, the amount of which varies from year to year with the prices of grain, afford a moderate competence to all, but affluence to none. Throughout the country parishes, in seasons of average prices, the medium amount may be about L. 200 a-year, with a good dwelling-house, and a glebe, worth at least L. 50 more. In 1810 all the stipends below L. 150, which, from the want of free tithe, could not be augmented by the Commissioners of Teinds, were, by the 50th Geo. III. cap. 84, raised to that sum; the deficiency, which amounts to about

Scotland. L. 10,000 a-year, being supplied by Parliament This, therefore, is the minimum stipend in the church of Scotland, though, from very low prices of corn, some of those that do not partake in this bounty may occasionally fall below it. Out of 899 parishes, this augmentation was required for 172, or 1 in  $5\frac{1}{4}$ .

Dissenters. The Dissenters from the Established Church do not amount to a fourth part of the population, and two-thirds of them differ from it rather in matters of discipline than in doctrine. The most numerous classes of Dissenters are the Burghers and Antiburghers (recently united), and the Relief denomination. The other dissenters are Roman Catholics, Episcopalians, Methodists, with a few hundred Quakers, and a very small number of Jews. All these sects have their own places of worship, to which they resort in preference, though few of them exclusively. They mix freely in society, and their children, at least all those whose parents are of the Presbyterian persuasion, are taught at the same schools; little or nothing now remaining of that religious animosity which was once so prevalent in this country.

The Poor. The poor of Scotland are provided for partly by rates levied under the authority of the laws, but chiefly by voluntary contributions; and altogether, both their number, and the sums applied to their relief, are comparatively inconsiderable. In the country parishes, the sum to be raised by assessment is fixed by the land-owners, or heritors, and paid in equal proportions by themselves and their tenants; and in the towns the rate is levied from the inhabitants according to the rent of their dwelling-houses, or the estimated value of their property. The voluntary contributions consist of collections at the church-doors, fees paid at marriages and baptisms, and other small sums under the management of the Kirk-Session; to which in many parishes there is added, in seasons of peculiar pressure, such as a year of scarcity and high prices, a sum raised from the heritors and their tenants, upon the same principle as the legal assessments. In addition to these funds, some of the greater proprietors occasionally bestow donations in money, oatmeal, and coals, to be distributed under the inspection of the clergyman, or his elders; and not a few of the parishes have had bequests made to them for the maintenance and education of their poor, the interest of which forms the greater part of the yearly disbursements.

The following results, taken from the "General Abstract of the Population, Poor, and means of maintaining the Poor in Scotland," subjoined to the *Supplementary Report* of the General Assembly laid before Parliament in 1820, present the best information we have access to on this interesting subject:

Population for which the returns were made . . . . .	1,764,987
Number of paupers . . . . .	44,199

Proportion of paupers to population	1 to $39\frac{9}{10}$	Scotland.
Assessments . . . . .	L. 49,718 10	$5\frac{3}{4}$
Collections, and other voluntary payments . . . . .	64,477 7	$3\frac{9}{12}$
Gross funds . . . . .	L. 114,195 17	9
Sum which each pauper costs . . . . .	L. 2 11	8
Expence to each individual of the population . . . . .	0 1	3

As this Report was prepared little more than a year before the last census, the proportion of paupers to the population, and the expence that falls upon each individual, is stated too high. On the population of 1821, the proportion will be *one* pauper to  $47\frac{5}{8}$ , and the expence 13d. for each individual of that population. If the whole sum applied to the relief of the poor were raised by a rate on the lands and houses, it would be equal to about L. 1, 18s. *per cent.* of the rent in 1812 (see preceding Table, containing the Extent and Rental of Scotland); or about  $4\frac{1}{2}$ d. *per* pound of that rental. The returns from which the Assembly's *Report* was prepared were complete, with the exception of twenty Highland parishes, having a population (in 1811) of 36,290.

According to other returns made to the Assembly in 1818, the number of Friendly Societies, exclusive of those of Edinburgh and Glasgow, amounted to 327, composed of 72,153 members; and with the same exclusion, 130 Savings Banks were reported, having 7000 contributors, and deposits to the amount of L. 30,000. It is stated, on the same authority, that a capital of L. 10,082, with L. 2034 of interest, was *mortified* for the support of the poor; and L. 100,750 of capital (including L. 70,000 lately bequeathed to the country parish of Dollar, in Clackmannanshire), and L. 793 of interest for their education. These sums do not include the funds of the great hospitals, of which an account will be found under EDINBURGH and the other towns in the *Encyclopædia* and in this *Supplement*.

VIII.—POPULATION.

The population of Scotland was taken, though not by authority, in 1755; and the writers of the *Statistical Account* afford the means of estimating its amount about 1798, when it appears to have been less by 72,576 than in 1801. But in the following Table, we shall confine ourselves to the three enumerations made under the authority of Parliament; presenting only the totals for 1801 and 1811, but giving that of 1821 under separate heads. The Table also shows the extent of every county in square miles, the increase of its population from 1801 to 1821, and the rate *per* square mile in 1821:

Scotland.

Counties.	Extent in Square Miles, exclusive of Lakes.	Population in 1801.	Population in 1811.	Population, 1821.							
				Males.	Females.	Totals.	Inc. per cent. 1801 to 1821.	Rate per Square Mile.	Occupations.		
									Families.		
									Agriculture.	Trade.	All Others.
Aberdeen	1960	123,082	135,075	72,383	83,004	155,387	26.2	79.3	13,775	16,029	5,897

Ross and Cromarty	2885	55,343	60,853	32,324	36,504	68,828	24.5	24.0	7,947	3,356	3,203
Roxburgh	715	33,682	37,230	19,408	21,484	40,892	21.4	57.2	3,613	2,822	2,204
Selkirk	263	5,070	5,889	3,205	3,432	6,637	30.9	25.2	421	409	542
Stirling	489	50,825	58,174	31,718	33,658	65,376	28.6	133.7	2,600	6,641	4,492
Sutherland	1754	23,117	23,629	11,088	12,752	23,840	3.1	13.6	3,362	642	818
Wigton	451½	22,918	26,891	15,837	17,403	33,240	45.0	73.6	3,525	2,089	1,160
Totals	29,600	1,599,068	1,805,688	983,552	1,109,904	2,093,456	30.9	70.7	130,699	190,264	126,997

From this Table it appears that, with the exception of Orkney and the small county of Nairn, there was an increase in all the counties of Scotland between 1801 and 1811; and that in every one of them the population of 1821 is greater than that of 1801; so far is it from being true that the Highlands of Scotland, as has often been alleged, are in the course of being depopulated. The greatest increase is in the manufacturing county of Lanark and in the county of Edinburgh; but several counties, which are wholly or chiefly agricultural, have also increased considerably in these twenty years. The rate of increase for the whole period is very nearly 31 per cent. on the population of 1801. From 1801 to 1811, the rate is nearly 13 per cent.; and from 1811 to 1821 it is 15½ per cent. If the population should go on increasing at the last rate, the period of doubling would be little more than 47 years. The average population, per square mile, is 70.7; the lowest being that of Sutherland, which is only at the rate of 3.1 per square mile, and the highest that of Edinburgh, which is 541.

From the want of correct registers, the proportions of births, marriages, and deaths, cannot be accurately stated; but in the absence of these, we give the following general results for the city and suburbs of Glasgow, of which the population, in 1822, was 147,043:

The number of Births, including still-born,.....5,624  
 Marriages, .....1,470  
 Burials, .....3,690  
 Births to one marriage, .....3,815  
 ——— to one burial, .....1,524  
 Burials to one marriage, .....2,510  
 One birth to persons, .....26,146  
 One marriage to persons, ...100,029  
 One burial to persons, .....39,849  
 (See Cleland's *Statistical Tables*.)

The population of the principal towns, at the periods of the three enumerations, was as follows. Those to which the letter B is added are royal burghs:

Scotla

Scotland.

Towns.	1801.	1811.	1821.
Edinburgh, <i>B</i> .....	82,560	102,987	138,235
Glasgow, <i>B</i> .....	77,385	100,749	147,043
Paisley .....	31,179	36,722	47,003
Aberdeen (city and district), <i>B</i> .....	35,412	44,211	55,094
Dundee, <i>B</i> .....	26,084	29,616	30,575
Greenock .....	17,458	19,042	22,088
Perth, <i>B</i> .....	14,878	16,948	19,068
Dunfermline, <i>B</i> .....	9,980	11,649	13,681
Kilmarnock .....	8,079	10,148	12,769
Inverness, <i>B</i> .....	8,732	10,757	12,264
Falkirk .....	8,838	9,929	11,536
Dumfries, <i>B</i> .....	7,288	9,262	11,052
Montrose, <i>B</i> .....	7,974	8,955	10,338
Campbellton, <i>B</i> .....	7,093	7,807	9,016
Ayr, <i>B</i> .....	5,492	6,291	7,455
Stirling, <i>B</i> .....	5,256	5,820	7,113
Irvine, <i>B</i> .....	4,584	5,750	7,007
Port-Glasgow .....	3,865	5,116	5,262
St Andrew's, <i>B</i> .....	4,203	4,311	4,899
Rutherglen, <i>B</i> .....	2,437	3,529	4,640

It appears from the Report made to the General Assembly in 1818, that there were of

Blind .....	1100
Deaf and Dumb .....	784
Insane .....	4650

6534, being in the proportion of 1 to 320 of the population of 1821; but for the insane, the returns were not complete, and the numbers of the blind and deaf and dumb are given partly on supposition.

IX.—REVENUE.

The revenue of Scotland, at the Union, was as follows :

Crown rents .....	L. 5,500 0 0
Feudal casualties .....	3,000 0 0
Carry forward,	L. 8,500 0 0

Brought forward,	L. 8,500 0 0	Scotland.
The customs .....	30,000 0 0	
The excise .....	33,500 0 0	
The post-office .....	1,194 0 0	
Coinage impositions .....	1,500 0 0	
The land-tax .....	36,000 0 0	
Total	L. 110,694 0 0	

For the year ending 5th January 1804, the amount is thus stated (Sinclair's History of the Revenue):

Customs .....	L. 729,694 0 0
The excise, including the salt-tax, but exclusive of the annual duties on tobacco and malt .....	1,281,856 0 0
Tobacco and malt, annual .....	112,467 0 0
Stamps .....	194,275 0 0
The post-office .....	117,321 0 0
Land and assessed taxes .....	215,839 0 0
The 6d. per pound on pensions, salaries, &c. ....	2,666 0 0
The 1s. on ditto .....	3,860 0 0
	L. 2,657,978 0 0

Of which there was paid for Collection .....	L. 230,721 0 0
Bounties, &c. ....	355,816 0 0
Expences of civil government of Scotland .....	137,165 0 0
Deduct .....	723,702 0 0
Remains	L. 1,934,276 0 0

Of which there was remitted to the Exchequer of Great Britain L. 1,932,397.

In 1813, the nett revenue was L. 4,155,599, including the property-tax, the gross receipt of which was L. 966,790.

The property-tax having been repealed, and other taxes reduced, the gross and nett revenue, and charges of management for the year ending 5th January 1822, were as follows :

	Gross Revenue accrued within the Year.			Nett Revenue accrued within the Year.			Charges of Management.			Rate per cent. of Ex- pence Collecting.					
	L.	s.	d.	L.	s.	d.	L.	s.	d.	The Gross Revenue.			The Nett Revenue.

Of the two great branches of customs and excise, Scotland pays considerably more than appears in this abstract; for several important articles, tea for instance, pay the duties in England, and are, there-

fore, included in the English accounts, though partly consumed in Scotland, to which they are carried duty free.

The following Abstract, made from an account

Scotland. presented to the House of Commons in May 1823, years ending 5th July 1792 and 1822 respectively, and the amount of duty on each: Scotland.

Civil Estab-  
lishment. The expence of the Civil Establishment of Scotland, for the year ending 5th January 1823, was L. 137,635, 17s. 7 $\frac{5}{12}$ d. This sum, to the amount of L. 114,250, 11s. 10 $\frac{5}{12}$ d., is composed of the salaries of the Crown Officers, of the Judges and Officers of the several courts in Edinburgh, and of the Sheriffs-depute and substitute of the counties.

X.—REPRESENTATION IN PARLIAMENT.

Of the Peers. The Peerage of Scotland is represented in the House of Lords by 16 members of their body; and the Counties have 30 and the Royal Burghs 15 members in the House of Commons.

At the Union, the number of Scotch Peers was 159; of whom, in 1812, 77 were extinct or dormant, or their titles merged in, or united to others, or forfeited; and of the remaining 82, 23 were British Peers and two Roman Catholics. The Peers who were qualified to vote at the election in that year were 74, but the number who actually voted was only 52.

Of the Coun-  
ties. Each county sends one member to the House of Commons, with the exception of Bute and Caithness, Clackmannan and Kinross, Cromarty and Nairn, which have only three members; each of these pairs choosing a member alternately.

Of the  
Burghs. The burghs, 66 in all (see SCOTLAND in the *Encyclopædia*), with the exception of Edinburgh, which sends a member by itself, are classed together, not fewer than four, nor more than five; every class or district choosing one member by means of delegates

sent from each of its burghs. These delegates are chosen by the magistrates and town-councils, who, with one or two exceptions, are themselves nominated by their predecessors in office, and not by the burgesses. The number of electors in each burgh varies with its particular Constitution, but may be averaged at 20, making 1320 in all. The population of the *royalties* of these burghs cannot be less than 456,000. (See Cleland's *Statistical Tables*.)

The population in 1821 being 2,093,456, and the number of representatives in Parliament 45, there is thus a representative for every 46,521 persons over all Scotland; and taking the burghs by themselves, one for every 30,400 persons residing within the *royalties*, exclusive of the inhabitants of the suburbs and dependencies; which, in the case of Edinburgh and Glasgow, are more numerous than those of the burghs themselves.

Again, as to the proportion of the inhabitants who enjoy the elective franchise, the number of the freeholders (at Michaelmas 1822) being, as already stated, .....2987 and the voters in the royal burghs 1320

the total number of voters is.....4307; or at the rate of one in every 486 of the population. Finally, the 30 members for the counties have each, at an average, 99 $\frac{1}{2}$  constituents, and the 15 members for the burghs 88; and taking all Scotland, the electors are to the members as about 95 $\frac{2}{3}$  to 1.

Several large or considerable towns, such as Pais-

Scotland. ley, Greenock, Kilmarnock, and Falkirk (see the preceding Population Tables), not being burghs, have no share in the elections; while Queensferry, Forthrose, New Galloway, and Anstruther, having each only from 500 to 1000 inhabitants, and other 16, less than 2000 each, have near one-third of the political influence of the Scottish burghs. The county of Fife, which in this respect may be called the Cornwall of Scotland, has 13 of the 66 burghs; of which nine are so inconsiderable as scarcely to deserve the name of villages.

The inadequacy, inconsistency, and inequality of this system of representation is abundantly obvious; but the discussion of these points does not belong to this place.

## XI.—JUDICIAL ESTABLISHMENTS.

### SECT. 1.—Civil Jurisdictions.

1. *Justices of the Peace.* These are magistrates appointed by royal commission, within the several counties of Scotland, chiefly for the preservation of the public peace, but with a right also of exercising a limited jurisdiction in other respects, derived partly from statute, and partly resting on consuetude. No particular qualification in point of rank, money, or property, is necessary here, as in England, to entitle a person to act as a Justice. The office is gratuitous, and is held during the pleasure of his Majesty.

The first introduction of Justices was above two centuries ago (1587, c. 82, 1609, c. 7), and their powers and duties have, from time to time, been regulated since, by various acts, both of the Scots and British Legislatures.

They are competent in questions of servants' wages, of aliment to natural children, of straightening marches and erecting fences between adjacent properties, &c. They issue warrants of *mediatio fugæ* against debtors intending to leave Scotland with a view of defrauding their creditors; and imprison them until they find caution *de judicio sisti*. They have ample powers in regulating highways, bridges, and ferries, and in determining questions concerning them. They judge in a numerous and important class of questions with regard to the revenue; particularly the Excise and Customs. They formerly had power to fix prices of work for artificers, labourers, and craftsmen, and to compel the service of these classes at the stated rates; but the old statutes authorizing this abuse are now repealed (53d Geo. III. c. 40).

The most important branch, however, of their civil jurisdiction, and certainly the most extensively useful to the public, is of modern date; viz. that which is vested under the Small Debt acts. Prior to these, there had existed in the city of Edinburgh, and it is believed in some other places, an ancient consuetudinary jurisdiction; under which the magistrates decided, in a summary way, questions of debt not exceeding L. 40 Scots. By 35th Geo. III. c. 123, the experiment was tried of extending such a jurisdiction over Scotland, by authorizing any two or more justices, within their respective counties, to hold courts, and try all causes for recovery of debts not exceeding the same limited amount; and this

Scotland. being eminently successful, the system was improved and rendered perpetual by 39th and 40th Geo. III. c. 46, which farther extended the amount of debt competent to be sued, to any sum not exceeding L. 5 Sterling.

In the period from 1st October 1795 to 1st June 1800, there were decided in the small debt court of Edinburgh 13,968 cases, making an annual average of 2991; and from 1st June 1800 to 1st October 1820, 96,979 cases, or an annual average of 4767. The maximum debt competent to be sued, during the first period, was L. 3, 6s. 8d. and the total value of the cases decided L. 16,865, 6s. 1½d. During the second period L. 5 was the maximum, and the total value of cases L. 191,991, 16s. 8½d. In other districts the results were correspondent. In Glasgow, the number of decided cases averaged annually 5200; in Paisley, 1279. In some districts, courts are held weekly; in others once a fortnight, and in few, it is believed, seldom more than once a month. The fees of every step of procedure are regulated by the statute; and so moderate are they, that where the defender resides on the spot, and where no examination of witnesses, nor oath of party is required, an extracted decree may be obtained, if in absence of the defender, for 2s. 5d., and if he appear for 2s. 11d. Arrestment may be used on it for 6d. more; the defender's goods may be poinded and sold for 4s.; and his person may be lodged in jail for 3s. Expence is farther prevented by the absence of all written pleadings, and by the salutary provision that the parties shall conduct their cases in person.

The proceedings of the Justices in these small debt courts, unless, indeed, they have exercised jurisdiction in matters to which they are incompetent, are subject neither to "advocation, nor to any suspension, appeal, or other stay of execution;" but they may be challenged within a year from their date, by action of reduction, "on the ground of alleged iniquity, or oppression;" the pursuer being bound to give surety "for payment of such expences as may be awarded against him." (39th and 40th Geo. III. c. 46, § 13.)

In most other branches of their civil jurisdiction, the proceedings of Justices are subject to the usual processes of review in the Court of Session, or Circuit Courts of Justiciary. The Justices have no power of reviewing their own judgments; except in as far as an appeal generally lies to the Quarter Sessions from the judgments of the ordinary sessions. The Quarter Sessions are the stated quarterly meetings of the Justices of a whole county, which are appointed to be held on the first Tuesdays of March, May, and August, and the last Tuesday of October: or regular adjournments of these meetings. The ordinary sessions are the subordinate meetings held as occasion requires for the dispatch of business.

2. *Burgh Courts.* These may be considered as existing, 1st, In royal burghs; or 2d, In burghs of barony or regality.

(1.) In most royal burghs, there are both a *Bailie Court* and *Dean of Guild Court*; in others only the former, which, in that case, exercises in addition to its own all the functions peculiar to the latter.

Scotland.

The civil jurisdiction of the Bailie Court is as extensive within the limits of the burgh as that of the Sheriff in his county. It comprehends all questions arising out of *personal* contract, bond, or obligation, claims of debt to any amount, actions of damages, &c.; likewise all actions as to *real* property, which are merely of a possessory nature, and do not involve the question of radical title.

The jurisdiction of the *Dean of Guild Court* was formerly more extensive than now, comprehending "all actions, and matters concerning merchants,—betwixt merchant and merchant,—and betwixt merchant and mariner." (1593, c. 184.) The maritime part of this jurisdiction was taken away by 1681, c. 16, and vested exclusively in the Court of Admiralty: Neither have the Guild courts of a long time exercised the powers conferred on them in causes between merchant and merchant. (*Ersk.* 1. 4. 24.) Their chief province now is "to take care that buildings within burgh be agreeable to law, neither encroaching on private property, nor on the public streets or passages; and that houses in danger of falling be thrown down." (*Ibid.*)

Within the limits of the burgh, the jurisdiction of the Dean of Guild is exclusive; the Bailies again exercise a jurisdiction, for the most part cumulative with that of the Sheriff. The proceedings in both courts are conducted in writing, by practitioners admitted under authority of the judge; and proofs, when necessary, are taken by commission, the clerk of court, or some still more subordinate person, being usually the commissioner. The judgments pronounced may, in the first instance, be submitted to reconsideration of the inferior court by petition; ultimately they may be brought before the Court of Session, or Circuit Court of Justiciary, by the usual processes of review.

From the constitution of these courts, the judicial functions can scarcely be said to be performed by the nominal judge; who, in few cases, has either experience, knowledge, or education, for the discharge of such an important duty. He is chosen for other purposes, deriving his authority from an annual election under the constitution peculiar to his burgh. The active and real discharge of the judicial office it has been found necessary to devolve upon the clerk of court, or other assessor appointed by the Magistrates and Council.

(2.) The judicial business in the courts of *Burghs of Barony* and *Regality* has in like manner been devolved upon assessors; the election of Magistrates being conducted there in a way precisely similar to what prevails in the royal burghs.

Their jurisdiction was originally commensurate and cumulative with that of the Baron or Lord of Regality, their superior; and embraced all questions of debt or personal contract, with most of the possessory actions, &c., but subject to review in the same way as the similar classes of actions in the royal burghs. In those burghs "which are independent of the Lord of Regality or Baron," this jurisdiction still remains entire, notwithstanding the judicial powers of the latter, along with every other heritable jurisdiction, were almost entirely annihilated by 20th Geo. II. c. 43.; commonly called the Juris-

diction Act. A similar reservation has been held to extend to such burghs of regality or barony as, though dependent, are dependent upon royal burghs. (*Fac. Col. Dowie*, May 30, 1817.) Since the Jurisdiction Act, his Majesty has been empowered to erect free and independent Burghs of Barony, on those parts of the sea coast where the fisheries are carried on (35th Geo. III. c. 122); but the Magistrates of such burghs are only to exercise the powers of Justices of the Peace, cumulatively with the Justices of the county. (*Ibid.*)

3. *Baron and Regality Courts.* Before the Jurisdiction Act, every lord of regality, and every proprietor of lands erected by the Crown in *liberam baroniam*, had an extensive jurisdiction, both civil and criminal; and "a baron, where he sold part of his barony lands to be holden of himself, was even understood to communicate to the purchaser a certain degree of jurisdiction over that part of the barony which he had sold." (*Ersk.* 1, 4, 27.) By that act, however, the civil jurisdiction of the baron, &c. was expressly taken away, except in actions where the debt or damages should not exceed 40s. Sterling, or in those brought for recovering from his own vassals and tenants the feu-duties and rents of his lands, and the multures or services prestable to his mills (20th Geo. II. c. 43)—an exception which has very seldom been taken advantage of.

4. *Sheriff and Stewart Courts.* The office of Sheriff is of such antiquity, that no distinct trace remains either of its first institution, or of the amount of jurisdiction originally conferred with it.

The present form of the Court was introduced by the same statute which abolished heritable jurisdictions. The office of Principal or High Sheriff is no longer a judicial one (20th Geo. II. c. 43), but is granted solely for purposes of the executive government, and generally in connection with the office of Lord Lieutenant of the county. The judicial character is exclusively vested in the Sheriff-depute, who holds his commission directly from the Crown, and is in every respect independent of the Principal or High Sheriff, where such officer exists.

The office of Stewart has undergone similar modifications: and the distinction between the offices of Sheriff and Stewart is now merely nominal. Both are now judges of precisely the same class, having the same sort of duties to perform in their respective territories, and invested with the same powers, and the same extent of jurisdiction. By the Jurisdiction Act, "One sheriff-depute, or stewart-depute, is to be appointed by the King in every shire or stewartry not dissolved; who is to be an advocate of three years standing, and who is declared incapable to act as an advocate in any cause that shall be brought from his county. These deputies are authorized to name each a substitute, or substitutes, either over the whole shire, or within such a particular district of it as shall be mentioned in the substitution; and they may not only hold stated courts at their head burghs, but itinerant ones, when and where they please, or shall be directed by the King, on previous notice to be published at the several churches, within the district where the court is to be held." (*Ersk.* 1, 4, 11.) They hold their offices *ad vitam aut culpam*.

Scotland.

The sheriff or steward exercises civil jurisdiction "in all personal actions upon contract, bond, or obligation, to the greatest extent, whether the suit be brought against the debtor himself or his representatives; in actions of rent and of forthcoming; in poindings of the ground; and even in adjudication of lands, when it proceeds on the renunciation of the apparent heir; in all possessory actions, as removings, ejections, spuilzies, &c.; in all briefs issuing from Chancery, as of inquest, terce, division, tutor, &c., and generally in all civil matters which are not by special law or custom appropriated to other courts." (*Ersk.* 1. 4. 3.) He judges also in questions of mutual inclosures, straightening of marches, runrig, &c. (1669, c. 17, &c.) By a recent statute (*4th Geo. IV. c. 97*), abolishing the inferior commissariats, he is invested with the office, powers, and jurisdiction of commissary. He has besides many important ministerial duties to perform.

The forms of procedure in the Sheriff-Court are much the same as in those of the Royal Burghs; and their judgments are liable to review in the same manner. As, however, in the Sheriff-Courts, it is the substitute who, in the first instance, generally decides, and as an appeal lies from his judgment to the sheriff-depute, an opportunity is in many cases given for a still more protracted litigation.

5. *Commissary Court.* This was originally an ecclesiastical court; but on the abolition of Episcopal jurisdiction in 1560, a new nomination of commissaries, one in every diocese, to act under the royal authority, was made by Queen Mary. Soon afterwards a supreme Commissary Court, consisting of four judges, who are now appointed *ad vitam aut culpam*, was established at Edinburgh; as already noticed, the inferior commissariats were abolished by a recent statute (*4th Geo. IV. c. 97*), and their jurisdiction conferred on the sheriffs.

The jurisdiction of the Edinburgh commissaries is exclusive in all strictly consistorial cases, viz. questions of marriage, divorce, separation, legitimacy, confirmation of persons dying abroad with estates in Scotland, &c. They have a cumulative jurisdiction with the sheriff and other civil courts, in actions of slander and defamation, aliment of wives against their husbands, applications for inspecting or sealing up the repositories of persons deceased, &c. Formerly the commissaries, both superior and inferior, had a jurisdiction in actions for the recovery of debts, not exceeding L.40 Scots; and, indeed, where their jurisdiction was prorogated there was no limit in point of amount; but this is now taken away, and all prorogation of their jurisdiction in questions of debt prohibited. (*4th Geo. IV. c. 97*.)

The Court of Session, as the King's great consistory (1609, c. 6), is vested with the power of reviewing all decrees pronounced by the commissaries, by advocacy or reduction. The commissaries of Edinburgh used to have a similar power of review as to the jurisdictions of the inferior commissaries: but this had long fallen into disuse, and by the late statute, transferring the jurisdiction of the inferior commissaries to the sheriffs, it is declared that "all such proceedings shall be reviewable only by the Court of Session."

Scotland.

6. *Court of Admiralty.* The judicial powers exercised in ancient times by the Admiral of Scotland are not distinctly known. The offices of High Admiral and Vice-Admiral of Scotland are no longer judicial ones. That character now belongs only to the Judge of the High Court of Admiralty, who derives his commission *ad vitam aut culpam* immediately from the Crown, and who must be chosen from the list of practising advocates of at least three years standing. (*26th Geo. III. c. 47*.)

The jurisdiction of this court is chiefly regulated by the Scots statute 1681, c. 16. In civil causes, it is *exclusive* in strictly maritime questions, viz. in questions of charter-party, freight, salvage, wrecks, &c.; but merely *cumulative* with that of other civil courts in ordinary mercantile questions, viz. in actions on bills of exchange, mercantile contracts, policies of insurance, &c. In the latter class of cases, it is, with few exceptions, incompetent to raise any action in the Admiralty Court, where the subject in dispute, exclusive of expences, is of less value than L. 25 Sterling. (*1st and 2d Geo. IV. c. 39*.)

The Judge of the High Court of Admiralty may name inferior deputies, whose jurisdiction is confined within particular districts, and whose sentences are subject to the review of the High Court. The High Court may also review its own judgments, even after extracted decree, by suspension or reduction: a peculiar privilege, and usually appertaining to courts of supreme authority alone. This court is not, however, in a proper sense, Supreme; for the Court of Session is vested with a power of review as to all its proceedings, even in those questions where the jurisdiction of the Admiral is in the first instance exclusive.

The procedure in the Admiralty Court is substantially the same as has already been described in the rest. One important distinction is, that the Admiral has power, where matters of fact are to be proved, to remit cases for trial upon issues in the Jury Court. (*59th Geo. III. c. 35*.)

7. *Court of Session.* This Court is the supreme civil judicature of Scotland. It superseded the ancient courts of *The Session* and *Daily Council*, and was instituted in 1532, during the reign of James V. after the model of the Parliament at Paris. In its present shape, it consists of fifteen Ordinary Lords, including the Lord President and Lord Justice Clerk; who, till lately, acted as one great Court; but the increasing business of the country requiring an additional tribunal, it was divided into two Chambers, called the *First* and *Second Divisions*, each exercising independent, but cumulative and co-ordinate jurisdictions.

The Court of Session has an universal jurisdiction in civil matters. As a Court of Review, it has, with a few exceptions in special cases, the power of advocating, suspending, or reducing the decrees of all the inferior tribunals. As a court of the first instance, its jurisdiction is, in some causes, privative; e. g. in declarators of property in heritage, and other competitions of heritable rights; restitutions of minors; provings of the tenor; *cessio bonorum*; reductions of deeds, &c.; judicial sales; mer-

Scotland.

cantile sequestrations; complaints against burgh elections; proceedings of courts of freeholders, &c. In all others, its jurisdiction is cumulative with that of the inferior courts; excepting, 1st, That in causes under the value of L. 25 it is incompetent to raise actions before the Court of Session, in the first instance; and 2d, That in maritime and consistorial cases, &c. the Court of Session has no primary jurisdiction, and can proceed only by way of review.

The Court of Session is a court of Equity, as well as of Law, but in this respect its powers are loose and ill defined; its decisions in equity not being, as in England, regulated by any distinct or settled general principles. It exercises, also, what is called a *nobile officium*; an expression which, in ancient times, seems to have covered every exercise of power for which no more satisfactory source could be pointed out; and under which may be classed all those acts of interference which appear in the Books of Sederunt; sometimes fixing the price of victual in the city of Edinburgh; at others, regulating the sale of butcher-meat, or framing enactments against the "vending and retailing of bad twopenny ale" (*A. S. 8th July 1725*), &c.

The judicial proceedings in the Court of Session may be considered as they take place, 1st, In the Bill-Chamber; 2d, In the Outer-House; or 3d, In one or other of the Inner Divisions.

In Session time, the junior, or last appointed judge of the fifteen, has devolved on him the business of the *Bill-Chamber*. This chiefly consists in disposing of the preliminary stages of the process of review, where bills of suspension or advocacy are presented against the decrees or proceedings of inferior courts; it embraces, also, questions of summary interdict against all illegal proceedings; suspension of diligence unduly put, or threatened to be put, in execution; liberation from prison, where execution has already taken place, &c. In time of vacation, the whole judges, with the exception of the Lord President and Justice Clerk, officiate in the Bill-Chamber by rotation. The judgments pronounced in the Bill-Chamber are subject to review in the Inner-House.

The business of the *Outer-House* is conducted by the five junior Lords of Session, including the Bill-Chamber judge, who has the particular department allotted to him of judging in actions of reduction, and in some other questions which are from time to time remitted from the Inner-House. The other four Lords Ordinary, as they are called (two belonging to either Division), officiate by rotation; they have separate rolls of causes, comprising, 1st, All actions brought in the first instance before the Court, except a few which are exclusively competent to the Inner-House; and, 2d, The class of cases which, passing through the Bill-Chamber, as above, have received the sanction of the judge there as deserving of further consideration. The proceedings in the Outer-House, like those in the Bill-Chamber, are subject to review in the respective Divisions of the Inner-House.

Each Chamber of the *Inner-House* consists of four Lords, three of whom are a quorum. The Lord President presides in the First Division, the Lord

Scotland.

Justice Clerk in the Second. They are chiefly occupied in reviewing the judgments which have been pronounced by the Lords Ordinary in the Bill-Chamber or Outer-House. But they have also a primary and exclusive jurisdiction in the sequestration of landed estates; the appointment of judicial factors, curators *bonis* &c.; proceedings for redemption of the land-tax; complaints in election matters; petitions and summary complaints under the bankrupt statute, &c. In cases of great importance or difficulty, either Division of the Inner-House is empowered to take the opinions of the other judges; but these opinions when taken are not always regarded; and one case is reported where judgment was ultimately pronounced by the votes of three judges in one of the Divisions, though an unanimous opinion to the contrary had been given by no fewer than ten of the other judges, including the two Heads of the Court. (*Auld, Nov. 12, 1819, Fac. Col.*)

The extent of business before the Court may be judged of, from an interesting document lately drawn up by the Clerks of Session, under the directions of the Court. Two tables are there given;—one of "causes appearing in the printed rolls of the Outer-House;" from which the total number of such cases during the period from 1802 to 1822, inclusive, appears to be 50,970; giving an annual average of 2427:—another, of "original petitions, petitions and complaints, and other summary applications to the Inner-House;" from which the total number of such cases in the period from 1811 to 1821, inclusive, appears to be 5302, giving an annual average of 482.

The forms of procedure in the Court of Session it would require much space to explain. There, as in the inferior courts, all the more important pleadings are conducted in writing; and proofs taken by commission. In this latter respect, the power of remitting cases for trial upon issues in the Jury Court is a vast improvement, and may eventually draw after it, what is of great and essential consequence,—viz. a distinct separation of the matter of fact from considerations of law, in pronouncing judgment, even in those cases which are not submitted to a jury.

An appeal lies from the judgments of the Court of Session to the House of Lords. The disparity in the proportion of such appeals from Scotland, compared with those arising in the sister countries, is striking enough. Between 3d May 1813, and 14th March 1823, the appeals presented from Scotland alone were 426, while from England there were only 56, from Ireland 84, and from Wales 4. In 291 Scots appeals decided during the same period, only 145 were affirmed, while 62 were reversed, two altered, and 80 remitted for reconsideration. The increasing load of Scots appeals, combined with the circumstance of such a number of alterations and reversals, has lately given rise to much discussion; and a Parliamentary Commission is at this moment (October 1823) sitting, from whose investigation into the sources of the evil, the country is entitled to anticipate the most important and beneficial results.

8. *Teind Court*. After various temporary Commissions of Parliament, the first of which was ap-

Scotland. pointed in 1617, c. 3, the Lords of Council and Session were at last created a perpetual "Commission for the Plantation of Kirks and Valuations of Teinds," by 1709, c. 9. This court, though consisting of the same individual judges, has always exercised a jurisdiction separate and distinct from that of the Court of Session; and when the latter was recently divided into two chambers, it was provided, that the former should in all respects continue untouched. The quorum of this court is nine: the same as that of the Court of Session before its division.

By the act 1707, the Teind Court was appointed to meet every Wednesday during the sitting of the Court of Session, but now it meets "once a fortnight only," viz. every alternate Wednesday. (48th Geo. III. c. 138.)

The extent of its jurisdiction is pretty fully set forth in the act 1707;—it has power "to determine in all valuations and sales of teinds; to grant augmentations of ministers' stipends; prorogations of tacks of teinds; to disjoin too large parishes; to erect and build new churches; to annex and dismember churches," &c.

9. *Jury Court.* This court is of very recent institution, having only been introduced so late as 1815. It is composed of one Chief Judge and two other judges, called "the Lords Commissioners of the Jury Court in Civil Causes;" but trials may proceed equally "in presence of one, or more than one, of the said three Commissioners." (55th Geo. III. c. 42.) The Commissioners must be either Lords of Session or Barons of Exchequer (*Ibid.*), with the exception of the Chief Commissioner, who may or may not hold such other judicial office, but must be qualified to be appointed a Lord of Session. (59th Geo. III. c. 35.) The court, as well as its forms of procedure, are framed very much on the English model; the jury also, as in that country, must be twelve in number, and their verdict unanimous.

As at present constituted, no action can originate before this court. It derives its jurisdiction by virtue of *Remits* either from the Court of Session, the Court of Admiralty, or the House of Peers, as the court of last resort. "In all processes raised in the Outer-House of the Court of Session, by ordinary action or otherwise, on account of injuries to the person, whether real or verbal, as assault or battery, libel or defamation; or on account of any injury to moveables, or to lands where the Title is not in question; or on account of breach of promise of marriage, seduction, or adultery; or any action founded on delinquency of any kind, where the conclusion shall be for damages or expences only" (59th Geo. III. c. 35), the Order for Remit after the lodging of defences is (unless a question of law or relevancy arises) peremptory. In other cases, "where matters of fact are to be proved," the Lord Ordinary in the Outer-House, or either of the Inner Chambers of the Court, the Judge of the High Court of Admiralty, and the House of Lords, judging on appeal, may or may not remit, as it shall seem expedient. (*Ibid.*) In all cases where such remits are made, it is declared incompetent to bring under review in any shape any interlocutor or judgment ordering a trial by jury.

VOL. VI. PART II.

Scotland. The Jury Court has its *terms* and *sittings* like the English courts. The judges also travel *circuits* twice a year, about the same periods as the Lords of Justiciary.

10. *Circuit Courts of Justiciary.* The constitution of these courts will be explained below. The only thing to be noticed in regard to them here is, that they have a civil jurisdiction conferred on them by statute (20th Geo. II. c. 43; 54th Geo. III. c. 67); whereby they judge, by way of appeal, from the sentences of inferior courts, in all cases not exceeding L. 25 in value, exclusive of the expences of litigation. The decision of the Circuit Judges in these cases is final; but in questions of difficulty they may certify the cause to the Court of Session.

11. *Court of Exchequer.* This is the King's Revenue court. The old Scots Court of Exchequer was superseded at the Union by the establishment of the present, which consists of a Chief Baron, and four (or rather, as the court is at this moment constituted, of three) Puisne Barons, who must be either Serjeants at law, or English Barristers, or Scots Advocates of four years' standing.

The judges of this Court have "a peculiar jurisdiction as to all duties of custom and excise, and other revenues pertaining either to the King or Prince of Scotland, and as to all honours and estates, real and personal, forfeitures and penalties of what nature soever, arising to the Crown within Scotland; and as to all questions relating to the said matters, which they are authorized to determine either in law or equity, by the same forms that have been used in the English Exchequer." (*Ersk.* 1. 3. 31.) By a late statute, this Court has also jurisdiction in questions as to the administration of what is called the *common good* of Royal burghs, at the instance of Burghesses against their Magistrates. (3d Geo. IV. c. 91.)

#### SECT. 2.—Criminal Jurisdictions.

Most of the Courts enumerated above as exercising civil, have also a certain jurisdiction in criminal matters.

1. *Justices of the Peace*, by the terms of their commission, &c. would seem here, as in England, to have power to judge even of the highest crimes; but in practice (perhaps from the circumstance of their never using juries), their jurisdiction is limited to the trial of petty delinquencies, *e. g.* all petty crimes tending to the disturbance of public tranquillity, petty acts of theft or pickery, &c. They are entitled to punish by fine or imprisonment, and perhaps also by banishment from the county, though this last seldom takes place, unless on the petition of, or consent of the party. Though the Justices, however, are not competent to the *trial* of the higher offences, they have full power, and it is a chief part of their duty, to take all necessary steps for securing the offenders, and making the proper investigations preparatory to trial: *e. g.* they lead precognitions as to all circumstances connected with the offence, grant warrant for apprehending the delinquent, for imprisoning him for examination, or trial, &c.; they issue warrants of search also as to stolen goods, &c.; and having thus so far brought the case into shape, they report their proceedings to the Crown officers,

Scotland  
||  
Selkirkshire.

with whom it lies to proceed or not before the competent court.

2. *Burgh Courts*, as to their powers in all those steps preparatory to trial of the graver offences, are on the same footing with the Justices;—but their own peculiar jurisdiction in the trial of criminal cases is somewhat more extensive. They are competent in all the lesser offences, where trial by jury is not required. Where the burgh grant carries an express right of Sheriffship, as is the case in Edinburgh, Stirling, Perth, &c. their jurisdiction within the bounds of the Royalty is co-extensive and cumulative with that of the Sheriff.

3. *Barony and Regality Courts*, since the Jurisdiction Act, have no criminal jurisdiction but in assaults, batteries, and smaller offences, which may be punished, either by a fine not exceeding 20s. Sterling, or by setting the delinquent in the stocks in the day time not exceeding three hours.

4. *Sheriffs* are competent to the trial of all crimes and offences, except treason, and the four pleas of the Crown, robbery, rape, murder, and wilful fire-raising:—in the lower classes of cases without, in the higher and more important with, the aid of a jury. Sheriffs cannot punish by transportation beyond seas, nor even by simple banishment from Scotland; but they may convict capitally; and sentence of death pronounced (28th January 1785) by the Sheriff of Forfar, in a case of house-breaking, seems actually to have been carried into execution. (2. *Hume*, 57 and 64.) In the preparatory steps towards trial of offences in the Supreme Court of Justiciary, Sheriffs exercise the same powers as Justices of the Peace, &c.

5. *Court of Admiralty*. This Court, in the first instance, has “the exclusive cognizance of the crimes of piracy, mutiny on shipboard, plundering of wrecks, destruction of insured ships, and others which may with propriety be called *maritime causes*.” But in such crimes as murder, theft, &c. which “offend not against the rules of navigation, its jurisdiction is not exclusive, though they should be committed on shipboard.” (*Ersk. I. 3, 35.*) It is the nature of the crime, not the local boundary of its perpetration, which regulates the Admiral’s jurisdiction as *exclusive*; it is, on the other hand, the occurrence of the offence within the local boundary which alone gives existence to his jurisdiction as *cumulative*. The Admiral may punish capitally; an instance of which, in a case of piracy, occurred so late as 1822.

6. *Court of Session*. This Court also has a certain criminal jurisdiction. It is “competent to the trial of deforcement and breach of arrestment (1581,

c. 118); of contravention of lawbutrows (1581, c. 117); of perjury and subornation of perjury, when these offences emerge in the course of business before themselves (1555, c. 47); of fraudulent bankruptcy (1696, c. 6); of wrongous imprisonment, usury, and clandestine marriage, to the effect of inflicting the pecuniary penalties of these several transgressions (1701, c. 6; 1597, c. 251; 1661, c. 34). By ancient custom they are judges also in cases of improbation and forgery;—also, “in the trial of the lower species of falsehood, when committed or discovered in the course of their judicial proceedings,” &c. (2. *Hume*, 68; *Ersk. I. 3, 21.*) They are likewise, to a certain extent, competent to the review of the proceedings of inferior courts. The criminal jurisdiction of the Court of Session is, in all cases, exercised without a jury.

7. *Justiciary Court*. This is the supreme criminal tribunal of Scotland. As at present constituted, it consists (besides the Justice General, who, by his commission, is constant President of the Court, but seldom if ever takes part in the judicial business) of six Judges, including the Lord Justice Clerk, all of them being likewise Lords of Session, and three being a quorum. (23d Geo. III. c. 35.) Its judgments proceed on the verdict pronounced by the majority of a jury of fifteen.

The jurisdiction of this Court, as it is supreme in degree, is also universal in extent. It embraces the four pleas of the Crown, and even High Treason, though this last is generally tried by a special commission of Oyer and Terminer, appointed by the Crown. As a Court of Review, also, the proceedings of all inferior judicatures, including the Court of Admiralty, may, with a few trifling exceptions, be brought before this Court.

The principal seat of the Justiciary Court is at Edinburgh. But, for the better dispatch of business, the act 1672, c. 16, divided Scotland into three districts; and *Circuit Courts*, with the full powers of the whole Court, are now appointed to be holden each spring and autumn, by two of the Commissioners, at Ayr, Dumfries, and Jedburgh; by two at Stirling, Glasgow, and Inverary; and by two at Perth, Aberdeen, and Inverness. It is “lawful for one judge to proceed on business in absence of his colleague.” (*Ersk. 13, 26.*) These Circuits have also a power to review, by way of appeal, all sentences of inferior courts, inferring “neither death nor demembration.” (20th Geo. III. c. 43.)

No appeal lies from the judgments and sentences of the Court of Justiciary, either to the House of Lords or any other tribunal.

(A.)\*

Situation,  
Boundaries,  
and Extent.

SELKIRKSHIRE, a county in Scotland, situated between 55° 21' and 55° 42' north latitude, and between 2° 48' and 3° 20' west longitude from

Greenwich. It has Mid-Lothian, or the county of Edinburgh, on the north; Roxburghshire on the east and south-east; Dumfries-shire on the south;

\* The last section, that, namely, on *Judicial Establishments*, was contributed by a Gentleman of the Bar, well qualified to execute it with accuracy. The preceding sections were written by the Gentleman whose Signature is annexed to the Article.—ED.

**Selkirkshire.** and Peebles-shire, or Tweeddale, on the west. The line which separates it from these counties being on all sides, but the south, exceedingly irregular, its area has been computed very differently; but, according to the latest authorities, it appears to be about 269 square miles, or 172,160 English acres. It includes only two entire parishes, with five parish churches: but other seven parishes belong partly to this, and partly to the adjoining counties.

**Surface.** This is almost entirely a pastoral district, and in many respects bears a resemblance to the higher parts of the contiguous county of Roxburghshire. Like the latter county, its general declivity is towards the north-east and north, where all its streams discharge themselves into the Tweed; and the surface differs principally, in so far as some of the hills are more elevated, its streams smaller, and the valleys in which they flow still more contracted. Several of the hills are more than 2000 feet high; such as Windlestraw Law at the northern extremity, on the confines of Mid-Lothian, Blackhouse Heights, and Minchmoor on the borders of Peebles-shire, and Ettrick-penn on the south-west boundary. The lower hills are for the most part green, and afford good pasturage for sheep; but heath prevails on many of the higher grounds, especially towards the south-west. The lowest land is about 300 feet above the level of the sea, and the sites of many of the houses are from 600 to 1000 feet high and upwards.

**Rivers.** The rivers are the Tweed, which crosses the north side of the county in its course from Peebles-shire on the west to Roxburghshire on the east; the Gala, which, for some distance, forms the boundary with Roxburghshire on the north-east, and falls into the Tweed, from the north, a little below the village of Galashiels; the Cador, a beautiful stream, which also joins the Tweed from the north; the Ettrick and Yarrow, which have their sources on the confines of Dumfries-shire, and, flowing north-east, almost parallel to each other, join their streams above Selkirk, and afterwards, under the name of Ettrick, passing to the west of that town, and, for a short distance along the boundary with Roxburghshire, enter the Tweed, in which their name is lost, and which then becomes the boundary with that county. The Ale, which rises in the north-east, soon after passes into Roxburghshire, and also the Borthwick, which washes the north-eastern boundary. Next to the Tweed, the most considerable waters are the Ettrick and the Yarrow, which receive, in the first instance, nearly all the other streams that traverse this district. Both have been celebrated in song, and given their names to some plaintive melodies of great beauty and feeling. The scenery on the Yarrow is exceedingly romantic and delightful. Soon after its rise, it passes through two lakes, the Loch of the Lows, and St Mary's Loch; the latter, which is separated from the former only by a narrow neck of level ground, and is three miles long, having its banks partly covered with coppice-wood, is the finest piece of water in the south of Scotland. From thence the Yarrow flows for eight or nine miles, through sheep-walks, without wood or cultivation; but afterwards the sides of the lofty hills in its course are covered with wood to a considerable height,

and its valley is embellished with a variety of bushes **Selkirkshire.** and wild flowers. Ettrick, the larger stream, has a wider and more cultivated valley, and a little before it receives the Yarrow, natural wood begins to appear on its banks. It afterwards flows for four miles through a rich tract, sheltered by plantations on the hills, till it loses its name in the Tweed. From this river the whole district has been sometimes called Ettrick Forest; but the name of Forest here, as elsewhere, has long since ceased to denote the existence of extensive woodlands, of which, whatever may have been the case formerly, there are now scarcely any traces here. Besides the two lakes we have mentioned, a great many smaller ones are scattered over the east and south-east quarters, of which the more considerable are Lochs Alemoor, the principal source of the Ale, and Oakermoor, noted for the vast quantity of marl which it contains.

The soil of the arable land, which does not much **Soil, &c.** exceed one-twentieth part of the whole, is light, dry, and easily cultivated; and produces oats, barley, or bear, turnips and potatoes; but very little wheat, for which the country is too elevated, and its climate in general too moist and rigorous. There is no coal, limestone, or sandstone, but a great deal of shell-marl in the lakes and mosses, which, when situated conveniently for the arable land, serves as a valuable manure. The rest of the county is almost exclusively occupied by sheep, which are now, for the most part, of the Cheviot breed, though not often pure, and scarcely, in any instance, equal to those of Roxburghshire. The heath or mountain race still keep their ground near the sources of the streams in the elevated districts on the south-west. There is but a small number of cattle, which are kept chiefly for their milk. The valued rent of the **Valuation and Rental.** county is L. 80,307, 15s. 6d. Scots, and the real rent of the lands and houses in 1812 was L. 41,162, 10s. Sterling. In the same year the land-rent was divided among forty-four estates, of which nine had each a valuation exceeding L. 2000 Scots, twenty were below L. 2000 and above L. 500, and fifteen below L. 500; a division which indicates that most of the district belonged to a few individuals. Two-fifths of the whole are held under entail. The principal proprietors are the Duke of Buccleuch, the Earl of Traquair, Lords Elibank and Napier, and gentlemen of the names of Pringle, Lockhart, Elliot, Murray, and Scott.

Selkirk, the county town, and a royal burgh, and the **Towns.** village of Galashiels, contain nearly all that part of the population that is not employed in husbandry; and both are small places. Selkirk is situated on a rising ground below the confluence of the Yarrow and Ettrick near the borders of Roxburghshire, and is a place of considerable antiquity. Galashiels, on the Gala, north from Tweed, also on the borders of the same county, has been long distinguished for its woollen manufacture, the most considerable of the kind in the south of Scotland; where all the various processes, from the sorting of the fleece to the finishing of the fabric, are conducted with much skill and success. For some time only coarse cloths were made, such as were formerly worn by farm servants, seldom worth more than 3s. the yard, and

Selkirkshire || Sicily. popularly known by the name of *Galashiel greys*; but within these few years some very fine broad cloths have been produced, and a hall has been opened for the sale of their cloths, similar to those long established at the woollen manufactories of England. A considerable proportion of the wool of the county finds a market at Galashiels. An inkle work and some tanneries are the only other branches carried on for sale out of the county; so that its exports consist chiefly of raw produce, of which its sheep and wool are by far the most considerable articles.

Representation. Selkirkshire, which has thirty-eight freeholders, sends one member to Parliament, and Selkirk, along with Peebles, Lanark, and Linlithgow, elect another for the Scottish burghs. Though it is a very thinly peopled district, containing, in 1811, only about twenty-two inhabitants to the square mile, yet poor rates have been long and universally established. The population, according to the census of 1801, was 5070; in 1811 it amounted to 5889; and in 1821 to 6637, of which 3205 were males, and 3432 females. The families employed in agriculture were 421, in all other occupations 409. The increase of population, from 1811 to 1821, was 748.

Population.

See the general works quoted under the former Scottish counties, and Douglas' *General View of the Agriculture of Selkirkshire.* (A.)

SHETLAND, NEW SOUTH, a large tract of uninhabited land, situate to the southward of Cape Horn, discovered in 1819 by Mr William Smith, the master of a British merchant Brig, and which, in some minds, revived the belief of a vast continent within the Antarctic Circle. Mr Smith gave to it the name of South Shetland, on account of its lying nearly in the same degree of south, as the Shetland Isles of north latitude. There is a full account of his observations in a letter written by Mr J. Miers, published in the *Edinburgh Philosophical Journal*, Vol. III. p. 367. Though he gave the appellation of *New* to the land in question, it rather appears, as we have observed in our article on the POLAR SEAS, that the first discovery of it was made so long ago as the year 1599, by a Dutch navigator of the name of Gherritz. We have also stated, in the same place, that this land appears to be an Island, and not part of a Continent. See p. 215 of this Volume.

Sicily. SICILY. This island, a part of the kingdom of the Two Sicilies, has undergone few or no changes, either in its government, manners, religion, or productions, during the convulsions which, for near thirty years, have agitated every part of the continent of Europe. Upon the overthrow of the government of Murat in Naples, the royal family returned to that capital, quietly resumed the authority that had formerly been exercised, and Sicily ceased to be the seat of government. The tranquillity which followed was interrupted by the late revolution in Naples, the promoters of which resolved to force their own regimen on the unwilling Sicilians. The island was invaded by the troops of the revolutionists, and after some most bloody encounters, was

compelled to submit to the dictation of the triumphant party. They were in their turn dispersed by the Austrians, and the ancient system in Sicily was speedily restored, to the high gratification of its inhabitants. Sicily || Singapore.

The commerce of this island consists in the export of the surplus of its raw productions; for its manufactures are inconsiderable, and by no means equal to the wants of the people. The chief exports are corn, nuts, hemp, flax, oil, wine, sulphur, fish, silk, and fruits; the whole amount of which does not commonly exceed 11,000,000 ducats, or about L. 240,000 Sterling. The imports are of nearly the same value. Commerce.

The revenues of the island, in the year 1820, amounted to 1,637,332 ounces, or about L. 200,000, and the expenditure to 1,665,355. The expences are restricted to 1,817,680 ounces; of which sum 150,000 ounces are applied to the discharge of that part of the public debt which bears no interest, and after that is liquidated, to form a sinking fund to extinguish those on which interest is payable: the amount of the latter is not known to the public. Finances.

The regular Sicilian army, including the different branches of horse, foot, and artillery, amounts to 10,000 men, besides which there is a militia force of 8000. The Sicilian navy is now united with that of the kingdom in general. The arrangements respecting the forces are at present (1823) undergoing revision, and therefore in a temporary state of confusion. Army and Navy.

Sicily has been recently divided into seven Intendancies, instead of the three great provinces, which before formed its component parts. These Intendancies, and their population, and principal cities, are as follows: Divisions.

Intendancies.	Population in 1817.	Capitals and their Population.
Palermo	405,231	Palermo 180,000
Messina	236,784	Messina 44,650
Catania	289,406	Catania 45,081
Siragosa	192,710	Siragosa 13,850
Caltanissetta	155,225	Caltanissetta 15,627
Girgente	288,877	Girgente 14,882
Trapani	145,712	Trapani 24,330
	1,713,945	

The whole extent of the island is calculated to be 12,533 square miles.

See Vaughan's *Views of the present State of Sicily*, 1812. Thompson's *Sicily and its Inhabitants*, 1815. Smyth's *Sicily and its Islands*, 1823. (w. w.)

SINGAPORE, or SINGAPORE, an island in the Straits of Malacca, situate at the extremity of the Peninsula of that name, upon which a British Settlement was formed in 1819, under the enlightened direction of Sir Thomas Stamford Raffles, the Lieutenant-Governor of Bencoolen. Of this island, upon which there is a town of the same name, nothing has

Singapore.

yet appeared, so far as we know, in the way of description, except some detached notices in periodical publications, particularly in the *Asiatic Journal*. We are thus unable to give any very distinct or detailed account, either of its situation, extent, or productions. In the interior, its surface is said to exhibit a succession of hills and dales, mostly covered with woods, and affording some fine prospects. The soil is fruitful; the water, a material circumstance, of good quality; the temperature remarkably cool for a tropical region; and the climate has hitherto proved extremely healthy.

The town of Singapore exhibits yet all the appearances of an infant settlement, but it is rapidly extending, and a site for its enlargement is laid out upon a regular plan. It is built near the shore, and the mercantile part of it extends along an inlet of the sea, which penetrates into the interior, and is near 300 feet wide at its mouth; affording every facility for the landing and shipping of goods. The harbour is safe, easily approached, and well sheltered. Several mercantile houses of respectability are already established here; and there seems every reason to believe, that if maintained on the present footing of a Free Port, Singapore will at no distant day become one of the greatest emporiums of the Eastern world. Its situation, in the centre, so to speak, of a vast Archipelago, in a strait through which the vessels of various countries are constantly passing, and within a few days sail of China, clearly points it out as well fitted to become the entrepot of an extensive commerce, equally beneficial to these countries and to Britain. There are several statements to this effect, in the Evidence annexed to the *Report of the Select Committee of the House of Lords relative to the Trade with India and China*, printed, by order of the House of Commons, in May 1821.

The establishment of a British settlement in Singapore is said to have excited some feelings of jealousy in the older one of Penang, or Prince of Wales' Island; but the Evidence just referred to shows, that if such a feeling exists, it ought to be discouraged and disregarded; for it there appears that a settlement situate farther within the Archipelago than Penang was highly expedient, and that Singapore presented the most eligible situation for founding such a settlement as was wanted. The rapidity of its progress affords, of itself, sufficient proof that the situation was well chosen. "The rapid rise of this important station," says its intelligent founder, in a letter written in 1820, annexed to the above-mentioned *Report*, "is, perhaps, without a parallel. When I hoisted the British flag, the population scarcely amounted to 200 souls; in three months the number was not less than 3000; and it now exceeds 10,000, principally Chinese. No less than 173 sail of vessels of different descriptions, principally native, arrived and sailed in the course of the first two months; and it already has become a commercial port of importance."

The latest accounts seem to contain additional proofs of the growing importance of this settlement. We copy the annexed statement from the *Asiatic Journal* for September 1823. (No. 93, p. 245.)

The settlement of Singapore was early disturbed, not merely by the conflicting interests of other British establishments in the East, but by certain pretensions brought forward by the Dutch to the possession of the country, as a dependency of Malacca, over which they claimed sovereignty. The discussions which arose between the British Government and that of the Netherlands, upon this point, have for some time, it is understood, been allowed to rest; and if they should be resumed, it is not very likely that this country will agree to sacrifice an important establishment, to satisfy claims which seem to have no better foundation than the commercial jealousy of the claimants.

SLIGO, a county in the province of Connaught, in Ireland, bounded by the ocean on the north-west and north, by Leitrim and Roscommon on the east and south-east, and by Mayo on the south and west. It extends about 40 miles from north to south, and from east to west 38, and contains 727 English square miles, or 465,280 English acres. The town of Sligo, which is about 13 miles from its northern extremity, is situated in west longitude 8° 26', and north latitude 54° 13'. The county is divided into six baronies and thirty-nine parishes.

Bogs, mountains, and waters, occupy more than a third of this district. The greater part of the waste land is found towards the north and west, though there are considerable tracts of the same description on the south; but except the range of the Ox and Foxford mountains, which begin on the

Surface.

Sligo.

confines of Mayo on the south-west, and occupy a considerable part of the western division, the waste grounds are everywhere intermixed with such as are productive, and in some parts very fertile. The better part of the district lies to the south of the town of Sligo; a few miles from which, along its whole breadth, the country is in general rich and beautiful, containing several gentlemen's seats, and presenting views of great variety and interest. For about 140 square miles in this quarter, the soil is equally fitted for tillage or grazing. In other parts much of it is shallow and moorish, incumbent on a close stratum, here called *leaclea*, or grey flag, which, in its natural state, is unfavourable to vegetation, though it becomes friable on exposure to the atmosphere.

Minerals.

Lead, iron, manganese, and copper, are known to exist in the mountains; of these iron only has ever been wrought, and that not for many years; and there is a variety of clays, some of them very fine, or fit for the pottery.

Waters.

The principal fresh water lakes are Loughs Gill, Arrow or Arva, Talt, and Gara. The scenery around Lough Gill, which contains a number of wooded islands, is particularly striking. On Innismore, one of these islands, are the remains of a church and other ruins. On the north, the sea has formed several considerable inlets, particularly at the bays of Sligo and Killala, the former of which communicates with Lough Gill, near the town of Sligo. To the north of this bay is the small Island of Innismurry. This district has also a great number of streams; of which the most considerable are the Sligo, Bonnet, Owenmore, Arrow or Arva, Cooloney, Esky, and Moy; the last of which is for some miles the boundary between this county and Mayo. The Sligo, which is merely the outlet of Lough Gill, is navigable from the lake to the town of that name; and the Moy for six or seven miles from the sea. On the Sligo and the Moy there are considerable salmon fisheries; trout is plentiful in the lakes, particularly in the Talt and Gara, and on the coast there is abundance of white fish. Herrings have not much frequented it for many years, yet a few are still caught in summer.

Estates and Farms.

Sligo contains estates of almost every size. A few are worth from L. 5000 to L. 9000 a year; yet a considerable proportion of the county is divided into small properties. The principal proprietors are absentees. Farms vary in size from three acres Irish to 500; the larger farms, however, are not held by individual tenants, but in partnership. The leases are for 31 years and three lives, and in some instances for 61 years and three lives, being, in general, longer here than in other parts of Ireland. Tillage farming is still in a very backward state. The plough is worked by three or four horses yoked abreast, directed by a man who walks backward before them. Oats, barley, and potatoes, are the principal crops. Of the two former, a great proportion is consumed in illicit distillation, which, within these few years, was carried on in almost every of the county. It was to the sale of the spirits that many of the small tenants looked as the means of paying their rents. In some parts, both cattle and sheep are kept in considerable numbers, and a great

deal of butter is exported from the town of Sligo; but the land occupied in this way bears but a small proportion to the whole; to grow corn being the principal object. Limestone and limestone gravel, which are in abundance in most places, are in general use as manures; also marl, and on the coast seaweeds.

The manufactures for export are linen, salt, and kelp. There is a linen hall at Sligo, where a good deal of business is done in this line; and from this place, which is situated on the bay of that name, the cloth is sent in large quantities to the English market in a finished state; there being many bleaching-greens in the county. This being the only town of any extent, and having a harbour that admits vessels of 200 tons close to its quay, all its exports and imports centre here. Besides linen and butter, Sligo exports a great deal of corn. Its population, according to the author of the *Agricultural Report*, is about 10,000. The other places called towns, of which there are 21 in all, are inconsiderable hamlets at which fairs are held.

The cabins, food, fuel, and clothing, of the lower classes seem to be as uncomfortable as in any of the Irish counties already described. About 20 years ago, the price of labour, near the town of Sligo, was about a shilling a day throughout the year. Cottiers who had a cabin, an acre of land, and grass for a cow, for L. 3 a year, got only 5d. or 6d. In 1815, the rate of common labour in the country parishes was only 10d., and 1s. 1d. in spring time and harvest. Beef and mutton were from 3d. to 5d. per pound; oatmeal 10s. to 12s., and potatoes 1s. to 1s. 4d. per cwt.

In 1790, the population of this county was about 60,000, and by the census of 1821, it was 127,879. According to Mr Wakefield, the Catholics are to the Protestants at least as 80 to 1. In one considerable landward parish, that of Kilmactige, there were, in 1815, 1200 Catholic and only 10 Protestant families. The Irish language is still very common, and in some places English is almost unknown. Within these few years, the London Hibernian Society has established several schools, which promise to effect a happy change among the lower classes, who seem to be very ignorant and superstitious, and of most irregular and improvident habits. Their marriages, which are generally contracted at an early age, and their christenings and funerals, are all conducted at a most unsuitable expence both of time and money. The numerous holidays of the Catholic Church, passed in sport or idleness rather than in religious observances, and their habit of attending fairs and markets without having any business at them, have also a very bad effect on the industry of the people; whose condition is still farther depressed by the payments that must be made to their clergy at baptisms, marriages, confessions, and on other occasions. Accordingly, while many of the men leave home in summer to find employment elsewhere, their wives and children set out at the same time and travel over the country as beggars till their return.

Sligo county sends two members to Parliament, and the town of Sligo, which has twelve self-elected burgesses, a third. Mr Wynne is patron of the

Somerset-shire. borough, and the political influence of the county is in possession of absentees.

See Mr Parlan's *Statistical Survey of the County of Sligo* (1802), and the general works quoted under the former Irish counties. (A.)

boundaries and Extent. SOMERSETSHIRE, a maritime county of England, lying in a crescent-like form on the Bristol Channel, to which its north-western side is turned. It is bounded to the north-east by Gloucestershire, on the east by Wiltshire, on the south by Dorsetshire and part of Devonshire, and on the west by the latter county. Its greatest length, from east to west, is 65 miles, and its greatest breadth, from north to south, 45 miles. Its boundary line has several considerable indentations. The whole area comprehends 1642 square statute miles, or 1,050,880 English acres; being in extent the seventh in the list of the English counties. The acreable value of the land, according to the late returns under the Property-tax, exceeded that of any other county except Leicestershire, being, including the tithes, L. 876 per square mile, or about 27s. per acre.

Divisions and Population. The civil divisions of this county are denominated the eastern and the western. The eastern division contains twenty hundreds and seven liberties, and the western twenty-two hundreds. The whole country is in the diocese of Bath and Wells; and is ecclesiastically divided into three archdeaconries, under which are 13 deans, who superintend 482 parishes. There are within the county two cities (besides a part of Bristol), seven boroughs sending members to Parliament, and twenty-nine market towns. The population, by the returns under the census of 1821, was 355,314, of whom the males were 152,447, and the females 165,357. The increase since the census of 1801 had been at the rate of 17 per cent. The inhabited houses were 61,852, the uninhabited 1974, and those building 850. The number of families was 73,537, of whom 31,448 were chiefly employed in agriculture, 27,132 in trade, manufactures, or handicraft, and 14,957 not included in either of the preceding classes.

face of the Country. Few districts contain a greater variety of soil and situation than the county of Somerset. In the north-east corner, the range of the Mendip hills present a lofty tract of country, of late improved on the surface, but chiefly valuable for the coal and other mines beneath it. On the western side are the Quantock hills, an extensive and sterile range, and beyond them the elevated bleak plane called the Forest of Exmoor, the highest district in the western counties. One spot on this forest, called Dunkeny, is 1668 feet above the level of the sea, and from it a prospect over an extended and diversified country is displayed; terminating on one side in the Bristol, and on the other in the English Channel. These hilly, and somewhat barren portions of the county, bear, however, but a small proportion to the whole; and between them is to be seen the richest meadows and arable lands, whose value more than counterbalances the sterility of the hills. In the better parts of the county, it may rather be described as rich than beautiful. There is a deficiency of woods; the streams that run in the valleys are sluggish, and in summer nearly stagnant; but the extent of orchards, especially when in full bloom,

produce a pleasing effect, and in some measure compensate for the want of woods.

The rivers of the county are the Avon, which enters it from Wiltshire, and becomes navigable at Bath, which city it nearly surrounds. It then passes, with many curvatures, to Bristol, and soon after is lost in the Severn. The Axe rises in the Mendip hills in two branches, one of which issues from a natural excavation, called Wookey Hole, resembling some of the Derbyshire caverns. Its course is short, and it empties itself through some marshes, below Axbridge, into the Bristol Channel. The Brue rises in Wiltshire, and also enters the Bristol Channel, being navigable not more than two miles from its mouth. The Parret rises at a village of the same name in Dorsetshire, becomes navigable at Langport, and in rainy seasons a few miles above that town. It is joined, at Boroughbridge, by the Thone or Tone, which proceeds from Taunton, and passing by Bridgewater, empties itself into the sea. The only navigable canal that has been completed is the Kennet and Avon, which unites together the two great rivers Thames and Severn. It commences near Bath, and soon enters Wiltshire. Other canals have been projected in different directions, but none of them have been prosecuted to completion; though on several of them large sums have been expended.

As Somersetshire contains, on the borders of its Cattle and rivers, large tracts of the richest meadow lands, the Dairy. most valuable branch of its rural economy is the fattening of cattle and the management of the numerous dairies. The oxen, bred chiefly in the less fertile pastures of Devonshire, when grazed in this county, afford the best beef, and furnish, in great numbers, the markets of the metropolis, as well as those of Bristol and Bath, in their immediate vicinity. The produce of the dairy is of the best kind. The cheese of Cheddar has obtained great celebrity, but that made in many other parts, and frequently sold as Gloucester, is equal to any in the world. The butter in the southern division of the county is excellent, and much of it, collected in the vicinity of Crewkerne, is sent to the London cheesemongers, who supply it to their customers under the denomination of Dorsetshire butter.

The next agricultural product is cider, which forms Productions of the Soil. almost the universal beverage of the working classes. It is a more pure and yet a stronger liquor than the cider either of Herefordshire or Devonshire; the consumption of it within the country is very large, and some is sent to distant parts. Nature has been so bountiful in furnishing spontaneous productions, that less attention is paid to those agricultural pursuits which depend on skill and industry in this than in many other districts. The abundance of natural grass is such, that the farmers do not find it necessary to grow a crop of clover, or other artificial grass, so uniformly between two corn crops as is necessary in other counties; nor is the practice of fallowing, or of introducing a rotation by commencing with turnips, much resorted to. Notwithstanding this, they grow good crops of corn, and in the hundred of Taunton Dean the wheat is of the very best quality. Barley is not cultivated very extensively, as the ge-

Somerset-shire. Rivers and Canals.

Somerset-  
shire  
||  
Spain.

neral use of cider causes but little consumption of malt. The bear crops are in general very good. Oats are cultivated extensively, but scarcely equal the demands of the county, and the easy intercourse with Ireland readily supplies any deficiency when it occurs. The soil is well calculated for the growth of flax, and a large proportion of that used in the manufactures of the county is raised within it. It is not unusual to rent land for half a year whilst a crop of flax is grown; after which it is taken again by the regular occupant, who finds the flax to be an excellent preparative for wheat, from the careful weeding which was necessary to its success. The rich loamy soils bring to maturity the best elm timber. Goose feathers were formerly afforded in great abundance, but the draining and inclosing many of the richest marshy plains has rendered these capable of yielding more profit by other productions, and the quantity of feathers is much diminished of late years. The landed property of the county is much divided, no one proprietor or great family having such extensive possessions as to give a preponderant political influence. There is a great number of yeomen who share the lands, many of whom maintain the homely independence of the past generations.

Mineral  
Products.

The mineral products of this county are valuable. The hills of Mendip supply with coals their vicinity, the cities of Bath and Wells, and the towns of Frome and Shepton Mallet. The other parts of the county use the coals of Newport, which are brought by sea to Bridgewater. Lead, of a quality superior to that of Derbyshire, is raised in Mendip and on the Cheddar hills. Calamine is extensively produced, and supplies the brass manufacturers of Bristol. Copper is found near Stowey. Manganese, bole, and red ochre, are among the other products of Mendip.

Manufac-  
tures.

Nearly the whole of Somersetshire is a manufacturing country. Cloths of Spanish and Saxon wool are made extensively at Frome, Shepton Mallet, and their vicinity. Some woollen goods, of a middle quality, are produced at Ilminster, Chard, Taunton, and Wellington; and some of a coarser kind at Welvelscombe, Milvarton, Watchel, and other places. The linen goods are chiefly dowlas, tickens, and sail-cloth; these are mostly made at Yeovil, Crewkerne, Montacute, and Martock. There are silk-mills at Bruton and Taunton. Gloves are extensively made

at Yeovil. Of late, the wove-lace manufacturers from Nottingham have found secure asylums at Chard, from the insanity of the *Luddites*, and carry on there large manufactories. Near Wells are establishments for making fine paper; and in the vicinity of Bristol the glass-houses produce a large quantity of valuable wares.

Somerset-  
shire  
||  
Spain.

The foreign commerce of Somersetshire passes chiefly through Bristol, which is the mart for such goods as are required in distant countries. Some of the woollen goods which are manufactured at Taunton and Wellington are shipped from Exeter. The far greater portion of the productions of the county are, however, destined to supply the demand for internal consumption. The cattle, butter, and cheese, are chiefly sent to London, and, in time of war, to Portsmouth and Plymouth. The linen and woollen goods are distributed through the western and Welsh counties, and, in general, are designed more for the home than for foreign markets.

Commerce.

The titles derived from this county are—Dukes of Somerset and Wellington; Marquises of Lansdowne and Bath; Earls of Bridgewater, Poulett, Bristol, and Ilchester; Barons Mendip and Glastonbury.

Peerages.

The county returns two members to the House of Commons, and two from each of the following places: Bath, Wells, Taunton, Bridgewater, Ilchester, Minehead, and Milborn Port; besides two for the city of Bristol, which is partly in this county, and partly in Gloucestershire, but retains an independent jurisdiction as a county of itself.

Members of  
Parliament.

Ilchester, from the elections being held there, and the gaol and county court, is usually considered the county town, although the assizes in the spring are held at Taunton, and in the summer at Wells and Bridgewater alternately.

The principal towns and their population are, Bath, 36,811; Taunton, 8534; Bridgewater, 6155; Wells, 5888; Shepton Mallet, 5021; Yeovil, 4655; Wellington, 4170; Frome, 12,411; Crewkerne, 3434; Bedminster, 7979; North Petherton, 3091; Wedmore, 3079.

SOUTH WALES, NEW. See WALES, NEW SOUTH.

## SPAIN.

THE Article SPAIN, in the *Encyclopædia*, contains a full view of the history of that country from the earliest periods down to the expulsion of the armies of Buonaparte by Lord Wellington. It also contains some descriptive and statistical details, drawn chiefly from the work of M. Laborde. We shall here endeavour to supply what appears to us wanting in the article referred to, as well as to exhibit a view of the more recent history of this interesting and unfortunate country,

and of its internal condition up to the date of its invasion by the army of Louis XVIII. in April 1823.

I. Spain may be considered as composed of a series of mountain terraces, which, projecting successively their rugged edges towards the south, present a flight of gigantic steps from the Pyrenees to the Mediterranean.\* From the Rock of Lisbon to Cape Creus, it stretches through a line of 216½ leagues,

External  
Structure of  
the Spanish  
Peninsula.

\* Wilson, *History of Mountains*, Vol. II. p. 113.

Spain.

Spain.

measuring  $12^{\circ} 18' 40''$  of longitude. The difference of latitude between Cape Ortegal, the most northern, and the islet adjoining Tarifa, the most southern point of Spain, is  $7^{\circ} 46' 10''$ .

The chains of mountains which terminate and divide the great plains of the peninsula, are branches of the immense ridge that, from the most elevated part of Tartary, runs across Asia and Europe, penetrates into the south of France, by Switzerland, and, entering Spain in the direction of the valleys of Roncál and Bastán, separates Navarre from Guipúscoa; Biscay from A'lava; the highlands of Burgos from the plains of Old Castille; and Asturias from the kingdom of León; it then crosses Galicia, and dips into the ocean at the Capes Ortegal and Finisterre.\*

The Pyrenees are lateral ramifications of this great trunk, which run east and west, on the eastern side of Spain, and take a south-west and north-west direction on the confines of Aragon and Navarre. The accumulated mass of these mountains presents, towards the peninsula, the convex side of a spherical segment, which, like a shield with its boss to the south, rounds its edges near the Atlantic and the Mediterranean, and rears the highest part of its curve on the Spanish territory, between the springs of the rivers Cinca and Ara. This eminence, called *Mont Perdu* by the French, is known, in Aragon, by the appellation of *Tres Sorores*, alluding to its three peaks, distinctly seen from Zaragoza, of which the highest, according to the French naturalist, Ramond, who examined it in 1802, rises 4114 Spanish yards above the level of the sea. The line of perpetual congelation is there at the height of 2924 yards. Till this measurement by Ramond, the peak of Canigú, on the French confines of Catalonia, had been deemed the highest point of the Pyrenees. It is, however, only 3364 feet above the sea. †

In the minor branches which strike off from the Pyrenees in a south direction, without forming a part of the great secondary chains, which we shall presently describe, there are some mountains too remarkable to be left unnoticed. Such are, the Monsein, on the coast of Catalonia, near the town of Arens, and the well known Monserfat, which rises,

on the same coast, to the height of 1479 yards above the sea:—such are the Sierras of Ribagorza, Barbastro, Huesca, and Jaca, which take their names from the principal cities in their neighbourhood:—such, finally, those numerous spurs of the great ridge which run into Navarre, whose various appellations would only tend to confuse the reader. The most remarkable object, among these hills, is the Higa de Monreal, probably so called from the fancied resemblance of its highest rock to a fig (*Higo*, or *Higa*). It stands about three leagues to the east of Pamplona, on the high land which divides the waters of the rivers Arga and Aragon.

Of the main ridges which run across the peninsula, that which rises to the west of the source of the Ebro was called *Idubeda* by the Romans, and formed the limits of the ancient *Celtiberia*. In its course towards the Mediterranean, the natives, according to a general custom, distinguish the various portions, or great links of the chain, by the appellation of *Sierras*, adding the name of some town or notable height in their vicinity. Such are the Sierra de Oca, of Urbión (the *Distertia* of the middle ages), of Moncayo (*Mons Caunus*), of Molina, Albarracín, and Cuenca. Part of this chain forms the limits of Aragon and Castille; it then penetrates into Valencia, Murcia, and Granada, and ends in the Capes Oropesa (*Tenebrium*), Martin, Palos, ‡ and Gata. The small town of Alcoléa, in the province of Sória, stands on this chain at the height of 1486 yards above the sea. Its mean elevation, on the road between Molina and Teruél, in Aragon, is 1580 yards.

It is this chain, which Antillon calls the *Iberian*, that, by its direction from its origin to the heights of Moncayo, drives the Ebro to the east, and feeds the Duero towards the west. The Duero proceeds, however, to the south till it comes to Almazán, where the great ridge, forming an elbow to the south-south-west, forces the stream into its westerly bed. Farther south, near the sources of the small rivers Xalón and Tajuña, the Iberian ridge, bearing the name of Sierra Ministra, divides the waters between the Tagus and the Ebro.

\* *Elementos de la Geografía Astronómica, Natural y Política de España*, por Don Isidoro de Antillon. Madrid, 1808. This is a book of great merit. Its author, whose premature death, while representing his native kingdom of Aragon in the second Cortes at Cadiz, is lamented by his numerous friends, as well as by all who, knowing his worth and talents, can appreciate the loss which his country sustained by that event, spared himself no trouble in the collection of materials for this elementary book, which he wrote for the use of his pupils at the Royal College of Nobles, at Madrid. Besides the extensive local knowledge he had acquired in his travels through Spain, these *Geographical Elements* contain a great deal of information derived from the unpublished works of other scientific Spaniards. Such is the *Ensayo de una descripción física de España*, por Don Josef Cornide, printed in 1803, but which had not come into circulation in 1808. Antillon professes himself indebted to Cornide for his description of the Spanish mountains, as we are to him for our geographical account of that country, and some valuable facts relating to its statistics.

† The divisory line, between Spain and France, formed by the Pyrenees, extends from Cape Higuér, on the Atlantic near Fuenterrabía, to Cape Cervéra, north of Cape Creus, on the Mediterranean, through a space of 92 leagues.

‡ Cape Palos derives its name from the sea lagoon (*Palus*) called Albuféra, from which one of the French Marshals derived his title. It communicates with the sea by an opening, which is easily closed. The *Albufera* is valuable for the great quantities of fish, especially mullets and john-dories, that abound in it. The Cape itself was called *Scombrarium*, from the abundance of the fish *Scombrus*, a kind of mackerel, on that coast.

The first point where this great ridge splits into the minor chains which lose themselves in the Mediterranean, is to the north of Albarraçín, in Aragon. Of these branches the most remarkable is that which, entering the province of Valencia, is again subdivided into the smaller ridges which terminate at Peñíscola and Cape Oropesa. The waters that descend from these heights, to the north, mix finally with the Ebro, while the Túria and the Mijares are swelled by those which flow from the southern declivities. On the branch stretching towards Peñíscola, and in the limits of Aragon, rises the Muela de Ares, \* a conical mountain, deprived of its apex; whose top is an extensive plain covered with luxuriant pasture, and surrounded by fearful precipices, at the elevation of 1562 Spanish yards above the sea. This is one of the highest spots in the peninsula; the Tagus, the Xucar, and the Cabriel, take their rise among these mountains, and divide the waters which flow from their sides, between the Atlantic and the Mediterranean. Numerous flocks of sheep, both itinerant and stationary, find, in the valleys formed by this chain, the most abundant summer pastures.

From Albarraçín, this chain strikes into the territory of Cuenca in a direction nearly north and south. It then sends off a branch to the east-south-east, on which the Collado de la Plata, or Silver Hill, rises 1598 yards above the sea. It contains a quicksilver mine, which was worked a few years ago, at the distance of four leagues west of Teruél. From the neighbourhood of this town the Sierra de Espadán runs, like an unbroken bulwark, to the sea near Murviedro, in a direction between south-east and north-west. The ruggedness of the hills, the terrific depth of the precipices, and the intricacy of the mountain passes, overhung with perpendicular rocks of black marble, are described in glowing colours by the great Spanish botanist, Cavanilles, whose account of a scientific tour in these highlands of his native province, Valencia, is quoted by Antillon. The Pico, which is considered the most elevated point in these mountains, rises 1303 yards above the sea. Its latitude has been determined by accurate observations to be 39° 31' 38". Its longitude 3° 0' 36" east of the meridian of Madrid.

Near the source of the Tagus, the Iberian ridge sends off another branch which, stretching in almost a southern direction, separates La Mancha from the province of Murcia, to the west of the town of Albacete, and rises into the lofty mountains of Alcaráz and Segúra (the ancient *Orospeða*), dividing the waters between the Guadalquivir and the Segúra, the

two main streams which severally and finally convey them to the ocean and the Mediterranean. † One of the two great limbs which terminate the Iberian ridge runs into the sea at the Cape Cervera; the other, bending to the south, skirts the kingdom of Granada, and disappears at the Cape Gata. To the latter belongs the mountain called Cabezo ‡ de María, between Cartagena and Cape Gata, one league west of the town of Vera on the coast of Valencia. It rises 2287 yards above the sea, and has its summit covered with snow during one-half of the year.

Smaller branches of this chain project between the Túria and the Cabriel, which loses itself in the Xucar at Cofrentes. A ridge runs between the last mentioned river and the Alcoy, another stream, which flows into the sea near Gandía. A minor chain separates the Alcoy and the mouth of the Segúra. The province of Valencia is, in fact, divided by mountains into most fertile stripes, watered by numerous streams, and enjoying every blessing which nature grants to the most favoured climates. The mountains on the right of the Xúcar, from Cofrentes to the sea, bear the two appellations of Cortes de Pallás and Milláres, each applying to a different portion of the ridge. To the left of the same river, the mountains are known by the names of Torres and Dos Aguas, which they change for that of Monte Caballón when they penetrate into Valencia from the province of Cuenca. The rock on which the castle of Monserrate stands, near the sea-shore, five leagues west of the lake Albuféra, may be considered as belonging to this ridge. The castle is 313 yards above the sea. From the mountains of Millares, to the right of the Xucar, another ramification projects between the provinces of Murcia and Valencia. Before reaching Villena it bends towards the sea, on the left of the Alcoy, where it is known by the name of Sierra de Marióla. The number, purity, and copiousness of the streams, which are fed by these hills, render them the main source of wealth and comfort to the neighbouring country. The highest summit of this ridge is called Moncabrer. Another arm stretches from Villena, in which we find the Sierra de Viár, the rock of Xixóna, the mountain of Aytána, and the pyramidal mountain of Mongó, near the Capes San Antonio and Martín. The longer duration of snow on its top makes Cavanilles believe that it surpasses Moncabrer in height, especially as the latter is at a greater distance from the sea. The southernmost part of the chain, which strikes off at Villena, sends out its waters to swell the stream of the Segúra.

Before we proceed to the next main branch of the

\* The insulated rocks which, rising above the ridges, terminate in a plain, are distinguished in Aragon and Valencia, where they abound, by the appellation of *muelas* (grinders).

† The Túria, though a considerable river during part of its course, is so drained by canals of irrigation, that it is reduced to a poor stream when it enters the sea. Cavanilles gives a very interesting description of that river, the constant theme of the Valencian poets. The Spanish naturalist represents the Túria, in its strength, as opening a way between the two ridges which decide the course of its waters, and presently "engaging into such fearful chasms, that, near the village of Chulilla, it rushes through a channel 600 feet deep, and not more than 50 in breadth, winding, in intricate curves, over a bed harder than common marble."

‡ The masculine termination in *o* is sometimes used in Spanish as an augmentative. Mountain heads are generally called *Cabezas*, instead of *Cabezas*. One of the beauties of the Provençal consisted in this power of varying the gender of nouns according to the colouring which the writer wished to give to his pictures. *Vide Sisonidi Literature du Midi*, Vol. I.

Spain. \* Spanish mountains, it will be proper to exhibit a general view of the Iberian chain, which we have hitherto pursued in detail. This would hardly be necessary if we possessed more accurate maps of Spain than are to be found even in that country. \* In the absence, however, of a graphic representation, the course of the rivers will sufficiently indicate the great valley formed by this chain, and which might be named the valley of the Ebro. Its skirts may be traced by a line passing over the sources of the smaller streams to the south of the Ebro, first, as far as Albarracín; then, in a direction nearly west and east, to the Cape Oropéssa. This latter part of the chain bears the names of Sierras de Gudar and Peñagolosa. All the rivers to the north of this ridge flow into the Ebro. From Albarracín to Cape Gata the waters are sent off, by the other branch, to the Mediterranean from the east declivity; and from the western, to the Tagus, the Guadiana, and the Guadalquivir, which convey them to the ocean.

Great Ridge between the Duero and the Tagus.

A map of Spain must be imperfect indeed which does not mark the great ridge whose summits divide the waters between the Duero and the Tagus. It grows out of the Iberian chain, not far from the sources of the Xalón and the Tajúña, † to the south of the city of Sória, and the site of the ancient Numantia. Where it divides the province of Guadalaxára from that of Sória, it is called Sierra de Parédes, and Altos de Baraona. On one of the hills, north of Siguénza, rises the Henáres, which gives its name to the ancient *Complutum*, now the seat of a Spanish University. Near the source of the Lozoya, a rivulet which runs into the Xaráma, these mountains are called Somosierra, till, more to the west, they bear the name of Guadarráma; an appellation which they preserve throughout the long course in which they skirt the provinces of Segovia, A'vila, Guadalaxára, and Madrid. The Puerto de Navacerráda, the highest point on the road from Madrid to the summer palace of San Ildefonso, is 2204 yards above the sea. The descent to the royal residence is excessively rapid, the difference of elevation between these two points being 816 yards in the space of about three leagues.

The mountains of Guadarrama are a very striking object when seen from the neighbourhood of Madrid, on the road to Old Castille. They principally consist, according to Mr Townsend, of naked, fractured granite rocks, heaped up together, and adorned only towards their bases with single evergreen oaks, while the upper parts are bleak, dreary, and barren, presenting fantastic prominences, and in many places covered with perpetual snow.

This chain, in its course towards Portugal, where it ends in the Rock of Lisbon, rises into some re-

markable elevations. We shall notice that of Peñalára, between the sources of the Eresma and the Lozoya, 2834 yards above the sea; the Puerto del Pico, in the province of Salamanca; the Peña de Francia, and Sierra de Gata, on the northern limits of Spanish Extremadura. In Portugal, this chain takes the name of Sierra de Estelha (*Mons Herminius*), and terminates under the well known appellation of Cintra. The Sierra de Estelha runs between the Mondégo and Cecere for a space of twelve leagues, where its summit expands into a plain three leagues in length, and one in breadth, containing three lakes, fed by the snow which covers that elevated spot from October till June. From one of these lakes the Mondégo takes its source.

Spain.

Our limits compel us to omit Antillon's accurate and interesting description of the minor branches which run nearly north and south from the main ridge, which that writer conceives to end in Cape Finisterre. They may be traced from the opposite course of the rivers which flow either into the Duero and the Miño, ‡ or into the ocean, on the western coast of Galicia.

Almost parallel to the mountains of Guadarrama, we find the ridge which divides the waters between the Tagus and the Guadiana. The rise of this branch out of the Iberian chain would hardly be perceptible, but for the separation of the waters, which begins in the vicinity of Huéte, south of Cuenca. The gradual elevation of the ground from Tarancón to Tembléque, in the province of Toledo, raises the latter town 740 yards above the sea. Bolder hills appear at Madrilejos; and the town of Consuégra has an elevation of 769 yards. Proceeding a short distance to the south-west, the Sierra de Yébenes clearly shows the direction of the ridge, which is soon after known by the name of Guadalúpe (*Montes Carpetani*); it then runs between Truxillo and Mérida, under the name of Sierra de Marchál, penetrates into Portugal by Castél de Vide and Portoalegre, is seen to the west of Elvas and Estremóz, and descends to Cape Espichél, having Beja and Setúbal to the south, E'vora and the mouth of the Tagus to the north.

Chain of the Tagus and the Guadiana.

The third great branch of the Iberian ridge is the Sierra Moréna (*Montes Mariani*), which divides the waters between the Guadiana and the Guadalquivir. It begins in the vicinity of Alcaráz, near the eastern limits of the province of La Mancha, issuing from that spur of the Iberian chain which terminates in Cape Palos, and, trending in a direction north-east and south-west, with La Mancha, Spanish Extremadura, to the north, and Jaén, Córdoba, Seville, and Algarve (Portugal), to the south, ends in the ocean at Cape St Vincent. The pass named Puerto del

Ridge of the Guadiana and the Guadalquivir.

\* The map which Antillon constructed for his work, though upon a very small scale, is the most accurate in existence; and we would strongly recommend it to the attention of those who devote their industry and talents to the important department of geography.

† The division of the waters occasioned by this ridge begins at these two rivers, the Xalón flowing into the Ebro, the Tajúna, through the Xaráma, into the Tagus.

