## ENCYCLOPÆDIA BRITANNICA.

### N A I

*Nairnshire.* **N**AIRNSHIRE, a small county in Scotland.

*Situation and Extent.* It is situated between  $57^{\circ} 22'$ , and  $57^{\circ} 40'$  north latitude, and  $3^{\circ} 35'$ , and  $4^{\circ} 7'$  west longitude, having the Moray Frith on the north, Morayshire on the east and south, and the county of Inverness on the west. Its extent, from north to south, is from 12 to 20 miles, and from east to west from 10 to 13; and its contents are 198 square miles, or 126,720 English acres, of which only about a fourth part is in cultivation; the rest consisting chiefly of wastes, with about 10,000 acres of wood, natural and planted, about three square miles of lakes, and a small proportion of moss. It has only four entire parishes, Ardclauch, Aultdearn, Calder, and Nairn, and portions of other five, which belong to the counties of Moray, Ross, and Inverness. Two detached districts, Ferintosh and Dunmaglass, belong to Nairnshire, the former lying near Dingwall, in Ross-shire, and the latter at the head of Strathnairn, in Inverness-shire.

*Surface, &c.* Along the Moray Frith, and for a few miles inward, the surface is generally low, and much of the soil productive, being partly loam, and partly clay, both of them fertile. Farther south the country rises into hills, containing but a small proportion of arable land, and this chiefly a sandy loam or gravel. The only streams of any note are the Nairn and the Findhorn, both of which it receives from Inverness-shire. They have a nearly parallel course from south-west to north-east. The former flows into the Moray Frith, at the town of the same name, but the

latter, before entering the Frith, passes into the Nairnshire. county of Moray. The Nairn is, therefore, the only river which can be said to belong to this county, and it is inconsiderable; but its banks are in many places well wooded, and it has a small salmon-fishery. Marl is found in several places, particularly on the estate of Lord Cawdor, in the vale of Litie, where it is of an excellent quality; and in the same quarter, and at Kilravock, there are some quarries of sandstone.

The territory of Nairnshire, exclusive of the lands belonging to the burgh of Nairn, is divided into fifteen estates, of which nine are under the valuation of L.500 Scots, other three under L.2000, and the remaining three above L.2000; and a few years ago the number of freeholders entitled to vote in the election of a member for the county was 22. The valued rent is L.15,162, 10s. 11d. Scots, of which about one-sixth is entailed; and the real rent, in 1811, was, for the lands, L.11,725, 14s. Sterling, and for the houses L.216. The principal seats are Cawdor Castle,—Lord Cawdor; Kilravock Castle,—Rose; Boath,—Dunbar; and Kinsterie,—Gordon.

This county is further subdivided into farms, for the most part small, and, with few exceptions, open, and ill cultivated, producing oats, bear or bigg, and potatoes, but very little wheat. Turnips and clovers do not yet enter into the usual course of crops. Its live stock presents nothing worthy of particular notice. Though the natural circumstances of the dis-

Naples.

Towns.

Representa-  
tion, &c.

trict do not seem to be very different from those of the contiguous county of Moray, except that it has no harbours, yet its rural economy is greatly behind that of the latter county.

Nairn, the county town, and a royal burgh, is a place of considerable antiquity, and pleasantly situated; but having no harbour, it is without trade or manufactures, and contains only about 2000 inhabitants. According to a survey made by Mr Telford, a commodious harbour may be formed for about L. 3000. The villages are Aultdearn and Calder.

This county sends a member to Parliament alternately with the shire of Cromarty; and the town of Nairn joins with Inverness, Forres, and Fortrose, in the election of a member for the burghs. The counties of Moray and Nairn are under the jurisdiction of the same sheriff, who has a substitute for the latter county in the town of Nairn.

Nairnshire formed a part of the ancient province of Moray. On the estate of Lord Cawdor, at a place called the *Hoar Moor*, Macbeth, according to Shakespeare, met the witches when upon his way from the Western Isles to Forres; and a bedstead, said to be that on which Duncan was assassinated by the usurper, is still preserved in the Castle of Cawdor. Near the village of Aultdearn, Montrose obtained a great victory over the Covenanters in 1645. The county contains the ruins of several castles, and other remains of an early age. The Castles of Calder or Cawdor, and Kilravock, both of great antiquity, are still the seats of their proprietors.

The population of this small county is shown in the following abstract.—See *The Beauties of Scotland*, Vol. IV.; *Leslie's General View of the Agriculture of Nairn and Moray*; *The General Report of Scotland*; and *Playfair's Description of Scotland*, Vol. II. (A.)

**NAPLES.**—The history of Naples, down to the period when Bonaparte bestowed its sceptre on Murat, is given in the *Encyclopædia*; where also will be found a general description of the country. The succeeding historical events of any importance will be found under the articles AUSTRIA and FRANCE, in this *Supplement*; and there is some notice of its statistics, under the general article on ITALY. The present article is limited to the late Revolution; of which, and of its issue, the Editor has received the following account from the pen of an intelligent Neapolitan.

The last revolution of Naples, although it ended unexpectedly, without advantage or honour to the nation, is very remarkable, if we consider the political death (if we may so speak) to which Italy had been doomed during three centuries, not only as

a power, but as a people; and when we recollect that this was the first political movement which, for seventy years, merited the name of a national one in Italy. It was attempted and brought about, not foolishly to benefit foreigners, and with foreign troops, according to the old custom of the Italians, but for Italian interests, and with Italian forces.

On the fall of the French empire, Murat was expelled by the Austrian arms from the throne of Naples, and Ferdinand restored (May 1815). The condition of the new government, though at first sight promising, was beset with great difficulties. The Bourbon ministers found, on their return from Sicily, that an immense power had been usurped by the Crown, during the French government, the period of which was now called the *Decennio*. All aristocratical hierarchy, all municipal franchises,

Naples. were destroyed. From the highest affairs of state, down to the meanest municipal concern, the prince ruled every thing by a host of public functionaries. But all this authority was supported solely by a standing army organized by the French, which the king did not trust; and by a revenue of 16,000,000 of ducats, which, having been only derived from the rapacity of the French financier, had, at the end of ten years, become intolerable. They found, besides, the dispositions of the people very much changed. The Neapolitans, who seldom liked their governments, had grown more than ever indifferent to the person of their prince, reluctant to submit to absolute power, and well aware of the only effectual remedy to restrain its abuse. But a cause, more powerful than all these, assisted in imbuing their minds with the principles of liberty. A political association, known by the name of *Carbonarism*, had sprung up, and experienced various fortunes under the French. At first it was despised, because its real object was yet misunderstood; it was afterwards fiercely persecuted by Murat, and finally caressed in vain by his ministers, who sought in it a support to his tottering throne. But such a forced retraction of his former steps availed Murat nothing in adversity. The nation was alienated from him, and hoped to gain by a change of princes. King Ferdinand had, in a proclamation from Palermo, promised a constitution, by which the people should be the *sovereign*, and the prince a mere *depository of the laws*. Murat, vanquished and despairing, attempted to throw out a lure to the Neapolitans, by causing a constitution to be proclaimed a few days before the Austrians occupied that capital. Chevalier Medici had now succeeded to Count Zurlo, and alone governed the state. This minister felt no blind party prejudices against reforms that had arisen out of the revolution. His objection was solely that of ministerial interest. Esteeming the Neapolitans to be unsteady in their wishes, he would not shock their political opinions, but rather strove to delude and rule, without satisfying them. Every thought of the new minister was bent upon finance; for the new government had assumed the discharge of enormous responsibilities. The negotiators for King Ferdinand, at the Congress of Vienna, were forced almost to redeem his crown from Austria, at a time when so much noise was made by the allies about the doctrine of legitimacy and restoration. They bargained to pay 6,000,000 of ducats to the imperial treasury; 1,150,000 ducats a year for the support of the Austrian troops in the kingdom; and 1,200,000 ducats to Beauharnois, ex-viceroy of Italy, for indemnities due to him by Austria. The disgraces and burdens imposed upon the nation did not stop here. Naples became tributary even to Rome and to the piratical states of Africa. Rome would not consent to satisfy the conscience of the king without a Concordat, by which an annual revenue of 12,000 ducats in land was assigned to the Roman treasury: thirty-six convents were re-established and richly provided for by the state. The ordinary administration was no less tainted with prodigality. Medici, following the example of France,

Naples. endeavoured to prop the immense authority of the crown with the order of public functionaries left by the French, who were so numerous, and so closely bound together, by their opinions and interests, that they resembled a new aristocracy. Hence the public offices, which already pressed so heavily upon the nation, far from being reduced, were daily augmented. From all such causes resulted a government that was passive, but rapacious. The prime minister seemed to govern only to raise taxes. The French imposts, chiefly the land-tax, which had been always burdensome to the nation, now caused general complaints, on account of the extreme depreciation of corn and oil, attendant upon the peace of Europe. These chief products of a country entirely agricultural, now scarcely brought a third of the price which they had held a few years before. Yet for a small profit of the treasury, foreign merchants were allowed to import their corn into the kingdom, where it sold at a very low price, and almost entirely interrupted the sale of home wheat. The distress augmented in a short time to such a pitch, that in Apulia, the old harvest was often thrown into the sea to make room for the new one in the granaries. The land proprietors, rich and poor, remonstrated with the government, and offered to discharge the imposts with the very products of the soil; and these soon becoming unequal to taxes and culture, the lands began to be abandoned—a lamentable, but certain mark of the rapacity of the government and of an approaching revolution. The country was overspread with internal custom-houses from one borough to another, for external trade yielded little; contraband commerce increased, and the amount of the loss was surreptitiously overcharged upon the lands. The most trifling transactions were committed to stamped paper, and registered. In short, every expedient, however ruinous, was esteemed good, provided it could afford immediate money. By such means the public revenues were in three years stretched to more than 20,000,000 of ducats; but, for this augmentation, the subject was wrung, moderately speaking, of half his real income, at a time when the national industry was sinking into a state of unprecedented wretchedness. This fiscal delirium could not have lasted long. The farmers were impoverished, the middle classes were reduced to despair; discontent rapidly spread into the provinces, and the general wish for a reform was little dissembled. Carbonarism, checked only for a time by the denunciations against all secret societies, which followed the restoration, now rose in double strength. But an event, which had once threatened its extermination, contributed even more to its revival. The minister of police, the Prince of Canosa, detesting the very name of French innovation, designed to force back the nation to the state in which it had been ten years before. He considered the Carbonari as *Muratites*, or partisans of the French, whilst they are only votaries of liberty and enemies to despotism, by whomsoever exercised. The seeds of another sect adverse to Carbonarism had been sown since the time of the French by a bishop, who was an enemy to their government. This was composed of a

Naples.

species of loyalists, the dregs of the people, chiefly rioters, who had participated in the counter-revolutionary massacres of 1799. They assumed the name of *Calderaj*. The minister of police exerted all his influence to rally them with mysterious rites and signs, and to arm as many of them as he could. In a little time their numbers exceeded 60,000, and they were generally believed to be ready to fall upon the Carbonari or Murattites on the night of Holy Thursday 1816, and, renewing the example of the Sicilian vespers, to massacre them all over the country. The minister, thus become master of the state, could have reformed it according to his own will. But the horrible plot was soon discovered; and Medici, who professed quite different politics, and was then all powerful, caused the minister of police to be banished to Lucca. Thus Medici saved his country from a dreadful civil war; the new sectaries were easily disarmed, and soon sunk into oblivion. But the Carbonari, who were aware of their danger, and had united more closely than ever, would no more separate, after having once rallied for their common defence. Nay, three years were sufficient to draw into their association all the active part of the people, and to convert the rest to their political religion. Whether by the lapse of time, or by the recent example of the free constitution of Sicily having been overturned at one blow, it had become evident that the promise from Palermo was mere state-craft to hasten the fall of Murat. The patriots, judging themselves strong enough in the provinces of Lecce and Bari, reminded the king of his pledge, with bold and reiterated remonstrances; and demanded a constitution, together with the repeal of the land-tax, within a certain term. These petitions being disdained, the town of Lecce rose in a commotion (1817), and nothing was wanting to a revolution but support from the other provinces. But the cause of Carbonarism was yet neither so strong nor so unanimous as it became soon afterwards. A new sect had sprung from it, which seemed to incline more to democracy, and was much spread among the lower classes of people in the provinces of Lecce and Bari. This sect, by introducing licentiousness and violence in popular opinions, divided and enfeebled the party, and soon became odious to the best intentioned of the patriots. On the first news of General Church having marched with some troops against Lecce, a few hundreds of the new sectaries took to arms, and overran the country in bands. The Government commander easily diverted or quelled this insurrection. By dexterously availing himself of the discord of the patriots, and showing the moderate they had nothing to fear from him, he succeeded in amusing a great many, and subduing the rest. All the armed were proscribed, many fell in the field, and several were put to death, or confined in the Sicilian islands. But discontent had crept even into the army. Most of the military having been trained by the French, when there were no bounds to fortune and honour in their profession, were impatient of the restored government, which used soldiers only to keep down the people. Besides, the mal-administration of the war minister (a German officer), the penury of the finances, the jealousy of the Austrians, and

Naples.

the partiality of the king towards the military who returned with him from Sicily, had greatly injured the army, and divided it into two adverse parties. This hostile disposition was soon turned to the national advantage by some patriotic chiefs, the principal among whom was William P  p  . This general had been disposing affairs for a revolution, during two years that he held the military command in the provinces of Foggia and Avellino. He had formed there no less than 10,000 militia, chiefly composed of small land-proprietors, armed and clothed at their own expence, and commanded by the country gentlemen, who were exasperated against the rapacity of the administration. Such a militia was well qualified for accomplishing a revolution; yet they were tolerated by the prime minister, on account of the great services, without any expence, he drew from them; for they had, in a short time, scoured the country of the banditti, who are ever swarming in that kingdom. Thus to save money, arms were entrusted to that very class which was most interested in national reform. So capital an error of despotic policy may well characterize the administration of Medici as entirely financial. Every thing, therefore, hastened to a revolution, when the news arrived of the movement at Cadiz. This example banished from the multitude all remaining doubts as to success. It taught the chiefs how to act; and in a natural spirit of imitation, they chose the constitution of the Cortes for their model. This constitution, moreover, seemed to be the only monarchical one fixed at one effort by the representatives of a great nation, and still unimpaired by the abuses of power and time. The patriots now began earnestly to think upon a general movement. William P  p  , considered as the chief of the enterprise, communicated his plan to some superior officers of his division, and a few citizens. They agreed that the general should, under pretence of a muster, assemble, on the 25th of June (1820), his 10,000 militia at Avellino, where he was to be immediately reinforced by five regiments of horse quartered at Foggia, Nola, Nocera, Aversa, and Naples, and by all the armed patriots of the two Principati and Capitanata: a camp was then to be formed, and a petition sent to the king, demanding the constitution. The signal being thus given, no doubts were entertained of a general and ready support from all the provinces. But owing to the want of resolution of one colonel, this plan failed. The general, judging it convenient to delay his design for a short time, went to Naples, where he had been repeatedly called by the government. But, in these perplexities, Morelli, a young lieutenant, unexpectedly departed from Nola, on the night of the 1st of July, with 130 horse, and, marching to Avellino, threw down the gauntlet. The revolution had been long since ripe in the minds of the Neapolitans, and the departure of Morelli was only the signal for its accomplishment. At the first intelligence of his march, Foggia, Avellino, and Salerno, took up arms, and proclaimed the Spanish constitution. An intrenched camp was formed by the constitutionalists in the strong passes of Monteforte, and thither the militia, the patriots, and most of the

Naples. standing army, flocked from all directions. General P  p   having defeated the precautions of the cabinet, by which he was still obstructed in the capital, led some more troops to the camp, and took the command of the whole. The government, awakened from its slumber, had already attempted force. Generals Carrascosa and Ambrosio were sent with some troops against the constitutional camp, whilst Generals Campano and Nunziante were to attack it rearwards from Solofra. But all proved vain. Campano was bravely repelled by the constitutionalists, led by Colonel Deconcilj. Carrascosa, perceiving the majority of his troops more inclined to join their comrades than to fight against them, would not hazard a battle. The government, now despairing of succeeding by force, recalled him, and prepared itself to satisfy the nation. The court, indeed, made a last effort to divert the storm by a royal promise of a constitution to be settled *in eight days*. But this state-expedient could not deceive men to whom no choice was left but between the scaffold and success:—The proposal was refused. The capital was in commotion. The King, yielding to the entreaties of his oldest friends, consented at last to the constitution of the Cortes. Secret protestations, however, are said to have been addressed from that very moment to the five great powers of Europe, ascribing that concession to mere force, and invalidating it in all its consequences.

The whole of this revolution was brought about in six days, with a facility and mildness that proved the public mind to be ripe for free institutions. But the royal personages were not so easily consoled for their loss of power. The king showed this, by resigning the government to his son Prince Francis, who assumed the title of Vicar of the Kingdom. The constitutional camp, 15,000 strong, was raised at Monteforte, and marched to the capital. Many errors were committed in that camp. An egregious one had been to intrust power to persons whose lives and fortunes were not staked on the revolution. Fortune no sooner seemed leaning to the side of the constitutionalists, than the disappointed ambitious spirits of *the decennio* awoke, and laid hold of the first places of the state. Count Zurlo, who had persecuted the patriots, and who had seconded various changes of power and principles, reappeared at the helm of the state. His colleagues had been, like him, the courtiers of Murat, and little cared for the new liberty of their country, if it was to be preserved at the cost of their personal danger and sacrifices. Almost all the offices, civil and military, were left in the possession of a set of men accustomed to change sides from the vanquished to the vanquisher. A revolution which had been thus defective in decision at home, was farther menaced from abroad. Austria soon evinced a profound resentment at the revolution of Naples, both by diplomatic protestations, and by rejecting the new Neapolitan envoys as the representatives of rebels. From the beginning these true patriots had no other chance of success than to have invited all Italians to arms, while the Austrians were still weak in Lombardy. But the new government had not courage for this, and the

opportunity for raising Upper Italy by surprise had nearly vanished, when the unfortunate revolution of Sicily broke out.

Naples. Sicily is the only country in Italy where the feudal aristocracy is still strong. This island had escaped French subjection to fall under that of the English, who here combated Bonaparte with the principles of liberty. Nevertheless the Sicilian constitution, given in 1812, left the power of the House of Commons in the hands of the nobility. But even the few benefits which could have accrued from English ascendancy were lost by the constitution being abolished as soon as it could be dispensed with. Medici attempted, in 1819, to introduce the French administration into Sicily, but the nobles generally resisted such innovations, and the people, through inveteracy against the rule of the Neapolitans, supported their resistance. After the revolution on this side the Pharum, the Spanish constitution had scarcely been proclaimed at Palermo, when the chief Sicilian nobility instigated the people to proclaim Sicily independent of Naples. The Neapolitan garrison of Palermo being furiously attacked by the mob, and overwhelmed with stones, boiling oil, and other missiles thrown from the houses, surrendered at discretion after a dreadful contest. But the Sicilian nobility, after they had allured the people by the promise of independence from Naples, wherewith they covered their design of re-establishing the aristocratic constitution, found that it was easier to raise than to guide a sedition. For the people proclaimed independence, and the constitution of the Cortes cut off the heads of Princes Aci and Catolica; and even whilst following their aristocratic leaders, menaced them with the axe. At last General Florestan P  p   was sent into Sicily with a squadron and 6000 troops. He landed at Messina, defeated the revolted Palermitans at Termini, and obliged Palermo to capitulate, delivering the city from a state of the most frightful anarchy. But that capitulation, which yielded to the independents the separation from Naples, which they had been unable to get by force, was soon annulled by the Neapolitan Parliament. The general was recalled, new troops were sent out, and Palermo was held neither in friendship nor enmity. The majority of the Sicilians, however, seemed to decide the question against independence by sending deputies to represent them at Naples.

The Parliament had now assembled at Naples, and received, on the 1st of October, the constitutional oath of the king. The liberty of Naples was to depend upon this assembly. The Spanish constitution had been granted, excepting the necessary alterations to be settled by the representatives in its adaptation to the Two Sicilies. Yet, at the bottom of this proviso from the court lay a design to increase, as much as possible, the constitutional power of the Crown by a servile Parliament. The ministry had endeavoured to influence the elections; but the name of Zurlo was so unpopular, that the slightest suspicion of interference had been sufficient to exclude a candidate, whatever might be his experience in public affairs. The people, suspecting the nobility of a wish to introduce an hereditary chamber in

Naples.

the constitution, had hooted them off the hustings. Owing to this national disposition, the Parliament had been mostly composed of men who had never exercised any public office. The majority of them were of an upright rather than firm mind; some were versed in literature, none in state-craft; many ignorant of every thing, trusting more to the justice of the public cause, and to the effects of mildness towards the Crown, than to their own intrepidity and credit with the people. The Parliament applied itself to the diminution of the public burdens, though the military expences had nearly exhausted the treasury; chose a new council of state; made good municipal laws; and reorganized the army. At first it was well seconded by the nation. The dismissed veterans flocked spontaneously back to their banners on the first call of the government, and soon exceeded the number demanded. The Calabrese militia gallantly supported the army in Sicily. Several provinces paid in advance the very land-tax which they felt so heavy. But the ministry made all this useless to the state. Every step of the executive power betrayed slackness, reluctance, and perfidy; in a word, it destroyed the liberty and independence of Naples. The court looked for support to that mysterious alliance which styles itself *Holy*. A congress had met at Troppau, where an independent people were to be sentenced for having offended against despotism. The Parliament, guessing the design of the court, applied itself to a speedy reform of the constitution, that it might be finally sanctioned by the king. The prospect of eluding the effects of the revolution in a pacific way being over, a *coup-d'état* was resorted to; and some members of the diplomatic body then at Naples agreed with Zurlo upon the manner and time of the new experiment. It was known by the public that the congress at Troppau had ended, and much uneasiness prevailed for some days in the capital. On the 7th of December, a royal message was brought into the Parliament by the ministry, in which a vague and conditional promise of a new constitution was substituted for the existing one. It was announced that the king was going to a new congress, and all farther deliberation was forbidden to the representatives. The message was at the same time placarded in the capital, and forwarded into the provinces, and every practice was employed to carry the point by surprise. But all this only tended, for the present, to the triumph of the nation. About 15,000 patriots assembled in arms, and remained together for three days, ready to repel force by force, if necessary. Speedy intelligence was dispatched into the country, and many places rose in arms at the same time. The Parliament, being thus supported, rejected the message, but permitted the king to go to Laybach, provided he should do so to plead the national cause. Then an impeachment was moved against the ministry, and two were called to the bar (Count Zurlo and the Duke of Campochiaro); but the cabal of the courtiers prevailing, it was adjourned *sine die*. The king, after declaring he never meant to injure the existing constitution, asked again for the opinion of the Par-

Naples.

liament as to his departure. A new consent was given, and the king embarked aboard an English man-of-war, landed at Leghorn, and proceeded to Laybach.

The departure of the king, to join the enemies of the nation, proved, no doubt, the immediate cause of the fall of Naples, and all Europe has reproached the Neapolitan Parliament for permitting it, as a signal act of blindness. But an English and a French squadron were anchored in the bay; 6000 royal guards were ready to fall upon the people; and the facility of embarking from the palace, and, above all, the firm resolution of the king himself, leave it even now doubtful whether that fatal departure could have been prevented. Certainly a new revolution would have been necessary for this attempt, and the Parliament decided according to what it conceived to be an unavoidable necessity. Yet the virtual failure to the enemies of freedom of their last *coup-d'état* was worth a victory to the patriots, had they fully known the value of it. The court was humbled, the credit of the Parliament re-established; and the representatives could have still saved the state, had they, during the flow of popular feeling, created a regency of a few tried and bold patriots. By transferring the seat of government to Calabria or to Messina, they ought to have prepared themselves, from that very moment, to have sustained a national war. But the Parliament was incapable of such counsels, which appeared to them rash and unconstitutional. *Moderation* was their motto. This assembly continued the regency to the Prince-Royal; suffered a weak ministry to succeed to a perfidious one; and slumbered in the capital, attending only to the reform of secondary abuses, while they trusted the cause of the country to the mediation of the king with the allies. Not having availed itself of the favourable moment, its credit and power decayed daily, and the national zeal abated simultaneously. These public perplexities lasted but a short time. The Parliament had already presented, and the Regent had finally sanctioned, the reformed code, when intelligence arrived that the Congress of Laybach had declared, that whatever had been done by the revolution was to be instantly undone at Naples, and that 50,000 Austrian troops were marching to occupy the country, and re-establish its despotic government. These *orders* were enforced by a letter from the king, in which his majesty, alleging the utter impossibility of obtaining anything from the allies, eagerly advised a ready obedience to them. The Parliament declared that it had no power to consent to the public ruin, and that the king was to be considered as a prisoner in the hands of the enemy. This was its last effort. Laws, indeed, were heaped upon laws for the safety of the state; but the circumstances requiring practical courage far more than debates and statutes, all that was done proved useless. Even whilst the danger grew imminent, the representatives did not dare to assume the whole public power. They were still frightened by the shadow of a compact, which had been already broken by the most responsible of the parties.

The effect of the news from Laybach was, to pro-

Naples.

duce mixed feelings of apprehension and indignation. The inhabitants of the provinces seemed disposed to defend themselves to the last; but they wanted experience and guides. A numerous militia had but just been formed in all the provinces, and 12,000 young men composed a national guard of an imposing appearance in the capital. But these militia, yet destitute of all military skill and habits, could only serve in a desultory warfare. Of the standing army 12,000 men remained in Sicily, in order to keep it in subjection; the rest were already cooled in the public cause, discordant in their opinions, rather relaxed in discipline, through the introduction of Carbonarism, and certainly not commanded by patriots. The Carbonari, too, fancying they had secured the revolution by the meeting of the Parliament, began to divide among themselves. Carbonarism never could settle itself into a federation before the revolution, and much less after it. Hence the upper council of Naples, which ought to have represented the whole order, and directed it to the same object, was not acknowledged in several provinces, and openly opposed in Salerno, where the opinions rather inclined to democracy. The consent of this council, which at first was required to establish inferior assemblies, was soon neglected. New societies sprang up everywhere. Indeed, all these dissensions were diligently promoted by money, promises, and every wicked practice of the agents of despotism at home and abroad. Confusion and anarchy were made pretexts both to colour and facilitate foreign invasion. After the revolution, Carbonarism ought no doubt to have been abolished by law, as dangerous to liberty itself, had the free government had nothing to fear. But this government, being undermined on one side, and attacked on the other, could not have found, in its early period, a better support than that association. The patriots of the frontier provinces attempted to rally themselves into a federation, which they called the *Samnitic League*, from the classic name of that country. But the society of the Carbonari was no longer susceptible of being recombined; and it must be confessed, that its untimely dispersion was another cause of the shameful fall of Naples.

Meanwhile an Austrian army, 50,000 strong, advanced by forced marches towards the country. The government, compelled at last by the public clamour, hastily called, by telegraph, the militia from the most distant points, when the enemy was already reaching the frontiers. The militia hastened from every quarter, but only 15,000 had arrived on the borders of Abbruzzo, when it was found necessary to fight. General P  p   was appointed to command that frontier. Near San Germano, on the left, was an entrenched camp of 30,000 men, most of them veterans who had served in the French wars. The plan of defence was, that, if the enemy attacked the right, the commandant of the left was to relieve it with troops and evolutions; if the left, P  p   should do the same. But the distance between the two camps was immense. General P  p  , with some militia and a few troops, which together did not amount to a third part of the enemy's forces, was obliged to guard a line

of 150 miles in length, and accessible at five points. And the Austrian general, as it appeared afterwards, had directed the main body of his army upon him, well aware that that corps once routed, no more resistance would be offered on the left. P  p   posted himself at Civita-Ducale, a frontier town in Abbruzzo, three miles from Rieti, where the enemy established his van-guard. The Neapolitan militia, then on the frontier, was composed chiefly of substitutes, badly armed and worse trained, and incessantly harassed by traitorous agents, who represented to them that they should be treated as rebels, if they vainly persisted in opposing the great powers of Europe allied against Naples. The king himself followed the Austrians close, declaring he was at full liberty, and ordering the national forces to welcome the invaders as friends. On a sudden, some battalions of militia, posted at Arguata and Tagliacozzo, disbanded. General P  p  , dreading the example, resolved to fight instantly. Having distributed his 10,000 men in three columns, he advanced towards Rieti on the 7th of March 1821. His left, led by Marshal Montemajor, was to begin the attack at day-break; but it was ten in the morning before the order was executed, and the Austrians had already concentrated most of their forces near the Cappuccini in the plain, when they were attacked. P  p   ordered Marshal Russo to advance at the same time on the right with 200 horse and some infantry, to sustain the charges of the Hungarian cavalry, 4000 strong. The fight continued for six hours with musketry, and the Neapolitans had made several unsuccessful attempts to carry the Cappuccini, when Montemajor suddenly began to withdraw with his division, an hour before sun-set. The enemy, who till then had been perplexed by the unexpected boldness of the militia, having now his right disengaged by the retreat of Montemajor, pushed forward great masses of infantry on his left, which being extended farther than the right of the Neapolitans, threatened to surround them. P  p   was then obliged to order a general retreat, which began in good order along his whole line, under the fire of the enemy. But the militia not being trained to retreat while fighting, began to get into disorder; and, breaking their ranks, they hurried to the hills, without any longer obeying their officers. Some companies of the line, which were intermixed with them, imitated the example, and all the troops speedily disbanded. But a few hundred soldiers, headed by a body of gallant officers, covered the retreat in such a way that the enemy was scarcely aware of the disbanding, and did not advance for that night.

This engagement was sufficient to decide the fate of Naples. The Parliament, astonished and discouraged at this first blow of adversity, laid aside all thoughts of farther defence, and secretly sued for pardon from the king, whom they had but just declared to be a prisoner of the enemy. The executive power, which only waited for a single disaster to throw off every constitutional disguise, immediately strained all its nerves to accomplish, in a few days, the subjugation of the country. More shame than loss,

Naples.

Invasion of  
the Aus-  
trians, and  
Overthrow  
of the New  
Government.

however, had been incurred; and had a patriotic ministry guided the helm, the nation might have been saved, or would have sunk with honour. To transfer the seat of government into Calabria without delay; to remove the yet unbroken first corps from San Germano into the middle provinces, and to collect behind them all the remnants of the corps of Pépé, there to be rallied into a second line,—were measures that seemed as practicable as they were advisable. Under such arrangements, the arrival of the enemy in the capital might have proved the commencement of his ruin. An immense town, and four citadels held by national forces; the almost impregnable fortress of Gaeta behind; an army 30,000 strong on the front; with Calabria in insurrection, and the Parliament calling to arms a people generally sanguinary and revengeful;—these were obstacles almost insuperable against the success of the invaders. Moreover, the Piedmontese revolution breaking out soon after, would have placed the Austrians between two fires, and spread the national war from one extremity of Italy to the other. Thus the Italians would have been perhaps at this hour an independent and free nation, or at least fighting to become so. But scarcely six days had elapsed from the action at Rieti, when the commandants of the divisions and regiments in the camp at San Germano were required, by an order of the day, to frame addresses in the name of the army, to the general-in-chief, requesting him to support we know not what authority of the regent, different from the constitutional one. The army was given to understand, that the capital and several provinces had fallen a prey to anarchy, while they remained as if plunged in stupor and consternation. The first plan of the court seems to have been to march the first corps to Naples, and to put down the constitution with the same national forces which had sworn to defend it. But as a strong feeling of reluctance was evinced by some regiments,

the royal guards were directed to protest openly against all resistance to the king, and this had the effect of dispersing the rest of the troops. The first corps had scarcely decamped from Mignano, and begun to retreat towards the Volturno, when suddenly it disbanded. The royal guards only, 6000 strong, were kept to their banners. Marching speedily to Naples, they shut themselves up in the fortress of Castelnovo, and began to fire upon the citizens. All was confusion in the capital. The Parliament lost more than half of its members, and all its authority. The mob only waited the arrival of the disbanded soldiers to run to plunder and outrage; whilst murderers were let loose upon the most determined patriots, to prevent them from making any effort to retrieve the public fortune. One member, who had the courage to set out for Calabria, in order to rally the broken ranks of the patriots, was put to death upon approaching Eboli, by assassins, who there waited his arrival. Twenty-four other members remained in the Parliament to the last, appealing against perjury and foreign injustice, and offering an honourable but useless example to their country. In a few days, the fortresses, the arsenal, the ammunition, the navy, the capital, Sicily, and whatever yet remained to the nation for its defence, was delivered up to the Austrians by the executive power. Of the patriots, hunted down in all directions, some took shelter in Spain, Greece, and the Ionian Islands, but the greater number fell into the hands of their enemies. The nation, forsaken by its guides, was struck with astonishment, and made no defence.

With regard to the actual state of the Two Sicilies, it is enough to say, that all the injustice and miseries which can fall upon a conquered people, punish their inhabitants for not having better defended their most valuable rights. Oppression, however, cannot consolidate that absolute power, which has no longer a foundation in the national sentiments.