‡ We have preferred the Spanish appellations of these rivers in a description of Spain. They, in fact, differ very little from the Portuguese names. Miño and Minho express the same sound, the Portuguese *nh* being exactly similar to the Spanish *ñ*. Both are signs of the *gn* of the Italians.

Spain.

Rey, where the road from Madrid to Andalusia crosses these mountains, is 821 yards above the sea. Near Cordoba, where the bold skirts of the *Montes Mariani* are seen, within a short distance to the north, like a skreen raised to protect the rich and extensive plains watered by the Guadalquivir, the ridge borrows the name of the neighbouring city. On the southern limits of Extremadura, and to the north of Seville, it is called Sierra de Guadalcanal. The chain now bends to the south-west, forms the northern boundary of the Portuguese province of Algarve, and, through the Sierras of Caldeiraon and Monchique, connects itself with Cape St Vincent.

Ridge of Granada and Ronda.

The brink of the last mountain plain towards the south of Spain is skirted by the ridge of Granada and Ronda, which, striking off at the extremity of the Iberian chain, is successively called Sierra de Gadór, Sierra Nevada, Bermeja, and de Ronda, till it ends in various points of the coast, but most conspicuously in the Rock of Gibraltar.

Part of Sierra Nevada rises above the highest Pyrenees. According to the geometric levelling performed in 1804 by Don Ramon de Roxas Clemente, the Cúmbre de Mulhacén is 4254 yards above the sea; the Picácho de Veléta 4153.\* The line of perpetual congelation is found in these mountains at the height of 3305 yards.

Rivers.

In describing the principal chains of the Spanish mountains, we have already mentioned the five great streams which water the intermediate plains, the Miño, the Ebro, the Duero, the Tagus, the Guadiana, and the Guadalquivir. We will now select a few particulars relating to each.

The Miño.

The Miño, or Minho (*Minius* or *Boenis*), rises in Galicia, in the district of Lugo, from a beautiful spring called Fuente Miña. This river is navigable only to Salvatierra, two leagues above Tuy.

The Ebro.

The Ebro rises, near Reynósa, out of so copious a spring, that it works a corn-mill a few steps from its source. After a course of 110 leagues, it flows into the Mediterranean at Alfáques. From the boundaries of Navarre to the sea, the Ebro makes a progress of  $1^{\circ} 12' 42''$  towards the south. The chief towns on this stream are Logróño and Calahorra, in the province of Rioja; Tudéla, in Navarre; Zaragoza, in Aragon; and Tortosa, in Catalonia. It is a misfortune for Spain that this great river presents strong obstacles to navigation, both in its course and where it joins the sea. Of the plans which have been conceived, and partly executed, to obviate these impediments, we shall presently have an occasion to speak.

The Duero.

The Duero, or Douro, has its source to the north of the city of Osmá, in a deep lake, at the summit of that portion of the neighbouring chain of mountains which has been mentioned by the name of Sierras de Urbión. Its course is at first towards the south, passing by Garay and Soria, where it turns to

the west, continuing in that direction till it reaches Miranda. From this town to Moncorvo the river falls again into a south direction. It lastly takes a decided course to the ocean, where it ends near Oporto, having traversed a distance of 150 leagues. The Duero advances  $10'$  to the south from Aranda to Tordesillas; from hence to Miranda it inclines  $40'$  to the north. Its mouth lies  $33' 45''$  south of Miranda. This river is navigable up to the tower of Moncorvo, a space of thirty leagues. The navigation, which was formerly obstructed by rapids, has been expedited through the exertions of the Portuguese Company of Alto Douro. Some of the smaller streams flowing into the Duero, rise at remarkable heights. The Adaja, which descends from the northern slope of the great chain between the Duero and the Tagus, is, at A'vila, 1271 yards above the sea; the Eresma, when it flows by the castle of Segovia, is 1107 yards above the same level.

The Tagus.

We have mentioned that elevated part of the chain between the Tagus and the Guadiana, which takes the name of Albarracín, and the truncated mountain called Muéla de San Juan. An inconsiderable spring, denominated Pié Izquierdo, is the source of the majestic Tagus. In its course through the province of Cuenca it is considerably augmented by the contributions of several streams. Before its waters reach Aranjuez, they surmount the rocky edge of its native mountain, and, dashing upon the plain beneath, sink into a pool of great depth, called Olla de Borláque. The Tagus, now running placidly through the plains of Zorita and the royal gardens of Aranjuez, at the elevation of 621† yards above the sea, directs its course to Toledo, passes by Talavera, Alcántara, Abrantes, and Santarem, losing itself finally in the sea, near Lisbon. The latitudes of several towns on the banks of the Tagus show the gradual inclination of its stream toward the south. It amounts to  $49' 6''$  from Trillo to Toledo, to  $6' 24''$  from the latter city to Alcántara, and no less than  $1^{\circ} 1' 40''$  from thence to the capital of Portugal.

The river Guadiana is, according to Antillon, very inaccurately represented in the Spanish maps of Lopez, both as to the point where it disappears, and that where, emerging from the ground, through which its waters are filtered, it resumes its sluggish course to the ocean.

The sources of the Guadiana have been rendered classical ground by the pen of Cervantes. They are found north of Alcaráz, in La Mancha, at the pools of Ruidera, well known to the admirers of *Don Quixote*. The course of the river is first to the north-west, for eight leagues. It is then absorbed by the soil, and disappears for seven leagues. The first gathering of its waters, after their subterraneous dispersion, takes place near Daymiel. The spot is called Ojos (Eyes) de Guadiana. The stream now proceeds to Ciudad Real, the head town of the pro-

\* The result of this, and several other measurements executed by Mr Clemente, was communicated to Mr Antillon, who has given them in his work, with the initials R. C. Those relating to Sierra Nevada have lately been published in the *Annales de Chimie*, Vol. XX. p. 99.

† This barometric measurement was taken by Humboldt in 1799.

Spain.

vince of La Mancha, to Mérida, Badajóz, Mértola, in Portugal, and, re-entering the Spanish territory, terminates in the ocean at Ayamonte. In its course to this point, the Guadiana passes over a space of more than one hundred leagues.

The abundance of pasture which betrays the hidden course of Guadiana is the origin of a boast often repeated in La Mancha, that their river has so broad a bridge as to allow thousands of cattle to feed upon it.\* That bridge affords, however, but a dangerous pastoral station; for the country being subject to sudden inundations, both flocks and shepherds are not unfrequently in the most imminent danger of being swept away by the waters. The stream of Guadiana, near Villarta, is only at the height of 710 yards above the sea. It is not navigable higher than Mértola in Portugal.

The Guadalquivir.

The Guadalquivir occupies the centre of the plain which lies between the Sierra Moréna and the chain of Granada, where it takes its source to the north-east of Jaén. The chief towns on its banks are Andújar, Córdoba, Seville, and San Lúcar (*Templum Luciferi*). At the ferry near Mengibar, on the road from Madrid to Granada, the Guadalquivir is 203 yards above the sea.† The Guadalquivir is navigable for large vessels up to Seville; but its bed being constantly raised and obstructed by growing shallows, the navigation is extremely tedious.‡

Population of Spain.

II. On the subject of population, the data which the Spanish government possessed before the French invasion must have been greatly deficient in accuracy. The suspicions of the inhabitants, constantly alive against every public measure, were roused into full activity by the domiciliary inquiries which took place in 1798, when a general *census* was made. It is, therefore, more than probable, that the number of inhabitants considerably exceeded what we find in the official reports. We subjoin the Table published by Antillon from documents in the possession of the Commissioners for the Encouragement of Trade (*Balanza Mercantil, y Fomento de Comercio*), in 1803.

A Table of the Population of Spain in 1803.

Provinces.	Total of Inhabitants.	Surface in square leagues, 20 to a degree.	Inhabitants to square league.
Province of Madrid§	228,520	110	2078
Guadalaxára	121,115	163	743
Cuénca	294,290	945	311
Toledo	370,641	734	505
Mancha	205,548	631	326
A vila	128,061	215	549
Segovia	164,007	290	566
Sória	198,107	341	581
Burgos	470,588	642	734
Extremadura	428,493	1,199	357
Kingdom of Cordoba	252,028	348	724
Jaén	206,807	268	772
Seville	746,221	752	992

Zamóra	71,401	133	537
Toro	91,370	165	590
Kingdom of Galicia	1,142,630	1,330	859
	10,351,075	15,005½	690

\* The Spaniards of old times delighted in this kind of startling metaphors about their country. In the same taste, they would say that the King of Spain had three noble subjects, who brought into the field six thousand knights, wearing gold spurs, meaning the Grand Masters of Santiágo, Alcántara, and Calatráva; that he had a lion (*León*), and a bull (*Tóro*), that fed daily on twelve beeves, in reference to the towns bearing these names; that he had three dogs (*Canes*), who served him with two hundred Castillian lances, such being the military service due by the three towns Can de Roa, Can de Muna, and Canes de Zuríta. *Can* is the Castillian pronunciation of the original Spanish word *Camp*, which afterwards became *Campo*, a field, or district.

† The following barometric measurements show the rising of the ground from that point to Alcalá la Reál, where the waters are divided between the Guadalquivir and the Genil. Mengibar is 350 yards above the sea; Torre-Campo, at the distance of four leagues, 705; Alcaudéte, five leagues, 835; Alcalá, three leagues, 1023.

‡ The Guadalquivir was navigable up to Cordoba in 1360, as appears by a petition of the Seville barge-men to Peter the Cruel, complaining that the openings required by law across the mill-dams had been narrowed, and, in some cases, closed against them. The king ordered the obstructions to be removed, and fixed for the breadth of the channel that of an arch in the cathedral of Cordoba, called the *Arch of Blessing*. *Crónica del Rey Don Pedro, anno 1360, p. 309.*

§ In comparing the respective population of the Spanish provinces, the inhabitants of Madrid, amounting to 168,000, should be excluded as adventitious, and mostly belonging to other parts of the kingdom.

Spain.

Population of Portugal, from the Official Returns of 1798.\*

Provinces.	Total of Inhabitants.	Surface in square leagues, &c.	Inhabitants to the square league.
Entre Douro e Minho	907,965	291½	3115
Tras os Montes	318,665	455	700
Beyra - -	1,121,595	753	1498½
Extremadoura	826,680	823	1004½
Alentejo -	380,480	883	431
Algarves -	127,615	232	550
	3,683,000	3437½	1071

Taking a general view of the population of Spain, it appears to have been distributed, in 1803, over the 15,005½ square leagues of its surface, in the following proportions:

	Inhabitants to the square league.
Maximum of population—province of Guipuzcoa - -	2009
Minimum—province of Cuenca	311
North maritime provinces, collectively (Galicia, Asturias, Burgos, Biscay, Guipuzcoa, and Catalonia)	887
South maritime provinces, collectively (Valencia, Murcia, Granada, and Seville)	926
Northern provinces of the interior, collectively (León, Palencia, Zamora, Toro, Valladolid, A'vila, Segovia, Soria, Guadalaxara, A'lava, Navarre, and Aragon)	604
Southern provinces of the interior, collectively (Salamanca, Extremadura, Cordoba, Jaén, Mancha, Toledo, and Cuenca)	428
Maritime provinces, collectively -	904
Inland do do -	507

Influence of the Extent of Sea Coast on Population.

The facilities afforded by an extensive sea coast, for the subsistence and consequent multiplication of the neighbouring inhabitants, appear in a striking light when the following facts are taken into consideration:

The extent of coast from Cape *Cervéra* to Cape *Trafalgar* is 251½ leagues; from the latter to Cape *Finisterre* it amounts to 262 leagues; from that point to Cape *Higuér* there is a line of 143 leagues. The subjoined Table exhibits the proportion of coast possessed by the maritime provinces of Spain and Portugal, compared with the areas of their territories. We shall add a column containing the number of inhabitants to the square league, that the reader may have all the necessary data before him:

Provinces.	Extent of Coast.	Ratio of the Coast to the area, the latter being represented by 1000.	Number of Inhabitants to the square league.
	Leagues.		
Catalonia -	68½	1000: 68	856
Valencia -	69	: 107	1283
Murcia -	21	: 32	582
Granada -	74	: 92	861
Seville (19 leagues on the Mediterranean, 35 on the Atlantic)	54	: 72	992
Algarve (Portugal)	43	: 185	550
Alentejo, do	19	: 22	431
Extremadura, do	60	: 73	1004½
Beyra, do	23	: 31	1489½
Entre Douro e Minho, do	27	: 93	3115
Galicia -	110	: 83	859
Asturias -	40	: 130	1180
Burgos -	27	: 42	734
Biscay -	13	: 123	1051
Guipuzcoa -	9	: 173	2009

Spain.

It appears from the preceding table, that Guipuzcoa, Asturias, and Biscay, are the most populous provinces of Spain; and that the excess of their population is nearly in the ratio of their coast to their territory, compared with the other divisions of the country. If Valencia, with less coast to its area than Biscay or Asturias, is more peopled than either, the extraordinary fertility of its soil, and the unrivalled salubrity of its climate, will easily account for the anomaly. The province of Granada, which possesses a greater proportion of coast than Galicia, is also more thickly inhabited. The same may be observed in comparing Galicia with Catalonia, Burgos with Murcia. Antillon attributes the excess of population in the province of Seville over Granada to the conflux occasioned by the two great towns of Seville and Cadiz, both enjoying peculiar advantages; the former from its sea-port, the latter from the navigation of the Guadalquivir.

The comparison of Portugal with Spain affords a further confirmation of this theory. The latter kingdom has 468 leagues of sea coast, Portugal 172. The ratios of their areas to their line of coast are 100:3,24—and 100:5. Now, in the *first* place, The mean population of Portugal exceeds that of Spain by 381 inhabitants to the square league; *2dly*, The most populous province of Spain falls short of the most populous in Portugal by 1106 souls to the same portion of territory; *3dly*, In the respective provinces where population is thinnest, the Portuguese exceed the Spaniards at the rate of 120 persons to the square league.

If we compare the population of the Portuguese provinces with the ratio of their areas to their line

\* These Tables are inserted here for the convenience of the reader, who would otherwise be obliged to keep the article *Portugal* constantly under his eye, in order to judge of the observations we shall presently make on the comparative population of the two peninsular countries. The Portuguese returns reckon by *fogos* (hearths), which Mr Antillon has calculated at the rate of five persons to each.

Spain. of coast, we shall find that Alentejo, the lowest in that scale, is also the least populous. Entre Douro e Minho, which has a greater proportion of coast than Beyra and Extremadura, is more inhabited than either.\* If the relative population of these two appears to be an exception, the fact may be easily explained by the consideration, that Beyra, besides the Mondégo, and some other copious streams, enjoys the navigation of the Douro and the Tagus from the farthest limits of its territory, while Extremadura has only a share in the benefits of the latter river. Entre Douro e Minho, possessing the Douro, the Lima, and the Minho, which are navigable a great way up the interior, may be reckoned to exceed Algarve in the advantages arising from a sea-coast, though the sea washes a smaller portion of its territory. The difference, too, of the soils affords an additional answer to the objection, since that of Entre Douro e Minho is confessedly the richest in Portugal, while the inhabitants of Algarve have the most sterile portion of the kingdom for their lot.

Whatever may be thought of the accuracy of the preceding theory, it cannot be denied, that, besides the great quantity of food afforded by the sea, the facility of communication and conveyance, which a neighbouring coast presents, must have a direct tendency to increase the wealth of the inhabitants, and consequently to multiply their numbers. The territory of Spain has been quaintly, though accurately, compared to an embroidered waistcoat; the edges full and ornamented, the centre a blank, with a few scattered flowers. Were it all as fully inhabited as Guipuzcoa, it would contain 30,146,050 souls, nearly three times the number in 1803. Even at the moderate rate of the Catalonian population, or 856 souls to the square league, Spain would have 12,844,708 inhabitants, about two millions and a half above the last returns. That this comparative dearth of population does not, either exclusively or chiefly, arise from the national system of government, is proved by the state of population in Portugal, a country which, from time immemorial, has been no less than Spain, under the influence of political and religious despotism. Capmany, † one of the most able and well informed Spaniards of our own times, has satisfactorily shown, that the accounts of some old writers, who make the population of Spain, in the sixteenth century, ascend to twenty or twenty-one millions, are groundless and exaggerated. We are, therefore, inclined to attribute more influence on this point to the physical or geographical circum-

stances of Spain than has been hitherto allowed by writers on Spanish statistics, and shall give it the first place in the consideration of the chief obstacles which have hitherto opposed the prosperity of that country.

Spain.

III. No depth of observation is required to perceive that, whatever opposes the internal trade and interchange of commodities, must, by checking the progress of wealth, check also the increase of population; while a mere glance at a good map of Spain will suffice to perceive how unfavourable the structure of that country must be to the purposes of national commerce. The enormous chains of mountains which traverse the peninsula in a direction almost parallel to the equator, and the consequent want of navigable rivers from north to south, the distance from the central provinces to the coast, the difficulty of cutting roads and canals through high ridges of mountains and extensive plains at very different levels, are obstacles which would require all the activity of a rich and well governed nation to smooth or to subdue.

Obstacles to the Prosperity of Spain.

Little, however, could be expected from the enfeebled and corrupt despotism into which the government of the Spanish Bourbons had settled after some fitful aims at improvement, which a court intrigue or the death of a minister was sure to defeat. Yet, it is but justice to say, that the only progress which Spain has made, since the time when the foreign influence of her monarchs, and the discovery of America, gave her a false appearance of internal vigour, has taken place under the present dynasty. ‡ How much was done for the encouragement of agriculture, in the reign of Charles III., may be deduced from the fact that, whereas that monarch found Spain under the annual necessity of importing corn § to the value of one hundred millions of francs, the deficiency was found so far reduced under his successor as to be supplied, in the more favourable years, at the expence of only fifteen millions of the same money. ||

How truly the necessity of importing corn arises from the want of easy communications between the provinces, appears from the average crops which, as we learn from the demi-official authority just quoted, amount to more than seventy millions of quintals by weight. ¶ In the kingdom of Aragon, there is an annual surplus of 388,000 cahices (2,910,000 bushels) of corn. \*\* The incorrectness of Spanish statistical documents is, however, so evi-

\* In the comparison of the Portuguese provinces it must be remembered, that Extremadura includes the adventitious population of Lisbon.

† Capmany, *Questiones Criticas*.

‡ See a *Memoir* of the Count of Floridablanca, published by Archdeacon Coxe as an Appendix to the 1st volume of his *History of the Spanish Bourbons*.

§ The quantity of corn supposed to be imported yearly into Spain is sixty millions of fanegas, or one thirteenth of the whole consumption. Upon a rough calculation, two fanegas are equal to three bushels.

Spain.

dent, that it would be rash to admit any inferences from them implicitly, or to their full extent. Yet, it cannot be doubted, that, in years of abundance, the produce of the interior is often allowed to waste, while corn is imported from Africa and Russia at a cheaper rate than the native produce could be sold for on the coast.

The benefits of the exportation of wine, which are now limited to some of the provinces bordering on the sea, might be extended to more than one-half of the country if, by means of canals or navigable rivers, that article could be transported to the coast at a cheap rate. But the luxuriant vineyards of Andalusia, not in the immediate vicinity of the water, are of little advantage to the owners; and the juice, which might ferment into a variety of exquisite wines, is often thrown away, when the small quantity, which will supply the demand of a very limited district, has been collected in the cellars.

Internal Navigation.

The water carriage in Spain is reduced to the inconsiderable portions of the intended canals of Aragon and Castille, which have been constructed; to the slow and laborious navigation of the Ebro from Zaragoza to Tortosa, performed, almost exclusively, for the conveyance of wheat; and to the floating of timber down that river, the Tagus, the Xúcar, the Segura, and the Guadalquivir. This last river, on which a steam-boat, built and worked under the direction of a British engineer, affords, of late, an easy and speedy communication between Seville and San Lúcar, is the only one from which Spain derives any considerable advantage in point of trade.

It may be reckoned among the unfortunate combination of circumstances which have hitherto checked the internal prosperity of Spain, that the navigable part of its finest rivers belongs to another kingdom. The Tagus and the Douro may be said to exist for the exclusive advantage of Portugal.

During the short and ill-fated union of the two peninsular crowns, the engineer Antonelli undertook to open the navigation of the Tagus as far as Toledo, and completed that useful work in 1558. After the separation of Portugal from Spain, several plans have been presented to the Spanish government for removing the obstacles which obstruct the bed of that river from Alcántara to Toledo, and even from the latter town to Aranjuez, which, by means of canals, was to be joined with Alcalá. Surveys were made by order of the government, from which, as Antillon observes, no benefit accrued to the country except an accession of topographical knowledge, and the fruitless conviction that the communication of La Mancha with the ocean was opposed, chiefly, by moral and political obstacles.\*

The Ebro, under the Roman dominion, is said to have been navigable up to Logróno, a distance of 65 leagues inland. In the twelfth century, the Emperor Don Alonso ordered galleys to be sunk near

Zaragoza, as a defence against the Moorish navy. Zurita relates, that, in the fifteenth century, King Don Juan sailed down the Ebro from Navarre into Aragon. We find, however, the Cortes of the latter kingdom, under Charles II. of Spain, towards the end of the seventeenth century, deliberating upon plans for expediting the navigation of the Ebro near the sea. A survey was made for the same purpose in 1738, but with no practical result. The grand canal of Aragon was at length begun under Charles III., the grandfather of the present king; and were it completed, it would stand a splendid monument of the spirit of the nation.† It is, however, much against the practical utility of the public works undertaken in Spain, that, by a natural disposition of the people, they are all begun upon a scale which would require the wealth and power of imperial Rome for their completion. The little that exists of the canal of Aragon might, if we believe Antillon, compete with the works of that period; but, instead of reaching the sea through the Ebro, and terminating in an artificial harbour, as was intended, it has been carried on for the space of eighteen leagues only, and contributes but little to the internal navigation of the country. Whether it is more favourable to agriculture, by the copious irrigation which it affords in its course, is, we find, a point in dispute among the Spaniards. Jovellanos, in his excellent *Informe sobre la Ley Agraria*, mentions the farmers' complaints against the canals for irrigation. It is hard, indeed, upon all land owners within a certain distance to be forced to pay a tax for irrigation, whether they have or not the means, the skill, or the inclination, to avail themselves of the proffered benefit.‡ The farms, for instance, near the canal of Aragon, from Zaragoza to Sástago, pay one-fifth of their corn, and one-seventh of all other produce, for irrigation. Lands newly brought into tillage pay only one-sixth of the corn, and one-eighth of the other produce.

Such complaints, it seems, were louder in the vicinity of the canal of Castille, where the Spanish practice of allowing the fields to lie fallow every other year was still adhered to, notwithstanding the abundance of water.§ This canal begins at Alár del Rey, in the province of Burgos. It is fed by the Pisuerga, whose right bank it follows till it joins that stream on the limits of the kingdom of León. It then runs to the south and south-west, crossing the river Cierza, and proceeds on its right bank till, passing through the Carrión, it turns to the west of Palencia, and terminates in the same river. The small canal of Campos, running more to the west, joins that of Castille to the north of Palencia.

According to one of these gigantic plans with which the Spanish government have often amused their vanity, providing, as it were, in the magnitude of the enterprise, a ready excuse for their inactivity,

\* Antillon, *Geogr. de España*, p. 162.

† The canal of the Ebro was begun under the Emperor Charles V., but being soon discontinued, the present canal is, properly speaking, a modern work.

‡ Jovellanos, *Ley Agraria*, p. 29.

§ *Ibid.* p. 39.

*Spain.* the canal of Castille was to reach the sea at Santander, through the river Camésa, through the Ebro, near Reynosa, and finally through the Besaya and the Pas. From its present termination near Palencia, it was, on the other side, to reach Valladolid, to strike off from the Duero, in order to join the Adaja, and then to follow the Eresma as far as Segovia. From thence it was to be directed to the canal of Aragon, and thus to unite the ocean with the Mediterranean, across the kingdom. Don Ramon de Pignatelli, the engineer who superintended the works of the canal of Aragon, laid the plans of this immense work before Charles III. whose sanction they received. We must, however, remind the reader, that the only traces which exist of this mighty dream attract but faintly the notice of the traveller, near Burgos, and in the vicinity of Madrid, where the head of one of the intended branches extends for four or five miles almost undisturbed by barge or boat

Such are the effects of a despotic government, even in its kindest moods, and when it, fairly and honestly, means to promote the good of its subjects. Unwilling to consult, and unable to ascertain the real opinion of those immediately concerned in the result of its measures, it moves with ponderous haste towards the object which dazzles its eyes, often crushing, in its way those it meant to relieve. Complaints are heard at length; which, joined to the exhaustion attending all unnatural exertions, never fail to put the despot in a passion with his subjects, and make him repent that he ever was so good and gracious as to try to improve their condition.

Had the Spanish farmers of the different provinces been fairly heard before their lands were indiscriminately drenched, in virtue of a royal decree, the treasure which was thus mispent might have been employed in opening roads across the provinces, by means of which the value of their crops would have risen at once. But the purblind projectors of these schemes forgot every circumstance of the case, except that, in the provinces bordering on the Mediterranean, irrigation increased agricultural produce. This was enough to convince them that it would have the same effect in the centre of Castille. The farmers declared, however, that the abundance of water deteriorated their lands; and, though much abused for their ignorance, they probably were in the right. Yet, supposing that irrigation could double their crops, they still had good reason to complain that, under the burden of an additional tax, the abundance of corn only lowered the price in the small district which formed their market; and that living, as they do, at the distance of many miles from their fields, they could not bestow that constant labour and attention, which alone might enable them to raise a yearly crop on the same soil.

We have just adverted to another of the great obstacles which oppose the agricultural wealth of Spain. The want of rural population, and the great distance of the farmers' dwellings from their farms. Independently of the loss of time and strength arising from a walk of four or six miles before the day's work is begun, there are long periods in the year

*Spain.* when the fields are scarcely visited by the owners, generally gentlemen farmers, and but seldom by the rustic, who acts as steward. Field work, in fact, is not continued throughout the year, but hastily and slovenly performed, at the sowing and the reaping season, by large parties of labourers, for whose accommodation, in farms at considerable distance from any town, there is a building not unlike a large barn, which affords a promiscuous shelter to man and beast. Bands of ploughmen, with thirty or forty team of oxen, are seen at the beginning of winter, slightly turning up the sods in the fields which have lain fallow the preceding year. The sowers walk slowly behind them, scattering the seed by handfuls, of which, part is picked up by the large flocks of birds which hover over those extensive solitudes, and part prevented from taking root by being improperly lodged in the earth. The harrow is hardly known in Andalusia, and weeding is an operation seldom resorted to. The corn-fields, thus abandoned to the influences of the climate, and the rank luxuriance of the soil, present, at the approach of summer, the colours of the rainbow to the eye of the traveller, who, but for the absence of all human habitation, might easily mistake them for flower gardens. We are, it is true, describing the Andalusian method of farming, with which we are best acquainted; but, with the exception of Murcia, Valencia, and Catalonia, on the coast, and part of Aragon, in the interior, we have reason to believe that agriculture is neither better understood nor practised than in Andalusia; the mismanagement of whose extensive and fertile plains has, by far, the greatest share in the agricultural disadvantages of Spain. Indeed, Andalusia and Aragon, alone, might, under an active and enlightened system of tillage, supply the whole country with corn.

It was once proposed to the Spanish government to distribute the uncultivated land, amounting to a large proportion of the whole country, among such of the natives as were disposed to bring their lots into tillage. This measure, it was hoped by Jovelanos, would tend to a wider and more equal distribution of the Spanish population, now crowded in towns at great distances from each other. But it is hardly less difficult to alter the original and confirmed constitution of the body politic than of the animal frame. The constant state of warfare against the Moors obliged the Spaniards, from the earliest period of that protracted struggle, to live in large towns, where they might find security against the surrounding enemy. The necessity also of arming the whole male population saved Spain, it is true, from that degraded state of vassalage, which so long oppressed the greatest portion of the people of Europe; but the want of a class of men bound to the soil, and forming part of the agricultural stock of their masters, prevented the existence of a numerous peasantry, which, being spread over the country, might, in the course of time, obtain their emancipation, and become the fathers of a free and happy agricultural population.

Under these circumstances, all schemes to alter the form and character which the growth of centuries has given to civil society in Spain, must prove,

Spain.

we fear, vain and visionary. It is not in the power of man suddenly to convert the idle and degraded inhabitants of large cities into sober and industrious farmers; nor, even if that were possible, could such a nation find means to furnish the home colonist with stock and implements, as well as support, till the new broken land should yield enough for their maintenance. Men will soon find their way to every spot, where either nature or the aggregate industry of the people that inhabit the country, affords them the means of living by moderate exertion. Whenever the Spanish government shall have opened an easy communication between the central provinces and the coast, and joined every important town in the peninsula by cross roads—when the means of internal traffic shall have opened a market for the produce of the soil—when the laws which fetter the industry of the Spaniards shall have been repealed long enough to allow them to perceive their real interests, and to exert themselves with the steadiness and confidence of habitual freedom, then, and not before, will the productive power of their land be called into action. Cultivation will gradually spread from the insulated spots which it always presents in its first stages; towns will join hands across deserts, and men will start up as it were from the furrows—a truth, we believe, recorded in fable by primitive philosophy, and placed in the light of demonstration by that which is the boast of our own times.

Wrong No-  
tions on  
Landed  
Property.

Before we close this part of our article, we cannot omit to mention an obstacle to the prosperity of Spanish agriculture, which, limited as we are for space, we would pass over in silence, were it not a curious instance of the influence of national circumstances upon ideas and sentiments which habit often represents as natural and invariable.

The rights of property in land, wherever the feudal system has existed in full vigour, are so exclusive and peremptory, that it must surprise an Englishman to learn, that there are but very few spots in Spain which the landlord can call his own, from the moment he has housed the harvest. The right of driving cattle into the stubble-fields is claimed and maintained with great obstinacy, not only by the powerful association of owners of *Merino* flocks, called *La Mesta*, but even by the poorest individuals. The arable land of Spain becomes, in fact, a vast common, every year, to which the lord has no more right than any one else. The privilege enjoyed by the Andalusian farmers of inclosing one-ninth of their fields from Michaelmas to May-day is, according to Jovellanos, who was for some years a judge in the Supreme Court of that province, the source of perpetual law-suits;—a proof of the impatience with which it is borne by the mass of the people.

If we seek the origin of a prejudice so injurious to agriculture, so incompatible with every improvement

in husbandry, we shall find it in the peculiar state of the country to which we have attributed the want of a rural population. The Spaniards, while recovering their country from the Moorish usurpers, could hardly consider any land as properly their own but what they had inclosed within the strong walls of their towns. All that the farmers could wish for was to escape an inroad of the enemy while the crops were on the ground. As they could not think of inclosing or improving any particular spot, they cared not whose cattle picked up a scanty feed upon their stubble-fields. When, by the gradual retreat of the Moors, the rights of exclusive property upon land might have been asserted by the owners, their very limited knowledge of agriculture did not allow them to see the advantages which might be derived from inclosures. Thus, in the course of centuries, the general right of pasture was established, which, from the immediate, though paltry, advantages it confers on the multitude, will, we fear, be found among the most intractable prejudices of the Spaniards.

Connected with the ignorance of the advantages arising from the exclusive rights of property in land, are the exorbitant privileges which the Spanish laws have granted to the owners of migratory or *Merino* flocks. From the mountains of Leon to the farthest limits of Extremadura, the members of the *Mesta*, an association composed of the wealthiest Grandees, gentlemen, and religious bodies, have a right to graze their sheep on a broad belt of land called *Cañada*, gradually and slowly changing their stations, as the mild winters of the south clothe the earth with grass, or the heat of summer thaws the snows of the Leonese mountains. The privileges of this body are defended and enforced by a court of judges created for that purpose, and in the appointment and pay of the *Mesta*, who, with a numerous host of dependants, are the terror of the agriculturist wherever their jurisdiction extends. Lands upon this pastoral road are scarcely the property of any but these formidable shepherds, who fix the price of pasture, obtain it by compulsion wherever it is found, and look upon farmers and their labours as the natural rivals and impediments to their gains. The total of *Merino* sheep was calculated in 1808 at six millions. A great part of that number were stationary in the different provinces, the fineness of the wool depending entirely upon the breed, and not on the change of soil.

Since Spain, however, seems to have no chance of becoming a manufacturing country, and must depend for wealth on her natural productions, we readily agree with Jovellanos\* as to the necessity of encouraging the growth of wool, an article which, for centuries, has constituted one of the main resources of that kingdom.† To balance the contending

\* Jovellanos, *Ley Agraria*, p. 47.

† The importation of the *Merino* sheep from England into Spain is a fact recorded both by Spanish and English authorities. It appears to have taken place at three different periods. The Bachellor Fernan Gomez de Ciudad Real, physician to John II. of Spain, says, that "the office of Judge of the *Mesta* had always been conferred on honourable *Hidalgos*."—"The first (he continues) was *Luigo Lopez de Oroasco*,

Spain. claims of the pastoral and the agricultural interests in Spain, must be the work of time under a wise legislature.

Spain. represented by the amount of its produce, was to that of France nearly as seven to forty."

"Our commerce in 1802, soon after the peace of Amiens, was to that of France as two to three—such, at least, is the result of the statistical documents published by the continental powers at that period. But according to the more accurate estimate presented to government by Mr Canga Arguelles, in 1803, the proportion was that of twenty-eight to one hundred and eighty-two, which, in fact, differs but little from the preceding."

"When Great Britain declared against us, in the following year, our commerce, which was just beginning to recover from the losses of the past war, may be said to have received its death wound. Our mercantile companies, then the most powerful in Europe,† were ruined by the general stagnation of trade, by the large and frequent loans made to a government, who never paid either interest or principal. The *Philippine Islands Company*, whose funds were immense, failed to the amount of six millions (of francs). The *Deputation of the five Gremios of Madrid*, well known to all Europe for its credit and wealth, was ruined, partly by the inactive state of our industry, partly by the financial operations

State of Commerce and Industry. IV. We have, in vain, tried to procure a satisfactory account of the state of commerce and industry in Spain. All we can find in the books which we have consulted amounts to little more than general complaints upon this topic. The only substantial fact contained in the first volume of the *History of the late War*, published by the government of Ferdinand VII., is that, in 1808, the annual exports of Spain were to the imports as three to seven; the value of the former amounting to seventy-five millions of francs (we leave the denomination unaltered), while the latter rose to one hundred and twenty-five millions of the same money. "In 1802 (say these official historians),\* the produce of our industry was calculated at three hundred and fifty millions of francs; but it was soon reduced to much less in consequence of the maritime war (with England), and the malversations of the Prince of the Peace. The effects of these checks were the more felt, as the remittances from the American colonies were inadequate to cover the deficit. Our industry in 1803,

whom King Don Alonso (XI.) appointed to that office when the sheep were first brought from England in the Carracks." (*Centon Epistolario*, Letter 73d, dated 1437.) The appointment of Iñigo Lopez was made in 1329. (See a note to the *Chronicle of Peter the Cruel*, p. 60. Madrid, 1779.) The second importation was in the reign of Henry III. of Castille, and formed part of the marriage portion of his wife, Catharine Plantagenet, daughter of John of Gaunt. (See *Historia de la Vida y Hechos del Rey Don Henrique Tercero de Castilla*, por Gil Gonzalez Davila, p. 11.) This marriage was celebrated in 1388. (Ib. p. 4.) The third importation is mentioned by Holinshed (Vol. II, p. 668), who relates that, in 1466, Edward IV. of England "concluded an amitie and league with Henrie King of Castile, and John King of Aragon, at the concluding whereof he granted licence for certaine Cottesholde sheepe to be transported into the countrie of Spaine (as people report), which have there so multiplied and increased, that it hath turned the commodity of England much to the Spanish profit." Stowe (p. 419) repeats the account of Holinshed; but adds, that "long ere this were sheep in Spaine, as may appear by a pattent of King Henry the Second, the 31 of his raigne, granted to the weavers of Loudon, that if any cloth were found to be made of Spanish wool mixed with English wool, the Maior of London should see it brent."

From this regulation of Henry II., it may be inferred that Spanish wool was, at that time, inferior in quality to English wool, and this conclusion is confirmed by Capmany, who remarks, that, till the middle of the fifteenth century, the Spanish wool could not be brought into competition with that of England, for the fine manufactures of Florence and Flanders (*Questiones Criticas*, p. 9); which again agrees with the complaints of Stowe, Harrison, Speed, and Sir Richard Baker, that Spanish wool was so much improved in their days as to rival that of England.

It cannot, however, be doubted that the travelling flocks, called *Trashumantes*, were known in Spain long before the importation of sheep from England; as the *Concejo de la Mesta*, which was created for the preservation of their privileges, possess a charter dated 2d of September 1273. (See *Quaderno de la Mesta*.\*)

The custom of changing the stations of the flocks according to the seasons, the Spaniards must have derived from the Romans, whose practice on this point of rural economy is thus described by Varro: "Illæ (oves) in saltibus quæ pascuntur—et a tectis abeunt longè, portant secum crates aut retia quibus cohortes in solitudine faciunt, cæteraque utensilia; longe enim et late in diversis locis pasci solent, ut multa millia absint sæpe hybernæ pastiones ab activis. Ego vero scio, inquam, nam mihi greges in Appulis hybernabant qui in Reatinis montibus æstivabant." *De Re Rust.* Lib. II. c. 2.

\* For the most valuable part of this historical information we acknowledge ourselves indebted to the friendship of John Allen, Esq. of Dulwich College.

\* Introduction, p. 123, et seq.

† The military historians seem not to have recollected the existence of the East India Company, in England. It is certainly to be regretted that habits of inaccuracy and exaggeration still prevail too much among the Spanish writers, especially upon subjects connected with national feeling.

Spain.

of our ministers. Neither the *National Bank of San Carlos*, which opened with a capital of seventy-five millions (of reals, about seven millions and a half Sterling), nor the *Royal Maritime Company*, created in 1789, could realize their objects, or even preserve their funds, which were soon drained, to fill the strong chests of the Favourite, or spent in France for the support of armies which were, at no distant period, to be employed against us."

"The failure of remittances from Spanish America, the enormous subsidies which we paid to France, and the ruinous measures by which the annual deficits were met, exhausted the treasury, and put an end to public credit. No funds were safe from the hands of the Favourite. The capital of the bank, that of the *Monte de Piedad*, the judiciary deposits, the pauper's fund,—all was seized by servile ambition, that it might support injustice and prodigality. The plans of internal navigation were forgotten, the public works then in progress were suspended, and those that had been concluded were left to decay for want of means to repair them."

"The government, wholly intent on guilty schemes of momentary advantage, not only neglected the country whose interests it was their duty to promote, but actually increased the obstacles which were opposed to her industry. Customhouses were found in every direction, the roads were crowded with revenue officers, and tolls were levied, at every step, upon travellers. The merchants were compelled to make declarations injurious to their interests; and, when they had gone through ten thousand vexatious forms, they could not yet feel secure, or beyond the reach of the fiscal vultures."

Recent History.

V. Such was the state of Spain in 1808, when the ambition of France, and the dissensions of the royal family, brought her to that dangerous crisis, of which the extraordinary events of the last fifteen years are not sufficient to point out the issue. We must, however, refer the reader for a sketch of that part of Spanish history to the Article GREAT BRITAIN in this *Supplement*; and attempt a more detailed view of the period beginning with the return of Ferdinand VII. from his captivity in France, and ending in the invasion of the French army in 1823.

New Constitution of Spain.

The hopes which had induced some of the most enlightened Spaniards to join in the popular struggle against the establishment of Joseph Buonaparte on the throne of their country, had been crowned with success on the publication of the New Constitution, at Cadiz, on the 19th of March 1812.

By one of the first articles in that code, the sovereignty is declared to reside essentially in the nation, which, being free and independent, neither is, nor can be, the patrimony of any person or family.—All Spaniards, without distinction, are subject to taxation.—"The religion of the Spanish nation is, and shall be for ever, the Catholic, Apostolic, and Roman, which is the only true religion."—"The nation," it is added, "protects it by wise and just laws, and forbids the exercise of any other whatever."—The government of the Spanish nation is stated to be "a limited hereditary monarchy."—

The power of making laws is vested "in the Cortes, jointly with the King."—In describing the class of Spaniards who enjoy the privileges of citizenship, persons "reputed of African origin, either by the father or the mother's side," are excluded. A similar exclusion is given to Spaniards who obtain naturalization in another country, or who, without leave, absent themselves five years from Spain. The only basis for the number of representatives in the Cortes is *Population*, to be taken from the *census* of 1797, till one more correct can be made. For every seventy thousand souls there is to be one deputy in the Cortes. The returns of the members are made by three successive elections. Every parish appoints electors for the district to which it belongs. These repair to the chief town of the district to choose another set of electors, who, lastly, meeting in the capital of the province, make the final appointment to the Cortes. The Cortes is triennial. No member can be elected for two successive representations. No debate can be carried on in the presence of the king; his ministers may attend and speak, but are not allowed to vote. There is a permanent deputation, or committee of the Cortes, composed of seven members, appointed by the whole body, before a prorogation or dissolution, whose duty is to watch over the executive, and report any infringement of the constitution to the next Cortes. It also belongs to them to convoke an extraordinary Cortes in the cases prescribed by the constitution.

The powers of the Cortes are chiefly these: *1st*, To move and pass the laws; and to interpret and alter them when necessary. *2d*, To administer the constitutional oaths to the King, the Prince of Asturias, &c. *3d*, To determine any doubt or fact relative to the succession. *4th*, To elect a regency, and define its powers. *5th*, To make the public recognition of the Prince of Asturias. *6th*, To appoint guardians to the king while a minor. *7th*, To approve or reject treaties previous to ratification. *8th*, To allow or refuse the admission of foreign troops into the kingdom. *9th*, To decree the creation or suppression of offices in the tribunals established by the constitution, as well as of places of public trust. *10th*, To fix, every year, by the king's proposal, the land and sea forces. *11th*, To regulate the military code in all its branches. *12th*, To fix the expences of the government. *13th*, To impose taxes, contract loans, and direct every thing relating to the revenue. *14th*, To establish a plan of public instruction, and direct the education of the Prince of Asturias. *15th*, To protect the *political* liberty of the press. *16th*, To enforce the responsibility of the secretaries of state, and other persons in office.

Laws may be proposed, in writing, by any one of the deputies. Two days after the motion, the bill is to be read a second time. It is then determined whether the subject is to be debated, or to be referred to a committee. Four days after the bill has been voted worthy of discussion, it is read a third time, and a day is appointed for the debate. A majority of votes decides the fate of the bill: the members

Spain. present on these occasions must exceed the half of their total number by one.

The powers of the king are, *1st*, To suspend the passing of a law by withholding his sanction. He can exercise this power against any decree of the Cortes, for two consecutive sessions; but is compelled to give his assent if the same law is passed by three Cortes successively. *2d*, The executive power resides exclusively in the king, and extends to whatever relates to the preservation of public order in the interior, and to the external security of the state, according to the constitution and the laws. The privileges and duties of the executive are thus detailed in the constitution: the King may issue decrees, regulations, and instructions, for the more effectually enforcing of the laws;—it is his duty to watch over the administration of justice;—he declares war, and makes peace, under the control of the Cortes;—he appoints judges to all the civil and criminal courts, on the presentation of the council of state;—all civil and military employments are of the king's appointment;—he presents to all bishopricks, ecclesiastical dignities and benefices which may be in the gift of the crown; all by the advice of the council of state;—the king is the fountain of honour; the army and the navy are at his command, and he has the appointment of generals and admirals;—he has the right of coinage, and the privilege of impressing his bust on the metallic currency of the realm;—the king can propose new laws, or amendments to those in existence.—It belongs also to him to circulate or withhold the Pope's rescripts and bulls;—he can choose and dismiss his own ministers.

The following checks are laid on the king's authority by the constitution:

*1st*, The king cannot prevent the meeting of the Cortes at the periods fixed by the constitution; neither can he dissolve them or disturb their sittings. His advisers and abettors in such attempts are guilty of treason. *2d*, If the king should quit the kingdom without the consent of the Cortes, he is understood to have abdicated the crown. *3d*, The king cannot alienate any part of the Spanish territory. *4th*, He cannot abdicate the crown in favour of his successor without the consent of the Cortes. *5th*, He cannot enter into any political alliance, or make commercial treaties without the consent of the Cortes. *6th*, He cannot grant privileges or monopolies. *7th*, The king cannot disturb any individual in the enjoyment of his property, nor deprive him of his personal liberty. If the interest of the state should require the arrest of any individual by virtue of a royal order, the prisoner must be delivered over to a competent tribunal within eight and forty hours. *8th*, The king cannot marry without the consent of the Cortes; he is supposed to abdicate the crown by taking a wife against their will.

The Council of State is composed of forty individuals, viz. two bishops, two priests, and four grandees; the other thirty-two must not belong to any of these classes. The members of the Council of State shall be chosen by the king out of a triple list presented to him by the Cortes. The Councillors

of State cannot be removed without a trial before the Supreme Court of Justice. Their salary is fixed by the Cortes. The functions of this Council of State are to advise the king on all important matters of government, and especially upon giving or refusing his sanction to the laws, declaring war, or making treaties. The king, besides, cannot bestow any ecclesiastical benefice, or appoint any judge, but at the proposal of the Council of State, who, upon every vacancy, are to confine his choice to one out of three individuals, whose names they are to lay before his majesty.

The laws for the security of personal liberty are these, *1st*, No Spaniard can be imprisoned without a summary process, wherein he is credibly charged with the infraction of some law which subjects the offender to corporal punishment; *2d*, The arrest cannot take place without the warrant of a competent judge; *3d*, Prisoners are not to be examined upon oath; *4th*, The gaoler shall keep a register of the prisoners, expressing the warrant, and the alleged cause of his confinement.

Such are the main articles of the Spanish Constitution; a production which, considering the circumstances of its appearance, highly deserves the attention of the politician and the philosopher. Spain had been for ages under the most effectual restraints which can be laid on the human mind, to prevent its dwelling upon subjects connected with the authority of civil and ecclesiastical rulers. Few Spaniards, out of the learned professions, devoted any part of their time to reading. The knowledge of the clergy was generally limited to scholastic divinity, as that of the lawyers to the forms of the civil courts. A small proportion of both classes had privately ventured to look beyond the bounds which church and government had set to their speculations, and, books being smuggled from France, an inconsiderable number were become initiated in the principles of the French Philosophical School. The seeds of doubt and dissent, in matters of religion and policy, had greatly spread for the last forty years; but the bulk of the nation was still without a thought on these subjects, and blindly followed the impulse which time and habit had given them. The events which dethroned Charles IV. had no farther broken these habits than merely to show the people how effectually they could oppose their own will to the constituted authorities. But their loyalty was not impaired by their successful efforts. The name of Ferdinand VII. was the great bond of union which preserved the Spaniards from anarchy. To defend the authority of the crown was the only object of their general insurrection; and, having deposited its unbounded powers in the hands of a few, the people retired to their homes, setting no limits to their obedience.

Had not the progress of the French armies dispersed the *Central Junta*, and concentrated the fugitive patriots at Cadiz, it is more than probable that the Cortes would have been assembled according to the ancient forms, and that the privileged classes, supported by the majority of the nation, would have defeated any attempt to alter the old

Spain.

constitution. But Cadiz offered to that party, which has been since known by the name of *Liberal*, the most favourable opportunity of striking a deadly blow at the very root of the monarchical power, under which they had so long groaned in hopeless, yet silent, restlessness.

Political  
Character of  
Cadiz.

From its maritime position, its commercial interests, and the foreign extraction of many of its inhabitants, Cadiz has, at all times, exhibited a scene of life so different from that which strikes the observer in the interior, that, upon entering its walls, he might imagine himself suddenly transported out of the kingdom. There, instead of the national prejudices in favour of birth, he might perceive the pride of wealth, and an ill disguised impatience of all other claims to respect and influence. If the rich merchants decked themselves with the marks of distinction so eagerly coveted by Spaniards, they still wore them without ease or satisfaction. Apparently raised by these externals to the ranks of the old titled gentry, the new marquis or knight still found himself but little removed above those of his former condition. He could not meet with the hereditary deference which the *Caballero* of the interior found in the labouring classes. Cadiz, in its days of prosperity, had no poor; for, while a stream of wealth was poured in from the American colonies, the sea forbade its population to spread beyond the limits of comfortable subsistence. The line of distinction between the higher and the lower classes was, therefore, less marked than in other large towns of the peninsula; and, when the season of mercantile prosperity was over, as the depression was general, it left the various classes at the same proportionable distance. Cadiz, unknown to herself, cherished, in fact, a republican spirit. The line which divided her rich and her poor, her workmen and their employers, was almost imperceptible when compared with the gulf of prejudice and pride which separated the merchant from the grandee. Thus, undivided by jealousies of rank, and feeling in common that impatience of political superiority which is inherent to the human heart, the people of Cadiz were ready to greet any prospect of change in the monarchical and aristocratical system of the country.

All that was wanting to bring these dispositions into action, and give them a definite aim, was driven into Cadiz by the advance of the French armies within sight of its walls. Madrid had, for a long time, been the resort of the most enlightened Spaniards; the only spot where persons, who had embraced *Liberal* principles, could feel the oppressive yoke of religious tyranny somewhat eased on their necks. As they generally belonged to that numerous class of the Spanish gentry who look up to the patronage of government for the means of subsistence, the court drew them together from the provinces. On the prospect of the political changes which the captivity of Ferdinand opened to the country, these men attached themselves to the *Central Junta*, and finally followed its members in their flight from Seville to Cadiz. Thither, too, flocked all the stragglers of the philosophical party; and, on the dissolution of that dull, dilatory knot of ill assort-

ed men, who, under the veil of dignified gravity, had for a time concealed their unfitness to direct the nation, the Spanish speculatists found themselves in the midst of a population highly disposed to listen to their doctrines, to embrace their views, and constitute them the organs of the new laws which were to remodel the kingdom.

Spain.

The majority of the first Cortes being composed of the class of men whom, by anticipation, we have called *Liberales*, the project of a Constitution was immediately set on foot, and a committee of the ablest members appointed to draw up the fundamental code of the monarchy. Such a task, at all times arduous, was, in the present circumstances of the country, beset with peculiar difficulties. The legislators, confined within the walls of a town where innovations could not fail to be popular, went through their task under a strong delusion, mistaking their own wishes and the applause of the surrounding multitude for the sense of the nation. Encouraged by the absence of the king, placed beyond any check from the privileged classes, and the weight of the landed property of the country, it is surprising that the framers of the new constitution were not more rash than they appear in the code, of which we have laid an abstract before our readers.

Character  
and Views of  
the Framers  
of the Consti-  
tution.

We strongly suspect, however, that the authors of the Spanish constitution were less disposed to consider the real sense of the nation, than to prepare, in their code, the most effectual means of working a radical change in the public mind. Perhaps they despaired of being able, by a more truly Spanish system of laws, to make a lasting reform in the state. Perhaps they feared that, if a portion of the legislative power was deposited in the hands of an upper house, composed of the Grandees and the Clergy, it would clog the motion which they wished to impress upon the almost disorganized machinery of the Spanish state. Perhaps they conceived that the power, which, in the hands of the crown, had been so outrageously abused, could not be reduced too much; and that, since the constitution must recognize a king, he could not be too strictly watched and fettered. We are not, indeed, surprised to find these views in the authors of the Spanish constitution—they were the natural result of their position—right feelings exasperated by a long endurance of tyranny and misrule. But we cannot, on the other hand, give them credit for any degree of that sound and practical wisdom which shone in the English patriots of 1688. The authors of the Spanish constitution had, it is true, to reconstruct the state almost from the foundations. But, professing that they only intended to re-establish the ancient constitution of the kingdom, they had not the ability even to preserve its external form. They certainly neglected all the old materials. Nor have they shown deeper views in the solution of the general problems of politics, such as the *basis* of representation, and the *form* of election. The Spanish legislators have, on both these points, shrunk at the view of difficulties which they wanted either the knowledge or the courage to meet fairly.

On one subject alone the authors of the constitu-

Spain.

tion yielded to national prejudice without reserve or modification. The article on religion is, unfortunately, an accurate expression of the opinions which the mass of the Spanish nation hold upon that point. Shall we, then, suppose the framers of the constitution sincere in the profession of the strong, undoubting, dictatorial faith, which blazes forth in that notable article? Must we not suspect that exuberance of belief which makes a *Liberal* party stand Catholic sponsors for generations unborn? For our part, we believe it equally impossible that men, whose course of reading and thinking had led them to embrace the political principles which have been enforced in the Spanish constitution, should approve the article in question, as that a nation, still bigoted to such doctrines, should be disposed to receive that constitution. It has been answered, we know, that the political part of the Spanish code was calculated to overturn the law concerning religion. But was it not to be feared that the reverse might happen? Or was it consistent with the wisdom of constitutional legislators to combine the most irreconcilable principles in the fundamental laws of the state? Had they been more temperate and yielding in their political views,—had they not alarmed every Spanish prejudice by their plan of reform, they might have found their religious adversaries less on their guard, and gained some ground on the side of toleration. But the Spanish constitution was like one of those treaties which wily politicians sign with a mutual hope that they contain the elements of destruction to the other contracting party. The *Liberales*, unable to cope with religious prejudice, trusted to the operation of democratic principle; the bigots, cut off from their main body within the walls of Cadiz, clung to their monstrous privilege of keeping the conscience of every Spaniard in bondage. The *Liberales* meant more than they dared to express—the bigots gained all they wanted. Thus, while victory was apparently on the side of the former, the latter held, in the religious intolerance of the country, now raised into a constitutional law, the strongest pledge of a future and more permanent triumph. The events which followed the return of Ferdinand must convince every impartial judge, that the great mass of the Spaniards were not disposed to second the views of the *Liberales*; and that, if the constitution has, at a later period, had influence enough to arm one part of the kingdom in its defence, it owes this support to the injustice and misconduct of the Court faction after the restoration, and not to an original attachment on the part of the people.

The rapid series of misfortunes which had shaken the imperial throne of France to its foundations opened the way for the return of the captive Ferdinand to Madrid. His appearance on the frontiers would, a short time before, have been hailed by his subjects with general and sincere joy. But an absence of six years, employed by the friends of constitutional liberty in disseminating the principles of political reform, and fomenting a spirit of jealousy against the crown, had now created an active party, who dreaded the appearance of a monarch, born and bred a despot, among a people whose habits were

those of implicit obedience. The arrival of the famous Palafox (who, since the taking of Zaragoza, had been a prisoner in France), bearing dispatches from the king to the regency, threw the constitutionalists into great consternation. Ferdinand announced to the regency that he had concluded a treaty with Napoleon, which, in his opinion, “contained no condition that did not accord with the honour, glory, and interests of the Spanish nation; as that country could not have obtained a more advantageous peace after a succession of victories.” This implied acknowledgment of successive defeats, this readiness to conciliation with Napoleon, were strong indications of a mind habituated to feelings very different from those which had influenced the Spaniards during the eventful war against the French emperor. Such want of sympathy with those national feelings, which might have been supposed most flattering to any other man in Ferdinand’s circumstances, gave little hope of his quiet submission to laws and principles which were plainly intended to reduce his power, and make him the first subject of the kingdom, instead of its absolute sovereign.

The Regency, composed of Cardinal Bourbon (a man, who, though related to the royal family, bore in the weakness of his mind the best security against ambition) and Agár and Ciscár, two naval officers of respectable abilities in their profession, whose only recommendation for that post seems to have been the absence of every qualification which might have given the slightest probability to their election—this Regency beheld with alarm the danger which threatened the system from which they derived their power. The treaty was, of course, rejected, and the attention of the constitutional government anxiously fixed on the means of averting the blow which was already aimed at their authority.

By a decree of the Cortes, the king was suspended from the exercise of all power till he should take the oath which the new constitution prescribed; a route was made out for his journey from the frontiers to Madrid, and an escort directed to watch over him in his progress. The Cardinal, president of the Regency, was to meet his royal relative on the road, under strict injunctions not to perform the usual ceremony of kissing the king’s hand. General Copons, the military commander of Catalonia, was made the bearer of copies of the constitution, and of the decree which suspended the royal authority. These he was to deliver into the hands of Ferdinand on the frontiers of the kingdom.

The king entered the Spanish territory on the 24th of March 1814, and followed the route prescribed by the Cortes, till the vicinity of Zaragoza afforded him a pretext for visiting that renowned scene of Spanish patriotism. He soon perceived a general indifference to the constitution among the lower classes; a jealousy of the new men who had risen into importance by means of the late changes; and a revival of those feelings of passive loyalty which the unbounded power of the Spanish monarchs, during so many centuries, had blended with the national character. From Zaragoza, Ferdinand repaired to Valencia, a city well affected to the crown, where

Ferdinand  
VII. from  
France.

Spain.

Elío, a royalist general, had the command of a considerable body of troops. Thither flocked many grandees and dignitaries of the church, anxious to inform the king of the favourable turn of public opinion in favour of an absolute monarchy. The cardinal, who, missing the king on the prescribed road, had been obliged to retrace his steps, arrived at Valencia, when a numerous train of royalists, ready to support their master, would have placed a bolder and abler representative of the Cortes in difficulties from which it would be almost impossible for any one to extricate himself with credit. The weak prelate's attempt to follow the directions he had received, added humiliation to the act of homage into which he was awed by the king's frown. His kissing hands, however, did not save him from banishment and deprivation of the two sees of Toledo and Seville, which he held together with the pope's consent.

Revulsion of  
Feeling in  
the Nation.

The progress which the constitutional principles had made was so slight, and the new political system had lately lost so much among people otherwise inclined to a reform in the state, that it was easy to foresee a revulsion of feeling in which the great mass, which had hitherto been nearly passive, would give the court party an irresistible preponderance. Ferdinand's advisers were sufficiently quick-sighted to seize the favourable moment. Elío, in the name of his military division, presented a memorial to the king, in which he was entreated to govern in the manner of his ancestors. A petition, signed by sixty-nine members of the sitting Cortes, reached the king, about this time, describing that body as a mere tool in the hands of a republican party, without freedom of debate, and acting under the control of a mob regularly hired to take possession of the galleries.

A more favourable opportunity has seldom presented itself to any monarch for consolidating the privileges of his crown, while he promoted the happiness of his people, than that which the circumstances of Spain offered to Ferdinand at this moment. The feeble roots, which the new political principles had struck in the nation, were just kept alive by a recollection of the ruinous follies of the preceding reign. The slightest security against the recurrence of similar excesses, granted by the throne to the people, would have deprived the *Liberal* party of the remnant of their influence. With his own party, the king was still absolute; and his will would have been obeyed without the least attempt at evasion or resistance. Ferdinand might have confirmed the abolition of the Inquisition, and the existence of the Cortes. He might have established a Chamber of Peers, and raised the grandees, by that means, from a state of moral and intellectual degradation, which renders them worse than a useless burden to the state. A few reforms in the internal administration of the kingdom might, if proceeding from the crown, have enabled Spain to rise gradually, and without convulsions, from her former languor into a state of convalescence; during which, life and energy would, in due proportions, diffuse themselves through the whole body. But unfortunate Spain was doomed to suffer from the same cause, which, in our opinion, threatens Europe with a long series of bloody strug-

gles between the people and their rulers. The popular leaders aimed at the possession of paramount power, while nothing but uncontrolled authority would satisfy the crown.

Spain.

On the 4th of May 1814, a decree was solemnly promulgated, in which the Cortes were declared illegal, and all their laws consequently rescinded. The spirit of the worst times of the Spanish monarchy seemed to have dictated this first act of the restored Ferdinand—that king for whom Spaniards of all classes, opinions, and denominations, had been lavish of their blood. Having thus announced his intention to wipe off the memory of constitutional freedom, he set off for the capital, preceded by a division of Elío's army, under the command of General Eguía. These troops found no resistance either on their way to Madrid, or upon entering that town. The people, on the contrary, seemed generally disposed to greet the approach of the absolute king. The Cortes, thus despised and neglected by the majority of the Spaniards, and internally cankered by the presence of a strong party, who had constantly aimed at the destruction of the system which they had sworn to support, were instantly dispersed by the soldiers. The arrest of the two inferior regents, Agár and Císcar, and of the president and secretary of the Cortes, which took place on the nights of the 10th and 11th, seem to have been considered as preparatory steps to the reappearance of Ferdinand in the capital.

Resumption  
of Absolute  
Power by  
the King.

The news of these events had scarcely reached the chief towns in the provinces, when the mob, headed by their usual leaders, the priests, broke out into fierce demonstrations of joy, calling for the instant restoration of the Inquisition, and hastening to demolish the lapidary inscriptions, which the Cortes, from the vanity of displaying their triumph over their opponents, had caused to be erected in every town and village. It is fortunate, indeed, that no bloody scenes followed this reaction of a long suppressed popular feeling; though a desperate attempt was made at Corunna against the most active members of the Liberal party in that town, who had been previously committed to prison.

Demonstrations of Joy  
in different  
parts of  
Spain.

Had Ferdinand and his advisers allowed their judgment to prevail over their resentment, they would have readily perceived that their future security was not consistent with the habits of insubordination which the Spanish mob was so rapidly acquiring; and that leniency and forgiveness were the most effectual means of thinning the ranks of their enemies. The court party, however, showed a fixed determination of allowing full sway to their revengeful spirit. The arrest of between thirty and forty deputies of the late Cortes, attended with seizure of papers and sequestration of property, was decreed by the king, who appointed a commission of three judges, two of whom had been fellow-deputies of the prisoners, to collect evidence against them. By another order, the members who had subscribed the above-mentioned petition for the repeal of the constitution, were invited to criminate the *Liberal* deputies for their conduct and opinions during the last session.

Spirit of Re-  
venge dis-  
played by  
the Court.

Spain.

Spain.

In the course of this persecution not one was spared who had, directly or indirectly, contributed to the establishment of the constitutional system. The number of state prisoners was increased in the month of June, by the arrest of forty-five individuals, formerly members of the Cadiz Cortes, and literary men of eminent talents, who had assisted the popular government with their pen. The trial of the prisoners, if such a name can be given to judicial proceedings, which precluded all chance of acquittal, was conducted with more than Spanish dilatoriness. Three sets of judges were successively appointed and removed; till the king, impatient of further delays, ordered a list of the prisoners to be laid before him; and in a decree of the 15th of December 1815, each of the names (about seventy in number) appeared before the public, bearing the sentence which Ferdinand, in his own writing, had affixed to them. We shall give the following by way of specimens. Count Toréno, Mina, and Florez de Estrada, who had evaded pursuit, and fled the country, were condemned to death. Arguelles, who may be considered the author of the constitution, was sentenced to eight years' exile at Ceuta, on the coast of Africa. Canga Arguelles was confined to the fortress of Peñíscola, in Catalonia, for an equal period. The same length of confinement was assigned to Martínez de la Rosa, and to Calatrava, two distinguished members of the Cortes. The four ecclesiastics, Villanueva, Muñoz-Torrero, Olivéros, and Cepéro, were sentenced to six years' imprisonment in different convents, and to the loss of their benefices. A'lvarez-Guerra and García-Herreros, who were ministers to the Regency on Ferdinand's return, and Generals Valdés, O'Donoghue, and Villacampa, who had evinced a firm attachment to the new system, were to be imprisoned for periods of eight, six, and four years. Quintana, one of the first ornaments of modern Spanish literature, who, probably from his great moderation, and love of studious retirement, had never been elected a member of the Cortes, was sentenced to be imprisoned six years in the fortress of Pamplona. Strict orders were issued to deprive the prisoners of all communication, and not to be allowed pen and ink. The persons contained in the list, who had not escaped, were seized in the night of the 17th December, and subsequently removed to their destinations.

It was not more safe to be admitted to Ferdinand's confidence than to side with the enemies of his arbitrary power. Macanáz, his confidant, in France, was arrested, the same night, by the king in person. Escóiquiz, Ferdinand's tutor, and one of his companions in exile, was, at this period, disgraced and removed to Zaragoza. The Duke of San Carlos, another of the king's adherents in his misfortunes, was dismissed from the ministry.

The court party having gratified their spite, wished now to secure the support of the clergy, whom the Liberals had offended. By a royal order of the 20th of May 1814, all purchasers of church property were compelled to restore it, without receiving compensation. The Inquisition was regularly re-installed, and urged to exert its powers against all persons suspected of *Liberal* opinions. A bull

was obtained from the Pope for the restoration of the Jesuits in Spain. Monks and bigots were the sole directors of the king's conscience. Conceiving that the times when Spanish monarchs could trample down their subjects, without being disturbed by a single murmur, had returned, he publicly declared himself "not accountable to any, except God and his confessor," and thus proclaimed his will to be the law.

The convulsions, however, which had agitated the kingdom, could not but have roused the dormant energy of such spirited people as the Spaniards. The novelty, it is true, of the political doctrines which the Cortes had sanctioned; the disturbance which the new order of things had given to the national habits; the doubtful, or still unperceived advantages of the *Liberal* institutions; the jealousy which is always created by the sudden elevation of new men;—such were the main sources of the dissatisfaction with the Cortes, which restored despotic power to the hands of Ferdinand. But a fresh disappointment awaited the fond hopes of the people. Ferdinand could not recal the languid repose of former days. The spell of custom, which bound the nation together, with the ties of mere form, and made the strength of millions shrink before the shadow of power, had been broken for ever. The court, besides, had found the treasury doubly drained, from the effects of former extravagance, and the demands of the late war. Bribery and venality were soon seen to prevail round the throne, to a greater extent than in the time of Godoy. The army, who had been hitherto amused with promises of regular pay and promotion, began to groan under want and neglect. Officers of high rank appeared about the streets in the night imploring the charity of their fellow countrymen. The armed bands, or *Guerillas*, who had assisted in the defeat of the French, having now nothing to expect from Ferdinand, and being unfit to resume habits of industrious labour, became regular and organized banditti. Melchor, the leader of a numerous band, infested the whole of Extremadura, for a considerable time, setting the helpless magistrates at defiance, and committing all sorts of atrocities.

A government so unable to gratify the ambition of its adherents, and so incapable of affording protection to the people, could not employ restrictive measures without hastening its own destruction. In vain did the court party silence the press, or bribe it into their service. Facts, which crowded before the eyes of the public, and addressed themselves to their feelings, pleaded, daily, the cause of liberty, in the most powerful language.

Many of the Spanish officers, who were prisoners in France, had become *Free-Masons* in that country, and numerous lodges were established in Spain, during the occupation by Napoleon's armies. Masonry had at all times been held in the utmost abhorrence by the church and government, and both had employed their respective weapons to deter their subjects from its mysteries. Finding now that the evil they dreaded had found its way into the country, nothing was left untried in order to check its progress. A fresh sentence of excommunication was

Progress of  
Discontent  
against Fer-  
dinand.

Secret Socie-  
ties.

Spain.

obtained from the Pope against Free-Masons. The Inquisition traced out, in every province, the officers who had been initiated in France, as well as the members of the Spanish lodges. Fortunately, they were too numerous to be punished with all the rigour of the law. But the imprisonment of some, and the fears of all, were sufficient to prevent the Spanish Masons from acting collectively.

Comuneros.

It was, however, about this time, we believe, that another kind of secret societies, exclusively political, were formed in Spain. The members assumed the name of *Comuneros*, to denote that they met in the spirit of Padilla and his followers, who, under the same appellation, rose against the encroaching despotism of Charles V.\* An extensive correspondence was established between the associates in the different provinces, who, acting in concert, and according to a fixed plan, were ready to seize the first opportunity of restoring the constitution.

Public burning of the Constitution.

Though we account it a signal misfortune that Spanish patriotism had not a less objectionable rallying point than the Code of the Cadiz Cortes, yet it is probable that, but for the existence of such a definite object for which to contend, the enemies of despotism would not have been able to combine their efforts. Men possessed of more talents than the purblind crew who surrounded the throne would have easily seen the necessity of setting up some rival Charter; any thing in the shape of a Fundamental Law, which might divide the public opinion, and divert it from a constitution which had been conceived in a spirit of violent hostility to the crown. But Ferdinand's counsellors took the course which was most apt to raise the new code in the estimation of the country. As many copies as could be obtained at Madrid were heaped on a cart, together with the journals of the Cortes. The guilty volumes were thus conducted, with ludicrous solemnity, to one of the public squares, and there committed to the flames by the hands of the hangman. This contemptible triumph was closed with a solemn *Te Deum* in the collegiate church of the capital.

The effect of prohibitions and *autos da fe* against books is well known; it gives them reputation in all countries; how much more among a people whose eyes were just opening to a perception of the intellectual thralldom in which they had been kept by similar means;—a country, where the notion that the merit of a work should be judged by the anathemas it lay under, was making a rapid progress?

The constitution of the Cortes, though ill suited to the institutions, habits, and feelings of the bulk of the Spanish nation, is a manual of popular principles, which might, under any circumstances, bring constant accessions of strength to the Liberal party. A train of reasoning, however powerful, upon the rights of the people, would make but a slight impression in a country where close and industrious reading is

scarcely known. But the effect of a small volume, containing the abstract principles of democracy disguised under monarchical forms, and reduced to practical laws or simple declarations, would engage the attention of thousands; for the shallowest and most undisciplined mind will readily catch the notion of sovereignty inherent in the people; and, in proportion to the want of deep views on the complicated machinery of human society, will be the self-complacency of the young politician, who imagines he has obtained a clue to every problem of government.

Spain.

The effects of the new Constitution, considered as a political pamphlet, could only be checked by the dignified and judicious conduct of a court supported by the most respectable classes. But Ferdinand was surrounded by a medley of cowed courtiers, intriguing priests, and old placemen, all poor, and all ambitious. The king himself had much to ask for, and but little to give, save empty titles. The army, who had now learnt their irresistible weight in political changes, became dissatisfied and restless under a state of things which doomed them to neglect and poverty. The inferior gentry, of which a great portion depend on court favour for places, saw, with dismay, that while the late reform had swept away many of the situations under government, such as remained were reserved for those only who had never wavered in their allegiance to monarchical despotism. The young men, lastly, of the middle classes, who, during the existence of the Cortes, had had a taste of the agreeable excitement of a popular system, could not brook the death-like apathy which followed the restoration.

The malcontents, though numerous, and constantly augmenting, would have found it difficult to communicate with each other, to calculate their strength, and direct it with skill, if the secret societies had not created among them something like the union and activity which, in free states, are the effects of a well-regulated party. In spite of the Inquisition and its emissaries, the *Comuneros* held meetings in most of the head towns, and kept up an active correspondence among their lodges. Cadiz, whose political temper has been described already, was, it seems, the head-quarters of the conspirators. They could not have fixed upon a more advantageous position; for, besides the opportunities which its numerous and changing garrison constantly afforded of tampering with the officers, some wealthy merchants of that place had devoted their fortunes to the restoration of liberty.

Cadiz and its neighbourhood had been made the rendezvous of the troops which, under the command of General Morillo, were ordered by Ferdinand's government against the revolted provinces of South America. † It being now agreed among the *Liberals* that the intended revolution should be effected

\* *Vide* Robertson's *Charles V.*

† The unyielding and illiberal spirit of the Cortes in regard to the Colonies was closely followed by the king's government on his resumption of absolute power. It is a curious circumstance that the *Liberal* party, who, by their obstinate refusal of the demands of the Colonies, urged them into open rebellion, should

Spain. by the army, the presence of a strong military division reluctantly engaging in a dangerous service beyond the seas, must have greatly raised their hopes and increased their activity. Morillo's loyalty was tried, and he seemed for a time to waver between the obvious duties of his station and the suspicious call of revolutionary patriotism.\* It is said that the General was found, at first, ready to listen to the offers of the patriots; and if it be true that he subsequently thought it necessary to make a spontaneous confession before the Inquisition, he must have been present at some masonic meetings;—a crime from which, we believe, none but the members of that tribunal could give absolution at that period. By what precautions of the patriots, or what subterfuge of Morillo (who, though shrinking from the proposed rebellion, might yet be unwilling to break for ever with a determined and fast growing faction), the effects of such a recantation were not felt by the lodges, we are not told, and cannot conjecture. It is a fact, however, that Morillo embarked with his troops while the secret societies continued their labours unmolested.

Galicia was one of the provinces to which the Cadiz patriots had extended their secret influence. Don Juan Diez Porlier, an officer who had distinguished himself against the French, was at this time confined, under suspicion of disaffection, to the Castle of San Antón, near Corunna. His health being impaired after a year's imprisonment, he obtained leave to proceed under an escort to a watering-place in the neighbourhood. The officer, to whom the prisoner was given in charge, was a member of the secret societies, in correspondence with the head lodge at Cadiz. He soon put Porlier in possession of the plans for a military insurrection which were then under discussion among the patriots, and earnestly urged him to strike the first blow in the province of Galicia. Many officers in garrison at Corunna and Ferrol offered also their services to Porlier, who, miscalculating his means, and judging of public feeling from that which prevailed among his friends, was not long in accepting the dangerous command to which he was invited. Attended by the officer, whose duty it was to prevent his escape, and the twelve soldiers commanded by that officer, Porlier entered the city of Corunna, about midnight of the 18th September 1815, and was soon joined by most of the troops in that town. Supported by his associates, he arrested the governor and the principal supporters of the *Servile* party. The imprisoned Liberals were set free, and such proclamations as are usual on these occasions were posted about the town. The oath to the constitution of 1812 was re-

Porlier's  
Attempt and  
Failure in  
Galicia.

peated, and a detachment of 800 men was ordered to march on Ferrol, where the garrison, it was said, only awaited the presence of Porlier to declare in favour of the constitutional system. But the royalist party had been actively employed in that town since the arrival of the news from Corunna. Emissaries were sent to mix with Porlier's troops on their march. They found him with his detachment at the village of O'rdenes, where the troops were to pass the night. The non-commissioned officers were soon gained over, and the men yielded to the first suggestion of making their peace with the king's government by the seizure of their leader. Porlier and some of his officers were at supper when the soldiers surrounded the house. The officers, it should seem, were able to escape; but the General, being obliged to surrender, was executed at Corunna, on the 3d of October. Porlier met his fate with the dignity and composure of a man who feels conscious of the justice of his cause and the purity of his intentions. Had that unhappy officer possessed means to keep his ground till Cadiz, Barcelona, Valencia, and Zaragoza, had declared themselves, the revolution would have been complete, as it happened at a subsequent period.

Our limits do not permit us to mention the numerous conspiracies which were discovered and quelled after the death of Porlier. But we cannot omit a brief account of the unfortunate attempt made by General Lacy in Catalonia, where, during the latter part of the war against France, he had commanded the Spanish army against the invaders. As a reward for his services, Lacy had been appointed Captain-General of Galicia; but being suspected by Ferdinand's government, he was removed to Catalonia, and confined within the limits of a certain district. In the spring of 1817, Lacy obtained leave to visit the mineral waters of Caldetes, near Barcelona. He there met with several discontented officers, with whom he planned an insurrection. It was expected that all the garrisons of Catalonia would mutiny on the 5th of April, a day on which Lacy was to raise the standard of rebellion by the assistance of the regiment of Tarragona, which was stationed at a short distance. Two companies had been gained over by the lieutenant-colonel, when the whole plan was disclosed to the colonel by two subalterns in Lacy's confidence. The colonel appealed to the loyalty of the yet undebauched part of the regiment, and he was answered by a display of zeal in the royal cause. The two revolted companies joined Lacy, who, perceiving no other movements in his favour, began a march to Mataró, proposing to raise the peasantry, or to escape into France if he failed of support. The peasants appearing everywhere either

Lacy's At-  
tempt in Ca-  
talonia.

have virtually sanctioned the separation, by stopping the reinforcements which might have given a chance of success to the Spaniards. For an account of the war of independence in Spanish America, see the Articles NEW GRANADA, MEXICO, and BUENOS AYRES.

\* We relate this and similar facts on the authority of Mr Blaquier's *Historical Review of the Spanish Revolution*, which we have followed in the narrative of that period. From our personal knowledge of Spain, we have considered ourselves entitled to use our own judgment in rejecting some circumstances which seem to have been admitted into that work from the author's honest but excessive confidence in some of his Spanish authorities.

Spain.

hostile or indifferent, the soldiers were dishcartened, and fell off to a man. Lacy took shelter in a cottage; but was soon betrayed and taken. It was not deemed safe by the government to execute the sentence of death which a court-martial pronounced against him, within the walls of Barcelona, where a strong feeling of compassion had shown itself towards the unfortunate Lacy. It was, therefore, reported that the king had commuted the sentence into that of imprisonment for life in the fortress of Majorca. Lacy's removal took place under that impression. He was cruelly undeceived, on his arrival, and desired to prepare for death within a few hours. Lacy was shot in the ditch of the castle at five o'clock in the morning of the 4th July 1817.

Successful Revolution near Cadiz.

From the character of these attempts, and the temper manifested by the bulk of the people, a dispassionate observer will readily adopt the conclusion, that the endeavours of the patriots depended for success on some happy combination of circumstances, which, by once disconcerting the weak government of Ferdinand, and making him yield even for a moment, would give an impulse to that impassive mass who had hitherto beheld the contest unwilling to share its dangers. For it is clear, that a great majority of the nation, though determined not to make or modify a government for themselves, would readily submit to any political system which might happen to obtain the ascendancy. The chances were, therefore, in favour of the active party, who, though so often defeated, had still sufficient courage and perseverance to renew their attacks on a dull enemy, who adhered, from ignorance and weakness, to a plan of defensive warfare.

Intended Expedition to reinforce the Royalists in South America.

It was not long before the erroneous policy of the court of Madrid, in regard to the revolted colonies, presented to its enemies at home the means of re-establishing the constitution, and making their party paramount in the state. Instead of paying the arrears of the army, the only body of men which could effect a revolution, the blind obstinacy of Ferdinand and his advisers employed all the money they had been able to collect, in fitting up a second expedition, which was to reinforce the Royalists at Venezuela. The troops which were to embark in the autumn of 1819 had been collecting in Andalusia, then governed by Henry O'Donnell, Count of Abisbal, whose assistance in the restoration of arbitrary power had been rewarded with the military command of that province. The expeditionary army was, consequently, under his command till it should sail from Cadiz, and the various corps had been quartered at no great distance from that residence of the Captain-General.

It will be readily admitted, that a more favourable opportunity could hardly offer itself to the Patriots than the presence of a military division, whose officers were favourably inclined to their cause, and where a general dislike of the service, for which it was intended, was prevalent. The prospect appeared the more favourable as it was credibly reported, that O'Donnell, wishing to atone for the mischief he had done by an excess of loyalty, had volunteered to be the leader of the insurrection. The report was, indeed, well-founded. The Captain-General himself

had fixed a day for proclaiming the constitution, and meetings had been held at his residence for the organization of a temporary government. Some offence, it seems, had been given him at one of these conferences, by the determination of separating the civil from the military command, when the revolutionary government should be established. He had continued, nevertheless, at the head of the conspiracy, and even urged the necessity of anticipating discovery by striking the blow on the 8th, instead of the 15th of July. On the 7th, O'Donnell repaired to Port St Mary's, where all the infantry had been collected by his orders. Sarsfield, his second in command, was to join them, the next morning, in the plain of Palmár, with the cavalry which was quartered at Xercz.

Soon after sunrise, on the 8th, the infantry was drawn up in the place of their rendezvous. The officers who were in the secret could hardly refrain from breaking it to the troops under their command; yet waited with impatience the arrival of the cavalry, and the presence of their general. Both were at length seen at a distance, and approaching in opposite directions. O'Donnell, with his staff, and Sarsfield at the head of the horse, came up at the same moment. But, instead of the expected signal, the cries of *Viva el Rey*, which were raised by the cavalry as they galloped along the line, were instantly re-echoed by the infantry. The deluded conspirators were immediately called in front of the troops, and Abisbal himself gave the necessary orders for their removal under an escort, to some of the neighbouring fortresses.

The duplicity of Abisbal had rendered such an effectual service to the cause of despotism, and the repeated defeats of the *Liberal* party had so clearly shown the difficulty of giving an impulse to the lower classes in its favour, that it is quite surprising to find a complete revolution effected within a few months of the event we have related. But the court party were not stupid enough to mistake Abisbal's conduct for pure unalloyed devotion to the crown; nor yet sufficiently politic to secure his services to the king by such rewards as might satisfy his ambition, and make him seal, by his subsequent conduct, the well-merited distrust and hatred to which he was exposed among the Patriots. He was removed from the command of the expeditionary troops, and a man scarcely known by his title of Count Calderon, and much less by any talents displayed in the service, appointed to succeed him.

The reappearance of the yellow-fever at Cadiz, soon after the imprisonment of the patriot officers at Palmár, obliged the government to remove the troops to more healthy spots, at some distance. Arcos was made the head-quarters; the rest of the army was divided between Las Cabezas de San Juan, to the north of that town, and Alcalá de los Gazúles, in the opposite direction. This was considered a favourable opportunity for carrying into execution the same plan which had failed through the treachery of O'Donnell. The members of the secret societies, at Cadiz, engaged to procure the escape of the prisoners, one of whom, Quiroga, had been appointed to be the commander-in-chief of the revolt-

Final Success of the *Liberals*.

Spain. ed army. Riego was, in the meantime, to be placed at the head of the insurrection.

The 1st of January 1820, being fixed upon, the soldiers were gradually gained over by means of the gold with which the officers were supplied from Cadiz. On the morning of that day, Riego drew out the battalion of Asturias, of which he had a temporary command, and having proclaimed the constitution, began his march towards Arcos, where, by the assistance of part of the officers in that town, he intended to seize the general-in-chief. Quiroga, who, it was expected, would be at liberty, by that time, was to march with the forces stationed at Alcalá, to the Isla, and from thence to the gates of Cadiz, which, if he could reach before the news of the insurrection, would be thrown open by some officers of the garrison, now enrolled in the bands of the insurgents. Riego, though arriving at Arcos much later than he had expected, effected the arrest of Calderon, with scarcely any difficulty. Quiroga, being much longer detained in his march, could only take possession of La Isla. Riego advanced to Xerez, thence to Port St Mary's, and finally joined Quiroga. The strength of the patriots was about five thousand men, unsupported by either artillery or cavalry.

The period which followed this junction is one which throws considerable light on the state of the public mind in Spain, and shows the difficulty, which we have pointed out already, of giving an impulse to the great mass, who, influenced by inveterate habits, will take no side in these political struggles.

Five and twenty days had elapsed since the proclamation of the constitution at Las Cabezas, without the revolution making any visible progress. A paper warfare was carried on by the leaders at the Isla, and the authorities at Cadiz; but the patriots were left to their own resources within a very limited spot, while troops were collecting about them, and the activity of the loyalists at Cadiz precluded all hope of assistance from the revolutionists who were within the walls. To rouse the spirit of the country, and spread the flame of the insurrection, Riego proposed to lead a flying column of 1500 men, in such direction as circumstances would allow. Followed by a division of the royalists, who seemed more determined to harass him than to fight, he successively proclaimed the constitution at Chiclána, Conil, Vejér, and Algeciras. Though ordered by Quiroga to march back to the Isla, Riego found it necessary to proceed in the only direction which the royalists had left him. In this situation, however, he spent three days at Vejer, in public balls and banquets, where officers and privates mixed indiscriminately with the town's people. From thence the flying column advanced to Malaga, closely pursued by the enemy. Meeting with no support from the inhabitants, Riego proceeded to Antequera. Harassed by incessant marches, and having sometimes to fight their way through detachments of the enemy's forces, Riego took the determination to push, with the remnant of his force, now reduced, by desertion, to about 300 men, into the fastnesses of Sierra Morena, where they eluded further pursuit by dispersion.

The patriots of the Isla had seen three long months elapse without any prospect of support from their countrymen, and trusting merely on the efforts of the secret societies, which had hitherto appeared unavailing. Mina had, however, entered the valley of Bastán, in Navarre, on the 25th of February. He had been, long before, obliged to fly into France in consequence of a fruitless attempt to overturn the government of Ferdinand, and now he hastened to lend his assistance to the patriots. He found a numerous band ready to follow his standard.

The garrison of Corunna, headed by Don Carlos Espinosa, a colonel of artillery, had risen, about the same time, against the Captain-General of Galicia, and proclaimed the constitution throughout the whole province. Similar movements took place on the first days of March at Zaragoza, Carthagena, Valencia, Murcia, and Granada.

These insurrections, though partial, could not but appal the weak, ignorant, and unpopular party, which surrounded the throne. Had Ferdinand been able to depend on the loyalty of an able general, he still would have found fidelity among the soldiers, and a great part of the officers. It was, however, an expiring feeling which, in the present circumstances of the country, a mere breath could extinguish. Should the general, to whom the command of a central army, which was to be formed in La Mancha, be inclined to betray his charge, the king himself would be obliged, by the constitutionalists of the capital, to save his life by the assumption of their badge, and surrender, at once, at discretion.

Abisbal was still at Madrid; and his late important service gave hopes that he would be faithful to the king, for whose sake he had sacrificed the honour he had pledged to the patriots. It was considered improbable that he would change a fourth time in his politics; and he was, accordingly, invested with the command of the army of La Mancha. But, before he quitted Madrid, on the 3d of March, he had plotted with the colonels and superior officers of the garrison, engaging to declare for the constitution as soon as he should reach Ocaña, where one of his brothers commanded a battalion of infantry. True to this last engagement, Abisbal proclaimed the constitutional system, the day after he had quitted the court. He established a communication with the patriots of La Isla, and left the final completion of the revolution to his reconciled friends, the liberals of Madrid.

The account of the military insurrection at Ocaña did not fail to produce the effect which had been prepared by the constitutionalists of the capital. An immense crowd surrounded the royal palace, who called on Ferdinand to accept the constitution. Things had now come to a point where there was no room for deliberation. The king appeared at the balcony holding a copy of the constitution in his hand, as a pledge of his readiness to swear observance to its laws. As, according to that code, the monarch cannot exercise his portion of authority till he has taken the oath therein prescribed, a committee of government was installed, who should convoke the Cortes, in whose presence alone the king can perform those acts which put him in full possession of his constitutional rights.

Spain.  
Insurrections in different parts of Spain.

Ferdinand accepts the Constitution.

Riego's March to spread the Insurrection.

Spain.  
The Inquisition is abolished, and the State Prisoners set free.

Whatever may be the merits of the political system which the success of the Spanish *Liberales* restored,—whatever the censure which competent and dispassionate judges may pass on the means which ensured their success,—there is something so glorious in the first results of the change, that, for a moment at least, the heart must give itself up to mere feeling, and oblige reflection to shrink and be silent. The instant dispersion of that abominable tribunal, the Inquisition, and the liberation of the state prisoners, whom Ferdinand allowed to linger in confinement, were acts which might ennoble a worse cause than that of the Spanish Liberals. They were performed without delay, and, as far as circumstances permitted, by the hands of the mob—a dangerous instrument indeed, which can never be employed without mischief; but which would lose much of its destructive character if it were only used, as the last resource, in the defence of humanity.

Massacre at Cadiz.

As it has been our study so to perform this rapid sketch, as to put the reader in possession of such facts as may enable him to understand the principles and temper of the two great parties which contend for political power in Spain, we cannot omit the bloody and disgraceful scene which took place at Cadiz on the 10th of March, the day which had been appointed to proclaim the constitution.

The accounts from Madrid had dashed the hopes, with which the unfavourable circumstances of the constitutional troops of La Isla, had flattered the Andalusian royalists. Urged by a blind and ferocious spirit of revenge—perhaps encouraged by some dark hints from persons who could effectually screen them—the partizans of absolute monarchy contrived a plot, of which the absurdity is hardly exceeded by its barbarity.

The Captain-General Freyre, on the receipt of dispatches announcing the King's acceptance of the Constitution, repaired to Cadiz from Port St Mary's, in the afternoon of the 9th of March. The impatience of the triumphant party to have the Constitution proclaimed, scarcely allowed him to postpone that ceremony till the next morning. But a desire that the chiefs of the patriotic army, whom he had invited, should be present, was a sufficient reason to check the eagerness of the people. Quiroga, the patriot general, was, however, too well acquainted with the temper and dispositions of his enemies, to acquiesce in the demand that he should disband his troops, and allow the unarmed soldiers to mix with the citizens, at the ensuing solemnity. Four officers alone, preceded by a flag of truce, were sent to witness the proclamation. Being admitted to the presence of the Captain-General, the evident uneasiness under which they perceived him labouring, and some expressions indicating a degree of anxiety for their safety, had just begun to raise their fears, when the report of musquetry, mixed with the cries of the suffering, or affrighted multitude, suddenly changed suspicion into the most appalling certainty. Freyre hastened out of the house, without providing for the safety of the deputies, who yet were so fortunate as to find the means of escaping the fury of their enemies.

In the mean time, the most atrocious massacre

Spain.  
was taking place in the streets, and in the principal square of Cadiz, where the people had assembled to witness the proclamation. The instruments of this barbarous deed were the privates and non-commissioned officers of two battalions of infantry, called the *Guides*, and the *Loyalists of Ferdinand the Seventh*. Instigated, as it is believed, by the governor of the town, and the chiefs of the royalist party, the soldiers had engaged to disperse the multitude, and prevent the intended ceremony. Large quantities of wine and spirits had been sent to the barracks, so that the men were in a state bordering upon intoxication, when they broke out with their arms. From the moment these monsters were loosed, they continued firing, indiscriminately, upon the people, till their ammunition was exhausted. About five hundred persons, men, women, and children, were seen in the streets of Cadiz, dead, dying, or wounded, before the authorities of the place had taken any measure to stop the massacre. Some officers of the Andalusian militia, not on duty, ran, of their own accord, to their barracks, and, drawing up in great haste, part of the men sallied forth into the streets, where they exercised themselves, with the utmost zeal, in protecting the lives of the defenceless citizens, and giving help to the wounded. The author of this article feels the greater satisfaction in recording this act of courage and humanity, as he believes it passed unnoticed, probably because the Andalusian militia had, to the last, remained in the royalist army. He received, at the time, an account of the whole transaction from an eye-witness of unimpeachable veracity. In the evening of the same day, the soldiers who had been employed in the massacre, were marched out of Cadiz. The deputies from the patriotic army, coming forward from their places of concealment, surrendered themselves into the hands of the Captain-General, who, still hoping some favourable turn in the affairs of the royalists, confined them within the Castle of Saint Sebastian. Indeed, so blindly confident were the leaders of that party that the insurrection would yet be quelled, as to have ventured on giving public thanks to the assassins. But the next dispatches from Madrid put an end to their hopes. The deputies were set at liberty. Both Freyre, the Captain-General, and Campana, the governor of Cadiz, were arrested, to take their trial. That trial was, however, delayed till public indignation died away; and we have not heard of any punishment inflicted on the criminals.