## NATIONS, LAW OF.

Ideas involved in the term Law.

IN the meaning of the word Law, three principal ideas are involved; that of a Command, that of a Sanction, and that of the Authority from which the command proceeds.

Every law imports, that something is to be done; or to be left undone.

But a Command is impotent, unless there is the power of enforcing it. The power of enforcing a command is the power of inflicting penalties, if the command is not obeyed. And the applicability of the penalties constitutes the Sanction.

There is more difficulty in conveying an exact conception of the Authority which is necessary to give existence to a law. It is evident, that it is not every command, enforced by penalties, to which we should extend such a title. A law is not confined to a single act; it embraces a class of acts: it is not confined to the acts of one man; it embraces those of a

community of men. And the authority from which it emanates must be an authority which that community are in the habit of obeying. An authority to which only a temporary obedience is paid, does not come up to the notion of that authority which is requisite to give existence to laws; for thus, the commands of a hostile army, committing plunder, would be laws.

The conditions, which we have thus described, may all be visibly traced, in the laws which governments lay down for the communities to which they belong. There we observe the *command*; there the *punishment* prescribed for its violation; and there the *commanding authority* to which obedience is habitually paid.

Of these conditions how many can be said to belong to any thing included under the term Law of Nations?

These ideas how modified in the term Law of Nations.

By that term is understood, something which either does, or which, it is supposed, ought to bind the conduct of one nation towards another.

But it is not understood, that one nation has a right to command another. When one nation can be commanded by another, it is dependent upon that other; and the laws of dependence are different from those which we are at present considering. An independent nation would resent, instead of obeying, a command delivered to it by another. Neither can it properly be said, that nations, taken aggregately, prescribe those laws to one another severally; for when did they ever combine in any such prescription? When did they ever combine to vindicate the violations of them? It is therefore clear, that the term Command cannot be applied, at least in the ordinary sense, to the laws of nations.

In the next place, it would not seem, that any thing, deserving the name of Sanction, belongs to them. Sanction, we have already seen, is punishment. Suppose nations to threaten one another with punishment, for the violation of any thing understood to be a law of nations. To punish implies superiority of strength. For the strong, therefore, the law of nations, may perhaps have a sanction, as against the weak. But what can it have as against the strong? Is it the strong, however, or is it the weak, by whom it is most liable to be violated? The answer is obvious and undeniable.—As against these from whom almost solely any violation of the laws of nations need be apprehended, there appears, therefore, to be no sanction at all.

If it be said, that several nations may combine to give it a sanction in favour of the weak, we might, for a practical answer, appeal to experience. Has it been done? Have nations, in reality, combined, so constantly and steadily, in favour of the law of nations, as to create, by the certainty of punishment, an overpowering motive, to unjust powers, to abstain from its violation? For, as the laws against murder would have no efficacy, if the punishment prescribed were not applied once in fifty or a hundred times, so the penalty against the violations of the law of nations can have no efficacy, if it is applied unsteadily and rarely.

On the mode in which it has been applied, we may appeal to a great authority. Montesquieu says—“Le droit public est plus connu en Europe qu'en Asie: cependant on peut dire que les passions des princes—la patience des peuples—la flatterie des écrivains, en ont corrompu tous les principes. Ce droit, tel qu'il est aujourd'hui, est une science qui apprend aux princes jusqu'à quel point ils peuvent violer la justice, sans choquer leurs intérêts.”—(*Lett. Persanes, XCIV.*)

To go a little deeper, we may consider, whether the interest of nations, that which, in the long run, governs them all, can ever produce combinations, from which an effectual sanction, of the nature in question, can be expected to proceed. That they would derive some advantage from the general observation of those maxims which have been called laws of nations, frivolous as are the points upon which the greater part of them turn, cannot be denied. These advantages, however, are seen at a dis-

tance, and with the mind's eye; they are speculative, rather than sensible. The inconveniences, on the other hand, which must be felt, from any movement to lend effect to the law of nations, are immediate and formidable; the whole train of the evils of war are almost sure to arise from them. The latter class of impressions must, in general, be far more powerful than the former; and thus the interposition, in favour of the law of nations, will generally be shunned. A nation is often but too easily stimulated to make war in resentment of injuries done to itself. But it looks with too much coolness upon the injuries done to other nations, to incur any great chance of inconvenience for the redress of them.

Besides, the object is to be gained by the means of combination. But the combinations of nations are very difficult things. Nations hardly ever combine without quarrelling.

Again, all nations ought to combine for an object common to all. But for all nations to combine in any one enterprise is impossible. Suppose a prince to have violated the law of nations, it would be absurd to suppose that all the countries on earth should conspire to punish him. But if not all, what is to be the selection? Who shall come forward; who stand excused? By those who are condemned to the sacrifice, in what proportion are the contributions to be made? Who is to afford the greatest, and who may come with the least?

It is unnecessary to pursue any farther the analysis of this extraordinary hypothesis. It is evident from what has been said, that it is full of impracticabilities.

Are we, then, obliged to consider the maxims or rules, which pass under the name of Laws of Nations, as utterly without force and influence; and the discourse which is made about them, as mere affectation and impertinence?

Not wholly so. It is of use, that the ordinary intercourse of nations should be conducted according to certain forms, generally known and approved; because they will be observed on all occasions, when there is no particular motive to violate them, and will often prevent disputes which might arise on frivolous occasions. They resemble, in this respect, the ceremonial of a court, or the established forms of polished society.

The objects, however, which are understood to be embraced by the law of nations, are of two sorts. The first are those minor objects, which partake more of form than of substance. The other are objects which deeply affect humanity. That there are certain interests of nations, which it were good to have considered as their rights, and of which it is infinitely to be desired that the violation could be prevented, is most true. But if national law has no penalty annexed to it; if the weaker party, who is wronged, has no means of redress, where, it may be said, is the advantage of such a law? Or where the propriety of calling that a law, which is only a declaration respecting rights; violated by the more powerful party with impunity, as often, and to as great an extent, as he pleases?

There is still, however, a power, which, though it be not the physical force, either of one state, or of a

The only sanction applicable to the Law of Nations is the popular sanction.

combination of states, applied to vindicate a violation of the law of nations, is not without a great sway in human affairs; and which, as it is very nearly the whole of the power which can be applied to secure the observation of that law, deserves to be carefully considered, that, by duly appreciating its efficacy in this important affair, we may neither trust to it where it will disappoint our expectation, nor neglect the use of it where it may be turned to advantage.

That the human mind is powerfully acted upon by the approbation or disapprobation, by the praise or blame, the contempt and hatred, or the love and admiration, of the rest of mankind, is a matter of fact, which, however it may be accounted for, is beyond the limits of disputation. Over the whole field of morality, with the exception of that narrow part which is protected by penal laws, it is the only power which binds to good conduct, and renders man agreeable and useful to man. It is evident, also, that where there is not great inequality, it is a power, the binding force of which must be necessarily great. Because every individual, considered in himself, is weak and helpless as compared with the rest of the community. Unless, therefore, he can prevail upon them to abstain from injuring him, he must be exposed to unlimited suffering. And if, on the other hand, he can prevail upon them to combine in doing, or in desiring to do him good, he is put in the way of receiving perpetually the greatest advantages. His motive, therefore, to obtain the favourable, and to avoid the unfavourable regards of the members of the society, in which he lives, is of the highest order. But he can obtain their favourable, and avoid their unfavourable sentiments, only by abstaining with scrupulous anxiety from doing any injury to them, and observing all such modes of conduct as are calculated to be useful and agreeable to them.

The value which men set upon these favourable regards of the persons among whom they live, is strikingly manifested by some of the most ordinary forms of their discourse and behaviour. What is more esteemed than character? What injury reckoned more deep and unpardonable than that of the man who exerts himself to take away unworthily any part of the reputation of his neighbours? But what is character, if not the title to the favourable sentiment of other men? And what is the loss of character, but the opinion of other men, that we do not deserve those favourable sentiments, with which they have been accustomed to regard us?

Honour and shame, those emotions, the intensity of which is proved by so many phenomena of human life, are but the feelings which attend upon those different situations. When a man finds himself in possession of the love, the esteem, and admiration of those by whom he is surrounded, he is filled with that delight which the belief of the secure possession of a great source of benefit, cannot fail to inspire: he is fearless, elated, and confident; the principal characteristics of that state of mind which we denominate pride. When he is conscious, on the other hand, of having forfeited in any degree the favourable sentiments of those among whom he lives, he suffers that depression which the loss of a highly valued possession is calculated to create; he ceases,

in some degree, to look forward to his fellow men for good, and feels more or less the apprehension of evil at their hands; he fears to prove how far their disapprobation of him reaches, or to excite them to define it too accurately for themselves; he hangs down his head, and dares not so much as look them in the face.

When men are favourably situated for having those impressions deeply struck; or more correctly speaking, when those combinations of ideas have consistently and habitually been presented to their minds, the association becomes at last so indissoluble and strong, as to operate, even where the connection among the things themselves may not exist.

When persons, who have been educated in a virtuous society, have, from their infancy, associated the idea of certain actions with the favourable sentiments, and all the advantages which flow from the favourable sentiments of mankind; and, on the other hand, have associated the idea of certain other actions with the unfavourable sentiments, and all the disadvantages which flow from the unfavourable sentiments of mankind; so painful a feeling comes in time to be raised in them at the very thought of any such action, that they recoil from the perpetration of it, even in cases in which they may be perfectly secure against any unfavourable sentiments of mankind, which it might be calculated to inspire.

It will, we apprehend, upon the most accurate investigation, be found, that this is the only power to which we can look for any considerable sanction to the laws of nations;—for almost the only species of punishment to which the violation of them can ever become amenable; and the only security, therefore, which mankind can ever enjoy for the benefit which laws, well contrived for this purpose, might be calculated to yield.

It is in the next place incumbent upon us to inquire, what dependence can be placed upon this security, in the set of cases now under consideration; and in what circumstances it is calculated to act with the greatest, in what with the least efficacy, toward this important end.

A power, which is wholly derived, from the good which may follow the favourable, the evil which may follow the unfavourable sentiments of mankind, will act most efficaciously upon him who is the most, least efficaciously upon him who is the least exposed to receive good and evil from the immediate inclination of his fellow men.

It seems to be evident, that he who is most weak, as compared with the rest of the community, is the most exposed to receive good or evil in consequence of their favourable or unfavourable sentiments; and that he, on the other hand, who is the most powerful, as compared with them, is the least exposed to receive good or evil in consequence of those sentiments.

When men are nearly upon equality, no one has any chance of inducing other people to abstain from hurting him, but by his abstaining from doing hurt in any way to them. He has no means of inducing them to do him any acts of service, but by their expectation of receiving similar acts of service from him. He is, therefore, intensely interested in its

Law of Nations.

being generally believed of him, that he is a man who is careful to abstain from injuring, and ever ready to exert himself to do services to others.

The case is exceedingly different, where one man is lifted high above others. In that case he has powerful means of protection against their hurtful acts, powerful means of obtaining their services, altogether independent of his conduct, altogether independent of his disposition either to abstain from injuring them, or to render them service.

So far, therefore, as good conduct arises from a man's dependence upon the sentiments of others; and from this is derived the moral power, to which alone the term moral sanction or obligation can properly belong; the security for good conduct is apt to be lessened, in exact proportion as any one is raised above the level of those composing the mass of the community. If any man possesses absolute power over the rest of the community, he is set free from all dependence upon their sentiments. In this, or nearly in this situation is every despot, having a well established authority. So far as a man is educated as a despot, he can therefore have but few of those associations, on which a conduct, beneficent to others, depends. He is not accustomed to look—for the services which he needs, or the evils which he apprehends, from others—to the opinion which they may entertain of the goodness or badness of his conduct; he cannot, therefore, have that salutary train of associations from an evil act to the condemnatory sentiments of mankind, and from the condemnatory sentiments of mankind to the forfeiture of all those delights and advantages which spring to him from the operation of their favourable regards;—associations which in men favourably situated become at last habitual, and govern the conduct, as it were, mechanically, without any distinct recurrence to the consequences, upon the thought of which, nevertheless, this salutary and ennobling sentiment ultimately depends, and from which it has been originally derived.

If such is the situation of the despot with regard to these important associations, it is in a proportional degree the situation of all those who partake of that species of elevation. In an Aristocratical country, for example, a country in which there is great inequality of wealth, those who possess the large fortunes, are raised to a great degree above any chance of receiving evil, or of standing deprived of any good, because the great mass, the lower orders, of their countrymen, think unfavourably of them. They are, no doubt, to a considerable degree dependent upon what the people of their own class may think of them; and it is accordingly found, that those qualities and acts, which are useful to that class, are formed into a particular, an Aristocratical code of morality, which is very effectually sanctioned by the favourable and unfavourable sentiments of the Aristocratical body, at the same time that it is exceedingly different from that more enlarged and all comprehensive code, on which the happiness of the greatest number depends, and to which alone the epithet moral in propriety belongs.

Such being the state of the facts connected with

Law of Nations.

this important case, it remains to see what are the inferences, bearing upon it, which we are entitled to draw from them. We have already ascertained, that the only power which can operate to sanction the laws of nations; in other words, to reward or punish any nation, according as it obeys, or disobeys them, is the approbation and disapprobation of mankind. It follows, that the restraining force is, in this case, determined by the associations which they who govern it may have formed with the approbation and disapprobation of mankind. If they have formed strong associations, of a pleasurable kind, with the approbation, strong associations, of the painful kind, with the disapprobation of mankind, the restraining force will be great; if they have not formed such associations, it will be feeble and insignificant. It has, however, appeared, immediately above, that the rulers of a country, of which the government is either monarchical, or aristocratical, can have these associations in but a very low degree; as those alone, who are placed on a level with the great body of other men, are placed in circumstances calculated to produce them. It is only then in countries, the rulers of which are drawn from the mass of the people, in other words, in democratical countries, that the sanction of the laws of nations can be expected to operate with any considerable effect.

Having thus ascertained, what is the power which restrains from violating the laws of nations, and what the description of rulers upon whom its restraining force is the greatest, we are next to inquire, by what expedients the force of it may be raised to the greatest pitch, and the greatest amount of benefit may be derived from it.

It is sufficiently recognized, that whatever is intended to produce any effect as a punishment, produces it in a greater degree, in proportion as it operates with greater precision and certainty. The inquiry, then, regards the means of giving precision and certainty to those sentiments of the world, on which the binding power of the laws of nations so greatly depends.

Two things are necessary to give precision and certainty to the operation of laws within a community. The one is, a strict determination of what the law is, the second, a tribunal so constituted as to yield prompt and accurate execution to the law. It is evident, that these two are indispensable requisites. Without them no penalties can operate with either precision or certainty. And the case is evidently the same, whether we speak of the laws which regulate the actions of individual and individual within the state, or those which regulate the actions of one state towards another.

It is obvious to remark, in the first place, that with regard to the laws of nations, not one of these two indispensable requisites has ever yet had any existence. It has neither been determined what the laws in question are, nor has any common tribunal for cognizance of the violations of them ever been constituted. With respect to the last, not so much as the idea of it seems to have been entertained. And with respect to the first, though much has been written, it has been almost wholly in the way of vague

What is required to give to the Law of Nations its greatest perfection.

Law of Nations.

and general discourse. Hardly a single accurate definition has yet been applied to any part of the subject.

Here, then, we come to what is obviously the grand inquiry; namely, *first*, What can be done towards defining the laws of nations? and, *secondly*, What can be done towards providing a tribunal for yielding prompt and accurate decisions in conformity with them? in other words, for applying with the greatest possible efficacy the opinion of the world for restraining the violation of them?

Necessity for a CODE of International Law.

In the Article JURISPRUDENCE, to which it is necessary for us here to revert, we have sufficiently made it appear, that the foundation of all law is the constitution of rights. Of two parties, unless it is previously determined what each shall enjoy, it can never be determined whether one has improperly disturbed the enjoyment of the other. To determine, however, what a party is to enjoy, is to determine his rights.

Now, then, with regard to nations, the question is, what ought to be constituted rights? or in other words, what would it be desirable, for the good of mankind upon the whole, that the several nations should respect as the rights of each other?

This, it is pretty obvious, is one of the most extensive of all inquiries, far exceeding the limits of an article in the present work. We can attempt little more than to show the way in which the inquiry may be carried on.

Rights of Nations.

In the Article JURISPRUDENCE, we have endeavoured to clear up the meaning which in legislation can, without leading to confusion, be alone attached to the term *Rights*; and we have there likewise seen, that there are but two classes of objects, in which individuals can have rights; namely, Things, and Persons.

The case, we believe, will be found the same with respect to nations. They also can have rights, in nothing but Persons, and Things. Of course, it follows, that they can receive injury in nothing but in Persons, or Things.

The inquiry, however, with respect to the rights of nations, is not so simple, as that with respect to the rights of individuals; because between individuals, subject to the same system of laws, the legislature recognizes no state of hostility; but between nations there is the State of War, and the State of Peace, and the rights which are understood to belong to nations are different in these two different states. In the state of war, nations recognize in one another very few rights respecting either persons or things; they kill the one, and take and destroy the other, with little other limit than the want of ability. In the state of peace, they respect as rights belonging to one another, nearly the same things which are constituted rights of individuals, by the ordinary systems of national law.

What should be recognized as Rights in time of Peace. We shall begin with the consideration of those things which it would be desirable that nations should respect as the rights of one another, in the time of peace.

And, *first*, of rights with respect to things. As the subject of the rights of nations, things may be divided into two sorts; things belonging to some in-

dividual member of the nation, and things belonging to the nation in its collective, or corporate, capacity.

Law of Nations.

Those rights in things which the nation guarantees to its individual members, within the nation, it would be desirable, with hardly any exception, that nations should respect in regard to one another; that those things, for example, which the government of the country to which a man belongs, would regard, and would compel all its subjects to regard, as his property, the governments of all other countries should respect, and compel all their subjects to respect as his property.

The Property of Individuals.

There are two states of circumstances in which questions may arise between nations, respecting the property of their respective subjects. The first, where the property in question, when the cause of dispute arises, is within the country of the individual to whom it belongs: The second, where the property has, by its owner, been previously removed into the country, with which, or some of the inhabitants of which, the dispute has arisen.

1. The first set of circumstances exists between two conterminous countries; the bordering inhabitants of which are neighbours to one another, and may, as any other neighbours, infringe the properties of one another. The proper mode of settling these disputes seems to be sufficiently obvious. The rights of the party complaining should be adjudged, according to the laws of the country to which he belongs. But the party sued or prosecuted, should be amenable only to the tribunals of the country to which he belongs; that is to say, the question should be tried before the tribunals of the country of the defendant; but the definition of the right in question should be taken from the law of the country to which the plaintiff belongs. It might in some cases be convenient for countries in this situation, to agree in constituting a common judicature, appropriated to these disputes, to consist, for example, of two judges, one of each country, with power to chuse a third, when they could not agree.

The injury complained of may be capable of redress by a remedy of the nature of a civil suit merely; or it may be of that more atrocious sort, theft or robbery, for which the remedy of punishment is required.

It would appear that punishment ought to be apportioned according to the laws of the country to which the party who has incurred it belongs. Whatever would be the punishment decreed for the offence, if committed against a man of his own country, such a punishment he ought to sustain, for the offence against the man of the other country. The question of punishment is here understood, as extraneous to that of compensation. This ought always to be made to the party injured, where it is capable of being made, and in a case of property it is always capable; if not by the author of the injury, from want of property, or other cause, at least by the government of the country to which he belongs.

2. Where a man has removed his property from his own into another country, there seems no peculiar reason why it should be regulated by any other laws than those of the country into which he has removed it; why the rights which it confers should be

Law of Nations.

otherwise determined; or the violation of them otherwise punished.

We have now considered, though in a very general manner (and our limits preclude us from attempting any thing more), the mode in which nations should agree about the rights of one another (in other words, the laws they should establish), in as far as the property of individuals, belonging to them, is concerned. After the *property* of individuals, their *persons* are to be considered as requiring the protection of laws.

The Persons of Individuals.

There is more difficulty in determining what is desirable, as international law, upon this part of the subject, than in that which regards the property of individuals. It is desirable that the persons of the inhabitants of every country should receive protection, according to the laws of their own country. But it is also desirable that each man should sustain punishment according to the laws of his country; and these two objects are to a certain extent inconsistent with one another.

The inconvenience, however, seems to be greater, in permitting the inhabitants of one country to be punished, according to the laws of another; than in leaving the inhabitants of one country to the same measure of protection against injury to their persons from the inhabitants of other countries, as is afforded to the inhabitants of those countries by their own laws. Many cases, indeed, may be conceived, in which this is a measure of protection which all reasonable men would allow to be inadequate. In such cases, however, the only remedy seems to be the formation of a compact, by which a mode of proceeding, agreeable to the sentiments of both parties, may be positively prescribed. This latter expedient is of course extraneous to that equitable construction which ought to be uniformly applied by the tribunals of one country to the injuries perpetrated, by those whom they may have to judge, upon the inhabitants of another country. If an inhabitant of Persia, for example, should force cow-broth down the throat of an inhabitant and native of Hindostan, the tribunals of Persia should not punish this outrage, as they would punish one Persian for making another swallow the same liquid. To the Persian it would be a trifling injury, and more than a trifling punishment would not be required. To the Hindu, it would be one of the greatest of all conceivable injuries. It ought to be, therefore, put upon the same footing, with an injury of an equal degree, done to a Persian; the nature of the injury, not the external act, should be the object of consideration: and whatever the punishment which would be awarded against a Persian for one of the greatest injuries of which he could be guilty to a Persian, the same ought to be inflicted upon him, for this, one of the greatest which he could occasion to a Hindu.

Besides the cases in which a government, as representative of the country, may be injured through the individuals who live under its protection, there are cases in which it may be injured more directly. Certain things belong as property to the government, without belonging to any individual; and there are persons who are members of the government, or agents of the government, and who may receive in-

Law of Nations.

juries in that capacity, distinct from those which affect them, as private individuals. These are the cases to which it now remains that we direct our attention.

Those things which belong to government as goods and chattels; its moveables, for example; or the lands which it holds, as any individual holds them, in the way of an estate; there seems to be no reason for considering as subject to any other rules, than those applicable to the goods and chattels which belong to individuals.

The Property or Dominion of the State.

Of other things, those to which any government can claim a right, as representative of a nation, must be, either, first, Portions of Land, or, secondly, Portions of Water.

1. The questions which relate to the rights which any nation may claim in any portion of land, are questions regarding boundaries; and these involve the whole of the questions respecting the acquisition of dominion.

Dominion in Land.

To have any standard for determining questions with regard to dominion, the different modes of acquiring dominion, must be recognized; those which are proper to be allowed and respected by other nations must be distinguished from those which are improper, must be accurately defined, and the definitions made known.

For this purpose it is easy to perceive, that the same process is necessary, as that for the definition of rights, described, at some length, in the Article in this work, entitled JURISPRUDENCE, to which we must again refer.

It is necessary, according to that example, that the events which are to be considered as giving commencement to a right of dominion, and those which are to be considered as putting an end to it, should be fully enumerated, and accurately defined.

This is the first part of the process. The other part is, to distinguish the different degrees of dominion. There is a dominion which is perfect, which includes every power over the subject in question, and leaves nothing farther to be acquired, a *dominium plenum*: there is also a dominion, which is but the commencement, as it were, of dominion, and includes the smallest possible fragment of a full dominion. These are the two extremes; and between them are various distinguishable degrees. All these should be fully depicted, and accurately defined.

When any of those events occurs which are to be considered as giving commencement to rights, it often happens that they are accompanied by circumstances which limit the right they would otherwise convey, and render the dominion less than full. These circumstances ought, also, to be completely enumerated; and the power of each to be accurately defined.

If this were done, an international code would be composed, in which the rights of dominion would be accurately defined; and to determine any question about boundaries, or about the degree of dominion, nothing farther would then be necessary than an adequate inquiry respecting the state of the facts.

The questions would exactly resemble those, which we have already described, in the Article JURISPRUDENCE, in analyzing what is called pleading in ju-

dicature. In a question about boundaries there is, let us suppose, a district, over which one country affirms that it has a right of dominion, a dominion more or less complete; and another country denies that it has that right. The first question is, Whether any of those events has occurred, which would give the affirming country a right of dominion? The second question is, Whether, if such an event had occurred, it was accompanied with any of those circumstances which limit dominion, and render it less than full, and if so, under what degree of limiting power they are classed? The third question is, Whether, if an event, thus giving commencement to a right of dominion had occurred, any other event, putting an end to that right, had subsequently occurred?

We need not here enlarge upon these several topics; because they will be sufficiently understood by those readers who bear in mind the expositions already given in the article referred to; and to those, who do not, we suggest the propriety of recurring to that article, as a preparation for the perusal of this.

It is evidently disproportionate to the limits which we must here prescribe to ourselves, to enumerate the events which it would be agreeable to the interests of mankind in general, that nations should regard as giving, and alone giving, commencement and termination to rights of dominion; because, in order to afford an enumeration which would be in any degree instructive, the reasons must be given why one set of events, and not another, should have the privilege in question conferred upon them.

It may be proper, however, in the mean time, to observe, that the events in question will not be found to be numerous, nor very difficult to discover. In fact, they are, and among civilized nations, almost always have been, pretty nearly agreed upon; and they are the questions of modification, and questions of fact, upon which, chiefly, differences have arisen. For example, there is no dispute, that Occupancy, where there is no prior right, is an event which should be considered as giving commencement to a right of dominion. Neither is there any doubt, that the Consent of those who have a right, may transfer that right to others: or in other words, that such consent is an event which gives commencement to a right in those others. Conquest, also, made in a lawful war, is recognized as an event of the same description; and, it will be found upon inquiry that these do, in fact, contain the whole. For on every occasion on which dominion is acquired, the territory so acquired must, before hand, either have belonged to some body, or have belonged to no body. If it belonged to no body, occupancy is the only event which can be supposed to give commencement to the right. If it belonged to some body, it must be taken from him, either willingly, or by force. If it is taken from him willingly, we have his consent. If it is taken by force, it is by conquest in war, that the new right is created.

It is evidently, however, farther necessary, that the different species of consent should be distinguished; and those to which it would be proper to attach this investitive power, separated accurately from those from which it should be withheld. It is here accordingly,

that the doctrine of contracts, would need to be introduced; that the different species of them applicable to this subject, in which all treaties would be included, should be enumerated; that the effects proper to be given to each of them should be defined; and the mode of interpreting them, or fixing the sense which they ought to bear, accurately laid down.

It would also be expedient, after the principal contracts, applicable to international concerns, are ascertained, to exhibit in the international code, *formulae*, with blanks to be filled up, which should be employed by nations on all occasions of such contracts, and being framed with the greatest possible accuracy, would go as far as it would be possible by words to go, in excluding ambiguity, and the grounds of dispute.

With respect to conquest, the last event, calculated to give commencement to rights of dominion, mentioned in the above general enumeration, it is allowed, that as there are some conquests which ought not to be considered as conferring rights of dominion, there are others which ought to be considered as doing so. It is evidently necessary, therefore, that the line of separation should be drawn.

Whether a conquest, however, should or should not be considered as conferring a right of dominion, depends very much upon the nature of the war, through which it is made. If the war be what is regarded as just, and the mode of warfare conformable to the recognized rules, the conquest is apt to be regarded as conferring a legitimate title; if the war, and mode of war, be of a contrary description, the validity of the title conferred by the conquest may be liable to dispute.

It is evident, therefore, that in order to define the species of conquest on which the investitive power in question should be conferred, the circumstances which render a war justifiable, and the mode in which it is justifiable to carry it on, must first be ascertained. This forms the second part of our inquiry: and the question regarding the investitive power of conquest must be deferred, till that inquiry is performed.

Having thus far considered the mode in which should be determined the rights which nations acquire over portions of territory, or Land, it remains that we consider the mode in which their rights should be determined with regard to Waters.

Waters, as concerns the present purpose, are, either rivers or the sea. Dominion in Water.

As the sea involves the questions of greatest extent and importance, we shall attend to that part of the subject first.

Even in the language of ordinary discourse, the sea is denominated the common domain of nations.

The first principle with regard to the sea is this, that all nations have an equal right to the use of it. The utility of recognizing this principle, is so apparent, that it has never been the subject of any dispute. And all the rights assigned to nations severally, in the enjoyment of this common domain, ought to rise out of this principle; and to be limited by it. Whatever use any nation makes of it, should be such as not to prevent a similar and equal use from being made by other nations. And every use which can-

not be shown to have that effect, should be recognized as a right by the law of nations.

The principal use which nations make of the sea, is that of a passage for their ships. Agreeably to the principle which we have recognized, the ships of one nation should pass in such a manner as not to obstruct the passage of those of another. The rules according to which the possible cases of interference should be regulated, are very simple; and are, in fact, laid down and acted upon, with considerable accuracy. They resemble, in all respects, those according to which the vessels of the same country are made to avoid and to regulate their interferences in the rivers of the country, or upon its coasts. There would be no difficulty, therefore, in making accurate definitions of the requisite rights, for insertion in the international code.

The rights being established, the violations of them should be punished, on the same principles, as those which we have laid down in regard to the preceding cases. Either property has been injured, or persons. In either case, compensation is an indisputable part of the remedial process, wherever it is practicable. In loss of property, it is fully practicable. It is also practicable in many of the injuries done to the person. As in the case of offences committed on land, the rights of the individual who has suffered should be estimated according to the laws of the country to which he belongs; but the punishment of the offender should be measured according to the laws of the country to which he belongs. In the case of piracy, which is robbery, or murder, committed by persons whom no country recognizes, and upon whom, therefore, justice can be demanded from no foreign government, it has hitherto been the practice that the nation suffering has taken the punishment into its own hands. Accordingly, the punishment of piracy has always been extremely severe. It would be, no doubt, better, if a mode were adopted, by which it would not be necessary for a nation to be judge in its own cause. A rule does not seem impossible to be framed, according to which the punishment of piracy might be provided for, by referring those accused of it, either to some general tribunal, constituted for that purpose, or to the tribunals of some nation other than that against which the offence has been perpetrated. A general law, on this subject, to be observed by all nations, would be highly desirable.

Rules, therefore, seem not difficult to be laid down, for regulating the proceedings of nations on the high seas. A distinction, however, is drawn between what is called the *high*, and what is called the *narrow seas*. By the narrow seas is commonly meant some portion of sea, to a greater or less extent, immediately surrounding a particular country; and in which that country claims peculiar privileges. The question is, whether any such privileges should be allowed, and if allowed, to what extent?

The regulating principle in this, as in other cases, is the general advantage, the principle of utility. There are cases, in which certain privileges, in the waters surrounding a particular country, are of so much importance to that country; and the exercise of those advantages occasions so very little inconve-

nience to other nations, that what is lost, by all of them taken together, bears no comparison with what is gained by that particular nation. In these cases, the exercise of such privileges should be allowed; they should, however, be defined, in as many instances as possible, and promulgated by insertion in an international code.

Of the privileges in question, are all those which are essential, or to a considerable degree subservient, to the national security. In some cases, the exclusive right of fishing might perhaps come under the same rule. But this is in general provided for, by the necessity of drawing the nets, or curing the fish upon the land, a privilege which, of course, it is in the power of any nation to give or to withhold.

In obedience to this equitable principle, it appears, that such foppish privileges, as have sometimes been insisted upon, and afford no advantage to one nation, which is not wholly at the cost of others—lowering the flag, for example, and such like impositions—should not be recognized by the code of nations.

It appears, also, that those tolls which have been, sometimes, and are levied at the narrow inlets of some seas, deserve to fall under the same condemnation. The passage through these inlets is a common good to all the nations of the earth which may have a motive to use them; a good of the highest importance to the nations which are situated within, and to which it is the only means of maritime communication; and, while it imparts no evil to the conterminous nation, the toll which that nation levies is an advantage obtained wholly at the cost of others; and imposing upon them a burthen, in the way of obstruction and trouble, which is compensated for by advantage to nobody.

The waters, we have said, in respect to which rights should be assigned to nations, are rivers and the sea. Having stated what appears necessary on the present occasion with respect to the sea, it remains that we offer the few observations required, on the subject of rivers.

Rivers are either the boundary between two countries, or they are wholly within a particular country.

Those which are wholly within a particular country, it seems most agreeable to the principle of utility to regard as wholly belonging to that country. In the case of navigable rivers which pass through several countries, it would indeed be desirable for those countries which are situated higher up than that at the mouth of each, as well as for all those who might thus have intercourse with them, that the navigation of such rivers should be free; but it would be difficult so to regulate this right, as not to affect the security of the country through which a free navigation should thus be allowed; and a slight diminution in its security would be so great a loss to that country as would require, to compensate for it, a very great advantage to those by whom the navigation was enjoyed. Unless where this advantage were very great, it would not, therefore, be agreeable to the principle which should dictate the laws of nations, that the freedom of the navigation should be regulated on any other principles than those of mutual agreement.