The Constitutional System being now completely restored, and in action, the Cortes assembled at Madrid in June 1820, and the King took his solemn oath, before them, on the 9th of the following month. Re-Assembled, Character, and Aims of the Cortes.

We might here conclude this article, leaving the task of describing the events of this new era to those who, free from the mists which always envelope and distort the passing transactions of political revolutions, would be able to record them without the danger of being misled by their own prejudices, or the misrepresentations of parties. But we feel that we should not do justice to our readers, did we con-

clude without attempting a brief sketch of the character and temper of the Government of the Cortes, their chief aims in the reform of the country, and the obstacles which have hitherto opposed their system.

The Cortes Extraordinary, which were convened on the restoration of the constitution, contained most of the patriots who had suffered during the arbitrary reign of Ferdinand—the original contrivers and supporters of the constitution. This was a measure which the military reformers of the Isla could not, and, probably, were not disposed, at that time, to oppose. But the seeds of jealousy between the two parties, the contending claims of the liberators, and those they had set free, could not remain dormant and inactive. The *Isla Patriots* naturally aspired to the first places and influence in the state: the *Old Liberals* soon felt their own dependence and inferiority. The *Secret Societies* were now more active than ever, and a rivalry between the *Free-Masons* and the *Comuneros* grew out of the different principles adopted by each of these parties, who, in their character and views, might be compared to the Old Whigs and the Radical Reformers in England. The *Free-Masons*, however, soon found themselves defeated; and those who had been forced upon Ferdinand, as his Ministers, were displaced to make room for the friends of the Revolutionary army.

The Cortes, though elected under the influence of the triumphant party, and acting under the direction of the popular leaders and their emissaries, who were regularly stationed in the galleries of the House, exhibited a degree of moderation which does honour to the national character. The measures of retaliation were limited, and infinitely less severe than those in which the king's friends had indulged. Even the most violent democrats, those who had placed themselves at the head of the populace, were satisfied, for a time, with the awe into which the Revolution had thrown their opponents. But the numerous conspiracies, subsequently discovered, increasing the fears of the new patriots, a deed of horror was perpetrated at Madrid, on the person of a dignified priest, which, from the perfect indifference shown, upon the occasion, by the existing authorities, we strongly suspect to have been planned by the secret societies. It was indeed evident, since that period, that nothing was done but through their influence in Spain.

Few of these atrocities were needed in that country to paralyze into perfect passiveness a great part of the population, especially among the middle and higher classes, and to revive those habits of silent submission to "the powers that be," which a tyranny of ages had confirmed. Had it been in the power of the new government to establish themselves without encroaching upon the rights of the church, and, thereby, confirming the suspicions of infidelity, under which all denominations of *Liberals* have long lain among the Spaniards, the resistance to the new order of things would have been limited, at least for a time, to a very inconsiderable and powerless minority of the nation. But, unfortunately for the interests of freedom in Spain, the old political system is too intimately blended with the strongest religious prejudices of the country.

To steer clear of this rock exceeded the powers of human wisdom. The Cortes *Extraordinary*, as well

as the *Ordinary*, which succeeded them, contained a large proportion of the talent, though scarcely any of the rank and property, of the country. Most of the clergymen, and perhaps all the lawyers, who had obtained seats, belonged to that class of Spaniards, who, free from religious prejudices, but having no system of their own to support upon these points, would shrink from an open contest with the zealots, without, however, letting pass any opportunity of showing their spite, by a side-blow. The pecuniary wants of the government; the desire of gaining partisans to the constitutional system by the transfer of property, exclusively under its sanction; together with the opportunity which the existing circumstances presented, of indulging the secret, though strong, feelings of aversion to the national system of religion, which rankle in the bosom of every liberal Spaniard, betrayed the Cortes into measures which could not fail to drive the bigots into an open and desperate resistance. One of the first steps against the religious orders was the suppression of those properly called *Monks*,—such as lived under the Ascetic institutions which preceded the establishment of the mendicant orders in the thirteenth century. As their houses were wealthy, this measure might be suspected to proceed rather from a wish to increase the resources of the government, than from ill will to the establishments themselves, which, besides, had long ceased to be objects of veneration for the mass of the people. But when, in the pure desire of removing the most odious nuisance to which the religion of the country has given birth, the Cortes decreed the abolition of the privileges hitherto enjoyed by the heads of the mendicant orders;—when they limited the number of convents, and subjected the individuals resident in each to a local superior, under the jurisdiction of the diocesan;—when impediments were thrown in the way of taking religious vows, and the admission into the secular clergy, of such as were willing to throw off the cowl, was encouraged;—when even the helpless victims of superstition, the nuns, were protected by the civil magistrate, in case they evinced a desire to break the perpetual imprisonment of the cloister;—the alarm of the bigots was turned into downright frenzy, and even the court of Rome, conscious as it is of its weakness, thought it necessary to resent the insult.

A step, much more questionable both as to its policy and justice, was taken by the Cortes against the church interest, in the abolition of one half of the tithes. Had they appropriated this portion of the church property to the use of the State, the spoliation might have been excused upon the plea of necessity. But the Cortes well knew that the farmers, once freed from the religious feeling which enforces the payment of tithes, would find means to defraud the civil authorities of nearly all the sequestered portion. The measure was, therefore, simply directed to the acquisition of friends to the new order of things.

We mention these detached specimens of the policy of the Cortes, not so much for the sake of their intrinsic importance, as in order to show the temper of the Liberal party, and contrast it with that of their opponents. And here we cannot help lamenting that want of space compels us to omit the details

Spain.

contained in the Reports of the Ministers, presented to the Spanish legislature in 1821 and 1822, as to the nature and extent of the resistance offered to the present system by one part of the nation. Cautious as they are in their language, and desirous to make light of the influence and resources of their adversaries, one great and important fact is clearly established from their evidence—a fact which has always forced itself upon our conviction, and which, from the knowledge we have of the country, appears to us in the shape of an almost insuperable obstacle to a speedy triumph of freedom in Spain—namely, that the present is a purely religious contest, in which one party engages with all the sincerity and straight-forwardness of zeal, while the other has to defend itself under the disadvantages of unavowed principles, and disguised views.

The Minister of *Grace and Justice* begins his Report of the 1st March 1822, by declaring that “the evils arising from the existing circumstances of the clergy are of the greatest magnitude.” He then proceeds to state the questions that had been agitated between the two courts of Rome and Madrid, giving a long detail of the theological and canonical arguments with which the Pope’s objections had been met. Of these points some were yielded to the Spaniards, some absolutely insisted upon. But the most resolute opposition had been made against a decree of the Cortes, prohibiting the remittance of Spanish funds for bulls and dispensations. And here we beg our readers to observe the circumstances of the whole transaction, as highly illustrative of the moral and intellectual relations in which the mass of the Spaniards stand, with the small party who have seized the reins of Government. When the Spanish Minister at Rome communicated this decree to the Papal authorities, he found that two thousand five hundred and forty-one bulls had been stopped for want of payment. Alarmed at the consequences of this spiritual embargo, the Spanish government paid the whole amount of the fees. But the sum had scarcely been laid down when the mail brought fifteen hundred petitions for bulls of the same private nature. Baffled by the irresistible power of religious prejudice, the Spanish Ministers were under the necessity of engaging for the payment of all bulls relating to Spain, until they should be able to compound with his Holiness for an annual sum. The account of this transaction concludes with the following observation of the Minister: “We shall thus be able to stop the contraband in bulls which has been set on foot already, and which is likely to increase the contributions to Rome to a much greater extent than before, as the parties concerned, finding the regular channels obstructed by government, have had recourse to others which, from their private and confidential nature, will require greater sacrifices on the part of the petitioners.” We cannot dismiss this topic without observing, that one of the most certain and abundant sources of revenue arises, in Spain, from the sale of an annual bull, called *the Bull of the Crusade*, which the government (even the liberal government) buy of the Pope, and retail to the people. The *Report* of the Minister of Finance for the same year observes, that by the Cortes having placed the produce of this pious sale in the

hands of the provincial treasurers, it had diminished from 1,500,000 of *reals* a month, to about 538,360 of the same money. The re-establishment of the *Commissary of the Crusades*, a dignified ecclesiastic, into his former authority, had, however, increased the sale to 1,073,674 *reals* a month.

Whatever might be the caution and timidity of the middle classes of Spain, especially those that are possessed of some wealth, or exercise any lucrative branch of industry, it was impossible that the more violent and daring of the sincere Catholics should remain perfectly inactive under a state of things so discordant with the truly national sentiments and habits. The rabble of the large towns, which is numerous, and quite worthy of that name, had, since the revolution of 1820, been gained over to the constitutionalists; but the peasantry, who, to this day, have shown a general dislike of the new system, would afford a considerable number of active and determined partisans to any who should be ready and able to marshal them under the standard of the *Faith*,—a word by which the Spaniards denote the Catholic religion, such as it was established in their country. Few months, indeed, had elapsed, when conspiracies were detected in various parts of the country; and Guerilla parties, in support of *Religion and the King*, were found ranging over the provinces. The seeds of a civil war had thus been brought into activity, and in the opinion of all who are well acquainted with the dilatoriness and obstinacy of the Spaniards, the character and circumstances of the contending parties were, alone, enough to threaten the destruction of every source of power, wealth, and happiness, in that devoted kingdom.

It was not long, however, before a determination was observed, on the part of France, to encourage and support the Spaniards, who were actually in arms, or ready to take them up, against the new system of government. Emigrants were protected on the French side of the frontiers, and enabled to organize themselves into military divisions. The yellow-fever, which attacked Catalonia, in the summer of 1822, afforded a pretext for establishing a *Cordon Sanitaire*, which might act as an army of observation. French money was employed in raising fresh disturbances in the kingdom; and, it is more than probable, French influence fomented the conspiracy of the Guards, which, on the 7th July of the same year, would have placed the King out of the hands of the Cortes if he had had either the will or the courage to join the troops, who awaited his presence at a short distance from the palace.

A congress of the powers which compose what is known by the name of the *Holy Alliance*, was, at this time, about to be assembled at Verona. From the character of the governments of Austria, Prussia, and Russia, and their habitual fears of the spirit of political reform, which for the last thirty years has shaken the foundations of all absolute monarchies, it could hardly be imagined that Spain should pass unnoticed at this meeting. Nor was it long before the disclosure of their views and principles, joined to the open avowal of hostile intentions against Spain, on the part of France, evinced a settled and systematic plan for restoring absolute mo-

Spain.

Hostility of France to the New Government.

Spain

shire.

narchy in the former kingdom, and opposing, throughout Europe, every curtailment of monarchical power, however exorbitant and oppressive, and every attempt to establish the liberties of the subject, upon permanent and definite grounds. In vain did England remonstrate against the impolicy and injustice of interfering with the domestic concerns of an independent nation. Notes, conceived in a spirit, and couched in a style which could only irritate the feelings of the constitutionalists, and strengthen their hands by wounding the pride of the nation, were addressed by the three Sovereigns of Austria, Prussia, and Russia, to their Ministers at Madrid, demanding a change in the constitution, as the condition of the permanence of these accredited agents at that court. Lest Europe should be left in doubt as to the nature of the changes thus peremptorily required, the French King, on the 28th of January 1823, announced to the Chambers, that he had one

hundred thousand troops ready to march into Spain, unless Ferdinand VII. were allowed to give to his people institutions which they cannot hold but from him.

Spain  
||  
Stafford-  
shire.

A principle so monstrous, backed by a threat so unbecoming and dissonant, in the mouth of one who has had so long to shrink from military force, could not but urge the Spanish governors into a determined resistance to any proposals of accommodation which should imply the least yielding on their side; and the invasion of Spain by a French army, with the avowed purpose of restoring despotism, the monks, and the Inquisition, took place on the 17th of April 1823, about the time when, fifteen years before, another French army violated that territory, under pretence of giving it a Constitutional Code, and wiping off the disgrace which those barbarous institutions cast upon the national character. \* (s. s.)

Extent,  
boundaries,  
and Divi-  
sions.

STAFFORDSHIRE, an inland English county of an oblong form. Its greatest length from north-east to south-west is about sixty, and its greatest breadth about thirty-eight miles. It contains 1,148 statute square miles, or 734,720 acres. It is bounded on the north by Cheshire, west by Shropshire, south by Worcestershire and Warwickshire, and east by Derbyshire. The great divisions are five hundreds; but, as each of these is subdivided into the north and south portions, there are effectively ten hundreds. These contain 181 parishes, 23 market towns, and one city. The whole of the county, with the exception of two parishes, is within the diocese of Lichfield and Coventry, and comprehended within the archdeaconry of Stafford.

Population.

According to the census of 1821, the increase of the population in the preceding ten years had been at the rate of sixteen *per cent.* At that period, the inhabited houses were 63,319, and the families occupying them 68,780; of these families, 18,285 were chiefly employed in agriculture, 42,435 in trade, manufactures, and handicraft, and 8060 comprised in neither of those classes. The whole number of persons was 341,040; of whom 171,668 were males, and 169,372 females.

Place of the  
country.

The middle and southern portions are generally level, but interspersed with gentle eminences. The northern division is of an opposite character, the surface being for the most part bleak and hilly.

The general elevation of this district above the southern part of the county is about two or three hundred feet; but some points rise to the height of from 1200 to 1500; of those the most elevated are Bunster and the Weever Hills. In the valleys on the banks of the rivers are some tracts of country equal to the most beautiful parts of the island; of these, the district betwixt Lichfield and Stone, and the picturesque banks of the Dove, especially at Ilam, are very remarkable.

The soil is various, but the strong clays are the most predominant; next in extent is the sandy soil, chiefly to the south of the Trent. There is no chalk, and only a small district is calcareous. The meadows, especially on the banks of the Trent, are most rich and luxuriant; and, though on spots there is much inert peat, yet, when it is drained properly, it becomes valuable pasture and meadow land. The climate is generally raw and moist; the rain that falls on an average of several years is about 36 inches. The quantity of snow, in the winter on the moorlands, is very great, which may contribute to the general coldness of the district.

Soil and  
Climate.

The Trent, the third river in England, is the principal stream of the county. It rises at Newpool on the confines of Cheshire, and enters Derbyshire below Burton, after having formed a junction with the Dove; through the whole of its course in this county it is a clear and rather rapid stream.

Rivers and  
Navigable  
Canals.

\* By a proclamation of the Spanish Regency, an authority established by the French, every public act since the Revolution of 1820 has been declared null and void, and the country is to be reinstated into the same condition as it had been before that change. The moderation with which, during the interval of writing and publishing this article, the Prince D'Angouleme has behaved in Spain, though it can never justify the armed interference of his government, might seem to invalidate our charge, as to the intended restoration of the Inquisition. What the real feelings of his Royal Highness's government may be upon this point, the author of the article has not the means to ascertain; but he knows too well the spirit of the party, into whose hands it appears that the French wish to put the fate of the Spaniards, not to fear that the execrable tribunal, to which Spain owes her degradation and sufferings, will re-appear in that unfortunate country. Should his suspicions prove true, he has no hesitation to assert, that all the blame and disgrace of such a restoration belongs to those who, when they were determined to interfere with the private concerns of the Spaniards, did not care to extenuate the infringement of national rights, by any stipulations in favour of the general interests of the invaded country.

Stafford-  
shire.

The Dove is celebrated for the picturesque scenery through which it flows. In its course it receives the Manifold and the Hamps, two streams which are lost in subterraneous channels, but again emerge at the distance of some miles, and rejoin it. The smaller rivers are the Tame, the Blythe, the Sour, and the Penk, all of which empty themselves into the Trent. No part of Great Britain is so intersected with navigable canals as Staffordshire, and in no country has their beneficial effects been so extensively experienced. The Grand Trunk was planned and executed by Mr Brindley, the most eminent engineer that ever exerted talent in this peculiar branch of inland navigation. This canal is about 91 miles in length; the fall of water to the north is 326 feet, and to the south 316 feet. It is 29 feet wide at the top, and about four feet deep. It unites by navigation the internal trade of the great marts of London, Liverpool, Hull, and Bristol. The branches that extend from it in every direction are very numerous, and serve to connect the great shipping ports with all those districts, in the centre of the kingdom, which produce those heavy commodities whose weight would make them almost worthless without the means of cheap conveyance to distant markets.

Minerals.

The chief mineral productions of the county are iron and coal, and these are so copious that they appear to be almost inexhaustible. Upwards of 50,000 acres have been already ascertained to have beneath them beds of coal; and, notwithstanding the length of time, and the extent to which they have been worked, it is calculated that not one-tenth of their contents have been yet consumed. The strata of this mineral, in the mines already worked, vary in thickness from 24 to 36 feet. Every portion of the coal district abounds in iron ore; and the strata of that mineral are generally found beneath a stratum of coal. Copper and lead are also raised, but not to an extent nearly approaching that of iron. Limestone, freestone, alabaster, marble, ochre, gypsum, and clays of various descriptions, applicable to the purposes of the potteries, are most abundantly extracted from the bowels of the earth. Though salt springs are both copious and richly impregnated with that mineral, no rock salt has been yet discovered; but it is supposed there are some abundant repositories of it beneath the surface.

Manufac-  
tures.

The relative proportion of the employment of the several families show the great preponderance of manufacturing labour in this county. The whole of the southern part is occupied in the different workings of metals. Wolverhampton is the chief seat of the manufacture of locks, keys, hinges, bolts, and the heavier kinds of iron ware. Walsal furnishes buckles, bits, stirrups, spurs, and all the kinds of hardware used by saddlers. Wednesbury supplies guns, iron axle-trees, saws, trowels, hammers, edge tools, and cast-iron works of every kind. Almost all the villages in the vicinity of these towns contribute in a greater or less degree to supply part of the work for which the town nearest to them is the great mart.

The northern part of Staffordshire is celebrated for the excellence of its earthenware, with which it supplies the consumption of the greater portion of

the civilized world. The great extension of this manufacture has been owing to the scientific skill and persevering energy of one distinguished individual, the late Mr Wedgewood; whose combinations of the different earths, and study of the arts of design, has given a value to that which before was almost worthless, and increased to a most wonderful extent the wealth of his neighbourhood, and the number and comfort of its inhabitants. By means of the canals, the pipe-clay from Dorsetshire and Devonshire, and the flints from Kent, are brought to the spots where the clays and coal abound; and the finished goods, by the same means, are conveyed to the great shipping ports, from whence they are distributed to all parts of the globe. Salt is made from natural springs at Shirleyweck, and, of late, at Lord Talbot's works at Ingestrie, to such an extent as to supply all those parts of the middle of the kingdom which are not in more close contact with the refineries of Northwich or Droitwich. There are some respectable establishments at Cheadle for making brass and copper goods. Shoes are manufactured on an extensive scale at Stafford and at Newcastle. At Tamworth are great works for printing calicos. Burton has manufactures of ale, of great celebrity, of hats, and of several kinds of cotton goods. At Leek there are large and flourishing establishments for ribbons, handkerchiefs, ferrets, gallions, and other kinds of silk goods.

Stafford-  
shire.

The cultivated lands of this county are nearly all inclosed within good hedges, chiefly of the white thorn, in fields of from twenty to thirty acres. The general rotation of crops in the clayey soils is, 1st, Fallow; 2d, Wheat; 3d, Oats, after which it is laid down with clover, trefoil, and rye-grass, for two or more years. On breaking up an old sward, the usual course is, 1st, Oats; 2d, Fallow; 3d, Wheat; 4th, Oats, and then the grasses. On the more friable soils the rotation is, 1st, Fallow; 2d, Wheat; 3d, Beans, or pease; 4th, Oats, and then the grasses. On the light soil, the Norfolk system of turnips, barley, clover, and then wheat, is most commonly followed.

Agriculture.

The black cattle are generally of the long-horned breed, and have, of late years, been much improved by the spirited exertions of some distinguished individuals. The sheep are of different races; the new Leicesters are said to be the most predominant. About Cannock and Sutton Colfield they have a breed much resembling the South Downs. On the moorland there is a breed with white faces, without horns, and long combing wool. The county is well stocked with timber, especially on the estates of some of the great proprietors. The lands in an unimproved state are still estimated to amount to nearly one-tenth part of the whole county.

The Roman antiquities are the Watling Street and the Ichnield roads, which pass through it, and the remains of ancient stations or encampments. The Saxons have left few remains here that merit particular attention.

Antiquities.

This county gives titles to the following peerages: Title, and Marquis of Stafford, Earls of Ferrers, Talbot, and Harrowby. The county returns two members to the House of Commons, and two each are sent from Lichfield, Stafford, Newcastle, and Tamworth.

STEAM-ENGINE, PERKINS'S. In addition to the detailed theory of STEAM, and of the STEAM-ENGINE,\* such as it has already been furnished by the science of a Robison, and the ingenuity of a Watt, some further theoretical investigations and computations are still required from time to time, in order to keep pace with that restless spirit of incessant speculation and practical improvement, to which Great Britain is indebted for so much of its prosperity; and none of the inventions which have of late been introduced are so striking, so promising, or at first sight so paradoxical, as those which have resulted from the skill and enterprise of Mr Perkins. In order that we may be prepared to appreciate the merit of these inventions, and to discriminate between the effects which are the results of new philosophical principles, and those which are only obtained from a high perfection of mechanical execution, and a just confidence in the admirable art with which the materials are selected and tempered; it will be necessary to recur to the theories of heat and of steam which have been already founded on acknowledged facts, and to inquire how far they will carry us in explaining all that has hitherto been made public respecting the machinery which has excited so much attention, before we allow ourselves to reject the principles [of *Atmology*] at present admitted, as either erroneous or insufficient.

Respecting the density, or specific gravity, of steam at different temperatures, there appear to have been three different opinions; that of Mr Wolf, who fancied that it was nearly equal in all cases, and that the difference of elasticity depended only on the immediate effect of heat; that of Mr Southern, who inferred from his experiments that the density was simply proportional to the elasticity, without any regard to the effect of temperature; and thirdly, the earlier and more probable theory of Mr Dalton, which is intermediate between them, and which at-

tributes the same effect to heat in the expansion of pure steam that it possesses with respect to all other gases, amounting for each degree of Fahrenheit to about  $\frac{1}{3000}$  of their bulk at 52°, or to  $\frac{1}{350}$  at 212°, provided that no additional quantity of moisture be present to furnish fresh steam by its evaporation. The elasticity might be computed from Dr Young's formula  $e = .1781 (1 + .006f)^7$ , in which  $f$  is reckoned from the freezing point, and which agrees sufficiently well with the latest experiments of Southern and Üre, as well as with the earlier ones of Watt, Schmidt, Biker, Bétancourt, Robison, Dalton, and others; and we might transform it into the more convenient expression  $E = (1 + .0029f)^7$ , for the number of atmospheres expressing the elasticity, reckoning the  $f$  from 212°. But since Mr Southern's experiments, as described in Robison's *System of Philosophy*, were carried to higher temperatures than any of those which had been before made public, it will be safer to adopt an exponent approaching more nearly to that which he has employed, and to make  $E = (1 + .004f)^5$ . Notwithstanding, however, the apparent accuracy of these experiments, it seems impossible to rely on them with perfect confidence; they give, for example, the absolute specific gravity of steam at 212°,  $\frac{1}{1600}$ ; while Sir Humphry Davy's very accurate observation of the perfect identity of the space occupied by oxygen and hydrogen before and after deflagration, makes it only  $\frac{1}{2600}$ , which agrees very nearly with the experiments communicated by Mr Davies Gilbert to Dr Young (*Nat. Phil.* II. p. 397), as well as with the much older determination of Desaguliers.

We obtain, upon these principles, the following Table of the elasticities and densities:

Atmospheres.	Temperature.	Difference.	Compar. Density.	Specific Gravity.
1	212°	37°	1.000	1:2600
2	249	24	1.896	1:1371
3	273	19	2.742	1:912
4	292	15	3.565	1:729
5	307	13	4.366	1:596
6	320	11	5.150	1:505
7	331	10	5.917	1:439
8	341	9	6.678	1:390
9	350	8	7.432	1:350
10	358	—	8.170	1:318
15	383	—	11.820	1:220
20	417	39	15.232	1:171
30	456	29	21.834	1:120
40	485	24	28.210	1:92
50	509	20	34.388	1:76
60	529	18	40.404	1:64

\* There are, in the *Encyclopædia Britannica*, very full articles under these heads, from the pen of the late Professor John Robison.

Steam-Engine.

There is another of Mr Southern's opinions, which it appears to be almost as difficult to reconcile with other considerations as his conclusions respecting the absolute and relative densities of steam: he imagines that the heat consumed in the formation of steam is almost all employed in the simple conversion of the liquid into a gas, without any great deduction for that which is required for its expansion; while, on the other hand, if we adopted Dr Young's computation, deduced from the effect of expansion and compression on the velocity of sound, we should be obliged to infer, that almost the whole of the heat is required for the expansion only, and very little, if any, would be left to supply what Mr Southern calls the *constitutional* heat of the steam, in contradistinction to the heat of *expansion*. Dr Young's book is so little known, though it has been sixteen years before the public, that it will not be superfluous to extract from it the computation in question, which bears immediately upon the utility of all engines with high pressure.

"We may deduce from" Mr Dalton's "experiment," says Dr Young (Vol. II. p. 409), "an acceleration of about  $\frac{1}{7}$  to be added to the calculation of the velocity of sound; and, since the results of [direct] experiments on sound require an acceleration of  $\frac{1}{5}$ , or only  $\frac{1}{6}$  more, which has been ascertained with great accuracy, it may be fair to allow the supposition of Laplace and Biot, that the whole acceleration of sound is owing to this cause. We may, therefore, make the exponent of the density  $\frac{1}{6}$  for expressing the change of capacity, and the heat produced  $1450(x^{\frac{1}{6}}-1)$ ; which, when the density is doubled or halved, becomes  $131.2^\circ$ ; [and] a compression of  $\frac{1}{180}$  will produce a heat of  $1^\circ$ ."

"Now, it appears from experiments on the sounds of different gases, and from the sound of a pipe in air of densities the most various, that the correction of the velocity of sound is nearly the same in all; hence it may be inferred, that the heat produced by condensation follows nearly the same law with respect to all gases. This principle may, therefore, probably be extended to steam. Supposing the conversion of water into steam to absorb as much heat as would raise its temperature  $940^\circ$ , we may call its capacity at  $212^\circ$ , 1.60, and may calculate a table for other temperatures, assuming, with Mr Dalton, that its simple expansion by heat is equal to that of air. Mr Watt has shown, by direct experiment, that steam has a greater capacity, as its temperature is lower.

"Hence, if a steam-engine work with double atmospheres, the heat being about  $247^\circ$ , it will require 1.87 times as much water, of which the capacity [as steam] is 1.48; and its excess above that of water  $\frac{1}{3}$  as much as at  $212^\circ$ ; it will therefore absorb about  $752^\circ$ , and the heat required for raising water from  $100^\circ$  will be as 1.87 ( $147+752$ ) to  $112+940$ , or nearly as 8 to 5, while the effect is doubled.

"Robison says, that four ounces of water, at  $100^\circ$ , will condense in a second nearly 200 cubic feet of steam, reducing its expansive force to  $\frac{1}{5}$ . If this is correct, it sets at defiance all theories of capacity. The only distant analogy that can be found for it, is

the facility with which rarified air is found to carry off heat, which would induce us to suppose, that the capacity of a given bulk of air is much less affected by its density than this calculation appears to demonstrate;" and this apology, if we allowed it any weight, would carry us still farther from Mr Southern's opinion."

The two steps by which Dr Young's argument proceeds are, first, the effect of compression on air, as deduced from Laplace's ingenious and fortunate suggestion respecting the velocity of sound; and, secondly, the identity of this effect, as observed by himself and others, in air of different densities, and in gases of different kinds; whence he infers, that the same law may *probably* be extended to steam; that is, as far as we can depend on such analogies as have been employed in the doctrine of the capacities of bodies for heat, which, however, appear to be by no means unobjectionable. A remarkable consequence of this mode of computation would be, that water might be converted into steam of its own density almost without any expense of heat whatever for what Mr Southern calls its constitutional heat; for if we make  $x = \frac{1}{180}$  in the formula  $1450(x^{\frac{1}{6}}-1)$ , we have  $907^\circ$  for the change of temperature attending such a compression or expansion; and the result would be still greater, if we supposed the heat evolved to be expressed by  $n \log x$ , taking  $n$  above  $400^\circ$ , for the multiplier of the common logarithm of the density. Probably, indeed, both these modes of computation give a change of temperature greater than the truth for the effect of any very considerable compression or expansion of steam; but the lowest estimate that we can form of this effect will still make it probable that steam is always cooled by its expansion below the temperature which would allow it to subsist in its rarified state as pure steam; or, in other words, that a deposition of moisture is always immediately produced by its expansion, and that steam is rendered drier by compression, supposing no heat to be absorbed or emitted in either case. The very low temperature at which a thermometer stands, in the steam that issues out of a boiler under a very high pressure, is a further proof of the great increase of its capacity, or of the great absorption of heat occasioned by the expansion.

Mr Perkins's invention, as described in the *Edinburgh Philosophical Journal* for July 1823, appears to consist in substituting for the boiler a strong vessel of gun metal, which he very properly calls a *generator*, intended to subject the water to a heat of between  $400^\circ$  and  $500^\circ$ , and allowing it to escape only through a valve loaded with a weight equivalent to 35 atmospheres, while it is furnished with a safety valve loaded to 37, and with a gage indicating, by means of a portion of compressed air, the actual pressure of the steam produced by it; and even the water that returns to the generator is subjected to a pressure of five or six atmospheres, which keeps it at a temperature of more than  $300^\circ$ . The generator contains eight gallons of water, or 2352 cylindrical inches, while the piston is two inches in diameter, and the cylinder 18 inches long, containing 72 cylindrical inches, or  $\frac{1}{33}$  as much as the generator: affording a stroke of 12 inches, with a pressure

Steam-Engine  
||  
Steam-  
Navigation.

initially of about 430 pounds on each square inch, that is, about 1300 pounds in the whole, or probably somewhat less, since the valve of the generator cannot be supposed to remain open long enough for the pressure on each side of it to become equal. The danger of explosion, which has hitherto prevented the general employment of engines with very high pressures, is here avoided by the great strength and the moderate dimensions of the apparatus; and besides the safety valves, a thin ball of copper, or a safety bulb, is provided, which will only sustain the pressure of 1000 pounds on the square inch, while every other part of the vessels is calculated to sustain 4000.

Mr Perkins's mode of applying heat to the water appears in reality to be extremely advantageous, not so much from any evidence that has been produced respecting the performance of the engine, as from the fact asserted by the writer in the *Journal*, that "as much low pressure steam, of four pounds on the square inch, may be generated by one bushel of coals," employed upon three tubes of gun metal, communicating, by means of a loaded valve, with the boiler of a common engine, as by nine bushels applied in the ordinary manner. It has been conjectured that the heat is more easily communicated by the generator to the water, on account of the more intimate contact which subsists between them, and the absence of any nascent bubbles of steam in the neighbourhood of the common surface: but it appears to be more probable, that by far the most material part of the advantage depends upon the more perfect combustion of the coal at a high temperature near the external surface of the thick boiler: for it has been sufficiently proved by Sir Humphry Davy and others, that an intense combustion evolves a much greater quantity of heat from the same materials than a more languid oxygenization.

However this may be, there is nothing paradoxical, and nothing marvellous in the operation of the engine itself, nor in the rapid production of a quart of steam from eight gallons of water "almost red hot." The writer in the *Journal* has fancied that the water, as it "flashes out," may rob the neighbouring particles of their heat, so as even to leave them below the freezing temperature, while it is itself much above the boiling: but this supposition is in direct oppo-

sition to every thing that we know of the properties of heat. If we reason at all in natural philosophy, we must reason from analogy: such a phenomenon as this would be incredible, even if it were asserted upon the direct and clear testimony of the senses; but to assume it as a probability, without pretending that it has been observed, appears to be setting completely at defiance the obvious dictates of common sense. There is *no other instance whatever* in which a body, contiguous to another, and exceeding it in thermometrical temperature, does not communicate heat to it rather than receive heat from it: nor, on the other hand, is there any one fact besides, that could be imagined to favour the hypothesis of a sudden and general communication of heat between the distant parts of a material substance, like that which appears to take place with regard to the electrical fluid.

The quantity of water, thrown out at each stroke, appears, from the table of densities inserted in this article, to be  $\frac{1}{110}$  of the quantity that would fill the cylinder, that is  $\frac{1}{3630}$  of the content of the generator, and its conversion into steam at any temperature would not require, at the utmost, more than  $940^\circ$  of heat, that is, a quarter of a degree for the whole of the water in the vessel, and possibly not above one fifth of a degree: and it is obvious that the parts nearest the surface might easily furnish this with sufficient rapidity, and yet without approaching very near to the "freezing temperature."

But whatever mistakes may have been made respecting the principles of Mr Perkins's engine, there can be no reason to doubt of its possessing some considerable advantages in practice, which he will probably soon be enabled to establish, by the accurate test of its performance in pumping up water, as compared with that of the engines at present in common use, which are said to be capable of raising a weight equal to that of the coals consumed to the height of above half a million of feet: so that, in order to make good the expectations that have been held out to the public, he will have to raise an equal weight to about five million feet; and when this has been performed, he will have triumphantly redeemed the pledge that has been given on his behalf.

(A. L.)

## STEAM-NAVIGATION.

History of  
Steam-Nav-  
igation.

THE idea of propelling vessels by the action of wheels or paddles, instead of oars, seems to have occurred at a remote period. The mode of carrying the project into execution is clearly, though concisely, described in a very curious and learned treatise, *De Re Militari*, by Valturius of Rimini. This remarkable work is justly deemed one of the finest and earliest specimens of typography and wood-engraving. It was first printed by John of Verona in 1472, and from the same press an Italian translation of it by Paul Ramusio issued in 1483. It was afterwards reprinted at Paris in 1532, in the original

Latin, by the celebrated Printer, Christian Wechelius.

Of the numerous machines described and delineated in that rare volume, several have been frequently reproduced as new inventions during the course of the last century. Such waste of ingenuity is really a serious evil, arising from inattention to the history of the mechanical arts, and the want of a public repository to exhibit their successive improvements. Mr Dibdin has given, in his *Bibliotheca Spenceriana*, fac-similes of several warlike engines from Valturius; but we have copied the figure of a

Steam-Engine  
||  
Steam-  
Navigation.

Steam-  
Navigation.

flat-bottomed boat for crossing rivers by the circum-  
volution of paddles or vanes. (See Plate CXVI.)  
These vanes consisted of pitched sail-cloth; and it  
will be seen, that the impulsion was communicat-  
ed by means of cranks. The action of each axle  
is said to have been equivalent to that of twelve oars.  
(Valturius, *De Re Militari*, p. 314.) We must not,  
however, suppose that the power thus applied was  
really augmented by such machinery. It has been as-  
certained that human force is advantageously exerted  
in the act of rowing; but this operation requires skill,  
and not more than one person can work convenient-  
ly at the same oar. Where paddles are substituted,  
mere strength is sufficient; and a number of men  
may combine their labour in turning a crank. Ani-  
mal power will, indeed, effect the same purpose.  
Accordingly, some of the broad ferry-boats in  
North America are fitted with paddles driven by  
gin-horses.

It is clear, therefore, that, three or four centuries  
ago, boats, propelled by the action of paddle-wheels,  
were used on some of the large rivers in Italy, and,  
most probably, in other parts of the Continent, for the  
transporting of troops. Valturius even speaks of pon-  
toons, composed of three parts, like drums, which  
could be conjoined at any time, and again separated,  
to facilitate their carriage over land. The method  
of changing a reciprocating into a rotatory motion,  
by the help of a crank, though not applied to the  
steam-engine till 50 or 60 years after its invention,  
had been understood and practised at the very dawn  
of the mechanical arts.

The atmospherical steam-engine, which had been  
invented by Newcomen and improved by Beighton,  
began to be pretty generally adopted in the coal-  
works about the year 1720; and it does not seem to  
have required any great stretch of imagination to direct  
such an efficient power to other purposes besides the  
raising of water.

Mr J. Hulls. The first attempt, however, on record to apply steam  
to navigation was made by a person of the name of  
Jonathan Hulls, who, on the 21st of December 1736,  
obtained a Patent, to endure for 14 years, for what  
may, without any impropriety, be called a *Steam-Boat*.  
The Letters Patent, and a description of this boat,  
illustrated with a plate, are contained in a very rare  
Tract, published by Hulls in 1737, under the following  
title: *A Description and Draught of a new invented  
Machine for carrying Vessels or Ships out of or into  
any Harbour, Port, or River, against Wind and Tide,  
or in a Calm*. As the origin of the invention has  
been much disputed, we shall subjoin some extracts  
from this pamphlet, which lay totally forgotten till  
within these few years, and is even yet, on account of  
its great rarity, but very little known.\*

He introduces his description by a concise view  
of the principles of experimental philosophy; in  
which he observes (p. 39), "If a person were  
to descend to the bottom of a well full of wa-

ter, his body would be pressed the same as if he  
descended the same depth into the sea; for there  
is the same pressure against a pool-head as there is  
against the sea-bank at the same depth, as hath be-  
fore been demonstrated.

Steam-  
Navigation.

"Thus I have endeavoured to explain the nature  
of the pressure of the air on other bodies, by com-  
paring it with other fluids that are visible to our eye,  
as mercury, water, &c. and, since the pressure is so  
very great, it is the more fit to be applied to a pur-  
pose wherein all sorts of manual operations are in-  
sufficient. For this present undertaking cannot be  
supposed to be done by strength of men or horses,  
or any machine driven by either.

"The atmosphere being of a great weight, and  
striving to get in where there is a vacuum, I shall  
endeavour to show how this vacuum is made, and  
in what manner this force is applied to drive the ma-  
chine.

"In some convenient part of the Tow-Boat there  
is placed a vessel about two-thirds full of water, with  
the top close shut; this vessel being kept boiling,  
rarifies into a steam. This steam being conveyed  
through a large pipe into a cylindrical vessel, and  
there condensed, makes a vacuum, which causes the  
weight of the atmosphere to press on this vessel, and  
so presses down a piston that is fitted into this cy-  
lindrical vessel, in the same manner as in Mr New-  
comen's engine, with which he raises water by fire.  
(See Plate CXVI.)

"It hath been already demonstrated, that a vessel  
of thirty inches diameter, which is but two feet and  
an half, when the air is driven out, the atmosphere  
will press on it to the weight of four tons, sixteen  
hundred weight, and upwards; when proper instru-  
ments for this work are applied to it, it must drive a  
vessel with a great force."

*Note.*—The bigness of the machines may be pro-  
portioned to the work that is to be performed by  
them; but, if such a force as is applied in this first  
essay be not sufficient for any purpose that may be  
required, there is room to make such addition as  
will move an immense weight with tolerable swiftness.

"It is my opinion it will not be found practicable  
to place the machine here recommended in the ves-  
sel itself, that is to be taken in or out of the port, &c.  
but rather in a separate vessel, for these reasons:—

"1st, This machine may be thought cumbersome,  
and to take up too much room in a vessel laden with  
goods, provisions, &c.

"2d, If this machine is put in a separate vessel,  
this vessel may lie at any port, &c. to be ready on all  
occasions.

"3d, A vessel of a small burthen will be sufficient  
to carry the machine to take out a large one.

"4th, A vessel will serve for this purpose for  
many years, after she is thrown off, and not safe to  
be taken abroad."

The passages above quoted are followed by the

\* It consists of forty-eight pages, in duodecimo; was "printed for the author, and sold, price sixpence,  
at the Pamphlet Shops in London and Westminster."

Steam-  
Navigation.

*Explanation of the Machine.* The Figure to which this *Explanation* refers is copied, from that given by Hulls, in Plate CXVI.

" *A* represents the chimney coming from the furnace.

" *B*, The tow-boat.

" *CC*, Two pieces of timber, framed together, to carry the machine.

" *Da*, *D*, and *Db*, are three wheels on one axis, to receive the ropes *F*, *Fa*, and *Fb*.

" *Note.*—*F* is the same rope that goes into the cylinder.

" *Ha* and *Hb* are two wheels on the same axis with the fans *IIIIII*, and move alternately in such a manner, that when the wheels *Da*, *D*, and *Db*, move backward or forward, they keep the fans *IIIIII* in a direct motion.

" *Fb* is a rope going from *Hb* to *Db*, that when the wheels *Da*, *D*, and *Db*, move forward, moves the wheel *Hb* forwards, which brings the fans forward with it.

" *Fa* is a rope going from the wheel *Ha* to the wheel *Da*, that when the wheels *Da*, *D*, and *Db*, move forward, the wheel *Ha* draws the rope *F*, and raises the weight *G*, at the same time as the wheel *Hb* brings the fans forward.

" When the weight *G* is so raised, while the wheels *Da*, *D*, and *Db*, are moving backward, the rope *Fa* gives way, and the power of the weight *G* brings the wheel *Ha* forward, and the fans with it, so that the fans always keep going forward, notwithstanding the wheels *Da*, *D*, and *Db*, move backwards and forwards, as the piston moves up and down in the cylinder.

" *LL* are teeth for a catch to drop in from the axis, and are so contrived, that they catch in an alternate manner, to cause the fans to move always forward, for the wheel *Ha*, by the power of the weight *G*, is performing his office, while the other wheel *Hb* goes back in order to fetch another stroke.

" *Note.*—The weight *G* must contain but half the weight of the pillar of air pressing on the piston, because the weight *G* is raised at the same time as the wheel *Hb* performs its office, so that it is, in effect, two machines acting alternately by the weight of one pillar of air of such a diameter as the diameter of the cylinder is.

" If it should be said that this is not a new invention, because I make use of the same power to drive my machine that others have made use of to drive theirs for other purposes; I answer, The application of this power is no more than the application of any common and known instrument used in mechanism for new invented purposes." P. 43.

This *Explanation* is followed with the annexed "*Answers to some Queries that have been made concerning the possibility and usefulness of this undertaking.*"

## " QUERY I.

" Is it possible to fix instruments of sufficient strength to move so prodigious a weight as may be contained in a very large vessel ?

" Answer. All mechanics will allow it is possible to make a machine to move an immense weight, if

there is force enough to drive the same; for every member must be made in a proportionable strength to the intended work, and properly braced with laces of iron, &c. so that no part can give way or break, if the braces, &c. necessary for this work had been put in the draught, it would have been so much crowded with lines, that the main instruments could not be so well perceived.

## " QUERY II.

" Will not the force of the waves break any instrument to pieces that is placed to move in the water ?

" Answer. *First*, It cannot be supposed that this machine will be used in a storm or tempest at sea, when the waves are raging; for, if a merchant lyeth in a harbour, &c. he would not choose to put out to sea in a storm, if it were possible to get out; but rather stay until it is abated.

" *Secondly*. When the wind comes a-head of the tow-boat, the fans will be protected by it from the violence of the waves; and when the wind comes side-ways, the wind will come edge-ways of the fans, and therefore strike them with the less force.

" *Thirdly*. There may be pieces of timber laid to swim on the surface of the water on each side of the fans, and so contrived as they shall not touch them, which will protect them from the force of the waves. Up inland rivers, where the bottom can possibly be reached, the fans may be taken out, and cranks placed at the hindmost axis, to strike a shaft to the bottom of the river, which will drive the vessel forward with the greater force.

## " QUERY III.

" It being a continual expence to keep this machine at work, will the expence be answered ?

" Answer. The work to be done by this machine will be upon particular occasions, when all other means yet found out are wholly insufficient. How often does a merchant wish that his ship were on the ocean, when, if he were there, the wind would serve tolerably well to carry him on his intended voyage, but does not serve, at the same time, to carry him out of the river, &c. he happens to be in, which a few hours work of this machine would do. Besides, I know engines that are driven by the same power as this is, where materials for the purpose are dearer than in any navigable river in England; therefore, experience demonstrates, that the expence will be but a trifle to the value of the work performed by those sort of machines, which any person that knows the nature of those things may easily calculate." P. 45—48.

Thus, Jonathan Hulls appears to have been the first person who suggested the propulsion of vessels by paddle-wheels moved by steam. His mode of converting the rectilinear into a rotatory motion was ingenious, though not so simple as the crank. It is most probable, however, that he possessed not the means, and did not receive at the time sufficient encouragement to carry his scheme into execution.

A long interval elapsed before a similar project was attempted. About the year 1772 the celebrated Mr Watt had completely remodelled the steam-engine; Marquis De Jouffroy.

Steam-  
Navigation.

Steam-  
Navigation.

and before 1779 it was, by various improvements, reduced to a compendious form, and adapted to almost every purpose where great power was required. The idea of employing it to propel vessels then naturally suggested itself. One of the first to whom it occurred was the Marquis De Jouffroy, who, in 1781, constructed a steam-boat on the Saone at Lyons; it was 140 feet long, and he made several experiments with it.

Messrs Fitch  
and Rumsey.

In the year 1785 two keen competitors for the invention of steam-navigation appeared in America; namely, James Rumsey of Virginia, and John Fitch of Philadelphia. The following extracts from a Pamphlet, very little known in this country, published by the latter in 1788, are curious: \*

—“ I confess the thought of a steam-boat, which first struck me by mere accident, about the middle of April 1785, has hitherto been very unfortunate to me; the perplexities and embarrassments through which it has caused me to wade far exceed any thing that the common course of life ever presented to my view.”—“ In June and July I formed models, and in August laid them before Congress, as will appear on their files. In September I presented them to the Philosophical Society, as *per* certificates.”—

“ Philadelphia, Sept. 27, 1785. At a special meeting of the American Philosophical Society, a model, accompanied with a drawing and description of a machine for working a boat against the stream, by means of a steam-engine, was laid before the Society by John Fitch.”

“ At a meeting of the American Philosophical Society on December 2, 1785, a copy of the drawing and description of a machine for working a boat against the current, which some time ago was laid before the Society by Mr John Fitch, he this evening presented to them.

“ Extract from the Minutes,

“ SAMUEL MAGAW,

“ one of the Secretaries.”

—“ In October I called on the ingenious Mr Henry of Lancaster, to take his opinion on my *drafts*, who informed me that I was not the first person who had thought of applying steam to vessels; that he had conversed with Mr Andrew Ellicot as early as 1775, and that Mr Paine, author of *Common Sense*, had suggested the same thing to him in the winter of 1778.”

“ In Virginia I waited on his Excellency General Washington, who, in the course of conversation, informed me, that the thought of applying steam was not original; that Mr Rumsey had mentioned steam to him: but nothing that passed in the conversation with General Washington had the least tendency to convey the idea of Mr Rumsey's relying on steam; and General Washington's letter, p. 10 of Mr Rumsey's pamphlet, clears up the matter—for the General himself did not conceive any such thing. Knowing that the thought of applying steam to boats had been suggested by other gentlemen long

before; I left his Excellency, with all the elated prospects that an aspiring projector could entertain, not doubting but I should reap the full benefit of the project: for although I found that *some* had conceived the thought before, yet I was the first that ever exhibited a plan to the public; and was fully convinced that I could not interfere with Mr Rumsey, otherwise the known candour of General Washington must have pointed out to me such interference. I immediately applied to the Legislature of Virginia for assistance to execute my plan, who signified their wish to encourage my designs, but that the state of their finances prevented it.”

“ Finding that undoubtedly I was the first person in America that could be termed the inventor of a steam-boat, either agreeably to custom or equity, I thought it prudent to apply to the different states for the exclusive privileges for the emoluments of such invention, which were granted by New Jersey in March 1786, by Delaware, New York, and Pennsylvania, in the winter and spring following, and by Virginia in October 1787.

“ I have from the time of my first thought pursued my scheme with unremitting application, without a suspension of an interruption, until the circulation of Mr Rumsey's invidious pamphlet, the contents of which I now find it necessary next to take under consideration, not doubting but that the design and tendency of that production will be a sufficient apology for the plainness with which I shall treat it.”

“ Mr Rumsey says, in page 2, that ‘in the month of September 1784, he exhibited the model of a boat to his Excellency General Washington, at Bath, in Berkeley county, calculated for stemming the current of *rapid rivers only*, constructed on principles very different from his present one. Satisfied,’ says he, ‘of the experiment of her making way against a rapid stream, *by the force of the stream*, the General was pleased to give me a most ample certificate of her efficacy.’ Here it is to be observed, that no mention was made to General Washington of *steam* at the time of such exhibition: the principles upon which the boat was propelled were entirely unconnected with, and distinct from steam; being simply a model, propelled by *water wheels, cranks, and setting poles*: a mode which was many years ago tried on the river Schuylkill by a farmer near Reading, but without success. From an exhibition of this plan it was that Mr Rumsey procured the certificate from General Washington, and on that certificate were Mr Rumsey's laws founded. In his petitions to the several legislatures, he prayed for no exclusive right for the use of steam-boats; neither did he make mention of steam to their committees, or even suggest an idea of the kind.”—

Patrick Miller, Esq. of Dalswinton, in Dumfriesshire, made many experiments on the best mode of impelling single, double, and triple vessels with paddle-

Mr Miller of  
Dalswinton.

\* *The Original Steam-Boat supported; or a Reply to Mr James Rumsey's Pamphlet, showing the true priority of John Fitch.* Philadelphia, 1788.

Steam-  
Navigation.

wheels, by the power of men and horses; and printed and circulated extensively an account of a *Triple Vessel and wheels*, in February 1787. In this Tract, he states,—“I have also reason to believe that the power of the *Steam-Engine* may be applied to work the *wheels*, so as to give them a quicker motion, and, consequently, to increase that of the ship. In the course of this summer (1787), I intend to make the experiment.”

As the power of men produced only the slow motion of five miles *per* hour, Mr James Taylor, then residing in Mr Miller's family, and now at Cumnock, suggested the application of a steam-engine as the moving power; and he carried Mr Miller to the house of Gilbert Meason, Esq. St Andrew's Square, Edinburgh, to see the model of a *steam-carriage* invented by Mr William Symington of Falkirk. Mr Miller was much pleased with the model, and desired Mr Symington to make him a small steam-engine, to work a *twin* or *double* boat on Dalswinton Loch. The engine having been accordingly executed and put on board the boat, the experiment was made at Dalswinton in autumn 1788; and it succeeded so well, that Mr Miller commissioned Mr Symington to purchase a *gabert*, or large boat, at Carron, and to fit up a steam-engine on board of her, to make a trial on a larger scale. Every thing being completed, the trial was made on the Forth and Clyde Canal, in summer 1789, Messrs Miller, Stainton, Taylor, &c. being on board, and the result answered their most sanguine expectations.

Mr Syming-  
ton.

From a manuscript *Memorial on Steam-Navigation*, drawn up by Mr Symington, with the perusal of which we have been favoured, we make the following extract:

“Mr Miller being then very much engaged improving his newly purchased estate in Dumfries-shire, and I also employed to construct large machinery for the use of the lead-mines at Wanlockhead, the idea of carrying the experiments, at that time, any farther, was entirely given up, till meeting with the late Thomas Lord Dundas of Kerse, who wished that I would construct a steam-boat for dragging vessels on the Forth and Clyde Canal, in place of horses. Agreeably to his Lordship's request, a series of experiments, which cost nearly L. 3000, were set on foot in the year 1801, and ending in 1802, upon a larger scale, and more improved plan, having a steam cylinder 22 inches diameter, and four feet stroke; a complete model of which, with a set of ice-breakers attached, may be seen (if not in Lord Dundas's house, Arlington Street) in the Royal Institution, London, which proved itself very much adapted for the intended purposes, as will appear from the following simple yet authentic narrative. Having previously made various experiments, in March 1802, at Lock No. 20, Lord Dundas, the great patron and steam-boat promoter, along with Archibald Speirs, Esq. of Elderslee, and several gentlemen of their acquaintance being on board, the steam-boat took in drag two loaded vessels, *Active* and *Euphemia* of Grangemouth, Gow and Espline masters, each upwards of 70 tons burthen, and with great ease carried them through the long reach of the Forth and Clyde Canal, to Port-Dundas, a distance of 19½

VOL. VI. PART II.

Steam-  
Navigation.

miles, in six hours, although the whole time it blew a very strong breeze right a-head of us; so much so, that no other vessels could move to windward, in the canal, that day, but those we had in tow; which put beyond the possibility of doubt the utility of the scheme in canals or rivers, and ultimately on open seas; though in this state of forwardness it was opposed by some narrow-minded proprietors of the navigation, under a very mistaken idea, that the undulation of the water occasioned by the motion of the wheel would wash and injure its banks: in consequence the boat was, with great reluctance, laid up in a creek of the canal, near Bainsford Draw-bridge, exposed for years to public view; where Henry Bell from Glasgow, who frequently inspected the steam-boat at Carron in 1789, did also particularly examine this; and afterwards, in conjunction with other gentlemen, in the year 1811, constructed the first steam-boat, *Comet*, to ply on the river Clyde, which was soon followed there by many more, and its use is now rapidly extending to different regions of the globe.”

It is indisputable, therefore, that Mr Symington was the first person who had the merit of successfully applying the power of the steam-engine to the propulsion of vessels. The boat which he constructed was, like that proposed by Halls, really a *Tug*. It is much to be regretted, that there existed not enterprise enough at that time in Scotland to encourage the ingenious artizan to repeat his experiments on the Clyde. All the subsequent improvements, however, in steam-navigation may be fairly traced to Mr Symington's attempt, and we cannot help thinking that he has a strong claim on the national gratitude. He is still alive, and we fear not in the most flourishing circumstances. Should the state decline rewarding such meritorious services, the opulent proprietors of steam-boats might well evince their liberality and discernment, by bestowing on him some recompence.

Considering the importance to America of navigating her mighty rivers, it is not surprising that the application of the power of steam to the propulsion of boats should, by persevering efforts, have been first carried into successful practice in that continent. This was achieved by the activity and zeal of Mr Fulton, who appears evidently, however, to have derived all his primary knowledge of the subject from Scotland.

Mr Symington's *Memorial*, above referred to, gives the following remarkable statement:

“When engaged in these last experiments in 1802, I was called upon by Mr Fulton, who very politely made himself known, and candidly told me that he was lately from North America, and intended to return thither in a few months, but having heard of our steam-boat operations, could not think of leaving this country without first waiting upon me in expectation of seeing the boat, and procuring such information regarding it as I might be pleased to communicate; he at same time mentioned, however advantageous such invention might be to Great Britain, it would certainly become more so in North America, on account of the many extensive navigable rivers in that country; and as timber of the first quality, both for

Steam-  
Navigation.

building the vessels, and also for fuel to the engine, could be purchased there for a small expence, he was decidedly of opinion it could hardly fail, in a few years, to become very beneficial to trade in that part of the world; and that his carrying the plan to North America could not turn out otherwise than to my advantage; as, if I inclined it, both the making and superintendence of such vessels would naturally fall upon me, provided my engagements with steam-boats at home did not occupy so much of my time as to prevent me from paying any attention to those which might afterwards be constructed abroad.

“Mr Fulton having thus spoken, in compliance with his most earnest request, I caused the engine fire to be lighted up, and in a short time thereafter, put the steam-boat in motion, and carried him from Lock No. 16, where the boat then lay, four miles west the canal, and returned to the place of starting, in one hour and twenty minutes, to the great astonishment of Mr Fulton, and several gentlemen, who, at our outset, chanced to come on board.

“During the above trip, Mr Fulton asked if I had any objections to his taking notes respecting the steam-boat, to which question I said, none; as I considered the more publicity that was given to any discovery intended for general good, so much the better; and having the privilege secured by letters-patent, I was not afraid of his making any encroachment upon my right in the British dominions; though in the United States, I was well aware, I had no power of control. In consequence, he pulled out a memorandum-book, and, after putting several pointed questions respecting the general construction and effect of the machine, which I answered in a most explicit manner, he jotted down particularly every thing then described, with his own remarks upon the boat, while moving with him on board, along the canal; but he seems to have been altogether forgetful of this, as, notwithstanding his fair promises, I never heard any thing more of him, till reading in a newspaper an account of his death.

“From the above incontrovertible facts, which can be corroborated by a number of people of respectability living at this day, it is very evident that commerce is not indebted to North America for the invention of steam-packets, it being hereby established beyond the possibility of doubt, to be truly British, both in idea and practice, and that Mr Fulton's steam-vessel did not make its first appearance in the Hudson River earlier than 1806 or 1807, four years at least posterior to his having been on board the Charlotte Dundas steam-boat, and minutely examined it, when at work upon the Forth and Clyde Canal, and 18 years later than the date of the first experiments made by me upon steam-boats, on the lake at Dalswinton, Dumfries-shire, in Great Britain.”

Mr Henry  
Bell.

The following statement upon the same point, by Mr Henry Bell of Glasgow, was addressed by him to the Editor of the *Caledonian Mercury*, and published in that paper in October 1816:—“SIR, I observed in your paper lately a paragraph respecting steam-boats, in which the Americans claimed the right to the discovery, which is become of so much utility to the public. On this account I propose to give you a full statement of

what I conceive to be the truth. Mr Miller of Dalswinton first wrote upon the method of moving or impelling vessels or rafts through water by paddles, wrought by a capstan, or by the wind, in the manner of a wind-mill, which idea he afterwards gave to all the different Courts in Europe. It will be recollected by most people in this country, that the French proposed to erect rafts for conveying troops to invade this country by means of Mr Miller's wind-mill or capstan plan; for it may be stated that this gentleman built two vessels at Leith, and put them in motion upon his new improvement, and even sent one of them to the King of Sweden, as a present. After this, he thought that an engine could be so constructed as to be applied to work his machinery for the moving of his paddles; and accordingly he employed an engineer to put his plans in execution; but they failed for want of being properly executed.—But to give you a more correct account of the manner Mr Fulton, the American engineer, came to the knowledge of steam-boats, that gentleman had occasion to write me about the plans of some machinery in this country, and begged the favour of me to call on Mr Miller of Dalswinton, and see how he had succeeded in his steam-boat plan; and if it answered the end, I was to send him a full drawing and description of it, along with my machinery. This led me to have a conversation with the late Mr Miller, and he gave me every information I could wish for at the time; I told him where, in my opinion, he had erred, or was misled by his engineer; and, at the same time, I told him that I intended to give Mr Fulton my opinion on steam-boats: the friends of Mr Miller must have amongst their papers Mr Fulton's letter to me, for I left it with Mr Miller. Two years thereafter I had a letter from Mr Fulton, letting me know that he had constructed a steam-boat from the different drawings of machinery I had sent him out, which was likely to answer the end, but required some improvement on it. This letter I sent to Mr Miller, for his information, which must also be among his papers. This letter led me to think of the absurdity of writing my opinion to other countries, and not putting it in practice myself in my own country; and, from these considerations, I was roused to set on foot a steam-boat, for which I made a number of different models, before I was satisfied. When I was convinced that they would answer the end, I contracted with Messrs John Wood and Company, ship-builders in Port-Glasgow, to build me a steam-vessel, according to my plans, 40 feet keel, and 10 feet 6 inches beam, which I fitted up with an engine and paddles, and called her the *Comet*, because she was built and finished the same year that a comet appeared in the north-west part of Scotland. This vessel is the first steam-boat built in Europe that answered the end, and is at this present time upon the best and simplest method of any of them; for a person sitting in the cabin will hardly hear the engine at work. She plies on the Frith of Forth, betwixt the east end of the Great Canal and Newhaven, near Leith. The distance by water is 27 miles, which she performs, in ordinary weather, in 3½ hours up, and the same down. There were many attempts to make steam-boats in this country

Steam-  
Navigation.

Steam-  
Navigation.

before this one, but none of them ever answered the end; and even three years after the Comet was set a sailing, there was a number of our first rate engineers joined together, and obtained a patent for what they conceived a new discovery on the paddles for impelling the vessel forward. They were disappointed in their plan, and had to return to the mode of the Comet."—

The first American steam-boat which completely succeeded was launched at New York on the 3d October 1807 (five years before the construction of the Comet at Port-Glasgow), and soon after plied between that city and Albany, a distance of 160 miles.

In Britain, steam-vessels were first brought into use in 1812 upon the Clyde. They were built at Port-Glasgow, Greenock, and Dumbarton, where the art of ship-building had for many years been conducted by carpenters eminent in their profession. When launched, they were towed at a very trifling expence up the Clyde to Glasgow, situated in the midst of inexhaustible mines of coal and iron, and where the number of skilful practical engineers and artificers rendered the construction of the engines and machinery easy, and the prices moderate.

The early experiments were, of course, made upon a small scale. The first steam-boat actually put to use there was the Comet (40 feet keel, 10½ feet beam, 4 wheels, 4 shovel-shaped paddles on each, with a cistern of fresh water to feed the boiler), built, as already mentioned, by Mr Henry Bell. She had an engine of only three horses' power, being intended merely for passengers; who, till then, had no other means of conveyance on the river than small row boats, either quite open, or supplied with only an awning to secure them from the weather. Small as this engine was, it rendered the passage certain in one tide; the vessel being able to make head-way even against the wind, and in rough weather.

The success of the first experiment soon excited competition; and a larger vessel, the Elizabeth (58 feet on deck, 11 feet beam, with an engine of 8 horses power), was completed in March 1813, and for a time proved very profitable to the proprietors. The third boat, the Clyde, which began plying in July of the same year, was still larger in her dimensions; being 70 feet keel, 75 feet on deck, 13 feet beam, with an engine of 14 horse power.

At present there are about thirty-five steam-vessels on the Frith of Clyde, some of which sail from Glasgow almost every hour, or half-hour, during day-light, to the various ports on the river, and the lochs communicating with it; as Dumbarton, Helensburgh, Loch-Long, Rothsay, Loch-Fine, and Campbellton, on the right bank, and Port-Glasgow, Greenock, Gourock, Innerkip, Largs, Milport, Ardrossan, Ayr, Irvine, Girvan, Stranraer, &c. on the left bank. Many of them occasionally visit Islay, Mull, Staffa, Icolmkill, and adjacent islands, during the summer months; and also Londonderry, Coleraine, and other ports of Ireland. Several vessels of larger dimensions, are employed as regular packets to Belfast, the Isle of Man, Liverpool, &c., and thus a constant communication between the united kingdoms is main-

Steam-  
Navigation.

tained. Since 1821, two steam-vessels have regularly sailed from Leith to Aberdeen, calling at several of the intermediate ports. Five or six steam luggers are constantly employed as lighters and druggers of other boats, for the speedy conveyance of goods from Glasgow to the ports of exportation, and occasionally towing large vessels in or out of harbour. The annual voyages of each of these 35 vessels may be averaged at 10,000 English miles; consequently, the whole sail 350,000 miles yearly, or nearly 14 times the circumference of our globe.

The success of steam-vessels at Glasgow soon excited attention in other quarters, and several of the Clyde vessels were purchased as models. It is worthy of mention, that shortly after the time of their appearance on the Clyde, Mr Lawrence of Bristol established a steam-boat on the Severn, and having carried her to ply on the Thames, the Company of Watermen made such opposition to this innovation, that he was obliged to take her back. Now, however, not only are all the chief navigable rivers in Britain thus navigated, but steam-vessels ply regularly from London to Aberdeen, sometimes passing the Pentland Frith.

On the Holyhead station, to carry mails between England and Ireland, there are three steam-vessels employed, viz. the Royal Sovereign, 210 tons, two 40-horse engines; the Meteor, 190 tons, two 30-horse engines; and the Ivanhoe, 165 tons, one 56-horse engine. They have answered the purpose much better than sailing vessels; as a proof of which, during the last year the latter were employed, exactly 100 Irish mails arrived in London *late*; while, during the nine months after the steam-boats were first established, only 22 arrived *late*; and that winter happened to be extremely boisterous. These boats use sails occasionally, and go to sea when sailing vessels dare not leave port. The average passage of the Royal Sovereign, from Houth to Holyhead, is six hours, fifty-seven minutes; from Holyhead to Houth seven hours, thirty-six minutes. Of the Meteor, from Houth to Holyhead, seven hours, four minutes, and back, eight hours, thirteen minutes. The average passage is half the time in which the average passage of sailing vessels used to perform the voyage. The shortest passage was from Houth to Holyhead, five hours, thirty minutes; which, the distance being about 73 miles, is nearly 12 miles an hour.

It is difficult to say what is the maximum speed of steam-vessels. Several of those between London and Margate make the voyage in seven hours and a half, a distance of 84 miles. The Hero made the voyage, wind and tide in her favour, in six hours, sixteen minutes. The Eclipse, from Belfast to Greenock, 120 or 130 miles, has been known to come in nine hours; and, on one occasion, having about 3000 square feet of canvas set, besides the engine at work, she came from Ailsa to Greenock at the rate of 9 miles. The Henry Bell, a new steam-trader between Glasgow and Liverpool, has delivered goods at various warehouses in Glasgow, several hours *before* the invoices, or advice of the shipment, had arrived *in course of post*. The New York steam-vessels run up

Speed of  
Steam-Ves-  
sels.Rapid Pro-  
gress of  
Steam-Nav-  
igation.

Steam-  
Navigation.

to Albany, 160 miles, in 21 hours, and down in 19; never in less than 19. They go from Newhaven to New York, 90 miles, in six hours and a half without sail; being nearly 14 miles *per* hour.

At present, steam-boats frequently ply between London and Dieppe, Rouen, Havre de Grace, Cadiz, Corunna, Alicant, Vigo, Lisbon, and other ports of France, Spain, and Portugal. One was lately established between Naples and Leghorn and Genoa; but soon abandoned, owing to the oppression of the quarantine laws, and the rapacity of the government of the Two Sicilies. Another steam-vessel was launched by an American gentleman on the Lake of Geneva, but, being a very bad sailer, it is about to be replaced by another. Every season they are becoming more numerous, and adventurous in sailing to greater distances and through heavier seas; such as the Bay of Biscay, the Mediterranean, the Baltic, the Gulfs of Finland, Bothnia, &c. A steam-packet, carrying the mail, now sails between Kiel, in Holstein, and Copenhagen. In the Adriatic, the Carolina goes every second day from Venice to Trieste, and the Eridano to Pavia; the latter voyage being usually accomplished in 37 hours. The Royal George steam-packet makes her passage from Portsmouth to Corunna in from 60 to 64 hours; a distance of between 400 and 500 miles.

Present State  
of Steam-  
Navigation.

Having thus endeavoured to give a sketch of the origin and progress of steam-navigation, we shall now proceed to describe the form and parts of a steam-boat (suppose of 100 tons), and to some other details, calculated to furnish a more particular view of the present state of steam-navigation in Britain and other countries.

Fig. 1, Plate CXVII., is an elevation; fig. 2, a longitudinal section; fig. 3, a ground plan; fig. 4, a transverse section. The same letters refer alike to the respective parts of each figure: A, the two boilers, with their two manhole doors, one to each; B, the chimney; C, the steam pipes; DD, the cylinders of the two engines; EE, the two air pumps; F, the side lever; one on each side of each engine; GG, the crank of the paddle-wheel shaft; H, the rod that works the steam valves or hand gear, moved backward and forward by an eccentric wheel on the shaft; I, the nozzles; K, pillars of the framing; LL, the area where the fireman stands to put coals into the furnace; MM, place where the coals are stowed away; NN, the paddle-wheels and covers; O, ladies' parlour; P, principal cabin; Q, second cabin; having each a raised lantern or sky-light, besides the lateral windows of P and Q; R, steward's room; S, breakfasting room; TT, refreshment rooms for the second cabin passengers; U, small boat ready to be let down on an emergency; V, rudder; WW, seamen's beds; XX, space for lumber or spare fuel. The fireman stands in the space LL; an iron trap-ladder leads down to it from the deck, flush with which are two horizontal gratings for the admission of fresh air to himself and the fire; his coals are built up behind him, and he brings down only a few lumps at a time, which he breaks into small pieces as required. The chimney B is a series of sheet-iron cylinders rivetted at the joints, and slipt the one over

the other. Each boiler has a flue within, making various convolutions under the surface of the water; through which the smoke and flame pass, until they enter the chimney.

Steam-  
Navigation.

These wheels being ponderous, acquire sufficient momentum to turn the crank, and supersede the necessity of a fly. The air-pump, feed-pump, and occasional cold water-pump, are wrought by rods from FF, the side horizontal levers. To prevent the waste steam of the boilers from annoying the passengers, a pipe conveys it into the chimney. Besides this, a waste steam valve is within reach of the engine-man, who loads and unloads it as he finds necessary. It is a curious fact, that a great flow of steam into the chimney prevents black smoke from issuing from it, which otherwise would. The paddle-wheels are firmly wedged on their shaft, and whatever pressure they exert against the water causes an equal re-action on the vessel, which is thus impelled either forwards or backwards according to the direction of circumvolution.

The principal cabin is painted, and otherwise tastefully fitted up, and furnished with a stove, the chimney of which rises up through the deck. The second cabin occupies the fore-end of the vessel, and is also completely furnished, less elegantly. Small steam-boats from 30 tons upwards are generally laid out much in the same way, only varying according to the nature of their employment. When intended for sea voyages, a great part of the internal space is allotted for sleeping births.

Plate CXVI. exhibits a sketch of one of the Clyde vessels, the *City of Glasgow*, of 300 tons.

The following is an alphabetical list of steam-vessels built in Britain:

When Built.	Names of Vessels.	Ton- nage.	Engines.	Horse Pow.

The Soho, the largest vessel in this list, indeed the largest steam-vessel yet built in Europe, was launched in July 1823, intended to ply between Leith and London, a distance of about 460 miles. She is impelled by two engines of 60 horse power each; her length of deck is 163 feet; breadth 27; depth of hold 16 feet, 10 inches; burden 510 tons. Her accommodations are extensive, having space for 112 beds. The ladies' cabin is eight feet high.

The Soho is, however, of somewhat smaller dimensions than the American steam-boat, the Chancellor Livingston, plying on the Hudson river between New York and Albany, constructed by Mr Fulton. The following are some particulars respecting this vessel. Her keel is 154 feet long; deck 165; 32 broad; burden 520 tons; draft of water about seven feet three inches; principal cabin 54 feet long, 7 high; ladies' cabin, above the other, 36 long, with closets; forward cabin 30 long, 7 high. Permanent sleeping-births, in principal cabin, 38; in ladies' cabin, 24; in fore cabin, 56; in captain's cabin on deck, 2; engineers' and pilots', 3; fore-castle, 6; fire-men, cooks, &c., 6; total, 135. Her engine is of 75 horse power; diameter of cylinder 40 inches, length five feet; piston rod, 8½ feet; stroke, five feet; boiler, 28 feet long, 12 broad, with two funnels; paddle-wheels, 17 feet diameter; paddle-boards five feet, ten inches long, with two fly-wheels, each 14 feet diameter, connected by pinions to the crank wheel. The machinery rises 4½ feet above the deck. Average rate of sailing eight and one-half to eight and three-fourths miles an hour. With a strong wind and tide in her favour, she has made twelve; but with a strong wind and tide, against her, not more than six miles *per* hour. The hands employed on board are—13 mariners, 11 cooks, waiters, stewards, &c.;—in all 24.

This vessel, however, is still much surpassed in size by the Lady Sherbrooke, of 787 tons, and 60 horse power; being the largest of eight which ply on the river St Lawrence. This gives 13 tons for each horse power, whereas in the Soho the same burthen has three times as much action applied to it. The American steam-vessels, though fast sailers, are thus impelled by comparatively smaller engines than those built in this country.

It appears from the *Report of the Select Committee of the House of Representatives*, for session 1817, that there were then 17 large steam-boats in constant employment on the American rivers, besides

ferry-boats. But since that time they have increased so rapidly, that there are now (1823) about 300.

The following are the names of 35 vessels, and their tonnage, plying on the Mississippi and its tributary rivers alone, viz. Alabama, 200 tons; Buffalo, 300; Cedar Branch, 250; Cincinnati, 120; Constitution, 75; Eagle, 70; Etna, 390; Exchange, 200; Experiment, 40; Frankfort, 320; General Jackson, 200; General Pike, 250; Governor Shelby, 120; Harnot, 40; Hecla, 70; Henderson, 85; Independence, 300; James Monroc, 90; James Ross, 320; Johnston, 80; Kentucky, 80; Louisiana, 54; Madison, 200; Maysville, 150; Napoleon, 332; Ohio, 443; Paragon, 400; Rifleman, 250; Rising States, 150; St Louis, 220; Tamerlane, 320; Vesta, 100; Vesuvius, 390; Volcano, 250; Washington, 400;—in all 7259 tons.

Belonging to some of the States, there are steam frigates and ships of war carrying guns, some of them 100 pounders. These vessels are 13 feet thick in the sides, of alternate layers of oak and cork; are so constructed, that they can eject boiling water on their enemies; and there are cases of cutlasses and pikes which project from their sides, and draw back again every fifteen seconds.

The Savannah, of 350 tons, was the first steam-vessel that crossed the Atlantic. She arrived at Liverpool 20th June 1819, in 21 days from land to land; 18 of which her engine was going; her daily consumption of coal was about 10 tons, so that she must have had at least 200 on board, leaving 150 for the weight of engine and cargo. Her paddles were occasionally taken off, when she sailed by wind and the whole of the paddle-wheels were capable of being taken to pieces and shipped, in case of bad weather. As the distance is not much short of 4000 miles, she must have averaged nearly 200 *per* day.

By far the greatest number of steam-vessels use low pressure engines. A larger proportion of American vessels have high pressure engines than in this country. High pressure engines are wrought with steam of a great variety of strengths, from 30 to 160 lbs. *per* square inch. Some engineers assert, that it is capable of being used at 1000 lbs. The steam is not condensed, but, after having acted on the piston, is allowed to blow off into the air. The diameter of their steam cylinders may be made of any size proportioned to the strength of the steam used. Thus, when it is 160 lbs., the area of the cylinder may be only a sixteenth part of the area of one using steam of 10 lbs.; consequently, a five inch cylinder wrought with such strong steam will be equal in power to a 20 inch cylinder wrought with such weak steam. High pressure engines require neither air-pump, conductor, nor the parts therewith connected; and as the volume of steam used is in proportion, their boilers may consequently be much smaller. Hence these engines occupy less room and tonnage, and require somewhat less fuel; but the risk of explosion is considerable. Were it otherwise, they would be very valuable at sea, because their power can be increased on emergencies, by merely increasing the fire, whereas the power of condensing engines is much more circumscribed, and confined to their original construction. The free effective power of large

SKETCH OF THE CITY OF GLASGOW STEAM BOAT

Steam-Navigation. low pressure engines is about eight or nine lbs. per square inch of their steam pistons, and of small ones under 30 horses, only seven or eight.

occupy the whole tonnage even of a large vessel. The *Rapid*, of 130 tons burden, and 60 horse power, required nearly a ton of coals every two hours, and could not therefore continue at sea above eleven days; and we have seen that the *Savannah*, which crossed the Atlantic, consumed ten tons of coals every day, or 210 tons during the passage of 21 days, leaving only 140 of surplus tonnage. Unless some great discovery, indeed, be made on the concentration of heat, we shall never dispatch steam-packets directly to the East or West Indies.

Steam-Navigation  
Steel-Engraving.

General Observations as to the Improvement of this Art. It is remarkable that, after the first successful trial, very little improvement has been made in the construction of steam-vessels. Experience has only fixed the suitable proportions of the several parts. Much, however, still remains to be done. The great objects wanted are to increase the power of the engine; to avoid the waste of force in the play of the paddles; and to render their action more equable. Notwithstanding the number and variety of steam-engines which have been erected in this island, it is truly surprising that some of the most important points of theory should be left uncertain and subject to dispute. We have neither ascertained exactly the density of steam formed under different pressures, nor the quantity of heat absorbed in its formation. Most of the conclusions of engineers are drawn rather from analogy than from facts; and a new set of experiments on steam, conducted with scrupulous attention, and on a comprehensive plan, are much wanted at present to guide all our practical operations. It seems probable that the most economical engines, on the whole, are those which work under a high steam pressure, though the statements given by different authors cannot be easily reconciled. The vapour of other fluids has sometimes been proposed instead of the steam from water. It would be an important object gained, if the same elastic force could be created with less expence of heat. The prodigious consumption of coals by the boilers proves a great hindrance to the extension of steam-navigation. The store of this ponderous species of fuel required for the supply of the engine in a distant voyage, would

The form and disposition of the paddles might certainly be improved. They seldom strike the water in the right direction, but splash it about, and leave it to impede the progress of the vessel. An irregular unpleasant motion is hence produced, and much force thereby lost. With a strong side-wind likewise, the larboard paddles are deeply immersed in the water, while the opposite ones are nearly suspended in the air, and scarcely act at all; the necessary consequence is, that, in such circumstances, the steam-vessel describes a winding path, and becomes unmanageable by the helm. Is it not possible to apply the immediate power of steam to propel vessels without dividing and diminishing its action by the intervention of a train of cranks and paddles?

Steam-navigation, though still limited in its operation, is a splendid triumph of ingenuity, and constitutes an epoch in the history of the mechanical arts. It has opened a most beneficial internal commerce in the vast regions of America; it has wonderfully facilitated the communication between the different parts of Europe; and by multiplying the friendly intercourse of men in all countries, it has essentially contributed to diffuse knowledge, to soften prejudices, and to quicken the efforts of general industry.\*

Steel-Plate Engraving.

STEEL, ENGRAVING UPON. At the first discovery of the Art of Printing from engraved metals, experiments would most probably be made with a view of ascertaining the fittest metal for the purpose; indeed it is known, that copper, tin, and silver, were employed by the early artists; and there are some prints, by Albert Durer, which are considered to be impressions from plates engraved or etched on steel. In the collection of Albert Durer's prints, in the British Museum, there are five of these prints, the chief of which are, *Christ in the Garden*, a print 6 inches by  $8\frac{1}{2}$  inches, dated 1515; the *Lady and the Monster*, 12 inches by  $8\frac{1}{4}$  inches, dated 1516; and the *Cannon*,  $12\frac{3}{4}$  inches by  $8\frac{1}{2}$  inches, dated 1518.

But, for the usual purposes of engraving, copper has some advantages which have led to its being nearly always employed in preference to other metals; and in one instance only have we found that steel plate was used for engraving upon in this

country, before the late attempts to prevent the forgery of bank-notes. The plate we allude to is the "*Ceiling of the Star Chamber*," in the *Topographical Illustrations of Westminster*, engraved by Mr J. T. Smith, in 1805.

The great expence of renewing plates for bank-notes, when any superior engraving is introduced, for rendering imitation difficult, suggested the idea of employing a harder material than copper to engrave upon. Steel plate was tried, and found capable of affording from 20 to 30 times the number of impressions that could be obtained from a plate of copper; while it was not much more difficult to engrave upon. The advantage to be derived from employing steel was first made public, in this country, in 1818, by the inquiry respecting the prevention of forgery, instituted by the *Society for the Encouragement of Arts, &c.* in London; when a specimen of engraving on soft steel was presented to the Society by the late Mr Charles Warren; and

\* This Article was written mostly by a Gentleman of Glasgow, well informed on the subject of Steam-navigation.—Ed.

Steel-En-  
graving.

it appeared, from evidence collected by the Committee, that notes, with ornamental borders, printed from steel plates, were then in use, in America. Soon after this period, Messrs Perkins and Fairman, from America, in conjunction with Mr Heath, an eminent engraver of London, formed an establishment for printing notes, and other engravings, from steel blocks.

The methods of engraving on steel, adopted by Warren and others, were similar to those employed in engraving on copper; differing only so far as was necessary on account of the nature of the material, and the process of hardening the plates. In addition to these methods, Perkins, Fairman, and Heath, employ a mechanical process for increasing the number of impressions. They first make the engraving on a thick plate of soft steel; the plate is then hardened, and the impression is transferred, in a spring press, to the surface of a soft steel cylinder, by rolling the cylinder repeatedly to and fro on the engraved plate, under a very considerable pressure. The transfer thus obtained is in relief, and the cylinder being hardened, it is made, by the same spring press, to repeat as many impressions as may be desired on soft steel, or on copper plates, for the purpose of printing from. They usually impress steel blocks, each of which will afford several thousand impressions, and when the cylinder becomes worn by transferring, a new one may be impressed from the original engraving; and, consequently, an inconceivable number of prints may be obtained from one original plate.

It ought, however, to be remarked, that an engraving cannot be transferred from steel to steel without injury; and that the injury will be greater in proportion to the spirit, freedom, and delicacy of the work. Indeed, where engravings are to be considered as works of art, it will always be preferable to engrave or etch on tempered steel, and print from it without hardening. A sufficient quantity of impressions may thus be obtained, and of a superior kind; because steel being more compact and hard than copper, it requires less labour to clean off the superfluous ink, and it is, consequently, less worn by this part of the process.\* But the power of transferring is of great value in all cases where a great number of impressions is the chief object desired; as in notes, plates for school-books, ornamental borders for pottery, labels, &c.

In preparing steel plates, for either engraving or etching, the surface should be well polished, so as to render it compact, of an equable degree of hardness, and perfectly smooth. The same tools are used as for copper, but they should be of the kind of steel which is endowed with the greatest degree of hardness and toughness. When a plate is to be etched, the point which removes the varnish should be sufficiently hard to penetrate the polish on the surface of the plate; the acid will then bite more freely and to a greater depth, without spreading so

as to produce a broad and shallow line. A point of diamond is, we believe, sometimes employed, particularly where the lines are drawn with the *ruling-machine*, invented by Mr Wilson Lowry, the founder of a new school of engraving, which has been of infinite use in diffusing correct taste in architecture and sound knowledge in mechanics. The same ingenious artist observed, in the first etchings on steel, that the lines were broad without depth; and, in consequence, tried to find a *menstruum* that would answer the purpose better than the common acids; in this he perfectly succeeded, and was enabled to bite the lines deep, and yet preserve the desired degree of fineness. This discovery he subsequently disposed of to Mr Heath: the exact nature of the process we have not been able to ascertain.

Of the common acids, diluted muriatic acid seems to answer best, but diluted nitric acid produces nearly the same effect.

When the plate is not to be hardened after being engraved, one of a spring temper may be employed; and if etching only is to be done on the plate, thin steel of a harder temper might be used; but the hardness must not be greater than will admit of its being scratched by the tracing point; otherwise a fine line cannot be produced of the necessary depth.

When the graver is to be much employed on a plate, it should be annealed (see ANNEALING in this *Supplement*), in order to render it uniformly soft. The plate, after being engraved, may be hardened most effectually, and with the least injury to the engraving, or risk of warping the plate, by heating it in a metallic bath, and quenching the whole in a cooling fluid. A bath of the fusible alloy of lead, tin, and bismuth, which Dr Wollaston proposed for hardening delicate steel-work, will, perhaps, answer better than any other. (See CUTLERY, p. 457, Vol. III. of this *Supplement*.) It will always be an advantage to employ a perfectly fluid medium for cooling; and we have reason to conclude, from some hasty experiments, that water heated to its boiling point is better than cold water for cooling steel: the quick abstraction of heat, by converting water into steam, seems to have more effect than the mere cooling power of a large body of cold water.

If plates are not to be transferred, there is some disadvantage in employing thick ones; and more especially in cases where an alteration may be necessary, or a mistake is to be rectified. In a thin steel plate it is as easy to rectify an error as in copper; but in a thick one it is a troublesome process.

Mezzotinto engraving on steel is also found to answer equally as well as the other kinds; some very fine prints have lately been done in this manner; and the great number of impressions a steel plate affords, will cause this beautiful style of engraving to be more generally cultivated.

The advantages of copper consist in its being

\* A steel plate, which had not been hardened, has been known to afford 95,000 impressions without material injury.

Steel-En-  
graving  
||  
Stirlingshire.

more easily prepared for engraving upon; in its softness, which renders it less difficult to engrave; and in the small degree of care necessary to protect the plate from injury, whenever it is not necessary to print at once the whole number of impressions the plate will afford. Now, it will always be difficult to preserve steel plates without more care and attention than can at all times be ensured; hence, each metal has its peculiar excellence; steel for the supply of a rapid and extensive demand; copper for the slow and regular progress of works on the sciences and arts.

As printing from engraved steel is now much used as a means of preventing forgery, we shall close this article with a few remarks on that subject. It appears to us, that there should be nothing complex in the figures that are selected for the engraving; their excellence should consist in the perfect evenness and parallelism of lines, whether straight or curved; but curved lines of difficult kinds should be preferred. Many crossings render a pattern intricate and confused: they distract the attention and dazzle the sight. Wavy patterns, with scattered lights, have the same effect. In such cases it is difficult to compare one specimen with another; and a general imitation is not so easily detected. It will be desirable to unite the work of an artist to that of a mechanical engraver; and in such cases the subject should be of sufficient size to allow of its being distinctly made out; because it will increase the difficulty of imitation. Where the circulation of notes is limited, good engraving on the note will be an effectual check upon forgery; but the notes of different banks should be made as distinct as possible, instead of the same work being introduced in different notes, as may easily be done with steel cylinders. Where a whole empire is served with one kind of notes, the temptation to forge is so great that it cannot perhaps be altogether prevented; and, therefore, while every proper expedient should be used to increase the difficulty of forgery, no apparent difficulty of copying should render bankers and others less on their guard against it.

See *Report of the Committee of the Society of Arts, &c. on the Mode of Preventing the Forgery of Bank-Notes*, 8vo. London, 1819. *Edinburgh Philosophical Journal*, Vol. III. p. 140. (H. H. H.)

STEREOTYPE PRINTING. See the Article PRINTING in this Supplement.

STIRLINGSHIRE, a county in Scotland, situated between  $55^{\circ} 55'$ , and  $56^{\circ} 17'$  north latitude, and between  $3^{\circ} 17'$ , and  $4^{\circ} 40'$  west longitude, on the isthmus between the Friths of Forth and Clyde. It has the counties of Perth and Clackmannan on the north, the Frith of Forth and Linlithgowshire on the east, Lanarkshire on the south, and Dunbartonshire on the south-west and west; and, extending from 12 to 17 miles from north to south, and about 35 from west to east, contains 645 square miles, or 412,800 English acres; divided into 21 entire parishes, with portions of other four, which partly belong to the adjoining counties. The river and Frith of Forth is, for the most part, the boundary on the north, though one entire parish, and parts of other two are on the north side of that river; on the

west it includes part of Lochlomond, and a narrow neck runs out on the north-west, the east side of which touches Loch Katrine. Like many other of the Scottish counties, it is of a very irregular form, yet most of its outline is well defined. Besides the Forth on the north and north-east, the Avon marks its separation from Linlithgowshire, on the east and north-east; the Kelvin flows along a great part of the southern boundary; and the Endric, before entering Lochlomond, divides it for some distance from Dunbartonshire on the west.

About two-thirds of Stirlingshire consist of hills unfit for cultivation, but affording good pasturage for sheep; being chiefly covered with green herbage, though sometimes intermixed with heath. The principal tract of this description, called the Lennox Hills, runs across the county, from Dunbartonshire on the west, to the town of Stirling on the north, but it seldom presents an elevation of more than 1500 feet. In other quarters, however, the elevation is greater; Benlomond, on the north-west, on the banks of Lochlomond, being 3262 feet high; and Bencloch, in the parish of Alva, on the north side of the Forth, upwards of 2400 feet. On the north, and still more on the east of the Lennox Hills, the country is low; the summit level of the Forth and Clyde Canal, which passes through the south-eastern side, being only about 162 feet above the sea, and much of the land along the Forth is a very rich plain, only a few feet higher than the water. Towards the western and southern extremities the surface is more varied, presenting tracts of heath, moss, and green pastures, intermixed with cultivated land; the latter confined, for the most part, to the banks of the streams.

Stirlingshire has every variety of soil common in Scotland; but that for which it is chiefly distinguished in this respect is the alluvial or *carse* land on the Forth; which is computed to extend to about 40,000 English acres within this county, and twice as much more in the adjoining counties of Perth, Clackmannan, and Linlithgow, or, in all, to about 200 square miles; certainly by far the richest tract in Scotland. It consists of the finest particles of earth, without stones; in point of friability approaching to the character of loam; in some places 30 feet deep, and seldom more than 25 feet above the level of the sea at high water; and contains beds of shells, moss, and clay marl. In one instance, at the depth of 19 feet, there have been found in a stratum of moss the roots of large trees, deer's horns, and bones, while the superior strata were composed entirely of fine earth.

Coal, limestone, ironstone, and sandstone, abound in this county. Coal has not been found to the north and west of the Lennox Hills, but prevails very generally along their southern base, from Baldernock on the west to Denny and St Ninian's on the east; and generally throughout all the eastern quarter, on both sides of the Forth and Clyde Canal. By means of the Union Canal carried from the city of Edinburgh to the Forth and Clyde near Falkirk (see EDINBURGHSHIRE in this Supplement), these extensive coal-fields have been rendered of easy access to the metropolis, which already receives large supplies of coal from that quarter at little more than two-thirds of the price which the inhabitants formerly paid for this neces-

Situation  
and Bound-  
aries.

Extent.