In regard to those rivers which flow between two

Law of Nations.

countries, the principle of regulation is sufficiently plain. The benefits derivable from the river should be shared equally between them. Its principal benefits arise from the fishing and from the navigation. The right of fishing in most cases may be fitly distributed, by each party fishing from its own bank to the middle of the stream. The right of navigating of each must be so exercised as not to obstruct the right of the other. In this case the same sort of rules are required, to prevent the ships of the two nations from obstructing one another, in a common river, as are found available to prevent the ships of different individuals from obstructing one another, in a river belonging to one country. There is no difficulty, therefore, here, which it is worth stopping to show how to remove.

What should be recognized as Rights in time of War.

We have now adduced, what our limits admit to be said, upon the first great branch of the inquiry relative to the law of nations; namely, the rights which they should recognize in one another in the state of peace. We proceed to the second branch, relating wholly to the state of war.

The questions which present themselves for solution relating to the state of war, are either those which respect its commencement, or those which respect the mode of carrying it on.

What should be regarded as necessary to render the commencement of a War just.

With respect to the commencement of a war, the principal question is, What are the conditions which should be regarded as necessary to render it just?

As men, in a situation where laws, and the protection derived from them, do not exist, are left to their own protection, and have no means of deterring other men from injuring them, but making them dread injury in return, so nations, which, with respect to one another, have, as we have seen before, but little protection from the legal sanction, are left to supply its place by this dread of injury in return, which, in the case both of individuals and of nations, may be called the *retributive sanction*, and of which, in the case of nations, war is the principal organ.

From this view of the essence and end of war, we lay down immediately one pretty extensive proposition with regard to the conditions necessary to render it just.

As the legal sanction, or punishment for the offences of individuals ought to operate only where some right has been violated, and the violation has been such as to require it, so the retributive sanction of nations, which is war, ought to operate only where some right of the nation, or something which ought to be treated as a right, has been violated, and where the violation has been such as to require that desperate remedy.

But as not all violations which may possibly be committed of the rights of a nation will justify it in inflicting war, the next object is, to draw the line of separation, and distinguish between those violations of the rights of nations which justify, and those which do not justify, the extremity of war.

As the evils which war produces are exceedingly great, it is, first of all, evident, that no violation of rights which is not very great, will, upon the principle which we have so often recognized, suffice to justify it. Of two evils, the least, is the choice of all sound legislation.

Law of Nations.

Of the violation of the rights of individuals, in the same country, the cases meet for punishment are capable of being pointed out, with a degree of accuracy, not wanting much of perfection. Of the violation of the rights of nations, committed by one nation against another, the cases which would justify the remedial operation of war are much more difficult to define. The difficulty, indeed, is not universal; for there are cases which may be very satisfactorily defined; and as far as definition can go, it is of the utmost importance that it should be carried. Uncertainty, then, pervades only one part of the field; which the more we are able to lessen, the greater the advantage in favour of humanity which we gain. If a proper code of international law were formed, there would be certain defined violations of the rights of nations which would be pointed out, not only as deserving the indignation and hatred of all the world, but as justifying the injured nation before all the world, in inflicting upon its injurer the calamities of war. There would also be certain other injuries pointed out, of a more doubtful character; which might, or might not, according to circumstances not easy to define, be such as to justify recourse to war. The injuries of this secondary character, also, which might, or might not, according to circumstances, justify a war, are capable of being pointed out with a certain degree of accuracy. To a certain degree, likewise, the circumstances which would convert them into justifying causes, are capable of being foreseen. So far definition is capable of extending, and so far, of course, it ought to be carried.

In illustration of this latter class of injuries, we may select the most remarkable, perhaps, and important of all the instances; preparations for a threatened attack. A sense of security is one of the most valuable treasures of a nation; and to be deprived of that sense of security, is one of the greatest of injuries. But what state of preparation shall, or shall not be considered as justifying the threatened nation in striking the first blow, in order not to give its enemy the advantage of completing his preparations, and making his attack just at the moment when it would be most destructive, it is perhaps impossible to determine, for all cases, beforehand; though, no doubt, a certain progress may be made towards that determination, and the bounds of uncertainty may be greatly reduced.

We are aware how general, and therefore how unsatisfactory, these observations are, on the important subject of defining those violations of the rights of nations which ought to be regarded as justificatory causes of war; but at the same time it is to be observed, that not much more could have been done without framing the code, by actually enumerating and defining the violations for which that remedy should be reserved.

Another consideration is now to be weighed. It is evident that whatever injuries are done by one nation to another, compensation may almost always be made for them. It is equally evident, that whatever injury may have been sustained, if compensation is made for it, the justificatory cause of war is removed.

Law of Nations.

The doctrine of compensation, therefore, is an important part of international jurisprudence. Before recourse is had to war, for any violation of rights, compensation ought first to be demanded; and no war, except in cases fit for exception, should be regarded as just, which this demand had not preceded; a demand which should be made through a constituted organ, and in a predetermined mode, as we shall more fully describe in a subsequent page, when we come to treat of an international tribunal.

As there can be no reason why the demand of compensation should not always precede the use of arms, except in cases of such a necessity as will not allow time for demanding compensation—a necessity for the immediate use of arms, in order to prevent an evil immediately impending—those cases of urgent necessity should, as far as possible, be sought out, and defined.

Other circumstances may be enumerated, as belonging to this first stage of the remedy, against a nation, which places itself in an attitude, affecting the sense of security of any of its neighbours. If a nation is making preparations, or executing any other measures, calculated to excite alarm, it may be called upon to desist from them; or it may be called upon to give security, that it will not make a hostile use of them. Of these securities, hostages are one of the most familiar instances. Various other instances will easily present themselves to the consideration of our readers. Upon this part of the subject, therefore, it is unnecessary for us to enlarge.

It thus appears, that we may lay down, with a considerable degree of precision, the conditions upon which the commencement of a war ought to be regarded as just. It remains, under this head of inquiry, that we show how it may, as far as possible, be determined, what ought to be regarded as just and unjust in the modes of carrying it on.

This is an inquiry of more complexity, a good deal, than the first. In looking out for a guiding principle, it is evidently necessary to keep in view the end to which every just war is of necessity restricted. That is, compensation for an injury received, and security that a fresh injury shall not be committed. Combining this with the grand principle of humanity and utility, in other words, of morality; namely, that all evil, wilfully occasioned, and not calculated to produce a more than equivalent good, is wicked, and to be opposed, we obtain one comprehensive and highly important rule; which is this: That in the modes of carrying on war, every thing should be condemned by the law of nations, which, without being more conducive, or more in any considerable degree, to the attainment of the just end of the war, is much more mischievous to the nation against whom it is done.

As the end is to be gained, in most cases, only by inflicting a loss of men and property, upon the opposing nation, it would be desirable that the distinction should be drawn between the modes of inflicting this loss, which are the most, and those which are the least calculated, to inflict pain and suffering, without being more conducive to the end.

One distinction is sufficiently remarkable; namely, the distinction between the men who are in arms or

actually opposed to the designs of the belligerent, and the men who are not so; also between the property which belongs to the government of the opposing nation, and that which belongs to private individuals composing the nation.

With respect to the first class of objects, the men in arms, and the property of the government, there is not much difficulty. To produce the loss of them, as rapidly as possible, till the end or purpose of the war is obtained, appears to be a privilege which cannot be separated from the right of warring at all.

With respect to the loss of the men, indeed, there is an important restriction. It means the loss of them for the purposes of the war, and no more. If it be practicable to put them in a situation in which they can no longer be of any service to the war, all farther injury to them should be held unjustifiable. Under this rule falls the obligation, so generally recognized, of making our enemies, as often as possible, prisoners, instead of killing them, and of treating them with humanity, while retained in that condition.

That part of the subject, therefore, which relates to men in arms, and to such property as belongs immediately to the government, it is not impossible to include in rules of tolerable precision. The difficulty is, with respect to those individuals who, composing the body of the nation, form no part of the men in arms, and with respect to the property of such individuals.

Though it would not be correct to say, that these do not contribute, or rather that they may not be made to contribute, to the means with which the government carries on the war; yet it would be absurd not to recognize a very broad distinction between them, and the men and things which are immediately applied, or applicable to the war. A difference, therefore, equally broad, ought, in reason, to be made in the mode of treating them. The mode of treating the one ought to be very different from that of treating the other. As the rule of destruction must be the rule with regard to the first, only limited by certain restrictions; so the rule of forbearance and preservation ought to be the rule with regard to the latter, only to be infringed upon special and justifying circumstances.

Thus far we seem to have travelled with the advantage of light to our path. We may go a little farther, with equal certainty, and say, that as far as regards the persons of those who are not engaged in the immediate business of hostility, very few occasions can occur, in which it would be allowable, upon any just principle of international law, to do them any injury. Leaving them out of the question, we narrow it to the case of the property belonging to individuals; and shall now proceed to see how far the protection of it can be embraced within general rules.

We must suppose the case, which is the strongest, that of an invading army. The advantage which is capable of being derived to such an enemy, by seizing and destroying the property of individuals, bears, unless in certain very extraordinary instances, no sort of proportion, to the evil inflicted upon the individuals. This, we presume, cannot admit of a dispute. Upon the principle, therefore, so often recognized,

Law of Nations.

What should be regarded as just and unjust in the modes of carrying on a War.

Law of Nations.

as that, the dictates of which ought in this affair to be solely obeyed, no such destruction, unless in such instances, ought to be sanctioned by the law of nations. Such property, it is well known, can rarely be counted upon, as any considerable resource; because it is to a very great extent in the power of the people invaded to drive their property away, or to destroy it. The property of individuals, in an invaded country, would in general be a much more certain resource to an invading army, if that army were to purchase from them the articles which it desired. And, perhaps, this would be the most advantageous compromise of which the circumstances admit; namely, that the invading army should abstain from the violation of private property; but that it should in return have the benefit of an unrestricted market; that nothing should be done on the part of the government of the invaded country to prevent its subjects from buying and selling with the invaders, as they would with any other parties.

It may no doubt be true, that the plunder and devastation of a province, or other portion of a country, must have an effect in diminishing the resources of the government for carrying on the war. In this point of view it must be allowed that the destruction of private property is of some importance to the invading nation with regard to the result of the war. But the question, in settling the difficulties of international jurisprudence, is not whether an advantage is gained, but whether the advantage, such as it is, be not gained, at too great a cost of evil.

If it be certain that the losing party, in consequence of the destruction in question, loses more than the gaining party gains, it is certain that the two parties, taken together, are losers by the proceeding; and of course that nations, in the aggregate, are losers upon the whole. Nay, it is certain that each nation, taken by itself, is a loser, upon the balance of the cases in which it is liable to lose, and those in which it is liable to gain. If it loses more in the cases in which it bears, than it gains in the cases in which it inflicts invasion; and if it is as liable to bear, as to inflict, which is the usual condition of nations, it follows clearly that it is its interest to concur in a rule which shall protect the property of individuals, in cases of invasion.

Even in that more civilized mode, which has been adopted by invading armies, of availing themselves of the property of individuals; by exacting contributions through the instrumentality of the local authorities; contributions which these authorities are left to partition among the people, as they may deem equitable; though it is admitted that this is a much less hurtful proceeding than military rapine, still we think, it will easily appear, that the evil inflicted upon the contributors is greater than the benefits derived to the receivers.

Unless the amount thus received by an invading army is very considerable, the benefit which is derived, the aid which is gained towards accomplishing the end of the war, must be considered as trifling. But if a contribution, the amount of which can be of any considerable avail towards attaining the object of the war, is levied suddenly upon a particular district, a comparatively small portion of the invaded

country, it must operate upon the contributors with a dreadful weight of oppression. Upon an equitable estimate of the circumstances, it can, therefore, hardly fail to appear, that, whether the contribution exacted is heavy or light (it must always be heavy to those who sustain it), the loss to those who suffer must greatly outweigh the advantage to those who receive. If it be so, this mode of exaction should, it is evident, be forbidden by the law of nations.

If these are the principles, upon which an international code, regarding this branch of the subject, ought to be constructed, they will enable us to determine the question with regard to the property of individuals in another set of circumstances, to which the rules of civilized society have hardly yet begun to be applied. Whatever rules apply to the property of individuals found upon the land, the same rules ought, by parity of reason, it should seem, to apply to it when found upon the sea.

The conduct of nations, however, has hitherto not been conformable to the parity which appears to belong to the two sets of cases. Some tenderness, more or less, according to the progress in civilization, appears to have been shown, by all but savages, to the property of individuals upon the land. To this hour the property of individuals upon the sea is made prize of without mercy by the most civilized nations in the world.

The notions of piracy, in fact, have, on this subject, unhappily prevailed, and governed the minds of men. Pirates make prey of every thing. Sailors, originally, were all pirates. The seafaring state was a belligerent state, of almost every vessel against every other vessel. Even when nations had gradually advanced into a more civilized state, and when their vessels abstained from injury to one another in a period of peace, they appear, when the ties of peace were dissolved, and they were placed with respect to one another in a state of war upon the seas, to have felt the force of none but their old associations, and to have looked upon the state of war as a state of piracy. Two nations at war with one another continue to act towards the property of individuals belonging to one another, exactly as two nations of pirates would do.

Assuredly this is a state of things to which the present intelligence and morality of the world ought speedily to put an end. The very same reasoning which we have applied to the ease of the property of individuals upon the land, is not less conclusive when applied to the property of individuals upon the sea. The loss to the party losing is more than an equivalent for the gain to the party that gains.

There is another consideration of great importance. All nations gain by the free operations of commerce. If then we were to suppose that the losses and gains of the two belligerent parties balanced one another, which yet they never do, there is an advantage derived from their commerce to every nation on the earth to which, in any degree, either directly or indirectly, that commerce extends; which advantage is either lost or diminished, by their preying upon the property of the individuals belonging to one another. This, therefore, is an unquestionable balance of loss, to the general community of na-

tions, which the law of that community ought to endeavour to prevent.

If, then, we should suppose that it were enacted as the law of nations, that the property of individuals passing on the seas should be equally respected, in peace and in war, we may proceed to consider whether any disadvantage, nearly countervailing the general good, would thence accrue to the belligerents.

It may be alleged, that a nation at war with another is retarded in reducing its antagonist, by the riches which the commerce of that antagonist, if undisturbed, will place at its disposal. But it is evident that an advantage to one of two antagonists, when compensated to the other, by a power to overcome that advantage, exactly equivalent, is in reality no advantage at all. Such is the case with the advantage accruing to the nation with which another is at war, when the property of individuals up on the sea is allowed to pass unmolested. If its riches are increased by freedom of commerce, so are those of its antagonist. The advantages are equal, where the circumstances are equal, which, in the majority of cases, they undoubtedly are.

If it be still objected, that there may be cases in which they are not equal, the answer is obvious, and incontrovertible. There is no general rule without its exceptions, but partial evil must be admitted for general good. Besides, if the case were very remarkable, it might be excepted from the general rule.

If this were adopted as part of the law of nations, all those questions respecting the maritime traffic of *Neutrals*, questions which have been the source of so much troublesome inquiry, so much animosity, and so much mischief, would be immediately at an end. If the traffic of the belligerents, so far as concerned the property of individuals, were free, so would be that of all neutral nations.

Places actually blockaded, that is surrounded with an hostile force for the immediate purpose of being reduced, either by arms, or by famine, would still form exceptions; because the admission of ships into them, with supplies either of food, or munition of war, would be directly at variance with the very object of the blockade.

In all other cases, the admission either of provisions or of instruments of war into a belligerent country, ought, undoubtedly, upon the principle of utility, not to be disturbed. The benefit, except in rare and remarkable cases, could not be material to the country into which they might enter, nor hence the injury to its antagonist; on the other hand, that antagonist would enjoy the same privilege of the free admission of those commodities, and thus they would be equal in all respects. The inconvenience, however, which would thus be saved to the neutrals—the annoyance of search, the loss by detention, the occasions of quarrel—are known to be evils of no ordinary magnitude.

The desertion of sailors from the ships of a belligerent to those of a neutral has given rise to disputes in one instance only, that of Great Britain and the United States of America. The question to be determined, in laying down the principles of international jurisprudence, is, whether this desertion ought to be considered as constituting a ground for the

general right of search; in other words, whether the evil to which a belligerent is exposed by desertion, or rather by that portion of desertion which can be prevented by the right of search, is an equivalent for all the evil which is unavoidably produced by it.

Desertion must take place either from the ships of war of the belligerent, or from its merchant ships.