Stirlingshire. sary article. Limestone abounds in the same quarters with the coal, and in many instances there is one stratum of it above, and another below the coal, the former always of the best quality. Sandstone also frequently accompanies both, though it is found in other parts. At Kilsyth there is a quarry of white sandstone, which takes a fine polish, and has been often used in ornamental work. Ironstone is in great abundance throughout the coal district, and is wrought in several places to a considerable extent, chiefly for the use of the Carron works. It is also found in the parish of Kilsyth, in balls from a quarter of an inch to a foot in diameter, which are richer in metal than the common stone. Copper has not been discovered in veins so rich as to encourage their working, though mines were formerly opened at one or two places. Veins of silver were discovered, about sixty years ago, in the parishes of Logie and Alva, on the northern extremity of the county, and for a few weeks the working was very successful, but was soon abandoned. Cobalt was found in the same quarter. There are indications of other minerals in different parts of the county.

Rivers.

The Forth.

Besides the Forth, the Avon, the Kelvin, and the Endric, already mentioned, which, though having their sources in Stirlingshire, soon cease to belong to it exclusively, flowing for the most part on its boundaries, this district is well supplied with other streams, which traverse its interior. The Forth, however, is by far the most important. It rises from a spring on the northern side, and near the summit of Benlomon; after a course of eight or ten miles, under the name of the Water of *Duchray*, it passes into Perthshire, where it is called *Avendow*, or Black River; and soon after, on returning to the borders of this county, obtains the name of the Forth. A few miles above Stirling it receives the Teith, and afterwards the Allan, from the north, and Bannockburn from the south. The tide, which flows a little above Stirling, renders it navigable to that town for vessels of 70 tons. Below Stirling the river winds in a remarkable manner across its valley, making so little progress, that, following its course to Alloa, the distance is about twenty miles, while in a direct line it is scarcely seven. These windings are called the *Links* of the Forth. Below Alloa it receives the Devon from the north-east, and soon after expands into the large estuary called the Frith of Forth, which washes the north-eastern side of the county till it meets with Linlithgowshire, a little to the south of Grangemouth. Next in importance, and the only other stream worthy of particular notice, is the Carron, which, rising in the interior, pursues an easterly course, and joins the Frith of Forth at Grangemouth. It is navigable for vessels of 200 tons, as far as the village of Carron Shore, the shipping place of the Carron Company, nearly two miles from its confluence with the Forth. Besides Lochlomon, of which the greater part is in Dunbartonshire, several small pieces of water occur in different parts, none of them remarkable. Salmon are caught in the Forth, and also in Lochlomon, and, some years ago, afforded a revenue of L. 1200 or L. 1400 a year to the town of Stirling; but they are not now so numerous as formerly.

The valued rent of Stirlingshire is L. 108,509, 3s. 3d. Scots, and the real rent of the lands and houses in 1812 was L. 207,236, 8s. 8d. Sterling. In 1811, the number of estates was 147; of which 109 were below L. 500 Scots, and only nine above L. 2000 of valuation, thus indicating that the landed property was much divided; and not a fourth of the whole was entailed, a smaller proportion than in most parts of Scotland. The estates of the Duke of Montrose, Lord Dundas, Sir Charles Edmondstone, and Mr Forbes of Callendar, the principal proprietors, were then rented at from L. 8000 to L. 14,000, and several others were worth from L. 1000 to L. 4000 a year; but the greater number were below L. 1000. Some of the proprietors have increased the value of their estates by means of embankments on the Frith of Forth. Several hundred acres, much of it worth a rent of L. 5 an acre, have thus been reclaimed and brought into cultivation, and a great deal more may be gained in the same manner. All the small proprietors, and most of the great ones, reside upon their estates; and several of the latter occupy considerable farms of their own, which they have improved, and continue to cultivate in a very judicious manner. There is, accordingly, a great number of seats over all the lower parts of the county. Before the Union between England and Scotland, considerable tracts were granted to the retainers and dependents, or the tenants of the principal proprietors and their heirs for ever; subject only to the payment of the rent of those times, which is now very trifling. These are called *feuars* or *portioners*, and, in some parishes, form a pretty numerous class. Their houses and fields still present a tolerably faithful picture of the rural economy of Scotland a century and a half ago.

There is a good deal of both natural and planted wood in Stirlingshire, and much of the former, in the state of coppice, has long yielded a regular income to the proprietors, little if at all inferior to the average rent of the arable land. Of oak coppice alone the extent is near 4000 English acres, of which more than two-thirds belong to the Duke of Montrose, growing near his seat of Buchanan, on the western extremity of the county. The Buchanan woods seem to be under very regular management, being divided into twenty-four *hags* or portions, of which one is cut every year. A few years ago, this produced from L. 16 to L. 24 the Scots acre, after leaving a number of *reserves* to stand for timber. Every acre gives at a medium about one ton and a half of bark, which, during the late war, sold at L. 18; and the small timber generally pays expences. Much of the land on which this wood grows is of little value for any other purpose; not worth half-a-crown an acre. On the same estate, and also in other parts of the county, extensive plantations have been made within the last fifty years.

The mountainous parts of Stirlingshire are occupied with sheep of the black-faced or heath breed, and the lower hills by Highland cattle; and there the farms are necessarily of considerable extent. The arable land, however, is for the most part divided into small farms, especially the Carse lands on the Forth, where the general size does not exceed 50 or 60 acres. The rotation of crops, accordingly, as well as the

Crops.

Stirlingshire. general management, is seldom so good as on the Carse of Gowrie, a similar tract on the banks of the Tay in Perthshire, or in the border counties of Scotland. Yet very great crops of wheat and beans, and the other kinds of grain, are obtained from this naturally rich soil, which in many parts affords a rent of L. 4 and upwards the English acre. But besides a money rent, it is still not uncommon to exact poultry, carriages, &c. from the tenants; burdens which, though once general, are now almost unknown in those districts where an improved system has made the greatest progress. The land on the banks of the Forth is exceedingly well adapted for orchards, of which there are a few, but of no great extent. The island of Inchmurrin, in Lochlomond, the property of the Duke of Montrose, has been stocked with fallow deer for more than a century, the number about 240, which are properly attended to, and kept always in a thriving condition. Goats, about fifty years ago, were an important article in the western district near Lochlomond, much of the rent being then paid in kids and goat milk cheese; but they are now almost extinct.

Deer.

Manufac-  
tures.Carron  
Works.

The manufactures are carpets and other coarse woollens in the town of Stirling; paper, cottons, alum, copperas, soda, Prussian blue, &c. on an extensive scale near Campsie on the south-west quarter; spirits at several large distilleries, and iron goods at Carron. The *Carron Works*, celebrated all over Europe, were established upon the banks of the river of that name about sixty years ago, by Dr Roebuck and Messrs Caddel and Garbet, who were joined in the undertaking by several other gentlemen. By the charter of the company, they are authorized to employ a capital of L. 150,000, which is divided into 600 shares, and ten of these are required to give a vote in the management. During the late war they employed upwards of 2000 able bodied men, and paid in wages above L. 120,000 yearly. At these works all sorts of cast-iron goods are made, and also bar iron, said to be equal to the Russian; but particularly cannon and that kind called *Carronades*, which having been invented here, take their name from the works. The boring of the cannon is a very interesting operation, which is performed in about forty-eight hours by machinery moved by water. One of their engines raises upwards of 30 tons of water in a minute; and so extensive are the works, that they are said to consume every day about 200 tons of coals. They have water carriage from the Frith of Forth by means of the Carron, and to the Frith of Clyde by the Forth and Clyde Canal, which passes through the district, a little to the south of the Carron.

Commerce.

Notwithstanding the favourable situation of Stirlingshire, on a navigable river, and between the east and west seas, which for thirty years have been connected by a Canal, it has but a small town population, and till lately, its commerce was inconsiderable. Even now half its exports, not including its agricultural produce, is supposed to be furnished by the Carron works. The principal town is Stirling,

Towns.

containing, in 1821, 7113 inhabitants; a place of great antiquity, which, though situated on the navigable part of the Forth, has little trade by water, and is chiefly indebted for its importance to its situation on the confines of the Highlands. Falkirk, on the eastern side of the county, a little to the south of the Forth and Clyde Canal, had a population in 1821 of 11,536, and is distinguished for its great fairs or *trysts* which are held in August, September, and October; where cattle, sheep, and horses, are brought for sale, to the value of almost half a million Sterling. Grangemouth, founded by Sir Lawrence Dundas, in 1777, on the angle formed by the junction of the Carron and the Forth and Clyde Canal, is now a considerable village, and the principal sea-port of the county: its trade is chiefly with the north of Europe, and along the east coast. It has a custom-house, a dry-dock, and other necessary works. The depth of water in the harbour is generally in spring-tides from 16 to 18 feet, and in neap-tides from 10 to 12. In 1810, the shipping of this port exceeded 60,000 tons. The only other town is Kilsyth, on the borders of Lanarkshire. On the east side there are a number of small villages, occupied partly by agricultural labourers and mechanics, and partly by weavers employed by the Glasgow manufacturers.

The county, which, in 1822, had 118 freeholders, Representation only one member to Parliament; and Stirling, its only royal burgh, is associated with Culross, Dunfermline, Inverkeithing, and Queensferry, in the elections for the Scottish burghs. A poor-rate is levied here only in a few parishes; the poor being chiefly supported, as in most parts of Scotland, by voluntary contributions.

Stirlingshire exhibits remains highly interesting to the antiquary, and has been the scene of some of the most remarkable events in Scottish history. The Roman Wall, called the Wall of Antoninus, and vulgarly Græme's Dyke, which traversed this county, may still be traced in several places. The battle of Bannockburn, which secured the independence of Scotland, was fought on 24th June 1314, about three miles south from Stirling, where a stone is still shown in which the royal standard is said to have been fixed. The eastern side of the county was the scene of many other battles between the Scots and English; but these belong to the history of Scotland, and have been noticed under that head in the *Encyclopædia*. We may also refer on this point to Roy's *Military Antiquities* and Chalmers's *Caledonia*.

The population of Stirlingshire, according to the census of 1801, was 50,825; in 1811 it amounted to 58,174; and in 1821 to 65,376; of which 31,718 were males, and 33,658 females. The families employed in agriculture were 2600; in trade and manufactures 6641; in all other occupations 4492. The increase of population from 1811 to 1821 was 7202.

See the general works quoted under the former Scottish counties, and Dr Graham's *View of the Agriculture of Stirlingshire*. (A.)

## STONE-MASONRY AND STONE-CUTTING.

Stone-  
Masonry.  
Masonry  
Defined.

1. MASONRY is the art of building with stones: the art of reducing stones to regular or determinate forms is sometimes called *stone-cutting*, but is usually considered a branch of masonry. Workers in marble are also called masons; but it is stone-masonry only which we intend to treat of in this article; as marble masonry is rather a manual than a scientific art.

Early His-  
tory.

2. The art of building with stone is undoubtedly of great antiquity; and its early history is difficult to trace beyond the existing remains of ancient buildings; the oldest of which are objects of wonder, chiefly on account of the difficulty of moving, with ordinary powers, the immense stones of which they are formed. There is one thing remarkable in these stupendous efforts of human labour; its directors have often been happy in the choice of almost imperishable materials, for a lasting evidence of their command of power. The remains of this kind of gigantic masonry are found in various parts of the earth; some of the finest specimens are the ancient Egyptian buildings; which seem to have been intended to resist the power of men, as well as the slow operations of time.

Greek  
Masonry.

3. The masonry of the ancient Greeks closely resembles that of the Egyptians: it is a more refined application of the same principles of construction, to a series of chaste and beautiful architectural forms, in which the ornamental part of the art has evidently been in that state of perfection, which is rarely, if ever surpassed. The roof of the Octagon Temple of the Winds may be considered the best example of their constructive skill, while it betrays their ignorance of the principles of the arch.

Roman  
Masonry.

4. In Roman masonry we find less of ponderous strength, and sound construction, than in the Egyptian and Greek, and rarely any thing approaching to the accurate and highly finished labours of the latter, but considerably more artificial and economical knowledge. If the manner of forming arches\* and domes was not actually invented by the Romans, at least the merit of applying them successfully, in the art of building, was undoubtedly theirs; they also excelled in the composition of mortars and cements: hence, they found it easy to construct large works at a moderate expense, which could not have been accomplished by the limited methods of building of their predecessors. It gives us a high notion of the

intrinsic value of the art of masonry, to examine its application by the Romans, whether it be in the celebrated Cloacæ, Aqueducts, Bridges, or the Military Roads of those enterprising people. To them also we owe the beautiful idea of covering a temple with a dome.

Stone-  
Masonry.

5. After the decline of the Romans, the art of masonry, in Europe, gradually acquired its former importance through its application to the construction of castles, towers, and other places of defence; and eventually, it gained a complete ascendancy over the other building arts in the construction of Cathedrals, Monasteries, and the like. In our own island it made an equal if not a greater degree of progress than on the Continent. The science of masonry† appears to have attained the most perfect state it arrived at in those times, about the period when King's College Chapel, at Cambridge, was built (about 1512). From that time, or soon after, the knowledge of construction declined; but the researches of men of science have, in modern times, more than replaced those lost principles which, there can be little doubt, the elder free-masons possessed. Unfortunately, such principles are, even at the present time, as inaccessible to a plain workman as the mysteries of the master-mason were to the apprentice and fellow-craft of former ages; unless it be in some rare instances where the force of natural genius has risen superior to the difficulties before it, and a mere workman, like the "prentice of Roslin Chapel," has outstripped the masters of technical science.

Principles of  
Gothic Ma-  
sonry.

6. The most important principle of the free-masons, or, as they are usually called, the "Gothic builders," was that of reducing all the pressures of a vaulted roof to a few principal supports. These supports were either strong pillars, or buttresses, accordingly as the support was within the area, or formed a part of the external wall. The buttresses were made of considerable depth in the direction of the pressure, with a thin wall from buttress to buttress, for enclosing the building. If they had made the external walls of uniform thickness, according to the modern practice, a much greater quantity of material would have been required to balance the pressure of the vaulting. For similar reasons, the strength of their best vaulting consists in deep moulded ribs; the spaces between these ribs being formed of thin light stones, supported from rib to

\* Perhaps the oldest arches, at present known, are those which Mr Belzoni discovered in Egypt; they are executed in bricks of the same size, and of the same material, as those the Egyptians used in the construction of their walls and pyramids. For farther remarks on the subject of Arches, see the Article BRIDGE, in this Supplement; and the Earl of Aberdeen's *Inquiry respecting Grecian Architecture*, page 191—211.

† What other term than *science* can be applied to that knowledge, which enables a mason to dispose large masses of stone-work over a considerable area, with only a few distant supports?

Stone-Masonry.

rib. The principles of construction of the Gothic builders may be readily shown by a model of wicker work, in the manner of Sir James Hall's truly elegant mode of explaining his ideas respecting the origin of Gothic vaulting.\* The earliest notice we have seen, in architectural works, of any thing resembling the principles of construction just noticed, is given by Alberti, who, alluding to a method of building known to former architects, says, "The arches on which the roof was placed being drawn quite down to the foundation with wonderful art, known but to few; so that the work upheld itself by being only set upon arches; for those arches having the solid earth for a chain, no wonder they stood firm without any other support." †

Masonry of the Sixteenth and Seventeenth Centuries.

7. Masonry, with some other arts, having been drawn out of their ordinary course by the peculiar state of society in the middle ages, fell back to their common level, if not below it, at the Reformation; the natural consequence of this change was the loss of the greater part of the knowledge which had been gained by the experience of several centuries. But even in the most depressed state of masonry, there were some individuals in whom the love of that excellence which animated their predecessors, was not subdued by want of encouragement; and some scattered works were executed which are worthy of notice, if our limited plan would allow of it.

Present State of British Masonry.

8. When Britain had become happily free from all internal disturbances, and there was little to occupy the time and attention of a rapidly increasing population, except the improvement of their own condition in life; the chief fruit of their exertions for this purpose was, an unprecedented extension of the foreign and domestic trade of the country; wharfs, docks, harbours, and lighthouses; canals, locks, roads, and bridges, became the necessary appendages of this new state of things; and, accordingly, it became desirable again to cultivate the art of masonry.

These important works also called forth a new profession, of which the celebrated Smeaton has been called the father. Smeaton's first work was the Eddystone Lighthouse, which, in originality of design, and soundness of construction, has not been equalled. Since its erection, such a succession of bold and useful works have been accomplished, that it would be difficult to enumerate them; ‡ it is sufficient to remark, that the masonry of our own age and country, as it is exhibited in these works, is without a parallel in preceding times.

State of Masonry on the Continent.

9. In the northern states of Europe, their best works are chiefly modelled after ours; and, with the exception of France, there is not in the southern states any considerable degree of encouragement given to any branch of masonry. It may neverthe-

less be remarked, that the principles of construction is a popular subject of study in Italy.

Stone-Masonry. French Masonry.

10. In France, masonry has always been a popular art; partly, perhaps, from Paris being situated in the midst of a district which abounds in excellent building stone. The French government has always directed a considerable share of attention to the construction of roads, bridges, and military works; and, consequently, has afforded sufficient scope for its improvement. When, however, the larger works of the French masons are compared with those of our own countrymen, one very remarkable difference may be observed; the French works have more of the character of daring experiments, than that which ought to belong to the works of regular professors of an art; while the British works of the same kind have evidently been directed by men better versed in practical construction than in the refinements of science. There is, perhaps, more of novelty in the French works than is to be found in ours; but it may be remarked, that this novelty of character is often obtained by a sacrifice of fitness; as in the catenarian dome of the Pantheon, &c.; or of strength, as in the bridges of Nogent, Neuilly, &c. The true criterion of excellence in a useful art seems to be, fitness for producing the desired end in the best possible manner.

SECT. I.—OF MATERIALS USED IN MASONRY.

11. The first object of attention, in a treatise on Materials. masonry, ought to be, the nature of the materials employed in it; because the greater part of the principles of an art always depend on the nature of the substances it is to be exercised upon.

Of Stones.

12. Building stone is a dense, coherent body, of Nature of considerable hardness and durability, but generally Stones. brittle. It possesses these qualities in various degrees, according to the nature of its chemical elements, or the state of aggregation of its parts.

The structure of stones is either laminated or granulated, or of a mixed kind.

The chemical constituents of building stones are silica, alumina, lime, magnesia, and metals; combined with acids, water, and sometimes with alkalies; some other chemical elements are found in building stones, but not often in sufficient quantity to affect the nature of the stones.

13. Laminated stones consist of thin plates, or Laminated Layers, cohering more or less strongly together; Stones. when the layers are of considerable size, and cohere so slightly that they may be easily separated, the stones are said to be slaty. The layers are always nearly parallel to the quarry-beds of the stone, and they should always be horizontal, or as nearly so as

\* *Essay on the Origin, History, and Principles of Gothic Architecture*, London, 1813. Ware has collected most of the forms employed, in his *Tracts on Vaults, &c.* London, 1822.

† *Architecture* of Leon Baptista Alberti (Leoni's Translation), Book I. Chap. XII.

‡ See the Articles BELL-ROCK LIGHTHOUSE, BRIDGE, BREAKWATER, CALEDONIAN CANAL, DOCKS, in this Supplement.

Stone-Masonry.

possible, in a building; otherwise the action of the weather will cause them to separate, and fall off in flakes. In sandstones, the direction of the layers may often be discovered by their different shades of colour; in others, by the position of minute scales of mica, which always lie parallel to the layers. In most stones the direction of the layers may be ascertained by the facility with which the stone yields to the tool in that direction; but a considerable degree of practice is necessary to acquire so nice a discrimination of resistance, and good workmen only attain it. Among laminated stones, those are the most durable in which the laminæ are least distinct, and the texture uniform. When the laminæ do not perfectly cohere, they are soon injured by frost, and they are wholly unfit for places alternately wet and dry.

Granular Stones.

14. Granular stones consist of distinct concretions resembling grains, either of the same, or of different simple minerals cohering together. When the structure is uniform, and the grains or concretions are small, stones of this kind are always strong and durable, if the concretions themselves be so. Granular stones are sometimes open and porous, but when they are uniformly so, they seldom suffer materially by frost; because their uniform porosity allows the expansive force of congealing water to be distributed in every direction.

Compound Stones.

15. Stones of a compound structure, partly laminated and partly granular, have more or less of the characters of the two classes before described; for it may be observed in coarse-grained granite that the laminated structure of some of its parts renders it very susceptible of disintegration.

All kinds of stone obtained from quarries are found divided by vertical or inclined seams, which are sometimes so close that they cannot be distinguished till the stones are wrought; but they often separate under the tool at such seams; and it is not safe to employ stone to resist any considerable transverse strain on account of the difficulty of knowing where those seams are.

Durability of Stones.

16. In the present state of our knowledge of this important subject, we may attribute the failure of building stones to two causes; the one chemical, and the other mechanical, which we shall here distinguish by the terms decomposition and disintegration.

Decomposition.

17. Decomposition consists in the chemical elements of a stone entering into new combinations with water, oxygen, or carbonic acid gas. Stones containing such elements as are readily acted upon by these external causes will be found most subject to decompose; and the process will be, in many kinds, much hastened by a loose texture.

Stones containing saline matter, as the felspar of some granites, are acted upon by water, particularly where the soluble salt is in considerable proportion; and in some stones the application of salt water soon destroys them. Dolomieu says, the houses at Malta are built with a fine-grained limestone, of a loose and porous texture, which speedily moulders away when

it has been wetted with sea water. (Kirwan's *Geological Essays*, p. 148, 149.)

Stone-Masonry.

Stones containing iron, which is not in a maximum state of oxidation, are often destroyed by the absorption of oxygen and carbonic acid; the presence of moisture accelerates their decomposition, and it is always still further hastened by increase of temperature. According to the observations of Kirwan, stones containing iron in a low state of oxidation are of a black, a brown, or a bluish colour; and in some instances, when united with alumina and magnesia, they are of a gray, or a greenish gray; the former, as they become more oxygenized, change to purple, red, orange, and finally pale yellow; the latter become at first blue, then purple, red, &c. (Kirwan's *Geological Essays*, p. 145, 6.) But stones containing iron, combined with its maximum of oxygen, do not readily decompose, such are red porphyry, jaspers, &c. When stones contain manganese, lime, alumina, carbon, or bitumen, in particular states, they are subject to decomposition, from the affinities of one or other of these bodies; but nothing very decisive is, or perhaps can be, known respecting such changes, till some improvement be made in analytical chemistry, by which the state of combination of the constituents of minerals can be determined with more certainty.

18. Disintegration is the separation of the parts of stones by mechanical action. The chief cause is the

congelation of water in the minute pores and fissures of stones, which bursts them open, or separates small parts according as the structure is slaty or irregularly granulated. The south sides of buildings, in northern climates, are most subject to fail; because the surface is often thawed and filled with wet in the sunny part of the day, and frozen again at night. This repeated operation of freezing is also very injurious to sea walls, the piers of bridges, and other works exposed alternately to water and frost.\* The decay and destruction of rocks being the effects of the same natural causes, the reader will find some further illustration of this subject in the Article MINERALOGY in this *Supplement*, Vol. V. p. 477.

19. The resistance of stones to wear and tear is, for many purposes, a subject which it would be useful to investigate, since on this resistance depends also the labour of working them. From some experiments made by Rondelet, it appears that granite will bear eight times as much wear as veined white marble; and that the labour of sawing granite was about ten times greater than that of sawing veined white marble. (*Traité de l'Art de Bâtir*, Tome I. p. 95.)

Scotland abounds in quarries of excellent building sandstone; such, in particular, are the quarries at Culello, in Fifeshire, which furnished the stones for the monument erected at Yarmouth to the memory of Lord Nelson, and that at Edinburgh to the memory of Lord Melville. Nothing can exceed the beauty of the sandstone used in those noble

\* The decayed state of the piers of Westminster and Blackfriars' Bridges shows us how very little this important subject has been studied; as well as the necessity of studying it.

Stone-Masonry. structures; and besides beauty, and other valuable qualities, it has in a high degree that of being easily chiselled into the smoothest and finest forms.

Stone-Masonry. considered the nature of chemical combination, that the cementing part of the materials employed in the composition of mortars and cements, should be in the finest state of division that it is possible to reduce them to.

*Of Mortars and Cements.*

Mortars and Cements. 20. In the greater part of works executed in stone, it is necessary to use some kind of cementitious matter for connecting the parts together, to render them firm and compact. Works to be exposed to the action of water, immediately after being built, require this cementitious matter to be of such a nature, that it will indurate under water. Hence it is, that we have occasion for two species of mortar; one which will set and harden under water, called a *water mortar*, or *cement*; and *common mortar*.

An attentive consideration of these principles will afford an easy solution of some of the most interesting questions to which this important subject gives rise; and correct some errors that have originated from a partial examination of the phenomena. We have now to examine the qualities of those materials which naturally occur in the earth; from these must be selected the kinds that can be obtained at the least expense for the place they are to be employed at, when their quality is suitable for the nature of the work.

Nature of common Mortar. 21. If a piece of limestone, or chalk, be slowly calcined, so as to expel the whole, or nearly the whole, of its carbonic acid, it loses about 44 per cent. of its weight; and on a small quantity of water being added, it swells, gives out heat, and falls into a finely divided powder, called *slacked lime*. The bulk of the powder is about double that of the limestone. If this powder be rapidly formed into a stiff paste with water, it sets or solidifies as a hydrate of lime, and ultimately hardens by the absorption of carbonic acid from the air. This constitutes *common building mortar*. Hydrate of lime consists of lime, 100 parts, and water 31 parts.

Limestones. 24. The cementing materials are chiefly from the different species of limestone, to which may be added puzzolana, terras, iron ores, basalt, and other substances of a like character. The limestones may be divided, as regards cements and mortars, into three classes; *common limestone*, *poor limestones* (*chaux maigre* of the French), and *cement stones*.

Water Mortar. 22. If any substance, in powder, which contains much iron in a low state of oxidation, be mixed with slacked lime, the mixture will become harder and more coherent than when lime alone is employed; and it possesses the valuable property of acquiring an equal, or perhaps greater degree of hardness, if it be immersed in water as soon as it is formed into a paste. This constitutes *water mortar*. A paste of hydrate of lime alone softens and dissolves in water.

Common Limestones. 25. Common limestones consist of carbonate of lime with very little of any other substance; they produce a white lime, which slacks freely when well burnt; they dissolve in diluted muriatic acid with only a small portion of residue, and never contain more than a trace of iron. They differ much in external characters, as chalk, marble, common compact limestone, &c.

Alumina, silica, and manganese, are endowed with the same property as oxide of iron, but in an inferior degree.

These limestones do not form water cements without the addition of other kinds of cementing matter; hence they are usually employed for common mortar. The hardest marble and the softest chalk make equally good lime when well burnt; but chalk lime will slack when not perfectly burnt, and, therefore, seldom has a sufficient quantity of fire; whereas stone lime must have sufficient to make it slack. It has also been observed, that stone lime does not reabsorb carbonic acid so rapidly as chalk lime. (*Higgins on Mortar and Cements*, p. 29.)

It may be observed, in forming such combinations, that when the lime is in excess, it separates; and in favourable situations, either crystallizes or forms stalactites; indicating that there is a definite proportion according to which the materials should be combined to form the best cement.

Lime, made from common limestones, sustains very little injury from being kept after it has been formed into a thin paste with water, provided the air be effectually excluded; indeed, Alberti mentions an instance of some which had been covered up in a ditch for a very long time, that was of an excellent quality.

Use of Sand in Mortar. 23. If some kind of matter, in the state of particles or grains, be mixed with the cementing material, and then the mixture be formed into a paste with water, the strength and hardness of the cement will greatly depend on the nature of the particles added to it. In order that the cement may be improved by such addition, it is necessary that the hardness of the particles should at least be equal to the greatest degree of hardness the cement can acquire; and also, that the affinity between these particles and the cementing matter should exceed the affinity between the parts of the cement itself.

Poor Limestones. 26. Poor limestones consist of carbonate of lime united with silica, alumina, and metallic oxides. They in general produce a buff-coloured lime, but sometimes it is white. When the lime is white, there are no metallic oxides present. They contain a considerable portion of matter, which is insoluble in acids. They differ considerably in external characters; the blue lias, the Sussex clunch, and Sutton limestones, may be cited as instances.

From this explanation it will readily appear, that any substance which is added to a cement for the purpose of increasing its bulk, its hardness, or its strength, ought to be in particles or grains; and that no soft, earthy, or pulverent matter is fit for this purpose.

The lime of poor limestones does not slack freely; and it would always be desirable to reduce it to powder by grinding, in preference to slacking, because in slacking a part of its setting property is destroyed. When poor lime is slacked, it should be made into mortar, and used immediately. Moisture does such lime more injury than the reabsorption of

It will be equally apparent, to those who have

Stone-Masonry.

carbonic acid. And mortar made of it ought not to be disturbed after it has begun to set or harden.

Poor limestones are subject to vitrify in burning, unless the heat be increased gradually; but by a little management in this respect they will bear a heat sufficiently intense to convert them into good lime.

The lime of poor limestones makes excellent common mortar, when the precautions we have pointed out have been attended to. It is much superior to mortar made from common limestones. It is not, however, sufficiently powerful for a water cement without the addition of Puzzolana, Terras, or other like substances.

Cement Stones.

27. Cement stones. We have taken the liberty of giving this name to the class of earthy bodies which afford a good water-cement without addition; and it appears to be essential for that purpose that there should be at least 50 *per cent.* of carbonate of lime in the stone. Those cements which answer best are made from stones containing about 60 *per cent.* The other substances usually contained in these stones are, silica, alumina, oxide of iron, sometimes oxide of manganese, carbonate of magnesia, with traces of other alkaline and earthy salts. Cement stones are in great part soluble, with effervescence, in diluted muriatic acid; they lose about one-third of their weight by calcination, after which they do not slack, but may be ground into a fine powder, of a brown colour, of different degrees of intensity according to the nature of the stone. Those now used to make cement are found in rolled pieces, or in nodules, with septa of carbonate of lime, on the sea-coast at Sheppy, Harwich, and near Whitby, and at Boulogne on the French coast. The nodules are plentifully dispersed through the London clay stratum, and the alum shale of Whitby; they are termed clay-balls, ludus helmontii, septaria, &c.

Cement stones are also liable to vitrify in burning, either from being quickly exposed to a strong heat, or by making the heat too intense.

When cement stones have been calcined and ground, the powder thus obtained should be kept in a very dry place, as its setting property is soon destroyed by moisture. It absorbs moisture rapidly from the air; and, therefore, it should be as little exposed as possible; but when closely packed, and in a dry place, it may be kept a considerable time.

Artificial Cement.

28. There are perhaps few mineral bodies which would answer as well as clay-balls for making cement; unless it be calcareous marls; but there are very few situations where the means of forming an artificial cement are wanting; the manner of proceeding must depend on the nature of the substances employed. In general it will be necessary to mix slacked lime with the substance containing silica, alumina, and oxide of iron, and calcine them together, and afterwards grind them. The iron should be in the state of protoxide, to the amount of from 13 to 18 *per cent.* by weight. The quantity of lime may be about 30 *per cent.* or 53 *per cent.* of carbonate of lime; the silica and alumina being in equal portions: hence, in the raw materials, one hundred parts by weight may consist of

Carbonate of lime....	53
Protoxide of iron.....	18
Silica and alumina.....	29
	100

29. There are several mineral bodies which, combined with lime, form good cements; some of these may be used in their natural state, others require calcination. Puzzolana and tarras are of the former kind; basalt, iron ores, and ferruginous clay, belong to the latter class.

Puzzolana is a volcanic production much used in making water cements. It was known to the Romans, and employed by them both in ordinary buildings and water works. Its colour is reddish or reddish brown; and gray or grayish black; that of Naples is generally gray, that of Civita Vecchia more generally reddish brown.

Its surface is rough and uneven, and it has a baked appearance; when broken and examined by a magnifying glass it appears to be a spongy substance, with innumerable small cavities like a cinder, and not much harder. It comes to this country in pieces varying in size from the bulk of a nut to that of an egg. It is very brittle, and has an earthy smell. Specific gravity from 2.570 to 2.785. It does not effervesce with acids; and is not diffusible in cold water.

The iron it contains is not oxidated; and, being finely divided and dispersed through its mass, offers a large surface which quickly decomposes the water with which it is mixed when made into mortar. The union of the oxygen of the water with the iron is the principal cause of the solidification of water mortar; and this union is greatly facilitated by the heat given out by quicklime.

30. The substance called Tarras or Trass, found near Andernach, on the Rhine, is endowed with similar properties. Its colour is light gray or brownish gray. Its surface is rough and porous; and it is often found mixed with other matter. It is sometimes so hard that it yields with difficulty to the knife. According to Bergman, it contains more lime than puzzolana does, and effervesces slightly with acids.

Smeaton found puzzolana to be equal, if not superior, to tarras in forming a water cement with Aberthaw lime; he also observed that tarras is inferior for work which is to be alternately wet and dry.

31. If any stone be employed in which the iron is perfectly oxidized, it will be necessary to abstract some portion of the oxygen from the iron in the process of calcination, on the same principle as the reduction of iron from the ore is effected. (See IRON-MAKING in this *Supplement.*) It is also necessary to employ similar means to restore the cementing power of materials that have attracted moisture after being calcined.

SECT. II.—OF THE PRINCIPLES OF STRENGTH AND STABILITY IN MASONRY.

32. The strength and stability of stone-work depends partly on its mass or weight, and partly on the

Resistance of Stones.

Stone-Masonry.

Stone-Masonry.

resistance of the materials. And, since we cannot imagine incompressible fulcra, nor that the materials of masonry are infinitely hard and inflexible, as writers on elementary mechanics consider them to be; therefore, it is essential that the resistance of materials should be considered, and the effect of their weight allowed for in estimating the power of the straining force.

The resistance of stones being dependent on their state of aggregation, and not on the hardness or density of their elementary parts, their comparative strength cannot be judged of by these qualities; indeed, there are few kinds of materials of which the resistance is so uncertain as that of stone; hence, it is not at all adapted for any support where its resistance depends on its cohesion only, unless it be very carefully examined, and abundant strength be allowed. (See § 15.) The resistance of stone to compression is less affected by its irregular nature, particularly as it is usually employed in blocks of inconsiderable height; and, in general, there is scarcely any reason to be sparing of a material which it is often more expensive to reduce than to employ in large blocks. When, however, works of great magnitude are to be constructed, the weight of the materials themselves forms the chief part of the straining force; and, consequently, in such cases it becomes desirable to form a tolerably accurate estimate of their power.

33. This power is limited by a property of bodies, which has not received that degree of attention its importance would lead us to expect: we shall in this place make it the basis of an investigation of the power of materials to resist a force applied in any given direction; and show its application to some of the cases where a mason is most likely to need the assistance of calculation.

When a material is strained beyond a certain extent, every time the strain is increased to the same degree, there is a permanent derangement of the structure of the material produced; and a frequent repetition will increase the derangement till the parts actually separate. (See CARPENTRY in this Supplement, p. 622, 623.) When a small base rests upon a considerable mass of matter, as a pier on the ground, the quantity of derangement will increase only till the mass be compressed to that degree which renders the increase insensible; but in many cases a number of years will elapse before the settlement becomes insensible.

34. The strain which produces permanent derangement in the structure of a material varies from one-fourth to two-fifths of that which would destroy its direct cohesion. In stone the lower value should be taken, on account of its being subject to so many defects; and, for the present, let this strain be denoted by  $f$  lbs. upon a superficial foot.

35. Imagine ABCD to be a block, Plate CXVIII. fig. 1, strained either in the direction EF or FE, by a force W; and let BDF be a line drawn in the same plane as the direction of the straining force; and perpendicular to the axis  $ab$  of the block. Now, if we consider the resistance of the block to be collected at the centres of resistance  $t$  and  $c$ ; then,  $tF$  will represent a lever acted upon by three

forces; that is, the resistances at  $t$  and  $c$ , and the straining force at F. If the angle,  $FEg$ , be denoted by  $a$ ; then, the effect of the force W, reduced to a direction perpendicular to the lever, will be expressed by  $\cos. a W$ . (1.)

Also, if T be the resistance at  $t$ , and C the resistance at  $c$ , we shall, in the case of equilibrium, have  $C - T = \cos. a W$ . (2.)

And, by the property of the lever,

$$\frac{\bar{tc} \times T}{cF} = W \cos. a \quad (3.)$$

$$\text{Hence, } \frac{\bar{tc}}{cF} = \frac{C}{T} - 1 \quad (4.)$$

36. Without stopping to notice some maxims furnished by this equation (see the Art. BRIDGE, Prop. B), we will proceed to explain the notation used in the investigation which follows:

$l$  = the length AB.

$d$  = the depth BD, measured in the same plane as the direction of the strain.

$b$  = the breadth.

$z$  = the distance of the neutral point  $e$  from the axis  $ab$ .

$y$  = the distance of the point  $g$  from the axis  $ab$ .

$p(\frac{1}{2}d - z)$ , and  $p(\frac{1}{2}d + z)$  the respective distances of the centres of resistance  $t$  and  $c$  from the neutral point; and, consequently,

$pd$  = the distance,  $ct$ , between them. And,

$g(\frac{1}{2}d - z)$ , and  $g(\frac{1}{2}d + z)$  the respective distances of the centres of gravity of the sections into which the neutral axis divides the block, counted from the neutral point.

The leverage,  $cF$ , expressed in this notation will

be  $\frac{l \sin. a}{\cos. a} + y - \frac{1}{2}pd + (1-p)z$ ; consequently, equation (4) becomes

$$\frac{pd}{\frac{l \sin. a}{\cos. a} + y - \frac{1}{2}pd + (1-p)z} = \frac{C}{T} - 1 \quad (5.)$$

37. Now, it is shown, by writers on the resistance of solids, that the resistance of any section, collected at its centre of pressure, is equal to its cohesive force multiplied by the distance of its centre of gravity from the neutral axis, and divided by the distance of the point of greatest strain from the neutral axis. (Emerson's *Mechanics*, Prop. 77. 4to. ed.)

$$\text{Accordingly we have } C = \frac{fbg(\frac{1}{2}d+z)^2}{\frac{1}{2}d+z} \quad (6.)$$

$$\text{And } T = \frac{fbg(\frac{1}{2}d-z)^2}{\frac{1}{2}d+z} \quad (7.)$$

Therefore  $\frac{C}{T} = \frac{(\frac{1}{2}d+z)^2}{(\frac{1}{2}d-z)^2}$ ; which being substituted in Equation (5), we obtain

$$(3p-2)z^2 - 2z \left( \frac{\sin. a \cdot l}{\cos. a} + y \right) + \frac{1}{4}pd^2 = 0 \quad (8.)$$

If the block be rectangular  $p = \frac{2}{3}$ , and, therefore,

Stone-Masonry.

the distance of the neutral point from the axis is

$$z = \frac{d^2}{12 \left( \frac{l \sin. a}{\cos. a} + y \right)} \quad (9.)$$

38. The value of  $z$  for a rectangular section being determined, the magnitude of the straining force is easily found, so that it may not exceed the power of the material; for, by the properties of the lever,

$$W \cos. a = \frac{pdC}{\frac{l \sin. a}{\cos. a} + y + \frac{1}{2}pd + z(1-p)}; \text{ and since } C$$

$$= fbg \left( \frac{1}{2}d + z \right) \text{ by Equation (6), and}$$

$$z = \frac{d^2}{12 \left( \frac{l \sin. a}{\cos. a} + y \right)} \text{ by Equation (9), and } g = \frac{1}{2} \text{ by the}$$

form of the section, we have

$$W = \frac{fbd^2}{d \cos. a + 6l \sin. a + 6y \cos. a} \quad (10.)$$

39. In particular cases this formula becomes more simple,—for example, when the distance of the point  $g$  from the axis  $ab$  is  $o$ , that is, when  $y=o$ ,

$$W = \frac{fbd^2}{d \cos. a + 6l \sin. a} \quad (11.)$$

In a column, or pillar, the section of greatest strain will be at the middle of the length, as at  $BD$  in fig. 2; and the direction  $EF$  of the straining force is usually parallel to the axis; and then  $\sin. a$

$$= o, \text{ and } \cos. a = 1, \text{ and therefore } W = \frac{fbd^2}{d + 6y} \quad (12.)$$

When the direction of the straining force coincides with the axis, or when  $y=o$ , the strain on a column or pillar is expressed by the equation

$$W = fbd \quad (13.)$$

These equations apply also to tensile forces.

When the strain becomes transverse, or when  $EF$  is perpendicular to the axis, as in fig. 3, then

$$\cos. a = o, \text{ and } \sin. a = 1, \text{ hence } W = \frac{fbd^2}{6l} \quad (14.)$$

If the block be supported at the ends, and the load be applied in the middle of the length, as in

fig. 4, the fracture will take place at  $BD$ ; and  $W$  in equation (14) will be the pressure on either support, which is obviously half the load in the middle.

40. In any of these equations it is immaterial how the load be distributed, provided that the line of direction be that which passes through the centre of gravity of the mass supported, and the weight be the whole weight of that mass. Or, if the strain be the combined effect of several pressures, then the direction must be that of the resultant of these pressures, as determined by the principles of mechanics. (See CARPENTRY, p. 627, in this Supplement.)

41. If a slab of equable thickness and width be supported along two of its sides, as at  $AC, AB$  in fig. 5, and it be strained by a force acting at  $D$ , in a direction perpendicular to its surface, and  $DE$  be made equal to  $DB$ , then the fracture will take place in the direction  $EB$ ; for it may be shown, by the principles of the maxima and minima of quantities, that the resistance, according to that line, is a minimum. And since, in that case,  $EB=2 FD$ , we shall have,

$$\text{by equation (14), } W = \frac{fd^2}{3} \quad (15.)$$

A force uniformly diffused over the surface of the slab would fracture it in the direction  $CB$ , shown by a dotted line in the figure, and if  $w$  be the load in pounds upon a square foot of the surface, then the proper values being substituted for the leverage and

$$\text{breadth in equation (14), } w = \frac{fd^2 (\overline{CD}^2 + \overline{DB}^2)}{\overline{CD}^2 \times \overline{DB}^2} \quad (16.)$$

The strength of a series of steps bearing upon one another, as in the perspective sketch, fig. 6, may be determined with sufficient accuracy by the last equation, supposing the depth to be the mean vertical depth of any one step; as, for example, taken at  $GH$  in fig. 7, the figure showing the ends of the steps.

42. The case to which equation (14) applies, affords the most convenient, as well as the most accurate, means of determining the value of  $f$  for any material; and, supposing it to be one-fourth of the absolute cohesion (§ 34), the last column of the following table of experiments gives its value for various stones, mortars, &c. in the nearest simple numbers under the calculated value.

TABLE I.—Experiments on the Transverse Strength of Stones, &c. to the Case Equation (14.)

No. of Expts.	Substance tried.	Weight of a Cubic Foot.	Length $l$	Depth $d$	Breadth $b$	Breaking Weight.	Values of $f = \frac{1}{4}$ of the absolute strength of a Square Foot.
1	Statuary marble . . . . .	169.12lbs.	15 inches	1.075 in.	1.075 in.	25 lbs.	65,000 lbs.

23	Mortar in the joints of two inch cubes of stone, one month after being joined		8 pou.	2 pou.	2 pou.	6.75liv.	1,400

Numbers 18, 19, and 20, are from Barlow's *Essay on the Strength of Timber*, &c. p. 250; each a mean of three trials.

Number 23, from Rondelet's *Traité de l'Art de Bâtir*, Tome III. p. 377, lowest result; the rest of the experiments were made by the writer of this article.

We have not availed ourselves of the experiments of Gauthey (Rozier's *Journal de Physique*, Tome IV.) on the transverse strength of stones; because those he fixed at one end appear to have been injured in fixing, and only a calculated result

is given for the other specimens supported at both ends; both of which are given in the Article STRENGTH OF MATERIALS in the *Encyclopædia*.

43. Several experiments have also been made, with the intention of measuring the direct resistance to extension or compression; but theory indicates so nice an adjustment of the direction of the straining force to be necessary in these experiments, that the reader may expect the results to differ as widely among themselves as they do from theoretical calculation.

TABLE II.—Experiments on the Direct Resistance of Stones, &c. to the Case Equation (13.)

No. of Expts.	Substance tried.	Weight of a Cubic Foot.	Area of Specimen.	Weight that pulled it asunder.	Value of $f = \frac{1}{4}$ of the absolute strength of a Square Foot.
1	Hard stone of Givry	147 lbs.	96 lines	164 livres	8,400 lbs.
2	Tender stone of Givry	130	324	183	1,400
3	Mortar of sand and lime 16 years old		1 pouce	53	1,800
4	Plaster of Paris		1	76	2,500
5	Adhesion of mortar to lias stone, joined 6 months		4	64	547
6	Adhesion of mortar to brick, joined 6 months		4	138	1,180
7	Adhesion of mortar to tile, joined 6 months		4	141	1,200

The experiments, Nos. 3, 4, 5, 6, and 7, are extracted from Rondelet's *L'Art de Bâtir*, Tome I. p. 312.

Nos. 1 and 2, by Gauthey, Rozier's *Journal de Physique*, Tome IV. p. 414. In the Article STRENGTH OF MATERIALS, in the *Encyclopædia*, these experiments have been quoted as experiments on compression, by mistake.

44. In the resistance to actual fracture, from a compressive force, the joint effect of cohesion and friction is concerned, and, therefore, a much greater force is required to crush than to tear asunder the same quantity of material. The resistance to fracture might be investigated on principles analogous to those we intend to employ in determining the pressure of earth against retaining walls, &c. (See also CARPENTRY, p. 623, in this *Supplement*.) But we conceive, that it is neither prudent, useful, nor

necessary, to load the parts of a structure beyond that limit we have made the basis of our investigation. (See § 34.) Rondelet has observed, that the load under which a stone began to split was, nearly always, two-thirds of that which crushed it; but that stone, of some kinds, began to split with half the load that crushed it (*L'Art de Bâtir*, III. 86 et 101): the value of *f* should, therefore, not exceed one-fourth of the force which splits stone, and supposing the splitting force to be always half the crushing one, we shall have  $f = \text{one-eighth}$  of the crushing force.

45. In this, as in the preceding tables, the reader will observe, that the results of all experiments are given in the original weights and measures; but that the value of *f* and the weight of a cubic foot are in English pounds Avoirdupois, and for an English foot. The foreign weights and measures are distinguished by their foreign names.

TABLE III.—Experiments on the Resistance to Crushing.

No. of Expts.	Substance tried.	Weight of a Cubic Foot.	Area of Specimen.	Weight that Crushed it.	Value of $f = \frac{1}{3}$ of the Crushing Force for a Square Foot.
1	Porphyry	179.44 lbs.	20 lines	5,208 livres	640,000 lbs.
2		174.9	4 pouces	119,808	500,000
3	Granite, Aberdeen blue	164.06	2.25 inch.	24,556 lbs.	196,000
4	— Peterhead, hard and close grained		2.25	18,636	149,000

Stone-Masonry.

The Experiments, Nos. 1, 21, 22, and 36, were made by Gauthey. (Roz. *Journal de Physique*, Tome IV. p. 406.) Those numbered 3, 4, 5, 8, 9, 11, to 20, 30, 31, 32, 34, 37, 38, and 39, were made by Mr George Rennie. (*Philosophical Transactions* for 1818.) The others were made by Rondelet. (*Traité de l'Art de Bâtir*, Tome I. and Tome III.) We have selected those which will be most useful, with others of a more interesting and curious nature; such are Rondelet's experiments on the effect of beating mortar, the strength and density of ancient mortar, and the resistance of stones used in ancient and modern structures.

46. It was observed by Rondelet, in the course of his very numerous experiments, that it was not the heaviest stones which offered the greatest degree of resistance to compression, but those of a fine even grain and close texture, with a deep colour; that of granites, the most compact and perfectly crystallized are the strongest (*L'Art de Bâtir*, I. 213, 215); and when all other qualities were the same, it appears that the strength was in proportion to some function of the specific gravity.

The writers who have contributed to our experimental knowledge of the strength of stones are not numerous; the chief are EMERSON, in his *Mechanics*, 4th Ed. p. 115; GAUTHEY, in his *Memoire sur la charge que peuvent porter les Pierres* in ROZIER'S *Journal de Physique*, Tome IV. 1774, and in his *Construction des Ponts*, Tome I. p. 267; COULOMB, *Mémoires présentés à l'Académie*, 1773; RONDELET, in his *Traité de l'Art de Bâtir*, Tome I. et III. The latter volume contains the experiments made by PERRONET and SOUFFLOT. RENNIE, *Philosophical Transactions* for 1818, or *Philosophical Magazine*, Vol. LIII.; TREGOLD, *Philosophical Magazine*, Vol. LVI. p. 290.

Actual Load put on Stone in Practice. 47. The last column in each of the three tables of experiments shows the greatest load that we suppose should be borne by a superficial foot of the different kinds of stone contained in those tables; we now propose to give the results of some calculations respecting the extent to which stone has been loaded in practice. The foreign ones are reduced to our own weights and measures, and the whole stated in round numbers.

The pillars of the Gothic church of Allsaints at Angers, of the stone, No. 24, Table III. support on each superficial foot a pressure of 86,000 lbs.\*

The pillars of the dome of the Pantheon at Paris, the lower part of which are of Bagneux stone (No. 25, Table III.), support on each superficial foot 60,000 lbs.†

The pillar in the centre of the Chapter-house at

Elgin, which is of red sandstone, supports on each superficial foot 40,000 lbs. ‡

The piers which support the dome of St Paul's, in London, sustain a pressure on each superficial foot of 39,000 lbs. †

The piers which support the dome of St Peter's at Rome, sustain a pressure on each superficial foot of 33,000 lbs. †

The pressure on the key-stone (No. 23, Table III.) of the Bridge of Neuilly has been estimated for each superficial foot at 18,000 lbs.§

On these examples we have to remark, that the calculators of them have considered the pressures to be uniformly distributed over the pressed surface; this can only be true when the direction of the resultant of the straining force coincides with the axis of the pier or pillar; besides, stones cannot be wrought absolutely level, nor bedded in perfect contact. From these circumstances, the strength of piers, columns, pillars, and arch-stones, should be estimated by equation (12), and when the line of direction falls within the pier, always making  $y =$  half the least dimension of the section, an allowance which will include the effect of the greatest possible inequality of action.

We shall, in that case, have 
$$\frac{fbd^2}{d + \frac{6d}{2}} = \frac{fbd}{4} = W. (17.)$$

If the pressure on the Bagneux stone in the piers of the dome of the Pantheon at Paris be estimated by this formula, it will be found that it is sufficient to split the stones, and this has actually happened.||

48. The chief elements of the theory of arches have already been given in the Article BRIDGE (Sect. II.) in this *Supplement*, to which we refer the reader, at the same time expressing a hope that the excellent article referred to will be useful in correcting some absurd notions respecting catenarian and other curves, which are too commonly entertained. The conical support of the lantern of St Paul's is a fine example of an appropriate form, while the catenarian dome of the French Pantheon exemplifies a scientific blunder of the first magnitude.¶

The principles of domes, of groins, and of vaulting of every kind, are the same as those of arches, excepting that each kind has its peculiar manner of distributing the load on the different parts. See Prop. M and N, Art. BRIDGE.

*Of the Pressure of Earth, Fluids, &c. against Walls.*

49. When a high bank of earth, or a fluid, is to be sustained by a wall, as it is often necessary to do in forming bridges, locks, quays, reservoirs, docks, and

Stone-Masonry.

Stone-Masonry.

military works, the construction is very expensive, however economical the means employed may be; hence it is desirable to devote some space to an object of which the importance is manifest.

Let EC, Plate CXVIII. fig. 8, be the line according to which the earth would separate, if the wall were to yield in a small degree; then AEC will represent the section of the prism of earth, the pressure of which causes the wall to yield.

Put W=the weight of the prism AEC, when its length is unity.

R=the resistance of the wall, when its length is unity.

a=the angle ECa, which the plane of fracture makes with a vertical line.

c=the angle ACa, which the back of the wall makes with a vertical line.

F=the friction of the earth when the pressure is unity.

h=the vertical height of the wall aC in feet. and S=the weight of a cubic foot of earth, water, or other matter to be supported.

If g be the centre of gravity of the prism of earth, the triangles rpg, CAE, being similar, the effort of the prism to slide, in the direction EC, reduced for the friction, will be=

$$\frac{W(1-F \tan. a)}{\sec. a} \quad (18.)$$

This effort is to be opposed by the resistance of the wall, which let us suppose to be collected at c, the centre of pressure, and, reducing it to the direction CE, the effect of friction being allowed for, it becomes

$$\frac{R(F + \tan. a)}{\sec. a} \quad (19.)$$

Hence, in the case of equilibrium,

$$\frac{W(1-F \tan. a)}{\sec. a} = \frac{R(F + \tan. a)}{\sec. a};$$

$$\text{Or, } R = W \left( \frac{1-F \tan. a}{F + \tan. a} \right) \quad (20.)$$

50. But, in the case now considered, the radius being unity,  $W = \frac{h^2 S}{2} (\tan. a - \tan. c)$ . Therefore,

$$R = \frac{h^2 S}{2} \left[ \frac{(\tan. a - \tan. c) \times (1-F \tan. a)}{F + \tan. a} \right]. \quad (21.)$$

And, from the state of the variable quantities in this equation, it is obvious that it has a maximum value, which determines the angle of fracture. By the principles of maxima and minima, the maximum pressure takes place when

$$\tan a = -F + \left( 1 + F \tan. c + \frac{\tan. c}{F} + F^2 \right)^{\frac{1}{2}} \quad (22.)$$

If the angle which the plane of repose (BRIDGE, Sect. III.) makes with a vertical plane be denoted

by i, then  $F = \frac{1}{\tan. i}$ ; and  $\tan. a =$

$$\frac{-1 + (\tan. c \tan. i + \tan. c + \tan. c \tan. i + 1)^{\frac{1}{2}}}{\tan. i} \quad (23.)$$

If the back of the wall be vertical,  $\tan. c = 0$ , and then this equation reduces to the simple form, which Prony obtained, of  $\tan. a = \tan. \frac{1}{2}i$ . (24.)

51. When we substitute in equation (21) the value of the  $\tan. a$ , which has been found in equa. (23),

it becomes  $R = \frac{h^2 S}{2 \tan. i} \left\{ \tan. i + \tan. c + \frac{2}{\tan. i} - 2 \left( \tan. c \tan. i + \frac{\tan. c + 1}{\tan. i} + 1 \right)^{\frac{1}{2}} \right\}$  (25.)

And, when the back of the wall is vertical, it becomes

$$R = \frac{h^2 S}{2} (\tan. \frac{1}{2}i). \quad (26.)$$

The  $\tan. i$  being the co-tangent of the angle of repose, if the matter to be supported be of so fluid a nature that it naturally assumes a sensibly level surface when at rest, the  $\tan. \frac{1}{2}i$  becomes equal to unity;

and, consequently,  $R = \frac{h^2 S}{2}$  (27.)

The same result may be obtained from the common principles of hydrostatics in the case of fluids.

Since the only variable quantity which enters into the calculation of the distance of the centre of pressure is the height h, whatever the nature of the supported material may be; therefore that distance counted from the base will always be  $\frac{1}{2}h$ , as in the pressure of fluids. (See HYDROSTATICS, in the Encyclopædia.)

52. TABLE IV.—Table of Constant Quantities necessary for calculating the Pressure of some Materials.

	Substance.	Angle of Repose.	Weight of a Cubic Foot =S.	Value of R in Equation (26.)	Value of R in Equa. (25) when c=10°.
1	Water .....	0°	62.5 lbs.	$R = 31 \frac{1}{2} h^2$	$R = 31 \frac{1}{2} h^2$
2	Fine dry sand .....	33°	92 —	$R = 13.8 h^2$	$R = 4.8 h^2$
3	Do. moist .....	—	119 —	$R = 17.85 h^2$	$R = 6.2 h^2$
4	Quartz sand (dry)	35°	102 —	$R = 13.77 h^2$	$R = 4.64 h^2$

In sand, clay, and earthy bodies, the natural slopes should be taken when the material is dry, and the clay and earth pulverised. When any of these bodies are in a moist state, the parts cohere,

and the angle of repose is greater, though the friction be actually less. The preceding Table shows that the pressure of water is greater than that of any of the other kinds of matter, and from the nature of

Stone-Masonry.

Stone-Masonry.

fluids it is evident, that if water be suffered to collect behind a retaining wall, calculated to sustain common earth only, it will most likely be overturned. Such accidents may be prevented by making proper drains.

53. The preceding analysis will apply, without sensible error, to the curved walls which have lately become fashionable. Fig. 10 is a section of one of these walls, as executed from a design by Rennie. The vertical height, AB, 21 feet; the wall of uniform thickness, with counterforts 15 feet apart; and the front of the walls described by a 69 feet radius, with the centre in the horizontal line DA produced. The wall is built of brick, and the uniform part is 4.5 feet thick. The radius is usually thrice the vertical height of the wall; when this proportion is adhered to, the angle  $c$  will be ten degrees, for which the value of  $R$  is calculated in the Table.

Resistance of Walls.

Resistance of Walls.

54. In the first place, we propose to investigate the resistance a wall offers to being overturned; and, in so doing, it appears desirable that the resistance of the mortar in the joints should be considered one of the elements of the strength of the wall. Good mortar adds much to the firmness of walls, and still more to their durability, and, all things considered, its first cost is less than that of bad; besides, the resistance of mortar to compression must be considered, for, in practice, we have no perfectly hard arrises to fulfil the conditions of common mechanical hypotheses.

Put  $A$  = the area of the wall.

$w$  = the weight of a cubic foot of masonry.

$y$  = the horizontal distance,  $ga$ , between the vertical passing through the centre of gravity of the wall, and the point where the axis cuts the plane of fracture, the same notation being applied to the other quantities as in the foregoing equations.

Let  $G$ , fig. 9, be the centre of gravity of the wall; and on the vertical  $Gg$  set off  $gI$ , the height of the centre of pressure: also, let  $IK$  represent  $A \times w$  = the weight of the wall, and  $HI$  the force  $R$  of the earth.

Then, completing the parallelogram,  $EI$  will represent the direction and intensity of the straining

force; consequently,  $\frac{R}{Aw} = \tan. a$  (28.)

Which determines its direction, and its intensity is

$$W = \frac{Aw}{\cos. a} \quad (29.)$$

But, we have found, equa. (10),

$$W = \frac{fb d^2}{d \cos. a + 6l \sin. a + 6y \cos. a}; \text{ and as } W =$$

$$\frac{Aw}{\cos. a} \left( \text{Equa. (29.)} \right); \tan. a = \frac{R}{Aw}; \text{ Equa. (28); } l =$$

$$\frac{1}{3}h, \text{ art. 51; and } b = \text{unity; the equation reduces to } f d^2 - Adw - 6Amy = 2Rh. \quad (30.)$$

If the section of the wall be a parallelogram, then  $A = hd$ , and  $-\frac{1}{3}h \tan. c = y$ ; these values of  $A$  and  $y$  being substituted in Equa. (30), it becomes  $-whd^2 + f d^2 + 3h^2 wd \tan. c = 2Rh.$  (31.)

$$\text{Or, } d = \frac{h^2 w}{f - hw} \left( \frac{-3 \tan. c}{2} + \frac{\sqrt{2R(f - hw)}}{h^3 w^2} + \frac{9 \tan. c^2}{4} \right). \quad (32.)$$

When the section of the wall is a rectangle  $y=0$ , therefore Equa. (31) reduces to

$$d = \sqrt{\frac{2Rh}{f - hw}} \quad (33.)$$

This last Equation is also correct for a wall of which the back is vertical, and the front sloping. We suppress the investigation, to afford the young student an opportunity of proving that the diminution of weight is exactly counterbalanced by the alteration of the distance of the centre of gravity from the axis.

The tendency of a wall to slide forward may be easily prevented, by giving an inclination to the joints.

55. To illustrate these rules we shall give two examples, and in these show the construction of a table, which the reader may enlarge at his pleasure.

Example I. Let it be required to determine the thickness of a rectangular wall for supporting the front of a wharf 10 feet in height, the earth being a loose sand, and the wall to be built of brick.

The weight of a cubic foot of brick-work may be estimated at 100 lbs., and the resistance of mortar being valued at 5000 lbs. per superficial foot, the experimental value being 7900 lbs., Table III. Experiment 42, and the difference an allowance for any irregularity in building, consequently,  $f=5000$ ;  $w=100$ ; and by Table IV,  $R=13.8h^2$ ; hence, Equa.

$$(33), d = \sqrt{\frac{2Rh}{f - hw}} = \sqrt{\frac{2 \times 13.8 \times h^3}{5000 - 100h}}$$

$$\sqrt{\frac{h^5}{181 - 3.62h}}. \text{ When } h=10 \text{ feet, then the thick-}$$

ness of the wall  $d=2.644$  feet. If  $h$  be made successively 10, 20, 30, 40, &c. feet, the numbers under the head of dry sand in the following Table will be obtained, observing that they are only calculated to the nearest tenth of a foot.

The proper thickness being found for supporting one kind of material, that for any other may be easily determined; as the thickness varies as the square root of  $R$ , Equa. (33). Let the thickness for dry sand be  $d$ , then  $\sqrt{13.8} : \sqrt{31.25} :: d : 1.5d$  the thickness for supporting water.  $\sqrt{13.8} : \sqrt{17.85} :: d : 1.14d$  the thickness for supporting moist sand. In this manner, by means of Table IV. the thicknesses for other kinds are easily calculated.

Example II. If a retaining wall be intended to support a sandy and loose kind of earth, to be constructed of brick, and to be inclined 10 degrees from the vertical, the thickness being uniform; it is required to determine that thickness for any given height.

$$\text{By Equa. (32), } d = \frac{h^2 w}{f - hw} \left( -\frac{3 \tan. c}{2} + \right.$$

Stone-Masonry.  $\sqrt{\frac{2R(f-hw)}{h^2w^2} + \left(\frac{3 \tan. c}{2}\right)^2}$  and as  $c=10^\circ, \tan.$

$c=.18$ , hence  $\frac{3 \tan. c}{2}=.27$ , and its square=.0729.

Also  $f=5000$ , and  $w=100$ , consequently,  $d=$

$\frac{h^2}{50-h} \left( -.27 + \sqrt{\frac{2R(.5-.01h)}{h^5} + .0729} \right)$

For sandy earth  $R=4.8h^2$ , therefore  $d=\frac{h^2}{50-h}$

$\left( -.27 + \sqrt{\frac{4.8}{h} -.0131} \right)$ ; and making  $h$  succes-

sively 10, 20, &c. feet, the numbers obtained will be the same within one-tenth of a foot, as those in the following Table, column 5.

56. TABLE V.—A Table of the Thicknesses for Retaining Walls, Revetments, Dock-walls, &c.

Height of Wall.	Thickness of Rectangular Walls to support.			Thickness of Leaning and Curved Walls (for supporting Dry Sand, the Angle of Inclination being 10°.
	Water.	Dry Sand.	Moist Sand.	
10 feet	4.0 feet	2.7 feet	3.1 feet	1.1 feet
20	12.9	8.6	9.8	2.8
30	29.2	19.4	22.2	5.2
40	62.5	41.7	47.5	9.2

Our investigation informs us that the mortar of high walls must be of a superior strength; indeed, we know that when its consolidation takes place, under considerable pressure, it is of much greater strength. According to what function of the pressure the strength increases, we have not experiments to determine, and we therefore point out the circumstance to the notice of experimental inquirers.

Construction of Walls.

57. The preceding analysis being confined to the conditions under which the equilibrium could not be disturbed by the pressure, it would be quite unnecessary to consider the phenomena of actual fracture, if it were not for the proof which even these phenomena afford of the defects of the common mode of constructing these walls. The back of the wall is generally formed of inferior materials, hence the technical term *face mortar* and *backing mortar*; but, even with inferior mortar, the workmanship is so carelessly done, towards the back of the wall, that when it fractures a portion is left behind. A moment's attention to the direction of the pressure (see fig. 9) must show the importance of using good mortar, and making good bond at the back of the

wall; if any part be neglected it ought to be the middle, which is of least importance, provided the wall be well bound together by cross bond stones.

The strength of a wall to sustain earth will always be greatly increased by any roughness or irregularity in the back of the wall, such as projecting stones or bricks; in stone work it is easy to gain much stability by this means. The friction against a smooth wall must add much to its strength; we have not thought it necessary to include its effect in our calculations; but intend that, with counterforts, it should be considered as a set-off against accidental pressures, &c.\*

Counterforts are usually placed at about three times the thickness of the wall apart, and are made of the same width as the thickness of the wall. In fig. 11 is shown a plan for building a wall to sustain the pressure of earth according to the form proposed by Vitruvius, Lib. VI. Cap. IX. And fig. 12 is a plan from Perrault's *Notes*. Various other plans have been proposed, the chief of which Colonel Pasley has collected in his *Course of Fortification*; but most of them have little to recommend them. It seems desirable that every kind of curved work should be avoided; and perhaps that plan which unites the most economy with the greatest stability is shown by figs. 13 and 14, Plate CXIX. The spaces A, A, A, are proposed to be filled with gravel or fragments of stone; the whole of the stone-work to be well bonded; and the front and back wall of that thickness which is best suited for bond, in the kind of material to be employed.

Bond of Walls and Cramps.

58. It is not sufficient to depend entirely upon the cementing power of mortar in the construction of walls; the stones themselves should also be bound together by their disposition. The art of disposing stones for this purpose is called bonding. Part of the longest stones should be employed to bind the wall in length, and the other part to bind it cross-ways; the former are called stretchers, the latter headers.

Bond of Walls.

Figs. 15, 16, 17, 18, and 19, show various methods of bonding walls; these are selected from Greek and Roman examples. The courses of stone are often irregular, as in fig. 17; and in some works we find both irregular courses and broken ones; that is, such as are intercepted by large blocks of stone. Broken courses should be avoided, because they occasion irregular settlements.

The bond of walls requires to be most carefully attended to in the construction of piers, angles, and, in general, every part exposed to great strain.

On this subject it also may be remarked, that crossing the joints properly is a more effectual means of bonding a wall than that of employing very long stones, unless they be very strong ones. For if a stone exceed about three times its thickness in

\* See *Philosophical Magazine*, Vol. LI. p. 401, where the effect of such friction is considered.

Stone-Masonry.

length, it cannot be so equally bedded but that it is liable to break from unequal pressure; and the fracture commonly takes place opposite to a joint, and therefore destroys the bond of the wall. This defective mode of construction we have often had occasion to notice.

In works of hewn stone destined to support great pressure, or to bear the action of a heavy sea, it is necessary that the stones should be of great bulk, and connected in the firmest manner. Sometimes this is effected by forming the stones so as to lock them together. The Eddystone and Bell-Rock Light-Houses are bound together at the base on this principle. (See BELL-ROCK in this *Supplement*.)

Where less strength is required, iron cramps are used, and sometimes pieces of hard stone are dovetailed into the adjoining blocks. We think cramps of cast-iron might be employed with much advantage in all these cases.

59. The proper quantity of mortar to be employed in stone-work is another point to which it will be useful to direct the mason's attention. A stone cannot be very firmly bedded upon a very thin layer of mortar; and if the stone be of an absorbent nature, the mortar will dry too rapidly to acquire any tolerable degree of hardness (*Vitruvius*, Lib. II. Cap. VIII.), however well it may have been prepared. On the other hand, if the bed of mortar be thicker than is necessary to bed the stone firmly, the work will be a long time in settling, and will never be perfectly stable.

When the internal part of a wall is built with fragments of stone, they should be closely packed together, so as to require as little mortar as possible. Walls are often bulged by the hydrostatic pressure of mortar, when it is too plentifully thrown into the interior, to save the labour of filling the spaces with stones.

The walls of houses are frequently built with hewn stone on the outside, and rubble stone on the inside. The settlement of these two kinds of stone-work during the setting of the mortar are so different, that the walls often separate: or where this separation is prevented by bond stones, the wall bulges outwards, and bears unequally on its base. These evils are best prevented by using as little mortar as possible in the joints of the interior part of the wall, and not raising the wall to a great height at one time.

*Foundations.*

Foundations.

60. The nature of the materials employed in masonry having been considered, and also the methods of uniting them, we have, in the next place, to turn our attention to the nature of those foundations on which it is commonly required to raise permanent structures of such heavy matter.

In founding on dry ground, the nature of the foundation is ascertained without much difficulty. When it is found to be of firm hard rock, that will bear the action of the weather, no particular precautions are necessary; but in all other cases it is desirable to level the trenches to such a depth as will prevent them from being affected by the change of

Stone-Masonry.

seasons. Frost, we believe, seldom penetrates so low as two feet below the surface (see CLIMATE in this *Supplement*, Vol. III. p. 179); but in clayey ground, the effect of shrinkage, by heat, is often sensible at four feet below the surface; for to that depth the cracks in summer often extend. Consequently, in clay, the depth of the foundations should never be less than four feet, and in heavy buildings, deeper in proportion to the weight they are to support.

In large works it is also necessary to examine the matter, inclination, and thickness of the under strata, particularly when the upper stratum is of inconsiderable thickness. For this purpose, the older writers on architecture, with much propriety, recommend that a well should be dug near the place, to ascertain these points. A knowledge of the inclination and nature of the strata will also be of use in planning drains, a subject of no small importance to the durability and comfort of a mansion.

In soft ground the base of the wall should be made wide, and it may be reduced to the proper thickness by small off-sets or steps, as in fig. 20. On clay or dry sand the breadth at the bottom may be double the thickness of the wall. On compact gravel or chalk the breadth may be to the thickness as 3 is to 2.

If the ground be soft and wet, with a firm bottom within the reach of piles, then piles may be employed with advantage; but they are very likely to rot, in a few years, where the ground is not wet; and, therefore, in the case of soft ground, not sufficiently wet to preserve piles from decay, we should recommend, in preference, a very wide base or footing, well bonded together, with bars of cast-iron, disposed so that one part could not settle without causing the adjoining ones to go down at the same time; and the whole of the base should, for greater strength, be built in the best water cement.

It is a practice with some architects to employ timber beams and planking in such cases, and in consequence of its decay, in many instances it has been necessary to replace the timber with stone and brick at an enormous expense. It should be a maxim in construction, never to employ timber in a permanent structure where it is not either absolutely wet or perfectly dry.

When ground is very soft and wet, and the solid stratum is beyond the reach of piles, a solid mass may be formed to erect the superstructure upon, by means of a grating of timber, planked over. The brick or stone work which is built upon the planking should be joined with a water cement.

When such ground is not absolutely wet, instead of planking we would employ a connected grating of cast-iron, with stone or brick work built in water mortar.

In all these cases the greatest difficulty consists in preventing irregular settlements; and hence the advantage of employing wood or iron to bind the base together, and render it, as far as possible, an inflexible and solid mass.

In all edifices which press perpendicularly on their foundations, the centre of pressure should coincide, as nearly as may be, with the centre of gravity of the surface which sustains it. In wharf walls, ter-

Stone-Masonry.

race walls, abutments and piers of bridges, and the like, the resultant of the pressures should fall in the centre of gravity of the surface which supports it.

Foundations are most difficult to manage where the ground is irregular, particularly for highly finished buildings, which are so much disfigured by a small settlement. In such cases we would endeavour to procure an inflexible base by means of cast-iron beams. It is a good plan to form counter arches under the openings, provided these arches be carefully built; but where they are not well built, they yield so much as to be no better than common walling.

Excavating and removing the earth from foundations is frequently a considerable part of the expense of large works; hence the peculiar species of management which will economize this branch of labour, has become an interesting subject of investigation. We intended to give an outline of the manner of treating it, but we find that it would extend this article far beyond its proper limits.

New Method of Founding in Water.

61. Founding in water may be done in various ways; most of them are very expensive, presenting many difficulties in deep and rapid water; we shall confine our attention to this case only. The best method now in use consists in excluding the water from the space to be founded upon by means of a dam, called a coffer-dam, formed by rows of piles, with bricks or clay between the rows. When bricks are used, it is necessary to caulk the interstices between pile and pile. The space is kept clear of water by means of engines, and the foundation deepened, and piled if necessary.

Considering the immense expense and risk of life, which is encountered in excluding water of 30 or 40 feet depth, we shall here propose, for suitable ground, a more economical and safe method, which is adapted for founding piers, abutments, sea-walls, &c.

The space for the foundation being cleared, let the space it is to occupy be inclosed by a single row of piles, driven near to one another, but not so close as is necessary for a dam. The upper ends of these piles must be high enough for a stage to be formed upon them; which should be just above the height of floods or tides as the case may be. From this stage, the ground within the inclosure may be excavated, by means of a machine, formed so as to combine the principle of the field plough with that of the dredging-machine. (See DREDGING-MACHINE in this Supplement.)

When the foundation has been cleared to a proper depth by this process, and levelled, the stone-work may be built in courses with a proper bed and joint of water cement. (See Sect. I. art. 22.) A simple machine might easily be contrived for the purpose. If brick be employed instead of stone, it may be done, by forming the bricks into blocks of three feet long, and eighteen inches square, with cement, and using these blocks instead of stones. This method

of building with blocks is already in use for constructing sewers in London. When the work is brought to that height which will enable the workmen to proceed in the ordinary manner, either then or afterwards, the piles may be cut off at low-water line, and a cap-sill being fixed upon their tops, they will remain, and serve as a protection to the work below water.

62. For many purposes it would not be necessary to excavate, nor yet to build in courses; for example, let us suppose it to be the pier of a light bridge, the row of piles being driven in an elliptical form, a strong chain should encircle it at one or two places, and the internal space filled with rough stones, thrown in with water cement, to fill the interstices between them. As the cement indurated, the whole mass would become one solid stone. This mode of construction is effected on the same principle as that the French term "*Les Enrochements en Béton*" (Gauthey, *Construction des Ponts*, II. p. 276); and we have the advantage of a much superior cement to any they have employed.

## SECT. III.—STONE-CUTTING.

63. Before we proceed to explain methods of forming stones to the particular shapes required for arches, vaults, &c., it may be remarked, that the young mason should be extremely careful to avoid making the beds of stones concave or hollow. For, if this be done, in any case where the stones have to bear much pressure, they will flush, or break off in flakes at the joints, and entirely disfigure the work. It is better that they should be slightly convex. In the construction of piers and columns, where perfectness of form is at least as much regarded as strength, this maxim should be carefully attended to. Nothing can be more offensive to the eye than a flushed joint, since it not only deforms, but also gives the idea of want of strength.

64. Stone-cutting may be equally well done by various methods; the most certain consists in forming as many plane surfaces to the stone as may be necessary, in such manner that these surfaces may include the intended form, with the least waste of stone, or in the most convenient way for applying the moulds. Upon the plane surfaces thus prepared, the proper moulds are to be applied, and the stone worked to them. It will generally happen that the bed of the stone will be one of the first plane surfaces, and the arrangement should always be made, so that there may be as little reworking as possible.\*

65. When an arch is square to the face of the wall, the only difficulty is in drawing it to the proper curve. When the arch is circular, it may be described from a centre, unless the centre be very distant; and in that case a method proposed by Dr T. Young † will be found extremely convenient for the mason's purposes. Fig. 21 represents the instrument. Three points in the curve being known, it is easily

\* Frezier may be consulted with advantage on this subject. *Coupé des Pierres*. Tome II. p. 14.

† *Lectures on Natural Philosophy*, Vol. I. Plate VI. fig. 83. This instrument might be usefully applied in Ship-building.

Of the Beds or Joining Surfaces.

Methods of Stone-Cutting.

Describing Arches.

Stone-Masonry.

adjusted to the curve, and will also answer as a mould in many cases. AB is a straight bar of any convenient length; at each end, a small roller is fixed by means of two plates of brass; against these rollers the elastic bar CD slides as it adapts itself to a regular curvature, when moved by the screw E. The natural form of the elastic bar is shown by C'D', the depth in the middle, H, should be double the depth at either end, and the breadth uniform throughout the length. This bar, when of wood, should be of straight-grained ash, or lance-wood; the latter is best.

An elliptic arch may be described by continued motion, in the following manner. On a straight bar AB, fig. 22, if AC be made equal to the height of the arch, and CB equal to half the span, then if the end A be moved along a straight edge, ED, while the point B moves along another straight edge, FD, the point C will describe an ellipse.\* If the bar be made to move on rollers, an arch on a large scale may be easily and accurately described in this way, when a tramnael would become very unmanageable. For other methods, see ELLIPTOGRAPH in this Supplement.

To find the direction of the joints, with a radius equal to half the span, from the point K, fig. 22, as a centre describe the arc GH, which determines the points G,H, called the foci. Let it now be required to draw the joint I, join IG, and IH, draw LI to bisect the angle GIH, and it is the joint at I.

A parabolical arch may be drawn very easily on a large scale by means of tangents. Make AE, fig. 23, equal to the rise CA, and join ED and EB. Draw FG parallel to DB, and divide DF and EG (which are equal) each into the same number of equal parts, then join 11, 22, 33, &c., as is shown in the figure; a curve drawn to touch these tangents is a parabola.

Arches are most conveniently drawn on a large scale by means of parallel ordinates; and an extremely simple method of this kind, for a parabolic arch, has been described by Professor Leslie. (*Inquiry into the Nature of Heat*, p. 503.) Let AB, fig. 24, be the span, and CD the height. Divide AB into twenty equal parts, and raise a perpendicular from each point of section. Let CD be 100 by a scale of equal parts, make the next ordinate on each side 99 parts, or 9 x 11, by the scale; the next pair of ordinates make 96 parts, or 8 x 12, and so on; those numbers being respectively as the rectangles of the segments into which AB is divided.

To draw the joints of a parabolic arch, let I be a point, at which a joint is to be drawn, fig. 24; draw Id parallel to BA; and make DT equal to Dd; join IT, and make EI perpendicular to IT, which is the joint required.

66. The finest form for a Gothic arch is a cubic parabola; it is easily constructed from its equation.

Stone-Masonry.

Observing that the vertex of the curve is at the springing of the arch, and making  $x$  the abscissa, and  $y$  its corresponding ordinate, by the nature of the curve  $x = \frac{y^3}{a}$ . Now, if we make  $y$  successively equal

to 1, 2, 3, &c. feet, we shall have  $\frac{1}{a} = x$ ;  $\frac{8}{a} = x$ ;  $\frac{27}{a} = x$ ;  $\frac{64}{a} = x$ ;  $\frac{125}{a} = x$ ;  $\frac{216}{a} = x$ ;  $\frac{343}{a} = x$ ;  $\frac{512}{a} = x$ ;  $\frac{729}{a} = x$ ; &c. To find  $a$ , when  $x$  is

equal to half the span CD, fig. 25, Plate CXX., and  $y =$  the height AD; we have  $a = \frac{AD^3}{CD}$ . If it be de-

sirable that the ordinates should be  $1-n^{\text{th}}$  part of a foot apart, then divide each by the  $n^5$ , which gives the dimensions in feet.

*Example.* In a Gothic building it is proposed to make an arch to an opening 10 feet wide, the height of which is to be 4 feet 6 inches above the springing line. There CD = 5 feet, and AD = 4.5 feet,

therefore  $a = \frac{AD^3}{CD} = \frac{91.125}{5} = 18.225$ . And using this number for a divisor, the ordinates are easily found, by once setting a slide rule, to be,

$x^{\text{I}}$	= .0548 feet	$o^{\text{I}}$	= .0068 feet
$x^{\text{II}}$	= .438		
$x^{\text{III}}$	= 1.48	$o^{\text{II}}$	= .185
$x^{\text{IV}}$	= 3.51		
$x^{\text{V}}$	= 6.86	$o^{\text{III}}$	= .857

And dividing the first, third, and fifth, each by 8 (considering  $n = 2$ ), gives the intermediate ordinates;  $o^{\text{I}}$ ,  $o^{\text{II}}$ ,  $o^{\text{III}}$ . The advantage of this method consists in the facility of setting out the work on either a large or small scale. Every practical man is aware of the trouble of dividing a distance into equal parts, or of performing other geometrical operations on a platform, or floor; but here, by an easy arithmetical operation, this is avoided. Draw the springing line CD, and the middle line AD; and let the line EC be drawn parallel to AD. Beginning at D, make a mark at every 6 inches on DA, and also on CE, beginning at C; then, through these divisions draw the parallel ordinates. Let the abscissas be measured off on these ordinates, from the line CE by a rod divided into feet, tenths and hundredths of a foot. Put a nail in at each point found in the curve, and bend an uniform lath against the nails, and mark the curve.

67. Our next example is for the purpose of show- Arches for large Bridges.

Gothic Arches.

\* See *Edinburgh Review*, Vol. VI. p. 387. A most ingenious extension of the principles of describing curved lines has been lately invented by Mr Joseph Jopling, which promises to be of much use in the arts, as well as a curious subject for mathematical speculation. The system is somewhat obscurely announced in a Pamphlet, entitled *The Septenary System of Generating Curves by Continued Motion*. London, 1823.

Stone-Masonry.

ing the principles of constructing an arch for a bridge, when the span is considerable. In the Article BRIDGE, Prop. S, the equation of the curve of equilibrium is found to be  $y = \frac{\frac{1}{2}ax^2 + \frac{1}{12}bx^4}{m}$ , for a disposition of the load which has place commonly in bridges. Making  $x$  successively 10, 20, 30, &c. feet, we have

$$y^I = \frac{50}{m}(a + 16\frac{2}{3}b).$$

$$y^{II} = \frac{200}{m}(a + 66\frac{2}{3}b).$$

$$y^{III} = \frac{450}{m}(a + 150b).$$

$$y^{IV} = \frac{800}{m}(a + 266\frac{2}{3}b).$$

$$y^V = \frac{1250}{m}(a + 416\frac{2}{3}b).$$

$$y^{VI} = \frac{1800}{m}(a + 600b).$$

$$y^{VII} = \frac{2450}{m}(a + 816\frac{2}{3}b), \text{ \&c. \&c.}$$

The curve of equilibrium being to pass at the middle of the depth of the arch-stones, CB, fig. 26, will be the height =  $h$ , and AB the semi-span =  $S$ ; also let the depth of the arch and roadway at the crown, or  $a$ , be 7 feet; and suppose the quantity of matter be so regulated by hollow spandrils that  $b = \frac{10}{S^2}$ .

Under these conditions we shall have

$$m = S^2 \left( a + \frac{1}{6}bS^2 \right) = \frac{S^2}{2h} \left( 7 + \frac{10}{6} \right)$$

If the semi-span be 7.2 feet, and the height 24 feet, then  $m = 936$ , and  $b = .00193$ . Calculating the ordinates from these data, we shall have

$$y^I = .375$$

$$y^{II} = 1.52$$

$$y^{III} = 3.5$$

$$y^{IV} = 6.4$$

$$y^V = 10.4$$

$$y^{VI} = 15.7$$

$$y^{VII} = 22.4$$

$$AD = 24.0$$

Construct the curve according to these ordinates, and divide it for the arch-stones. The joints should be perpendicular to this curve; but great accuracy is not necessary in this respect, provided the inclination from that perpendicular be considerably within the angle of repose. (See BRIDGE, Prop. Z.)

The joints may be drawn thus, with any radius:

Stone-Masonry.

from the next division on one side of the joint  $a$  describe an arc, and from the next division on the other side, with the same radius describe another arc to intersect the former one, through the intersection and the division  $a$  draw the direction of the joint.

To find the depth of the key-stone, let the horizontal thrust  $m = 936$  be multiplied by the mean specific weight of a cubic foot of the materials to form the bridge, and calculate the depth by equation (17). Suppose the mean to be 160 lbs. then the horizontal pressure will be 149,760 lbs. and  $\frac{fbd}{4} = 149,760$ ; which, considering  $b = \text{unity}$ , gives  $d = \frac{599.040}{f}$ . For Craighleith stone, No. 15, Table III. the key-stone should be 6 feet deep.

To find the depth of the arch-stones at any other part of the arch, set off Bc equal the depth at the key-stone, and draw  $bc$  parallel to a tangent to the curve of equilibrium at the point where the depth is to be determined, then  $bc$  is the depth at that point. The depth at a sufficient number of points being found as above, and set off equally on each side of the curve of equilibrium, the form of the intrados will be determined, which may be terminated by a circular arc at the springing; and it is not a little remarkable that the arch, thus described from principle, is a *pointed arch*.

68. When an arch cuts a plane wall in an oblique direction, there is a little more scope for the art of the stone-cutter. But previously to attempting to proceed further, we would recommend the young student to make himself master of the principles of projection, developement, and solid angles. The first section of the Article JOINERY in this Supplement is wholly restricted to these principles; all of which being equally applicable to both arts, it will be unnecessary to repeat them in this place.

Let an elliptical arch be supposed to cut a plane wall obliquely, and the wall to be inclined, ABCD, fig. 27, is the plan of the arch; EF a section at right angles to its direction; IH a section at right angles to the line AB. Project the inclined face of the wall, as shown at AO PB, by the method of projecting planes (JOINERY, Sect. 1 and 7); and in doing this it will be found an advantage to produce the joints till they cut the base line EF, because the angles will be set out with greater accuracy from long lines. In the case where the wall is vertical, the section and projection of the face are not required. Next let the soffit be developed, on the supposition that the arch is a polygon of as many sides as there are arch-stones. (See JOINERY, Sect. I. art. 13.) KLMN shows the developement of the soffit or soffit moulds. The form of the bed of each stone is

\* Monge, in an elaborate article on the application of Descriptive Geometry to the use of Architects, has drawn a very erroneous conclusion respecting the joints of vaults and arches; for it is the direction of the pressure, and not the form of the soffit, which determines the best direction for a joint; but the views developed in the Article BRIDGE were not known at the time Monge wrote. In other respects, the article of Monge is well worthy of the attention of the mason. See *Géométrie Descriptive*, article 130, 4me ed. Paris, 1820.

shown by the planes  $a, b, c,$  and  $d,$  and is thus found, for the joint, 4, draw  $he$  and  $mf$  parallel to  $EF,$  and produce the joint 84 on the development to cut  $he$  in  $g;$  set off  $ge$  equal to  $4i,$  and draw  $ef$  parallel to 48; then, a line drawn from  $e$  through the point 4, will give the bevel at one end, and a line drawn from  $f$  through 8 gives the bevel at the other end; its width is equal to  $4k$  on the section. As there are no curved parts, except the soffit of the arch, the stones may be worked by means of bevels, without having moulds made for the soffits and beds.\*

69. When a road crosses a canal in an oblique direction, the bridge is often made oblique. When the angle does not vary more than ten or twelve degrees from a right angle, the arch-stones may be formed as already described; but in cases of greater obliquity, a different principle of construction is necessary. These cases should, however, be avoided wherever it is possible; as, however solid the construction of an oblique bridge may be in reality, it has neither that apparent solidity nor fitness which ought to characterize an useful and pleasing object.

An oblique arch may be constructed on the principle of its being a right arch of a larger span, as is shown in fig. 28. Let  $ABCD$  be the plan, and  $EFGH$  the corresponding points in the elevation, in this elevation the dotted lines show the parts which would not be seen.

The joints of the arch are supposed to be divided upon the middle section, and therefore drawn to the mean centre  $K,$  which corresponds to the point  $I$  on the plan.

Divide  $AD$  into any number of equal parts, as at 1, 2, 3, &c. and transferring these points to the elevation; describe the arch belonging to each point, and also draw the parallel lines 11, 22, &c. on the plan.

To find the mould for the arris of any joint, as  $a,$  draw  $ab$  parallel to the base line  $EF,$  and from  $a,$  as a centre, transfer the distances of the points where the arches cut the joint, to the line  $ab.$  Then let fall perpendiculars from the points in the line  $ab$  to the lines 11, 22, &c. in the plan, whence we find  $a, m, n, o, p,$  in the curve of the mould for the arris of the joint  $a.$  The mould for any other joint may be found in the same manner. The ends of the arch-stones will be square to the joints, and  $pode$  will be the mould for one end, and  $acdf$  the mould for the other end. It will be of some advantage in working the arch-stones to observe, that the arch-stone being in its place, the soffit should be everywhere perfectly straight in a direction parallel to the horizon.†

70. If it be required to construct an arch in the wall of a circular building, as in fig. 29, where  $ABCD$  is the plan of the wall, the elevation  $EF$  should be drawn, and the joints in the same manner, as if the arch were in a plane wall. The curved surface of the soffit should be correctly developed by the process described in the Article JOINERY, art. 13, and the moulds made of some flexible material; these soffit moulds are shown at  $a, b, c,$  &c. The mould for the joint 2 may be found by dividing the joint into any number  $m, n,$  &c. parts; and let a perpendicular fall from each point of division to the curved lines representing the faces of the wall on the plan, and from each point in which the curved lines are intersected by these perpendiculars, draw a line parallel to  $EF.$  Also, from 2, as a centre, transfer the divisions on the joint to the horizontal line  $f2,$  and from thence let perpendiculars fall, which will cut the lines that are parallel to  $EF$  in the points through which the curves of the mould must be drawn, as shown by the shaded part  $P$  on the plan. Any other joint may be described in the same manner. ‡ In the figure, the section is drawn, because it shows somewhat more distinctly the size of the arch-stones; it is not necessary in finding the moulds, except the face of the wall be inclined, a case of very rare occurrence in practice. An arch in a circular wall always has the appearance of a want of strength on the convex side; and when the curvature is considerable, it becomes absolutely insecure.

The method describing the raking mouldings, so as to mitre with horizontal ones, has been explained in the Article JOINERY in this Supplement, art. 21—24, and the same methods apply in masonry.

71. Respecting the general principles of stairs, we may also refer the reader to JOINERY, art. 39, 40, where the proportions of steps, &c. are shown; in masonry the kinds termed geometrical stairs are the only ones which offer any considerable difficulty in the execution.

Each step of a geometrical stair is partly supported by wedging its end into the wall of the staircase, and it is further strengthened by resting upon the step below it. The outward end of a series of these steps is represented by fig. 7, Plate CXVIII.; the line  $abc$  shows the form of the joint between two adjoining steps; in the straight part of a flight of stairs,  $ab$  is made about an inch, and the part  $bc$  is made perpendicular to the soffit of the stair, and of such a depth as may be required for the kind of stone. As this depth is determined by the mean depth necessary to render a stair safe, we shall here give an example of computing the mean depth of a step for Craighleith stone, by

\* Our method is analogous to that called *Biais par abregé* by the French writers. See Frezier, Tome II. p. 133. Other methods are given by Frezier, Simonin, Rondelet, Nicholson, &c. in the works referred to at the end of this article.