In respect to ships of war, it is so easy for a belligerent to prevent desertion to neutrals, at least in any such degree as to constitute a great evil, that it would be altogether absurd to speak of it as an evil to be compared with those arising from the right of search. The only occasions on which ships of war can be exposed to desertion to neutrals, must be, on those occasions on which they go into a neutral port. But on those, comparatively rare, occasions, they can so easily take precaution against desertion, that the danger to which they are exposed is hardly worth regarding.

When the sailors belonging to merchant ships transfer their services to the ships of a neutral, it is not to be called desertion. It can only take place, in very considerable numbers, when seamen's wages in the neutral country are much higher than in that of the belligerent. The sailor, in this case, leaves his own for another country, only because he improves his situation by so doing. This is a liberty, which, as it ought to belong to every body, so it ought not to be withheld from the sailor. If, indeed, any nation thinks proper to forbid any class of its people to leave their country, as England with regard to its artificers, other countries cannot help that, but they ought not to be called upon to lend their aid to such an antisocial regulation, by allowing their vessels to be searched, as security against its infringement. Besides, it is evident, that there is a much greater security, arising from the very nature of the case, against the chance of a nation's being, to any considerable degree, deprived of its sailors by any such means. If the sailors go into the neutral country because wages are higher there, a small number only will have gone, when wages, from diminution of the numbers, will begin to rise in the country which they have left, and from increase of the numbers, will begin to fall in the country to which they have been tempted to repair. When the wages of seamen have thus sufficiently risen, in the belligerent country, which they are sure to do if the demand for them rises, the sailors will not only come back from every country in the world, but the sailors of other countries will hurry along with them; and the evil of desertion cures itself.

Only two questions, of any great importance, appear to remain; that relating to the march of troops, for a hostile purpose, through a neutral country, and that relating to the extent to which the operations of a successful war ought to be pursued.

According to the principles which we have already laid down for regulating the proceedings of a hostile army even in the invaded country, namely, that of committing no plunder, and enjoying the right of market, it appears that the right of passing through a neutral country on similar terms should be refused to no party. This rule, while it holds out equal advantages to all belligerents, admits, less than any other rule, grounds of dispute.

Law of Nations.

The end, which we have already described as that alone the pursuit of which can render any war justifiable, sufficiently defines the extent to which the operations of a successful war ought to proceed. The end of every justifiable war is to obtain compensation for an injury sustained, and security against the repetition of it. The last point, that of security, alone contains any uncertainty. Nations are apt to exaggerate the demand for security, to require too much; very often unconsciously, from the mere cravings of self-love; sometimes fraudulently, as a cover for ambitious views. As the question, however, respecting what may or may not, in each instance, be sufficient security, is a question of fact, not of law, it must be determined, if determined at all, by a tribunal empowered to take cognizance of the facts.

Of the construction of an International Code, and an International Tribunal.

We have now then laid down the principles by which, in our opinion, the rights of nations, in respect to one another, ought to be determined; and we have shown in what manner those principles should be applied, in order to come to a decision, in the most remarkable cases. The minor points it is, of course, not in our power to illustrate in detail; but that will not, we should hope, be difficult, after the exemplification exhibited, and the satisfactory solutions at which we seem to have arrived, of all the more considerable questions which the subject presents.

From what has been shown, it is not difficult to see, what would be the course pursued by nations, if they were really actuated by the desire of regulating their general intercourse, both in peace and in war, on the principles most advantageous to them all.

Two grand practical measures are obviously not only of primary importance toward the attainment of this end, but are of indispensable necessity toward the attainment of it in any tolerable degree. These are, first, the construction of a Code; and, secondly, the establishment of a Tribunal.

It is perfectly evident, that nations will be much more likely to conform to the principles of intercourse which are best for all, if they have an accurate set of rules to go by, than if they have not. In the first place, there is less room for mistake; in the next, there is less room for plausible pretenses; and last of all, the approbation and disapprobation of the world is sure to act with tenfold concentration, where a precise rule is broken, familiar to all the civilized world, and venerated by it all.

How the nations might concur in framing an International Code.

How the nations of the civilized world might concur in the framing of such a code, it is not difficult to devise. They might appoint delegates to meet for that purpose, in any central and convenient place; where, after discussion, and coming to as full an understanding as possible upon all the material points, they might elect some one person, the most capable that could be found, to put these their determinations into the proper words and form, in short, to make a draught of a code of international law, as effectually as possible providing for all the questions, which could arise, upon their interfering interests, between two nations. After this draught was proposed, it should be revised by the delegates, and approved by them, or altered till they deemed it worthy of their approbation. It should then be referred to the several governments, to receive its final sanction

from their approbation; but, in the mean time, it should be published in all the principal languages, and circulated as extensively as possible, for the sake of two important advantages. The first would be, that, the intelligence of the whole world being brought to operate upon it, and suggestions obtained from every quarter, it might be made as perfect as possible. The second would be, that the eyes of all the world being fixed upon the decision of every nation with respect to the code, every nation might be deterred by shame from objecting to any important article in it.

As the sanction of general opinion is that upon which chiefly, as we have already seen, such a code must rely for its efficiency, not a little will depend upon the mode in which it is recognized and taught. The recognition should in each country have all possible publicity and solemnity. Every circumstance which can tend to diffuse the opinion throughout the earth, that the people of each country attach the highest importance to such a code, is to themselves a first-rate advantage; because it must be of the utmost importance to them, that all the nations of the earth should behave towards them upon the principles of mutual beneficence; and nothing which they can do can have so great a tendency to produce this desirable effect, as its being generally known that they venerate the rules which are established for its attainment.

If nations, then, were really actuated by the desire of regulating their mutual intercourse upon principles mutually beneficent, they would adopt measures for having a code of international law constructed, solemnly recognized, and universally diffused and made known.

But it is not enough that a code should exist; every thing should be done to secure a conduct conformable to it. Nothing is of so much importance for this purpose as a tribunal; before which every case of infringement should be tried, the facts of it fully and completely explored, the nature and degree of the infringement ascertained; and from which a knowledge of every thing material to the case should be as rapidly as possible diffused through the world; before which also all cases of doubt should regularly come for determination: and thus wars, between nations which meant justly, would always be avoided, and a stigma would be set upon those which justice could not content.

The analogy of the code, which is, or ought to be, framed by each state for regulating the intercourse of its own people within its own territory, throws all the illustration which is necessary upon the case of a tribunal for the international code. It is well known, that laws, however carefully and accurately constructed, would be of little avail in any country, if there was not some organ, by means of which it might be determined when individuals had acted in conformity with them, and when they had not; by which also, when any doubt existed respecting the conduct which in any particular case the law required, such doubt might be authoritatively removed, and one determinate line of action prescribed. Without this, it is sufficiently evident, that a small portion of the benefit capable of being derived from laws would actually be attained. It will presently be seen how much

Law of Nations.

of the benefit capable of being derived from an international code must be lost, if it is left destitute of a similar organ. We shall first consider in what manner an international tribunal might be constructed; and, next, in what manner it might be appointed to act.

How an International Tribunal should be constructed.

As it is understood that questions relating to all nations should come before it, what is desirable is, that all nations should have equal security for good judicature from it, and should look with equal confidence to its decisions.

An obvious expedient for this purpose is, that all nations should contribute equally to its formation; that each, for example, should send to it a delegate, or judge. Its situation should be chosen or its accessibility, and for the means of publicity which it might afford; the last being, beyond comparison, the advantage of greatest importance. As all nations could not easily, or would not, send, it would suffice if the more civilized and leading nations of the world concurred in the design, with such a number of the less considerable as would be sure to follow their example, and to be desirous of deriving advantage from an instrument of protection, which to them would be of peculiar importance.

As it is found by specific experience, and is, indeed, a consequence of the ascertained laws of human nature, that a numerous assembly of men cannot form a good judicatory; and that the best chance for good judicial service is always obtained when only one man judges, under the vigilant eyes of interested and intelligent observers, having full freedom to deliver to the world their sentiments respecting his conduct; the whole of these advantages may be obtained, in this case, by a very effectual expedient. If precedent, also, be wanted, a thing which in certain minds holds the place of reason, it is amply furnished by the Roman law; according to which a great number of judges having been chosen for the judicial business generally of the year, a selection was made out of that number, according to certain rules, for each particular case.

Every possible advantage, it appears, would be combined in the international tribunal, if the whole body of delegates, or judges, assembled from every country, should, as often as any case for decision came before them, hold a conference, and, after mature deliberation, choose some one individual of their body, upon whom the whole duty of judge should, in that case, devolve; it being the strict duty of the rest to be present during the whole of his proceedings, and each of them to record separately his opinion upon the case, after the decision of the acting judge had been pronounced.

It would be, no doubt, a good general rule, though one can easily foresee cases in which it would be expedient to admit exceptions, that the judge, who is in this manner chosen for each instance of the judicial service, should not be the delegate from any of the countries immediately involved in the dispute. The motive to this is sufficiently apparent.

We apprehend, that few words will be deemed necessary to show how many securities are thus provided for the excellence of the judicial service.

In the first place, it seems impossible to question,

Law of Nations.

that the utmost fairness and impartiality are provided for, in the choice of the judge; because, of the two parties involved in the dispute, the one is represented by a delegate as much as the other, and the rest of the delegates are indifferent between them. In general, therefore, it is evident, that the sinister interest on the two sides being balanced, and there being a great preponderance of interest in favour of nothing but a just decision, that interest will prevail.

The best choice being made of a judge, it is evident that he would be so situated, as to act under the strongest securities for good conduct. Acting singly, he would bear the whole responsibility of the service required at his hands. He would act under the eyes of the rest of the assembled delegates, men versed in the same species of business, chosen on account of their capacity for the service, who could be deceived neither with respect to the diligence which he might exert, nor the fairness and honesty with which he might decide; while he would be watched by the delegates of the respective parties, having the power of interest stimulating them to attention; and would be sure that the merits or demerits of his conduct would be made fully known to the whole, or the greater part of the world.

The judicatory being thus constituted, the mode of proceeding before it may be easily sketched.

Form of procedure before the International Tribunal.

The cases may be divided into those brought before it by the parties concerned in the dispute; and those which it would be its duty to take up, when they were not brought before it by any of the parties.

A variety of cases would occur, in which two nations, having a ground of dispute, and being unable to agree, would unite in an application to the international tribunal for an adjustment of their differences. On such occasions, the course of the tribunal would be sufficiently clear. The parties would plead the grounds of their several claims; the judge would determine how far, according to the law, they were competent to support those claims; the parties would adduce their evidence for and against the facts, on which the determination of the claims was found to depend; the judge would receive that evidence, and finally decide. All this is so perfectly conformable to the course of pleading, and receiving proof, in the case of suits between individuals, as analyzed and explained in the Article JURISPRUDENCE, that it is unnecessary to be more particular here. If farther exposition is required, it will be found upon a reference to the article to which we allude. Decision, in this case, it is observable, fully accomplishes its end; because the parties come with an intention of obeying it.

Another, and a numerous class of cases, would probably be constituted, by those who would come before it, complaining of a violation of their rights by another nation, and calling for redress.

This set of cases is analogous to that, in private judicature, when one man prosecutes another for some punishable offence.

It should be incumbent upon the party thus applying to give notice of its intention to the party against which it is to complain, and of the day on

which it means that its complaint should be presented.

If both parties are present, when the case comes forward for trial, they both plead, according to the mode described in the Article JURISPRUDENCE; evidence is taken upon the decisive facts; and if injury has been committed, the amount of compensation is decreed. When it happens that the defendant is not present, and refuses to plead, or to submit, in this instance, to the jurisdiction of the court, the inquiry should notwithstanding go on; the allegations of the party present should be heard, and the evidence which it adduces should be received. The non-appearance of the party defendant should be treated as an article of evidence to prove the truth of its opponent's allegations. And the fact of not appearing should, itself, be treated as an offence against the law of nations.

It happens, not unfrequently, when nations quarrel, that both parties are in the wrong; and on some of these occasions neither party might think proper to apply to an equitable tribunal. This fact, namely, that of their not applying to the international tribunal, should, itself, as stated before, be marked in the code as an international offence, and should be denounced as such by the international tribunal. But even when two offending parties do not ask for a decision from the international tribunal, it is not proper that other nations should be deprived of the benefit of such a decision. If these decisions constitute a security against injustice from one another to the general community of nations, that security must not be allowed to be impaired by the refractory conduct of those who dread an investigation of their conduct.

Certain forms, not difficult to devise, should be laid down, according to which, on the occurrence of such cases, the tribunal should proceed. First of all, it is evident, that the parties in question should receive intimation of the intention of the court to take cognisance of their disputes, on a certain day. If the parties, one or both, appeared, the case would fall under one of those which have been previously as above considered. If neither party appeared, the court would proceed to estimate the facts which were within its cognisance.

It would have before it one important article of evidence, furnished by the parties themselves, namely, the fact of their non-appearance. This ought to be considered as going far to prove injurious conduct on both sides. The evidence which the court would have before it, to many specific facts, would be liable to be scanty, from the neglect of the parties to adduce their pleas and evidence. The business of the court, in these circumstances, would be, to state correctly such evidence, direct or circumstantial, as it had before it; giving its full weight to the evidence contained in the fact of non-appearance; and to pronounce the decision, which the balance of the evidence, such as it was, might be found to support.

Even in this case, in which the practical effect of a decision of the international court may be supposed to be the least, where neither party is disposed to respect the jurisdiction, the benefit which would be derived would by no means be inconsiderable. A

decision solemnly pronounced by such a tribunal, would always have a strong effect upon the imaginations of men. It would fix, and concentrate the disapprobation of mankind.

Such a tribunal would operate as a great school of political morality. By sifting the circumstances, in all the disputes of nations, by distinguishing accurately between the false colours and the true, by stripping off all disguises, by getting at the real facts, and exhibiting them in the true point of view, by presenting all this to the world, and fixing the attention of mankind upon it by all the celebrity of its elevated situation, it would teach men at large to distinguish. By habit of contemplating the approbation of such a court attached to just proceeding, its disapprobation to unjust; men would learn to apply correctly their own approbation, and disapprobation; whence would flow the various important effects, which these sentiments, justly excited, would naturally and unavoidably produce.

As, for the reasons adduced at the beginning of this article, the intention should never be entertained of supporting the decisions of the international court by force of arms, it remains to be considered what means of another kind could be had recourse to, in order to raise to as high a pitch as possible the motive of nations respectively to yield obedience to its decisions.

We have already spoken of the effect which would be produced, in pointing the sentiments of mankind, giving strength to the moral sanction, and by the existence of an accurate code, and by the decisions themselves of a well constituted tribunal.

To increase this effect to the utmost, publicity should be carried to the highest practicable perfection. The code, of course, ought to be universally promulgated and known. Not only that, but the best means should be in full operation for diffusing a knowledge of the proceedings of the tribunal; of the cases investigated, the allegations made, the evidence adduced, the sentence pronounced, and the reasons upon which it is grounded.

The book of the law of nations, and selections from the book of the trials before the international tribunal, should form a subject of study in every school, and a knowledge of them a necessary part of every man's education. In this manner a moral sentiment would grow up, which would, in time, act as a powerful restraining force upon the injustice of nations, and give a wonderful efficacy to the international jurisdiction. No nation would like to be the object of the contempt and hatred of all other nations; to be spoken of by them on all occasions with disgust and indignation. On the other hand, there is no nation, which does not value highly the favourable sentiments of other nations; which is not elevated and delighted with the knowledge that its justice, generosity, and magnanimity, are the theme of general applause. When means are taken to make it certain that what affords a nation this high satisfaction will follow a just and beneficial course of conduct; that what it regards with so much aversion, will infallibly happen to it, if it fails in the propriety of its own behaviour, we may be sure that a strong security is gained for a good intercourse among nations.

Law of Nations  
||  
Navy.

Law of Nations  
||  
Navy.

Besides this, it does not seem impossible to find various inconveniencies, to which, by way of penalties, those nations might be subjected, which refused to conform to the prescriptions of the international code.

Various privileges granted to other nations, in their intercourse with one another, might be withheld from that nation which thus demeaned itself in a way so contrary to the general interests. In so far as the withholding of these privileges might operate unfavourably upon individuals belonging to the refractory nations,—individuals who might be little, or not at all, accessory to the guilt, the effect would be the subject of proportional regret. Many, however, in the concerns of mankind, are the good things which can only be attained with a certain accompaniment of evil. The rule of wisdom, in such cases, is, to be sure that the good outweighs the evil, and to reduce the evil to its narrowest dimensions.