† For further information respecting oblique or skew bridges, the reader may consult Gauthey, *Construction des Ponts*, Tome I. p. 390; Chapman, in Rees' *Cyclopædia*, Art. OBLIQUE ARCH; and the Article NAVIGATION, INLAND, in the *Edinburgh Encyclopædia*.

‡ Other methods are given by Frezier, Nicholson, &c.

equa. 16 (art. 41). Put  $w$  = the greatest uniform load on a square foot, including the weight of the stone itself, = 300 lbs. the horizontal distance between C and D (fig. 6), = 10 feet, and the length of the step  $BD = 6$  feet, then  $\frac{w \times (CD)^2 \times (DB)^2}{f(CD^2 + DB^2)} = d^2$ , or

$$\sqrt{\frac{300 \times 100 \times 36}{26,000 \times (100 + 36)}} = .55 \text{ feet, the mean depth}$$

GH, fig. 7.

That part of a step which is inserted into the wall of the staircase is made about eight or nine inches long for ordinary staircases, but ought to be longer when the steps are longer.

Steps, and landings, and balconies, should be made to bear as evenly and firmly as possible upon their supports; and from a little consideration of the nature of the strains to be resisted in such operations, the mason may perhaps derive some instruction, since a mistaken view of the subject is likely to be attended with serious consequences.

Let AB, fig. 30, Plate CXX., be a step fixed in a wall, CD being the face of the wall, and CA the part inserted in the wall. It will be obvious that the weight of the projecting part, DB, of the step, with any load upon it, will tend to raise the fixed part at A, and to depress it at C. But it will require a less force at A to sustain the step than at any other point between A and D; and the nearer to D, the greater the strain will be, consequently a greater risk of failure. Hence the effectual resistance on the upper side should be at the extremity, A, of the step, and the support at C should be immediately at the face of the wall.

We have often observed in stone stairs, where

steps are alternately in straight flights and winding ones, the soffit of the stair to be irregular, with sudden and abrupt changes of form where the winding steps began and terminated. These may always be avoided, by making a development of the ends of the steps, and forming the abrupt changes into easy curves, as a joiner does the hand-rail of a stair. (See JOINERY, Plate LXXXVII. fig. 35.\*)

The earliest author on stone-cutting appears to have been Philibert De L'Orme; and in the introduction to the fourth book of his work he remarks, that he had "never heard of any thing that had been written on stone-cutting, either by ancient or modern architects." The labours of De L'Orme on this subject form the third and fourth books of his *Treatise on Architecture*, in folio, Paris, 1567. We shall close this Article with the following list of some other authors on stone-cutting, in the order they were published:

Mathurin Jousse, *Le Secret de l'Architecture*, folio, 1642. Francois Derrand, *L'Art des Traits et Coupé des Voûtes*, folio, Paris, 1643. Abraham Bosse, *Practique du Trait à preuves de M. Desargues*, 1643. J. B. De la Rue, *Traité de la Coupé des Pierres*, fol. 1723; this was a republication of Derrand's work, with additions. Batty Langley, *Ancient Masonry*, folio, London, 1733. Frezier, *Traité des Coupé des Pierres*, 3 tomes 4to, 1737—1739. *Encyclopédie*, Article MAÇONNERIE. *Encyclopédie Méthodique*, MAÇONNERIE, 1785. Simonin, *Traité Élémentaire de la Coupé des Pierres*, 4to, 1792. P. Nicholson, *Carpenters' and Joiners' Assistant*, 4to, London, 1797. J. Rondelet, *Traité Théorique et Practique de L'Art de Bâtir*, Tom. II. 4to, Paris, 1804. (H. H. H.)

Boundaries,  
Extent, and  
Divisions.

**SUFFOLK**, an English maritime county on the borders of the German Ocean. It is bounded on the east by the sea; on the south by Essex, from which it is divided by the river Stour; on the west by Cambridgeshire; and on the north by Norfolk. Its medium length from east to west is forty-seven miles, and its breadth from north to south twenty-seven. The square contents are 1512 miles, or 967,680 statute acres. It consists of two grand divisions, one called the Liberty of Bury, the other the Guildable Land, each of which furnish a distinct grand jury at the county assizes. The next division is into twenty-one hundreds, and these are subdivided into five hundred and twenty-three parishes. The whole county forms a part of the diocese of Norwich.

Population.

The number of houses in 1821 was 42,773, inhabited by 55,064 families; of whom 30,795 were chiefly employed in agriculture; 17,418 in trade, manufactures, or handicraft; and 6851 were not comprehended in

either of those classes. The whole number of inhabitants was 270,542; of whom 132,410 were males, and 138,132 females. The increase in population since the preceding census, ten years before, was at the rate of 16 per cent.

Suffolk is generally a level tract of country, in which, as there are few elevations, there are scarcely any extensive prospects. It is, however, tolerably well clothed with trees, but wants running water; most of the streams being very sluggish in their course, and by no means copious. The soil is as various as in other districts of the same extent. On the sea-coast it is in general sandy, but rendered productive by the application of shell marl, which is found in abundance. In the middle of the county, from north to south, called usually *High Suffolk*, which is the larger part, the soil is a tenacious, loamy clay, affording good pasturage for cows, whose butter is chiefly used to supply the London markets.

Suffolk.

The north-western division is a poor sandy soil, in many places covered with heath, and scarcely fit for any other purpose than that of feeding sheep, or breeding rabbits; of which latter animals it is said the skins of more than 40,000 annually supply fur to the hatters. The corn furnished by the eastern division of the county, besides supplying its vicinity, is sent to London from the ports of Ipswich and Woodbridge. The cultivation is commonly conducted on the Norfolk system of turnips, barley, clover, and wheat, and the husbandry being well executed, the crops are generally very good. The beans are peculiarly productive. Turnips, and, in some districts, carrots, are extensively cultivated. Hemp is grown in the garden of almost every peasant, and spun into linen for their domestic uses. Some few hops are grown in the vicinity of Stowmarket.

Cattle.

They have an excellent breed of draught horses, well known by the name of Suffolk *punches*. The cows have been long celebrated for the abundance of their milk, which, in proportion to their size, and the quantity of food which they consume, exceeds the produce of any other race in the kingdom. They are all without horns. The sheep, of which large flocks are kept, are mostly of the Norfolk breed; but, of late years, they have been changed for those of the South Downs.

Manufactures.

There are few manufactures in this county, though it was the first in which the Flemings introduced the clothing trade. Until the extension of machinery in the northern counties, the females found constant winter employment in spinning worsted, but that has ceased. At Stowmarket there is some occupation in making coarse linen for bags, bed-sacking, and other similar uses. At Sudbury there are manufactures of says, and bunting for ships' flags, and of some kinds of silk goods. Near Eye some bone-lace is made. Salt is refined at several places on the sea-shore, from a solution of rock-salt in sea-water.

Fisheries and Commerce.

The branch of industry which, next to agriculture, gives employment to the greatest number of inhabitants, is the fishery. Many vessels are equipped at Lowestoffe and Southwold to take herrings, which are cured in houses appropriated for that purpose in those towns. The taking of mackerel is beneficial before the season when the shoals of herrings arrive on the coast. There is little other commerce in the county than that which arises from the transmission of the agricultural products to the metropolis.

Rivers and Canals.

The navigable rivers are the Lark, which passes by Thetford, and runs to the Ouse. The Deben, of short course, which runs by Woodbridge to the sea; the Orwell, a beautiful river, navigable to Ipswich; and the Blythe, navigable to Framlingham. To these may be added the Waveney, which forms the northern boundary of the county, and the Stour, which is its southern. The only navigable canal is one between Ipswich and Stowmarket.

Landed Property.

The landed property of the county is much di-

Suffolk.

vided. There are scarcely any estates so large as to create a decided political preponderance; and there are a larger number of proprietors occupying their own lands, of a value of from L. 100 to L. 400 *per annum*, than in any other county. Except in the heavy clay districts, the farms are generally large, and the tenants being possessed of ample capitals, the agricultural business is admirably conducted. There are neither mines nor mineral springs in this county. In the summer season, sea-bathing attracts a considerable portion of company to the shore at Lowestoffe, Southwold, and some other spots, where every accommodation for such parties is provided.

Antiquities.

Among the antiquities of this county stand first the remains of the ancient Roman castle at Burgh, on the banks of the Yare. It is said to have been the ancient Garianonum erected by Publius Ostorius Scapula, in the reign of the Emperor Claudius. The walls, which are still standing, inclose a space 642 feet in length, and 320 in breadth; they are fourteen feet in height, and nine feet in thickness. The whole ground plan, including the walls, is more than five acres, and is capable of containing a cohort and half; having been built to keep in subjection the Icenii, a people inhabiting Suffolk, Norfolk, Huntingdonshire, and Cambridgeshire. The most remarkable of the Saxon antiquities are the monastery at Bury St Edmund's, that of Framlingham, and several ancient churches.

Titles, and Representation.

The following peers derive their titles from places in this county: Marquis Cornwallis; Earls of Suffolk, Orford, and Stradbroke; and Baron Rendlesham. The county returns two members to the House of Commons; and two are chosen for each of the boroughs, Ipswich, Bury St Edmund's, Sudbury, Eye, Dunwich, Alborough, and Orford.

The most remarkable seats among a very great number belonging to noblemen and gentlemen in this county, are Euston-Hall, Duke of Grafton; Broom-Hall, Marquis Cornwallis; Ickworth, Earl of Bristol; Henham, Lord Stradbroke; Boston-Hall, Sir Charles Banbury; Rendlesham, Lord Rendlesham; Benacre, Sir Thomas Gooch; Heveningham-Hall, Lord Huntingfield; Sotterly Park, Miles Barne, Esq.; Flinton-Hall, Alexander Adair, Esq.; Redgrove-Hall, Admiral Wilson; Woolverston-Park, Charles Berners, Esq.; Long Melford, Sir William Parker; Shrubland-Park, Sir William Middleton; and Tending-Hall, Sir William Rowley.

Principal Towns.

The chief towns and their population are, Ipswich, 17,186; Bury St Edmund's, 9990; Woodbridge, 4060; Sudbury, 3950; Lowestoffe, 3657; Beccles, 3493; Bungay, 3290; Stowmarket, 2252; Mildewhall, 2974; Hadleigh, 2929; Framlingham, 2327; and Halesworth, 2166.

## SURGERY.

Surgery.

SURGERY, rich as it is in sound information, well-established facts, and plans and means for the relief and cure of numberless injuries and diseases, to which the human body is liable, cannot be presumed to have yet reached all the perfection and efficiency of which it is susceptible. Were any doubt entertained upon this point, it would be immediately dispelled by the consideration, that scarcely a year passes away without new and improved modes of practice being suggested, and receiving the sanction of impartial experience. Besides, who can pretend yet to understand every thing relative to a long list of very difficult subjects which enter into the surgical department of the healing art; as, for instance, inflammation, suppuration, cancer, syphilis, scrofula, &c. &c.? Many questions, connected with these and numerous other affections, still remain in the deepest obscurity, presenting an extensive field, in which the diligent and faithful observer may gather immortal fame for himself, and confer infinite and lasting benefit upon the rest of mankind. The great deal that has been done for the advancement of surgery, in the course of the last fifty years, ought to furnish the assurance that much more will be done for its improvement in the half-century that is to come; particularly when the zeal, the emulation, and the ardent love of truth, now presiding over every useful scientific inquiry, are duly contemplated. The design of the present article is, to collect and place before the reader a few of the most interesting novelties in surgery; comprising those which have been produced subsequently to the period when the article upon this subject in the *Encyclopædia* was composed, and others which, though known earlier, escaped notice in that article. In performing this task, we shall take up the subjects in the order in which they present themselves in the original article, to which this is meant to be a supplement.

Of Wens.

The first topic that seems to us to admit of a few additional remarks is that of *encysted tumours*, or *wens*, as they are popularly called. Though tumours and excrescences of various kinds form one of the most frequent classes of diseases, and, what is more, though they often afford convincing illustrations of the efficacy of surgery, the exact causes and manner of their origin cannot be said to have received hitherto any very successful elucidation. In the article referred to, some notice is taken of the interesting opinions of Bichat respecting the production of encysted tumours; and of his refutation of a common notion, that they are not new formed parts, but only dilated cells of the cellular membrane. At the same time, his own particular belief is mentioned, that their formation more probably depends upon laws, which regulate the growth of the different parts of our bodies; which laws, however, not being known and comprehended, leave us as much in the dark respecting the matter in question as if no reference to them had been made. But, what particularly claims

our attention here, is the great analogy which Bichat finds between the cysts of encysted tumours and serous membranes; because, if such analogy prevail, it is a strong fact against the correctness of an explanation of the origin of encysted tumours, lately promulgated in this country. Bichat says,—“The cysts, like serous membranes, form a species of sac, *without an opening*; they contain the fluid which they exhale, and they have a smooth and polished surface contiguous to the fluid, whilst the other surface is unequal, and connected with the adjacent cellular membrane.” Now, this account is singularly at variance with the doctrine that has been recently proposed by an English surgeon of the highest reputation; who, in his description of the nature of encysted tumours, at least of those which are so frequently seen upon the head, face, and back, and sometimes under the skin of other parts of the body; instead of regarding the cysts as at all analogous to serous membranes, represents them as *dilated cutaneous follicles*, lined with cuticle, and, of course, partaking rather of the character of mucous membranes. Speaking of the origin of encysted tumours, Sir Astley Cooper expresses his conviction, that it depends upon “a follicle extremely enlarged, and incapable of discharging its contents, from an obstruction of the orifice by which it opens upon the surface of the skin.” Then, advertent to the nature of follicles, he observes, that, upon superficial examination, they appear to be only pores in the skin; but that, when a small probe is introduced into them, they are found to proceed through the skin into the subjacent cellular membrane. “The first circumstance (says he) which induced me to believe that an encysted tumour was an obstructed follicle, was examining a tumour of this kind situated upon my own back. It had acquired a diameter of about two inches, and was situated at the lower part of the dorsal vertebræ. I thought of requesting a friend to remove it, but, on examining it by means of two mirrors, I saw a small black spot in the centre of the swelling, and by pricking this, I extracted a piece of sebaceous matter with a black head, like those seen in the follicles of the nose. I then squeezed the tumour, and through the orifice occupied by the black sebaceous matter, I emptied the tumour by squeezing out a large quantity of sebaceous substance. This was effected without pain, and without succeeding inflammation; but, gradually, the secretion became renewed; by frequent pressure, however, I have now for several years kept it empty, although the bag and its orifice still remain. A lady applied to me with one of these swellings upon her shoulder. It had a small black spot upon its centre, through which I could squeeze its curd-like contents. I removed it with the skin over it, and found that the opening was a follicle leading into the hollow of an encysted tumour, which contained sebaceous matter, was lined with cuticle, and had a cyst of the usual cha-

Surgery.

Surgery. racter. Often have I seen the follicular aperture over these swellings, by which the point of a tent-probe was readily admitted into the cavity of the cyst, and through which I could immediately squeeze its contents. The follicle is, however, generally obstructed at its orifice, and a depression only is seen (and not always even this) when the sides of the swellings are compressed." (*Surgical Essays*, Part II. p. 236.)

This experienced surgeon conceives, that an encysted tumour begins in the following way: a follicle becomes obstructed at its termination upon the skin, and the secretion, still proceeding, its sides are extended in the cellular membrane wherever this most readily yields. If it be inquired, how it is possible for a follicle to be thus extended, the answer is, that other membranes expand to a much greater comparative size. An ovarium, that would not contain within its membrane more than two drachms of water, will expand to a magnitude capable of holding nearly a hundred. The same author also considers pressure, and a want of moisture in a diseased state of the secretions, as occasional causes of encysted tumours. When we first perused Sir Astley Cooper's explanation of the formation of these swellings, a difficulty presented itself to the admission of the doctrine, on account of many encysted tumours being found in situations, where any suspicion of their connection with the follicles of the skin cannot for a moment be entertained. Upon referring to his essay upon the subject, however, we find, that his observations are meant to apply only to the kind of encysted tumour, which is situated just under the skin, and that he acknowledges different species of these swellings. Such difficulty is obviated, therefore, in the particular cases spoken of by this gentleman, as far as the consideration goes upon which it was founded; yet, for various other reasons, the doctrine is not to us, by any means, satisfactory; and it may even be doubted, whether the same mistake may not here have been made respecting the *enlarged follicle*, as surgeons once made about the *dilated cell of the cellular membrane*. That there is a particular class of encysted tumours, having upon their centre a minute dark spot, through which a small probe can be introduced into them, is a fact, which Sir Astley has most correctly described, and he is entitled to the credit of having first made this original observation; but it does not follow, that because there is such a dark spot, or even an aperture, that it must be that of a cutaneous follicle. With respect to the sebaceous substance said to have been pressed out of the opening, some experiments would also be requisite to determine whether it were actually of the same nature as the secretion of the cutaneous follicles. Nor does the occasional presence of cuticle in the cyst prove the truth of the doctrine advanced; because, in the formation of wens, nature presents unaccountable irregularities, sometimes producing in the cyst a substance resembling cuticle, sometimes hair, and, in a few instances, even teeth. The inner surface of almost all the encysted tumours that we have examined, corresponded rather to that of a serous membrane, as explained by Bichat. If en-

VOL. VI. PART II.

Surgery. cysted tumours arose in the mechanical way, above specified, we should expect them not only to be a much more frequent disease, than they actually are, inasmuch as the cutaneous pores are innumerable, and must very often be obstructed, as we see happen on the nose; but, when the disease is formed, we should expect its cure by the simple removal of the stoppage would be more commonly practicable, than experience shows. Even in the cases which take place near the eye-lids, and have an opening, out of which the contents may be completely pressed, a cure will not follow, unless the cyst be removed. These reflections, at all events, tend to the conclusion, that there must be some other important cause concerned in the production of encysted tumours, besides the mere obstruction of the cutaneous follicles. As the subject, however, is yet obscure, and the new observations upon it come from so high an authority, we have deemed it our duty not to pass them over in silence.

The following practice is adopted by Sir Astley Cooper: If the follicle can be seen only as a black spot, filled with hardened sebaceous matter, a probe is passed through it, and the sebaceous matter squeezed out of the tumour, which may be done with little inconvenience. But, when the contents cannot be pressed out without violence, the preference is given to the plan of enlarging the opening, in order to avoid bringing on inflammation. When an encysted tumour is to be removed, the plan of first making an incision into it is preferred; and the sides of the skin are then pressed together, by which means the cyst, it is said, may be easily everted and removed. This way of operating was recommended for particular cases in the *Encyclopædia*; but doubts may be entertained concerning the advantages of the plan as a general practice.

The removal of encysted tumours is not altogether unattended with danger: Sir Astley Cooper has seen three instances of severe erysipelatos inflammation after operations of this kind upon the head, and one of them ended fatally; one or two other cases, equally unfortunate, have also been reported to us.

In the history of encysted tumours, the curious circumstance of the occasional growth of horny excrescences upon the human body deserves to be noticed: recent investigations prove, that the horny matter is, in fact, the secretion of the cysts of some of these tumours out of which it protrudes, and assumes various shapes, sometimes even that of a ram's horn, as happened in the remarkable case mentioned by Dr Roots of Kingston. This is a subject which has been particularly considered by Sir Everard Home, in the *Philosophical Transactions* for 1791. The case that fell under the observation of Dr Roots may be perused in the Article HORNY EXCRESCENCE, in Dr Rees's *Cyclopædia*. Such horns will be reproduced, if care be not taken in the operation to cut away every particle of the cyst.

On the subject of erysipelas, the remarks of Mr <sup>Of Erysipel-</sup> Hutchison claim attention: he has found seafaring <sup>las.</sup> men particularly liable to phlegmonous erysipelas of the legs, frequently occasioned, as he supposes, by the exposure of these parts to the irritation of salt

Surgery.

water, and the friction of coarse trowsers. In such patients, the disease is said to proceed with extraordinary rapidity to the gangrenous state. Even when mortification is prevented, large abscesses very often form, and spread to a surprising distance between the muscles and under the skin. Now, according to Mr Hutchison's experience, the best way of hindering all these evils, is to make several free incisions into the inflamed surface as early in the disease as possible, the knife being carried through the integuments and down to the muscles. We fear many practitioners will consider this practice severe, more so, perhaps, than circumstances can ever justify in as early a stage as the author speaks of; because, at this period, who can predict, that the case will ever be serious enough to require the employment of the knife? However, as Mr Hutchison never had any unfortunate cases after he adopted the preceding method, and the contrary used to happen under the other plans, which he was formerly in the habit of trying, the proposal appears to deserve mature consideration.

In most works on surgery, little valuable practical information is to be met with respecting the best local applications for erysipelas; the sentiments of the late Dr Bateman, therefore, concerning this unsettled part of practice, may here not be unacceptable. In the early stage of the disease, Dr Bateman found powdery substances, like flour, starch, chalk, &c. increase the heat and irritation, by forming, with the concreting fluid, hard crusts upon the tender surface. In this gentleman's opinion, the only unobjectionable plan is that formerly advised by Dr Willan, which consists in fomenting, or washing the parts, from time to time, with milk, bran and water, or a decoction of elder-flowers. Great benefit is stated to result from tepid bathing, and sometimes from the application of the diluted liquor *ammoniacæ acetatis*.

Gonorrhœa.

With regard to the complaint termed gonorrhœa, it seems right just to notice a medicine that has been of late very much employed, and frequently with great benefit. Cubebs, a spice brought from China and Java, is the remedy here spoken of; it has been recommended (no doubt in terms rather too high) as a specific for gonorrhœa, equally proper in the early inflammatory stage, and in the later chronic form of the disease. The dose is a dessert spoonful of the powder, an hour before breakfast, a second six hours afterwards, and a third at bed-time. The powder is to be taken in water. If given while the discharge is copious, and the inflammation severe, the painful symptoms, it is asserted, will be removed in two days, and the discharge will generally cease on the third or fourth day. The antiphlogistic regimen is to be observed, and the powder continued a day or two after the stoppage of the discharge. (See *Edin. Med. and Surgical Journ.* Jan. 1819, p. 61, &c.) Cubebs appears to act upon the mucous membrane of the urethra very similarly to the balsam of copaiva, or turpentine medicines; that is to say, through the medium of the urine, to which it communicates particular qualities, and, amongst them, a powerful smell; its operation, however, is certain-

ly more potent, than that of the above mentioned Surgery. balsam, and, on this account, it may be sometimes more effectual.

As a supplement to the observations on strictures of the urethra, a short account of the manner of using bougies, armed with caustic potassa, as introduced into practice by the late Mr Whately, may not be uninteresting; and to the same subject we mean to annex a brief description of the way, in which a passage is sometimes forced through bad strictures by means of a catheter of a conical shape; as done at the present day by some surgeons of considerable eminence, particularly in France.

Our reason for introducing an account of Mr Whately's plan of treating strictures, is not that the practice seems to us by any means entitled to the reputation which it acquired, but because there are some surgeons, whose judgment and talents we respect, who think more highly of such treatment, than we could ever yet venture to do ourselves. Mr Whately regarded strictures of the urethra, not merely as contractions, but as really diseased portions of the membrane lining that canal, with a continued disposition to increased contraction. Hence, he conceived, that the remedy should be calculated both to remove the diseased affection, and to dilate the contracted part, without putting the patient to the inconvenience of wearing a bougie. Such a remedy he deemed caustic, when employed with skill and judgment. That to which he gave the preference was the caustic potassa, applied in a particular manner, as being, according to his description, more efficacious, and less painful and hazardous, than bougies armed with lunar caustic.

The following is the practice detailed and recommended by Mr Whately: Before the caustic potassa is used, the urethra should be rendered sufficiently capacious to let a bougie, rather above the smallest size, pass into the bladder, and the irritability of the strictures, if very considerable, should be lessened, in the first instance, by the use of common bougies.

A small quantity of the caustic potassa is to be put upon a piece of paper, and broken with a hammer into small pieces of about the size of large and small pins' heads. When thus broken, it is to be preserved for use in a phial closed with a ground stopper. A suitable curvature is to be communicated to the bougie, by drawing it several times between the fore-finger and thumb of the left hand, and it ought to be just large enough to enter the stricture with some degree of tightness. It is to be gently introduced into the urethra, and when its point stops at the stricture, a notch is to be made on the upper portion of the bougie, precisely half an inch from the extremity of the penis. As soon as the bougie has been withdrawn again, a small hole, described as about the sixteenth part of an inch deep, is to be made in its rounded end. Then a bit of the caustic, less than the smallest pin's head, is to be selected for the first application. It is to be fixed in the hole of the bougie with a pocket knife, and pushed into it with the blunt end of a pin, rather below its margin. In order to hinder the caustic from slipping out, the hole is next to be contracted a little with the finger,

*Surgery.* and the remaining vacancy filled with hog's lard. The bougie, after being oiled, is to be introduced with its concavity upwards, as far as the anterior part of the stricture, the situation of which has been previously ascertained, and the bougie marked, as already noticed. The instrument should rest there a few seconds, for the purpose of letting the dissolution of the caustic begin to take place; it is then to be very gently pushed towards the bladder, about one-eighth of an inch, when it is again to be kept quiet for a second or two. The bougie is now to be introduced further, in the same gentle manner, until it reaches beyond the stricture. The next business is to withdraw it immediately, by a very gentle motion, to the part at which it was made to rest awhile. Then it is to be very slowly passed through the stricture a second time, but not allowed to stop in its passage. If pain or faintness arise, the operation is now to end, and the bougie to be removed; but if no such consequences occur, the instrument is to be moved backwards and forwards once or twice more.

The foregoing process is to be repeated once every seven days, and if the stricture be found to be dilated, the size of the bougie must be increased accordingly. This method of treating strictures having attained some celebrity, we deemed it worthy of brief notice in the present Work; but our experience leads us to regard the practice as very inferior to that executed with other armed bougies: to the particle of potassa, indeed, we can impute little certain effect, dissolved and blended as it may or may not be with the oil on the end of the bougie, and the mucus of the passage. Its regulation also, in the precise manner described by Mr Whately, so that it may operate exactly on the diseased portion of the urethra, and not upon the sound part, appears to us rather visionary, than really performed. How, then, has the method succeeded at all? Our answer would be, that it has effected cures principally by means of the mechanical dilatation of the bougies, without the potassa having any effect, or at least any that is not much more likely to do harm than good. The practice seems already to be on the decline,—a fact confirming the judgment here delivered concerning it.

We quit Mr Whately's suggestion to make a few observations upon another modern proposal relating to the cure of strictures. Every body, at all acquainted with the history of this disease, knows, that, in France, the use of armed bougies of any kind never met with much approbation, having been there, for the most part, represented as a very dangerous and harsh remedy. Yet, who would have anticipated in this same country, where caustic is abused on the principle of its being a harsh mode of treatment, the origin of another method of cure, in which every thing is to be completed by actual force? Mr Cross, a surgeon at Norwich, who visited the medical schools at Paris for the express purpose of ascertaining the state of the practice of surgery in France at the present day, gives a relation of what he saw there in reference to the treatment of strictures. He informs us, that, when he first went to *La Charité*, there were fifty-three male patients in the surgical ward, amongst whom were five with strictures of the ure-

*Surgery.* thra. The caustic bougie, he says, is not used in any of the hospitals, and it was censured by all the surgeons whom he conversed with, as a perilous and harsh remedy. Mr Cross justly observes, however, that the Parisian method of treating many cases of stricture is not milder than the use of caustic. A case is then detailed, which this gentleman saw in *La Charité*. A man, who had had a permanent stricture a long while, had been repeatedly under surgical treatment for it. There was difficulty of making water, but not complete retention. For several days, unsuccessful attempts were made to pass an instrument into the bladder by gentle means. The patient was still able to void his urine, although with great pain and difficulty. M. Roux, the surgeon, now took a conical silver catheter, with a very slight curvature, and an almost pointed extremity, and by means of force, regularly applied, he passed the instrument into the bladder, notwithstanding all obstacles. Care was taken to keep the catheter in a central position, and the direction of its point was judged of by the lateral rings. The rule, laid down by M. Roux, for commencing the great depression of the outer end of the catheter was, when he could feel, by means of his finger in the rectum, that the point had reached the apex of the prostate gland. The patient was put to considerable pain; but the instrument really went into the bladder. The urine was not allowed to flow out immediately, the outer orifice of the catheter being stopped up with a bit of wood. In general, M. Roux suffers the conical catheter to remain in the urethra three or four days; but, the sufferings of this patient from it were so intolerable, that it was taken out in twenty-four hours. Rather a large elastic gum-catheter was then easily introduced, the end of which was fastened to the abdomen, while the orifice was closed with a stopper, and the urine permitted to flow occasionally. The next day, the patient was comparatively easy. On the fourth day, there was a swelling of the testicle, scrotum, and perinæum. A poultice was applied, and the elastic catheter continued. In four days more, the swelling of the parts had subsided so considerably, that the poultice was unnecessary. A fresh gum-catheter of large size was now used, and, in about six weeks, one of the largest dimensions could be introduced.

The event of another case was less fortunate: The *sonde conique* had been employed for making a passage into the bladder, and a gum-catheter afterwards introduced; but, in less than a week, the patient, supposing he could make water without its assistance, withdrew it of his own accord. The next day, an effusion of urine in the scrotum had taken place, and it became necessary to let out the extravasated fluid by two free incisions. Unfortunately, the elastic catheter could not be introduced again. The incisions did indeed prevent sloughing of the scrotum; but the patient, who was in a very reduced state, died in a few days. It is but fair to add, that this case was so inveterate, that Mr Cross believes the patient would have sunk under any mode of treatment. On dissection, the bladder was found to be half an inch thick, the stricture cartilaginous, and extensive sinuses were traced, communicating with the once membranous part of the urethra.

Surgery.

The promptitude with which relief may be afforded in some very bad cases of stricture, where no bougie, nor elastic catheter, can be introduced, is the reason given for the foregoing practice; and M. Roux even assured Mr Cross, that he had never seen any inflammation or irritation produced by it, that did not readily yield to proper means. We suspect, however, that, by this declaration, M. Roux meant to refer all disastrous circumstances to the disease, when they happened, so as to screen the mode of treatment from all suspicion of being sometimes itself a source of dangerous consequences. Yet, we cannot understand, how he could hope to produce an universal conviction of the accuracy of such an insinuation; because, in his Clinical Lectures, he spoke of two fatal cases, which he dissected, where he found false passages, extravasation of urine, sloughing, &c. amongst other mischief. On the whole, without pronouncing this forcible use of catheters to be always bad practice, we shall venture to say, that it is generally so, and ought very seldom to be attempted. M. Ducamp, an intelligent writer on the present subject, differs altogether from some of his countrymen, by whom the treatment has been carried to a high degree of absurdity. "Surgeons (says he), who are ambitious of the title of *operators*, despise the slow progress and minute attention which the bougies require; nothing but what is prompt, great, and striking, is agreeable to their taste; they thrust a silver catheter through every obstacle into the bladder: at the end of three or four days, they exchange it for one of elastic gum; this last they withdraw every eighth or tenth day, and this they call practising good surgery on a grand scale!" The result is, in general, that a false passage is established, and inflammation of the urethra and prostate is produced by the presence of the instrument. In short, Ducamp clearly shows, from the nature of the stricture itself, that the operation, even when the instrument does not wander from the urethra, does not depend upon dilating the stricture, but upon tearing it; and as the stricture is more resistant than the rest of the canal, the chance is, that a false passage is made.

Having mentioned M. Ducamp, we shall not quit him without recommending to the attention of surgeons, his ingenious contrivances for the application of the lunar caustic to strictures; contrivances which are meant to regulate the action of the caustic more precisely than in the common mode: indeed, the whole of his work deserves, to be consulted. See *Traité des Retentions d'Urine, causées par le Rétrécissement de l'Urètre, et des moyens à l'aide desquels on peut détruire complètement les Obstructions de ce Canal*, Paris, 1822, 8vo.

While we are upon the subject of strictures, Mr Arnott's dilator occurs to us as a very ingenious instrument deserving to be mentioned, though we are not exactly acquainted with the degree in which it has yet been found to answer in practice. It was conceived, that, for the purpose of dilating strictures, an instrument was needed, calculated to pass through the obstruction with facility, then to admit of its diameter being increased to any size, and with any force, yet, when the surgeon wishes to extract it, to

be capable of being reduced to its primitive smallness. The dilator consists of a tube of oiled silk, lined with the thin gut of some small animal to render it air-tight, and then fixed upon the end of a small canula, by means of which it can be distended with air or water from a bag, or syringe at the outer end, while a stop-cock or valve serves to confine the air after it has been received. It is said generally to pass as easily down to the stricture as a small bougie; but Mr Arnott sometimes prefers introducing it through a smooth canula, especially when the urethra is irritable, and unaccustomed to the presence of instruments. As soon as the bag is sufficiently within the stricture or strictures, as much air as the patient can easily bear is to be injected into it. The dilator, it is asserted, can be made to act with more effect than a bougie, which, as soon as it yields, loses its power of distention, while the force of the dilator is concentrated at the stricture, and unceasing. In principle, it resembles Bromfield's contrivance for dilating the *meatus urinarius*.

Here the subject of diseases of the urinary passages must not be quitted, without mention being made of the success with which Mr Earle formed a canal, which answered perfectly as a substitute for a considerable portion of the urethra that had been destroyed. The details of this case, which appear to us very interesting, may be perused in the *Phil. Trans.* for 1821.

To what is delivered concerning hydrocele, in the *Encyclopædia*, a few new and useful observations may be annexed. Since the article on *Surgery* in that work was written, Professor Scarpa has laid down in his valuable treatise upon Hernia some cautions, highly necessary to be recollected by surgeons in the operation of tapping a hydrocele. The analogy, existing between large scrotal herniæ and hydroceles of considerable size, led Scarpa to suspect, that, in the latter disease, a displacement and separation of the vessels of the spermatic chord from each other might also happen. Careful investigations, afterwards made upon the dead subject, fully justified the conjecture. In fact, in all considerable hydroceles, he found the spermatic vessels so displaced and separated, that the artery and vas deferens were commonly situated upon one side of the tumour, and the veins upon the other. Sometimes all these vessels extended over the lateral parts of the tumour, as far as its fore part, principally towards the bottom of the swelling. Now, in numerous examples, the operation of puncturing a hydrocele has been followed by copious extravasation of blood within the tunica vaginalis; but, it was not until within the last few years that Scarpa became acquainted with a case of this kind, sufficiently well detailed and authentic to be quoted as an instance of the spermatic artery being wounded in the operation. Such a fact, however, was at length communicated to him by Gasparoli, an eminent surgeon at Pallanza; who, in introducing the trocar into the lower part of the swelling, wounded the spermatic artery, and the accident terminated in the patient's being obliged to submit to castration. As Scarpa justly observes, the accident may be avoided by taking care to puncture the tumour at a considerable distance from its bottom, that is to say, a little below

Of Hydrocele.

Surgery. its middle, and on a line that would divide the swelling longitudinally into two perfectly equal parts. Experience proves, that, for the purpose of completely emptying a hydrocele, there is not the slightest occasion to make the opening at the lower part of the swelling: the natural corrugation of the scrotum, and a little pressure made with the hand, will suffice for discharging all the fluid contained in the tunica vaginalis, even though the puncture be not lower than the middle of the tumour. These remarks upon the proper method of tapping hydroceles, which are amongst the most frequent cases in surgery, cannot fail to be highly interesting to every practical surgeon, and both on this account, and because they are modern, and perhaps not yet sufficiently known and understood, a short notice of them here appeared to us desirable.

The old method of curing hydroceles by the excision of a portion of the scrotum, and the greater part of the tunica vaginalis, has been very properly rejected from practice; as being an operation of an unnecessarily painful nature, liable to many severe ill consequences. This remark, however, should not be extended to the mode of excision, proposed a few years ago, and practised with success by Mr Kinder Wood: it is indeed a very different proceeding from that which was anciently adopted, inasmuch as it is perhaps the mildest of every plan hitherto devised for the radical cure of this disease, as it simply consists in puncturing the hydrocele with an abscess-lancet, drawing out a little piece of the sac with a tenaculum, and cutting it off. (See *Med. Chir. Trans.* Vol. IX.) If it prove as little subject to failure as the mode of cure by means of an injection, a point yet remaining to be settled in the extensive field of experience, we should say, that Mr Kinder Wood's simple and mild operation is as good a practice as any that has yet been suggested, with reference to the present disease. To us it seems not barely a transient novelty in surgery, but a proposal that may become a solid and lasting improvement.

The cure of an encysted hydrocele of the spermatic chord with an injection, is generally considered by modern surgeons less certain and advantageous, than the excision of a part of the cyst. That judicious and excellent practical surgeon, the late Mr Hey of Leeds, has left some useful observations upon this subject, though he does not appear to be aware, that his method of curing encysted hydroceles of the spermatic chord is substantially the same as that long ago recommended by Bertrandi: it consists in cutting down to the cyst, and removing the fore-part of it, while the portion, closely attached to the cord, is not at all interfered with, by which means, all hazard of doing injury to the spermatic vessels is avoided, and the operation itself shortened.

The next subject, on which we shall have to dwell a little, is that treated of in the article referred to, under the head of Diseases of the Synovial Membranes. From the observations of Mr Brodie, it appears, that the usual consequences of inflammation of the synovial membrane, or capsular ligament of a joint, are, first, a preternatural secretion of synovia; secondly, an effusion of coagulating lymph into the cavity of the joint; thirdly, a thickening of the syno-

vial membrane, a conversion of it into a substance resembling gristle, and an effusion of coagulating lymph, and probably of serum, into the cellular substance, by which it is connected to the external parts. Mr Brodie has met with several cases, where, from the appearance of the joint and the symptoms, there was every reason to believe, that the inflammation had produced adhesions of the reflected fold of membrane, and in dissection, he has sometimes noticed adhesions, which might have arisen from inflammation at some former period. These effects of inflammation of the synovial membrane, he conceives, bear a strong resemblance to those of inflammation of serous membranes. There are, however, some points of difference. In the former, Mr Brodie thinks, that suppuration rarely takes place independently of ulceration, while, in the latter, this is a frequent occurrence. Some cases have fallen under this gentleman's notice, where there was extensive destruction of the cartilages, apparently in consequence of neglected inflammation of the synovial membrane; but, he believes, that, in most cases, where ulceration of the cartilage is combined with such inflammation, the former is the primary affection, and the latter takes place subsequently, in consequence of the formation of an abscess within the joint. According to the same writer, original inflammation of a synovial membrane seldom happens in young children; but is frequent in adult persons;—the reverse of what takes place in some other diseases of the joints.

Synovial inflammation frequently becomes chronic, and is then liable to be confounded with other more formidable diseases, under the general name of white swelling. The complaint is described by Mr Brodie as frequently proceeding from cold, and being on this account more common in the knee and ankle, than in the hip or shoulder. It may also arise from the immoderate use of mercury, and, in particular constitutions, from rheumatism and general debility. In such examples, it often leaves one joint, and attacks another; and it is less severe, and less disposed to produce an effusion of coagulating lymph, or a thickening of the membrane, than when apparently a local disease. In this last case, the disorder is more likely to assume a severe character, and may be of long duration, leaving the joint more or less impaired, and sometimes ending in its total destruction. The following are represented by Mr Brodie as the chief symptoms of inflammation of the synovial membrane: Though, in the beginning, some pain is felt over the whole joint, the patient complains principally of one point, and generally a week or ten days pass, before the suffering attains its greatest severity. Sometimes, even at this period, the pain is trifling; but, frequently, it is considerable, and every motion of the joint distressing. In a day or two after the commencement of the pain, the joint swells, the enlargement arising at first entirely from fluid within the capsular ligament, and where the joints are not covered by much flesh, an undulation may be distinguished. After the inflammation has lasted some time, however, the fluid becomes less perceptible, either in consequence of the synovial membrane being thickened, or lymph effused; and the more solid the swelling is, the more is the mobility of the joint impaired.

Surgery.

Surgery.

The shape of the diseased joint does not correspond to that of the heads of the bones ; but, as the swelling is chiefly produced by the distention of the synovial membrane, its figure depends in a great measure upon the situation of the ligaments and tendons, which resist it in certain directions, and allow it to take place in others. Thus, when the knee is affected, the swelling is principally observable on the anterior and lower part of the thigh, where there is only a yielding cellular structure between the extensor muscles and the bone. It is also frequently considerable in the spaces between the ligament of the patella and the lateral ligaments, because at these points the fatty substance is propelled outwards by the fluid. In the elbow, the swelling occurs principally above the olecranon, under the extensor muscles of the fore-arm ; and in the ankle, it is between the lateral ligaments and the tendons in front of the joint. In the hip and shoulder, where the disease is not so common, the fluid cannot be felt ; but the swelling may be perceived through the muscles. In the beginning of this disease in the hip, a fulness both in the groin and nates may be remarked ; but afterwards, the nates become flattened, and the glutæi waste away, from want of exercise. The pain is usually confined to the hip ; but Mr Brodie has seen cases, in which it was also referred to the knee. The disease may be discriminated from the case, in which the cartilages of the hip are ulcerated, by observing that the pain is more severe in the beginning than in the advanced stage of the complaint ; it never amounts to the excruciating sensation felt in the other disease ; and it is aggravated by motion, but not by pressing the cartilaginous surfaces against each other. The wasting of the glutæi is also preceded by a fulness of the nates. After the subsidence of the inflammation, the fluid is absorbed, and the joint frequently recovers its natural figure and mobility ; but, in the majority of cases, some stiffness and swelling remain, and the patient continues very liable to relapse, the pain returning and swelling increasing, whenever the patient exposes himself to cold, or exercises the limb much. When the synovial membrane is thickened, a slow inflammation sometimes continues in the part, notwithstanding the absorption of the fluid, and the subsidence of the principal swelling, the disease at length extending to the cartilages, suppuration taking place, and the articular surfaces being completely destroyed. In this advanced stage, the history of the disease, and not its present appearance, is the only thing, by which one can learn, whether the primary affection was inflammation of the synovial membrane, or ulceration of the cartilages. (See Brodie's *Pathological and Surg. Obs.* p. 21, &c.)

In cases where inflammation of the synovial membrane has arisen from an ill managed, or a tedious course of mercury, this gentleman recommends a trial of *sarsaparilla* ; and, when it is connected with rheumatism, the medicines praised are opium with diaphoretics, preparations of colchicum autumnale, and other remedies usually prescribed in cases of rheumatism. When several joints have been affected, however, he has known benefit result from moderate doses of mercury.

Surgery.

We need not here enter into a description of the treatment of the acute stage of synovial inflammation ; as soon as this is over, the surgeon's aim should be, to remove the thickened state of the capsular ligament ; the rigidity of the joint ; the pain on motion ; the fluid remaining within the capsule, &c. The inflammation having abated, a blister may be applied, and kept open with the savine cerate, or a succession of blisters kept up, as preferred by Mr Brodie. The blisters, he says, should be of considerable size ; and, if the joint be deep-seated, they may be applied as near it as possible, but otherwise, at a little distance. Mr Brodie thinks blisters have more effect, than any other means, in removing the swelling ; but, excepting in very slight cases, he very rightly condemns their use, unpreceded by bleeding. After the inflammation has sufficiently subsided, exercise of the joint, and stimulating liniments, are recommended. The camphor liniment is to be strengthened with the addition of liquor ammoniæ, or tinctura lyttæ. A very good liniment, much employed by the same practitioner, consists of three parts of olive oil, and of one of sulphuric acid. Mr Brodie has also a favourable opinion of the effects of the antimonial ointment. Plasters of gum ammoniac, he considers, as sometimes useful in preventing relapses. Issues and setons are said to be never serviceable, unless the cartilages are ulcerated. For the removal of the remains of the swelling and stiffness, friction and exercise are set down as the best means. The friction may be made with camphorated mercurial ointment, or with powdered starch ; but it is to be adopted with caution, as otherwise it may produce a return of the inflammation. When this is the case, it must be left off, and blood taken from the part. On the whole, Mr Brodie seems to regard friction as more calculated for cases where the stiffness depends upon the state of the external parts, than for others, where it arises from disease in the joint itself. The plan of letting a column of warm water fall on the part is allowed to be sometimes beneficial ; but it requires the same caution as friction.

In the article in the *Encyclopædia*, some account is given of the *moveable bodies occasionally found within the synovial capsules*, and the method of cure by an operation is mentioned. This practice, though generally successful, has sometimes brought on severe, and even fatal consequences. Hence, in addition to the observations made upon this subject in the above article, it seems right to state, that the plan of fixing and making pressure on the cartilaginous body has been tried by various surgeons of considerable eminence, as a means of relief. Here we shall only mention the late Mr Hey of Leeds, as an advocate for such practice. Duly impressed with the unfortunate event of some attempts that have been made to cure the disease by the extraction of loose cartilaginous substances from the knee-joint, this judicious practical surgeon preferred trying what relief might be obtained by the employment of a laced knee-cap ; and the cases which he has published tend to prove that the plan answers extremely well, the benefit not being temporary, but lasting at least as long as the patient continues the bandage. One of Boyer's patients used a knee-cap a year, at the end of which it

*Surgery.* was discontinued, and the patient remained free from inconvenience. This practice appears to us to deserve notice, as a safer, though perhaps a less certain plan of relief, than the operation of extracting the substances which are the cause of annoyance.

*Spina Bifida.* With regard to spina bifida, treated of in the same article, some observations of considerable interest were published a few years ago by Mr Abernethy and Sir Astley Cooper. The first of these surgeons may be said to have the merit of suggesting the principles, on which a few successful attempts at relief have now been made. His reflections upon the nature of the malformation led him to think the trial of a gentle degree of pressure upon the tumour from its commencement extremely plausible; because it might have the effect of promoting the absorption of the fluid, and, at the same time, prevent the distention of the dura mater by keeping it supported. But, if this method were unavailing, and the fluid to increase, Mr Abernethy conceived that, as the disease, now left to itself, would unavoidably soon end in death, it might be a warrantable experiment to let out the fluid by means of a fine puncture, which could be immediately closed with sticking-plaster, and healed by the first intention. He proposed, that an endeavour should then be made to prevent another collection by bandages and topical applications; but, if the swelling returned, notwithstanding such means, he recommended the small puncture to be repeated, and the same mode followed again. We shall not here detail the case, in which Mr Abernethy put the plan to the test of experience, but shall merely state, that, though the child was not ultimately saved, there were circumstances in the case affording a degree of encouragement to future trials of the same kind. Sir Astley Cooper, proceeding on the principles already specified, tried the effect of puncturing spinæ bifidæ with a fine needle, letting out the fluid from time to time, and promoting the closure of the opening in the spine with a compress and bandage. In one case upon record, the treatment in this manner led to a complete cure. (*Med. Chir. Trans.* Vol. II. p. 326.) Sir Astley Cooper, however, follows two methods, according to the circumstances of the case, the one being palliative, the other radical. The first consists in treating the case as a hernia, and applying a truss to prevent its descent; the second in pricking the tumour with a small needle, and producing adhesion of the sides of the sac, whereby the opening in the spine is closed, and the disease altogether prevented. The first is attended with no risk; the second exposes the patient to a great deal of illness; but if successful, hinders the return of the disease. It deserves to be remembered, also, that, when the adhesive process cannot be effectually accomplished by the plan intended for a radical cure, the palliative treatment will yet admit of trial.

In order to be able to practise judiciously in these difficult cases, the surgeon should know, that there are particular examples, which afford not the slightest chance of a cure; they are unfortunately very frequent; for a statement of their nature, the profession is indebted to the last mentioned practitioner. If the tumour is connected with an unnatural en-

largement of the head, and hydrocephalus; if the lower extremities are paralytic, or the feces and urine come away involuntarily, there is no hope. Also, if the tumour is burst at the period of birth, or soon afterwards, little expectation of a cure can be entertained. The deficiency of the spine is sometimes so considerable, that the tumour, at the time of birth, is already very large; the nerves protrude from the spinal canal; the medulla itself is injured; and, under these circumstances, all surgical treatment must of course prove ineffectual.

Palsy of the lower extremities, from a diseased state of the spine, a case considered in the article referred to, has had, of late years, a great deal of attention bestowed upon it; and surely no disease, in the long list of those to which the human body is liable, has a stronger claim to be most carefully investigated, whether the difficulty of cure, or the degree of affliction brought on by the disorder, be contemplated. From Mr Brodie's observations, it would appear, that the affection of the spine is not always of one kind, but that the disease sometimes originates in ulceration of the intervertebral cartilages, and sometimes in a morbid condition of the cancellous structure of the bodies of the vertebræ. This gentleman concurs with Mr Pott, and other writers, respecting the fact, that the actual curvature of the spine must be preceded by disease of this part, unaccompanied with any visible deformity, and cannot take place until caries has made considerable progress. Hence, in the early stage of the case, when the diagnosis is of the highest importance, no information can be obtained from the appearance of the spine itself, the shape of which is yet unchanged; and frequently the symptoms, which do come on early, are rather ambiguous, being, according to Mr Brodie, a pain, and some degree of tenderness in that part of the spine, where the disease has begun; a sense of constriction of the chest; an uneasiness at the pit of the stomach, and over the whole abdomen; a disturbed state of the functions of the alimentary canal, and of the urinary bladder; a sense of weakness and aching, and occasional cramps in the muscles of the extremities. But, it is also acknowledged by the same writer, that very similar complaints may arise from other causes, and sometimes no particular ailments are mentioned previously to the curvature. Mr Brodie is inclined to think that the disease, which begins in the cancellous structure of the vertebræ, is more immediately followed by suppuration, than that which commences in the intervertebral cartilages; and that the first form of the disease seldom produces so extensive a destruction of the vertebræ as the last. But, with the exception of these circumstances, nothing which he has hitherto observed enables him to point out any differences in the symptoms of these different diseases.

The deformity of the spine, as Mr Brodie remarks, is generally of a peculiar kind, and such as nothing can produce, except the destruction of the bodies of one or more vertebræ. The spine is bent forward so as to form an angle posteriorly; and, although the destruction of the vertebræ may be to the same extent, the distortion is more obvious in some parts of the spine than others. For example, the spinous

*Surgery.*

Palsy from  
Diseased  
Spine.

Surgery.

processes in the middle of the back being long, and projecting downwards, the elevation of one of these must occasion a greater prominence, than that of one of the spinous processes of the neck, which are short, and stand directly backwards.

A curvature of the spine forwards may arise from other causes, as a weak condition of the muscles, or a ricketty affection of the muscles. In such cases, it generally occupies the whole spine, which assumes the shape of a segment of a circle. At other times, however, it occupies only a portion of the spine, usually that which is formed by the superior lumbar and inferior dorsal vertebræ. But, in this circumstance, Mr Brodie finds, that the curvature is always gradual, and never angular; a circumstance distinguishing it from the curvature produced by caries. The cases, he thinks, have often been confounded, and some speedy and complete cures of carious spines on record, he infers, must have been cases of quite a different nature.

Besides the form of disease described by Mr Pott, the observations of the late Mr Wilson prove, that another form commences within the theca vertebralis, and thence extends to the bones. In his lectures at the College of Surgeons, the same gentleman also demonstrated what he called scrofulous tumours in the spinal marrow. Such diseases would create a loss of power in the parts below them, without any curvature of the spine.

We shall not here dwell upon the common treatment of diseased vertebræ, attended with a particular palsy of the limbs; it is already detailed in the former article, and consists principally in keeping open issues near the diseased bones. In France, it seems, the moxa is preferred to caustic issues, and cupping in the vicinity of the disease is often practised.

The great influence of the opinions of Mr Pott concerning the present distemper, has generally kept regular practitioners from making any trial of mechanical means for the support of the spine. It is questionable, however, whether Mr Pott may not have entertained prejudices against machinery, which, under some circumstances, may perhaps be useful. In these cases, mechanical contrivances are never now recommended, under the idea of there being any dislocation; an error sometimes prevailing in former times. We entirely coincide with Mr Brodie, and (we may say indeed) with the great mass of modern practitioners, that machines ought never to be employed with the view of elongating the spine, and correcting the deformity; but, if they be used merely for the purpose of taking off the weight of the head, chest, and upper extremities, from the diseased part of the spine, they may sometimes be of service. No doubt, Mr Brodie is fully justified in the observation, that they ought never, in the first instance, to supersede the constant maintenance of the horizontal position, though they may become advisable, when it is afterwards considered right for the patient to begin to sit up a part of the day.

The good which Mr Pott described as arising in these cases from issues, was imputed by the late Mr Baynton, not in reality to them, but to the long observance of the horizontal posture. Now, although

we fully agree, that keeping the patient as quiet as possible in the recumbent position is judicious practice, it does not follow that, because we entertain this belief, we must subscribe to the notion, that issues should be rejected, and that quietude will do every thing. Mr Baynton appears to us to have fallen into an error in supposing, that the process by which the diseased part of the spine is to be restored, and united, should be conducted exactly on the same principles as the union of bones free from disease. The truth is, there is an additional indication, namely, that of checking the progress of the disease, for which purpose experience proves, that issues, aided by rest, are the means affording the best chance of success. That issues frequently do render essential benefit is fully proved by the fact noticed by Mr Brodie, that many patients find themselves improved almost as soon as the issues are made; or regularly experience amendment each time the caustic is applied.

To the section on diseases of the bones, in the former article, we deem it right to add a few observations respecting the new and bold operation of removing the lower jaw; a proceeding which has been adopted several times in France by Dupuytren, Lallemand, &c. An interesting case of this practice was detailed a short time ago by the latter gentleman, who is Professor of Surgery at Montpellier. The patient, a robust man, aged 68, was received into the hospital St Eloy, on the 23d of May 1822. Nearly the whole of the lower lip, from one commissure to the other, extending downwards to the lower margin of the chin, was in a state of cancerous ulceration, in which disease the periosteum and bone itself appeared to participate. M. Lallemand began the operation with two semi-elliptical incisions, which commenced in the upper lip, about five or six lines from the commissure, and ended about the middle of the thyroid cartilage. The cheek on each side was dissected up to the front edge of the masseter. In this situation, the periosteum appeared perfectly sound; and here M. Lallemand sawed through the jaw, commencing with the left side. He then detached the muscles and soft parts on the internal side of the bone, and sawed through the right side from behind forwards, as he had done with respect to the left. The labial, submaxillary, and ranial arteries were successively tied, as well as a few less considerable branches. The lower angle of the wound was afterwards brought together with the twisted suture, and the branches of the jaw, and soft parts covering them, approximated by means of adhesive plaster. Soon after the operation, a considerable hemorrhage arose, which could not be suppressed without the actual cautery. In fifty days, the wound completely healed. There was then an interspace of nearly two inches between both ends of the jaw, through which the tongue passed, and the saliva dribbled away. For this last inconvenience, Lallemand contrived a silver chin, upon the concave surface of which was placed a sponge, secured by straps that passed back over the neck. (*Journ. Univers.* December 1822.) It is to be hoped that the successful instances of the removal of the lower jaw, now upon record, may not have the

Surgery.

Removal of the Lower Jaw.

**Surgery.** effect of leading young zealous admirers of every thing in the shape of a new and grand operation to repeat the practice in any cases, where the necessity for it is not clear, urgent, and unequivocal; for with the knowledge that we possess of the great deal that nature will do for the cure of necrosis of this bone, and of the bad, but temporary, disfigurement attending some stages of this disease, we would caution surgeons against any propensity to be too officious in such a case, which may even be erroneously considered as a cancerous affection. It is far from our intention, however, to insinuate, that the above case did not truly demand the bold measure which was put in execution.

is instituted, whereby the bulk of the tumor is removed. (*On the Diseases of Arteries*, p. 114.)

**Surgery.**

External aneurisms, when they burst, give way by the sloughing of the extremity of a thin conical prominence that is previously formed upon them; but the bursting happens in a different manner in internal aneurisms. As Mr Allan Burns first noticed, these generally burst by actual laceration, and not by the sphacelation of the cyst. But the most correct account of this subject is to be found in Mr Hodgson's work. We are there informed, that when the sac points externally, it rarely or never bursts by laceration, but the extreme distention causes the integuments and investing parts to slough; and upon the separation of the eschar, the blood issues from the tumour. A similar process takes place, when the disease extends into a cavity, which is lined by a mucous membrane, as the œsophagus, intestines, bladder, &c. In such cases, the cavity of the aneurism is generally exposed, by the separation of a slough, which is formed upon its most distended part, and not by laceration. But when the sac projects into a cavity lined by a serous membrane, as the pleura, the peritonæum, the pericardium, &c. these membranes do not slough, but the sides of the tumour having become extremely thin from distention, at length burst by a crack, or fissure, through which the blood is discharged.

Of Aneurismal Diseases.

Since the former Article on SURGERY was composed, a great many new and very interesting observations have been made upon *aneurisms*; and the share which English surgeons have had in the modern improvements that have taken place in the treatment of these formidable diseases, reflects such credit upon them, for science, judgment, and enterprise, that, in all works, devoted to the consideration of the diseases of the blood-vessels, their names must be inseparably connected with every successful attempt to meliorate this part of practice, and every praiseworthy effort to throw light upon the nature of the morbid changes to which the arteries and veins are liable. Whoever looks over Hodgson's valuable work on the diseases of the blood-vessels, will find the justness of this encomium completely established; and it is a book to which we refer with considerable pleasure, on account of the perspicuity and correctness prevailing in every part of it.

A few years ago, Professor Scarpa published a valuable treatise upon aneurism, maintaining the ancient doctrine, that no aneurisms consisted in a dilatation of all the arterial coats, but that they were all attended with a rupture of the proper coats of the vessel, the muscular and internal. Scarpa considers it an error to suppose, that aortic aneurisms, produced by a violent and sudden exertion of the body, or of the heart in particular, and preceded by a congenital relaxation of a certain portion of this artery, or a morbid weakness of its coats, ought always to be regarded as a tumour, formed by the distention or dilatation of the proper coats of the artery itself, that is, of its internal and fibrous coats. On the contrary, he deems it fully demonstrable, that such aneurisms are produced by a rupture of these tunics; and, consequently, by the effusion of arterial blood under the cellular sheath, or other membrane covering the vessel. At the same time, he does not deny, that, from congenital relaxation, the proper coats of the aorta may occasionally yield and be disposed to give way; but he will not allow that dilatation of the vessel precedes and accompanies all its aneurisms, or that its proper coats ever yield sufficiently to constitute the aneurismal sac. The root of an aneurism of the aorta, he observes, never includes the whole circumference of the artery: and the aneurismal sac arises from one side of it, in the form of an appendix, or tuberosity. But what is called a dilatation of an artery, he says, always extends to the whole circumference of the vessel, and therefore differs essentially from aneurism. Hence, he argues, that there is a striking difference between a dilated and an aneurismal artery, although the two affections are sometimes found combined together, especially at the origin of the aorta. It is also noticed, that the dilatation of an artery may exist, without any

As an aneurism grows larger, its pulsations become weaker, and when the magnitude of the tumor is considerable, they are sometimes hardly distinguishable. This diminution of the pulsation has been accounted for by the coats of the artery losing their suppleness, in proportion as they become distended, and consequently the aneurismal sac no longer admitting of an alternate diastole and systole from the action of the heart. There can also be no doubt, that the fact is in a great measure owing to lamellated coagulated blood being deposited on the inner surface of the sac. This is an occurrence of great importance; for, when the disease undergoes a spontaneous cure, the deposition of lamellated coagula within the sac, is the mode by which this desirable event is accomplished. As Mr Hodgson remarks, one of the circumstances, which, in the most early stage, generally attend the formation of aneurism, is the establishment of that process, which is the basis of its future cure. The blood, which enters the sac soon after its formation, generally leaves upon its internal surface a stratum of coagulum, and successive depositions of the fibrous part of the blood, gradually diminish the cavity of the tumour. At length, the sac becomes entirely filled with this substance, and the deposition of it generally continues in the artery, which supplies the disease, forming a firm plug of coagulum, which extends on both sides of the sac to the next important ramifications given off by the artery. The circulation through the vessel is thus prevented, the blood is conveyed by collateral channels, and another process

Surgery.

organic affection, the blood being always within the cavity of the vessel; that, in an artery so affected, no lamellated blood is deposited; and that the dilatation never gives rise to a swelling of considerable size. In fact, no doubt can be entertained, that these circumstances fully warrant the inference, that aneurism differs essentially from one kind of dilatation of an artery.

According to the observations of Scarpa, the aneurismal sac never comprises the whole circumference of the vessel. Where the tumour joins the side of the artery, the aneurismal sac presents a kind of constriction, beyond which it is more or less expanded. This, he says, would never be the case, if the sac were formed by an equable distention of the tube and proper coats of the affected artery. In incipient aneurisms, at least, the greater size of the tumour would then be in the artery itself, or root of the swelling, while its fundus would be the smallest part. But whether aneurisms be recent and small, or of long standing and large, the passage from the artery is always narrow, and the fundus of the swelling greater in proportion to its distance from the vessel. Scarpa further explains, that the sac is always covered by the same soft, yielding, cellular substance, which, in the healthy state, united the artery to the surrounding parts. In aneurisms of the thoracic aorta, this cellular substance is covered by the pleura, and, in those of the abdominal aorta, by the peritonæum, which membranes include the sac and ruptured artery, presenting externally a continued smooth surface, just as if the artery itself were dilated. But Scarpa observes, that, if the aorta be opened lengthwise on the side opposite the constriction, the place of the rupture of the proper coats of the artery immediately appears within the vessel, on the side opposite to that of the incision. The margin of the fissure, that has occurred, is sometimes fringed, and often indurated, and through it the blood passed into the cellular sheath, which was itself converted into the aneurismal sac. If, as sometimes happens in the arch of the aorta near the heart, the artery, before being ruptured, has been somewhat dilated, it seems, at first, as if there were two aneurisms; but the constriction, which the nearest part of the sac and the artery presents externally, denotes precisely the limits, beyond which the internal and muscular coats of the aorta had not been able to resist the distention, and where, of course, they were ruptured. The partition, which Scarpa asserts may always be seen dividing the tube of the artery from the aneurismal sac, and is lacerated in its centre, consists of nothing but the remains of the internal and muscular coats of the ruptured artery.

Scarpa states, that, when an incision is made lengthwise in the side of the vessel opposite the rupture, its proper coats are found either perfectly sound, or a little weakened, and studded with earthy points, but still capable of being separated into distinct layers. On the contrary, in the opposite side of the aorta, where the rupture is, the proper coats are unusually thin, and not separable from each other without difficulty, or even not at all; they are frequently brittle, like an egg-shell, and are disor-

ganized and torn at the place, where they form the partition between the ruptured artery and the mouth of the aneurismal sac. Continuing to separate these coats from within outwards, we arrive at the cellular sheath surrounding the aorta. As in large aneurisms, this sheath is considerably thickened, and very adherent, at the constriction of the sac, to the subjacent muscular coat of the artery, it is liable to be mistaken for a dilated portion of the vessel itself. But even in such cases, it may at length be separated without laceration from the tube of the artery, above and below the injury, and successively from the muscular coat, as far as the neck of the aneurism. It then becomes manifest that the muscular coat does not pass beyond the partition between the cavity of the artery and that of the aneurismal sac, over which it is not extended, but terminates in a jagged manner at the edge of the rupture. The aorta and the sac being both covered by the pleura, or peritonæum, is a circumstance tending very much to lead surgeons into mistaken views of the real state of things.

As the portion of the aorta within the pericardium is covered only by a thin reflected layer of this membrane, such layer may also give way, when the proper coats of the vessel burst, and the consequence be an instantaneous effusion of blood within the pericardium itself. But every other part of the aorta makes long resistance to the fatal effusion, because there is between it and the peritonæum or pleura, a cellular sheath of a strong and elastic nature, which is capable of expanding into a sac, and while it is strengthened externally by the peritonæum or pleura, its strength is inwardly augmented in a very material degree, by the layers of coagulated blood.

Scarpa's doctrine, that all aneurisms are attended with rupture of the proper coats of the artery, great as the weight and influence of his opinion justly are, is far from having received general or even extensive sanction; for, in France, it is rejected by Richerand, Boyer, Dubois, Dupuytren, Sabatier, Breschet, &c.; and, in this country, every lecturer has continued to adopt the common division of aneurisms into true and false, or into some cases accompanied with dilatation, and into others attended with rupture of the arterial coats. The foundation for Scarpa's sentiments has now been very ably and impartially considered by numerous correct observers; and the love of truth obliges us to confess, that the mass of facts and authorities is decidedly against the doctrine which he maintains, without exceptions. As Mr Hodgson has remarked, the proofs of a partial dilatation of the coats of an artery, particularly of the aorta, are incontestably established by the possibility of tracing the coats of the vessel throughout the whole extent of the expansion, and by the existence of those morbid appearances in the sac, which are peculiar to the coats of arteries.

In the year 1811, this gentleman dissected an aneurism of the aorta. The sac was equal in size to a small melon, and the disease had proved fatal by bursting into the posterior mediastinum, and subsequently into the cavity of the thorax. This aorta exhibited the formation of aneurism in three distinct

Surgery. stages. The internal coat was throughout inflamed, and presented a fleshy and irregular appearance. At the arch of the aorta there was a dilatation, not larger than the half of a small pea. About two inches lower was a second dilatation, which would have contained a hazel-nut, and immediately above the diaphragm was the large aneurism, which had proved fatal. Mr Hodgson removed that portion of the vessel which contained the smallest dilatation, and he then macerated it until its coats could be separated without violence. The dilatation was found to prevail equally in the three coats of the vessel, and, after being separated, each presented the appearance of a minute aneurism. The second dilatation exhibited the same circumstance in a more advanced stage; the coats of the vessel being, however, more closely adherent to each other than in the natural state. Yet it was perfectly evident that the dilatation comprised all the coats of the vessel, the internal, middle, and external. In the large aneurism, the disorganized internal and middle coats could be traced for some distance into the sac, and then the parts contained in the posterior mediastinum, and the vertebræ, formed the remainder of the cyst. Mr Hodgson has met with this partial kind of dilatation at the division of the carotids and iliaes, in the arteries of the brain, and in almost all the arteries which are subject to aneurism. Partial, as well as general dilatation, he observes, frequently precedes the formation of aneurism in the extremities. A gentleman had a large femoral aneurism, which underwent a spontaneous cure. Upon examining the limb after death, the popliteal artery was found to be thickened and covered with calcareous matter. A small pouch, which would have contained the seed of an orange, originated from the side of this artery, and was evidently formed by a dilatation of the coats of the vessel; for the internal and middle coats could be traced in its circumference, and the former in that situation exhibited the same morbid appearances which it possessed in other parts of the vessel. A man died from the sloughing of an aneurism in the ham: in the femoral artery there was a small aneurism of about the size of a walnut. The external coat was dissected from the surface of the tumour to a considerable extent. The internal and middle coats were plainly dilated, and contributed to the formation of the sac. Their dilatation was gradual, and, after making part of the sac for a considerable distance, they were inseparably blended with the surrounding parts. (See Hodgson's *Treatise on the Diseases of Arteries*, &c. p. 70, &c.)

With respect to differences existing on the pathology of aneurism between Scarpa and other modern writers, they seem to us to be reduced to one question, viz. Whether any of the dilatations on record, alleged to comprehend all the arterial coats, ought, or ought not, to receive the name of aneurism? This eminent professor has always distinctly admitted, that the arteries may be dilated, though the kind of dilatation to which he refers is thought by him, as well as by Mr Allan Burns and Mr Hodgson, to require discrimination in a pathological point of view. Dissection shows, says Scarpa, that the morbid dilatation is circumscribed by the proper

Surgery. coats of the diseased artery; and that the inner surface of the sac, formed by the partial, or total protrusion of the arterial tube, is never filled with poly-pous laminæ, or layers of fibrine, disposed over each other, which layers never fail to be formed, in greater or smaller quantity, in the cavity of an aneurism. The notion, that these layers of coagula are not met with in small dilatations of arteries, but are found in large expansions of them, he says, is contradicted by numerous careful observations, and especially by a specimen actually before him when he was writing, where a morbid dilatation of the arch of the aorta, in the vicinity of its origin from the heart, six inches in length and five in breadth, was completely free from the lamellated coagula always found in aneurisms. On the contrary, the sac of an aneurism being formed of the parts surrounding the wounded or ruptured artery, and the blood never entering it as a natural receiver, the latter fluid always deposits in it these layers of fibrine, and this sometimes so copiously as to fill the whole cyst. At the same time, it is particularly explained by Scarpa, that, if accidentally furrows or fissures exist on the inside of the morbid dilatation, the fibrine may be deposited in these rough places, but only in them. Such fissures and inequalities of the inner surface of the morbidly dilated artery, he regards strictly as so many beginnings of another disease of the vessel, quite different from dilatation, that is, of aneurism subsequent to dilatation.

Scarpa, in his first publication on aneurism, repeatedly mentions, that the morbid dilatation of an artery constantly extends to the whole circumference of it. But this point seems from the appendix to be renounced; as he now observes, where the morbid dilatation is *partial*, or on one side of the artery, like a thimble, (for, very frequently, even in the arch of the aorta, this partial dilatation does not exceed the size of half a bean,) the entrance for the blood into this capsule is as large as the bottom of the sac. Where the dilatation occupies the whole circumference of the arterial tube, the swelling always retains a cylindrical or oval form; and if compressed, it yields very readily, and is found after death much smaller than during life. On the contrary, Scarpa remarks with respect to aneurism, that, whether it be preceded by dilatation or not, it constantly originates from one side of the ruptured artery. The entrance for the blood is small compared with the size of the fundus of the sac; the tumour assumes an irregular shape; yields with difficulty to pressure; retains nearly the same size in the dead that it had in the living subject; and its sac, instead of becoming thinner as the swelling enlarges, or the coats of an artery do when they are simply affected with dilatation, grows thicker the larger the aneurism becomes. According to Scarpa, cases of morbid arterial dilatations are positively incurable; which is not absolutely the fact with respect to internal aneurisms, difficult and rare as such an event may be.

The conclusions, justified by facts, seem to be those laid down by Mr Hodgson. 1st, That numerous aneurisms are formed by the destruction of the internal and middle coats of the arteries, and the expansion of the outer coat into a small cyst, which,

*Surgery.* giving way from distention, the surrounding parts, whatever may be their structure, compose the remainder of the sac. *2dly*, That the disease sometimes commences with a dilatation of a portion of the circumference of the artery. Such dilatation increases until the coats of the vessel give way, when the surrounding parts form the sac in the same manner as when the disease is, in the first instance, produced by destruction of the coats of an artery.

Whenever an aneurismal sac beats strongly, and for a long while, against a bone, as the sternum, ribs, clavicle, and vertebræ, the bones are, in the end, always destroyed; so that the sac then lifts up the integuments of the breast, or back, and throbs directly under the skin. This effect is referred by all the best modern writers to the action of the absorbent vessels, which, under these circumstances, take away the particles of bone, against which the tumour beats. J. L. Petit found the condyles of the femur, and the upper head of the tibia, nearly destroyed by a popliteal aneurism, and another case, in which the injury of the bone had proceeded to a great extent, is recorded by Rosenmüller. It is correctly noticed by Mr Hodgson, that the carious and corroded state of the bones in aneurism is rarely or never attended with the formation of pus. In this respect, therefore, the morbid change differs essentially from common caries or ulceration of bones. Exfoliation also very rarely accompanies it, from which fact one important practical observation is deducible, namely, that if the aneurism be cured, the bones will recover their healthy state, without undergoing those tedious processes which take place in the cure of caries or necrosis.

Mr Hodgson confirms the remark first made by Dr W. Hunter, and subsequently repeated by Scarpa and others, that cartilage is less rapidly destroyed by the pressure of an aneurism than bone itself.

Aneurisms are much less frequent in women, than men. The following comparative Table, affording information on this point, is contained in Mr Hodgson's work :

	Total.	Males.	Females.
Of the ascending aorta, the arteria innominata, and arch of the aorta	21	16	5
Descending aorta - - -	8	7	1
Carotid artery - - -	2	2	
Subclavian and axillary - -	5	5	
Inguinal artery - - -	12	12	
Femoral and popliteal - -	15	14	1
	63	56	7

A common notion amongst surgeons is, that an operation for aneurism should not be undertaken until the disease has continued sufficiently long for the collateral arteries to enlarge, so that the circulation may be more sure of going on in the parts beyond the ligature, and the danger of mortification be lessened. Gangrenous mischief was formerly a very

frequent consequence of operations for the cure of aneurism, and constituted the practitioner's chief dread; but, while his mind was anxiously directed to the risk of such an occurrence, and while he was even so much alarmed at it, that he, not unfrequently, recommended amputation of the limb, when the aneurism might have been cured by the ligature, and the member preserved; yet, it never struck him, that the frequency of mortification was generally owing to the bad method of operating, formerly practised in cases of aneurism, and not to the mere stoppage of the flow of blood through a part of the main artery of the limb. We here allude to the severe plan of opening the sac, and turning out the lamellated coagula, previously to the application of the ligature, which, after all, was generally put upon a diseased portion of the vessel; so that, if the patient escaped mortification, he rarely escaped the equally formidable consequence—secondary hemorrhage.

At the present day, operations for the cure of aneurism have reached a great degree of perfection; and, generally speaking, they are mild proceedings, compared with what they used to be in the hands of the older practitioners. The result is, that mortification now much less frequently follows them, and surgeons entertain greater confidence in the powers of nature to supply the limb with blood. Hence, also, some of the most judicious practitioners condemn all delay of the operation, merely for the purpose of affording time for the enlargement of the collateral vessels. Certain it is, that delay often does a great deal of harm, by letting the tumour become so large, and the effects of its pressure so extensive and injurious, that, after the artery is tied, the swelling is frequently attacked with severe inflammation, suppuration, and sloughing, and the patient sometimes falls a victim to what would not have taken place had the operation been performed sooner. Nay, delay may have an opposite effect to that expected by its advocates, with reference to allowing time for the anastomosing vessels to dilate; for, as Mr Hodgson has remarked, the large size of an aneurism is in reality a circumstance which must materially prevent the establishment of a collateral circulation. When the tumour is of immense bulk, it has probably destroyed the parts in which some of the principal anastomosing branches are situated, or may prevent their dilatation by its pressure. Nor can it be doubted, that, where the tumour has been suffered to attain a large size, before an attempt is made to cure it, and where, from this cause, both the neighbouring soft parts and the bone are considerably altered, the completion of the cure, that is to say, the full restoration of the use of the limb, must be far more distant, than in other cases, where the cure is attempted in an earlier stage.

According to Scarpa, the complete cure of an aneurism cannot be effected in whatever part of the body the tumour is situated, unless the artery, from which the aneurism is derived, be obliterated, either by nature or art; and converted into a perfectly solid, ligamentous substance, for a certain extent above and below the place of the ulceration, laceration, or wound. Notwithstanding the general cor-

Surgery.

rectness of this observation, we believe there are exceptions to it in a few aneurisms of the aorta, especially those of its arch, which seem to have been occasionally lessened and cured by Valsalva's treatment, repeated bleeding, very spare diet, &c. Here, we are not to suppose, that the aorta is obliterated at its very beginning; but that the diminution of the quantity of circulating blood, the reduced impetus of this fluid, the lessened distention of the aneurismal sac, the general weakness induced in the constitution, and the increased activity of the lymphatic system, all necessary effects of Valsalva's treatment, have combined to bring about a greater or lesser subsidence of the tumour. Certain facts, recorded by Mr Hodgson, satisfactorily prove, 1<sup>st</sup>, That a deposition of coagulium may take place in an aneurismal sac to such an extent as entirely to preclude the communication between its cavity and that of the artery, from which it originates; 2<sup>dly</sup>, That a sac, thus filled with coagulium, cannot prove fatal by rupture; and, 3<sup>dly</sup>, That the gradual absorption of its contents, and the consequent diminution of the sac, may proceed to such an extent, that the disease shall be cured without any obstruction taking place in the calibre of the vessel, from which it originates.

Both the spontaneous and surgical cures of aneurism have generally two stages; in the first, the entrance of blood into the aneurismal sac is prevented; in the second, the parietes of the artery approach each other, and, becoming agglutinated, the vessel is converted into a solid cylinder. In order that compression may be the means of uniting the opposite sides of the artery, and thus of producing a radical cure of aneurism, the degree of pressure, according to Scarpa, must be such as to place these opposite sides in firm and complete contact, and such as to excite the adhesive inflammation in the coats of the artery. The point of compression must also fall above the laceration, or wound of the artery. Another condition is essential to success; the coats of the vessel, at the place where the pressure is made, must be sufficiently free from disease to be susceptible of the adhesive inflammation. When the arterial coats, round the root of an aneurism, are much diseased, Scarpa considers them as unsusceptible of the adhesive inflammation, although compressed together in the most scientific manner, and even when tied with a ligature. This statement would appear to be corroborated by the following fact: Mr Langstaff amputated the thigh of a person seventy-five years of age; but the vessels were so ossified that they could not be effectually tied, and, in less than twenty-four hours, the patient died from loss of blood. It is generally supposed, says Mr Lawrence, that this condition of the arterial coats is incompatible with their union under the application of the ligature. The opinion should be received, however, with some limitation. In a man fifty-nine years of age, bleeding took place nearly a month after amputation, from an ossified femoral artery; and Mr Lawrence was, therefore, obliged to expose and tie that vessel again for the suppression of the hemorrhage, when he found a hard tube, which cracked immediately after the ligature was tightened; the bleeding, however, never returned. This case is mention-

Surgery.

ed, not with any view of encouraging surgeons to apply ligatures round diseased portions of arteries, a thing which should always be avoided when possible; but, to make them aware, that the ossified state of an artery, unfavourable as the circumstance may be, is not an absolute and constant prohibition to the successful application of the ligature.

Whenever the treatment by pressure is attempted, the plan should be promoted by repeated bleedings, spare diet, and strict repose in bed. Digitalis may also be prescribed, with the view of lessening the impetus of the circulation. Snow, or powdered ice, is sometimes applied to the tumour, with the design of facilitating the coagulation of the blood within the aneurismal sac, and thus bringing about the obliteration of the cavity of the aneurism and the artery. Ice should be employed, however, with some degree of caution. We learn from Breschet, that, when the swelling is large, the parts very tense, their texture changed, and the skin thin, the practice is likely to accelerate the formation of a slough; and he confirms a remark, made by Mr Hodgson, that some patients cannot continue this treatment longer than a few minutes, while others find it absolutely insupportable.

Modern experience has fully confirmed the fact, that the plan which can be most depended upon for the cure of external aneurism, is that of tying the artery some way from the tumour, in the direction towards the heart. The following general instructions respecting the ligature, have received the sanction of many of the best surgeons in this country.

1. The cord should be thin and round, such a ligature being most likely to effect a clean division of the internal and middle coats of the vessel, and not liable to occasion extensive ulceration and sloughing.

2. The ligature should be tightly applied, in order to insure the complete division of the internal and middle coats of the artery, and to prevent its detachment; it being almost impossible, even with the thinnest ligatures, to cut entirely through a healthy artery.

3. The vessel should be detached from its connection, only so far as is necessary for the conveyance of the ligature underneath it.

4. The immediate adhesion of the wound should be promoted by all such means as are known to promote that process in general. (See Hodgson's *Treatise on Diseases of Arteries*, p. 225.)

The late Dr Jones, in his interesting experiments upon animals, performed with the view of ascertaining the effects of a ligature upon the blood-vessels, made out a fact, which at first raised the expectation that it would lead to a considerable improvement of the operation for the cure of aneurisms. After having assured himself of the correctness of an observation, first made by Desault, that, when a firm ligature is applied to an artery, it causes a division of the internal and middle coats, he discovered, that if such ligature be afterwards removed, an effusion of lymph takes place between the cut surfaces into the cavity of the vessel; and that, if several divisions of the internal and middle coats be thus effected in the vicinity of each other, the effusion of lymph was

*Surgery.* sufficiently extensive to obliterate the cavity of the vessel.

Here we see that Jones's experiments did not really justify any hope that a single division of the internal coats of the vessel with one ligature would lead to the obliteration of the tube at the tied part, though the cord were removed immediately after its application. On the contrary, his experiments proved that several ligatures, and several divisions of the inner coats of the vessel with them, were necessary, if they were to be taken away directly after being tightened. However, surgeons overlooked this difference, and their zeal allowed them to form hopes, which, in fact, had no foundation in any of the true results of Dr Jones's experiments. At the same time, it cannot be doubted, that if, immediately after tying the trunk of an artery for the cure of an aneurism, the ligature could be altogether removed, and yet the vessel become obliterated, it would be highly advantageous; as no extraneous substance would then be left in the wound to prevent its union, or increase the chance of secondary hemorrhage, by causing the sloughing, or ulcerative process to extend too far. Suffice it here to state farther, with reference to this scheme, that the trials which have been made of it fully prove that it is ineffectual; a conclusion which might have been drawn from Dr Jones's own experiments. Still the fact of the ligature, though applied only for a moment, bringing on an effusion of lymph within the vessel, and a permanent constriction of it on the part operated upon, continued to keep the attention of surgeons fixed upon the subject; and their genius exerted itself in every possible way to render the new information the means of leading to some great and beneficial change in the operation for the cure of aneurism. In particular, it appeared to Mr Travers, that the want of union was chiefly owing to the circumstance of the opposite sides of the vessel not being retained in a state of contact, so that they might have an opportunity of adhering together. This object is fulfilled by the ligature in the common mode of its application; and for the success of Dr Jones's experiment, it was conceived, it would be sufficient to let the ligature remain on the vessel only until the adhesion were strong enough to resist the passage of the blood through the tube. In short, Mr Travers thought, that if a ligature were applied to an artery, and suffered to remain only a few hours, the adhesion of the inner surface of the vessel would then be sufficiently advanced to insure the permanent obliteration of the cavity of the vessel. The early removal of the ligature, it was hoped, would prove highly advantageous by diminishing the chance of hemorrhage, and facilitating the union of the wound.

The trials which have been made of the temporary application of the ligature for the cure of aneurism, we regret to say, have not had such decidedly favourable results, as to enable us to rank the practice as an established improvement. On the contrary, though some cases treated in this manner have been encouraging; the greater number has been of the opposite description. Sir Astley Cooper operated upon a popliteal aneurism in this way; the flow of blood

to the tumour was completely stopped by the ligature for thirty-two hours, and the cord then removed; but the pulsations of the disease returned. A ligature was then applied forty hours longer, at the end of which time no pulsation followed the removal of the ligature; but, on the twelfth day, a considerable bleeding came on, and it was necessary to take up the vessel again. The careful consideration of this and various other cases, and, in particular, the perusal of Scarpa's examples of the practice, have perfectly satisfied us that, however flattering the suggestion deduced from Dr Jones's observations might at first be, the plan of removing the ligature, previously to its natural separation, will never answer in the operation for the cure of aneurism, unless either an obliteration of the arterial tube follow, with reasonable certainty, the taking away of the ligature directly after it has been applied, and it has divided the inner coats of the vessel; or, at all events, unless the ligature can always be withdrawn at a determinate period, and the same obliteration either certainly ensue, or be already complete. All this, too, ought to be effected with such regularity and infallibility in every case, that there would be no chance of the surgeon being obliged to apply another ligature, do a second operation, or cause disturbance of the artery in any manner whatsoever.

Independently of the uncertainty of the period, when the arterial tube is closed by the adhesive inflammation in various patients, it appears that the disturbance of the vessel and wound by the steps necessary for the loosening and removal of the ligature, will ever form an insuperable objection to the practice. Scarpa has some apprehension of this kind himself; for he remarks, "In the act of removing the ligature, there can be no doubt, it is of great consequence that the artery be not rudely handled or stretched. And, indeed, if, on untying the running knot, the subjacent knot could be with the same facility untied, we could not wish for a better mode of performing this part of the operation. But the knot, although a simple one, is not so readily untied as the running knot; on account of the moisture with which the threads forming the ligature are soaked, or because the ligature has been previously waxed." These apprehensions lead him to suggest the scheme of placing a thread longitudinally on each side of the cylinder of linen, interposed by him between the knot and the artery. This he does before the knot is made; and at the time of removing the ligature, the threads are to be drawn in opposite directions, in order to undo the knot without displacing or stretching the artery. Thus, instead of one small ligature, which is all that an English surgeon leaves in the wound, Scarpa recommends his ligature of four or six threads, a roll of linen, and two other threads; a quantity of extraneous substances, which cannot fail to be a source of serious irritation and mischief. Were there, however, only the following single objection to this practice, it would never be established in this country; its advocates are necessarily obliged to renounce the infinite advantage of bringing the edges of the wound together directly after the operation. If it had been practicable to withdraw the li-

*Surgery.* gature as soon as the inner coats of the vessel had been divided by it, and the obliteration of the momentarily constricted portion of the artery followed as a matter of certainty, the case would have been very different, as there would then have been no foreign body at all left in the wound; the parts might have been immediately brought together, so as to leave the greatest chance of union by the first intention, and no future disturbance either of the artery or of the wound would have been incurred.

In the section upon the popliteal aneurism, in the former Article, two things are recommended, which the experience of many of the best surgeons does not at present sanction. The first is the application of a double ligature, and then dividing the vessel at a point between the two cords; the second is using a ligature of sufficient thickness to hinder it from cutting through the coats of the vessel. With respect to the first of these proceedings, it seems to be of great antiquity, but had fallen into oblivion, when again brought into notice by Mr Abernethy. The reflections which led this gentleman to revive the practice were ingenious; for, when the artery was tied with two ligatures, and divided in the interspace between them, it was argued, that it would be quite lax, possess its natural attachment, and be as nearly as possible in the same circumstances as a tied artery upon the face of a stump. Strictly speaking, however, as Mr Hodgson first pointed out, an artery tied in two places, and cut through in the interspace, cannot be regarded as placed exactly in the same condition as an artery tied in amputation. In the latter case, the retraction of the vessel corresponds with that of the surrounding parts, which are divided at the same instant, and therefore its relative connections stand as before the operation. But, in the operation for aneurism, the retraction of the artery takes place without being attended with a corresponding retraction of its connections. How far the retraction of the artery is beneficial or injurious, is by no means evident; and the advantages arising from it may be obtained in most situations by simply placing the limb in a bent position, without dividing the vessel. One important object, however, is gained by the division of the artery; namely, that in this case it is generally tied close to its connections, and it is very evident how liable the application of the ligature, in the middle of a denuded extent of the vessel, must be to produce ulceration, or sloughing of its coats. The same object, however, will be gained by tying the undivided artery close to its connections, at the end nearest to the heart; and the presence of a single ligature at the bottom of the wound will be less liable to give rise to suppuration, and the formation of sinuses, than the employment of two. When an artery is divided, the portions situated beyond the ligatures must slough, and be an additional cause of suppuration in the wound. Experience has amply proved, as Mr Hodgson correctly states, the safety of employing a single ligature, and it is at present preferred by many of the most experienced operators in this country.

The second thing recommended in the section upon the popliteal aneurism; namely, the use of a largish

*Surgery.* ligature, with the view of not cutting the coats of the vessel, is a plan which by no means corresponds with the valuable doctrines inculcated by the late Dr Jones in his excellent work upon hemorrhage; nor is it found to be advisable on any practical grounds. On the contrary, the advantage of lessening, as much as possible, the quantity of extraneous substance in the wound, and the manner in which the dividing the inner coats of the vessel by the ligature insures the effusion of lymph within it, and the quick obliteration of its cavity, are considerations which dictate the propriety of always employing a round and slender, but very firm ligature, made of such materials as will combine these properties in the greatest degree. A larger ligature than is absolutely necessary, must ever be disadvantageous, not only by being less calculated, than a smaller one, to cut through the inner coats of the vessel, but by acting as a source of considerable irritation at the bottom of the wound; whereby the healing process, with respect to the wound itself and the tied part of the artery, must be placed in less favourable circumstances.

A few years ago, Mr Lawrence extended to operations for aneurism the plan of tying the artery with a very firm, small, silk ligature; the whole of which is immediately afterwards cut off, with the exception of the noose and knot; and an attempt is then made to heal the wound by the first intention. When this plan is adopted, it is of importance to use a ligature made of dentists' silk, and not catgut, and other substances, which are less fitted for the purpose. Every case, in which any deviation in this respect is made from the directions given by Mr Lawrence, cannot be received as a fair trial of the practice.

Various pincers and compressors have been devised by different surgeons, as means well calculated to obliterate the artery; and, in the opinions of the inventors, they accomplish this business more certainly and securely, than a ligature. Some of these contrivances may, indeed, answer better than the large clumsy cords which are sometimes employed, accompanied with the further irritation and dangers of what are called ligatures of reserve; but all the best surgeons in this country unite in a decided preference to the ligature when of proper construction and skilfully applied. As Scarpa justly observes, metallic instruments, designed to be applied directly to an exposed artery, for the purpose of obliterating it by compression, are liable to all the inconveniences which are inseparable from the presence of hard bodies, introduced and kept for several days in the bottom of the wound; particularly of a recent wound, where they cannot be retained in a proper direction without difficulty, or precisely at such a depth as will not be attended with hurtful pressure upon the wound itself, and the important parts in its vicinity. And, with regard to Asalini's forceps, Monteggia has observed, that, if the obliteration of the artery is retarded, the forceps divides the artery just like the ligature, by causing the death of the included portion. In one case, the same surgeon also saw the extremity of the instrument resting at the bottom of the wound upon the subjacent

Surgery.

femoral vein, the anterior half of which it ruptured, though such portion had not been taken hold of by it.

As a recent improvement in the operation for popliteal aneurism, that of making the incision somewhat higher up the thigh, than was commonly the practice a few years ago, deserves to be noticed. For this suggestion, we are principally indebted to Scarpa, some of whose other measures in the operation seem to us far less deserving of imitation. "The surgeon," says Scarpa, "is to explore with his fore-finger the course of the artery from the crural arch downwards; and, when he comes to the place where the vibration of the vessel begins to be less distinctly felt, this point is to be fixed upon for the lower end of the external incision. This angle of the wound will fall nearly on the inner edge of the sartorius, just where this muscle crosses the track of the femoral artery, and at the very apex of the triangle formed by the convergence of the triceps and vastus internus. A little more than three inches above the place here fixed upon, the surgeon is to begin with a convex-edged bistoury the incision through the integuments and cellular substance, and carry the wound down the thigh in a slightly oblique line from without inwards; so as to make it follow the course of the artery as far as the apex of the triangle already specified, or the point where the vessel passes under the inner edge of the sartorius muscle." Scarpa's reason for making the incision higher up in the thigh than Mr Hunter did, is to avoid the necessity of removing the sartorius muscle from its position, or of turning it back, in order to get at the artery. We have seen the best operators, and even professors of anatomy, perplexed by having the sartorius muscle immediately in their way after the first incision had been made; and, as the vessel is more superficial a little higher up, the place is farther from the diseased portion of the artery, and the method does not interfere with the profunda, which arises about an inch and a half, or an inch and three quarters, below Poupart's ligament, the practice seems to us on every account right and unobjectionable.

Subsequently to the period when the former Article on SURGERY was written, the operation of tying the external iliac artery, for the cure of femoral aneurisms, has been repeated with a degree of success, that the most ardent practitioners could scarcely have anticipated. Indeed, as far as our observations and inquiries extend, it is an operation attended with nearly, if not quite as much success, as that of taking up the artery in the thigh for the cure of popliteal aneurism. Out of twenty-five cases, we know of only three in which the limb was attacked with gangrene. The proportion is not so much as one in eight.

The following is Sir Astley Cooper's method of performing this operation. A semilunar incision is made through the integuments in the direction of the fibres of the aponeurosis of the external oblique muscle. One extremity of this incision will be situated near the spine of the ilium; the other will terminate a little above the inner margin of the abdominal ring. The aponeurosis of the external oblique

Surgery.

muscle having been exposed, is to be divided throughout the extent, and in the direction, of the external wound. The flap, which is thus formed, being raised, the spermatic cord will be seen passing under the margin of the internal oblique and transverse muscles. The opening in the fascia, which lines the transverse muscle, through which the spermatic cord passes, is situated in the mid-space between the anterior superior spine of the ilium and the symphysis pubis. The epigastric artery runs precisely along the inner margin of this opening, beneath which the external iliac artery is situated. Hence, if the finger be passed under the spermatic cord, through this opening in the fascia, it will come into immediate contact with the artery, which lies on the outside of the external iliac vein. The artery and vein are connected together by dense cellular membrane, which must be separated to enable the operator to pass a ligature by means of an aneurism-needle round the former of these vessels. (See Hodgson's *Treatise on Diseases of Arteries, &c.* p. 421.) In this operation, as well as in all others for aneurisms, a single ligature is now mostly preferred by all the best surgeons of this country.

Perhaps, no branch of surgery has received so much attention and decided improvement during the last twenty years, as that which has for its object the cure of aneurismal diseases. Cases formerly abandoned as certainly fatal, or in which the patient was saved only by amputation, are now cured, and this without any severe mutilation, or irremediable disfigurement. Nay, aneurisms, seemingly almost out of the reach of the surgeon's hand, are now not relinquished as a matter of course, but every possible means of checking and removing the disease is considered; and the boldest operations, conceivable by the most enterprising surgeon, are planned and undertaken. One proof of this advancement of modern surgery we find in an operation that has now been performed with success in two examples; we allude to that of *tying the internal iliac artery* for the cure of aneurisms of the gluteal artery. This proceeding, which was not before the public at the time when the former article came out, was first adopted by Mr Stevens, a surgeon at Santa Cruz. "An incision, about five inches in length, was made in the left side, in the lower and lateral part of the abdomen, parallel with the epigastric artery, and nearly half an inch on the outer side of it. The skin, the superficial fascia, and the three thin abdominal muscles, were successively divided; the peritonæum was separated from its loose connection with the iliacus internus and psoas magnus; it was then turned almost directly inwards, in a direction from the anterior superior spinous process of the ilium to the division of the common iliac artery. In the cavity which I had now made (continues Mr Stevens), I felt for the internal iliac, insinuated the point of my fore-finger behind it, and then pressed the artery betwixt my finger and thumb. Dr Lang now felt the aneurism behind; the pulsation had entirely ceased, and the tumour was disappearing. I examined the vessel in the pelvis; it was healthy, and free from its neighbouring connections. I then passed a ligature behind the artery, and tied it about half an inch from

Surgery. its origin. The tumour disappeared almost immediately after the operation, and the wound healed kindly. About the end of the third week the ligature came away, and in six weeks the woman was perfectly well." (*Med. Chir. Trans.* Vol. V.) The operation is represented as free from any particular difficulty; and it is said, that not an ounce of blood was lost. The ureter was easily avoided, which followed the peritonæum, when this membrane was pushed inwards.

A second example of the performance of the same operation is recorded in the 38th volume of the *Medical and Physical Journal*, p. 267. The operator was Mr Atkinson of York, the disease a gluteal aneurism, and the patient a stout bargeman, aged 29. This case, however, had not a fortunate result, as the patient sunk partly from the discharge, and partly from hemorrhage, about nineteen days after the operation. That the internal iliac artery was really tied, seems verified not only by the effect of the ligature upon the swelling, but by the still more positive evidence obtained by the examination of the body after death.

The possibility of tying the carotid artery in cases of wounds and aneurisms, without any injurious effect upon the functions of the brain, has been of late years repeatedly illustrated. Hebenstreit, in Vol. IV. p. 266, 3d ed. of his *Translation of Mr B. Bell's Surgery*, reports an instance in which the carotid artery happened to be wounded in the extirpation of a scirrhus tumour; and the hemorrhage would have been fatal, had not the surgeon immediately tied the trunk of the vessel. The patient lived many years afterwards. This is probably the earliest authentic case, in which a ligature was applied to the carotid artery. Mr Abernethy's case is perhaps the second, and that in which Mr Fleming, a naval surgeon, tied the common carotid in a sailor, who attempted suicide, and who was saved by the operation, is still later, not having occurred till the year 1803. (See *Med. Chir. Jour.* Vol. III.)

These were all cases of wounds. Sir Astley Cooper first tied the carotid artery for the cure of an aneurism in the year 1805. An incision, two inches in length, was made at the inner edge of the sternocleido-mastoideus from the lower part of the tumour to the clavicle. This wound exposed the omo-hyoideus and sterno-hyoideus muscles, which were drawn aside towards the trachea, and the jugular vein presented itself. The motion of this vein produced the only difficulty in the operation, as in the different states of breathing the vessel sometimes became tense and distended under the knife, and then suddenly collapsed. This vessel was kept out of the way of the knife by the finger, and the carotid artery having been exposed by another cut, two ligatures were passed under it with a common aneurism-needle. Care was taken to exclude the recurrent nerve, on the one hand, and the par vagum on the other. The ligatures were then tied about half an inch asunder; but the intervening portion of artery was left undivided. This case had not a favourable termination; and Sir Astley Cooper concludes his account of it with expressing his belief that, in future, the causes of failure may be avoided by operating before the tu-

mour is of such size as to make pressure upon important parts; or, if the swelling is large, by letting out its contents as soon as inflammation invades it. (*Med. Chir. Trans.* Vol. I.)

In another case of carotid aneurism, operated upon by the same surgeon in 1808, success was complete. The patient was a man aged 50, and the aneurism was attended with severe pain all over one side of the head, throbbing in the brain, hoarseness, cough, slight difficulty of breathing, nausea, giddiness, &c. The patient perfectly recovered, and resumed his occupation as a porter. The intellects remained perfect; the nervous system was unaffected; and the severe pain which, before the operation, used to affect the side of the head adjoining the aneurism, never returned. In this example, two ligatures were applied, and the intervening portion of the artery divided: subsequent cases, however, have fully evinced the sufficiency of a single ligature, and the inutilty of applying two, and cutting through the vessel between them.

The carotid artery has also been several times taken up with the view of checking the progress of the disease well known to surgeons under the name of aneurism by anastomosis. Of course, the complaint must be so situated as to afford a rational chance of such application of the ligature being capable of cutting off the main supply of blood to the tumour, to justify the practice. A very encouraging case is recorded by Mr Travers, who, by means of the operation, effectually cured an aneurism by anastomosis in the orbit. (*Med. Chir. Trans.* Vol. II.) And another very interesting case of the same kind has been published by Mr Dalrymple of Norwich, in the 6th volume of those *Transactions*. These examples, however, should not lead surgeons to be too confident of being always able to cure aneurisms by anastomosis on the above principle; namely, that of tying the main artery, from which the swelling receives its supply of blood. The great cause of failure is the impossibility of preventing, in some situations, the transmission of a considerable quantity of blood into the tumour, through anastomosing vessels. For cases proving the caution, with which the prognosis should be made in attempts of this kind, see one published by Mr Wardrop in the *Med. Chir. Trans.* Vol. IX. p. 206; and another detailed by Breschet, in his translation of Mr Hodgson's work *On the Diseases of Arteries*, T. II. p. 296.

The carotid artery was tied by Mr Goodlad of Bury, in Lancashire, previously to the removal of a large tumour from the side of the neck, involving the parotid gland; this proceeding was adopted with the view of diminishing the danger of hemorrhage. (See *Med. Chir. Trans.* Vol. VII.)

There are two methods of operating for the cure of axillary aneurisms; in one, the axillary artery is taken up by cutting below the clavicle; in the other, the necessary wound is made above that bone, and the subclavian artery secured at the point where it emerges from behind the anterior scalenus muscle.

Mr Hodgson recommends the first mode to be performed in the following way: A semilunar incision through the integuments, with its convexity downwards, is to begin about an inch from the sternal

Surgery.

end of the clavicle, and to be continued towards the acromion to the extent of three or four inches, so as to terminate near the anterior margin of the deltoïd muscle, without reaching into the space between the deltoïd and pectoral muscle, in order to avoid wounding the cephalic vein. This incision will expose the fibres of the pectoral muscle, which are now to be divided in the direction and extent of the external wound. The flap is then to be raised by dividing the loose cellular membrane, which connects the pectoral muscle to the parts underneath it. The pectoralis minor will now be seen crossing the inferior part of the wound, and the surgeon, by introducing his finger between the upper edge of this muscle and the clavicle, may feel the pulsations of the axillary artery. Here one of the cervical nerves lies above, but in contact with the artery; the other nerves are behind it. In the dead subject the axillary vein is situated below it, but in the living the vein is distended, and conceals the artery. The cellular membrane connecting these parts is to be separated by careful dissection, or by lacerating it with a blunt instrument; then a ligature having been drawn under the artery with an aneurism-needle, the ends of the cord are to be raised, and a finger passed down, so as to compress the part surrounded by the ligature. If the artery be included, the pulsation in the aneurism will immediately cease. This precaution is highly necessary, lest one of the cervical nerves should be tied instead of the artery. The axillary artery has been tied with success below the clavicle by the late Mr Keate (see *Med. Review*, 1801), Mr Chamberlaine (*Med. Chir. Trans.* Vol. VI. p. 128), and others.

The subclavian artery may be tied at the place where it comes from behind the anterior scalenus muscle, and this plan indeed is necessary whenever the aneurismal swelling extends beyond a certain distance towards the neck. It is observed by Mr Hodgson, that, when the subclavian artery has emerged from behind the anterior scalenus muscle, it passes obliquely over the flat surface of the first rib, with which it is in immediate contact. The cervical nerves are situated above, and a little behind, the artery; the subclavian vein passes before it, and underneath the clavicle. If the finger be passed down the acromial margin of the anterior scalenus muscle, the artery will be found in the angle formed by the origin of that muscle from the first rib. The shoulder being drawn down as much as possible, the skin is to be divided immediately above the clavicle, from the external margin of the clavicular portion of the mastoid muscle, to the margin of the clavicular insertion of the trapezius. No advantage whatever is gained by cutting the clavicular attachment of the mastoid; the exposed fibres of the platysma myoides are then to be divided, the utmost care being taken not to wound the external jugular vein, which lies immediately under them, near the middle of the incision; the fibres should be detached and drawn towards the shoulder with a blunt hook. The cellular membrane in the middle of the incision is then to be cut, or separated with the finger, until the surgeon arrives at the acromial edge of the anterior scalenus muscle. His finger is then

to be passed down its margin, until it reaches the part where it arises from the first rib; and in the angle formed by the origin of the muscle from the rib, the artery will be felt. The ligature is now to be conveyed under the vessel, either by means of an instrument, constructed on the principle of Desault's *aiguille à ressort* (see his *Works* by Bichât); or of the still better one lately invented by Mr Weiss, surgical instrument-maker, London.

As the difficulty of several operations for aneurisms chiefly consists in getting a ligature under the deeply situated artery, in consequence of the very little room afforded for turning the common aneurismal-needle; and even when the ligature is thus far introduced, an equal difficulty presents itself when the thread requires to be extricated from the eye of the needle; the ingenious instrument made by Weiss, and found completely to answer in practice by Sir Astley Cooper, Mr Travers, and Mr Brodie, deserves on every account to be made known to, and procured by, all operating surgeons. A particular description of it, illustrated by an engraving, may be seen in the *Edinburgh Medical and Surgical Journal*, No. LXXVI. p. 492.

Though the operation of taking up the subclavian artery at the point where it emerges from behind the anterior scalenus muscle, has now been very frequently performed, we believe only two successful cases are upon record; and these were operated upon by Dr Post of New York (see *Med. Chir. Trans.* Vol. IX.) and by Mr Liston of Edinburgh. (See *Edinb. Med. and Surg. Journ.*, No. LXIV.) In some instances, the want of contrivances calculated to pass the ligature under the deeply seated artery, when the clavicle was much raised by the swelling, has prevented the completion of the operation; which unpleasant circumstance, it is to be hoped, will never happen again; the instrument constructed by Mr Weiss removing every difficulty of this kind. It should also be a maxim amongst surgeons always to recommend the operation before the swelling has attained a very large size, by which the operation is rendered more complicated, and the chances of recovery seriously lessened.

In America the arteria innominata has been lately tied by Dr Mott of New York, and in Germany by Professor Graefe of Berlin. The proposal was made several years ago in this country, but was never put in execution; owing to the common belief that such an operation would be almost necessarily fatal of itself, either from the inflammation likely to be excited by it in the neighbouring important organs; or from the danger of hemorrhage, in consequence of the adhesion of the vessel being exposed to be broken by the force of the circulation. In the case operated upon by Dr Mott, two incisions were made, one in the direction of the clavicle, and the other along the mastoid muscle. The carotid was laid bare, and traced towards the subclavian, which was found so diseased, that the only alternative left was to tie the arteria innominata. The incisions were accordingly carried more deeply, and Dr Mott having separated the recurrent and phrenic nerves, arrived at the division of the artery, and with a curved needle, passed the ligature above half an inch from this point. The

Surgery.

*Surgery.* wound was then closed with a suture. In the operation, a branch of the internal mammary artery, and two of the inferior and superior thyroid, were divided, but not more than three ounces of blood were lost, and the operation was completed in about an hour. It is said, that the patient immediately after it felt quite well; his pulse was 69; the temperature of the right arm was nearly the same as that of the left; and the breathing was undisturbed. Until the 22d day after the operation, he continued to improve; the suppuration went on favourably, the ligatures came away without accident, and the pulse, which, at one time, had risen to 120, was reduced by venesection to its natural standard; the cough was disappearing, cicatrization was going on properly, and the swelling diminishing. He was now in high spirits, and so far recovered, that he walked daily in the garden of the hospital. All on a sudden, however, on the 24th day, hemorrhage from the wound took place, and though it was soon stopped, and little blood was lost, it recurred twice the next two days, difficulty of breathing came on, and the patient died on the 26th day.

Upon dissection, no mark of inflammation was traced in the arch of the aorta, the origin of the arteria innominata, or the lungs. The inner coat of the arteria innominata is described as being sound, smooth, and soft, but the parietes of the vessel were so thick, that it would scarcely admit a crow-quill. It is to be regretted that various interesting particulars, relating to the state of the tied portion of the artery, are omitted in the history.

A similar operation was performed by Graefe at Berlin on the 5th of March 1822. The patient was laid upon his back, with his head hanging down over one side of the table. A longitudinal incision was made near the front edge of the mastoid muscle, down to the sternum. The carotid artery was thus exposed, and its course followed to the point, at which it unites with the subclavian, so as to form the trunk of the arteria innominata. When the latter vessel had been distinctly exposed, a ligature was passed round it with a bent needle, and then tied. No alarming symptoms followed the operation, and the ligature came away in about a fortnight. Some time afterwards, however, a considerable bleeding arose, which was stopped by means of cold water and pressure. The patient then complained of pain in the tumour, and as a fluctuation could be plainly felt, Graefe was led to make an incision into the aneurismal sac. A large quantity of pus and grumous blood was thus discharged, and matter continued to be discharged daily from this opening, while the other granulated in the most favourable manner. The patient became feverish, however, spit blood, and died on the 68th day. Upon dissection, the lungs were found diseased. In the arteria innominata, a clot had been formed, extending from the origin of the vessel to the place where the ligature had been applied. When an injection was thrown into the aorta, the wax completely filled the arteries of the right arm, and right side of the head, proving that the circulation in these parts had been fully re-established by means of the anastomosing vessels.

As a conclusion to the remarks here introduced upon

*Surgery.* the subject of aneurism, we deem it right to notice the memorable case, in which Sir Astley Cooper tied the aorta itself. He had often placed ligatures round the aorta in dogs, and found, that the blood was readily conveyed by the anastomoses into their posterior extremities. (*Med. Chir. Trans.* Vol. II. p. 158.) The case, in which he judged it warrantable to make the experiment of tying the aorta in the human subject, was one of inguinal aneurism, on the left side, reaching so far upwards, that no operation was practicable without opening the peritonæum; and, at length, notwithstanding the trial of every means that could be thought of to check the disease, the tumour burst, and the patient was on the brink of the grave. In short, he was so reduced by repeated hemorrhages, that his feces passed involuntarily, and immediate death was only prevented by keeping up pressure upon the opening. In these desperate circumstances, Sir Astley Cooper made a small incision into the sac, above Poupart's ligament, and introducing his finger, tried if it were practicable to pass a ligature round the external iliac artery, within the cavity; but the thing was found impossible, as, instead of the vessel, "only a chaos of broken coagula" could be perceived. At the moment of withdrawing the finger, two students compressed the aorta against the spine, and the incision was then closed with a dossil of lint. It was now determined to apply a ligature to the aorta itself. An incision, three inches in length, was made in the direction of the linea alba, but slightly curved towards the left, so that the navel, which was in the centre of it, might be avoided. After the linea alba itself had been divided, a small aperture was made in the peritonæum, and the end of a finger introduced. This opening was now enlarged with a probe-pointed bistoury to nearly the same extent as the outer wound. Neither the omentum nor the intestines protruded; and during the progress of the operation, only one small convulsion projected beyond the wound. With his finger-nail, the operator now scratched through the peritonæum on the left side of the aorta, and then conducting it between the aorta and the spine, he again penetrated the peritonæum on the right side of the aorta. A blunt aneurism-needle, armed with a single ligature, was next conveyed under that vessel, and tied, with the precaution of excluding the intestines from the noose. The wound was then closed by means of the quilled suture and adhesive plaster. During the operation, the feces were discharged involuntarily, and the pulse for an hour after the operation was 144. An opiate was given, and the involuntary passage of feces soon ceased. The sensibility of the right leg was very imperfect. In the night, the patient complained of heat in the abdomen; but no pain was felt on pressure being made upon it; and the lower extremities, which had been cold a little while after the operation, were now regaining their warmth, though their sensibility was very indistinct. At six o'clock, the following morning, the sensibility of the limb still continued imperfect; but, at eight o'clock, the right one was warmer than the left, and its sensibility beginning to return. At noon, the temperature of the right limb was ninety-four, and that of the left, or aneuris-

Surgery.

mal one, eighty-seven and a half. At eight o'clock on the second morning after the operation, the aneurismal limb appeared livid and cold, more particularly round the aneurism; but the right leg was warm; and between one and two o'clock of the same day, after a great deal of vomiting, involuntary discharge of the urine and feces, pain in the abdomen and loins, cold sweats, &c. the patient died. In the examination of the body, not the least appearance of peritonæal inflammation was found, except at the edges of the wound; and the omentum and intestines were of their natural colour. The ligature, which included no portion of intestine or omentum, was placed round the aorta, about three quarters of an inch above its bifurcation. When the vessel was opened, a clot, of more than an inch in extent, filled it above the ligature; and below the bifurcation, another clot, an inch in extent, occupied the right iliac artery, while the left contained a third, which extended as far as the aneurism. As there were no appearances of inflammation of the viscera, Sir Astley Cooper refers the cause of death to the want of circulation in the aneurismal limb, which never recovered its natural heat, nor any degree of sensibility, though the right limb was not hindered from doing so: and he believes, that, in order to have any chance of success in a similar case, the ligature must be applied before the swelling is very large. Here, however, some doubts may be entertained concerning the propriety and necessity of such an operation: indeed, even in the desperate circumstances of the above mentioned patient, there are many good surgeons, who consider, that it would have been better to have suffered him to meet his fate in tranquillity. Be this as it may, the case is highly interesting, both in a physiological and a surgical point of view, as proving, by what took place in the limb of the sound side, that where no other impediments exist, the circulation will continue in the lower extremities, though the abdominal aorta be *suddenly* tied, or obstructed. Obliterations of portions of this vessel by disease happen gradually, and though several instances of this kind upon record, also prove the possibility of the continuance of the circulation, notwithstanding the obstruction, they do not inform us, what would be the result of a stoppage suddenly made to the course of the blood, through such a vessel as the aorta. The particulars to be gathered from the preceding case, respecting the effects of this kind of change, cannot fail to interest the studious observer of the phenomena of the animal economy.

Of Varicose Veins.

Following the subjects in the order in which they are arranged in the Article, in the *Encyclopædia*, we next find that of varicose veins; a disease sometimes very annoying and difficult to cure. The practice of tying veins for the cure of varices was well known to Pare and Dionis, who have correctly described the operation of tying and dividing the vein between the two ligatures. In modern times, Sir Everard Home has related many cases of varicose

Surgery.

veins of the leg; some of them accompanied with tedious ulcers, which, after the vena saphena major had been tied, where it passes over the inside of the knee, were readily healed, and the dilatations of the veins relieved. There cannot be a doubt that such practice frequently succeeded; but it is quite as certain that it had many failures. Amongst other evils, an inflammation of the tied vein has been observed, extending very far in the vessel, and succeeded by great constitutional disorder, symptoms very analogous to those of typhus fever and rapid dissolution. In some of these cases, previously to their termination, abscesses form in the direction of the vessel below or above the ligature; while, in other examples, such collections of matter are not observed.\* In short, the dangers arising from an inflammation of the internal coat of the veins form the most serious objection to the old manner of operating for the cure of varices. The occasional subsequent attack of this membrane by inflammation, followed by a fever of a very serious nature, rendered several judicious surgeons doubtful of the propriety of continuing the practice. Certain reflections, however, induced Mr Brodie to suspect, that the same ill effects would not follow a similar operation upon the branches themselves. He remarks, that "where the whole of the veins of the leg are in a state of morbid dilatation, and the distress produced by the disease is not referred to any particular part, there seem to be no reasonable expectations of benefit, except from the uniform pressure of a well-applied bandage. But, not unfrequently, we find an ulcer which is irritable and difficult to heal, on account of its connection with some varicose vessels; or, without being accompanied by an ulcer, there is a varix in one part of the leg, painful, and perhaps liable to bleed, while the veins in other parts are nearly in a natural state, or, at any rate, are not the source of particular uneasiness. In some of these cases (says this gentleman), I formerly applied the caustic potash, so as to make a slough of the skin and veins beneath it; but I found the relief, which the patient experienced from the cure of the varix, afforded but an inadequate compensation for the pain to which he was subjected by the use of the caustic, and the inconvenience arising from the tedious healing of the ulcer, &c.

"In other cases, I made an incision with a scalpel through the varix, and the skin over it. This destroyed the varix as completely as it was destroyed by the caustic; and I found it to be preferable to the use of the caustic, as the operation occasioned less pain, and in consequence of there being no loss of substance, the wound was cicatrized in a much shorter space of time." Mr Brodie employed this method with advantage in several instances; but he afterwards improved and simplified it as follows: "It is evident (says he) that the extensive division of the skin over a varix can be attended with no advantage. On the contrary, there must be a disadvantage in it,

\* See Travers *On Wounds and Ligatures of Veins, Surgical Essays*, Part I.; Oldknow, in *Edin. Med. and Surg. Jour.* Vol. V.; R. Carmichael, in *Transactions of the King's and Queen's College of Physicians*, Vol. II.

Surgery. as a certain time will necessarily be required for the cicatrization of the external wound. The improvement consists in this: the varicose vessels are completely divided, while the skin over them is preserved entire, with the exception of a moderate puncture, which is necessary for the introduction of the instrument, with which the incision of the veins is effected." For this operation, Mr Brodie has generally employed a narrow sharp-pointed bistoury, slightly curved, with its cutting edge on the convex side. Having ascertained the precise situation of the vein, or cluster of veins, from which the distress of the patient appears principally to arise, he introduces the point of the bistoury through the skin, on one side of the varix, and passes it on between the skin and the vein, with one of the flat surfaces turned forwards, and the other backwards, until it reaches the opposite side. He then turns the cutting edge of the bistoury backwards, and in withdrawing the instrument the division of the varix is effected. The patient is to be kept quiet in bed for four or five days after the operation, and the bandage and other dressings removed with the utmost care and gentleness. In none of the cases in which Mr Brodie had operated at the time, when he published an account of the plan, had the operation been followed by inflammation of the coats of the divided veins. The examples, for which the method is considered by him advisable, are not those in which the veins of the leg generally are varicose, or in which the patient has little or no inconvenience from the complaint; but those in which there is considerable pain referred to a particular varix; or in which hemorrhage is liable to take place from the giving way of the dilated vessels; or in which they occasion an irritable and obstinate varicose ulcer. (*Med. Chir. Trans.* Vol. VII.)

Many useful additions might be made to what is stated concerning amputation, in the former Article; but we must confine our remarks to a few of the most interesting things, on which the genius and industry of modern surgeons have been beneficially exerted in this part of practice. Every person accustomed to see much of surgery knows very well, that it is frequently a matter of greater difficulty to understand precisely when amputation ought, or ought not to be performed, than how the operation is to be done; and certainly a more important question, with reference to the patient's safety, and his future crippled or unmutilated condition, cannot be imagined.

Compound fractures of the thigh from gunshot violence are injuries, in which the prompt performance of amputation is frequently the only chance of preserving life. However, in these examples, the urgency for the operation varies. According to Schmucker, all gunshot fractures of the middle and upper part of the femur are attended with very great danger. But, says he, if the fracture be situated at the lowest part of the bone, the risk is considerably less, the muscles here not being so powerful. In such a case, therefore, amputation should not be performed before every other means has been fairly tried; and very frequently he treated fractures of

this kind with success, though the limb sometimes continued stiff. Of course, these remarks imply, that, in addition to the mere solution of continuity in the bone, the soft parts are not extensively contused and lacerated, nor the bone very much smashed; circumstances which, as far as our experience in military surgery extends, would form a just reason against any attempt to save the limb; as the delay would neither be attended with success, nor leave a second opportunity of amputating with an equal chance of rescuing the patient from danger. When the bone was completely fractured, or splintered by a ball at its middle, or above that point, Schmucker, very judiciously, never waited for the bad symptoms to commence, but amputated before they had had time to originate; and, when the operation was done early enough, most of his patients were saved. On the contrary, when the operation had been delayed some days, and inflammation, swelling, and fever had come on, the issue was much less fortunate. The correctness of the opinion of this experienced surgeon is confirmed by the valuable testimony of our army surgeons, who had opportunities, in the course of the late war, of seeing many of those severe gunshot injuries of the thigh. In particular, the following observations upon the point under consideration, delivered by Mr Guthrie in his *Treatise on Gunshot Wounds*, are entitled to the greatest attention. "The danger and difficulty of cure, attendant on fractures of the femur from gunshot wounds," says he, "depend much on the part of the bone injured, and, in the consideration of these circumstances, it will be useful to divide it into five parts. Of these, the head and neck, included in the capsular ligament, may be considered the first; the body of the bone, which may be divided into three parts; and the spongy portion of the lower end of the bone, exterior to the capsular ligament, forming the fifth part. Of these, the fractures of the first kind are, I believe, always ultimately fatal, although life may be prolonged for some time. The upper third of the body of the bone, if badly fractured, generally causes death at the end of six or eight weeks of acute suffering.\* I have seen few escape, and then not with an useful limb, that had been badly fractured in the middle part. Fractures of the lower or fifth division are in the next degree dangerous, as they generally affect the joint; and the least dangerous are fractures of the lower third of the body of the bone." With respect even to these, Mr Guthrie also admits, that, when there is much shattered bone, the danger is great; so that a thigh fractured by gunshot, even without particular injury of the soft parts, is one of the most dangerous kinds of wounds that ever occur.

The very important maxim in military surgery is now completely settled by the general assent of every experienced army surgeon, namely, that, when a limb is so injured as to leave no rational chance of ultimately preserving it, amputation should be performed without delay, before inflammation, fever, and other bad symptoms originate. This rule is parti-

\* None of the cases of this kind which fell under our own observation lasted so long.

*Surgery.* cularly applicable to the cases of compound fracture of the femur above specified as requiring the operation.

Another kind of injury, urgently demanding the immediate performance of amputation, is that in which a considerable portion of the whole thickness of a limb has been carried away by a cannon-ball or bomb. The necessity of this practice was inculcated by M. Faure himself, in former days one of the chief opponents of operating in the early stage of gunshot injuries; and it is strongly insisted upon in the valuable writings of Schmucker, Larrey, &c.

When a body, propelled by the explosion of gunpowder, strikes a limb so as to smash the bones, and violently contuse, lacerate, and deeply tear away the soft parts, amputation ought not to be delayed. If the operation be put off, all the injured parts will soon be attacked with gangrene, and the constitution be so generally and severely disordered, that a second opportunity of removing the limb will hardly be afforded. It is but justice to the memory of Mr Faure to mention, that this was a kind of case, which he particularly pointed out, as requiring the operation without the least delay.

If a similar body were to carry away a great mass of the soft parts, and the principal vessels of a limb, without fracturing the bone, immediate amputation is proper. Mr Guthrie also lays it down as a rule, to operate without loss of time, when the artery and vein on the inside of the thigh are injured, even though there should be no fracture. This gentleman likewise approves of the same practice, when a wound of the femoral artery accompanies a fracture of the thigh-bone.

Another case, demanding the immediate performance of amputation, is where a grape-shot has struck the thick part of a limb, broken the bone, divided and torn the muscles, and destroyed the principal nerves, without interfering, however, with the main artery. Mr Guthrie says, that if a cannon-shot strike the back part of the thigh, and carry away the muscular part behind, and with it the sciatic nerve, amputation is necessary, even though the bone be unhurt. In this case, he would not make a circular incision, but save a flap from the fore part, or sides, to cover the bone.

If a spent cannon-ball, or one that has been reflected, should strike a limb obliquely, without producing a solution of continuity in the skin, as often happens, the parts which resist its action, such as the bones, muscles, tendons, aponeuroses, and vessels, may be crushed and lacerated. Here, if the bones should feel through the soft parts as if they were smashed, and a kind of fluctuation indicate the rupture of the large vessels, amputation should take place without delay. The real state of the parts under the skin, however, should first be examined by means of an incision, which, when the principal vessels and the bones have escaped injury, will be of itself adequate to afford relief, by letting out the large quantity of extravasated blood generally found in such cases under the integuments.

When the articular heads of the bones are much broken, especially those which form the joints of the knee or foot, and the ligaments are lacerated, imme-

mediate amputation is the right practice. Fractures of the patella, without injury of the other bones, will sometimes admit of delay. Even extensive sword wounds of the elbow joint are alleged by Baron Larrey to demand immediate amputation.

The common doctrine in the treatment of mortification has always been, not to attempt amputation until the stoppage of the disorder is denoted by the appearance of a red line on the margin of the living skin. However, the observations of Baron Larrey tend to prove that this maxim, if acted upon in cases of mortification from gunshot wounds and external injuries, would be productive of the worst consequences, and leave the patient hardly a possibility of recovery. On the contrary, he strongly urges the speedy performance of the operation, even though the mortification be yet in a spreading state. It was formerly imagined that the stump would always be attacked with gangrene, if amputation were done under these circumstances; but modern experience contradicts this opinion, and some observations, made by Mr Lawrence on this point, will be found to corroborate the view of the subject given by Larrey. (*Med. Chir. Trans.* Vol. VI.)

The establishment of the propriety of the severe operation of amputation at the hip-joint; the determination of the circumstances under which this attempt to save the patient should be made; and the settlement of the best manner of performing the operation, are also some of the useful results of the attention and zeal, with which the practice of surgery has been cultivated in modern times. As there are unquestionably some descriptions of injury where life must inevitably be lost if this proceeding be rejected, and experience proves that it sometimes answers, an important consideration is, What cases are most proper for it? Here we fully agree with Dr Thomson, that the examples in which it is particularly called for, and where no delay should be suffered, are those in which the head or neck of the thigh-bone has been fractured by a musket-ball, grape-shot, or small piece of shell. Larrey thinks the operation proper where the thigh has been shot off high up, or where the femur and soft parts near the hip have been broken and extensively lacerated by a cannon-ball or shell. Under such circumstances, however, the operation, though perhaps the only chance, must almost always fail, because injuries of this description occasion a shock to the constitution, of which the patient mostly sinks either immediately or in a few hours. There have now been at least three successful amputations at the hip-joint; the first was done by Larrey, the second by Mr Brownrigg, and the third by Mr Guthrie. All the examples were gunshot injuries, the only cases, we believe, in which the operation is ever justifiable. For further observations on this subject, the reader may consult Cooper's *Dictionary of Surgery*, where will be found a description of the various methods of operating, and a detail of the reasons for or against all the different modes which have been proposed.

Amputations, in general, have been of late years much improved by the rejection of the large clumsy ligatures, which were formerly used; whereby considerable irritation was kept up, union by the first

Surgery.

intention materially prevented, the formation of large abscesses promoted, and secondary hemorrhage rendered much more frequent, than at the present time. Mr Lawrence adopts the plan of tying the vessels with fine silk ligatures, and cutting off the ends as close to the knot as is consistent with its security. Thus the extraneous matter in the wound is reduced to the insignificant quantity, which forms the noose actually surrounding the vessel, and the knot by which that noose is fastened. Of the silk which he commonly employs, a portion, sufficient to tie a large artery, when the ends are cut off, weighs between  $\frac{1}{80}$  and  $\frac{1}{60}$  of a grain; a similar portion of the thickest kind weighs  $\frac{1}{20}$  of a grain, and of the slenderest  $\frac{1}{30}$ .

Mr Lawrence observes, that the kind of silk twist, which is commonly known in the shops by the name of dentists' silk, and which is used in making fishing lines, is the strongest material, in proportion to its size, and, therefore, the best calculated for the purpose, which requires considerable force in drawing the thread tight enough to divide the fibrous and internal coats of the arteries. This twist is rendered very hard and stiff by means of gum, which may be removed by boiling it in soap and water; but the twist then loses a part of its strength. The stoutest twist which Lawrence uses is a very small thread, compared with ligatures made of inkle. The quantity of such a thread necessary for the noose and knot on the iliac artery weighs  $\frac{1}{20}$  of a grain; or, if the gum has been removed, about  $\frac{1}{26}$ . This gentleman's experience fully proves, that there is no danger of these ligatures cutting completely through the vessel, as certain surgeons have apprehended. Some objections have been urged against the practice, on the ground of its giving rise occasionally to little festerings, and even to ill-looking abscesses; but, it is justly remarked by Mr Lawrence, in reply to these objections, that as they are not accompanied by any description of the materials, or size of the ligature, nor by any details of the unfavourable cases, we cannot judge whether the events alluded to are to be attributed to the method itself, or to the way in which it was executed. (*Med. Chir. Trans.* Vol. VI.) In a paper of later date, he says, his further experience has confirmed the usefulness of the method; that, by diminishing irritation and inflammation, and simplifying the process of dressing, it very materially promotes the comfort of the patient and the convenience of the surgeon; while it has not produced ill consequences, or any unpleasant effect in the cases which have come under his own observation. The small knots of silk generally separate early, and come away with the discharge; where the integuments have united by the first intention, the ligatures often come out rather later with very trifling suppuration, and, in some instances, they remain quietly in the part. (*Op. cit.* Vol. VIII.)

Surgery.

*Syphilis.* In relation to syphilis, the judicious and impartial investigations of modern surgeons have succeeded in dispelling a considerable number of erroneous doctrines formerly entertained respecting this intricate and perplexing disease. Amongst other things, Mr Hunter inculcated, that "the venereal matter,

Surgery.

when taken into the constitution, produces an irritation, which is capable of being continued, independent of the continuance of absorption, and the constitution has no power of relief; therefore, a lues venerea continues to increase." The same criterion was proposed by Mr Abernethy, who states, that the "constitutional symptoms of the venereal disease are generally progressive, and never disappear, unless medicine be employed." And, notwithstanding some dissent may be traced in both old and recent writers, from the belief that mercury was absolutely essential to the cure of syphilis, and an opposite conclusion might easily have been made from a review of the whole history of the subject, including the practice of former and present times; still the contrary hypothesis was what was always taught in all the great medical schools of this country, even till within the last few years. But this mistaken notion no longer prevails; and no facts are more completely established, than that mercury, however useful it may frequently be in the treatment of this disease, is not absolutely necessary for the cure either of the primary or secondary symptoms; and that the disease, so far from always growing worse, unless mercury be administered, ultimately gets well of itself, without the aid of this or any other medicine. If any man yet doubt the general truth of this statement, let him impartially consider the many facts and arguments brought forward in proof of it, in the writings of Dr Fergusson, Dr Hennen, Dr Thomson, Mr Rose, Mr Guthrie, Mr Bacot, and others. In short, if there be such a sceptic now living in this country, let him peruse the returns made by the surgeons of the whole British army; let him consider the evidence of the surgeons of other countries, especially that of Cullerier, who annually demonstrates to his class of pupils the cure of venereal ulcers without mercury; and the testimony and practice of the German surgeons, who were attached, during the war, to regiments of their countrymen in the British service. The fact is, therefore, indisputable, that the venereal disease, in all its ordinary and diversified forms, is capable of a spontaneous cure; and, consequently, that the question, whether a disease is syphilitic or not, can never be determined by the circumstance of the complaint yielding, and being permanently cured, without the aid of mercury. Yet, as Mr Rose has observed, the supposition that syphilis did not admit of a natural cure, and that mercury was the only remedy that had the power of destroying its virus, was of late so much relied upon, that, where a disease had been cured without the use of that medicine, and did not afterwards return,—such fact alone, whatever might have been the symptoms, was regarded as sufficient proof, that it was not a case of syphilis. And, as the same writer very judiciously remarks, the refutation of these notions is of considerable importance, "not so much in reference to the treatment of syphilis, under common circumstances (for the strikingly good effects of mercury will probably not render it advisable, in general, to give up the use of that remedy"), as to the change it will produce in our views of the diagnosis of the disease. The distinction, which has engaged such a share of attention of late years, and which is evidently so important be-

Surgery.

twecn syphilis and syphiloid diseases, has been made to depend so much on the former admitting of no cure, except by mercury, that, if this principle should be found to be erroneous, the difficulties which have attended it will be in a great measure explained. (*Med. Chir. Trans.* Vol. VIII.)

Dr Fergusson assures us that, in Portugal, the disease, in its primary state amongst the natives, is curable without mercury, by simple topical treatment; that the antisyphilitic woods, combined with sudorifics, are an adequate remedy for constitutional symptoms; and that the virulence of the disease has there been so much mitigated, that, after running a certain course (commonly a wild one) through the respective orders of parts, according to the known laws of its progress, it exhausts itself, and ceases spontaneously. (*Op. cit.* Vol. IV.) The conclusion to which the writings of Mr Pearson led, long before recent investigations began, was, that venereal sores might be benefited, and even healed, under the use of several inert insignificant medicines. But, amongst modern writers, we find Dr Clutterbuck one of the earliest in distinctly asserting, that the healing of a sore without mercury was no test of its not being venereal. (*Remarks on the Opinions of the late J. Hunter*, 1799.) It is curious to remark, that this important truth is rendered conspicuous in the treatises of Mr Pearson and Dr Clutterbuck, though both these gentlemen were, at the time of their publishing, as much advocates for full mercurial courses as can well be conceived. But, although the whole history of syphilis, and of the effects of various articles of the materia medica, if carefully reflected upon, must have led to the above-mentioned inference; the truth was never placed in such a view as to command the general belief of all the most experienced surgeons in this and other countries of Europe. It is not meant, that the truth was not seen and remarked by several of the older writers; for that it was so any man may convince himself by referring to their works. But it is to be understood, that a great deal of indecision could never be renounced as long as prejudices interfered with the only rational plan of bringing the question to a final settlement; we mean that of instituting experiments upon a large and impartial scale, open to the observation of numerous judges, yet, under such control, as insured the rigorous trial of the non-mercurial treatment. Nor could such investigation be so well made by any class of practitioners as the army surgeons, whose patients are numerous, and obliged to follow strictly the treatment prescribed, without any power of going from hospital to hospital, or from one surgeon to another, as caprice may dictate; or of eluding the observation of the medical attendants after a seeming recovery. To us it appears, that the most important and cautious document yet extant, on the two questions of the *possibility* and *expediency* of curing the venereal disease without mercury, is the paper of Mr Rose. For, let it not be assumed, that, because the army surgeons find the venereal disease curable without mercury, they mean to recommend the total abandonment of that remedy for the distemper, any more than they would argue that *possibility* and *expediency* are

10

synonymous terms. At the time when Mr Rose published his observations, he had tried the non-mercurial treatment in the Coldstream Regiment of Guards, during a year and three quarters, and had thus succeeded in curing all the ulcers on the parts of generation which he met with in that period, together with the constitutional symptoms to which they gave rise. "I may not be warranted in asserting," says this gentleman, "that many of these were venereal, but, undoubtedly, a considerable number of them had all the appearances of primary sores produced by the venereal virus, and arose under circumstances where there had been at least a possibility of that virus having been applied. Admitting that there is nothing so characteristic in a chancre as to furnish incontrovertible proof of its nature, it will yet be allowed, that there are many symptoms common to such sores, although not entirely peculiar to them; and whenever these are met with, there are strong grounds to suspect, that they are the effects of the syphilitic virus. In a sore, for instance, appearing shortly after a suspicious connection, where there is loss of substance, a want of disposition to granulate, and an indurated margin and base, there is certainly a probability of that poison being present. Amongst a number of cases of such a description, taken indiscriminately, the probability of some being venereal is materially increased, and must at last approach nearly to a certainty. On this principle, some of the sores here referred to must have been venereal. They were also seen by different surgeons, on whose judgment I would rely, who agreed in considering many of them as well-marked cases of true chancre." The men thus treated were examined almost every week for a considerable time after their apparent cure, "both that the first approach of constitutional symptoms might be observed, and that any deception from an underhand use of mercury might be guarded against." In Mr Rose's practice, all idea of specific remedies was entirely laid aside. The patients were usually confined to their beds, and such local applications were employed as the appearances of the sores seemed to indicate. Aperient medicines, antimony, bark, vitriolic acid, and occasionally sarsaparilla, were administered. Upon an average, one out of every three of the sores, thus treated, was followed by some form or another of constitutional affection; this was in most instances mild, and sometimes so slight, that it would have escaped notice, if it had not been carefully sought for. The constitutional symptoms were evidently not such as could be regarded as venereal, if we give credit to the commonly received ideas on the subject. Caries of the bones, and some of the least equivocal symptoms, did not occur. In no instance was there that uniform progress, with unrelenting fury, from one order of symptoms and parts affected to another, which is considered as an essential characteristic of true syphilis. The constitutional symptoms also yielded without the aid of mercury; and frequently, primary sores, corresponding to what has been called the true chancre with indurated base, were cured in this manner; yet without being followed by any secondary symptoms. We are also

Surgery.

Surgery. informed, that several cases occurred of a cluster of ill-conditioned sores over the whole inner surface of the prepuce, and behind the corona glandis; and also of a circle of small irritable sores, situated on the thickened and contracted ring at the extreme margin of the prepuce. These occasionally produced buboes. None of the sores of this description were followed by any constitutional affection. Mr Rose bears testimony to the ill effects of mercury and stimulants in cases of phagedenic ulcers, and confirms an opinion, not uncommonly prevailing, that they are seldom followed by secondary symptoms; which opinion, perhaps, ought to be qualified with the condition, mentioned by Mr Guthrie (*Med. Chir. Trans.* Vol. VIII.), that no mercury be given; for, in this circumstance, secondary symptoms are more frequent.

But, although the fact of the *possibility* of curing every kind of ulcer on the genitals without mercury is now completely established, and it is of great importance with regard to the removal of an erroneous doctrine concerning the diagnosis, and also in encouraging practitioners even not to be frightened into the use of mercury, when the patient's constitution is in an unfavourable state for its exhibition, or the case is of a doubtful nature; yet, the *expediency* of the non-mercurial practice must evidently be determined by other considerations; the principal of which are, the comparative quickness of the cures effected with or without mercury; the comparative severity and frequency of secondary symptoms; and the generally acknowledged fact, that a syphilitic sore is not indicated, with any degree of certainty, by its mere external appearance, or, indeed, any other criterion. For the consideration of the evidence on these, and various other points connected with the present subject, we must refer to the last edition of Cooper's *Surgical Dictionary*, from which many of the foregoing remarks are selected.

In the former article, a short section will be found upon inflammation of the iris; a disease upon which modern surgeons have bestowed all the attention which its importance required, and the results, as might be expected, have been greater accuracy in the discrimination of the complaint, and much improvement in its treatment. The iris, next to the conjunctiva, is found to be that texture of the eye, which is most frequently affected with inflammation. It often becomes inflamed in consequence of surgical or accidental wounds of the eye-ball. A peculiar and characteristic iritis is generally supposed to be one of the constitutional effects of syphilis. Scarcely any disease, to which the eye is subject, has a more immediate or rapid tendency to destroy vision.

In the *idiopathic iritis*, as Professor Schmidt has remarked, besides the common symptoms of ophthalmia, certain changes happen at the very commencement of the case, indicating the seat of inflammation. The pupil appears contracted, the motions of the iris are less free, and the pupil loses its natural bright black colour. The brilliancy of the colour of the iris fades, and the part becomes thickened and puckered, with its inner margin turned towards the crystalline lens. The change of colour

happens first in the lesser circle of the iris, which becomes of a darker hue; and afterwards in the greater circle, which turns green, if it had been greyish or blue; and reddish, if it had been brown or black. The redness accompanying these changes is by no means considerable, and is at first confined to the sclerotic coat, in which a number of very minute rose-red vessels are seen, running in straight lines towards the cornea. In the words of Mr Saunders, the vascularity of the sclerotica is very great, whilst that of the conjunctiva remains much as usual, the plexus of vessels lying within the latter tunic. The inosculation of these vessels are numerous, and at the junction of the sclerotica with the cornea, they form a kind of zone. Here the vessels disappear, not being continued over the cornea, as in a case of simple ophthalmia, but penetrating the sclerotica in order to reach the inflamed iris. The irritation of the light is distressing, and the patient is much annoyed by any pressure on the globe of the eye, or by the rapid or sudden motions of this organ. Considerable uneasiness is felt over the eyebrow, and acute lancinating pains shoot through the orbit towards the brain. The pupil loses its circular form, becomes somewhat irregular, and presents a greyish appearance. When examined with a magnifying glass, this appearance is found to be produced by a substance very like a cobweb, occupying the pupil, and which can soon afterwards be distinguished, even without the aid of a glass, to be a delicate flake of coagulable lymph, into which the dentations of the irregular margin of the iris seem to shoot, and at these points adhesions are apt to be formed. In consequence of these adhesions, the patient, whose vision has been all along indistinct, now complains of being able to see only on one side, or part of an object. Lymph is next deposited on the anterior surface of the iris, and between the iris and the capsule of the lens, and often in such quantity, that it extends through the pupil, and hangs down to the bottom of the anterior chamber. If this process is not checked, the pupil becomes entirely obliterated, or the iris adheres to the capsule of the lens; a very small opening only being left, which is usually occupied by an opaque portion of the capsule, or of organized lymph, and the patient is quite blind.

Schmidt, Beer, and many English surgeons, believe one form of iritis to be *syphilitic*. The affection of the iris may be accompanied with other symptoms of lues venerea, or it may take place singly before any of these have appeared. A pale redness, all round the cornea, is the first symptom perceived in the *syphilitic iritis*: it is at first confined to the sclerotic coat, but the conjunctiva very soon participates in it, and afterwards is the reddest of the two parts. However few the vessels may be elsewhere, there is always a broad zone of them all round the cornea. The redness is also described as having a peculiar tint, being brownish, something like the colour of cinnamon; or, as Mr Travers expresses himself, having a brick-dust, or dusky red, instead of a bright scarlet hue. The lymph, he says, is compact and brown, and intimately adherent to the iris, instead of being curd-like, loose, and

Surgery.

of a yellowish white colour. (*Surgical Essays*, Part I.) The whole of the cornea now grows hazy, without being at any point actually opaque. The pupil becomes contracted, and the iris limited in its motions, as in common iritis; but the pupil, instead of preserving its natural situation, is drawn in the direction upwards and inwards, towards the root of the nose, and is irregular. The iris also loses its natural colour, and projects forwards. An aggravation of the symptoms always takes place towards evening; the intolerance of light, and painful sensibility of the whole eye increasing, and a gush of tears following every change of light and temperature. At length, a regular nightly pain begins, which is extremely severe, and strictly limited to that part of the cranium which is immediately over the eye-brow. It reaches its greatest severity about midnight, and then diminishes till about four or five o'clock in the morning, when it ceases. Afterwards, one or more reddish-brown tubercles, of a spongy look, arise either on the pupillary or ciliary edge of the iris, or on both of them, and grow rather fast. Sometimes little ill-conditioned ulcers are produced on the cornea, conjunctiva, or skin of the eye-lids. Even when the case terminates in the most favourable manner, the eye remains, for a long time, peculiarly sensible to the influence of cold and moisture. In the iritis, which appears in conjunction with eruptions, supposed to be connected with the abuse of mercury, the inflammation is less active, than in the other forms of iritis. The pupil is not much contracted, and lymph is less apt to be effused.

The principal danger of iritis is ascertained to depend upon the effusion of lymph, its quick organization, the rapid formation of adhesions between the iris and other parts, and the closure and obstruction of the pupil. Now, in modern practice, the management of the disease is much more successfully effected than twenty years ago, when in truth the nature of the case was but incorrectly known; and the great thing that has led to the improved treatment is the discovery of the fact, that mercury is one of the most effectual means of stopping the effusion, and promoting the absorption of lymph in the adhesive inflammation; a fact which was first particularly insisted upon by Dr Farre.

In idiopathic iritis, before lymph is effused, the means most likely to do good are copious bleeding and cathartics, followed by nauseating doses of tartarized antimony. This plan is to be assisted with leeches applied near the eye, and repeated according to the urgency of the case. When the inflammation stops in this stage, Saunders states, that the cure may be completed by covering the eye with linen wet with a collyrium of acetite of lead, and keeping the patient for some time in a dark room. Schmidt, however, condemns all cold applications in iritis as quite useless; and he asserts, that the only admissible topical treatment consists in fomenting the eye with warm water. In the first stage of the disease, he says, blisters on the temple, or behind the ears, have little or no effect, though they are sometimes useful when put on the nape of the neck.

But no sooner is lymph effused, than the principal

aim of the surgeon should be to bring about its absorption. Of all remedies for this purpose, none answer so well as mercury, which is to be freely exhibited, so as to affect the constitution as quickly as possible. The ointment, or pil. hydrargyri with opium, may be employed, and, in very urgent cases, the medicine may be used both externally and internally. In the second, or adhesive stage of iritis, Beer prescribes calomel combined with opium; applies to the eye itself a collyrium, containing oxy-muriate of mercury, mucilage, and a considerable proportion of vinum opii; and, when this application ceases to be effectual, he has recourse to a salve, composed of two drachms of fresh butter, six grains of red precipitate, and eight grains of the extract of opium. Frictions over the eye-brow once a day, with mercurial ointment, containing mercury, he says, will also have great effect in producing the absorption of the effused lymph. The late Mr Saunders used to resist the tendency of the pupil to contract by means of the extract of belladonna; with which he smeared the eye-lids and eye-brows, or which he diluted with water, and then dropped between the eye and eye-lids.

In the syphilitic iritis, general bleeding is not considered so necessary as in idiopathic cases. When the pain in the eye and head is severe, leeches may be applied, and the bowels emptied. The nightly attacks of pain are to be prevented by rubbing a small quantity of mercurial ointment, with opium, just above the eye-brow, a short time before the pain is expected to begin, and then covering the eye with a folded piece of warmed linen. Mercury is to be employed so as to affect the system, either in the form of ointment, or of calomel pills joined with opium.

The form of iritis, conjectured to proceed from the abuse of mercury, or accompanying ambiguous eruptions of the papular sort, or such as are not syphilitic, also requires a combination of the depleting with the mercurial plan. This circumstance, in relation to the first of these cases, seems extraordinary, as involving the seeming inconsistency of mercury being both the exciting cause, and the antidote of the disease. But, though iritis does present itself, accompanied or connected with various suspicious symptoms, and in individuals who have used considerable quantities of mercury, it cannot be said that mercury alone, that is, without the agency of some other additional causes, is really an exciting cause of iritis; or, if such assertion be made, the clear proof of the fact is yet wanting; and here we should also be disinclined to receive, as such proof, any rare and solitary instance of an attack of iritis after the free use of mercury in a case of a totally different nature from syphilis, or syphiloid disease. Mercury cannot be supposed to render a patient insusceptible of iritis; and, therefore, a few uncommon attacks after its administration for liver complaints, or other disorders quite unconnected with lues venerea, or the many diseases resembling it and confounded with it, would prove little or nothing to the point. In the meanwhile, the good effect of mercury in the examples of iritis, *supposed* to arise from the

previous abuse of it, seems to be established; which is the information of most value to the practical surgeon.

Lastly, we shall enumerate, amongst recent inventions of great utility in practice, the bed, invented by Mr Earle, for patients with accidents and dis-

eases requiring a state of permanent rest; also his apparatus for more effectually securing the upper extremity; an object of great consequence in fractures of the clavicle, and other injuries of the bones about the shoulder.

**Surgery**  
||  
**Surry.**

(T. T. T.)

**Boundaries**  
and Extent.

**SURRY**, an inland English county on the banks of the Thames, by which, on its northern side, it is separated from Middlesex. On the west it is bounded by Berkshire and Hampshire; on the south by Sussex; and on the east by Kent. Its shape is an oblong, of moderate regularity, except on its northern side, where considerable indentations are formed by the curvatures of the Thames. Its length, from east to west, is about thirty-seven miles; and its breadth, from north to south, about twenty-five. The area is 758 square miles, or 485,120 statute acres.

**Population**  
and Divisions.

By the census of 1821, the houses were found to be 64,790, inhabited by 88,806 families; of whom 14,944 were chiefly employed in agriculture; 46,811 in trade, manufactures, or handicraft; and 27,051 were comprehended in neither of those classes. The number of persons was 398,658; of whom 189,871 were males, and 208,787 females. From its vicinity to the metropolis, more than two-thirds of the inhabitants may be included in the numerical population of London. Southwark, one of the suburbs to the capital, and the hundred of Brixton, adjoining to it, contain 267,994 inhabitants; and the other portions of the county are more thinly peopled than most parts of England. The divisions are thirteen hundreds; and the boroughs of Southwark and Guilford, comprising 146 parishes; all of which are within the diocese of Winchester.

**Face of the**  
**Country.**

The face of the country exhibits great varieties. On the north, by the banks of the Thames, from Lambeth to Egham, the richness of the highly improved country, the abundance of trees, the verdure of the meadows, the undulation of the hills, with the numerous elegant private houses, all display the most pleasing marks of taste, wealth, and comfort. The centre of the county is a range of chalk hills, much covered with thick underwood, intermixed with arable fields badly cultivated, and utterly destitute of water. The south part, at the foot of this range of hills, is a flat clayey country, nearly impassable in the winter; but covered with some of the best and largest oak trees that are to be found in the island. The north-western part exhibits a considerable tract of the most sterile black heaths that can exist; whilst, on the south-west, near Farnham, is some of the most productive land in England.

**Productions.**

The productions of agriculture are various; and, at a distance from the capital, scarcely differ from those of other districts in similar circumstances. A greater proportion of clover and of sanfoin is cultivated on the hills, where there are no natural meadows, than in most other parts of the kingdom. Woad is also grown in the same districts very extensively. It is commonly sowed with turnips, which are to be fed with sheep who will not touch

that plant. It is generally harvested before the corn crops are ready for the sickle. Near London, the garden ground extends over several thousand acres. The growing of plants, for the use of the druggists and perfumers, engages much attention; and those gardens supply peppermint, lavender, wormwood, chamomile, anniseed, liquorice, poppy, and other similar articles. Hops are extensively cultivated near Farnham, and are sold for higher prices than those of any other districts.

There are no minerals now raised in the county; for, though iron is known to exist, and was formerly worked with charcoal, the improvements in chemistry have fixed that operation to the coal districts. The fossil riches are valuable, especially fuller's earth, which is of the best quality, and in abundance, and supplies the cloth manufacturers both in the west and north of England. Limestone is plentiful; and that, as well as chalk, is converted into lime, upon a great scale, for the use of the builders of the metropolis. The quarries of Mersham produce an excellent firestone; and the sand near Dorking and Ryegate is in great request for making glass, hour-glasses, writing, and other purposes.

The manufactures are various and extensive; but, being almost exclusively near the metropolis, more properly be considered as belonging to London than to the county of Surry. The principal of those are breweries and distilleries on a magnificent scale. The tanners, rope and sail makers, glass-makers, starch and hair-powder makers, and the preparers of vinegar and raisin wines, carry on large trades. A few miles farther from London, chiefly on the banks of the river Wandle, the calico printers and bleachers have large establishments.

All the rivers of this county empty themselves into the Thames; the only navigable river, besides that fine stream which bounds it, is the Wey, on which barges pass above Guildford into the Basingstoke canal. The Mole is a beautiful small stream, celebrated for sinking into the ground, and at some few miles lower again emerging; it runs to the Thames. The Wandle is of short course, but of great value, from the vast quantity of mill machinery which it keeps in motion, and the employment it thus affords to several thousand persons. It rises in one spring near Croydon, turns a large mill within a few yards of its source, and runs nine miles before it joins the Thames. The Medway rises in Surry; but is a very small stream till it enters the county of Kent. The Loddon, a small river on the western border, is chiefly valuable for the supply of water it affords to the Basingstoke canal. That canal was one of the first executed in this part of the king-

**Rivers, Canals, and Rail-Roads.**

Surry.

dom, having been finished in 1796. The Croydon canal only reaches that town from the Thames; and the little success attending it has put a stop to its being carried farther, as was originally intended. The Surry canal runs parallel to the Thames; but, by avoiding the sinuosities of that river and the whole of the metropolis, is expected to be beneficial to the inhabitants on the upper banks, by conveying coals and other heavy commodities to them, from ships, at a cheap rate. Its entrance, from the Thames below London Bridge, has a fine bason, capable of containing 100 sail of square-rigged vessels. Rail-roads have been constructed from Merstham to the Thames; but the project has not repaid the persons who have advanced the capital a sufficient interest to induce any farther attempts.

Antiquities and Interesting Objects.

Among the Roman antiquities of this county are the Ermine way, which traversed it, and the remains of which may still be traced near Dorking. The piles are still standing in the river Thames at Walton, which were placed there by the ancient Britons, to impede the passage of Julius Cæsar. The vestiges of the encampments of the Romans may be distinctly traced at Bottlehill, at Waltonhill, and some other spots. Among the antiquities of later date, are the Palace of Lambeth, belonging to the see of Canterbury; that of Farnham, belonging to the see of Winchester; the remains of the Abbey at Croydon; the Castle of Guildford; Waverley Abbey, and some other Saxon edifices. The meadow of Runnymede, St Anne's Hill, the seat of the late Mr Fox, the park of Richmond, and the terrace there, with the palace and gardens of Kew, are all objects that excite a high degree of interest.

Titles and Representation.

The titles derived from this county are, Duke of Richmond, and Earls of Surry, Guildford, and Onslow: Two members are returned to the House of Commons from the county, and two each from the boroughs of Southwark, Guildford, Gatton, Ryegate, and Haselmere. It is difficult to say which is the county town. The elections are held at Guildford, and the assizes once in the year; the other assizes are held alternately at Kingston and at Croydon. The gaol is in the borough of Southwark, and county meetings are generally convened at Epsom.

Chief Seats.

The number of seats belonging to noblemen and gentlemen in this county is so great, as to forbid the noticing of even all those which in any other county would be deemed highly worthy of notice. The most remarkable are, his Majesty's palace of Kew; Claremont, Prince Leopold; Clandon Place, Earl of Onslow; Pepper Harrow, Lord Middleton; Oatlands, Duke of York; Painshill, Lord Carhampton; Ockham Park, Lord King; Busbridge, H. H. Townsend, Esq.; Addington Palace, Archbishop of Canterbury; Rooks-nist, C. H. Turner, Esq.; Nonsuch Park, S. Farmer, Esq.; Gatton, Sir Mark Wood; Nork House, Lord Arden; Betchworth, Right Honourable H. Goulbourne; Norbury Park, Joseph Dennison, Esq.

Chief Towns.

The chief towns and their population are, Southwark, 85,905; Croydon, 9254; Richmond, 5994; Chertsey, 4279; Godalming, 4098; Kingston, 4908; Dorking, 3812; Farnham, 3132; Guildford, 3161; Ryegate, 2961.

See Manning and Bray's *History of Surry*; Salmon's *Antiquities of Surry*; Stevenson's *View of the Agriculture of Surry*; Lyson's *Environs of London*. (w. w.)

Surry  
||  
Sussex.

SUSSEX, an English maritime county, bounded on the east by Kent, on the north by that county and Surry, on the west by Hampshire, and on the south by the British Channel. It is of an oblong shape, being about seventy miles in length from east to west, and no where more than twenty-six miles in breadth, from north to south. Its area is 1463 square miles, or 936,320 statute acres. It is divided into six portions, called provincially *Rapes*, which are again divided into sixty-five hundreds, and contain 313 parishes. The greater part of the county is within the diocese of Chichester; but the deaneries of Pagham and South Malling, and All Saints in Chichester, form a part of the peculiar of the Archbishop of Canterbury.

Boundaries,  
Extent,  
Divisions.

The number of houses in 1821 was 36,283, inhabited by 43,565 families; of whom 21,920 were chiefly employed in agriculture; 15,463 in trade, manufactures, or handicraft; and 6182 comprehended in neither of those classes. The number of inhabitants was 233,019, of whom 116,705 were males, and 116,314 females.

Population.

The northern part of the county was formerly wholly a forest, and still is very thickly covered with wood, and adorned with the finest oak trees in the kingdom. The soil is generally of so tenacious a clay, and so deep, that, until within a few years, in which roads have been made, and the navigation of the river Arun improved, the timber scarcely paid the expence of carriage to districts where it was needed. A range of chalk hills, known as the South Downs, runs through the county parallel to the coast, and in some points terminating in the sea. On these, vast flocks of sheep are fed; and in the small vallies intervening, the heaviest crops of wheat and other grain are raised. In the south-west part of the county, there is a track of arable land of most singular fecundity. On some parts of the coast, where the chalk hills recede from the shore, there are rich level plains, which feed some of the best oxen that supply the markets of the metropolis.

Face of the  
Country.

The size of the estates vary much, but there are no very large proprietors. The farms in the weald or eastern vales are generally small, those on the South Downs as generally large. The average rent of the land, according to the returns under the late Property-tax, was 3s. 9d. *per acre*. More than 100,000 acres are not estimated at above 1s. 6d. *per acre*: 70,000 acres of down land are estimated at 6s. *per acre*, and 170,000 of woodland at 8s. *per acre*. The arable and woodland in the weald, amounting to about 420,000, are estimated at 12s. The marsh land and the arable land in the south-west have been let as high as 50s. *per acre*. In the weald about one-third is arable, one-third pasture, and one-third wood and waste land. On the south side of the Downs, the arable exceeds the pasture in the proportion of thirty acres to one.

Landed  
Property.

The agriculture of the county is as various as the differences of the soil. In the stiff lands of the weald,

Agriculture.

**Sussex.** the practice of fallowing is generally prevalent ; but to the south of the downs it is rarely resorted to. The growing of turnips, potatoes, pease or beans, is commonly found sufficient to prepare the land for corn. Hops are very extensively cultivated in the eastern part of the county; and as nearly the whole manure of the farms is applied to that plant, the crops of wheat and other grain are usually scanty.

**Cows.** The cattle of Sussex are celebrated through the whole kingdom. The cows are of a deep red colour, with small heads, and horns, thin and transparent, which run out horizontally, and turn up towards the tips. The quality of their milk is not equal to that of some other breeds ; hence, there are few dairies, and the cattle are chiefly reared for the sake of the meat, which is excellent. As much of the ploughing is performed by oxen, they usually labour in harness three or four years before they are fattened. They are but lightly worked, that their growth may not be impeded ; and it is not unusual to see eight and sometimes even ten oxen to a plough. The sheep of Sussex have spread gradually over most parts of the island. The sheep, known by the name of South Downs, have no horns, and their faces and legs are black or dark coloured. The flesh is surpassed by none in England. Their wool is as fine as that of Herefordshire, and they require less food for their support than sheep of any other breed.

**Employ-  
ments.** There are no manufactures in the county. The making of iron formerly gave employment to many persons in the weald ; but the invention of making it with coke instead of charcoal has removed it to those districts where mines of iron and of coal are to be found. The only branch of industry that gives any employment to the population, besides that of agriculture, is the fishery, which, in the summer, especially when the mackerel appear, is extensive. The prosperity of many places on the coast has arisen from the crowds of visitors who frequent them, for the pleasures of sea air and bathing. Among those places Brighton, as the favourite residence of his present Majesty, is the most prominent ; besides which, much company is annually collected at Hastings, East Bourne, Rottendeau, Worthing, and Bognor.

**Rivers.** The rivers of Sussex are all streams of short course. The Lavant and Arun are navigable but a few miles from their mouths. The other rivers are the Adur, which, joining with the Ouse, runs by Lewes to Newhaven ; and the Rother, which forms an estuary near Rye. The only canal is one that connects the towns of Petworth and Midhurst with the river Arun.

**Antiquities.** There are several remains of Roman camps in different parts of the county, and the Stane Street road may still be traced between Chichester and Dorking. The Saxon remains are very numerous, among which the most remarkable are Pevensy Castle, and Battle Abbey. Arundel Castle is a most splendid modernized edifice, upon the site of the ancient erection of that name. Besides these, Bayham Abbey, Eridge Castle, Bodiham Castle, and the buildings at Winchelsea, are worthy the attention of the antiquarian.

**Titles and  
Representa-  
tion.** The titles derived from this county are—Duke of Sussex ; Earls of Winchester, Ashburnham, and Chi-

chester ; Lords Arundel, Gage, Selsey, and Sheffield. The county returns two members to Parliament, and two for each of the following places, Chichester, Arundel, Bramber, Horsham, East Grinstead, Lewes, Midhurst, Shoreham, and Steyning.

The most remarkable seats are, the Pavilion at Brighton ; Goodwood, the Duke of Richmond ; Petworth, Earl of Egremont ; Arundel Castle, Duke of Norfolk ; Sheffield Place, Earl Sheffield ; Eridge Castle, Earl of Abergavenny ; Ashburnham House, Earl of Ashburnham ; Stanstead, Reverend Lewis Way ; Parham, Sir Cecil Bishop ; Kidbroke, Lord Colchester ; Marisfield Park, Sir John Shelly ; Firl, Lord Gage ; Stanmer Park, Earl of Chichester ; Ovingdean, Nathaniel Kemp, Esq. ; Eartham, Right Honourable William Huskisson ; Weshdean House, Lord Selsey.

The most considerable towns and their population are, Chichester, 7362 ; Brighton, 24,429 ; Lewes, 7083 ; Hastings, 6085 ; Horsham, 4575 ; Battle, 2852 ; East Grinstead, 3153 ; Arundel, 2511 ; Rye, 3599.

See Young's *Agricultural Survey of Sussex* ; Russell's *Description of Kent and Sussex* ; Gilpin's *Observations* ; Pennant's *Journey from London to the Isle of Wight* ; *Beauties of England and Wales.* (w. w.)

**SUTHERLAND**, an extensive county in the north of Scotland, situated between 57° 53', and 58° 36' north latitude, and between 3° 39', and 5° 15' west longitude from Greenwich ; having the sea on the south-east, west, and north, Caithness on the north-east, and Ross-shire on the south. From north to south it extends from 35 to 50 miles, and from west to east from 45 to 50, and contains, according to the latest authorities, which cannot, however, be depended on as accurate, about 1,800,000 English acres, divided into 13 parishes, which belong to the synod of Sutherland and Caithness. Of the other divisions, the principal are, Assynt and Edderachy on the west, and Strathnaver on the east ; names recognized by the inhabitants, and which still serve to designate the locality of the natural objects and other circumstances of the country.

The coast of Sutherland, like that of the other Highland counties of Scotland, presents a succession of inlets of the sea, and bold promontories, with a number of rocks and islets. The principal arms of the sea are Lochs Assynt, Laxford, and Inchard, on the west ; Durness Bay, Loch Eriboll, the Kyle of Tongue, and the bays of Torrisdale and Strathy on the north ; and Loch Fleet in the Frith of Dornoch, on the south-east ; and the more remarkable promontories are, Ru Stoir, on the south side of Loch Assynt ; Cape Wrath on the north-west extremity of the county ; Far-out Head, and Whitten Head, on the north ; and Strathy Head on the north-east. The interior consists of mountains, mosses, lakes, and streams, presenting great variety in form, but almost all having the same general character of being barren, rugged, and dismal, more especially on the western side ; and so closely thrown together, that there is no valley of any extent, and seldom a tree or a shrub to relieve the eye. The Assynt mountains have not even heath to cover their naked-

and Bound-  
aries.**

**Surface.**

Sutherland-shire.

ness, except in patches among the rocks near their base. Some exceptions to this general character occur on the eastern coast, along the Dornoch Frith, and on the banks of a few of the lakes and rivulets; but in a general view, these are so inconsiderable, that, according to the writer of the *Agricultural Report*, the cultivated land, green pastures, and woods, do not much exceed 60,000 acres, or about one-thirtieth part of its area; and the cultivated land alone is little more than one acre in a hundred. The climate of the east coast, however, is not so severe as to prevent the growth of wheat, which sometimes ripens as early here as in many parts of England.

Rivers.

The principal streams are, Oickel, Fleet, Brora, and Helmsdale, which fall into the Dornoch Frith on the south-east. The tide renders the Oickel navigable by vessels of 50 tons, for about 12 miles, and for boats for about eight miles farther; and they have all good salmon fisheries. These rivulets have their source among the mountains, in the centre of the district, and flow south-east. In the same quarter a number of streams take their rise, and flow north; such as Strathy, the Naver, which gives its name to the tract called Strathnaver, the Dinart, &c., most of them containing salmon. The most considerable lake is Loch Shin, about 20 miles long, and one broad, situated on the southern side of the county, through which flows a stream of the same name, which falls into the Oickel. There are several others of considerable extent in different parts, the whole occupying about 47 square miles, or upwards of 30,000 acres. On the north coast the sea has formed some remarkable caves in the limestone rock, particularly one at Snow, to the east of Balna-keel of Durness, 32 yards wide, and 20 yards high; and another at Fraisgill, 50 feet high, and 20 feet wide at its entrance, but contracting by degrees till its termination, more than half a mile under ground.

Caves.

Minerals.

Coal, limestone, marble, and sandstone, are found in Sutherland; and it is supposed to contain other minerals, which either have not been explored, or turned to any account. On the rivulet Brora coal is now worked to some extent; and connected with these works, a railway has been recently formed from them to the harbour at its mouth, with salt-works, at which the small coal is consumed. Limestone of a good quality abounds on the coast, and is also found in some parts of the interior. At Leadmore and Lead-beg, in Assynt, excellent marble, some of it white and pure as alabaster, has been wrought by Mr Jopling from Newcastle; and a black kind, streaked with yellow veins, occurs in Edderachylis. Clay fit for bricks, tiles, and the coarser kinds of pottery, is also found on the east coast upon the Sutherland estate.

Valuation and Rental.

This county, which is valued in the cess-books at L. 26,193, 9s. 7d. Scots, is divided among 13 proprietors. Of this valuation the Sutherland estate, belonging to the Marchioness of Stafford, Countess of Sutherland in her own right, is almost two-thirds, and that of Lord Reay nearly a seventh part. The former contains about 890,000 English acres. Skibo, Bighouse, and Strathy, are each above L. 500

Scots, the others under that valuation. In 1812 the gross rental of the lands and houses, as returned under the Property-tax Act, was L. 28,458, 8s. 4d. including about L. 1700 as the rent of the salmon and other fisheries. More than half the valuation is held under entail. The principal seats are Dunrobin Castle, the Marchioness of Stafford, on the coast of the Dornoch Frith, in the parish of Golspie; Skibo, Dempster, on an inlet of the same frith, near the south-eastern corner of the county; and Tongue Castle, Lord Reay, on the Kyle of Tongue, on the north coast. Most of the other proprietors have good modern houses, all of which are situated near the coast. In no part of Britain has a greater change been effected in so short a period as in Sutherland, and this chiefly by the spirit and liberality of its greatest proprietor, the Marquis of Stafford. Within these twelve or fourteen years, roads, bridges, harbours, and villages, have been constructed wherever they seemed to be required; and both the natural and moral obstructions to the improvement of this extensive territory have, as far as it appears practicable, been in a great measure overcome.

Sutherland-shire.

Seats.

In this, and in some other parts of the Highlands, there is still a class of landholders called *wadsetters*, once numerous in the other counties of Scotland. These men, having advanced money to the owner of an estate, obtained from him a temporary right to a certain portion of it as a pledge for their security, corresponding in yearly value to the interest of the money lent, and subject to redemption upon its repayment. The practice of granting securities of this kind has long since fallen into disuse; but several of them still subsist, or subsisted very lately, upon the Sutherland estate, especially upon the south-east coast. Lands of L. 200 Scots valuation, instead of L. 400 Scots, as in other counties, afford a vote in the election of a member for Sutherland, whether held of the Crown, or of the Earls of Sutherland.

The tenantry include nearly all the other inhabitants; and small as is the population of this county, the number of these tenants is out of all proportion to the extent of the productive land. Excepting along the south-east coast, where there is a stripe of arable land, seldom so much as a mile in breadth, there is nothing that deserves the name of an arable farm; and scarcely any where as much and lying contiguous as would form one; the valleys in which the waters flow being very narrow, and the soil often of an inferior description, besides being exposed to inundations from the swelling of the mountain torrents. Yet these valleys or straths, in many instances, are tenanted at the rate of one family for every acre of arable land; the people living in miserable huts, without chimneys or windows, under the same roof with their live stock, which pasture on the higher grounds; and cultivating the ground for oats, bear, and potatoes, with a crooked spade, or *cascrom*, instead of the plough; their cattle perishing for want in hard winters, and themselves sometimes reduced to the necessity of living upon their blood. Such is the system that prevailed till lately over all the Highlands of Scot-

Penantry.

Sutherland-shire. land, and which, though giving way, still prevails over a great part of Sutherland. The change, where it has occurred, has been owing to the introduction of sheep; of which there are now several considerable flocks, chiefly of the Cheviot breed, which, under proper management, are found to answer, notwithstanding the severity of the climate. Much loss, however, was sustained by the earliest adventurers in this line, chiefly, it is alleged, from the hostility of the natives; and eagles and other birds of prey, and foxes, still commit great ravages among the flocks. The number of sheep has been computed to be about 140,000, producing about 18,000 stone of wool, of 24 lbs. *per* stone. Of the rent paid by the small tenants on the south-east coast the exact amount cannot be ascertained; the arable land not being let by the acre, but by the quantity of grain that may be sown; which is at the rate of from 15s. to L. 1, 1s. *per* boll, paid partly in money, and partly in oatmeal and bear; but to this we must add personal services, customs and casualties, exacted by the tacksman or the landlord. In other parts of the county, where the proportion of arable land is still much smaller than on the south-east, the tenants pay in proportion to the number of black cattle they can rear and maintain; these affording the only surplus for the landowners. It is the general practice to make butter and cheese, and to rear a calf for every two cows. The quantity of butter is from 24 to 48 lbs. *avoirdupois*, and of cheese, about twice as much *per* cow. "The leases between the proprietor and principal tacksman," says Captain Henderson, "are generally 19 or 21 years, but the tacksman seldom gives a lease to his subtenants or cottars, and when he does, it is generally for three, five, or seven years. This is done with a view of making them submissive in performing personal services, &c."

Manufac-  
tures. Until the recent establishments of the Marquis of Stafford, which are still in their infancy, there was no manufacture in this county, if we except that of kelp, of which the quantity used to be 250 tons. A cotton mill had been erected at Spinningdale, on a branch of the Dornoch Frith, by a Glasgow company, but the building having been burnt down in 1806, the undertaking was abandoned. A good many boats are employed in the fisheries on the west and north coast for cod, ling, haddock, and herring; and lobsters and muscles are got in considerable quantities. At Helmsdale, on the east coast, many of those small tenants who were removed by the introduction of sheep farming have also embarked in the fisheries with considerable success; and large sums have been expended within these few years by the noble proprietor of the Sutherland estate in erecting the necessary buildings. The principal exports are cattle, horses, sheep, wool, salmon, and cod; their butter and cheese are nearly all consumed at home; and besides the usual imports of cloths, groceries, &c., they require some corn, chiefly oatmeal, especially on the west and north sides of the county, where they have very little corn land. Dornoch, a royal burgh, situated on the south-eastern extremity, on the Frith of that name, is the only town, and contains little

more than 500 inhabitants. Golspie, Helmsdale, and Brora, are the principal villages. With these exceptions, the inhabitants are scattered along the coast, and, in some of the principal straths, passing much of their time in idleness; a healthy, robust, and simple, though not ill informed race, who have contributed largely to the public service. For the last half-century, the Earls of Sutherland have raised among them, at the commencement of every war, a corps of 1000 men, well known by the name of the Sutherland Fencibles; but this spirit, founded in attachment to their chiefs, has now become much weaker than formerly.

The county, in which the number of voters may vary from 20 to 25, sends one member to Parliament; and the town of Dornoch joins with Dingwall, Tain, Wick, and Kirkwall, in electing one for the Scottish burghs.

The population, according to the census of 1801, was 23,117; in 1811 it amounted to 23,629; and in 1821 to 23,840, of which 11,088 were males, and 12,752 were females. The *families* employed in agriculture were 3362; in trade and manufactures 642; in all other occupations 818. The increase of population from 1811 to 1821 was only 211.

There are some remains of antiquity in various parts along the coast. The most interesting are two circular buildings, called Dun Dornadil, or Dornadilla's Tower, and Castle Coll, both reared of large stones, nicely fitted, but without cement, and of which considerable portions are still entire, after the lapse of probably 1000 years. Castle Coll, which is situated on the east side of the county, on a stream that falls into the Brora, has an exterior circumference of 54 yards, with walls four and one-half yards thick at the base, inclining inwards nine inches in every three feet in height; and two small apartments on each side of the door-way, as if intended for guard-rooms. The highest part of the wall is now only eleven feet high, but old people remember it twice that height. Dun Dornadil is in the parish of Durness, on the northern side of the county. It is a building of the same character with the former, but still more dilapidated, and is celebrated in the ancient Gaelic ballads as a place of renown at a very early period. The ruins of Dornoch Cathedral still display the original grandeur of that edifice, which is said to have been built in the eleventh century, and repaired and enlarged in the thirteenth. Circular cairns with subterraneous passages, tumuli, and some small forts, may yet be traced in various situations along the coast.

See the general works quoted under the former Scottish counties; Henderson's *General View of the County of Sutherland*; and Loch's *Account of the Improvements of the Marquis of Stafford in Sutherland*. (A.)

SWEDEN. The recent changes that have been produced in this monarchy consist of the loss of Finland, conveyed by cession to Russia, as a condition of peace, with that of Pomerania, now subject to Prussia; and the acquisition of Norway, as the price of the services of Sweden in the struggle which terminated with the downfall of Buonaparte.

Sweden and Norway.

As the inhabitants of Norway discovered an aversion to becoming subject to the kingdom of Sweden, assurances were given that their ancient usages and privileges should be preserved to them; and that, though united with Sweden under the same monarch, the legislative power, the finances, the national debts, the laws, the army, and other establishments, should be maintained distinct, and almost every purpose of an independent nation be preserved.

Bernadotte, one of the Generals of the French army, had been chosen, by the senate and the king, Charles XIV., as Crown Prince, or successor to the throne; perhaps without any intrigues on his own part, but certainly without any on the part of the French Emperor, chiefly on account of the reputation he had acquired through the north of Europe, by his wise and humane conduct whilst exercising the military power in Hanover. On the demise of Charles, after his co-operation with the allies in the deliverance of Europe, Bernadotte mounted the throne, and seems to have succeeded in uniting Sweden and Norway under his government, and in establishing in his family the succession to the crown.

Divisions.

The Swedish geographers divide the kingdom into three portions, called by them the North, the Middle, and the South Provinces. These are again divided into districts, according to their political and fiscal relations, denominated *Laens* or Stadtholderships; but the ancient distinction of provinces is still kept up among the greater part of the inhabitants.

The places containing more than 3000 inhabitants, and their population, are as follows: Sweden and Norway.

Stockholm, 65,474; Gottenburg, 17,760; Carls-crona, 10,553; Norrkopping, 9,428; Gefleborg, 5,930; Malmoe, 4,932; Upsal, 4,897; Falun, 4,709; Udde-walla, 3,971; Wisby, 3,819; Landskrona, 3,776; Carlsham, 3,387; Orebro, 3,242; Lund, 3,224; Christianstad, 3,106; Calmar, 3,058.

There are 88 places denominated cities, and four called market towns. They are mostly small, except the few above enumerated. The inhabitants of these cities and towns, according to the tables of 1815, were 248,029, making about one-tenth of the whole population; and the other nine-tenths were living in 2214 parishes, containing 65,284 farms. At the same period the classes of the people are thus indicated. Learned, including clergy, professors, students, and servants, employed in the churches, with their wives and children, 25,986; civil officers, 24,652; military of all ranks, 113,465; sailors, 22,178; burgesses, including manufacturers, merchants, tradesmen, handicraftmen, and their several apprentices, 160,922; private persons, including retired officers and tradesmen, owners of estates, funded property, or mortgages, 79,814; peasants, 1,391,606; domestic servants to the nobility and gentry, 43,659; poor, and prisoners, 24,131; orphan, and foundling children, 13,757; and females who are either single or widows, with their children, 555,496. By a table, the data for which were collected in 1810, it appeared that the families were 451,116; that the learned classes formed 1 in 110 of the males; the civil officers, 1 in 140; the military, including the militia, 1 in 27; the tradesmen, 1 in 260; the farmers, 7 in 10; the domestic servants, 1 in 44; the workmen in factories, 1 in 52; the sailors, 1 in 146; the poor, 1 in 60; and the children one-eighth of the whole male population.

Not more than one-twentieth part of the surface of Sweden is capable of cultivation, and of that only one-half is actually cultivated. The harvests are by no means productive, and estimated by Akrel to yield not more than five times the seed that is sown in good years. In a cycle of ten years, the same writer states, that one of them fails, two are scanty, five are moderate, and two are abundant. The deficiency of corn for the support of the inhabitants compels them to mix the rind of the *Pinus silvestris*, and the roots of some bog-plants, with their flour, to eke out their scanty stock of food. The extensive cultivation of potatoes, which has taken place of late years, has been found to afford most valuable aid to the general subsistence. Hemp, flax, and tobacco, are grown for domestic use. Hops are cultivated and exported to Denmark and Germany. The breeding of cattle is a productive branch of industry, though the races of horses, cows, and sheep, are generally small in size. The stock of cattle was as follows, soon after the loss of Finland: horses, 405,030; oxen, cows, and calves, 1,312,594; and sheep and lambs, 1,243,315: goats and pigs are thinly scattered. In the north, the reindeer is a valuable domestic animal: some proprietors have herds of more than 1000, which are fed through the winter on the moss, which instinct teaches them to find under the deep snow. The fisheries yield employment, subsistence, and articles for export; but,

**Sweden and Norway.** of late years, the shoals of herrings have greatly diminished. The chief production of the soil is timber, as two-thirds of the surface is covered with woods. The far greater part of the dwellings are composed wholly of wood; the demand for fuel is very great; and yet the export of planks, masts, pitch, tar, potashes, and charcoal, forms the chief part of the foreign trade. The mines of Sweden have long been worked, and have suffered little increase

**Productions.** or diminution of late years. Their average products have been 64 ounces of gold; 12,900 ounces of silver; 24,800 quintals of copper; 431 quintals of lead; 100,000 tons of iron; 22,000 quintals of alum; 35,000 tons of coal; and 65,000 quintals of saltpetre. The manufactures of Sweden are confined to the few articles required for the scanty supply of its needy population. Cloths, cottons, silks, and linens, and many smaller articles, are furnished from the different fabrics within the kingdom, whose annual amount is calculated to be about L. 280,000 Sterling. The merchant ships, in 1816, were 1107; their burden 64,290 lasts, and their crews 9014 men and boys.

**Government.** The government is a limited monarchy, hereditary in the male line of Bernadotte; but in case of the failure of males in that family, a successor is to be nominated by the King, and approved by the Legislature. The appointed civil list for the King is 320,000 rix dollars banco, or about L. 50,000 Sterling; that of the Crown Prince one-third of that sum. The States are composed of 1100 Nobles, 50 to 80 Clergy, from 100 to 200 Burgesses, and 100 Peasants, who vote by classes, not by the head. They necessarily assemble every fifth year, and more frequently if convened by the King. They make laws, grant taxes, regulate the coinage and the press, and superintend the administration of justice. The laws are contained in a volume of 480 pages, which is looked up to with much veneration from its antiquity, having been adopted as early as the year 1442. All new cases of differences that occur are referred to the principles contained in this fundamental code. There are courts of revision and courts of appeal, whose judgment is final.

**Religion and Education.** The established religion is the Lutheran, but since the year 1799 all other sects have been tolerated. It is modified somewhat in a manner different from what exists in Germany, and approaching in its government more nearly to the English Church. There are twelve Bishops and one Archbishop, that of Upsal. The benefices are endowed with the tithes, and the condition of the clergy is respectable. The University of Upsal is the highest seminary, containing twenty-four professors. The University of Lund has twenty-two professors. In these establishments, the system pursued differs from that of the German universities, both in the length of time required for a degree, and the restrictions upon the conduct and attention of the students. In most of the Episcopal cities there are endowed classical schools. In all the towns there are burgher schools, and in the parish churches in the villages; in which the Lancasterian method of teaching reading and writing has been successfully introduced.

**Army.** The army, at present, is reduced, and consists of 3505 cavalry, 24,144 infantry and artillery, and an

extraordinary division of 3387 men of all arms. The army may be made up in war by the reserve and recruiting to 100,000 men. The navy, which, in 1806, had sunk from 20 sail of the line to 13, since 1799, is now so much further reduced, that there are scarcely six sail fit to be sent to sea, and eight or nine frigates. There are a considerable number of gun-boats and other flotilla, calculated to convey land forces.

**Sweden and Norway.** The expenses of the government are very rigidly watched, and have recently been considerably reduced; at present they stand on the following scale:

Establishment of the Royal Households, L. 210,000	
For the Senators and the Government, .....	180,000
For the Judicial and Police Branches, .....	50,000
For the Military Branch, .....	370,000
For the Marine Branch, .....	180,000
For Extraordinary Expences, including Interest on the Public Debt, .....	150,000
	L. 1,140,000

The public income is nearly commensurate with the expenditure on an average of years. It is derived in a small degree from national domains, from a land and capitation tax, from duties on imports which are let to farm, from stamps, from taxes on liquors, from the monopoly of saltpetre, from the mines, and some smaller sources. The public debt, on 16th April 1819, amounted to 6,371,862 Reichsthalern Banco, or about L. 1,387,500 Sterling; having been reduced L. 250,000 since the year 1813. It is wholly owing to residents in Sweden; and, on the plan of a sinking fund now in progress, will be extinguished in fourteen years. The chief financial evil under which the kingdom suffers, is from the vast quantity of paper money which circulates, and which has driven out the metallic money. Measures are adopted by which this paper is gradually withdrawn by the bank, for accomplishing which, certain extraordinary taxes are appropriated.

See *Erdebeschreibung*, von Gasparai, &c., Weimar, 1822; *Swerige's Civil och Krigskalender for Aret*, Stockholm, 1819; *Utkast til en Svensk statistik, Första Afdelingen*, Stockholm, 1818; Thomson's *Travels in Sweden*, London, 1814.

NORWAY.