We may take an instance first from trivial matters. The ceremonial of other nations might be turned against the nation, which, in this common concern, set itself in opposition to the interests of others. The lowest place in company, the least respectful situation on all occasions of ceremony, might be assigned to the members of that nation, when travelling or residing in other countries. Many of those marks of disrespect, implying neither injury to person nor property, which are checked by penalties in

respect to others, might be free from penalties in respect to them. From these instances, adduced merely to illustrate our meaning, it will be easy to see in what manner a number of considerable inconveniencies might, from this source, be made to bear upon nations refusing to conform to the beneficial provisions of the international code.

Besides the ceremonial of other nations, means to the same end might be derived from the law. A number of cases might be found in which certain benefits of the law, granted to other foreigners, might be refused to them. They might be denied the privilege of suing in the courts, for example, on account of any thing except some of the higher crimes, the more serious violations of person or property.

Among other things it is sufficiently evident, that this tribunal would be the proper organ for the trial of piracy. When preponderant inconvenience might attend the removing of the trial to the usual seat of the tribunal, it might delegate for that purpose the proper functionaries to the proper spot.

By the application of the principles, which we have thus expounded, an application which implies no peculiar difficulty, and requires nothing more than care in the detail, we are satisfied that all might be done, which is capable of being done, toward securing the benefits of international law.

(F.P.)

## N A V Y.

An insular empire, like that of the United Kingdom of Great Britain and Ireland, which is so much indebted, and always must be, for that power, prosperity, and renown which she enjoys, to the glorious deeds of her Navy, cannot but take a peculiar degree of interest in every thing that concerns it. This vast machine, indeed, has at all times been the pride and boast of Great Britain, the terror of its enemies, and the admiration of the world. It is under the impression of its vast importance that we have been induced to give, under their proper heads, such details of the civil and military branches of the naval departments, as may afford, without entering into too minute details, a comprehensive sketch of this great national bulwark, of which it is now proposed to take a general view.

The term NAVY is generally intended to express all ships of commerce as well as of war—the mercantile as well as the military marine; but the observations contained in the present article are meant to relate only to the latter, excepting that, in speaking of the progressive enlargement of ships, and improvements in naval architecture, the remarks may sometimes equally apply to ships of commerce and of war.

*Navy composed of MATERIEL and PERSONEL.*

The composition of a navy may be considered under the two distinct heads into which it naturally divides itself, and under which the French generally

distinguish an army, the *materiel*, and the *personel*; the former embracing every thing that appertains to the ships, their capacity, construction, armament, and equipment; the latter all that concerns the rank, the appointment, the various duties, &c. of the officers, seamen, and marines.

### I.—MATERIEL OF THE NAVY.

It would occupy too large a space to give even a short sketch of the origin and progress of naval architecture, from a bundle of branches, or the hollow trunk of a tree—the rude raft and the frail canoe—to the more perfect coracle, or the wicker boats of the ancient Britons covered with hides. For many centuries after the expulsion of the Romans from, or their abandonment of, the British Islands, very little progress appears to have been made by us in the art of navigation or ship building: the natives would appear, for many centuries afterwards, to have acted merely on the defensive against naval invasions.

“The whole of our naval history,” say the Commissioners for Revising the Civil Affairs of the Navy, “may be divided into three periods. The *First*, comprehending all that preceded the reign of Henry VIII. The *Second*, ending with the Restoration of Charles II.; and the *Third*, coming down from the Restoration to the present day.”

To what size, and to what extent, the amount of the English ships or vessels were carried, which sup-

History.

First Period.

Navy.

ported so many contests with the invading Danes, in the ninth century, our naval history has not preserved any record. We are told, however, that Alfred increased the size of his galleys, and that some of them were capable of rowing thirty pair of oars. These galleys were chiefly employed in clearing the Channel of the nests of pirates by which it was infested. It is also said, as a proof of his attention to naval matters, that under his auspices, one Ochter undertook a voyage into the Arctic Regions, made a survey of the coasts of Lapland and Norway, and brought to Alfred an account of the mode pursued by the inhabitants of those countries to catch whales. It is, moreover, on record, that his two sons, Edward and Athelston, fought many bloody actions with the Danes, in which several kings and chiefs were slain; and that Edgar had from 3000 to 5000 ships, divided into three fleets, stationed on three several parts of the coast, with which, passing from one fleet or squadron to the other, he circumnavigated the island; that after this he called himself "Monarch of all Albion, and Sovereign over all the adjacent Isles." Some notion, however, may be formed of the size of the vessels which composed his fleets, from the imposition of a land-tax, which required certain proprietors to furnish a stout galley of three rows of oars to protect the coast from the Danish pirates. The more effectually to check these marauders, and protect the coasts of the kingdom, William the Conqueror, in 1066, established the Cinque Ports, and gave them certain privileges, on condition of their furnishing 52 ships with 24 men in each for 15 days, in cases of emergency. We should not, perhaps, be far amiss in dating the period of our naval architecture from the Conquest. "The Normans," says Sir Walter Raleigh, "grew better shipwrights than either the Danes or Saxons, and made the last conquest of this land; a land which can never be conquered whilst the kings thereof keep the dominion of the seas." But Raleigh does not describe what the ships were which the Normans taught us to build; nor can it now be known in what kind of vessels William transported his army across the Channel, or what was the description of the hundred large ships and fifty galleys of which the naval armament of Richard I. consisted on his expedition to the Holy Land. We are told, however, that having increased his fleet at Cyprus to 250 ships, and 60 galleys, he fell in, with a ship belonging to the Saracens, of such an extraordinary size, that she was defended by 1500 men, all of whom, with the exception of 200, Richard, after taking possession of her, ordered to be thrown overboard and drowned.

There can be no doubt that the nations of the Mediterranean, particularly the Genoese and Venetians, introduced many improvements as to the capacity and stability of their ships, in consequence of the crusades and the demands for warlike stores and provisions, which such vast and ill-provided armies necessarily created; but these improvements would seem not to have reached, or, at least, to have made but a tardy progress in Great Britain. King John, it is true, stoutly claimed for England the sovereignty of the sea, and decreed that all ships belonging to foreign nations, the masters of which should refuse

Navy.

to strike to the British flag, should be seized and deemed good and lawful prize. And this monarch is said to have fitted out no less than 500 sail of ships, under the Earl of Salisbury, in the year 1213, against a fleet of three times that number, prepared by Philip of France, for the invasion of England; of which the English took 300 sail, and drove 100 on shore, Philip being under the necessity of destroying the remainder, to prevent their falling also into the hands of the English. Of the kinds of ships of which his fleet consisted, some notion may be formed by the account that is related of an action fought in the following reign with the French, who, with "80 stout ships," threatened the coast of Kent. This fleet being discovered by Hubert de Burgh, governor of Dover Castle, he put to sea with 40 English ships, and having got to the windward of the enemy, and run down many of the smaller ships, he closed with the rest, and threw on board them a quantity of quicklime, which blinded them so effectually, that all their ships were either taken or sunk.

Whatever the size and the armaments of our ships were, the empire of the sea was bravely maintained by the Edwards and the Henrys in many a gallant and glorious sea-fight with the fleets of France, against which they were generally opposed with inferior numbers. The temper of the times, and the public feeling, were strongly exemplified in the reign of Edward I. by the following circumstance: An English sailor was killed in a Norman port, in consequence of which a war commenced, and the two nations agreed to decide the dispute on a certain day, with the whole of their respective naval forces. The spot of battle was to be the middle of the Channel, marked out by anchoring there an empty ship. The two fleets met on the 14th April 1293; the English obtained the victory, and carried off above 250 sail.

In an action with the French fleet off the harbour of Sluys, Edward III. is said to have slain 30,000 of the enemy, to have taken 200 great ships, "in one of which, only, there were 400 dead bodies." This is no doubt an exaggeration. The same monarch, at the siege of Calais, is stated to have blockaded that port with 730 sail, having on board 14,956 mariners; 25 only of which were of the Royal navy, bearing 419 mariners, or about 17 men each. In various other sea actions did this great sovereign nobly support the honour of the British flag. But though we then, and ever after, claimed the "dominion of the seas," that dominion, says Raleigh, "was never absolute until the time of Henry the Eighth." It was a maxim of this great statesman, that "whosoever commands the sea, commands the trade of the world; whosoever commands the trade, commands the riches of the world, and consequently the world itself."

The reign of Henry V., however, was most glorious, in maintaining the naval superiority over the fleets of France. From a letter of this Sovereign to his Lord Chancellor, dated 12th August 1417, discovered by the late Mr Lysons among the records in the Tower, and of which the following is a copy, it would appear that there was something like an established

Navy.

Navy.

Royal navy in his reign, independently of the shipping furnished by the Cinque Ports and the merchants, for the King's own use, on occasion of any particular expedition. The letter appears to have been written nine days after the surrender of the castle of Touque in Normandy, from whence it is dated.

*" Au revéend pere en Dieu L'evesque de Duresme nre Chancellor D'Engleterre.*

" Worshipful fader yn God We sende you closed within this letter a cedula conteyning the names of certain Maistres for owr owne grete Shippes Carakes Barges and Balyngers to the whiche Maistres We have granted annuitees such as is appointed upon eche of hem in the same Cedula to take yerely of owr grante while that us lust at owr Exchequer of Westm<sup>r</sup> at the termes of Michelmasse and Ester by even porcions. Wherefore We wol and charge yow that unto eche of the said Maistres ye do make under owr grete seel beyng in yowre owre letters patentes severales in due forme after th'effect and pourport of owr said grante. Yeven under owr signet atte owr Castle of Touque the xij day of August."

*Extract from the Schedule contained in the preceding Letter.*

The remainder, to whose masters pensions were thus granted, consist of seventeen "niefs, barges, and ballyngers," some with three, and others two mariners only. But history informs us, that about this time Henry embarked an army of 25,000 men at Dover on board of 1500 sail of ships, two of which

carried purple sails, embroidered with the arms of England and France; one stiled the King's Chamber, the other his Saloon, as typical of his keeping his court at sea, which he considered as a part of his dominions. Still we are left in the dark as to the real dimensions of his ships, and the nature of their armament; they were probably used only as transports for his army. It would appear, however, from a very curious poem, written in the early part of the reign of King Henry the Sixth, that the navy of his predecessor was considerable, but that, by neglect, it was then reduced to the same state in which it had been during the preceding reigns. The poem here alluded to is entitled, "The English policie, exhorting all England to keep the sea, and namely the Narrow Sea; showing what profit cometh thereof, and also what worship and salvation to England and to all Englishmen," and is printed in the first volume of Hackluyt's *Collection of Voyages*. It was evidently written before the year 1438, when the Emperor Sigismond died, as appears by the following passage in the prologue:

*" For Sigismond, the great Emperour,  
Which yet reigneth, when he was in this land,  
With King Henry the Fifth, Prince of Honour,  
Here much glory, as him thought, he found  
A mightie land, which had take in hand  
To werre with France, and make mortalitie,  
And ever well kept round about the sea."*

The part of the poem which alludes to the navy of King Henry the Fifth is entitled, "Another incident of keeping the Sea, in the time of marvellous werriour and victorious Prince, King Henrie the Fifth, and of his great Shippes."

The following are the most remarkable passages:

*" And if I should conclude all by the King  
Henrie the Fift, what was his purposing,  
Whan at Hampton he made the great dromons,  
Which passed other great ships of the Commons;  
The Trinitie, the Grace de Dieu, the Holy Ghost,  
And other moe, which as now be lost.  
What hope ye was the Kings great intent  
Of thoo shippes, and what in mind he meant:  
It was not ellis, but that he cast to bee  
Lorde round about environ of the see.  
And if he had to this time lived here,  
He had been Prince named withouten pere:  
His great ships should have been put in preese,  
Unto the ende that he ment of in chiefe.  
For doubt it not but that he would have bee  
Lord and master about the round see:  
And kept it sure, to stoppe our enemies hence,  
And wonne us good, and wisely brought it thence,  
That no passage should be without danger,  
And his licence on see to move and sterre."*

Shortly after the time when this poem must have been written, it appears from the Parliament Roll (20th Hen. VI. 1442), that an armed naval force, consisting only of eight large ships, with smaller vessels to attend them, was to be collected from the ports of London, Bristol, Dartmouth, Hull and Newcastle, Winchelsea, Plymouth, Falmouth, &c.; and, of course, the Royal ships of 1417, the names or which are contained in the foregoing schedule, were then either gone to decay or dispersed. We are not to judge of the size of these ships from the few mariners appointed to each. These were merely the

Navy.

ship-keepers, or harbour-duty men, placed on permanent pay, to keep the ships in a condition fit for the sea when wanted.

Second Period.

It is very probable that, until our merchants engaged in the Mediterranean trade, and that the attention of the government was turned in the reign of Henry VII. (about 1496), to imitate Portugal in making foreign discovery, under the skilful seaman Sebastian Cabot, very little was added to the capacity or the power of British ships of war. It is said, however, that on the accession of Henry VII. to the throne in 1485, he caused his marine, which had been neglected in the preceding reign, to be put into a condition to protect the coasts against all foreign invasions; and that, in the midst of profound peace, he always kept up a fleet ready to act. In his reign was built a ship called the Great Harry, the first on record that deserved the name of a ship of war, if it was not the first exclusively appropriated to the service of the state. This is the same ship that Camden has miscalled the Henry Grace de Dieu, and which was not built till twenty years afterwards, under the reign of Henry VIII. The Great Harry is stated to have cost L. 14,000, and was burnt by accident at Woolwich in 1553.

We now come to that period of our naval history in which England might be truly said to possess a military marine, and of which some curious details have been left us by that extraordinary man of business Mr Pepys, a commissioner of the navy, and afterwards secretary to Charles II., at a time when the King executed in person the office of Lord High Admiral, and also to James II. until his abdication. His minutes and miscellanies relative to the navy are contained in a great number of manuscript volumes, which are deposited in the Pepysian Library in Magdalene College, Cambridge. From these papers it appears, that in the thirteenth year of Henry VIII., the following were the names and the tonnage of the Royal Navy:

	Tons.
Henry Grace de Dieu, - - - -	1500
Gabriel Royal, - - - -	650
Mary Rose, - - - -	600
Barbara, - - - -	400
Mary George, - - - -	250
Henry Hampton, - - - -	120
The Great Galley, - - - -	800
Sovereign, - - - -	800
Catherine Forteleza, - - - -	550
John Baptist, - - - -	400
Great Nicholas, - - - -	400
Mary James, - - - -	240
Great Bark, - - - -	250
Less Bark, - - - -	180
Two row-barges of 60 tons each,—making, in the whole, 16 ships and vessels measuring 7260 tons.	

The Henry Grace de Dieu is stated in all other accounts, and with more probability, to have been only 1000 tons; the rule for ascertaining the measurement of ships being still vague and liable to great error, was probably much more so. at this early period. This ship was built in 1515 at Erith, in the river Thames, to replace the Regent of the same tonnage,

which was burnt in August 1512; in action with the French fleet, when carrying the flag of the Lord High Admiral. There is a drawing in the Pepysian papers of the Henry Grace de Dieu, from which a print in the *Archaeologia* has been engraved, and of which a copy has been taken as a frontispiece to Mr Derrick's *Memoirs of the Rise and Progress of the Royal Navy*. From these papers it appears, that she carried 14 guns on the lower deck, 12 on the main deck, 18 on the quarter-deck and poop, 18 on the lofty fore-castle, and 10 in her stern ports, making altogether 72 guns. Her regular establishment of men is said to have consisted of 349 soldiers, 301 mariners, and 50 gunners, making altogether 700 men. Some idea may be formed of the awkwardness in manœuvring ships built on her construction or similar to her, when it is stated that, on the appearance of the French fleet at St Helens, the Great Harry, built in the former reign, and the first ship built with two decks, had nearly been sunk, and that the Mary Rose of 600 tons, with 500 or 600 men on board, was actually sunk at Spithead, occasioned, as Raleigh says, "by a little sway in casting the ship about, her ports being within sixteen inches of the water." On this occasion the fleets cannonaded each other for two hours; and it is remarked as something extraordinary, that not less than 300 cannon-shot were fired on both sides in the course of this action. From the prints above mentioned, which agree very closely with the curious painting of Henry crossing the Channel in his fleet, to meet Francis on the "Champ de drap d'Or," near Calais, (and now in the great room where the Society of Antiquaries hold their meetings in Somerset House,) it is quite surprising how they could be trusted on the sea at all; their enormous poops and fore-castles making them appear loftier and more awkward than the large Chinese junks, to which, indeed, they bear a strong resemblance.