**Norway.** When the power over Norway was assumed by the Swedish monarch, its independence of Sweden was secured by resolutions of the States, or the Storting, guaranteed by the King on the 4th November 1814. These fundamental rules decree, 1st, That only citizens of Norway, of the Lutheran religion, shall be nominated to fill any office. 2d, That Norway shall be answerable for its own national debt alone. 3d, That none shall be judged but by the law, and that torture shall not be practised. 4th, That no retrospective law shall be enacted. 5th, That no one shall be arrested, or confined, but in cases specified by the law. 6th, The liberty of the press shall not be infringed. 7th, Landed property shall not become forfeited. 8th, No nobles shall be created. 9th, Each Norwegian, without regard to

rank or wealth, is bound to serve a certain time to be fixed. 10th, Norway shall retain its own bank and coins. 11th, Norwegian merchant ships may carry their own national flag.

Under these stipulations, Norway is a limited hereditary monarchy, in which the executive power is vested in the King, and the Legislature in the States, or Storting. The King exercises his power through a Viceroy, who resides in the royal palace at Christiana. The members of the Legislature are chosen by electors, who are nominated for that purpose by those who have a right to vote. In the cities, the number of electors to be chosen is one to every fifty voters; in the country, one to every hundred votes. These electors choose the deputies for the respective districts; from five to fourteen electors choose one deputy; from fifteen to twenty-four, two deputies; from twenty-five to thirty-four, three deputies; and from thirty-five upwards, four deputies, which is the greatest number that any electoral assembly can nominate. The deputies must be thirty years of age, and have resided the last ten years within the kingdom. Whoever is chosen is bound to serve. They are free from arrest, and are paid for their time and travelling expences. The number of the representatives of the country are as two to one of those from the cities. The whole number is from 75 to 100. The servants of the Crown, the Members of the Council, and Pensioners, are ineligible. The assembly meets every third year on the first working day in February. There are two chambers, or bodies, one called the Lagthing, consisting of one-fourth the members, the other called the Odelsting, comprehending the other three-fourths. All laws must originate in the Odelssting, from its own members, or from the suggestion of the King; but the assent of the other body is required for their enactment. The forms of passing laws are complicated, but they insure great deliberation. The assembly continues its session three months, but the King may prolong it beyond that period, or call it together in the intervals of the regular assemblings. The Senate, appointed by the King, is rather an executive than a legislative body, but must consist of Norwegians.

The expences of the government are nearly equal to the income, both being about L. 300,000 Sterling *per annum*. The revenue arises principally from a territorial impost, and from duties on importation and consumption, which amount to three-fourths of the whole. The national debt is in annuities, amounting to nearly L. 10,000 *per annum*. It would be speedily redeemed but for the great mass of paper money in circulation, which had depreciated it to such an extent, that, in 1817, one silver dollar was worth ten paper dollars. Attempts have been made by the establishment of a national bank to remedy this evil, but its success has been hitherto very slight.

The army consists of 12,000 men, of whom 2000 form the garrisons of the several fortified places.

The militia amount to 7000. The navy of Norway consists of six brigs, eight schooners, and about forty gun-boats, with some smaller flotilla.

The religion is Lutheran, and the ecclesiastical affairs are under the superintendence of five bishops. The provision for the clergy is scanty, and many of the parochial churches are consequently destitute of pastors. The University of Christiana has sixteen professors, and somewhat more than 100 students; and the seminaries of Tönsberg and of Töten assist in providing education for the gentry and clergy. In each of the episcopal cities there are endowed schools.

Norway is divided into four provinces, called Stifts, viz.

Stifts.	Extent in Square Miles.	Population.	Capitals.
Aggerhaus.....	32,789	378,646	Christiana
Christiansand ...	10,304	117,852	Christiansand

SWISSERLAND, or SWITZERLAND. This league of independent states, whose constitutions, both local and general, had been overturned in the course of the French Revolution, and a part of whose territory had been added to France, has been reinstated by the Congress of Vienna in its former independence, and has received additions of territory. This settlement has led to new divisions, and the Swiss Confederacy at present consists of twenty-two cantons, whose names, extent, population, and capitals, are as follow:

Sweden and Norway.

Sweden and Norway  
||  
Swisserland.

			Geneva ..... 22,000
	18,681, or 11,955,840 acres.	1,757,810	

The only other towns whose population exceeds 3000 inhabitants are in the canton of Zurick; Horgen, with 3700; Wädenschwyl, 3460; Stäfa, 3360; and Wald, 3200; in the canton of Vaud, Vevay, with 3780; and in the canton of Geneva, Carouge, with 3200 souls.

Government. Each of the cantons has its own system of government and laws; but they all form a general community, by means of representatives chosen from each of them, who meet to regulate the external relations of the union, and to provide the means, both in troops and money, for the general defence.

The delegates from the different cantons assemble yearly in July, or more frequently, on the requisition of any five of them. Treaties of peace, or declarations of war, require the assent of three-fourths of the votes. All other matters are determined by majority. The place of meeting is in rotation, Zurick, Berne, and Lucerne, each for two years, where the supreme court is held, and the Chancellor and State-Secretary hold their offices.

Forces. Although every man capable of bearing arms is a soldier, and occasionally trained and exercised, yet a more disposable force is arranged, to which each of the cantons must furnish their proportion, at the rate of two men out of every hundred of the appropriate age. These form an army, when required, as follows:

Artillery .....	32 companies	2,272 men.
Sappers .....	2 do.	142
Pontoniers .....	1 do.	71
Carry forward		<u>2,485</u>

Brought forward	2,485
Train .....	1,400
Light Cavalry... 17 troops	1,088
Sharpshooters... 10 companies	1,000
Infantry ..... 204 do.	25,199
Yagars ..... 20 do.	2,000
Staff Corps .....	586
	<u>33,758</u>

The militia, mustered under the direction of each individual canton, amount together to 67,516 men, besides which is the landwehr, or *levy en masse*, which comprehends the whole of the male population. In order that the military spirit of the Swiss may not become dormant, the cantons have permitted great numbers of their young men to enter into the service of foreign states. In the year 1816 the numbers so engaged were estimated to be about 30,000; of whom 12,370 were in France; 10,000 in the Netherlands; 430 in Prussia; and the others in Spain and Sardinia. The expences of the general government are defrayed by contributions from each canton, according to their estimated wealth, which, as well as the military contingent, is adjusted to existing circumstances at the termination of every period of twenty years. The revenues, expences, and debts of the several cantons, are generally kept with much privacy, and the taxes are various, but in general very light.

The cantons of Lucerne, Uri, Schwitz, Unterwalden, Zug, Fryburg, Solothurn, Tessino, and a part of Appenzell, adhere to the Roman Catholic church. The reformed Protestant church is established in

Switzerland

||  
Taxation.

Zurick, Berne, Basle, Schaffhausen, Vaud, Neuchâtel, Geneva, and a part of Appenzell. Both religions are established in Glarus, Thurgaw, Aargau, St Gall, and the Grey League, but in them the majority of the people are Protestants. The number of the Reformed, or Calvinists are estimated to be 1,046,000; of the Catholics 682,000; and in the remainder are comprised a few Lutherans, Anabaptists, and Jews.

Productions  
and Trade.

As Switzerland does not grow sufficient corn for its own subsistence, though its harvests are eked out by the recent extension of the culture of potatoes, that necessary article is supplied to it from the neighbouring states; to which it makes returns in the products of its soil, wine, live cattle, butter, and cheese. Besides these it sells some manufactures, the principal of which are various cotton goods. These are chiefly produced in Zurick, St Gall, Berne, and Appenzell, where extensive machinery is constructed both for spinning and weaving. Some of the goods produced in Switzerland are the most suc-

cessful in rivalling the fabrics of Lancashire and Glasgow at the great fairs of Frankfort and Leipsic. In the cantons of Thurgaw and St Gall there are many manufactories both of fine and coarse linen. Silk goods of various descriptions are made in Basle, in Schaffhausen, and Lucerne, but especially in Tessino, where the raw material is produced; but this description of productions has of late suffered a great declension. Watchmaking gives employment to more than 4000 workmen in Geneva, and to as many in Neuchâtel and other places. The number of watches annually sent from Switzerland is estimated to be about 250,000. These means of subsistence and employment are found insufficient to check the progress of poverty, which is making rapid strides, and which has produced extensive emigrations to the United States of America, to Canada, and to Brazil.

## TAXATION.

Definition.

A TAX is a portion of the produce of the capital and labour of individuals, taken from them by authority of Government, and placed at its disposal.

A tax may be either *direct* or *indirect*. It is said to be *direct* when it is immediately taken from income or capital; and *indirect* when it is taken from them by making their owners pay for liberty to use certain articles, or to exercise certain privileges.

A tax may be either *general* or *particular*—that is, it may be made either to affect all classes indiscriminately, or to affect only one or more classes.

TAXATION is the general term used to express the aggregate of particular taxes. It is also the name given to that branch of the science of Political Economy which explains the mode in which the revenue required for the public service may be most advantageously raised.

### PART I.—GENERAL OBSERVATIONS ON TAXATION.

*Necessity of Taxation—Present System of Taxation originated in the decline of the Feudal System—Taxes estimated by Values, and not by Quantities—Every Improvement in the Arts, a Means of enabling a Country to bear Additional Taxes—Opposite Effects of Moderate and Heavy Taxes—Fallacy of the Doctrine of those who contend that Taxes are not really lost to the Contributors, but that they are again restored to them by the Expenditure of Government or its Agents—Erroneous Opinion of Locke and Quesnay with respect to the ultimate Incidence of all Taxes on the Land—Maxims to be observed in the Imposition of Taxes—Agreement or Disagreement of certain Taxes with these Maxims—Excise Scheme of Sir Robert Walpole—Expence and Mode of collecting Taxes—Corvées.*

We conceive it would be quite superfluous to enter into any lengthened argument to show the utility, or rather necessity, of raising a revenue for the use of the public. It is sufficient to observe, that security from foreign invasion, the speedy and impartial administration of justice, and the maintenance of good order and tranquillity, are absolutely indispensable to the successful exertion of industry, and to the advancement of society in the career of civilization and refinement. And when such is the case—when it is admitted on all hands, that security and good order are productive of *universal* advantage—and that, without them, there could be no considerable accumulation of national wealth—it is plain no individual can justly complain that he is made to contribute, in the same proportion to his means as others, for their attainment; or, which is the same thing, that he is made to pay his fair share of the sum required to procure the services of the soldiers and sailors necessary to repel hostile aggression; and to support the various institutions and public functionaries necessary to maintain the internal peace of the country, to promote its prosperity, and to protect every citizen in the undisturbed enjoyment of his property and rights. It is certainly true, that the public are frequently made to contribute larger sums than are necessary for the ends of good government. But, as this abuse must obviously originate either in the misconduct of administration, or in the defective political organization of the State, it does not properly come within the scope of our inquiries. In treating of taxation, the object of the Political Economist is not to inquire whether the revenue raised by the State exceeds its necessary wants, or whether it has been judiciously ex-

Necessity of  
Taxation.

General Observations on Taxation.

Present System of Taxation rose out of the Decline of the Feudal System.

pendent; but to point out the general effect of taxation on individual and public wealth; and, by analyzing the various methods in which a revenue may be raised, and comparing them together, to show which is most advantageous, or rather which is *least injurious*, to the State.

The scheme of taxation now in force in modern Europe had its origin in the decline of the feudal system. According to the principles of that system, all the lands of a country were held by their actual possessors as fiefs of the Crown, on condition of their performing certain stipulated services; of which the obligation to support the sovereign when he took the field, with a body of retainers, armed and maintained at their own expence, was by far the most important. The tenants in chief of the great fiefs, or those who held directly under the sovereign, were either originally invested with, or subsequently usurped, the prerogative of distributing justice in their respective lordships; and, in those days, the administration of justice, instead of being a source of expence, became, in consequence of the corruption and abuses with which it was infected, a considerable source not of influence only, but also of emolument. The expence of the clergy was either defrayed from the produce of their own estates, or by a tithe levied from the estates of others. And the labour of the peasantry, during a few days before and after harvest, sufficed to put the roads and bridges into that state of repair, which the depressed situation of commerce, and the little intercourse between the different parts of the country, seemed to require. Nor was it even necessary to levy a tax for the support of the monarch and his court. The produce of the Crown estates, or of the royal demesnes which had not been feued to others, but which remained in the immediate possession of the sovereign, were generally sufficient to defray this part of the public expence. When the feudal system was in its vigour, the demesnes of the Crown were, in most countries, very extensive; and the alienations occasioned by the profusion of some princes, and the thoughtlessness of others, were compensated by the forfeitures and escheats that were always taking place.

The vicious and defective nature of this system of policy is too obvious to require to be pointed out; and it had for a long series of years the most destructive influence on the peace and prosperity of Europe. But the progressive, though slow, advance of civilization, ultimately led to its overthrow. Money payments were gradually substituted for personal services; and the institution of standing armies, in France, \* by Charles VII., an institution which was soon after introduced into other countries, entirely broke the power and spirit of the feudal aristocracy; and enabled the different governments to introduce a regular plan of government, and to impose that system of pecuniary contribution now universally established.

The amount of a tax is not to be estimated by the *bulk* or *species* of the produce transferred from individuals to government, but exclusively by its *value*.

A heavy taxation consists in the abstraction of a large value, and a light taxation in the abstraction of a small value. When a fall takes place in the cost of producing any particular commodity, its price necessarily declines in an equal degree; and, supposing the value of money, the medium in which taxes are most commonly estimated, to continue invariable, the producers will be obliged to dispose of a proportionally larger quantity of that commodity whose price has fallen, to obtain the means of paying the same amount of taxes. It is plainly, however, an error to suppose, as is very commonly done, that the burden of taxation is thereby increased. The *value* paid by the producers has remained the same; and it is by *values*, and not by *quantities*, that the weight of taxation is always to be measured. If, owing to an improvement in agriculture, in machinery, or any other cause, we could produce *two* quarters of wheat, or *two* yards of cloth, with the *same* expenditure of capital and labour it now takes to produce *one* quarter or *one* yard, it could not certainly be considered as any hardship to have to give *double* the quantity of those commodities in payment of our taxes.

The want of attention to the principle we have now stated, has led to much erroneous reasoning on the subject of taxation. Even Dr Smith made no sufficient allowance for the effects of improvements, in enabling a country to bear additional taxes. Nothing, however, can be more certain than that the amount of the produce of national industry taken by the Government as revenue, may be regularly increased, in every country in which the arts are progressive, without occasioning any additional burden to the people. Every new invention and discovery, by which the production of commodities can be facilitated, and their value reduced, enables individuals to spare a larger quantity of them for the use of the state. The sacrifice we make in paying taxes really consists in the sacrifice of the labour and expence necessary to procure the money or commodities wherewith to pay them. But every increase in the productive powers of industry, by diminishing the labour and expence required in production, gives us the means of transferring a proportionally greater quantity of commodities to the state, without subjecting ourselves to any additional inconvenience. To pay a given sum of money, or a given value, to Government at this moment, will cost a cotton manufacturer not less, perhaps, than ten or twenty times the *quantity* of cottons that would have been sufficient to make the same payment in 1760: But as this reduction in the value of cottons has been the effect of an equivalent diminution in the expences of their production, the manufacturer is not thereby placed in any respect in a worse situation; nor is he really making

\* It was on this occasion that the *taille* was first imposed in France. Hallam's *History of the Middle Ages*, I. p. 118.

General Observations on Taxation. a greater sacrifice now than he did before. This shows, that Governments have precisely the same interest as their subjects in facilitating production. Every increase of the powers of industry affords the means of putting them in possession of a larger quantity of useful and agreeable products; while every diminution of those powers must either diminish the quantity of produce at their disposal, or force them to lay heavier burdens on their subjects. A rich people is the foundation of a rich treasury. Public wealth is merely a portion of private wealth transferred from individuals to Government; and the greater the wealth of individuals, the greater will be the magnitude of the portion they can conveniently spare for public purposes.

Taxes fall either on Revenue or Capital.

Though taxation be necessary, it ought always to be kept within the narrowest limits possible. All taxes occasion inconvenience and privations. The best are those which are lightest; but there are none so light as not to be productive either of an increase of toil, or of a diminution of enjoyments, or of fortune. All taxes must ultimately fall either on the *revenue* of a country, or on its *capital* or stock. Perhaps there is no one tax whose produce has not been partly derived from the one of these funds, and partly from the other. There can be no doubt, however, that by far the largest proportion of all taxes judiciously imposed, and not carried to too great a height, is paid out of revenue. The desire which every one has to preserve his place in society, stimulates most people to exert themselves to defray their taxes, either by increased industry, or by making a corresponding diminution in their expenditure, without allowing them to encroach on their capitals. But the power to make increased exertions, and to save from expence, though not easily defined, is not illimitable. Every fresh increase of taxation must obviously contribute to its exhaustion: and whenever this has been effected, whenever the burden of taxation is not fully compensated by increased production, or increased saving, it *must* encroach on the means of future production, and the country will begin to retrograde. Taxation, when carried to this extent, is one of the severest scourges to which any people can be subjected. By diminishing capital, or the funds destined to support productive industry, it lessens the *revenue* of the people, the only fund out of which taxes can be permanently paid; and thus lays the sure foundation of national poverty and disgrace, in the destruction of individual fortunes. Like falling bodies, which are precipitated with a constantly and rapidly increasing velocity, a system of taxation acting on capital multiplies pauperism and distress in a geometrical proportion, and destroys alike the desire and the means to reproduce.

It would, however, be an error to suppose, that a tax is necessarily a tax on capital, because it is laid on capital, or a tax on income, because it is laid on income. A moderate tax laid on capital may be, and generally is, defrayed out of a saving of income;

while an oppressive tax laid on income has in most cases to be paid from capital. But of all species of taxes, those are plainly the most injurious which necessarily fall on capital, without giving the contributors an opportunity to defray them from revenue. Every such tax, by diminishing the funds for the maintenance of labour, must in so far diminish the future taxable income of the country. The legacy-duty is, as we shall afterwards show, chiefly censurable on this ground.

Most of the writers on finance, patronized by the Governments of the different European countries, have laboured to show that taxation is never a cause of diminished production; but that, on the contrary, every new tax creates a new ability in the subject to bear it, and that every increase of the public burdens becomes the *cause* of a proportional increase in the industry of the people. The fallacy and absurdity of this opinion has been ably exposed by Mr Hume in his *Essay on Taxes*. It is indeed true, as we have already stated, that the desire to preserve their capitals unimpaired, and to improve their condition, will stimulate most men to endeavour to discharge the burden of a moderate tax, by an increase of labour and exertion, or by a saving in articles of unproductive expenditure, without allowing it to encroach on their capitals, or even to lessen the rate at which they may have been previously increasing them. But although this holds good in the case of moderate taxes, we are not to conclude from thence that it continues to hold good to whatever extent they may be carried! An individual might be able to defray a tax of L. 50, by increased exertion and economy, while it might be utterly impossible for him to defray a tax of twice or three times that amount without sacrificing a portion of his capital. The truth is, that the effect of exorbitant taxes is not to stimulate industry, but to destroy it. No man will ever be really and perseveringly industrious, whose industry does not yield him a visible increase of comforts and enjoyments. If taxation be carried so high as to swallow the whole, or even the greater part, of the produce of industry above what is required to furnish us with more necessaries, it must, by destroying the hope and the means of rising in the world, take away the most powerful motive to industry and frugality, and, instead of producing increased exertion, will produce only *despair*. The stimulus given by excessive taxation to industry has been not unaptly compared to the stimulus given by the lash to the labour of the *slave*—a stimulus which the experience of all ages and nations has proved to be as ineffective as it is inhuman, when compared to that which the expectation of improving his condition, and of enjoying the fruits of his industry without molestation, gives to the productive energies of the moderately taxed citizen of a free state.

It would be easy to illustrate the effects of oppressive taxation in destroying industry, by references to the History of most European nations.\* In

\* For an instructive account of the effect of heavy taxes on the commerce and industry of Holland, see the second volume of the excellent work of M. Luzac, *De la Richesse de la Hollande*.

General Observations on Taxation.

Spain they have been particularly fatal. The decline of that country has been commonly ascribed to the expulsion of the Jews and Moors, and to the emigrations to America. But had the policy of the Spanish Government been otherwise sufficiently liberal—had industry been properly protected, and moderate and equal taxes levied, the losses occasioned by the expulsion of so many of her most industrious citizens would have been gradually repaired, and the emigration to America would have acted only as a stimulus to population. But oppressive taxes have not only prevented Spain from recovering from the wounds inflicted on her by the bigotry of her rulers, but have gone far to extinguish the very spirit of industry. Of the taxes most instrumental in producing this effect, the *alcavala* is justly entitled to the pre-eminence. The *alcavala* is a tax originally of ten, but subsequently of fourteen *per cent.*, charged on all commodities, whether raw or manufactured, as often as they are sold, and rated always according to their selling price. Such a monstrous impost was of itself sufficient to annihilate all industry. The manufactures of Castile and the other provinces subjected to its destroying influence were irretrievably ruined. And Ustariz, Ulloa, and Campomanes, Spanish authors of the highest credit, agree in opinion with Mr Townsend, that it is to their exemption from this odious tax that the comparatively flourishing state of industry in Catalonia and Valencia is entirely to be ascribed.

Besides contending that the effect of taxes is to create a new ability in the people to bear them, the Government financiers have also contended that the value of the taxes is not really lost to the consumers, but that it is again restored to them by the expenditure of Government and its agents! And notwithstanding the gross and almost obvious fallacy which this statement involves, it still forms the substance of the answers most commonly made to those who complain of the injurious effects of heavy taxes. To show its absurdity, let us suppose that a farmer is taxed to the extent of L. 50, and let us endeavour to ascertain whether the expenditure of this sum by the public functionary, or individual to whom it has been paid by the tax-gatherer, affords any compensation to the farmer for its loss. If the receiver of the tax does not lay it out on commodities produced by the farmer, it is obvious it cannot again return to him, and he can derive no advantage whatever from its expenditure. But let us suppose, which is the most favourable hypothesis for the argument we are combating, that the tax receiver comes to the farmer to buy produce from him, and let us trace the successive steps and effect of the whole transaction. First of all, then, the farmer sold as much corn, or other produce, as was worth L. 50; he next paid away these L. 50 to a tax-gatherer; and the person who received the L. 50 from the tax-gatherer now comes to the farmer and offers them back to him, on condition of his receiving an *equivalent* in corn or other produce.

This is the way in which the money drawn from the pockets of the public by taxation always reverts to them; and if it enriches any one, it is obvious it must do so by making him pay *twice* for the same sum of money! It is to no purpose to endeavour to escape from this *reductio ad absurdum*, by telling us that industry is always benefited by every extension of the market, and that the consumption of soldiers and sailors is advantageous, because it increases demand! To benefit industry a market must be a *real*, not a *nominal* one—it must be one in which the demanders have themselves produced the equivalents they offer for commodities. It is plainly absurd to suppose that either individuals or states can ever receive the smallest benefit from the demand of those whom they have been previously obliged to furnish with the means of buying. Such, however, is always the case with the demand of those who live on the produce of taxation; and to keep up useless regiments and overgrown establishments, on pretence of encouraging and stimulating industry by increasing demand, is to the full as inconsequential and irrational, as if a shopkeeper were to attempt to increase his business and get rich, by furnishing his customers with money to buy his goods.

The fallacy of the doctrine against which we have been contending has been forcibly illustrated by Dr Hamilton. "To argue," says he, "that the money raised in taxes being spent among those who pay it, is, therefore, no loss to them, is no less absurd than the defence of a housebreaker, who, being convicted of carrying off a merchant's money, should plead that he did him no injury, for the money would be returned to him in the purchase of the commodities in which he dealt."\*

It is obvious, therefore, that the services rendered by the public functionaries, or by those who receive taxes, form the only compensation given by them to those who pay them. And when neither the number nor the salary of those functionaries is too great, these services are a sufficient return for the sums they receive. But every shilling that is drawn from the people by means of taxes, to be expended in maintaining unnecessary functionaries, or in paying them higher salaries than would suffice to procure the services of others, is absolutely and totally lost to them—as much so as if it were *thrown into the sea or the fire*.

That security, protection, and good government, which it is the object of taxation to procure, are highly valuable, cannot be disputed. But they are like all other values—the smaller the sacrifice for which they can be obtained, so much the better. Every means by which the expences of Government can be diminished and taxation reduced, is an advantage to the public precisely of the same kind that a diminution in the cost of procuring any useful or agreeable commodity is to an individual. There is really no mystery whatever in the manner in which Government is supported and taxation operates.

\* This sophism is equally well exposed in the *Lettres d'un Citoyen sur les Vingtiemes*, &c. (p. 113), published in 1768.

General Observations on Taxation.

Taxes do not revert to the Contributors.

General Observations on Taxation.

Government is not a producer: its expenditure is not defrayed from the produce of its own labour, but from the produce of the labour of its subjects. And hence it is obvious, that the higher the expences of Government become, the deeper must they encroach on the income or capital of its subjects, and conversely. In other words, all countries are impoverished by an increase of taxation, and enriched by its reduction: and M. Say is perfectly correct when he says, that the best system of finance is to spend little; and the best of all taxes, the least. *Le meilleur de tous les plans de finance est de depenser peu, et le meilleur de tous les impôts est le plus petit.*

Erroneous Opinion of Locke and Quesnay with respect to the Incidence of Taxes on the Land.

Various and very discordant opinions have been entertained respecting the ultimate incidence and effect of particular taxes. Mr Locke in England, and M. Quesnay and his followers in France and Italy, contended that all taxes, in whatever manner they might be imposed, fell ultimately on the land. This erroneous opinion proceeded from their supposing the industry employed in the cultivation of the land to be the only really productive species of industry; whereas it is in no respect more productive than the rest. The truth is, that every burden, directly or indirectly, affecting those engaged in the production of any class of commodities, falls ultimately on its consumers. A tax on hats, for example, must raise the price of hats, as a tax upon leather must raise the price of shoes; for, if this were not the case, the profits of the hatter and shoemaker would be reduced below the general level; and as there can be no reason why they should be satisfied with a lower rate of profits than their neighbours, they would begin to withdraw their capital from such losing businesses, and would continue to do so until the diminution of the supply of their particular commodities had raised their prices to their proper height, or to such a height as would yield them the average profits of stock exclusive of the tax. There are natural limits, however, to the extent to which taxes on commodities can be carried; and their effects are widely different according as they are laid on commodities required for the consumption of the labouring class, or on those which are exclusively consumed by the higher classes. But before proceeding to examine the effects of particular taxes, we shall make a few observations on the following maxims laid down by Dr Smith with regard to all taxes, and which are drawn up with singular judgment and comprehension, viz:—

Dr Smith's Maxims.

*First maxim.* "The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities; that is, in proportion to the revenue which they respectively enjoy under the protection of the state. The expence of Government to the individuals of a great nation is like the expence of management to the joint tenants of a great estate. In the observation or neglect of this maxim consists what is called the equality or inequality of taxation."

*Second,* "The tax which each individual is bound to pay ought to be certain, and not arbitrary. The time of payment, the manner of payment, the quan-

tity to be paid, ought all to be clear and plain to the contributor and to every other person. When it is otherwise, every person subject to the tax is put, more or less, in the power of the tax-gatherer, who can either aggravate the tax upon any obnoxious contributor, or extort, by the terror of such aggravation, some present or perquisite to himself. The uncertainty of taxation encourages the insolence and favours the corruption of an order of men who are naturally unpopular, even where they are neither insolent nor corrupt. The certainty of what each individual ought to pay is, in taxation, of so great importance, that a very considerable degree of inequality, it appears, I believe, from the experience of all nations, is not near so great an evil as a very small degree of uncertainty."

General Observations on Taxation.

*Third,* "Every tax ought to be levied at the time and in the manner in which it is most likely to be convenient for the contributor to pay it. A tax upon the rent of land, or of houses, payable at the same term at which rents are usually paid, is levied at the time when it is most likely to be convenient for the contributor to pay, or when he is most likely to have wherewithal to pay. Taxes upon such consumable goods as are articles of luxury are all finally paid by the consumer, and generally in a manner that is very convenient for him. He buys them by little and little, as he has occasion to buy the goods; and as he is at liberty, too, either to buy or not to buy as he pleases, it must be his own fault if he ever suffers any considerable inconveniency from such taxes."

*Fourth,* "Every tax ought to be so contrived as both to take out and to keep out of the pockets of the people as little as possible, over and above what it brings into the public treasury of the state."— (*Wealth of Nations*, III. p. 255.)

A system of taxation may be pronounced to be either good or bad, according as it approaches to or recedes from these maxims. For example, the great defect in the system of taxation in France and Spain under the old *regime*, consisted not so much in its magnitude, or in the oppressive manner in which it was collected, as in its *inequality*. Instead of all the citizens contributing to supply the wants of the state in proportion to their respective abilities, those who had the largest fortunes, and who, consequently, derived the greatest advantage from the security and protection afforded by Government, were entirely relieved from the burden of direct taxation. The nobility and clergy, at the same time that they engrossed every situation of power and emolument to themselves, were, as far as possible, exempted from contributing any thing to the support of Government. And it is now no longer a question that the disgust occasioned by this inequality of taxation, the impatience of the feudal privileges of the nobility, and the desire of equal rights, were the leading causes of those revolutions which have made so much havoc amongst the ancient institutions of the Continent.

French Taxation inconsistent with the First Maxim.

The system of taxation generally established in Eastern countries has the defect of not corresponding with the second maxim laid down by Dr Smith. The amount of the contribution is fluctuating and arbitrary, not fixed and certain. In despotic coun-

Taxation of Eastern Countries inconsistent with the Second Maxim.

General Observations on Taxation.

tries, all the agents of Government are despots in their own peculiar sphere; and although the sum demanded by the Sultan should be defined and ascertained, there are no limits to the extortion and rapacity of his agents. An individual who has paid the tax imposed by the Sultan has no guarantee against being called upon to pay three or four times as much to the Pacha of the province. The security of property is thus completely subverted; and the arbitrary nature of the public burdens is entirely destructive of that spirit of industry which might have supported and extended itself under a far greater weight of equitable and well defined taxes.\*

Warehousing System agrees with the Third Maxim.

The establishment of the *warehousing* system, or the granting of liberty to the merchant, on payment of a moderate rent, to deposit his imported goods in *public warehouses*, under the King's lock and his own, without his being obliged to pay the duties until he finds it convenient to withdraw them, has powerfully contributed to make a large branch of our taxation correspond very closely to the *third maxim* laid down by Dr Smith; or to cause a large class of duties to be levied at the time and in the manner which is most convenient for the contributor to pay them. Previously to the act of the 43d of George III., establishing the warehousing system, the duties on all goods imported, and which amount to a very large proportion of the public revenue, had either to be paid at the moment of their importation, or a *bond*, with sufficient security for their future payment, had to be given to the revenue officers. The hardship and inconvenience of such a system is obvious. Sureties were very difficult to be obtained, and the merchant, in order to raise funds to pay the duties, was frequently reduced to the ruinous necessity of selling his goods immediately on their arrival, at a time when perhaps the market was already glutted. Neither was this the only injury entailed on the country by this system; for the duties having to be paid *all at once*, and not by degrees, as the goods were sold for consumption, their price was raised by the amount of the profit on the capital advanced in payment of the duties; competition, too, was diminished in consequence of the greater command of funds required to carry on trade under such disadvantages; and a few rich individuals were thus, in a great measure, enabled to monopolize the business of importing those commodities on which heavy duties were payable. The system had, besides, an obvious tendency to discourage the carrying trade of the country, and to endanger the security of the revenue. For the necessity of paying import duties even on those commodities which were destined for re-exportation, deprived us of all chance of ever becoming considerable as an *entrepot*; by preventing the importation of almost all foreign commodities, except those colonial products of which we had a monopoly, that were not likely to be speedily required for home consumption; at the same time that the difficulties attending the granting of a really equivalent draw-

back to the exporters of such as had paid the duty, opened a door for the commission of every species of fraud.

General Observations on Taxation.

Sir Robert Walpole appears to have had a very clear conception of the injurious consequences of this system; and it was the object of the famous *Excise Scheme*, proposed by him in 1733, to allow the importers of tobacco and wine to deposit them in public warehouses, and to relieve them from the necessity of paying the duties chargeable on such commodities until they chose to withdraw them for home consumption. The celebrity of this scheme, and the misconceptions that have been so very generally entertained respecting it, incline us to think that we shall only be gratifying our readers by quoting the following passages from the speech made by Sir Robert on submitting his plan to the consideration of the House of Commons.

"The duties now payable upon tobacco, on importation," said Sir Robert, "amount to 6d. and one-third part of a penny *per pound weight*; all which must be paid down in ready money upon importation, with the allowance of ten *per cent.* upon prompt payment; or otherwise there must be bonds given, with sufficient sureties, for the payment thereof; which is often a great loss to the public, and is always a great inconvenience to the merchant importer. Whereas, by what I am to propose, the whole duties to be paid for the future will amount to no more than 4d. and three farthings *per pound weight*; and *this duty not to be paid till the tobacco comes to be sold for home consumption. So that, if the merchant exports his tobacco, he will be quite free from all payment of duty, or giving bond therefor, or finding out proper sureties for joining in such bond: he will have nothing to do but unload his tobacco on board a ship for exportation, without being at the trouble to attend for having his bonds cancelled, or for taking out debentures for the drawbacks; all which, I conceive, must be a great ease to the fair trader; and to every such trader, the preventing of frauds must be a great advantage, because it will put all the tobacco traders in Britain upon the same footing; which is but just and equal, and what ought certainly to be accomplished, if it be possible.*

"Now, in order to make this ease effectual to the fair trader, and to contribute to his advantage by preventing as much as possible any frauds in time to come, I propose, as I have said, to join the laws of excise to those of the customs, and to leave the one penny, or rather three farthings, *per pound*, called the further subsidy, to be still charged at the custom-house upon the importation of any tobacco; which three farthings shall be payable to his Majesty's civil list as heretofore. And I propose, that all tobacco, for the future, after being weighed at the custom-house, and charged with the said three farthings *per pound*, shall be lodged in a warehouse or warehouses, to be appointed by the commissioners of the excise for that purpose, of which

\* For an excellent account of the effects of the arbitrary nature of Eastern taxation, see Volney, *Voyage en Syrie*, Tom. II. cap. 33, and cap. 37.

General Observations on Taxation.

warehouse the merchant importer shall have one lock and key, and the warehouse-keeper to be appointed by the said commissioners shall have another, in order that the tobacco may lie safe in that warehouse till the merchant finds a market for it, either for exportation or home-consumption. And if his market be for exportation, he may apply to his warehouse-keeper, and take out as much for that purpose as he has occasion for, which, when weighed at the custom-house, shall be discharged of the three farthings *per* pound with which it was charged upon importation; so that the merchant may then export it without any farther trouble. But if his market be for home-consumption, that he shall then pay the three farthings charged upon it at the custom-house upon importation; and that then, upon calling his warehouse-keeper, he may deliver it to the buyer, on paying an inland duty of 4d. *per* pound weight to the proper officer appointed to receive the same."

Sir Robert concluded his speech by saying, "I look upon this as a most innocent scheme; it can be hurtful to none but smugglers and unfair traders. I am certain it will be of great benefit to the revenue, and will tend to make LONDON A FREE PORT, AND, BY CONSEQUENCE, THE MARKET OF THE WORLD. If I had thought otherwise of it, I should never have ventured to propose it in this place."\*

Nothing can be more clear and explicit than this statement; and no doubt can now remain in the mind of any one, that the adoption of the scheme would have been of the greatest advantage to the commerce and revenue of the country. But such and so powerful was the delusion generated in the public mind with respect to it, that its proposal had well nigh caused a rebellion. Most of the merchants of the day had availed themselves of the facilities which the existing system afforded of defrauding the revenue; and they dexterously endeavoured to thwart the success of a scheme which would have given a serious check to such practices, by making the public believe that it would be fatal to the commercial prosperity of the country. The efforts of the merchants were powerfully assisted by the spirit of party, which then ran very high. The political opponents of the ministry, anxious for an opportunity to prejudice them in the public estimation, contended that the scheme was only the first step towards the introduction of such an universal system of excise, as would inevitably prove alike subversive of the comfort and liberty of the subject! In consequence of these artful misrepresentations, the most violent clamours were everywhere excited against the scheme. On one occasion the minister narrowly escaped falling a sacrifice to the ungovernable fury of the mob, which beset all the avenues to the House of Commons: and after many violent and lengthened debates, the scheme was ultimately abandoned.

The disadvantages of the old plan, and the benefits to be derived from the establishment of the warehousing system, were very clearly and forcibly stated by Dean Tucker in his *Essay on the Comparative Advantages and Disadvantages of Great Britain and France with respect to Trade*; published in 1750. But so powerful was the impression made by the violent opposition to Sir Robert Walpole's scheme, and such is the force of habit and ignorant prejudice, that it was not until 1803 that this obvious and signal improvement—the greatest, perhaps, that has been made in the financial and commercial system of the country—was adopted.

The comparative facility and cheapness with which taxes can be collected, ought to be particularly attended to in their imposition. Every tax should, as Dr Smith has stated in his fourth maxim, be contrived so as to take out, and keep out, of the pockets of the people as little as possible above what it puts into the public treasury. The principle of this maxim is obvious—it is the nett produce of taxation, or the sum which it yields after the expences of collection are deducted, that is alone applicable to national purposes; and to impose taxes which it costs a great deal to collect, is to impose a heavy burden on the people for the sake of a small advantage to Government. It is stated by Sully, in his *Memoirs*, as an unquestionable fact, that the expence of collecting a nett revenue of thirty millions of livres in France in 1598, cost the enormous sum of 120 millions; or, in other words, that of a sum of 150 millions taken from the people by means of taxation, only thirty millions found their way into the coffers of the treasury! Under the administration of M. Necker, a revenue of about 557 millions of livres was collected at an expence of 58 millions; being about 10½ *per cent*.

The expence of collecting the public revenue of Great Britain, for the year ended the 5th January 1822, amounted to L. 6, 6s. 7d. *per cent*. on the nett produce; while in Ireland its expence for the same year amounted to L. 22, 2s. 9d. *per cent*. or to more than three times as much as in England. A good deal of this difference of expence must be ascribed to the different situation of the two countries; but a good deal is also owing to the more defective system of taxation established in Ireland, and to the greater corruption of the officers. The difference in the cost of collecting the Post-office revenue of the two countries is the most extraordinary. In Britain the nett produce for the year ended 5th January 1822 was collected at an expence of L. 38, 18s. 10d. *per cent*.; while in Ireland it cost L. 148, 4s. 10d. *per cent*.! The adoption of the plans and suggestions of the commissioners appointed to inquire into the state of Irish revenue, will undoubtedly be productive of a great saving in the expence of its collection.

Taxes may be collected by officers employed by

\* Tindal's *Continuation of Rapin*, VIII. p. 154. ed. 1769; Cox's *Sir R. Walpole*, I. p. 372, 4to ed. Had the resolutions with respect to tobacco been carried, those regarding wine, which were to have been exactly similar, would have been proposed.

General Observations on Taxation.

Mode of Collecting Taxes.

Government to receive them directly from the contributors; or Government may let them *in farm* to individuals for a rent certain, giving to such individuals or their servants the power of collecting them. The question, Which of these modes of collection should be adopted? depends on a variety of circumstances, and does not admit of any general solution. Where a tax is very well defined, and its collection may be effected without requiring any very minute inspection of the private concerns of individuals, it may be almost uniformly farmed with advantage. In such a case the proceedings of the farmers could not excite the prejudices of the contributors; and the greater skill and economy with which all businesses carried on by individuals on their own account are conducted, would enable the farmers to pay, exclusive of the profits made by them, a larger sum to Government on account of the tax, than it would have any chance of receiving from its own agents. But if a tax were not very well defined, or if it required a close examination of the affairs of individuals to assess it fairly, there cannot, we think, be a doubt that it ought to be directly collected by the servants of Government. It is indeed extremely probable that such a tax would be more productive were it farmed; but this, though an important one, is not the only consideration to be attended to. All taxes which occasion any investigation into the private concerns of individuals are necessarily unpopular; and it is obvious that this unpopularity must be immeasurably greater when these investigations are conducted by those who have a direct personal interest in prosecuting them with the greatest strictness, than when they are conducted by the agents of Government—by persons who, in most cases, derive none, and in all cases only a very slender benefit from the increased productiveness of the tax. The mass of the people would most assuredly ascribe much of the hardship of such taxes to the vigilance and keenness of the farmers; and would be disposed to believe that a considerable portion of their produce went into their pockets, and that they were not only assessed to defray the charges of the State, but to add to the fortunes of a class of persons who are universally objects of popular indignation. We admit that these suspicions and complaints are in most cases totally destitute of foundation. The farmers can only enforce payment of a tax according to the provisions in the law imposing it; and if its pressure is either unequal or severe, or the mode of its collection vexatious and troublesome, it is plain the fault lies with those who imposed it, and not with the farmers. But however groundless the public prejudice against the farmers of the revenue may be supposed to be, it is one which will always exist, and ought to be respected. Perhaps we overrate its influence; but really we have very little doubt that, had an income-tax of 5 or 6 *per cent.*, let in farm, been established in the place of the late income-tax of 10 *per cent.*, it would have been generally considered as the most oppressive and vexatious of the two! Although, therefore, we cannot concur with Dr Smith, in his opinion, that *all* taxes ought to be collected by the officers of Government (III. p. 386), neither can we concur

with Mr Bentham, who has endeavoured to prove that *farming* is in every case the preferable mode of collection. (*Theorie des Peines et des Recompenses*, Tome II. p. 203.) We certainly think that all taxes laid on such articles as stamped paper, houses, windows, horses, carriages, &c., and perhaps also the duties on exportation and importation, might be very advantageously collected by letting them to farmers; but any attempt to farm taxes on income, or taxes which require an examination of and interference with private affairs, would excite the most violent clamour and irritation, and could not be otherwise than pernicious.

The *corvée* system, or the compelling of individuals to execute public works by requisitions of labour, is one of the worst species of taxation. Those who get no pay for their labour, and who are made to work against their will, waste their time and industry: and there is, besides, a very great loss incurred by the interruption of the regular pursuits of the labourers. When Turgot entered on his administration, he sent a circular letter to the Road-surveyors and Engineers of the different provinces of France, ordering them to transmit estimates, framed on the most liberal scale, of the sums of money for which the usual repairs might be made on the old roads, and the ordinary number of new ones constructed. The aggregate of the different estimates showed that a money contribution of about *ten* millions of livres a-year would suffice for the repair and construction of all the roads in the kingdom; whereas Turgot showed, that the execution of these repairs and constructions by contributions of forced labour, or *corvées*, cost not less than *forty* millions, or four times as much as the other! (Say, *Traité d'Economie Politique*, II. p. 345.) The method of repairing roads, by contributions of labour instead of money, was at one time general throughout Europe, and is still acted on in many countries. In Scotland the agricultural population of the country were compelled, by an act passed in 1669, to work *six* days each year at the public roads. This contribution was denominated statute-labour, and was commuted, in the early part of the reign of his late Majesty, for a tax on land, rated according to its valuation in the cess-books. This commutation has been productive of the greatest advantage. Previously to its taking place, our roads were, perhaps, the very worst, and they have since become among the very best in Europe.

#### PART II.—DIRECT TAXES.

It is impossible, for the reasons we have stated in the previous section, to regard such taxes as really fall on capital as a permanent source of public income. Capital consists of that portion of the produce of industry which has been saved from immediate consumption, and which is applied partly to maintain those who are engaged in the great work of production, and partly to facilitate their labours. It is by its amount that the amount of the productive industry of every country must always be regulated. And such being the case, it is plain that whatever has a tendency to diminish capital, or to convert it into revenue, must, by diminishing the means of em-

General Observations on Taxation.

Corvées.

Direct Taxes.

Taxes on  
Rent.

ploying and facilitating labour, and consequently the annual produce of the country, be a most fruitful source of pauperism and misery. This, however, would be the precise effect of taxes on capital; and it is for this reason that they ought always to be regarded in the light of an extraordinary resource, and ought never to be imposed except in cases of very urgent necessity. The misapplication and destruction of the means of production which they infallibly occasion, would not only defeat every attempt to render them permanent, but would, by impoverishing and exhausting the country, render all other taxes comparatively unproductive.

It is not from capital, therefore, but from revenue, that all permanent taxes ought to be derived. And the revenue of every individual in every country, who does not subsist on the produce of taxation, being derived either from rent, profit, or wages, it is plain that all taxes which do not fall on capital must, howsoever imposed, ultimately fall on one or other of these three sources. Without further preface, therefore, we shall now proceed to trace the ultimate incidence and effect of such taxes as are laid *directly* on rent, profit, and wages; and when we have ascertained the way in which they operate, it will be comparatively easy to investigate the effect of those direct taxes which are meant to fall equally on all the various sources of income.

#### SECT. I.—*Taxes on Rent.*

Taxes on  
Rent.

1. *Taxes on the Rent of Land.*—A tax on the rent of land, properly so called, or on the sum paid by a tenant to a landlord for the use of the *natural and inherent powers of the soil*, would fall wholly on the landlord. Rent is entirely a consequence of the decreasing productiveness of the capital and industry successively applied to the land. If capital could have been always applied to the best soils with *equal* advantage, it is plain no one would ever have thought of resorting to those of an inferior degree of fertility, and no such thing as rent would ever have been heard of. But this is not the case. The best lands in every improving country are speedily exhausted; and it is always found to be more advantageous to lay out capital on the inferior soils, which require a greater expenditure to make them yield the same supplies, than to continue forcing the best lands. Suppose, to illustrate the effect of this constantly operating principle, that a series of soils of various degrees of fertility are in cultivation, and that they respectively yield, in return for the same expenditure of capital, 100, 90, 80, 70, 60, &c. quarters, it is plain, as there cannot be two prices of the same article, at the same time and in the same market; that, when two or more of these soils are cultivated, their produce must all sell for the *same price*; and it is farther plain, that this price must be such as will sufficiently remunerate the cultivators of the worst soil, for otherwise they would not continue to employ their capital in its cultivation. But

Taxes on  
Rent.

the price which will remunerate the cultivators of the worst land, will more than remunerate the cultivators of the more fertile lands, precisely in proportion to the greater quantity of produce obtained from them. Now, as there cannot be *two rates of profit* in the same country, any more than two prices, *this excess of produce necessarily constitutes rent*. Thus, when *five* qualities of land are cultivated, the rent of the *first* quality would be 40 quarters; for such is the difference between its produce (100), and the produce (60) of the *fifth* and last quality of land cultivated. In like manner, the rent of the *second* quality would be 30 quarters, or 90—60; the rent of the *third* 20 quarters, or 80—60; and the rent of the *fourth* 10 quarters, or 70—60. But it is obvious no rent would be paid by the cultivators of the soil of the *fifth* quality, and which was last taken into cultivation; nor is it really possible to conceive a case in which rent could enter, for any considerable period, into the cost of that portion of the produce of a country which is raised by the agency of the capital last applied to the soil, whether it be laid out on new land or in the improvement of the old. For, if it did, it would be a proof that agriculture was the best of all businesses, and, in consequence, capital would be immediately attracted to the land, and would most certainly continue flowing in that direction until the produce raised by the portions last employed in cultivation would only yield the common and ordinary rate of profit. It may, therefore, be laid down as a general principle, and one from which there are really no exceptions; that, wherever industry is free, *raw produce is always sold at its necessary price*—that is, at the price which is just sufficient to yield the common and average rate of profit, and no more, to the producers of that portion of the necessary or required supply which is raised in the most unfavourable circumstances, or by means of the capital last laid out on the soil.\*

It results, from this principle, that a tax on rent would have to be entirely defrayed by the landlords. Such a tax would neither raise the price of raw produce, nor operate as a discouragement to cultivation; for, as we have just seen, that that portion of raw produce which regulates the price of all the rest pays no rent, it is impossible it could be affected by its imposition. In fact, all sorts of farm produce would continue at precisely the same price after the tax had been laid on as before, and there would be just the same motives to extend cultivation. In so far, therefore, as the income of the landlords really consists of rent, it might be entirely taken from them by means of direct taxes, without its being possible for them to elude their pressure, and without their occasioning any injury to the other classes of the community. This arises from the circumstance of the landlords not being producers, but only receivers of income. Rent is altogether extrinsic to the cost of production. It really consists of the excess, or of the value of the excess, of the produce

A Tax on Rent, properly so called, would not raise Prices, and would fall entirely on the Landlords.

\* For a further account of the origin and nature of rent, see the Article POLITICAL ECONOMY, Part III. Sect. 3, in this Supplement.

Taxes on  
Rent.

obtained from the best soils, or by the agency of the capital first laid out on the land, over that which is obtained from the worst soils under tillage, or by the agency of the capital last laid out on the land. That the consumers must pay the value of this excess to some one or other is certain; for such payment is one of the absolutely indispensable conditions to their obtaining the necessary supplies of raw produce, and must be made the moment that the increase of population has compelled recourse to be had to inferior soils. But it is plainly of no consequence whatever to them whether they have to pay it to the proprietors of the land, or to a tax-gatherer.

A Tax on that portion of the gross Rent of a Farm which consists of Interest of Capital, would raise Prices, and fall on the Consumer.

It must be observed, however, that a tax on rent, in the common acceptation of the word, would not have quite the same effect that we have now stated, and would not wholly fall on the landlord. By rent is commonly meant the whole sum paid by a tenant to a landlord, as well for the use of the buildings, fences, &c. on a farm, as for the use of the natural and inherent powers of the soil. But the sum paid by a tenant for buildings and improvements is not really rent, but interest on the capital expended on them. To whatever extent, therefore, the gross or nominal rent of a farm is made up of interest on capital, to the same extent would a tax on it operate to raise the price of its produce. Suppose, for example, that the gross rent of a farm is L.500, and that L.250 are interest of capital laid out on its improvement. If a tax of 10 per cent. were laid on rent, only L.25 would have to be permanently paid by the landlord. The other L.25 might be paid by him for a short period; but, as it would form a deduction from profits, capital would, in consequence, be withdrawn from the soil until the diminished supply of produce had raised prices to their proper level—that is, to such a level as would yield the common and ordinary rate of profit on the capital still employed in cultivation. This part of a tax on gross rent would not, therefore, fall on the landlord, or the farmer, but on the consumer of raw produce.

Effects that would follow from Government reserving to itself the Property of Land.

The circumstance of rent unavoidably arising in the progress of society, inclines us to think that it would be good policy for the governments of countries such as the United States, who are possessed of large tracts of fertile and unappropriated land, to retain the property of this land in their own hands, and to let it by public auction, in such portions, and for such a number of years, as might be deemed advisable. Such a system might perhaps discourage some of those expensive and ostentatious undertakings entered into by individuals who have the absolute property of the lands which they occupy; but there are no grounds whatever for thinking that it would contribute in the smallest degree to prevent any of those improvements which are really conducive to the raising of raw produce. The leases might be made of such a length as to encourage every necessary outlay of capital; and the tenants who had the State for their landlord would certainly run a less risk than those who occupy the estates of individuals of being disturbed in their possession, or of being harassed by vexatious prosecutions. But

if no real disadvantage would arise from the adoption of this system, it would be productive of many very great advantages. According as population increased, and as the expenses of Government were necessarily augmented, an increasing revenue would be provided to meet them—a revenue, too, it must be recollected—raised without hardship to any individual whatever—and which, even though the Government should not take it, would notwithstanding exist, and have to be paid by the consumers of raw produce. “Under such a system the owners of capital would enjoy its profits; the class of labourers would enjoy their wages, without any deduction whatsoever; and every man would employ his capital in the way which was really most advantageous, without receiving any inducement, by the mischievous operation of a tax, to remove it from a channel in which it was more, to one in which it would be less productive to the nation.”—(Mill's *Elements of Political Economy*, p. 199.)

But after land has been appropriated and converted into private property, it would certainly be unjust to lay the burden of supporting the State exclusively on the landlords. Mr Mill is, however, of opinion, that this exemption from exclusive taxation ought only to extend to the present rent, and that the State has a just right to enact that all future increase of rent shall be applied to its use. We cannot assent to this proposition. When an absolute right of property has once been established in land, the owners seem to us to be fairly entitled not only to all the advantages now derivable from it, but to all those of which it may hereafter be made productive. Mr Mill contends, that inasmuch as Government may, by their own act, and without any effort on the part of the landlords, raise rent, there can be no good reason why they should not appropriate to themselves all the excess they have created. But if we establish this principle in one instance, it is difficult to see why it should not be established in others. It is possible for the Government, by repealing the corn laws, and admitting the free importation of raw produce, to raise the profits of stock. But no one would, therefore, contend, that Government would be justified in laying a tax on profits equivalent to the rise that had thus been occasioned; and if not, why should they be justified in laying an exclusive tax on rent when it rises in consequence of any measure of theirs? All classes should be made to contribute, in the same proportion to their means, to the support of the State. But it would certainly be a departure from this just principle to tax those who have acquired a property in land to a greater extent than others, or to give to the State all the advantages they would otherwise have derived from the growing prosperity and improvement of the country.

The greater part of the revenues of the principal monarchies of Asia seems, in all ages, to have been derived from the soil. “The land has been held by the immediate cultivators, generally in small portions, with a perpetual and transferable title; but under an obligation of paying, annually, the government demand, which might be increased at the pleasure of the sovereign, and seldom amounted to less

Taxes on  
Rent.  
Land-Taxes  
in England.

than a full rent." (Mill's *Elements of Political Economy*, p. 199.) \*

The scutages on knights' fees, the assessment of hydragage on other lands, and the subsidies chargeable on the proprietors of estates, so often referred to in the history of England, were, to all intents and purposes, land-taxes. (Blackstone, I. p. 312.) But the existing land-tax has supplanted all those more ancient assessments. This tax was first imposed in 1693; a new valuation of all the lands in the kingdom having been made in the previous year. According to this valuation, it was found that a tax of 1s. on the pound of the ascertained rental, afforded an annual clear revenue of L.500,000. No change has ever been made in the valuation of 1692. The tax, which was at first an annual one, has been generally as high as 4s. a pound of the valued rent: In 1798, it was made perpetual at that rate, leave being, at the same time, given to the proprietors to redeem it.

The land-tax was very unequal at its first imposition. For such proprietors as were friendly to the Revolutionary establishment, generally returned their estates at a much higher value than the proprietors who were attached to the Stuarts. The different degrees of improvement that have since taken place in the various districts of the country, have, in some instances, tended to correct the inequalities in the original imposition of the land-tax, and, in others, to increase them.

Taxes on  
the Rent of  
Houses.

2. *Taxes on the Rent of Houses.*—The principal part of the rent of houses generally consists of the profits of the capital laid out in their construction, or, as it is more commonly termed, of *building* rent, a comparatively small part only being *ground* rent, or rent payable for the soil on which they are erected. It is evident, therefore, from the principles already established, that, if the supply of houses could be as easily diminished and increased as the supply of raw produce, a tax on their rents would fall entirely on the occupiers and ground landlords, in the proportion that the profits of the capital laid out on them bore to the rent of the land on which they stood. But as the supply of houses is not susceptible of speedy diminution, the builders would have no means of immediately raising rents when a tax was laid on them; and, unless the capital of the country, and, consequently, the population and demand for houses, were rapidly increasing, a considerable number of years would necessarily elapse before they would be able to relieve themselves of the tax. Houses, however, though slowly, are yet certainly perishable; and, as no more of them would be built after they had been taxed, until the increasing demand had raised their rents so as to indemnify the builders for the tax, and to elevate their profits to the common level, there can be no question that, in the end, the tax

would be thrown wholly on the occupiers and ground landlords in the proportions already mentioned.

Taxes on  
Profits.

#### SECT. II.—*Taxes on Profits.*

A tax proportioned to the nett profits derived from the capital employed in every branch of industry would fall wholly on profits.

Such a tax would affect all capitalists to precisely the same extent. When 5 or 10 *per cent.* was laid on the profits of the farmer or manufacturer, an equal 5 or 10 *per cent.* would be laid on the profits of the merchant, the ship-owner, and of all the other employers of capital. It is evident no individual could hope to evade the burden of such a tax by changing his business; and it could not, therefore, occasion any transference of capital from one employment to another. Neither would it occasion any variation in the supply and demand of commodities, nor in their money price. For, as the tax does not fall on capital, but on profits, the means of producing would not be impaired by its imposition; the means of purchasing possessed by those who live on profits, previously to the imposition of the tax, would indeed be diminished; but, as the means of purchasing, possessed by the Government and its agents who receive the tax, would be proportionally augmented, the aggregate demand of the society would continue the same—and hence, as the tax could neither lessen the quantity of capital in the country, nor the power to purchase its produce, it is obvious it could not, supposing the value of money to continue invariable, occasion any variation in the money prices of commodities.

The immediate effect of an equal and universal tax on profits would, therefore, be to sink them in the same proportion. And as the *power* to accumulate capital, and consequently to feed and employ an additional number of people, must ever be in *direct proportion to the rate of profit*, it follows that the tendency, and, when they are carried to such a height as to prevent them being balanced by increased exertion and economy, the ultimate and necessary effect of all such taxes is, to check the accumulation of capital and the progress of population.

A tax laid only on the profits of the capital employed in a particular business would have a different effect: it would *raise* prices, and would not, therefore, fall on the capitalists, except in so far as they were themselves consumers of their own produce. Suppose, for example, that a tax of 10 *per cent.* is laid exclusively on the profits of the shoemaker. The slightest consideration will show that such a tax must make an equivalent addition to the price of shoes; for, if it did not, the shoemakers would gain less profit than was gained by those engaged in other businesses, and they would, in consequence, have an immediate inducement to withdraw

\* For a full and excellent account of the taxation of Eastern countries, see the same author's *History of India*, Vol. I. chap. Taxes. Some curious and valuable details, with respect to the land-taxes of the ancient Egyptians, may be found in the first volume, liv. i. § 4, of the admirable work of the President De Goguet, *Sur l'Origine des Loix*, &c.

Taxes on Profits.

from their employment; nor can there be a question that they would continue so to withdraw, until, by diminishing the supply of shoes, their price had reached such a height as would yield the common and average rate of profits, exclusive of the tax. For the same reason, an exclusive tax on the profits of the hatter, the clothier, the farmer, &c. would make a proportional addition to the price of hats, cloth, and agricultural produce, &c. In these cases the capitalists have the power to raise prices, and consequently to throw the burden of the tax on the consumers; because they have the power to withdraw from those businesses in which profits are taxed, and to employ their capital in those which are not taxed. But, when the profits arising from the capital employed in every different business are equally taxed, the capitalists are deprived of this resource; and have no means either of raising prices or of evading the tax.

An equal and general Tax on Profits would not affect Rent.

It is easy to see, from the principles we have already established, that a general and equal tax on the profits of agricultural and other capital could not occasion any diminution of rent. When the farmers are taxed equally with all other producers, there will obviously be no motive to induce them to withdraw capital from the land, and no variation will take place in the price of corn; nor, as rent consists in the excess of the produce obtained by the capital first applied to the land over that which is obtained by the capital last applied, will it be affected by such a tax. But if the tax, instead of being a general and equal one, were laid exclusively on the profits of the farmer, it would really cause an immediate increase of rent. No rent, as we have shown in the preceding section, ever enters into the cost of producing that portion of the required supply of raw produce raised by the agency of the capital last laid out on the land. It is plainly impossible, therefore, that its raisers could indemnify themselves for any burdens laid on them by making an equivalent deduction from rent. And hence, when a tax is laid exclusively on the profits of agricultural capital, the price of raw produce must sustain a corresponding rise; for in the event of its not rising, the producers of that portion which pays no rent would abandon their business, and the necessary supplies would not be obtained. Inasmuch, however, as the rise of price which is required to remunerate those who raise corn that pays no rent, after a tax is imposed on profits, must be universal, it must raise rent. Thus, on our former supposition, that five equal capitals applied to soils of various degrees of fertility, respectively yield 100, 90, 80, 70, and 60 quarters, their corn rents would be 40, 30, 20, and 10 quarters; and if the price required to remunerate the cultivators of the fifth and worst quality of land which pays no rent were L. 4 a quarter, the money rent of the first quality would be L. 160, of the second L. 120, of the third L. 80, and so on. Suppose, now, that an exclusive tax is laid on the profits of agricultural capital, and that, to remunerate the cultivators of the worst land, the price rises from L. 4 to L. 4, 10s. a quarter, it is plain the rent of the first quality would be immediately raised to L. 180, the second to L. 135, the third to L. 90, and so on; being an increase of L. 20 on the rent of

A Tax on the Profits of the Farmer only would raise Rent.

the first, of L. 15 on the rent of the second, of L. 10 on the third, &c.

Taxes on Profits.

This is a principle of the highest importance. It shows the unfounded nature of the complaints made by the landlords of the injuries they suffer from the operation of taxes on agricultural industry: It shows that such taxes as fall equally on agriculture and on other businesses neither affect rents nor prices, and cannot, therefore, be injurious to the landlords: And it further shows that such taxes as fall exclusively on agricultural profits must, by raising the relative value of corn, raise rents, and materially improve their condition! "That the profits of the farmer," says Mr Ricardo, who was the first to discover and establish this important principle, "only should be taxed, and not the profits of any other capitalist, would be highly beneficial to the landlords." It would, in fact, be a tax on the consumers of raw produce, partly for the benefit of the state, and partly for the benefit of the landlords." (*Principles of Political Economy*, 3d edit. p. 241.)

In estimating the profits of the farmers under the late income-tax act, it was assumed that in England they amounted, in all cases, to three-fourths, and in Scotland to a half of the rent; and power was given to the commissioners to make a new valuation of the farm at the end of every seven years during the currency of the lease, and if they found it was then worth a higher rent than was paid by the tenant, his income-tax was proportionally augmented. Many complaints were made against this method of assessing the profits of farmers; and certainly nothing could be more arbitrary and fallacious than the assumed rule for estimating them. But, notwithstanding the general opinion to the contrary, it is not very difficult to discover that the inequalities it occasioned in the collection of the tax were really advantageous to the farmer. The reason is, that while the farmers who occupied rich and well-situated lands, whose rents were comparatively high, were taxed far above their profits, those who occupied poorer lands, the rents of which were comparatively low, were not taxed to the extent of their profits. In these circumstances, the tax had necessarily a two-fold operation: In the first place, its effect was to lower the profits of the capital employed in farming proportionally to its pressure on those tenants who occupied the worst lands—for it is by the profits that they make that the profits of all other stock whatever must be regulated: And, in the second place, it had the effect of lowering the rent of the superior lands, by burdening it with all the excess of tax falling on the profits of those by whom they were occupied, over that which fell on the profits of the occupiers of the inferior lands. Such was the only way in which, as the tax was actually imposed, the indestructible level of profit among the farmers of the various descriptions of land could be preserved. And it is plain, that if the tax had pressed to its full extent on the occupiers of the worst lands in cultivation, it would have made a much greater deduction from the profits of all classes of farmers, at the same time that it would have made no deduction from rent.

Mode of estimating the Profits of the Farmer under the Income-Tax Act.

The income-tax fell equally on the profits derivable from the other branches of industry as on those

Taxes on Profits.

of the farmer: If his profits had been exclusively taxed, the inequalities in the tax would have been corrected, and the burden thrown off his shoulders to those of the consumers, partly by a *rise* of prices, and partly by a decline of the rents of the best lands.

Account of the *Taille*.

The *taille*, such as it subsisted in France at the epoch of the Revolution, was intended to be a tax on the profits of the farmer. Instead, however, of attempting to estimate these profits by the amount of his rent, or by endeavouring to ascertain the value of the produce remaining in his possession after his rent and other outlays had been deducted, they were commonly estimated by *the amount of the capital employed by him in cultivation*. In consequence of resorting to this criterion for estimating profits, the tax had the effect of inducing the farmer to employ the smallest possible quantity of capital, and of deterring him from making any considerable or expensive improvement. The *taille* was also injurious in another respect; for, as it did not affect the nobles who farmed their own lands, but fell exclusively on those who rented lands of another, or who possessed lands held by a base tenure, it was considered as a degrading tax, and as a mark of the ignoble, or rather servile condition of those by whom it was paid. All who made any thing by farming were thus rendered anxious to withdraw from so degraded a business; while rich merchants and capitalists were prevented from becoming tenants. Not only, therefore, did the *taille* hinder the greater part of the capital generated on the land from being laid out on it, but it turned from it all the capital that had been accumulated in other employments! It is very difficult to suppose that any tax could have been devised better calculated to retain agriculture in a rude and infant state, and to extinguish all emulation and enterprise among the farmers. And considering the long period to which France was subjected to this tax, our wonder is, not that her agriculture was in a very backward and depressed condition at the Revolution, but that it was so far advanced as it really was.\*

Contribution foncière.

The present French land-tax—*contribution foncière*—equally affects all lands, by whomsoever they may be occupied. It amounts, according to Garnier, to about an *eighth* part of the *net produce* of the land—that is, of its produce, exclusive of the expences of cultivation, but inclusive of rent. Garnier says that the tax is very fairly assessed, and that it is very moderate compared with the various charges with which landed property is burdened in most other countries. It is certainly a very great improvement on the old system. (*Richesse des Nations*, par Garnier, Tome VI. p. 404.)

### SECT. III.—*Taxes on Wages.*

Taxes on Wages.

The common and ordinary effect of direct taxes on wages, or on the commodities necessary for the subsistence of the labourer, is to cause a proportional increase of wages and fall of profits.

In every discussion respecting the effect of taxes on wages, or on the necessaries consumed by the labourer, it is of the greatest importance to distinguish between the *natural* or *necessary* rate of wages, or the rate which is required to enable the labourers to exist and continue their race, and the *market* rate, or the rate which they really receive at any particular period.

Taxes on Wages.

The natural or necessary price of labour, like the natural price of every thing else which is bought and sold, and which may be indefinitely increased or diminished, is determined by the cost of its production. The capacity of the labourer to support himself, and to rear as many children as may be required to keep up the supply of labourers, does not, it is plain, depend on the quantity of money he receives as wages, but on the quantity of food, necessaries, and conveniences essential to his support, for which that money will exchange. The natural rate of wages must, therefore, depend on the cost of producing the food, and other necessaries, required for the maintenance of the labourer. A rise in the market rate of wages does not always coincide with a rise in the price of necessaries; but they can never be very far separated. However high the price of necessaries may rise, the labourers, it is quite clear, must always receive such a quantity as is sufficient to enable them to support themselves and to continue their race. For if wages were to fall below this necessary level, the labourers would be left destitute; there would, in consequence, be a rapid diminution of their numbers; and this diminution would raise wages: and if, on the other hand, they were to rise considerably above it, a proportional stimulus would be given to the principle of population, and the increase of labourers would lower wages.

Natural Price of Labour.

The opinion maintained by those who contend that the rate of wages does not depend on the cost of producing the articles consumed by the labourers, but on the demand for their exertions compared with their numbers, has obviously originated in their confounding the principles which govern the *market* price of labour, at a particular period, with those which govern its *natural* or *necessary* price. It is undoubtedly true that the market price of labour at any given moment depends on the state of the *supply* as compared with the demand; but it is easy to see that the supply cannot be permanently brought to market unless the rate of wages is such as will suffice to maintain and bring up labourers—that is, unless the *cost of their production be paid*. From whatever point of the political compass we may set out, this is the grand principle to which we must always come at last. Let us suppose, to illustrate this principle, that, owing to a scarcity, the price of the quarter loaf rises to 5s.: It is plain, inasmuch as the same number of labourers would be seeking for employment after the rise as before, and as there is no reason why a scarcity should increase the demand

Agreement of the Market rate of Wages with the Natural rate.

\* For a farther account of the *taille* the reader is referred to Forbonnais, *Recherches sur les Finances de France*, Tome I. p. 107; *Wealth of Nations*, III. p. 303; and to Storch, *Cours d'Economie Politique* (ed. de Say), III. p. 191.

Taxes on Wages.

for labour, that wages would not be advanced; the labourers would, in consequence, be forced to economise, and the rise of price would thus have the effect of lessening consumption, and of distributing the pressure equally throughout the year. But suppose that the rise, instead of being occasioned by a deficient crop, has been occasioned by an increased difficulty of production, and that it will be permanent, the question is, Will wages continue at their former rate, or will they rise? Now, in this case, it is plain that wages must rise: For the comforts of all classes of labourers would be greatly impaired by the rise of prices; and those who, previously to its taking place, had only wherewithal to subsist, would be reduced to a state of extreme destitution, or rather, we should say, of absolute famine. In such circumstances, an increase of *mortality* could hardly fail to take place; while the greater difficulty of providing subsistence would interpose a powerful check to the formation of matrimonial connections and the increase of population. By these means, therefore, either the amount of the population, or the ratio of its increase, or both, would be diminished; and this diminution would continue until the smaller supply of labourers in the market had enabled them to raise wages to their natural rate; that is, as Dr Smith has defined it, to such a rate as would enable them to obtain "not only the commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without."

Variations in the natural rate of Wages.

If a given specific quantity of certain articles were necessary to enable the labourers to exist, it would clearly and directly follow that the rate of wages could not be reduced, for any considerable period, below what would procure them these articles. But there is no such absolute standard of natural wages. It depends essentially on custom and habit. The articles considered as necessaries are perpetually changing. The labourers of Hindostan principally subsist on rice, those of Ireland on potatoes, and those of England on wheaten bread and beef. In one country it is discreditably for the lowest class of labourers to be destitute of comfortable clothing, and of shoes and stockings, while in others shoes and stockings are looked upon as luxuries to be used only by the rich. In many provinces of France and Spain a certain allowance of wine is considered indispensable to existence; and in England the labouring class entertain nearly the same opinion with respect to beer and porter. Nor have the habits of the people, and the standard by which the natural rate of wages has been regulated at different periods in the same countries, been less fluctuating and various. The articles which custom and habit have rendered necessary for the comfortable subsistence of the English and Scottish labourers of the present day are as widely different from those which were judged necessaries by their ancestors, in the reigns of Elizabeth, James I., and Charles I., as they are from those which form the ordinary subsistence of the labourers of France and Spain. The standard of natural wages has been raised, and the poor have been taught to form much more elevated notions re-

specting the quantity and the species of the articles which it would be disgraceful for them to be without.

Taxes on Wages.

The natural rate of wages is not, therefore, a fixed and unvarying quantity; and though it be strictly true that the market rate of wages can never, when reference is made to periods of average duration, be sunk below its contemporary natural rate, it is no less true that the natural rate has a tendency to rise when the market rate rises, and to fall when it falls. The reason is, that the supply of labour in the market can neither be speedily increased when wages rise, nor speedily diminished when they fall; and it is also on this circumstance that the powerful influence which fluctuations in the market rate of wages have on the condition of the labouring classes principally depends: If the supply of labour could be suddenly increased when wages rise, that rise would be of no advantage whatever to the existing labourers. It would increase their number, but it would not enable them to mount in the scale of society, or to obtain a greater command of the necessaries and conveniences of life. And, on the other hand, if the supply of labour could be suddenly diminished when wages fall, that fall would merely lessen the numbers of labourers, without having any tendency to degrade the habits or to lower the condition of those who survived. But in the actual state of things no rise of wages can ever be counteracted by an increased supply of workmen coming into the market until eighteen or twenty years after it has taken place; for there are few or no branches of industry in which an active and skilful labourer can be bred in a shorter period. During all this interval, therefore, the labourer is placed in a greatly improved situation. He has a greater supply of wholesome and nutritious food; he has better clothes and better habitations; he is rendered more attentive to personal cleanliness; and as he rises higher in the scale of society, he naturally uses more providence and circumspection in the forming of matrimonial connections. In short, his opinions respecting what is necessary for his decent and comfortable subsistence are raised, and the natural rate of wages is in consequence proportionally augmented.

Supply of Labour not speedily accommodated to variations in the rate of Wages.

Advantages of a Rise of Wages.

But it is equally impossible suddenly to diminish the number of the labourers when wages fall. Such a diminution cannot, as we have already stated, be effected otherwise than by the operation of increased mortality, or by a decrease in the number of births. But unless the fall were very sudden and extensive, it would require a considerable number of years to render the effects of increased mortality very apparent; and it is so difficult to change the habits of a people, that, though the demand for labour were to decline, it would, notwithstanding, continue for a while to flow into the market with nearly the same rapidity as before. Nor would the ratio of the increase of population be sufficiently diminished, until the misery occasioned by the restricted demand on the one hand, and the undiminished supply on the other, had been very generally and widely felt.

Disadvantages of a Fall of Wages.

In whatever way, therefore, wages may be restored to their natural level when the market rate declines—whether it be by an increase of mortality, or

Danger of a degradation in the Habits of the Labourers from a Fall of Wages.

Taxes on  
Wages.

a decrease in the number of births, or both—it can never be the work of an instant. It must always require a considerable time before it can be effected; and there is in consequence an obvious risk lest the habits of the labouring class should be degraded in the interim. When wages are considerably reduced the poor are obliged to economise; and should the coarse and scanty fare that is thus, in the first instance, forced upon them by necessity, ultimately become congenial from habit, no check would be given to population, and the *natural rate of wages would be permanently reduced*. In such a case the cost of raising labourers would be diminished; and it is by this cost that the natural rate of wages, with which the market rate must generally correspond, is always regulated. A fall of wages is, therefore, as peculiarly injurious to the labourers as a rise of wages is peculiarly beneficial to them. Its obvious tendency is to sink the natural rate of wages, and to degrade the condition of the largest and not least valuable class in society; and wherever the labourers can bear to retrench, or to descend from a higher to a lower station, it will have this effect, unless their desire to preserve their place in society should occasion a greater prevalence of moral restraint, and a slower increase of population. It is certain, indeed, that to whatever extent wages may fall, the labourers always possess the means of raising them to their former, or to a higher level. If they understock the market with labour, wages will continue high, notwithstanding the means of employment should be diminished; while, if they overstock the market with labour, wages will be low, notwithstanding these means should be very considerably increased. The labourers are thus really in a great measure the arbiters of their own fortune. Nor is there any very great reason to think that their condition will ever be materially improved until they are made acquainted with the circumstances which govern the rate of wages, and are impressed with a full conviction of the important truth, that they are themselves the masters of the only means by which their command over the necessaries and luxuries of life can be really extended.

Taxes on  
Wages  
would occasion a corresponding  
Rise in the  
Rate.

Dr Smith has said, that, “while the demand for labour and the price of provisions *remain the same*, a direct tax on the wages of labour can have no other effect than to raise them somewhat higher than the tax.” (III. p. 323.) It is plain, however, from the principles we have just laid down, that in the event of the demand for labour continuing the same after the tax had been imposed as before, the rise of wages could only be gradually effected; and it would, in consequence, depend entirely on the circumstance of the opinions and habits of the people undergoing no degradation during the period of the rise taking place, whether wages would regain their former elevation. But Mr Ricardo has shown that, in the great majority of cases, the demand for labour would not, as Dr Smith has supposed, continue the same after the imposition of the tax. Sup-

pose, for the sake of illustration, that Government lays a direct tax on wages; as no part of this tax is taken from the capital of the masters, it is obvious it cannot lessen *their* means of employing labour; and it is equally obvious that it must make an equivalent addition to the means of employing labour, or of purchasing the produce of labour, possessed by the Government or its agents who have received the tax. As soon, therefore, as these increased means are brought into market, the greater competition will infallibly raise wages, so as to place the labourers in their previous condition.

This is the way in which taxes are generally expended. But if we suppose that the produce of the tax, instead of being laid out at home, had been remitted as a subsidy to a foreign state, the demand for labour would not be increased in consequence of the competition of Government, and wages could only be raised by slow degrees in the way we have previously described. In all those cases, however, in which the produce either of direct or indirect taxes on wages is laid out at home, they never fail to occasion an equal and immediate rise of wages. The agents of Government then enter the market for labour with means of purchasing which have not been derived from the capitalists, but from the labourers themselves, and wages are thus necessarily raised precisely in proportion to these additional means; or, in other words, to the amount of the tax. Although, therefore, Dr Smith failed in demonstrating his proposition, that a direct tax on the wages of labour is never defrayed by the labourer, the proposition is, nevertheless, strictly true in all those cases in which the tax is laid out at home; and it is also true in those cases in which it is sent abroad as a subsidy, provided the habits of the people and their opinions, respecting what is necessary for their comfortable subsistence, undergo no change after the tax is imposed.

We have already shown that every rise of wages must necessarily occasion a corresponding fall in the rate of profit.\* It is, therefore, really the same to the capitalists whether a tax on labour, which is to be spent at home, be laid directly on profits or on wages. The capitalists must defray it either at first or second hand. And hence it is that the real injury which such taxes inflict on the labourer does not consist in their immediate but in their remote effects. By falling on profits, their direct tendency is to diminish the power to accumulate capital; and when carried so far as to have this effect, they must, unless the stimulus previously given to population be at the same time diminished by the more powerful operation of the principle of moral restraint, depress the condition of the labourers, and lower the natural rate of wages.

It must, however, be observed, that this is not an effect peculiar to a tax laid directly on profits or wages, but to every tax which is not defrayed either from rent or from a duty on exported goods. Labourers cannot, in any circumstances, be made to

Wages.

contribute considerably to the wants of the state; and if they were sufficiently alive to their own interests, and made a proper use of the power which they possess of regulating the quantity of labour in the market, no tax, even though the produce were remitted to a foreign country, could ever occasion any permanent reduction of the natural rate of wages. It is from profits and rent, therefore, that almost all taxes must be derived. And it is not really of much importance, provided the sum demanded of a capitalist be ascertained, whether he is made to pay it by a direct tax or by taxes on expenditure. If L. 500, for example, be his fair proportion of the revenue required by the state, "the virtue of taxation consists in making sure that he shall pay this sum, neither more nor less." (Ricardo's *Principles*, &c. p. 183, 3d edit.)

Effect of  
Taxes on  
Profits and  
Expendi-  
ture in forc-  
ing Capital  
and Individ-  
uals  
abroad.

It is alleged, however, and the allegation is undoubtedly true, that, when the rate of profit, in a particular country, is as low, or but very little higher than the rate of profit among the countries in the vicinity, a heavy direct tax on profits or wages would, by reducing the rate of profit below the common level, have a powerful tendency to cause the transfer of capital to other countries, whereas heavy taxes on expenditure merely occasion the emigration of individuals or families, without prompting them to take their stock along with them. But, although it cannot be doubted that an efflux of capital is much more injurious than an emigration of individuals, still, as the emigrants would thereby avoid taxes laid on expenditure, it is obvious, that if no taxes were laid directly on profits and rents, they would escape taxation altogether, and a disproportionately heavy burden would, in consequence, be thrown on those who continued to reside at home. The truth is, that it is quite impossible to carry either direct or indirect taxes beyond moderate limits, without encountering difficulties. Inasmuch, however, as *equality* of pressure is one of the very highest recommendations of a system of taxation, and *inequality* of pressure one of its greatest defects, the objection to such direct taxes as can be fairly assessed, that they tend to force capital abroad, ought not to be held as conclusive. So long as an individual derives a revenue from capital, so long ought that revenue be made to contribute, in the same proportion as the rest, to the supply of the wants of the country in which the capital is employed. If you cannot draw the L. 500 of taxes, which a capitalist ought to pay, from him, by means of duties on wines, horses, or coaches, or any other article of expenditure, you ought certainly to resort to direct taxation: For, if you do not, this capitalist will not furnish his proper quota of the public revenue, and other individuals will have to pay the portion not paid by him. To prevent taxes on profits or expenditure from forcing either capital or individuals abroad, the only way is to keep them as low as possible. In this respect, as in most others, there is no difference between the expenditure of a state and that of a family. And in both it will be found, as Cicero long ago observed, that *Optimum, et in privatissimis familiis, et in republica vectigal est, PARSIMONIAM*.

Having thus endeavoured to trace and exhibit the effects that would result from the imposition of

taxes separately affecting rent, profits, and wages; we shall now proceed briefly to inquire into the effects that would result from the imposition of a tax proportioned to the income of each individual.

Taxes on  
Wages.SECT. IV.—*Taxes on Income.*

As all income must either be derived from rent, profit, or wages, the effects of a tax on income would necessarily vary according as the incomes of the contributors were derived from one or other of these sources. In so far as income is derived from rent, a tax on it would be really a tax on rent, and would fall wholly on the landlords; and in so far as income is derived from profits, a tax on it would be really a tax on profits, and would fall wholly on the capitalists: But such would not be the case with a tax laid on that part of the income of a country which consists of wages; for, we have already shown, that when the produce of a tax on wages is laid out at home, it causes them to rise to an equal extent; and is, therefore, really the same in its effects as if a tax calculated to raise the same sum were laid directly on profits; and that, when the produce of the tax is remitted abroad, the same rise is brought about, though not so immediately, by the operation of increased mortality, or by a diminished increase of population.

By tracing the effects of this principle, we discern the fallacy of the objection to an income-tax, on account of its pressing with equal severity on all incomes, *from whatever sources they may be derived*. There is certainly a great appearance of truth in the statement of those who affirm that it is a monstrous hardship and injustice to make the same deduction from the income of a lawyer or a physician, on whose exertions a numerous family may perhaps be dependent, as from the rent of a landlord or the profit of a capitalist. But if it can be shown that the condition of professional men must be affected by every tax laid exclusively on the incomes of landlords and capitalists, exactly to the same extent as if it had been extended to them, these objections must obviously fall to the ground, and there can be neither hardship nor injustice in making the tax universal. Now it is not very difficult to demonstrate that this would really be the case; and that, in point of fact, it is altogether immaterial to professional men whether, when a tax is laid on income, they pay their full share, or obtain a total exemption.

No injustice  
done to Pro-  
fessional  
Men by Tax-  
ing their In-  
comes to the  
same extent  
as those of  
Landlords  
and Capital-  
ists.

The revenue or wages of professional men depends partly on the expence necessarily incurred in their education, and partly on the peculiar habits of the society in which they live, and the station they must support. If their wages amounted only to a bare compensation for the expences of education, it is easy to see they could not be permanently affected by a tax on income; for, as soon as the tax was imposed, their wages would become insufficient for their remuneration, and while young men would thus be deterred from entering on professional pursuits, those already engaged in them would have a powerful temptation to withdraw; nor would this double operation cease, until it had, by diminishing the supply, raised the wages of those who remained to their proper level;—that is, until it

Taxes on  
Income.

had increased them by the whole amount of the tax. It is clear, therefore, that no lasting or real injury could be done to those professional men, whose earnings are proportioned to the necessary expences of their education, by subjecting them to a tax on income.

It may be supposed, however, that the effect would be different in the case of those whose incomes are not regulated so much by the expence of their education, as by the expence of maintaining themselves in the station in which custom and the habits of society require they should live. But this circumstance does not really make the slightest difference on the result. The situation of professional men must always bear some certain relation to the situation of those among whom they reside. If you either improve or depress the condition of the landlords and capitalists of a country, it will be found to be utterly impossible to maintain professional men in their previous situation. Their interests are inseparably and indissolubly connected with those of the other classes: they must rise when they rise, and they must fall when they fall. Suppose, to illustrate this principle, that a tax is laid on the incomes of landlords and capitalists, from which the incomes of professional men are exempted. It is plain, that the immediate effect of such a tax would be to derange the previously subsisting relations among the different classes and orders of society. The condition of professional men, as compared with that of landlords, farmers, manufacturers, and merchants, would be improved. But this improvement would be of very short duration. For the greater inducements, which the exemption from the tax would hold out to young men to enter on professional pursuits, would not fail to attract additional numbers, until, by the increase of competition, their wages had declined so as to balance the advantage of exemption from the tax, and to place them in the same relative situation as before. If we reverse this hypothesis, and suppose, that, instead of professional incomes being exempted from an income-tax, it is laid exclusively on them, the result will be precisely similar. The situation of professional men, as compared with that of the other classes, would in this case be changed to the worse. There would, in consequence, be a greater disinclination to engage in professional pursuits: and the usual supply of entrants not being obtained, their numbers would be progressively diminished, until the greater competition for their services had again restored them to their proper relative situation; or to the situation they would have occupied, had the tax been levied equally on all classes.

Still, however, it may be said, that though no injustice is done to professional men by taxing them to the same extent as capitalists, when an income-tax forms a *permanent* source of revenue, an injustice would be done them were they taxed to the full extent of the other classes, in the event of its only being imposed during the continuance of a war; because, in such a case, sufficient time would not be afforded to permit the natural principles of adjustment we have described to operate their full effect. But this objection is as untenable as the former. Wars are calamities to which every people must always be

liable; and if it were once known that the supplies required to defray their expence were to be raised within the year, by an equal income-tax, the chances of being subjected to this tax would most certainly enter into the calculations of all professional men, and the rate of their natural or necessary wages would be regulated accordingly. In every case, therefore, whether an income-tax is made one of the ordinary sources of revenue, or is only resorted to on extraordinary emergencies, professional incomes ought to be taxed to the same extent as others. To give abatements in their favour, serves only to introduce an apparent inequality into the tax, and to render its collection more difficult, without doing them any real service. If you give them an abatement, their fees will be diminished; and if you do not give it, they will be raised; so that, in either case, they will preserve the same relative situation with respect to the other classes of society.

The only class in whose favour it would be just and equitable to grant an abatement from the full charge on account of an income-tax, are those who derive their incomes from *fixed* and *terminable* annuities. It is obvious, that such a tax would press with greater severity on them than on landlords or capitalists, whose incomes are derived from what may be considered as inexhaustible sources; and it would also press with greater severity on them than on professional men, whose incomes would be augmented in consequence of its imposition; and, therefore, it would be necessary to avoid laying any greater burden on the possessors of *terminable* annuities, than on the other classes; or, to preserve them in the same relative situation, to make an abatement in their favour in an inverse proportion to the duration of their annuities.

If an income-tax were extended to the wages of common labourers, it would not really fall upon them, but on the capitalists who employ them. And it would, therefore, be necessary, in the event of such a tax being imposed, to increase the proportion affecting the rents of the landlords; for otherwise they would be less heavily taxed than the capitalists, who would have to pay the portion which falls on wages.

It has been urged by M. Say, and other able economists, that an income-tax ought not to bear the *same* relation to all incomes. A tax of L. 10, for example, is said to be more severely felt by the possessor of an income of L. 100, than a tax of L. 100 or L. 1000, by the possessor of an income of L. 1000 or L. 10,000; and it is contended, that, in order fairly to proportion the tax to the *ability* of the payers, such a *graduated scale* of duties should be adopted, as would press lightly on the smaller incomes, and increase according as they became larger, and more able to bear taxation. We cannot, however, concur with those who hold this opinion. It is surely no part of the business of Government to impose taxes, in the view of regulating the incomes of the contributors, or for the purpose of depressing one class and elevating another. *Every just tax will leave individuals in the same relative situation in which it found them*; and it cannot do this otherwise, than by taking the *same proportion* of their incomes from each. That such a tax will be more acutely

Taxes on  
Income.

An Income-tax ought not to increase with the Increase of Incomes.

Taxes on  
Income.

felt by the poorer than by the wealthier classes is undeniable; but the samething is true of taxes on commodities, and of every imposition which does not subvert the already subsisting relations among the different orders of society. The hardship in question is, in fact, *one of the evils of poverty*, and not of equal taxation; and to attempt to alleviate it, by adopting such a graduated scale of duties as has been proposed, would really be to impose taxes on the wealthier part of the community, for the benefit of their less opulent brethren, and not for the sake of the public revenue. The establishment of such a principle would be most mischievous; if carried to its full extent, it would sanction the total exemption of limited incomes from the burden of taxation, until those that were higher had been reduced to the same level; and would thus be subversive of almost every motive to industry and economy.

The objections to an equal income-tax, on the ground of its making "no distinction between the income which has a numerous family to support, and that of the retired bachelor or the unexpensive maiden,"\* are still more destitute of foundation. In fact, the peculiar excellence of an income-tax consists in its making no such distinction,—in its sweeping, with indiscriminating severity, its equal demands from all. If taxes be not laid on income, they *must* be laid on expenditure; and it is obvious, that while an individual who has an expensive station or a large family to support, must contribute largely to taxes on expenditure, misers and those who have no families may nearly escape them altogether. It has been suggested, that this inequality might be got rid of by making distinctions in the duties on commodities, proportioned to the relative condition of those who buy them; or by enacting, that those who have so many children shall pay a certain duty, and those who have so many more, a different duty. But the extreme complexity of such a plan, and the facilities it would give to every species of fraud and evasion, will always prevent its adoption. Supposing, however, that it could be adopted, it would be, in the highest degree, unjust and inexpedient:—unjust, in as much as a reduction of duties in favour of those who have small incomes, would proportionally depress the wealthier classes, and change the relative situation of individuals; and inexpedient, in as much as a reduction in favour of those who have large families, would act as a stimulus to marriage, which, if it ought not to be discouraged, certainly stands in no need of encouragement. So long, therefore, as taxes affect only expenditure, those who are obliged to spend must unavoidably pay more than their just proportion of the public revenue. But a fairly levied tax on income would obviate this defect, and would make misers, bachelors, and maidens, contribute equally with the other classes to the demands of the state.

For these reasons, we have no hesitation in giving it as our decided opinion, *that if a tax on income could be fairly collected*, it would be one of the most impartial and least objectionable taxes that it is pos-

sible to impose. It may, however, be laid down as an indisputable axiom, that every tax which affords a great *facility of evasion* is essentially defective; and there are very cogent reasons for thinking that this must always be the case with an income-tax. The income derived from lands, houses, and other fixed property, may be learned without much difficulty; but it has hitherto been found to be quite impossible to ascertain the wages of professional persons, or the profits of the capital engaged in manufacturing and commercial undertakings with any thing like tolerable precision. It is this extreme difficulty of making an equal and impartial assessment, that constitutes the real and only good objection to an income-tax. By setting the interests of the contributors in direct opposition to their duties, and tempting them to conceal and underrate their incomes, it obviously operates as a bounty on perjury and fraud; and, if carried to a very great height, it would undoubtedly generate the most flagrant and barefaced prostitution of principle, and would do much to obliterate that nice sense of honour which is the only sure foundation of national probity and virtue. The discovery of means by which these highly injurious effects might be obviated, and incomes ascertained without the necessity of instituting an odious and generally ineffectual inquisition into the private affairs of individuals, would be the greatest practical improvement which it seems possible to make in the science of taxation. But until such means are devised,—and we are not certainly very sanguine in our expectations on the subject,—an income-tax must, besides its injury to public morals, be partial and unequal in its operation, and ought not, therefore, to be imposed, except in cases when a large revenue must be raised.

In order to furnish the means of defraying the enormous cost of the war begun in 1793, Mr Pitt proposed, in 1797, to triple the amount of the assessed taxes, or duties on houses, windows, horses, carriages, &c. This plan, however, did not answer the expectations of its projectors, and next year it was abandoned, and a tax on income substituted in its stead. According to the provisions of the act imposing this tax, all incomes of less than L. 60 a year were exempted from assessment; an income of from L. 60 to L. 65 was taxed one *one hundred and twentieth* part; and the rate of duty increased through a variety of gradations, until the income reached L. 200, or upwards, when it amounted to a *tenth* part, which was its utmost limit; a variety of deductions being at the same time granted, on account of children, &c. The commissioners to whom the management of this tax was entrusted were chosen by the freeholders of counties, and the electors of burghs, in the same way as their representatives in Parliament, only that a smaller qualification was sufficient to enable any one to be elected a commissioner. The services of the commissioners were gratuitous; and they were sworn to preserve the most inviolable secrecy with respect to the affairs of individuals. They

Income.

were authorized to call for returns from every person whose income they supposed to exceed L. 60 a year; and in the event of their being dissatisfied with these returns, they were empowered to call for written explanations, and ultimately for the oath of the party. But this examination was rarely necessary, except in the case of incomes derived from wages, from capital employed in manufacturing and commercial business, or from the interest of loans; the rental of landlords being, in most cases, learned from the terms of the leases held by their tenants; and the profits of the tenants being, as we have already observed, estimated at a certain proportion of the rent. The commissioners were assisted, or rather overlooked, by the tax-surveyors appointed by Government, who were required to see the provisions of the act strictly enforced, and whose duty it was to scrutinize all returns of income, to challenge such as they considered fraudulent, to object to the deductions allowed by the ordinary commissioners, and to bring the matter under the review of the commissioners of appeal, whose sentence was final. Notwithstanding the apparent complexity of these regulations, they worked extremely well; and though much fraud and evasion were certainly practised, yet, on the whole, the tax was collected with infinitely less difficulty, and with greater fairness and equality, than could have been rationally anticipated.

This tax was repealed in 1802, after the peace of

Amiens, having produced, on an average, about *five millions and a half* annually.

Taxes on  
Income.

In 1803 the income-tax, under the name of property-tax, was again revived. The assessment began, as before, on incomes so low as L. 60 a year, and gradually increased until the income reached L. 150 a year, when it amounted to 5 per cent., which was its highest rate. An addition was made to this tax in 1805; and in 1806, during the short-lived administration of Mr Fox and Lord Grenville, the assessment was raised to 10 per cent. on all incomes, however small, arising from land or capital; professional incomes under L. 50 were exempted from the tax; and incomes of that sort exceeding L. 50, and under L. 150, the limit at which they became subject to the full assessment of 10 per cent., were allowed deductions, varying inversely as their magnitude. A very great outcry was made against the ministers who proposed this addition to the income-tax; but it may safely be affirmed that, in the then situation of the country, it was a highly necessary measure, and one for which they really deserved the thanks of the public. The income-tax was finally repealed in 1816.

We subjoin, from a Parliamentary paper presented to the House of Commons on the 26th February 1823, a return of the total *gross* and *net* assessments to the property or income-tax, for the year ending 5th of April 1815:—

	Gross Assessment.	Net Assessment.
A. Lands, Tenements, Hereditaments, or Heritages	L. 5,923,486 ...	L. 5,923,189
B. Houses, Lands, and Tenements	2,734,451 ...	2,176,228
C. Funded and Stock Properties	2,885,505 ...	2,885,505
D. Profits and Gains of Trade	3,831,088 ...	3,146,332
E. Salaries, Pensions, &c.	1,174,456 ...	1,167,678
Totals	L. 16,548,985	L. 15,298,982

The following is the Return of the Value of the several species of Property on which the Assessment was made for the Years ending 1813 and 1814, ending the 5th April 1814 and 1815, viz.—

Schedules.	1813.	1814.
A. ....	L. 56,701,923 ...	L. 60,138,330
B. ....	36,336,883 ...	38,396,144
D. ....	36,080,167 ..	38,310,935
E. ....	11,380,748 ...	11,744,557
C. not stated, but estimated at	30,000,000 ...	30,000,000
Totals	L. 170,499,721	L. 178,589,966

SECT. V.—*Poor Rates.*

Poor Rates.

The incidence and effect of poor rates depend on the mode in which they are imposed. If they were laid exclusively on the land, and levied proportionally to its rent, they would be really a tax on rent, and would be wholly defrayed by the landlords. If they were laid exclusively on the rent of houses, they would, in certain circumstances, fall wholly on the occupiers, in others on the builders, and in others on the occupiers and ground landlords; and, if they were laid on profits, they would fall equally on farmers, manufacturers, and merchants, or on capitalists in general. In the actual state of things in this coun-

try, we believe that a much larger proportion of the poor rates falls on the farmer than on any one else; and they, consequently, contribute to raise the price of his produce just as any other tax affecting either his crop or the instruments used by him in cultivation. Mr Ricardo has made an allowance for this greater pressure of the poor rates on the farmer in his estimate of the countervailing duty to be laid on foreign corn, to balance the excess of taxes affecting that which is raised at home.

Having thus endeavoured to exhibit the operation, and to trace the ultimate incidence and effect of such taxes as fall *directly* on income, we come now to the second branch of our subject, or to the

Advantages and Disadvantages of Indirect Taxes.

consideration of those taxes which fall *indirectly* on income.

## PART III.—INDIRECT TAXES.

## SECT. I.—Advantages and Disadvantages of Indirect Taxes.

Though most governments have had recourse to direct taxes, they have rarely formed the sole or even principal source of their revenue. Indirect taxes have almost invariably been the greatest favourites both of princes and their subjects; and there are a variety of reasons why this should be the case. The burden of direct taxation is palpable and obvious. It admits of no species of disguise or concealment, but makes every one fully sensible of the exact value of the portion of his income taken from him by government. There is, however, a natural and inherent repugnance in the human breast to part with the produce of industry, except for the purpose of obtaining some more acceptable equivalent in its stead. And as the benefits derived from the institution of government are neither so very obvious nor striking as to be easily and readily felt and appreciated by the great body of the people, there is, in the great majority of cases, an extreme disinclination to pay a large amount of direct taxes. It is for this reason that governments have so generally had recourse to indirect taxes. Instead of exciting the prejudices of their subjects by openly demanding a certain specific portion of their incomes, they have taxed the articles on which these incomes are in general expended! The effect of this ingenious plan is to conceal the amount of taxation, and to make its payment appear in some measure voluntary. The tax being generally paid, in the first instance, by the producers, the purchasers confound it with the natural price of the commodity. No separate demand being made upon them for the tax, it escapes their recollection; and the article they have received seems a full equivalent for the sacrifice they have made in acquiring it.\* Such taxes have also the advantage of being paid by degrees, in small portions, and at the time when the commodities are wanted for consumption, or when it is most convenient for the consumers to pay them.

Besides their greater facility of imposition, indirect taxes have been frequently supposed to have the further and exclusive advantage of acting as a stimulus to industry. "Dans la perception, directe," says the Marquis Garnier, "l'impôt se montre sans nul deguisement; il vient sans être attendu, à cause de l'imprévoyance si ordinaire au commun des hommes, et il apporte toujours avec lui de la gêne et du découragement. Mais l'impôt indirect, en ajoutant successivement un surcroît de prix aux articles de consommation générale et journalière, au moment où tous les membres de la société ont

contracté l'habitude des ses consommations, rend ses divers articles un peu plus coûteux à acquérir, c'est-à-dire, qu'il donne lieu à ce qu'il faille, pour se les procurer, un surcroît proportionné de travail et d'industrie. Or, si cet impôt est mesuré de manière à ne pas aller jusques à décourager la consommation, ne semble-t-il pas, dans ce cas, agir comme un stimulant universel sur la partie active et industrielle de la société, qui l'excite à un redoublement d'efforts, pour n'être pas obligé de renoncer à des jouissances que l'habitude lui a rendues presque nécessaires, et qui, en conséquence, donne un plus grand développement aux facultés productives du travail et aux ressources de l'industrie? Ne doit-il pas en résulter, qu'après l'impôt, il y a la même somme de travail et d'industrie qu'auparavant pour fournir aux besoins et aux jouissances habituelles des hommes qui composent la classe laborieuse, plus la somme de travail et d'industrie qui a dû pourvoir au surcroît de prix destiné à l'impôt? Or, cet impôt, ou ce surcroît de produit que se paye, étant dépensé par le gouvernement qui le recueille, sert à alimenter une nouvelle classe des consommateurs, qui forment des demandes qui l'impôt les met à porté de payer." (*Preface à la Traduction de la Richesse des Nations*, Tome I. p. 66, ed. 2de.)

The truth of the greater part of this statement cannot be disputed. It is, however, essential to observe, that the whole effect ascribed by M. Garnier to indirect taxes, in stimulating industry, depends on the circumstance of their being so moderate as not to discourage consumption; or, which is really the same thing, that they are so moderate as to give the contributors the power of defraying them by increased exertion and economy. If this were not the case, they would have a precisely opposite effect, and instead of acting as a stimulus to production, they would certainly occasion its decline. But we can perceive no grounds for supposing that a moderate income-tax would have a different effect on industry from moderate taxes on expenditure. It would most undoubtedly serve as a spur to excite every one to make additional exertions, otherwise he would be unable to preserve his capital unimpaired, and to retain his former command over the necessaries and luxuries of life. Increase of exertion is not an exclusive consequence of indirect taxation; but it is an exclusive consequence of moderate taxation, whether it be direct or indirect. Just as a decay of industry, and a general impoverishment, is not the exclusive consequence of any particular species of taxation, but of all taxes whatever, when they are carried to an excessive height.

We doubt, therefore, whether the generality of taxes on expenditure possess any real advantage over taxes on income, except in the facility of imposition, while they certainly labour under many very considerable disadvantages. In the first place, taxes on commodities necessarily alter the natural distribution of Capital.

\* Nero was supposed to have abolished the duty of 4 per cent. on the slaves sold in Rome, when he really did no more than order it to be paid by the seller instead of the buyer. "*Remissum*," says Tacitus, "*specie magis quam vi; quia cum venditor pendere juberetur, in partem pretii emptoribus accrescebat.*" *Annal.* lib. 13, cap. 32.

Advantages  
and Disad-  
vantages of  
Indirect  
Taxes.

bution of the capital and industry of the country, and force them into less advantageous channels. They do this, because, when a tax is laid on a particular class of commodities, the producers, in order to raise the price proportionally to the tax, diminish the supply in the market, by transferring a portion of the capital employed in the production of the taxed commodities to some other business. But an equal income-tax would operate as an *equal tax on profits*; and when all profits are equally taxed, no advantage would be gained by transferring capital from one business to another, and the producers would have no means whatever of raising prices. Under the operation of such a tax, every individual would continue, just as he would have done had he not been taxed at all, to employ himself in those businesses which are naturally most advantageous. Capital and industry would not be forced into artificial channels. The pay of troops and of public functionaries would not be raised, because of a rise of prices occasioned by taxation; at the end of a war, every thing would be found in its proper position; there would be no revulsion; and we should be immediately enabled to avail ourselves to the utmost of all our natural and acquired resources.

Raise the  
price of Com-  
modities to a  
greater ex-  
tent than the  
amount of  
the Tax.

In the *second* place, taxes on commodities are almost always paid by the producers before they are sold to the consumers, and are frequently, indeed, advanced in an early stage of the manufacture. Their effect is, therefore, not only to increase the price of the commodity, by the whole amount of the duty, but also by the profit due to the manufacturer for the time it has been advanced by him. But it should be observed, that though this circumstance undoubtedly operates to increase prices, its influence in this respect has been greatly over-rated by Sir Matthew Decker, M. Say, and M. Sismondi. The latter has calculated that a tax of 4000 francs, paid originally by a manufacturer, whose profits were 10 *per cent.* would, if the commodity manufactured only passed through the hands of *five* different persons, be raised to the consumer to the sum of 6734 francs! This calculation proceeds on the supposition, that he who first advanced the tax would receive from the next manufacturer 4400 francs, and he, again, from the next 4840 francs; so that at each step 10 *per cent.* on its value should be added to it. "But this," as Mr Ricardo has justly observed, "is to suppose that the value of the tax would be accumulating at *compound interest*; not at the rate of 10 *per cent. per annum*, but at an absolute rate of 10 *per cent.* at every step of its progress. M. Sismondi's statement would be correct, if *five years* elapsed between the first advance of the tax and the sale of the taxed commodity to the consumer; but if one year only elapsed, a remuneration of 400 francs, instead of 2734, would give a profit at the rate of 10 *per cent. per annum*, to all who had contributed to the advance of the tax, whether the commodity had passed through the hands of *five* manufacturers or  *fifty.*" (*Principles, &c.* 3d edit. p. 459.)

Encourage  
Smuggling.

In the *third* place, duties on commodities encourage smuggling. "They tempt," says Dr Smith, "persons to violate the laws of their country, who

are frequently incapable of violating those of natural justice, and who would have been in every respect excellent citizens, had not the laws of their country made that a crime which nature never meant to be so." (III. p. 378.) In consequence of this tendency, duties on commodities require the employment of a great number of revenue officers; and as they expose the producers of the taxed articles to considerable inconvenience and hardship from domiciliary visits, they force them to indemnify themselves by making a corresponding addition to the price of their goods.

Advantages  
and Disad-  
vantages of  
Indirect  
Taxes.

But the great objection to taxes on expenditure consists in their inequality. We have already shown that such taxes cannot possibly be rendered equal and impartial in their operation; that they do not affect the different classes of society in proportion to their ability to bear them; and that, while they may be almost wholly evaded by rich misers, and those in unexpensive stations, they press with disproportionate severity on those who have large families and expensive stations to support. At the same time it should be remembered, that in taxation we have only a choice of difficulties. And notwithstanding it does not appear possible to free taxes on expenditure from these very weighty objections, the greater readiness with which they are paid, combined with the extreme difficulty of laying an income-tax equally on rent, profits, and professional wages, will always prevent their abolition. Neither, perhaps, would it be really desirable to take off those duties which affect only luxuries. But without entering on the discussion of this question, we are satisfied that if the difficulties, in the way of a fair income-tax, could be removed, it would be among the least objectionable of any; and if it were not exclusively adopted, it ought at all events to be made one of the *principal* sources of the public income. It is unnecessary, however, after what we have previously stated, to insist farther on this point; and we shall, therefore, proceed to inquire into the effects on their price, of taxes on commodities, and on whom they ultimately fall.

#### SECT. II.—*Inquiry into the Incidence and Effect of Indirect Taxes.*

1. *Taxes on a particular Commodity.*—With regard to the effect of taxes on the price of commodities, it is clear that if a duty be laid on a particular commodity, and not on others, its price will sustain an equal rise; for, if it did not rise to this extent, the profits of the producers would be sunk below the common level, and their business would be abandoned. But it depends on the circumstance of the commodity being of the class denominated *luxuries*, whether a tax on it will fall wholly on the consumers. In so far as *necessaries* are consumed by landlords or capitalists, taxes on them are also defrayed by the consumers; but, in so far as they are required for the consumption of labourers, the effect of taxes on them is in no respect different from the effect of an equal amount of taxes laid directly on wages: And we have already shown that there are very few cases in which taxes affecting wages are really defrayed by the labourers; and that their common and ordinary effect is to cause an immediate

Taxes on a  
particular  
Commodity.

Taxes on  
Commodi-  
ties.

and equivalent rise in the rate of wages, and a proportional fall of profits. It appears, therefore, that taxes on necessaries do not wholly fall on the consumers; but that they are partly defrayed by them, and partly also by the proprietors of stock, in consequence of their reducing the rate of profits. Such, however, is never the case with taxes on luxuries, or on commodities used only by the rich. A duty on velvets, on claret, and on coaches; for example, falls immediately on the consumers, and cannot be thrown on any one else. Such articles not being used by labourers, a duty on them can neither raise wages nor affect the rate of profit.

Taxes on all  
Commodi-  
ties.

2. *Ad valorem Taxes on all Commodities.*—It is not so easy to trace the effects, on their price, of an equal *ad valorem* duty on all commodities. Such a duty could not, it is obvious, at all affect their values relatively to each other; and supposing their quantity and the quantity of money in the country to continue the same, it has been contended that it could occasion no rise of prices. But a very few words will be sufficient to show the fallacy of this statement. The Government must receive the tax either in money or in goods. Now suppose, for the sake of illustration, that the duty is ten *per cent.*, and that it is paid in kind; in this case the supply of produce remaining in the market after the tax is paid being diminished *one-tenth*, the purchasers will only get *nine-tenths* of the commodities they previously got in return for the same quantity of money, or, in other words, prices will rise ten *per cent.* If the Government receives the tax in money, the result will be precisely similar. The purchasers will still have to reimburse the producers for the tax, or to pay them ten *per cent.* additional for their goods. For if this were not really the case—if the purchasers who do not directly pay the tax to Government, continued to get the same quantity of produce for the same sum of money, after its imposition as before, there would be no cause in operation to occasion the smallest diminution of individual consumption; and it is plainly impossible that the tax could, in such circumstances, give the Government the means of obtaining an increased share of the produce of the country, which is absurd. Not only, therefore, is it certain that a tax on a particular class of commodities will raise their price; but it is also certain that an equal *ad valorem* duty on all commodities will, without any increase of money, occasion an equal and universal rise of prices. The real effect of every such tax is to transfer a portion of the produce of the industry of the country into the hands of Government, and consequently to cause a *less* portion of that produce to come into the hands of every individual whose means of purchasing are not increased. Such a rise of prices is widely different from the rise which is occasioned by an increase in the quantity of money. When it is increased prices rise, because *more money* is given for the *same quantity of goods*; but when an *ad valorem* duty is levied, prices rise, because the *same sum of money* is given for a *less quantity of goods*, a portion of them having been transferred to Government.

Taxes on  
Raw Pro-  
duce.

3. *Taxes on Raw Produce.*—It has been very generally supposed that the taxes laid on the raw produce of the soil have a different incidence from taxes

laid on manufactured commodities; and that, instead of raising prices, and falling on the consumer, they have no influence on prices, and fall wholly on the landlord. We believe, however, that we shall be able to show that this opinion is entirely without foundation; and that the real effect of taxes on raw produce is to cause a proportional rise of prices, and to affect all classes equally in proportion to their respective consumption of the taxed articles.

If land yielded no surplus to its possessors above Tithes. the common and ordinary profit of the capital employed in its cultivation, it is plain that the imposition of a tax on its produce, a tithe, for example, would occasion an equivalent increase of its price. The level of profit may be temporarily, but it cannot be permanently, elevated or depressed in any particular branch of industry. And as there can be no reason why the agriculturists should content themselves with a reduced rate of profit, when all other employments are yielding a higher rate, as soon as tithes were imposed they would set about transferring a portion of their stock to some more lucrative business; and this transference would be continued until the diminution of supply had raised prices to their proper level, and restored the equilibrium of profit. In such a state of things, tithes would indisputably operate precisely as an equivalent addition to the price of raw produce. But after various qualities of soil have been brought under cultivation, and rents have, in consequence, been pretty generally introduced, it is not so easy to trace their ultimate incidence and effect. They then appear to occasion rather a diminution of the rent of the landlord than a rise of prices. Farms which are tithe-free always bring a proportionally higher rent than such as are subject to that charge; and it is naturally concluded, that, were tithes abolished, the depressed rents would be raised to the same level as the others. For this reason, in an advanced stage of society tithes have not been considered as increasing the price of raw produce to the consumers, but as falling on rent, and as diverting a portion of it into the pockets of its rightful owners, the clergymen and lay-impropriators. "Taxes on the produce of land," says Dr Smith, "are in reality, taxes upon rent; and, though they may be originally advanced by the farmer, are finally paid by the landlord. When a certain portion of the produce is to be paid away for a tax, the farmer computes as well as he can what the value of this portion, one year with another, is likely to amount to, and makes a proportional abatement in the rent which he agrees to pay to the landlord. There is no farmer who does not compute, beforehand, what the church tithe, which is a land-tax of this kind, is, one year with another, likely to amount to." (III. p. 274.)

That this is the general opinion on the subject cannot be doubted; but notwithstanding the high authority by which it is supported, it is most certainly without foundation. We have shown, in treating of taxes on rent, that in every country that portion of the required supply of raw produce which is raised by the agency of the capital last applied to the soil, and which governs the price of all the rest, never yields any rent but merely the common and average rate of profit to the landlord or the occupier. Now

Taxes on  
Raw Pro-  
duce.Dr Smith's  
Opinion with  
respect to the  
Incidence of  
Tithes.Error of this  
Opinion.  
Tithes and  
other Taxes  
on Raw Pro-  
duce do not  
fall on the  
Rent of the  
Landlord,  
but on the  
Consumers  
of Raw Pro-  
duce.

Taxes on  
Raw Pro-  
duce.

this principle is decisive as to the effect of tithes and other taxes on raw produce. If tithes were only levied from the superior soils, they would not, after inferior soils had been cultivated, occasion any rise of price, but would fall entirely on the rent of the landlord. But this is not the case with tithes. They affect every quality of land indiscriminately, and being exacted equally from the produce raised in the least favourable, as from that which is raised in the most favourable circumstances, occasion only an increase of prices. Suppose no tithes are levied, and that the wheat raised on the poorest lands, or with the capital last applied to the soil, and which determines the price of the whole crop, yields a sufficient profit to the cultivator, and no more, when it sells for 70s. a quarter—the price must rise to 77s. before the same profit can be obtained after tithes are imposed. In this case the tithe cannot possibly occasion any diminution of rent; for this produce pays no rent; so that if it were not compensated to the cultivators by an increase of prices, they would withdraw their capital from cultivation, and the necessary supplies would no longer be obtained.

If Tithes  
were abolish-  
ed, the Rent  
of Tithe-free  
Farms would  
fall.

This account of tithes is nowise inconsistent with the admitted fact, that farms which are free from this burden bring a proportionally higher rent. The expenses attending their cultivation are not increased by the levying a tithe from the produce of other farms; but, as there cannot be two prices, their occupiers obtain the same increased price for their produce which is necessary to indemnify the cultivators of the tithed lands. There must, however, be an equality of profits, as well as of prices; and hence, whatever advantage the occupier of a tithe-free farm may gain by being relieved from a burden to which his neighbours are subjected, is compensated by a corresponding increase of rent.

Thus it appears, that, if tithes were abolished, the rent of such farms as pay tithe would not rise to a level with the rent of those which are tithe-free, but the rents of the latter would fall to the level of the former. As raw produce is uniformly sold at its necessary price, or the price necessary to afford the customary rate of profit to the cultivators of the worst land, it would fall the moment they had been relieved from this heavy charge. And the advantage previously enjoyed by the proprietors of tithe-free lands, and which was the only cause of their obtaining a higher rent, being done away, their rents would decline to the level of those around them.

Tithes dimi-  
nish the  
Quantity,  
but increase  
the Value of  
Corn Rents.

If rents were uniformly paid *in kind*, the imposition of tithes would undoubtedly diminish the share of the produce paid to the landlord; but as its value would be increased in the precise proportion that its quantity had been diminished, this reduced share would continue to exchange for the same quantity of all other commodities. Thus, if lands of the qualities Nos. 1, 2, 3, &c. respectively produced, in return for the same expenditure, 100, 90, 80, &c. quarters, the rent of No. 1 would be twenty quarters, of No. 2, ten, and so on. But they would no longer preserve that proportion after the imposition of tithes; for, supposing a tenth to be deducted from their gross produce, the remaining quantities would be 90, 81, 72, &c.; and, therefore, the corn rent of No. 1 would be reduced to 18, and of No. 2 to nine quarters. It

is clear, however, that their money rents, or their rents estimated in any other commodity except corn, would not be at all affected. If corn sold at L. 4 before the imposition of the tithe, it would afterwards sell at L. 4, 8s. 10 $\frac{3}{4}$ d.; for, unless ninety quarters now brought as much as one hundred quarters previously brought, the cultivators of those soils, or the employers of those capitals which pay no rent, would not be able to realize the common and average rate of profit. Money rents would, therefore, continue unaltered; on the land No. 1, they would still be L. 80, and on No. 2, L. 40.

Taxes on  
Raw Pro-  
duce.

It appears, therefore, that in every state of society, whether rents are high or low, and whether they are paid in kind or in money, the charge of tithes is defrayed entirely by the consumers of raw produce. They do not consist of a portion of the rent of land belonging to the clergy, or the lay-impropriator; but they are a burden which falls equally on every individual in the kingdom—on the poorest beggar as well as the richest lord—in proportion to their respective consumption of the articles from which a tithe is levied.

But, independently of these considerations, the fact that tithes and other taxes on raw produce do not form a deduction from rent, but go to increase the price of produce, is obvious from the circumstance that the tithe of expensive crops, and which require a great expenditure in their cultivation, frequently amounts to four or five times the rent of the land. The Rev. Mr Howlett, by far the ablest advocate of tithes, and whose authority cannot, therefore, be questioned, informs us that the tithe of an acre of hops, raised on land worth 40s. or 50s. an acre, is, after deduction of drying and duty, generally worth from L. 3 to L. 4; and he farther states, that he had known L. 7 or L. 8 paid for the tithe of an acre of carrot-seed where the land was not worth 20s. In such cases, it is plainly as great an absurdity to affirm that tithes fall exclusively on the rent of the landlord, as it would be to affirm that a part is greater than a whole. Tithes cannot justly be objected to on the ground of their being a partial tax. It is a mistake to suppose that they are borne by any particular class. They are not a local but a general burden; and fall equally on the consumers of the tithed articles. Had the raiser of carrot-seed been relieved from the burden of tithes, he would have obtained precisely the same rate of profit by selling his produce for L. 7 or L. 8 less; nor, had such been the case, would it have been optional with him to have made this reduction; the competition of his neighbours would infallibly have forced him, whether he were so disposed or not, to make a corresponding diminution in his prices. (*Influence on Tithes on Agriculture*, p. 4.)

The Tithe  
frequently  
exceeds the  
Amount of  
the Rent.

An abolition of tithes is not, therefore, a measure in which landlords and farmers only are interested. It is obviously one of the greatest importance to the public in general. If 80s. be a remunerating price for wheat when tithes are levied, 72s. would be an equally high remunerating price were they remitted. When wheat sells at 80s., tithes, supposing them to be rigorously exacted, are really equivalent to a tax of 1s. a bushel, or 8s. a quarter. And as the average annual consumption of the different kinds of grain by each individual, when reduced to the standard of

Effect of  
Tithes on  
Prices.

Taxes on  
Raw Pro-  
duce.

wheat, has been estimated, apparently on good grounds, at a *quarter*, it follows, that when the medium price of wheat is 80s., a tithe on corn is really the same thing as a capitation tax of 8s.; and consequently constitutes an *item* of 40s. in the expenditure of every family of five persons.

But tithes are objectionable on other grounds. They are not a permanent and fixed tax, but they increase according as the difficulty of raising raw produce increases; and are infinitely more burdensome and oppressive in a year of scarcity than in a year of plenty. If the price necessary to afford a sufficient supply of corn were 60s. a quarter, the tithe would be equal to a direct tax of 6s. a quarter; but if, in consequence of being forced to resort to inferior lands, the increased difficulties of production had raised the price to 80s., the tithe would be 8s.; when prices rose to 100s., the tithe would be 10s., and so on. Nor is this all.—The tithe is not only increased in *value*, but it is also increased in *amount*, according as cultivation is extended. When land of the *first* quality, and which we have supposed would yield 100 quarters, was cultivated, the tithe would be 10 quarters: But after land of the *second* quality, and which only yields 90 quarters, had been cultivated, the tithe would be levied on 190 quarters: When land of the *third* quality had been cultivated, it would be levied on 100 + 90 + 80, or 270 quarters, and would go on progressively increasing, both in *value and quantity*, as fresh soils were brought under tillage.

“Not only,” says Mr Ricardo, “is the amount of the tax increased from 100,000 quarters to 200,000 quarters, when the produce is increased from one to two millions of quarters, but, owing to the increased labour necessary to produce the second million, the relative value of raw produce is so advanced, that the 200,000 may be, though only twice in *quantity*, yet in *value* three or four times that of the 100,000 quarters which were paid before.

“If an equal value were raised for the Church by any other means, increasing in the same manner as tithes increase, proportionably with the difficulty of cultivation, the effect would be the same. The Church would be constantly obtaining an increased portion of the *net* produce of the land and labour of the country. In an improving state of society, the net produce of the land is always diminishing in proportion to its gross produce; but it is from the net income of a country that all taxes are ultimately paid, either in a progressive or in a stationary country. *A tax increasing with the gross income, and falling on the net income, must necessarily be a very burdensome and a very intolerable tax.* Tithes are a tenth of the gross, and not of the net produce of the land; and, therefore, as society improves in wealth, they must, though the same proportion of the gross produce, become a larger and larger portion of the net produce.”\*

Tithe is certainly in one respect the same as rent; both the one and the other are portions of the produce of the soil converted into a revenue, for the sup-

port of those who bear no share of the trouble and expence of its cultivation. But in every other respect they are entirely dissimilar. Rent, when once fixed, must continue the same during the currency of the lease. Though an industrious and enterprising farmer should raise ten or twenty times the quantity of produce raised by a sluggard, his rent would not, therefore, be increased; and he would reap, as he ought, all the advantages of his greater industry and intelligence. Such, however, is not the case with tithes. To the sluggard they are invariable; to the industrious man they become more and more oppressive, and increase with every fresh outlay of capital and labour. It is indisputable, therefore, that in their practical effect, tithes operate as a premium on idleness, and as a heavy and constantly increasing tax on industry! By preventing the cultivator from deriving the full and entire advantage of superior skill and increased exertion, they discourage his efforts, and powerfully contribute to render him indolent, careless, and indifferent. A farmer pays his rent willingly to the landlord; but, he considers the clergyman as an interloper, who, without having contributed in any way to raise the crop, claims a *tenth* part of its *gross* amount. The occupier of a farm, subject to this galling and vexatious charge, can never be brought to consider himself as realizing the same rate of profit from the capital he employs, as his neighbours in tithe-free farms; and so strong is this feeling, that we are told by Mr Stevenson, the well-informed author of the *Agricultural Survey of the County of Surrey*, that it is the common opinion that a farm tithe-free is better worth 20s. an acre, than a tithed farm equally favoured in soil and situation is worth 13s. In this way, tithes contribute indirectly as well as directly to raise prices—indirectly by generating an indisposition to apply fresh capital to the improvement of the soil, and directly by the positive addition they make to the expence of cultivating bad land.

“Of all institutions,” says Dr Paley, who cannot surely be reckoned unfriendly to the real interests of the church, “adverse to cultivation and improvement, *none is so noxious as that of tithes.* A claimant here enters into the produce, who contributed no assistance whatever to the production—when years, perhaps, of care and toil have matured an improvement—when the husbandman sees new crops ripening to his skill and industry—the moment he is ready to put his sickle to the grain, he finds himself compelled to divide the harvest with a stranger. Tithes,” Dr Paley continues, “are a tax not only upon industry, but upon that industry which feeds mankind—upon that species of exertion which it is the object of all wise laws to cherish and promote.” (Paley’s *Works*, II. p. 105, ed. 1819.)

“Tithe,” says Dr Smith, “is always a great discouragement both to the improvements of the landlord and to the cultivation of the farmer. The one cannot venture to make the most important, which are generally the most expensive, improvements; nor the other to rear the most valuable, which are

generally, too, the most expensive crops, when the church, which lays out no part of the expence, is to share so largely in the profit. The cultivation of madder was for a long time confined by the tithe to the United Provinces, which, being Presbyterian countries, and, upon that account, exempted from this *destructive tax*, enjoyed a sort of monopoly of that useful dyeing drug against the rest of Europe. The late attempts to introduce the cultivation of this plant into England have been made only in consequence of the statute which enacted that 5s. an acre should be received in lieu of all manner of tithe upon madder." (III. p. 275.) As a farther illustration of the principle here stated, we may mention, that the cultivation of flax and hemp in Ireland never succeeded until a *low modus* had been fixed by law; since then it has made a most rapid progress.

Inquiry into  
the effect of  
Taxes on  
Raw Pro-  
duce on the  
Freedom of  
Intercourse  
between dif-  
ferent Coun-  
tries.

The effect of tithes and other taxes on the price of raw produce has been urged as a reason why an equal duty should be imposed on all such produce when imported from abroad. But all foreign corn imported must be paid either directly or indirectly by an exportation of some species of manufactured commodities; and it is, therefore, clear, that the home producers of corn can have no claim whatever to a protecting duty on the importation of foreign corn, unless the tithes, and other taxes falling on raw produce, exceed those which fall on manufactured goods. A tax which equally affects every description of products, leaves their relative values exactly where it found them. It does not render any particular class less able to withstand the unrestricted competition of foreigners than the others, and cannot, therefore, entitle them to a protecting duty. But if higher duties be laid on a particular class of commodities, the case is different. If, for example, while the duty on commodities in general is only 10 *per cent.*, a duty of 20 *per cent.* were laid on a particular class, their price must rise 10 *per cent.* higher than the price of the rest, in order to maintain their producers in the same relative situation as before. It is plain, however, that in the event of the ports being opened to the importation of every description of foreign goods free of duty, the producers of the heavily-taxed commodities will be deprived of the means of limiting their supply, and consequently of raising their price, so as to indemnify them for the excess of the tax. The 10 *per cent.* excess of duty would then really operate as a bounty on the importation of the class of commodities on which it is charged; and if it were not defeated by a protecting duty of 10 *per cent.*, the home producers of that class would be placed in a relatively disadvantageous situation, and would abandon their business.

But this principle only holds in the case of duties affecting manufactured products. If a direct tax of 10 *per cent.* were laid exclusively on the hats produced in England, and on no other commodity, the hatters would most likely be ruined were foreigners permitted to import hats duty free. Manufactured goods are produced under the same, or, at all events, under *very similar* circumstances; so much so, that foreign competition must either be injurious to all the manufacturers of a particular description of goods, or to none. But in agriculture the case is otherwise. Corn is produced under *very different*

circumstances, or from soils of very different degrees of fertility; and though the cultivators of the worst lands in tillage at any particular period might be injuriously affected by the unrestricted admission of foreign corn, the other cultivators, instead of being injured, would be really benefited by the rise of profit which must always follow every *permanent reduction* in the price of raw produce. Thus, suppose no duties are imposed on manufactured commodities, and that the ports are thrown open to the importation of foreign corn, without any protecting duty to balance the tithe—the whole effect of such a measure would be to cause such a small additional quantity of bad land to be thrown out of tillage as would enable the cultivators to obtain *eleven* quarters for the same outlay that had previously been required to produce *ten* quarters. As soon as this contraction of tillage had been effected, the farmers would have nothing to fear from foreign competition. They would still obtain the same rate of profit that was obtained by the undertakers of other businesses; and the consumers would be able to purchase their corn for *ten per cent.* less than if a protecting duty had been imposed.

But notwithstanding it is thus most certainly true, that the cultivators are always in a condition to relieve themselves of such taxes as affect them to a greater extent than they affect the other classes of society; yet, as they can only do this by contracting tillage and withdrawing capital from the cultivation of inferior soils, the effect of admitting foreign corn without a protecting duty equivalent to the *excess* of taxation affecting the home-growers, would be to cause a diminution of rent. We have already shown that rent consists of the difference between the produce obtained from the best and worst lands under cultivation; and if, by admitting foreign corn duty free, bad land should be thrown out of cultivation, the rent of the landlords would be reduced, and their relative situation lowered. Although, therefore, it is not necessary for the protection of the cultivators that any countervailing duty should be laid on raw produce imported from abroad; still, if it be really true that higher duties are laid on the raw produce raised at home than on manufactured goods, justice to the landlords requires that a duty should be laid on all foreign raw produce equivalent to the *excess of duty affecting home produce*. Such a duty, by fitting all classes equally to withstand foreign competition, will preserve them in the same relative situation after the opening of the ports as previously; and will treat all parties, as they ever ought to be treated, with the same equal and impartial justice.

To whatever extent a countervailing duty might be laid on a foreign commodity, it would be proper to give the home producers of the same commodity an equal, or nearly equal drawback. If the home producers were refused such a drawback, they might say, "Before your duty, and before the price of our produce was raised in consequence of it, we could compete with the foreign grower in foreign markets; by making the remunerating price of our corn higher, you have deprived us of that advantage, therefore give us a drawback equal to the duty, and you, in every respect, restore us to the position, both as it regards our own countrymen, as producers of other

commodities less heavily taxed, and foreign growers of raw produce, in which we were before placed." On every principle of justice, says Mr Ricardo, and consistently with the best interests of the country, this demand should be acceded to. (*On Protection to Agriculture*, p. 16.)

Mr Ricardo thinks that the tithes and other taxes exclusively affecting raw produce, over those affecting manufactured goods, may be taken at about 10s. a quarter; and he therefore proposes that foreign corn should be freely admitted on paying this duty, and that a drawback of 7s. should be allowed on exportation. "The duty of 10s. a quarter is, I am sure, rather too high as a countervailing duty for the peculiar taxes which are imposed on the corn-grower, over and above those which are imposed on the other classes of producers in the country; but I would rather err on the side of a liberal allowance than of a scanty one; and it is for this reason that I do not propose to allow a drawback quite equal to the duty." (*Ibid.* p. 80.)

The necessity of imposing this countervailing duty, originating, as it almost entirely does, in the imposition of tithes, affords another and a very powerful argument in favour of their abolition or commutation. Were tithes abolished, the protecting duty proposed by Mr Ricardo might be reduced to 3s. or 4s. a quarter, and the drawback to 2s. or 2s. 6d.

Taxes on raw produce, by raising the price of the articles required for the food of the labourer, necessarily raise wages and lower profits. Such taxes, therefore, fall with double weight on the capitalists; affecting them both as employers of labour, and as consumers. Indeed, the principal disadvantage of taxes on raw produce consists in their tendency to lower profits. "With a permanently high price of corn," says Mr Ricardo, "proportional wages would be high; and, as commodities would not rise on account of the rise of wages, profits would necessarily fall. If goods, worth L.1000, require, at one time, labour which cost L.800, and, at another time, the price of the same quantity of labour is raised to L.900, profits will fall from L.200 to L.100. They will fall not in one trade only, but in all. High wages equally affect the profits of the farmer, the manufacturer, and the merchant; nor is there any other way of keeping profits up than by keeping wages down. In this view of the law of profits, it is at once seen how important it is that so essential a necessary as corn, which so powerfully affects wages, should be sold at a low price; and how injurious it must be to the community generally, that, by prohibitions against importation, we should be driven to the cultivation of our poorer lands to feed our increasing population."

4. *Custom Duties, or Duties on the Importation and Exportation of Commodities.*—These, like all other duties, are paid by the consumers of the com-

Custom  
Duties.

modities on which they are laid. When a government lays a duty on the foreign commodities which enter its ports, the duty falls entirely on its own subjects who purchase such commodities; for the foreigners would cease supplying their markets with them, if they did not get the full price of the commodities exclusive of the tax; and, for the same reason, when a government lays a duty on the commodities which its subjects are about to export, the duty does not fall on them, but on the foreigners by whom they are bought. If, therefore, it were possible for a country to raise a sufficient revenue by laying duties on exported commodities, such revenue would be wholly derived from others, and it would itself be entirely relieved from the burden of taxation; except in so far as duties might have been imposed by foreigners on the commodities it imports from them! Care, however, must be taken in imposing duties on exportation, not to lay them on such commodities as can be produced at nearly the same cost by foreigners, for the effect of the duty would then be to put an entire stop to their exportation, by causing the market to be supplied by others. But when a country possesses any exclusive, natural, or acquired advantage, in the production of commodities, a duty on their exportation is really the most unexceptionable of all taxes. Such a duty would not fall upon itself, but upon its foreign customers; and if it were not carried so high as to balance the superior facilities of production, it would have only a very slight tendency to diminish the demand for the taxed articles. If the Chinese chose to act on this principle, they might derive a very considerable revenue from a duty on exported teas, which would have to be entirely paid by the English and other foreigners who buy them. And there is perhaps no country which does not possess some commodity demanded by foreigners that might not be advantageously charged with a moderate duty on exportation. The coal and tin, and probably also some species of the manufactured goods of Great Britain, seem to be in this predicament.

It was the great object of the professors of the mercantile system of political economy to facilitate the exportation of commodities of domestic growth, and to fetter and restrict the importation of those produced abroad; and it is to the prevalence of this system in modern Europe, and its influence on financial legislation, that we are to ascribe the almost total exemption of exported commodities from duties, and the ruinous extent to which they have been heaped on those that are imported.

Duties on imports and exports have been levied in almost every country which had any foreign commerce. The Athenians laid a tax of a fifth on the corn and other merchandise imported from foreign countries, and also on several of the commodities exported from Attica.\* The *portoria*,† or customs payable on the commodities imported into, and exported

\* Anacharsis's *Travels*, IV. p. 375, Eng. Trans. The quantity of corn usually imported from the countries on the Euxine into Athens amounted to about 400,000 medimni. See Clarke *On the Connection between the Roman and English Coins*, p. 58.

Custom Duties.

from, the different ports in the Roman empire, formed a very ancient and important part of the public revenue. They were imposed, as Tacitus has observed, when the spirit of liberty ran highest among the people. *A consulibus et tribunis plebis instituta, acri etiam populi Romani tum libertate.* (Annal. lib. 13, cap. 50.) The rates at which they were charged were fluctuating and various, and little is now known respecting them. Cicero informs us (Cic. in II. Ver. cap. 75), that the duties on corn exported from the ports of Sicily were, in his time, 5 per cent. Under the Imperial Government the amount of the *portoria* depended as much on the caprice of the Prince as on the real exigencies of the state. Though sometimes diminished, they were never entirely remitted, and were much more frequently enlarged. Under the Byzantine Emperors they were as high as 12½ per cent. (Burman, *De Vectigalibus Pop. Rom.* cap. 5, *passim.*)

Customs seem to have existed in England before the Conquest. But the King's first claim to them was established by statute of the 3d Edward I. The inconveniences arising from the multiplicity of the various separate acts relative to the customs, caused Mr Pitt to introduce a bill, in 1787, for their consolidation. This bill was passed into a law, and several similar consolidations have since been effected. The last was by a statute passed in 1819. To this statute are subjoined tables, containing lists, ranged in alphabetical order, of the various articles of import and export, with the duties payable on each, and the drawbacks and bounties allowed on the exportation of particular sorts of British goods.

Seignorage.

5. *Duties on the Coinage of Gold and Silver.*—For an account of the incidence and effect of these duties, the reader is referred to the article MONEY in this Supplement, cap. *Seignorage.*

Stamp Duties.

6. *Stamp and Legacy Duties.*—Stamp duties are duties laid on the paper or parchment, on which certain deeds, contracts, legal proceedings, receipts, acquittances, &c. are written. They are called stamp duties, from the paper being impressed with a public stamp, stating the amount of the duty. The ultimate incidence of these duties varies according to the nature of the deed or writing, for which it is necessary to use stamped paper. The duties payable on the sale of land, or on the paper used in its conveyance from one party to another, commonly fall on the seller. This arises, as Dr Smith has observed, from the circumstance of “the seller being almost always under the necessity of selling, which forces him to take such a price as he can get. The buyer is scarce ever under the necessity of buying; he will, therefore, only give such a price as he likes. He considers what the land will cost him in tax and price together. The more he is obliged to pay in the way of tax, the less he will be disposed to give in the way of price. Such taxes, therefore, fall almost always upon a necessitous person, and must, therefore, be frequently very cruel and oppressive.” (III. p. 318.) It is ob-

Duties on the Sale of Land generally fall on the Sellers.

vious that the same reasoning must hold in the case of the duties chargeable on the granting of mortgages; and that they will commonly fall on the borrower or poorer party.

Stamp and Legacy Duties.

This, however, is not the only objection to the imposition of duties on the transference of property. Both M. Say and Mr Ricardo have observed, that the tendency of such duties is to prevent property from coming into the hands of those who would use it most advantageously; and consequently to prevent the national capital from being distributed in the best way for the community. For the general prosperity, there cannot be too much facility given to the conveyance and exchange of all kinds of property, as it is by such means that capital of every species is likely to find its way into the hands of those who will best employ it in increasing the productions of the country. “Why,” asks M. Say, “does an individual wish to sell his land? it is because he has another employment in view in which his funds will be more productive. Why does another wish to purchase this same land? it is to employ a capital which brings him too little, which was unemployed, or the use of which he thinks susceptible of improvement. This exchange will increase the general income, since it increases the income of these parties. But if the charges are so exorbitant as to prevent the exchange, they are an obstacle to this increase of the general income.”\*

Disadvantage of Stamp Duties when they affect the transfer of Property.

Taxes on law proceedings fall upon the suitors; and consequently operate as a check to prevent an injured party from seeking redress in a court of justice. The impolicy, hardship, and injustice of such taxes, have been admirably exposed by Mr Bentham, in his *Protest against Law Taxes.*

Taxes on Law Proceedings.

Stamp duties, on the voluntary sale of all those articles which are the produce of human industry, fall, like all other taxes on such articles, wholly on the consumer; for, unless such were the case, the articles would not be offered for sale, subsequently to the imposition of the duties. Thus, the duties on cards and dice, on advertisements, newspapers, &c. are all paid by those who use them. Such, too, is the case with the stamp duties, payable on licences to retail any species of goods, or to exercise any profession. The taxed party invariably adds as much to the price of the articles in which he deals, or of the services which he performs, as is sufficient to indemnify him for the tax.

Stamp duties were first levied in Holland. Most of the accustomed methods of taxation having been resorted to, the Republic, in order to provide additional funds for carrying on her contest with the Spanish monarchy, offered a considerable reward to any one who should devise the best new tax! Among many other taxes, that of the *vectigal chartæ*, or stamp duty, was suggested; and having been approved of, it was introduced by an Ordinance issued in 1624, setting forth its necessity, and the benefits which it was supposed would result from its imposition. † Since that period, stamp duties have

Stamp and  
Legacy  
Duties.

become almost universal, and now form a very prominent branch of the revenue of almost every country; affording a striking example of the justice of Dr Smith's remark, that "There is no art which one government sooner learns of another, than that of draining money from the pockets of the people." (III. p. 317.)

Stamp duties were introduced into England in 1671, by a statute entitled, "An act for laying impositions on proceedings at law." The duties were at first granted for only nine years, and were afterwards continued for three years more, when they were allowed to expire. They were again revived in 1693, and have since been gradually and greatly increased.

*Legacy Duties*, or duties on the transference of property from the dead to the living, are now a very common species of tax. The *vicesima hereditatum*, or the twentieth penny of inheritances, imposed by Augustus on the Romans, is the earliest example of a tax on successions. Dion Cassius (lib. 55) informs us, that this duty was laid on all successions, legacies, and donations in case of death, except upon those to the nearest relations and to the poor. Pliny has given some of the reasons for this exception; in speaking of the *Vicesima*, he calls it *tributum tolerabile et facile hæredibus duntaxat extraneis, domesticis grave*. And a little after he adds, *Itaque illis (that is strangers) irrogatum, his (that is near relations) remissum, videlicet, quod manifestum erat, quanto cum dolore laturo, seu potius non laturo homines essent, distringi aliquid et abradi bonis, quæ sanguine, gentilitate, sacrorum denique societate meruissent, quæque nunquam ut aliena et speranda, sed ut sua semperque possessa, ac deinceps proximo cuique transmittenda, cepissent.* (*Panegyricus*, cap. 37.) In addition to these very cogent reasons for exempting the successions of near relations from the *vicesima*, it may be observed, that the death of a father is seldom attended with any increase, and frequently with a considerable diminution, of revenue to such of his children as live in the same house with him; and when this is the case, the burdening of his inheritance with a tax must plainly be a very galling and cruel aggravation of their loss. But, if taxes on successions are always paid with very great reluctance by the children and immediate relations of the deceased, it is quite otherwise when they fall to distant relations or strangers. Those on whom an unexpected or remote inheritance devolves, are glad to accept it on any condition; and uniformly pay such moderate duties as may be laid on it with greater good will than any other impost whatever!

England. In Great Britain, a duty of *one per cent.* is laid on all successions devolving either to the children, or to any lineal descendant of the children of the deceased, or to his father or mother, or to any of his lineal ancestors; a duty of *three per cent.* is charged on successions devolving to brothers and sisters; of *four per cent.* on those devolving to cou-

sins; and of *ten per cent.* on those devolving to strangers. Exclusive of this, a farther duty, varying according to the amount of the property left by the deceased, is also charged on the probates of all wills, without regard to the propinquity of the successors. This duty amounts, at present, to L. 11 on a property worth from L. 450 to L. 600; to L. 22 on a property worth from L. 800 to L. 1000; and to L. 180 on a property worth from L. 8000 to L. 10,000, increasing according to the farther increase of the property. This tax presses more severely on lineal successors, and is more objected to by them than the legacy duty.

The great objection to taxes on successions, or on transference of property from the dead to the living, consists in the circumstance of their falling wholly on capital, without occasioning any effort to replace it, either by increased exertion or economy. If a legacy of L. 1000 be subject to a tax of L. 100, the legatee considers his legacy as only L. 900, and feels no particular inclination to save the L. 100 from his expenditure; whereas, had he received the whole L. 1000, and been required to pay L. 100 in taxes on income or commodities, the desire to preserve his capital unimpaired would have prompted him to endeavour to defray the tax by increased industry and economy. The real advantage of the legacy duties consists in the facility with which they are collected; for by tending directly and necessarily to diminish capital, they are, in most other respects, extremely injurious.

7. *Postage of Letters*.—The conveyance of letters by post has, in almost all countries, been conducted by the agents of government; and it is one of the few industrious undertakings which appear to be better managed by them, than they could be by private individuals. This species of conveyance was originally established, and kept up by the Roman Emperors, for the safe, regular, and speedy transmission of the public dispatches to the most remote parts of their dominions; and such was also the purpose for which posts were first established in modern Europe, by Louis XI. Subsequently, however, private individuals were allowed to avail themselves of this institution, for the conveyance of their letters; and governments, by imposing higher duties, or rates of postage, on the letters and packages sent through the post-office than are sufficient to defray the expence of the establishment, have rendered it productive of a considerable revenue.\* Nor, while the rates of postage are confined within reasonable limits, is there perhaps a more eligible species of tax. The English post-office was placed on nearly its present footing in 1649, by the exertions of Mr Edmund Prideaux, Attorney-General to the Commonwealth.—(See Blackstone's *Commentaries*, I. p. 321.)

The limits within which this article must be confined will not allow us to enter at greater length into the inquiry concerning the incidence of taxes on commodities. We shall, therefore, proceed briefly to investigate their capacity to produce a revenue.

High and  
Low Duties.

SECT. III.—*Circumstances which determine the extent to which Taxes ought to be laid on Commodities—Causes of Smuggling—Means by which it may be prevented.*

Low Duties  
most Pro-  
ductive.

With regard to the capacity of a tax on a commodity to raise a revenue, it depends, *first*, on the nature and extent of the demand for the commodity; and, *second*, on the means of preventing its being smuggled. Every tax, by raising the price of the commodity on which it is laid, has a tendency to bring it within the command of a smaller number of purchasers, and to lessen its consumption. An individual who might be able and disposed to pay 1s. a bottle of duty on wine, might neither have the means nor the inclination to pay 2s. or 3s.; and instead of being augmented, the revenue might be diminished by such an increase of duty. And hence, whenever the duties on commodities are raised beyond a certain limit—a limit, however, which it is impossible to define, and which must necessarily vary according to the nature of the commodity on which the duties are laid, and the varying tastes and circumstances of society—their effect is to depress consumption to such an extent, as to render them less productive than if they had been lower.

Variations in the amount of the duties affecting commodities have exactly the same effect on their price, and consequently on their consumption, as corresponding variations in the cost of their production. But it is clear that any reduction in the price of commodities, whose natural cost is very considerable, and which can, therefore, be used only by the rich, could not have so powerful an effect, in increasing consumption, as would follow the same proportional reduction in the price of easily produced commodities in general demand. A reduction of 50 *per cent.* from the price of coaches would not add greatly to the demand for them; for, notwithstanding this reduction, they would still be luxuries, for which none but the rich could afford to pay; whereas, a reduction of 50 *per cent.* from the price of whisky, gin, beer, tea, sugar, or any article in general request, would extend the demand for it in a much greater ratio. The reason is plain:—The poorer classes form by far the most numerous portion of society; and as such commodities are even now partially used by them, a fall of 50 *per cent.* in their price would bring them fully within their command, and would thereby add prodigiously to their consumption. The truth of this observation may be strikingly exemplified by a reference to the case of cotton goods. At the Accession of his late Majesty, in 1760, the price of cottons, owing to the difficulty of producing them, was extremely high; and the value of the manufactured cottons annually brought to market did not exceed L. 200,000. But thanks to the genius and inventions of Hargreaves, Watt, Arkwright, Crompton, and others, the price of cottons has been so far sunk, as to bring them within reach of the poorest individual; and yet, such has been the vast increase of demand, that, notwithstanding this reduction of price, the value of the cottons annually manufactured in Great Britain, and either disposed of at home, or sent abroad, a-

mounts, according to the very lowest estimate, to the amazing sum of FORTY MILLIONS! It is obvious, however, that if cottons had been loaded with high duties; and if the same reduction in them, which has been brought about by the improvement in machinery, had been brought about by a reduction of the duties affecting them, precisely the same effects would have followed. The demand would have equally increased; and the greater consumption of the low taxed articles would have rendered the reduced duties more productive than the higher. Similar effects have uniformly followed from similar causes: low duties on commodities in general demand being invariably found to be more productive than when they are carried to a greater height—and more productive than high duties on commodities used only by the rich.

Besides diminishing the revenue by diminishing consumption, oppressively high duties tend to diminish it by encouraging and promoting the ruinously destructive trade of smuggling. The risk of being detected in the smuggling of commodities, under any system of fiscal regulations, may always be valued at a certain average rate; and whenever the duties exceed this rate, smuggling will be immediately practised. Now, there are plainly but two ways of checking this nefarious practice—either the temptation to smuggle must be diminished by lowering the duties, or the difficulties in the way of smuggling must be increased. The first is obviously the most natural and efficient method of effecting the object in view; but the second has been most generally resorted to. In the great majority of cases, governments have attempted to put down smuggling, without reducing the duties, by establishing a more vigilant system of collection, and by increasing the number and severity of the penalties affecting the smuggler. As might have been expected, these attempts have, in the great majority of cases, proved signally unsuccessful. And it has been, almost invariably, found, that no vigilance on the part of the revenue officers, and no severity of punishment, can prevent the smuggling of those commodities which are loaded with oppressive duties. The smuggler is generally a popular character; and though we have no desire to become the apologists of those who endeavour to defraud the revenue, and to injure the fair trader, it is idle to expect that the bulk of society will ever be brought to consider that those who furnish them with cheap tea, gin, whisky, brandy, &c. are guilty of any very heinous offence.

“To pretend,” says Dr Smith, “to have any scruple about buying smuggled goods, though a manifest encouragement to the violation of the revenue laws, and to the perjury which almost always attends it, would, in most countries, be regarded as one of those pedantic pieces of hypocrisy, which, instead of gaining credit with any body, seems only to expose the person who affects to practise them, to the suspicion of being a greater knave than most of his neighbours. By this indulgence of the public, the smuggler is often encouraged to continue a trade, which he is thus taught to consider as in some measure innocent; and when the severity of the revenue laws is ready

to fall upon him, he is frequently disposed to defend with violence what he has been accustomed to regard as his just property: and from being at first, perhaps, rather imprudent than criminal, he at last too often becomes one of the hardest and most determined violators of the laws of society."—(III. p. 378. See also Montesquieu, *Esprit des Loix*, liv. 13, cap. 8.)

A Reduction of Duties the only effectual means of preventing Smuggling.

To create, by means of high duties, an overwhelming temptation to indulge in crime, and then to punish men for indulging in it, is a proceeding completely subversive of every principle of justice. It revolts the natural feelings of the people, and teaches them to feel an interest in the worst characters—for such smugglers generally are—to espouse their cause, and to avenge their wrongs. A punishment which is not proportioned to the offence, and which does not carry the sanction of opinion along with it, can never be productive of any good effect. The true way to put down smuggling is to render it unprofitable—to diminish the temptation to engage in it; and this is to be done, not by surrounding the coasts with cordons of troops, by the multiplication of oaths and penalties, and making the country the theatre of ferocious and bloody contests in the field, and of perjury and chicanery in the courts of law, but simply and exclusively by *reducing the duties on the smuggled commodities*. It is in this, and in this only, that we must seek for an effectual check to smuggling. Whenever the profits of the fair trader become nearly equal to those of the smuggler, the latter is forced to abandon his hazardous profession. But so long as oppressively high duties are kept up, or, which is really the same thing, so long as a *high bounty* is held out to encourage the adventurous, the needy, and the profligate, to enter on this career, we may be assured, that an army of excise officers, backed by the utmost severity of the revenue laws, will be insufficient to hinder them. The truth is, that the too great severity of these laws prevents their execution. "It stimulates the trader to corrupt the officer to conceal a fraud; and it influences the officer to overlook what he would otherwise discover." (Hamilton *On the Principles of Taxation*, p. 244.)

Duties should vary directly as the Price of the Commodity.

Heavy duties on any description of commodities will occasion smuggling; but, it is chiefly caused by their being laid on commodities in general demand, whose natural or necessary price is not very considerable. It is commonly said, when a proposal is made for laying a heavy duty on a low priced article, that its lowness of price fits it to bear such a duty, and that, notwithstanding its imposition, it may still be brought to market at a sufficiently moderate rate. But the encouragement to smuggling depends more on the *proportion* which the duty bears to the price of the commodity, than on the circumstance of the duty being absolutely high or low. To illustrate this principle, let us suppose, that a taxed commodity, as soap, costs, exclusive of duty, 10d. a pound. If a duty of 1d. *per lib.* were laid on it, the inducement to smuggle would be equal to 10 *per cent.* of the value of the article, and if the duty were 2d. the inducement would be 20 *per cent.*, and so on. Now, let us suppose, that the cost of producing the soap, or its natural price, falls to 5d.: a duty of 1d. *per lib.* would then make an inducement to smuggle of 20

*per cent.* of its value, and a duty of 2d. would make an inducement of no less than 40 *per cent.*! And hence, it is obvious, that, in order to prevent smuggling, a system should be adopted, precisely the reverse of that which is generally followed in the imposition of taxes. Instead of making duties to vary *inversely* as the price of commodities, or of raising them when the natural prices of the taxed articles fall, and reducing them when they rise, they ought to be made to vary *directly* as these prices—to rise when they rise, and to fall when they fall. *Disproportionally* heavy taxes are the great cause of smuggling; and they have the farther and most injurious effect of preventing its being corrected by its natural and proper punishment, the *confiscation* of the commodities. Recourse is, in consequence, had to extraordinary pains and penalties, and all proportion of punishment being done away, "men who," as Montesquieu observes, "can hardly be considered as culpable, must be punished as atrocious criminals." (*Esprit des Loix*, liv. 13, cap. 8.)

Comparative Productiveness of High and Low Taxes.

Certain commodities, from their greater bulk, from their susceptibility of being impressed with a permanent stamp, or from any other cause, are less liable to be smuggled than others, and may, therefore, be loaded with comparatively higher duties. But as a general rule, it cannot be doubted, that, in order to prevent fraud, the duties should always be proportioned to the cost of the articles on which they are laid.

#### SECT. IV.—Comparative Productiveness of High and Low Taxes.

The arguments adduced in the foregoing *section* are sufficient to establish the superior productiveness of moderate taxes. But the subject deserves to be treated at greater length: and as the history of taxation, both in this and other countries, furnishes numerous direct, conclusive, and well established proofs of the same principle, we shall take this opportunity to bring a few of them under the notice of our readers. We shall class them under two different heads: the *first*, consisting of instances where-in a reduction of duty has been followed by an increase of revenue; and the *second*, of instances where-in an increase of duties has been followed by a diminution of revenue.

1. The effects produced by the reduction of the tea duties, in 1745 and 1784, are among the most striking examples of the superior productiveness of low duties on articles in general demand. Previously to 1745, the excise duty of 4s. a pound on tea yielded, at an average, about L.150,000 a year; which, had there been no smuggling or adulteration, would have shown that the consumption was equal to about 750,000 lbs. But it was well known that smuggling was then carried to a very great height, and that the real consumption of tea was much greater than the apparent consumption. To put a stop to this clandestine importation, a bill was introduced into Parliament in 1745, in pursuance of the recommendation of a Committee of the House of Commons, and passed into a law, by which the excise duty of 4s. was reduced to 1s., and 25 *per cent.* *ad valorem*. This measure was signally successful.

History of the Tea Duties.

Comparative Productiveness of High and Low Taxes. In 1746, the year immediately subsequent to the reduction, the sales of tea for home consumption amounted to above TWO MILLIONS of pounds weight, and the revenue was increased to L. 243,309! But to set the effects of this wise and salutary measure in a still clearer point of view, we shall subjoin an account of the net produce of the tea duties from 1743 to 1748, both inclusive.

In 1743 it amounted to	L. 151,959
1744	— — 147,065
1745	— — 145,630
1746 (Duties reduced)	243,309
1747	— — 257,937
1748	— — 303,545.*

But notwithstanding this unanswerable demonstration of the superior productiveness of low duties, they were again increased in 1748; and fluctuated, between that epoch and 1784, from 64 to 119 *per cent. ad valorem*. The effects which followed this inordinate extension of the duties are equally instructive with those which followed their reduction. The revenue was not increased in any thing like a corresponding proportion; and as the use of tea had become general, smuggling was carried to an infinitely greater extent than at any former period. In the *nine* years preceding 1780, above 118 millions of pounds weight of tea were exported from China to Europe, in ships belonging to the Continent, and about 50 millions of pounds in ships belonging to England. But from the best information attainable, it appears that the real consumption was almost exactly the reverse of the quantities imported; and that, while the consumption of the British dominions amounted to above 13 millions of pounds, the consumption of the Continent did not exceed  $5\frac{1}{2}$  millions! If this statement be nearly correct, it follows that an annual supply of about *eight* millions of pounds must have been clandestinely imported into this country, in defiance of the utmost vigilance on the part of the revenue officers. But this was not the worst effect of the high duties; for many of the retail merchants, who purchased tea at the East India Company's sales, being in a great measure beat out of the market, were, in order to put themselves in a condition to stand the competition of the smugglers, tempted to adulterate their teas, by mixing them with sloe and ash leaves.† At length, in 1784, ministers, after having in vain tried every other resource for the suppression of smuggling, resolved to follow the precedent of 1745, and reduced the duty on tea from 119 to  $12\frac{1}{2}$  *per cent.* This measure was as successful as the former. Smuggling and the practice of adulteration were immediately put an end to. The following official statement shows, that the *quantity* of tea sold by the East India Company was about *tripled* in the course of the *two* years immediately following the reduction!

In 1781, the quantity of tea sold at the East India Company's sales amounted to	5,023,419 lbs.	Comparative Productiveness of High and Low Taxes.
1782	— — 6,283,664	}
1783	— — 5,857,883	
1784 (Duties reduced)	10,148,257	
1785	— — 16,307,433	
1786	— — 15,093,952	
1787	— — 16,692,426 ‡	

While the quantity of tea sold at the Company's sales was thus rapidly augmenting in consequence of the reduction of the duty, the quantity of tea imported into the Continent from China, which had, in the year 1784, amounted to 19,027,300 lbs., declined with still greater rapidity, and, in 1791, was reduced to only 2,291,500 lbs.! §

The duties on tea, on an average of the five or six years preceding 1784, produced about L. 700,000 a year. And, at the same time that Parliament reduced them to  $12\frac{1}{2}$  *per cent.*, they laid an additional duty on windows, estimated to produce L. 600,000, as a *commutation* tax, to compensate the deficiency which it was supposed would take place to that extent in the revenue formerly derived from tea. But instead of the duties falling off in the proportion of 119 to  $12\frac{1}{2}$ , or from L. 700,000 to L. 73,000, owing to the increased consumption, they only fell off in the proportion of about *two* to *one*, or from L. 700,000 to L. 340,000! The commutation act has been always regarded, and with justice, as one of the most successful financial measures adopted in the course of Mr Pitt's administration. The plan was generally understood, at the time, to have been suggested by Mr Richardson, Accountant-General of the East India Company. But the popularity of the measure was so great as to induce several other individuals to claim this honour, and even to occasion some hot disputes on the subject in the House of Commons. In point of fact, however, the merit of having first suggested the plan did not really belong either to Mr Richardson, or to any of those who then claimed it; and such of our readers as will take the trouble to look into a pamphlet of Sir Matthew Decker's (*Serious Considerations on the Present High Duties*), published in 1743, will find that the measure adopted in 1784 had been strenuously recommended forty years before.

But the principle of the commutation act, and the striking advantage that had resulted from the reduction of the duty, were soon lost sight of. In 1795, the duty was increased to 25 *per cent.*; and after successive augmentations in 1797, 1798, 1800, and 1803, it was raised, in 1806, to 96 *per cent. ad valorem*, at which it continued till 1819, when it was raised to 100 *per cent.* Now, although it cannot be disputed that the duty on tea yields, at present, a vastly greater revenue than was derived from it in 1795, there are the strongest possible reasons for believing that the revenue would have been considerably greater,

\* Hamilton's *Principles of Taxation*, Appendix, No. 19; and Postlethwaite's *History of the Revenue*, p. 293.

‡ Macpherson's *Commerce with India*, p. 416.

§ *Ibid.* p. 210.

Comparative Productive-ness of High and Low Taxes. had the duty not been carried so high. The quantity of tea sold by the East India Company in 1795 and 1796 amounted to very nearly 20 millions of pounds a year, and in 1799, to very nearly 25 millions of pounds (24,853,508). Since then, there has been *no increase*. For, according to the account given in the *Lords' Report on the East India Trade* (p. 334), the average quantity of tea sold at the Company's sales in 1818, 1819, and 1820, is rather under 25 millions of pounds a year. But the population of Great Britain, which is ascertained by the late census to amount to 14,379,000, amounted to only 10,817,000 in 1800; and had there been no diminution of the individual consumption of the Company's tea in the interval between these enumerations, their sales ought plainly to have been increased in the proportion of 10,817 to 14,379, or from 25 to 33 millions of pounds. Nor is this all. The sales made by the East India Company supply the markets of Ireland as well as Britain; and, if we take into account the extraordinary increase of population in that part of the empire, the diminution of consumption will appear still more striking. But, notwithstanding the Company's sales have thus continued stationary since 1795, it is, we believe, pretty generally admitted, that the individual consumption of tea, or rather of the compound sold under its name, has not been considerably diminished in the towns, while it has increased greatly in the country since that epoch. It is plain, however, that this increased supply can have been obtained only by clandestine importation, or adulteration; and, as there was no opportunity of smuggling during the latter part of the war, and as the powerful force that has been employed in the preventive service since the return of peace, must have rendered it extremely difficult to import any considerable quantity of foreign tea, we should be disposed to conclude, that the vacuum, caused by the high duties, has been chiefly supplied by adulteration,—and such, we find, is really the case. There is, indeed, every reason to think that the practice of adulterating by the intermixture of ash and sloe leaves, and by drying tea that has been already infused, and mixing it with fresh tea, is carried to a greater extent at this moment than in 1784. In proof of this, we may mention, that, in London, in 1818, upwards of twenty grocers were convicted of having spurious tea in their possession. And it is worthy of remark, that in the case of the *King v. Owen*, the counsel for the defendant declared, that *the practice was so general, that his client was not aware of the existence of any law by which it was forbidden!* Since then, several additional convictions have taken place; but it is not in the nature of things that the evil can be materially diminished by such means. If we are really desirous of putting a stop to the practice of adulteration, we must follow Mr Pitt's example, and take 50 or 60 *per cent.* from the present duties. The experience of the effects of the reductions in 1745 and 1784, enable us confidently to predict, that such

Comparative Productive-ness of High and Low Taxes. a reduction would not be followed by any corresponding diminution of revenue; while, besides putting an instant stop to smuggling and adulteration, it would be a considerable boon to the lower classes, to whom tea is now become an article of prime necessity, and would powerfully contribute to extend our commerce with China.

We have been thus particular in noticing the variations in the tea duties, because the Company's sales afford the means of ascertaining the precise effect of their increase and diminution on consumption. The results are both curious and instructive; and would of themselves be sufficient to establish the truth of Dr Swift's observation, that, in the arithmetic of the Customs, two and two do not always make *four*, but sometimes only *one!*

The narrow and contracted policy on which most ministers have generally acted, puts it out of our power to refer to many such conclusive instances as the reduction of the tea duties in 1745 and 1784, to prove the superior productiveness of diminished taxation; there are, however, one or two others which deserve to be pointed out. In 1742, the high prohibitory duties upon spirituous liquors, and upon licences for retailing the same, were abolished, and such moderate duties imposed, to commence after Lady Day 1743, as were expected to increase the revenue by increasing the legal consumption of spirits. This measure was vehemently opposed by the Bishops; but their opposition was ineffectual; and the increase of the duties, and diminution of smuggling which followed, proved that the measure was alike advantageous to the revenue and to the morals of the people. (*History of our Debts and Taxes*, Part IV. p. 110.) In 1787, Mr Pitt reduced the duty on wine and spirits 50 *per cent.* and the revenue was, notwithstanding, considerably *augmented*. Perhaps, however, the progress of the duties on coffee illustrates this principle in a still more striking manner. In 1805, they were raised a *third*, and that year their produce *fell off* an eighth instead of increasing a third; in 1806, they had increased only a *sixteenth*, so that the consumption had diminished above a fourth. But it was at length found that the tax had been overdone, and it was lowered from 2s. to 7d. the cwt. Mark the immediate effects of this step. The average annual produce of the high duty for the three years, previous to 1808, when it was lowered, was L.166,000; and the average annual produce of the reduced duty for the next three years was L.195,000—a proof that the consumption had been increased in a *quadruple* proportion.\*

The history of other countries abounds with equally conclusive examples of the superior productiveness of moderate duties. In 1775, M. Turgot deducted a *half* from the customs and other duties chargeable on the fish sold in the Paris market; but, notwithstanding this reduction, the amount of the duties collected was not diminished. The demand for fish must, therefore, have been doubled, in con-

\* Mr Brougham's *Speech on the State of the Nation in 1817*, p. 57.

Comparative sequence of the inhabitants being enabled to supply themselves, at a comparatively cheap rate, with a nutritious and agreeable food.\*

In 1813, all sugar imported into the French empire paid a duty of one franc sixty cent. the *livre* or pound. The quantity imported that year amounted to about fourteen millions of pounds, which, as France, and the countries then incorporated with her, contained about forty-two millions of inhabitants, gives the *third* part of a pound weight to each. In 1814, this exorbitant duty was reduced to about a *fifth* part, or to thirty cent. the pound; and, though the population of France had now been reduced from forty-two to about twenty-eight millions, the average annual importations of 1814 and 1815 amounted to forty-four millions of pounds, being upwards of a *pound and a half* to each individual; or about *FIVE times as much as the consumption had amounted to under the high duty*. In consequence of this increase of consumption, the low duty yielded very near as large a revenue as the high duties; and, since 1815, both consumption and revenue have continued to increase. (*Richesse des Nations*, par Garnier, V. p. 304, 2de Ed.)

Ustariz gives a variety of instructive details respecting the disastrous effects which the levying of certain taxes have had on the industry of the Spaniards, and of the advantage which has resulted from the repeal and modification of others. We shall give a single example. Valencia, he tells us, though very barren of grain and flocks, and not equal in extent to two-thirds of Arragon, paid *a much larger revenue to the Royal Treasury*. He says, that this was owing to the comparatively flourishing state of commerce and manufactures in Valencia; and he then adds—"This increase and improvement in manufactures and commerce is ascribed to the equitable and kind treatment the weavers receive in that province, and to his Majesty's goodness in *reducing the excessive taxes* which were charged upon *flesh meat and other provisions*; and his taking off wholly that which was laid on *bread* in ancient times; as also, the imposts known by the name of *ancient duties and generalities*. These duties were partly replaced by others, but in such a manner that they were rendered much lighter, the people in general eased, and the royal revenue improved." †

2. But the superior productiveness of low duties on articles in general request may be equally shown from the consequences of the attempts to increase them beyond their proper limits. The history of the sugar duties is, in this respect, extremely important. In the three years from 1803 to 1806, the former duties were increased about *50 per cent.* Now, the average produce of the old duties, for the three years before that rise, was L. 2,778,000. The produce of 1804, after they had been raised *20 per cent.*, was not L. 3,333,000, as it ought to have been, had the

consumption remained the same, but only L. 2,537,000, being L. 241,000 *less* than the produce of the low duty; and the average produce of 1806 and 1807, after the whole *50 per cent.* was added, was only L. 3,133,000, instead of L. 4,167,000; which it should have been had there been no falling off since 1804. Thus, both consumption and revenue declined, in consequence of the increase of duty in 1804; and the consumption has declined, in consequence of the succeeding augmentations, while the revenue has gained very little. ‡ The duties on leather, after being stationary for nearly a century, were *doubled* in 1813. In 1812, the low duties produced L. 394,000; but, instead of being doubled, or of producing L. 788,000, when the tax was doubled, the annual revenue has scarcely ever since exceeded *half a million*, and has frequently fallen short of that sum.

The duties on foreign wines have been *tripled* since 1792. The last increase took place in 1815, when L. 30 *per ton* was added to the former duty on French, and L. 20 to that on Portuguese wine. Now, observe what has been the effect of this increase of duty. In the *Second Report* of the Lords' Committee on the Silk and Wine Trade (ordered by the House of Commons to be printed, 28th June 1821), a series of accounts are given, showing the quantity of wine imported into Great Britain, and re-exported, for a considerable number of years past, and the amount of the duties. From these accounts, we have drawn up the following Table of the number of tons of wine imported into Britain from 1809 to 1820, both inclusive; the number of tons re-exported during the same period; and the quantity remaining for home consumption.

	Tons imported.	Do. re-exported.	Remains for Home Consumption.	Average annual Consumption during the five years previous to 1815.
1809	49,762	14,501	35,261	Tons.
1810	47,058	12,729	34,329	
1811	20,787	5,928	14,864	
1812	35,082	6,716	28,366	
§ 1813	—	—	—	Do. for five years subsequent to 1815.
1814	31,465	11,838	29,627	
1815	30,874	5,855	25,019	
1816	18,218	5,163	13,055	
1817	27,073	4,457	22,616	
1818	35,763	4,021	31,742	
1819	23,408	3,843	19,565	
1820	22,782	4,625	18,157	21,027
Average annual diminution of the consumption of wine for the five years subsequent to 1815, as compared with the five preceding years,				7,462

\* Say, *Traité d'Economie Politique*, Tome II. p. 339. Lord Kames, in his *Sketches of the History of Man*, states, that these duties amounted to *48 per cent. ad valorem*. Vol. II. p. 406. Edit. 1788.

§ The Records for the year 1813 were destroyed by fire.

Comparative Productiveness of High and Low Taxes.

Comparative Productiveness of High and Low Taxes.

Thus, it appears, that the increase of the duties on wine in 1815 has occasioned a diminution in the consumption of 7462 tons a year, or of ONE-FOURTH part of the total quantity annually consumed, on an average of the *five* years preceeding the increase. Let us next see whether any augmentation of revenue has taken place to balance this diminution of the comforts of the people, and the loss of the market for the products which were previously exchanged for the wine.

From a Table in the same *Report* (p. 78), it appears that the produce of the duties of *excise* on the wines consumed in England from 1810 to 1820, both inclusive, has been as follows:

		Average annual duty for the five years previous to 1815.
1810	L. 1,406,417	L. 1,162,382
1811	1,215,507	
1812	1,065,159	
1813	1,061,604	
1814	1,065,223	
1815	1,277,481	Do. for the five years subsequent to 1815.
1816	943,987	
1817	928,473	
1818	1,195,427	
1819	1,085,500	
1820	949,328	L. 1,020,540

The *average* drawback, as given in the same Table, for the five years previous to 1815, is L. 63,674; and for the five years subsequent to 1815, L. 48,676; and, deducting these sums from the above, we have L. 1,098,708 for the amount of the average annual *excise* duty on wine for the five years preceeding 1815; and L. 971,867 for the average annual amount of that duty for the five years after it had been increased about 20 *per cent.*; showing that the revenue, instead of being augmented, has sustained a *diminution* of L. 126,841 a year by this increase of duty.

The effect of the increase on the Custom duty has been equally striking. The accounts laid before Parliament do not go farther back than 1814; but in that year the *low* Custom duties amounted to L. 1,061,416. In 1816, the *high* duties only amounted to L. 780,238; and except in 1818, when they amounted to L. 1,056,894, they have never since reached *one million*.

It is unnecessary to make any commentary on this decisive statement. The facts we have brought forward prove, beyond all question, that the revenue, the comforts of the people, and the commerce of the country, have all been *diminished* by this inordinate extension of the duties; and entitle us to conclude, that they would be all increased by their diminution.

There are, perhaps, no better objects of taxation than spirituous and fermented liquors, and none in which the injurious effects of over taxation are more

striking and obvious. They are essentially luxuries; and while moderate duties on them are, in consequence of their being very generally used, exceedingly productive, the increase of price which they occasion has a tendency to limit their consumption by the poor, to whom, when taken in excess, they are extremely pernicious. Few governments, however, have been satisfied with the imposition of moderate duties on spirits; but, partly with the view of increasing the revenue, and partly with the view of placing them beyond the reach of the lower classes, they have almost invariably loaded them with such oppressively high duties as have entirely defeated both objects. The imposition of such duties does not take away the appetite for spirits; and as no vigilance of the officers, or severity of the laws, have been sufficient to secure a monopoly of the market to the legal distillers, the real effect of the high duties has been to throw the supply of a large portion of the demand into the hands of the illeite distiller, and to superadd the crimes and vices of the smuggler to those of the drunkard.

Nowhere, perhaps, have these injurious consequences of the excessive increase of spirit duties been more distinctly manifested than in Ireland. In proof of this, we may mention, on the authority of the *official* statements in the *Fifth Report*\* of the Commissioners of Inquiry into the State of Irish Revenue (p. 19), that in 1811, when the duty on spirits was 2s. 6d. *per* gallon, duty was paid in Ireland on 6,500,361 gallons; while in 1822, when the duty was 5s. 6d., only 2,950,647 gallons were brought to the charge. The commissioners estimate the annual consumption of spirits in Ireland at about *ten* millions of gallons; and as scarcely *three* millions pay duty, it follows that *upwards of SEVEN millions are illegally supplied*; and "taking *one* million of gallons as the quantity fraudulently furnished for consumption by the licensed distillers, the produce of the *unlicensed stills* may be estimated at *six millions of gallons!*" (p. 8.) It is material, too, to observe, that this extraordinary increase of smuggling took place in defiance of the utmost efforts of the revenue officers, police, and military, to prevent it. The only result of these efforts being the exasperation of the populace, and the committal of atrocities, both by them, and those employed in the collection of the revenue, that are hardly to be matched in the annals of civil warfare. "In Ireland," say the Commissioners, "it will appear, from the evidence annexed to this *Report*, that *parts of the country have been absolutely disorganized, and placed in opposition not only to the civil authority, but to the military force of the Government.* The profits to be obtained from the evasion of the law have been such as to encourage numerous individuals to persevere in these desperate pursuits, notwithstanding the risk of property and life with which they have been attended." (p. 1.)†

\* Printed, by order of the House of Commons, 30th May 1823.

† The revenue and morals of no country, perhaps, have suffered so much from the injudicious extent to which taxes have been laid on commodities in general request as Ireland. This, however, is a subject on which our limits will not permit us to enter more at large; but our readers will find most of the necessary information in an article on High and Low Taxes in No. LXXII. of the *Edinburgh Review*.

Duties on Spirits.

Comparative Productiveness of High and Low Taxes.

Increase of Spirit Duties in Scotland.

Reduction of the Spirit Duties in Ireland and Scotland.

Duty on Spirits in England.

Salt Duty in France.

The too great height to which the duties were carried, and the injudicious mode in which they were charged and collected, produced similar effects in Scotland. The system of illicit distillation made great progress of late years, and had the most injurious influence on the morals and industry of the people in the mountainous districts, where it was principally carried on.

Such having been the effects of their excessive increase, we have great satisfaction in stating, that the duties on both Scotch and Irish spirits have been reduced during the last session of Parliament (sess. 1822—23), from 5s. 6d. per gallon to 2s. 9d. Leave has also been given to use stills of a much smaller size,—a regulation which will have the effect of enabling minor capitalists to engage in the business of distillation, and which, by increasing competition, will tend both to improve the quality and to reduce the cost of the spirits. The country is indebted for this change of system to the recommendations in the excellent *Reports* of the Commissioners on Irish Revenue. It will certainly go far to suppress smuggling; and there is every reason to expect that the greatly increased consumption of *legally distilled* spirits, which the reduction of the duties will occasion, will make it have the same beneficial effects on the revenue as the reduction of duties in 1743 and 1787.

In England, the duty on spirits is as high as 10s. 6d. a gallon; and the trade in spirits between it and the other divisions of the empire is prohibited. This system is liable to many objections; but owing to the decided preference given by the lower classes in England to malt liquors over spirits, it has not given so great a stimulus to smuggling and illicit distillation as might have been expected.

The revenue collected within the United Kingdom on spirits distilled from grain, and the number of gallons on which it was paid in the year 1822, were respectively as follows:

	Revenue.	Gallons.
England .....	L.2,749,372	L.5,222,094
Scotland .....	687,467	2,499,880
Ireland.....	811,428	2,950,647
Totals...	L.3,248,267	L.10,672,621*

In France, previously to the Revolution, the average annual consumption of salt, in the provinces subjected to the *grande gabelle*, or high duty on salt, was estimated by M. Necker, who had the best means of coming to a correct conclusion, at  $9\frac{1}{8}$  lib. to each individual; and at 18 lbs. in the *pays redimées*, or provinces that had purchased an exemption from the greater part of this hateful tax. (*Administration des Finances*, Tom. II. p. 12.) It is evident, from this well authenticated statement, that a very great reduction might have been made from the duty paid on the salt consumed in the heavily taxed provinces,

without occasioning any diminution of revenue; while, besides directly increasing the comforts of the people, it would have relieved Government from the necessity of surrounding particular provinces with cordons of troops, and would have put an instant stop to that smuggling of salt, which occasioned the sending of between 3000 and 4000 persons every year either to prison or to the galleys. (Arthur Young's *Travels in France*, Vol. I. p. 598.)

Taxation of different Countries.

SECT. V.—Method of Comparing the Amount of Taxation in Different Countries—Circumstances which Depress the Rate of Profit—Its Fall in this Country rather a Consequence of the Corn Laws and of Tithes, than of Taxation.

It has been usual to endeavour to ascertain the relative weight of the public burdens of different countries by comparing them with their population. But this is obviously a most false and erroneous criterion. In proof of this, we may observe, that, if the amount of population in a country were a true test of its capacity to bear taxes, it would follow that Ireland, which has a population of seven millions, could afford to pay three times the amount of the taxes paid by Scotland, which has only a population of two millions. So far, however, from this being the case, the actual revenue of Scotland is very little less than that of Ireland; and yet there is no reason whatever to think that the pressure of taxation is felt more severely here than amongst our neighbours.

Amount of Population not a proper test of the ability of a Country to bear Taxes.

The amount of the capital belonging to different countries has been suggested as a test by which to ascertain the relative weight of their burdens. But this would also lead to the most erroneous results; for, it is plain that a small capital in a country where profits are high may be more productive than a large one in a country where profits are low. The market rate of interest, which is always proportional to the customary rate of profit, is at this moment only about 4 or 5 per cent. in England, while it is not less than 8 or 10 per cent. in the United States. One million of capital laid out in America must, therefore, be about as productive, that is, it must yield about as large an annual income as two millions laid out in this country. And, hence it is obvious, that, if taxation, as compared with the amount of capital, were the same in both countries, it would, as compared with the profits on revenue derived from that capital, be about twice as heavy in England as in America.

Amount of Capital not a proper test.

It is not, therefore, by the amount either of the population or the capital of a country, that its capacity to bear taxes is to be determined. Taxes, as we have already shown, really consist of a portion of the incomes of individuals transferred from the public to the State; and hence, to determine whether they are relatively higher or lower in one country than in another, it is necessary to ascertain the respective incomes of the States to be compared together, the number of their inhabitants, and the amount of their

The relative Taxation of Countries to be learned by comparing their Incomes with the number of their Inhabitants and their Burdens.

burdens. Supposing, for example, that the income of Great Britain, which has fourteen millions of inhabitants, is three hundred millions of pounds Sterling, which is believed to be very near its actual amount, and that its taxes, including poor rates, tithes, and public burdens of every description, amount to seventy millions, this sum deducted from the former would leave two hundred and thirty millions, which would give a free income of L. 16, 9s. a-year to every individual in the empire: Suppose, now, that the income of France is four hundred and fifty millions, and that the aggregate amount of her taxes, and public burdens of every description, is fifty millions, the four hundred millions of remainder, when divided among a population of thirty millions, would only leave a free income of L. 13, 6s. to each. There is good reason to think, that these estimates are not very wide of the mark: we do not, however, give them as being correct, for in such matters it is impossible to attain to any thing like accuracy; but as illustrations of the method to be followed in comparing the burdens laid on different countries; and as showing that, in proportion to her means of paying, a country with a small population, and a large absolute amount of taxes, may be really less heavily taxed than a country with a much larger population, and a smaller absolute amount of taxes.

vary inversely as wages—that they fall when wages rise, and rise when wages fall. Now, as the labourer must always have wherewithal to subsist and continue his race, it is plainly impossible to go on constantly adding to the price of the articles necessary for his subsistence, either by forcing him to purchase in dearer markets, or by loading them with taxes, without, at the same time, raising his wages and depressing profits. It is undoubtedly very difficult to say how much of the decline of the rate of profit in this country is to be ascribed to the effect of taxes laid on the necessaries of life, and how much to the corn-laws and other restrictive regulations. But that these laws must have a powerful influence in this respect is abundantly clear; for, in ordinary years, their effect is to maintain the price of corn in this country at nearly *double its elevation in any other country!* Tithes also contribute to raise the price of corn; and as corn, though not the sole, is the main regulator of wages, we are inclined to think that it is to the combined operation of the corn-laws and tithes that the decline in the rate of profit in this country is chiefly to be ascribed.

Circumstances which  
have de-  
pressed the  
rate of Pro-  
fit.

The depression in the rate of profit—a depression which can only proceed either from heavy taxes on the necessaries of life, or from the effects of monopoly enhancing their price, or both—is by far the most unfavourable symptom in the economical situation of this country. The common and ordinary rate of profit is the sum which usually remains to those capitalists who employ their stock in productive businesses, after all their outlays, including a premium for the insurance of the capital itself, are compensated. It is by its amount, therefore, that the productive powers of industry are to be estimated. Wherever the rate of profit is relatively high, as in the United States, there is a proportional power of accumulation; and, provided the right of property be well secured, the capital, and, of course, also the population of the country, increase with comparative rapidity: But in countries such as Holland, where the rate of profit is relatively low, there is but little power of accumulation; and not only is their progress in wealth and population proportionally slow, but there is, besides, a very powerful motive to transmit capital to those countries where it is more productive. It is plainly, therefore, of the utmost consequence that the rate of profit, in every country, should be maintained at as high a level as possible. This, however, can only be effected by allowing the labourer to purchase his food in the cheapest market, and by exempting, as far as it can possibly be done, the necessaries of life from taxation: For we have shown, \* that profits always

are those which, with the exception of tithes, fall heaviest on necessaries, and consequently exercise the greatest influence on profits. We think we are entitled to conclude, from the preceding investigations, that a very considerable reduction might be made in the amount of the duties affecting them, without occasioning any decrease, and even with a positive increase, of revenue. At all events, it is clear that the public interests imperiously require that every practical effort should be made to lighten the pressure on the national resources, and to check the efflux of capital to other countries, by adding to the productive powers of industry, or, in other words, by increasing the rate of profit. And this will be most effectually done by making every possible deduction from the taxes affecting necessaries, and by ceasing to bolster up and protect any single species of industry at the expence of the rest.

Tables illustrative of the progress of the public revenue of Great Britain have been given in Postlethwaite's and Sir John Sinclair's *Histories of the Revenue*, Chalmers's *Comparative Estimate*, Dr Colquhoun's *Treatise on the Wealth and Resources of the British Empire*, and a variety of other publications. We subjoin a copy of the Parliamentary paper (No. 157, Session 1822), which gives an account of the *gross* and *net* aggregate revenue of the united kingdom for the year ending 5th of January 1822, at the same time that it exhibits the amount of each separate branch of revenue in England, Scotland, and Ireland, and the expences of its collection. (s. s.)

\* Art. POLITICAL ECONOMY in this *Supplement*, Part III. Sect. 5.

TAXATION.

A Return of the Gross and Net Amount of the Revenue of the United Kingdom, in the year ending the 5th January 1822, for England and Wales, Scotland and Ireland; distinguishing each Country, and stating the Amount of the Charges of Management, and the Rate per cent. on the Gross and on the Net Receipt under each distinct Head of Revenue.