Henry VIII. may justly be said to have laid the foundation of the British navy. He established the dock-yards at Deptford, Woolwich, and Portsmouth; he appointed certain commissioners to superintend the civil affairs of the navy, and settled the rank and pay of admirals, vice-admirals, and inferior officers; thus creating a national navy, and raising the officers to a separate and distinct profession. The great officers of the navy then were, the Vice-Admiral of England; the Master of the Ordnance; the Surveyor of the Marine Causes; the Treasurer, Comptroller, General Surveyor of the Victualling, Clerk of the Ships, and Clerk of the Stores. Each of these officers had their particular duties, but they met together at their office on Tower-Hill once a week, to consult, and make their reports to the Lord High Admiral. He also established the fraternity of the Trinity-House, for the improvement of navigation and the encouragement of commerce, and built the castles of Deal, Walmer, Sandgate, Hurst Castle, &c. for the protection of his fleet and of the coast.

At the death of Henry VIII. in 1547, the Royal navy consisted of about 50 ships and vessels of different sizes, the former from 1000 to 150 tons, and the latter down to 20 tons, making in the whole about 12,000 tons, and manned by about 8000 mariners.

Navy.

Navy. soldiers, gunners, &c. In the short reign of his son Edward, little alteration seems to have taken place in the state and condition of the Royal navy. But the regulations which had been made in the reign of his father, for the civil government of naval affairs, were revised, arranged, and turned into ordinances, which form the basis of all the subsequent instructions given to the commissioners for the management of the civil affairs of the navy. In the reign of Mary the tonnage of the navy was reduced to about 7000 tons; but her Lord High Admiral nobly maintained the title assumed by England of "Sovereign of the Seas," by compelling Philip of Spain to strike his flag that was flying at the main-top-mast head, though on his way to England to marry Queen Mary, by firing a shot at the Spanish admiral. He also demanded that his whole fleet, consisting of 160 sail, should strike their colours and lower their top-sails, as an homage to the English flag, before he would permit his squadron to salute the Spanish monarch.

The reign of Elizabeth was the proudest period of our naval history, perhaps surpassed by none, previous to the Revolution. She not only increased the numerical force of the regular navy, but established many wise regulations for its preservation, and for securing adequate supplies of timber and other naval stores. She placed her naval officers on a more respectable footing, and encouraged foreign trade and geographical discoveries, so that she acquired justly the title of the "Restorer of Naval Power, and Sovereign of the Northern Seas." The greatest naval force that had at any previous period been called together was that which was assembled to oppose the "Invincible Armada," and which consisted, according to the notes of Mr Secretary Pepys, of 176 ships, with 14,992 men; but these were not all "Shippes Royall," but were partly composed of the contributions of the Cinque Ports and others. The number actually belonging to the navy is variously stated, but they would appear to have been somewhere about 40 sail of ships, manned with about 6000 men. At the end of her reign, however, the navy had greatly increased, the list in 1603 consisting of 42 ships of various descriptions, amounting to 17,000 tons, and manned with 8346 men. Of these two were of the burden of 1000 tons each, three of 900 tons, and ten from 600 to 800 tons.

James I. was not inattentive to his navy. He warmly patronized Mr Phineas Pett, the most able and scientific shipwright that this country ever boasted, and to whom we undoubtedly owe the first essential improvements in the form and construction of ships. The cumbrous top-works were first got rid of under his superintendence. "In my owne time," says Raleigh, "the shape of our English ships hath been greatly bettered—in extremity we carry our ordnance better than we were wont—we have added crosse pillars in our royall shippes, to strengthen them; we have given longer floors to our shippes than in older times," &c. The young Prince Henry was so fond of naval affairs, that Phineas Pett was ordered, by the Lord High Admiral, to build a vessel at Chatham in 1604 with all possible speed, for the young Prince Henry to disport himself in, above

Navy. London Bridge; the length of her keel was 28 feet, and her breadth 12 feet. In 1610 Pett laid down the largest ship that had hitherto been built. She was named the Prince Royal; her burden 1400 tons; her keel 114 feet; and armed with 64 pieces of great ordnance; "being in all respects," says Stowe, "the greatest and goodliest ship that was ever built in England." He adds, "the great workmaster in building this ship was Mr Phineas Pett, gentleman, sometime Master of Arts, of Emanuel Colledge, in Cambridge."

This excellent man, as appears from a manuscript account of his life in the British Museum, written by himself, was regarded by the shipwrights of the dock-yards, who had no science themselves, with an eye of jealousy, and a complaint was laid against him before the King, of ignorance in laying off a ship, and of a wasteful expenditure of timber and other matters. The King attended at Woolwich with his court, to inquire in person into the charges brought forward, and, after a painful investigation, pronounced in favour of Mr Pett. One of the charges was, that he had caused the wood to be cut across the grain; but the King observed, that, as it appeared to him, "it was not the wood, but those who had preferred the charges, that were cross-grained."

The state of the navy at the King's death is variously given, by different writers, but on this subject the memoranda left by Mr Secretary Pepys are most likely to be correct. From them it appears, that, in 1618, certain commissioners were appointed to examine into the state of the navy; and, by their report, it appears there were then only 39 ships and vessels, whose tonnage amounted to 14,700 tons; but in 1624, on the same authority, the numbers had decreased to 32 or 33 ships and vessels, but the tonnage increased to about 19,400 tons. The commissioners had, in fact, recommended many of the small craft to be broken up or sold, and more ships of the higher rates to be kept up.

The navy was not neglected in the troublesome reign of Charles I. This unfortunate monarch added upwards of 20 sail to the list, generally of the smaller kind; but one of them, built by Pett, of a description, both as to form and dimensions, far superior to any that had yet been launched. This ship was the celebrated "Sovereign of the Seas," which was launched at Woolwich in 1637. The length of her keel was 128 feet, and main breadth 48 feet, and from stem to stern 232 feet. In the description of this ship by Thomas Heywood, she is said to have "bore five lanthorns, the biggest of which would hold ten persons upright; had three flush-decks, a fore-castle, half-deck, quarter-deck, and round-house. Her lower tier had 30 ports for cannon and demi-cannon; middle tier, 30 for culverines and demi-culverines; third tier, 26 for other ordnance; fore-castle, 12; and two half-decks, 13 or 14 ports more within board, for murdering pieces; besides 10 pieces of chace ordnance, forward, and 10 right aft, and many loop-holes in the cabins for musquet-shot. She had 11 anchors, one of 4400 pounds weight. She was of the burthen of 1637 tons." It appears, however, that she was found, on

Navy.

trial, to be too high for a good serviceable ship in all weathers, and was, therefore, cut down to a deck less. After this she became an excellent ship, was in almost all the great actions with the Dutch; was rebuilt in 1684, and the name changed to that of "Royal Sovereign;" was about to be rebuilt a second time at Chatham in 1696, when she accidentally took fire, and was totally consumed. In this reign the ships of the navy were first classed, or divided into six rates; the first being from 100 to 60 guns; the second from 54 to 36, &c.

In 1642 the management of the navy was taken out of the King's hands, and in 1648 Prince Rupert carried away 25 ships, none of which ever returned; and such, indeed, was the reduced state of the navy, that at the beginning of Cromwell's usurped government, he had only 14 ships of war of two decks, and some of these carried only 40 guns; but under the careful management of very able men, in different commissions which he appointed, such vigorous measures were pursued, that, in five years, though engaged within that time in war with the greatest naval power in Europe, the fleet was increased to 150 sail, of which more than a third part had two decks; and many of which were captured from the Dutch; and upwards of 20,000 seamen were employed in the navy. Our military marine was, indeed, raised by Cromwell to a height which it had never before reached; but from which it soon declined under the short and feeble administration of his son.

Though Cromwell found the navy divided into six rates or classes, it was under his government that these ratings were defined and established in the manner nearly in which they now are; and it may also be remarked, that, under his government, the first frigate, called the Constant Warwick, was built in England. "She was built," says Mr Pepys, "in 1649, by Mr Peter Pett (son of Phineas), for a privateer for the Earl of Warwick, and was sold by him to the state. Mr Pett took his model of this ship from a French frigate, which he had seen in the Thames."

During the first period of our naval history, we know nothing of the nature of the armament of the ships. From the time of Edward III. they might have been armed with cannon, but no mention is made of this being the case. According to Lord Herbert, brass ordnance were first cast in England in the year 1535. They had various names, such as cannon, demi-cannon, culverins, demi-culverins, sakers, mynions, falcons, falconets, &c. What the calibre of each of these were is not accurately known, but the cannon is supposed to have been about 60 pounders, the demi-cannon 32, the culverin 18, falcon 2, mynion 4, saker 5, &c. Many of these pieces, of different calibres, were mounted on the same deck, which must have occasioned great confusion in action in finding for each its proper shot.

On the Restoration of Charles II. the Duke of York was immediately appointed Lord High Admiral; and by his advice, a committee was named to consider a plan, proposed by himself, for the future regulation of the affairs of the navy, at which the Duke himself presided. By the advice and able as-

sistance of Mr Pepys, great progress was speedily made in the reparation and increase of the fleet. The Duke remained Lord High Admiral till 1673, when, in consequence of the test required by Parliament, to which he could not submit, he resigned, and that office was in part put in commission, and the rest retained by the King. Prince Rupert was put at the head of this commission, and Mr Pepys appointed secretary to the King in all naval affairs, and of the admiralty; and by his able and judicious management, there were in sea-pay, in the year 1679, and in excellent condition, 76 ships of the line, all furnished with stores for six months, eight fire-ships, besides a numerous train of ketches, smacks, yachts, &c. with more than 12,000 seamen; and also 30 new ships building, and a good supply of stores in the dock-yards. But this flourishing condition of the navy did not last long. In consequence of the dissipation of the King, and his pecuniary difficulties, he neglected the navy on account of the expences; the Duke was sent abroad, and Mr Pepys to the Tower. A new set of commissioners were appointed, without experience, ability, or industry; and the consequence was, as stated by the commissioners of revision, that "all the wise regulations, formed during the administration of the Duke of York, were neglected; and such supineness and waste appear to have prevailed, that, at the end of not more than five years, when he was recalled to the office of Lord High Admiral, only 22 ships, none larger than a fourth rate, with two fire-ships, were at sea; those in harbour were quite unfit for service; even the 30 new ships which he had left building had been suffered to fall into a state of great decay, and hardly any stores were found to remain in the dock-yards."

The first act on the Duke's return was the re-appointment of Mr Pepys as secretary of the admiralty. Finding the present commissioners unequal to the duties required of them, he recommended others. Sir Anthony Dean, the most experienced of the ship-builders then in England, was joined with the new commissioners. To him, it has been said, we owe the first essential improvement in the form and qualities of ships of the line, having taken the model of the Superbe, a French ship of 74 guns, which anchored at Spithead, and from which he built the Harwich in 1664. Others, however, are of opinion that no improvement had at this time been made on the model of the Sovereign of the Seas after she was cut down. The new commissioners undertook, in three years, to complete the repair of the fleet, and furnish the dock-yards with a proper supply of stores, on an estimate of L. 400,000 a year, to be issued in weekly payments; and in two years and a half they finished their task, to the satisfaction of the King and the whole nation; the number of ships repaired and under repair being 108 sail of the line, besides a considerable number of vessels of smaller size. The same year the King abdicated the throne, at which time the list of the navy amounted to 173 sail, containing 101,892 tons, carrying 6930 guns, and 42,000 seamen.

The naval regulations were wisely left unaltered at the Revolution, and the business of the Admiralty continued to be carried on chiefly, for some time,

Third  
Period.

Navy.

Navy.

under the immediate direction of King William, by Mr Pepys, till the arrival of Admiral Herbert and Captain Russell from the fleet, into whose hands, he says, "he silently let it fall." Upon the general principles of that system, thus established with his aid by the Duke of York, the civil government of our navy has ever since been carried on.

In the second year of King William (1690), no less than 30 ships were ordered to be built, of 60, 70, and 80 guns each; and in 1697, the King, in his speech to Parliament, stated that the naval force of the kingdom was increased to nearly double what he found it at his accession. It was now partly composed of various classes of French ships which had been captured in the course of the war, amounting in number to more than 60, and in guns to 2300; the losses by storms and captures on our side being about half the tonnage and half the guns we had acquired. At the commencement of this reign, the navy, as we have stated, consisted of 173 ships, measuring 101,892 tons; at his death, it had been extended to 272 ships, measuring 159,020 tons, being an increase of 99 ships and 57,128 tons, or more than one-half both in number and in tonnage.

The accession of Queen Anne was immediately followed by a war with France and Spain, and in the second year of her reign, she had the misfortune of losing a vast number of her ships by one of the most tremendous storms that was ever known; but every energy was used to repair this national calamity. In an address to the House of Lords in March 1707, it is declared as "a most undoubted maxim, that the honour, security, and wealth of this kingdom does depend upon the protection and encouragement of trade, and the improving and right encouraging its naval strength . . . therefore, we do in the most earnest manner beseech your Majesty, that the sea-affairs may always be your first and most peculiar care." In the course of this war were taken or destroyed about 50 ships of war, mounting 3000 cannon; and we lost about half the number. At the death of the Queen in 1714, the list of the navy was reduced in number to 247 ships, measuring 167,219 tons, being an increase in tonnage of 8199 tons.

George I. left the navy pretty nearly in the same state he found it. At his death, in 1727, the list consisted of 233 ships, measuring 170,862 tons, being a decrease in number of 14, but an increase in tonnage of 3643 tons.

George II. was engaged in a war with Spain in 1739, in consequence of which the size of our ships of the line ordered to be built was considerably increased. In 1744, France declared against us; but on the restoration of peace in 1748, it was found that our naval strength had prodigiously increased. Our loss had been little or nothing, whilst we had taken and destroyed, of the French 20, and of the Spanish 15 sail of the line, besides smaller vessels. The war with France of 1755 added considerably to the list, so that, at the King's decease, in 1760, it consisted of 412 ships, measuring 321,104 tons.

In the short war of 1762, George III. added no less than 20 sail of the line to our navy. At the conclusion of the American war in 1782, the list of

the navy was increased to 600 sail; and at the signing of the preliminaries in 1783, it amounted to 617 sail, measuring upwards of 500,000 tons; being an increase of 185 ships and 157,000 tons and upwards since the year 1762. At the peace of Amiens, the list of the fleet amounted to upwards of 700 sail, of which 144 were of the line. The number taken from the enemy, or destroyed, amounted nearly to 600, of which 90 were of the line, including 50 gun ships, and upwards of 200 were frigates; and our loss amounted to about 60, of which 6 were of the line and 12 frigates.

The recommencement and long continuance of the Revolutionary war, and the glorious successes of our naval actions, the protection required for our extended commerce, of which, in fact, we might be said to enjoy a monopoly, and for the security of our numerous colonies, contributed to raise the British navy to a magnitude to which the accumulated navies of the whole world bore but a small proportion. From 1808 to 1813, there were seldom less than from 100 to 106 sail of the line in commission, and from 130 to 160 frigates, and upwards of 200 sloops, besides bombs, gun-brigs, cutters, schooners, &c., amounting in the whole to about 500 sail of effective ships and vessels; to which may be added 500 more in the ordinary, and as prison, hospital, and receiving ships; making at least 1000 pendants, and measuring from 800,000 to 900,000 tons. The commissioners appointed to inquire into the state and condition of the woods, forests, and land revenues of the Crown, state, in their report to Parliament, in the year 1792, that, "at the accession of his Majesty (Geo. III.) to the throne, the tonnage of the Royal navy was 321,104 tons, and at the end of the year 1788, it had risen to no less than 413,467 tons." In 1808 it had amounted to the enormous extent of 800,000 tons, having nearly doubled itself in twenty years.

It must not, however, be supposed that the effective navy consisted of more than half this amount of tonnage. Since the conclusion of the war, it would appear that at least one-half of the number of ships then in existence have been sold or broken up as unfit for the service; and as, by the list of the navy at the beginning of the year 1821, the number of ships and vessels of every description in commission, in ordinary, building, repairing, and ordered to be built, has been reduced to 609 sail, we may take the greatest extent of the present tonnage at 500,000 tons; but the greatest part, if not the whole, of this tonnage may be considered as efficient, or in a state of progressive efficiency.

According to the printed list of the 1st January 1821, the 609 sail of ships and vessels appear to be as under:

	No.
1st Rates from 120 to 100 guns,	23
2d Rates — 86 — 80 do.	16
3d Rates — 78 — 74 do.	90
4th Rates — 60 — 50 do.	20
5th Rates — 48 — 22 do.	107
6th Rates — 34 — 24 do.	40
Sloops — 22 — 10 do.	136
Making a total of	432

Navy.

Brought forward, -	432
To which being added gun-brigs, cutters, schooners, tenders, bombs, troop - ships, store- ships, yachts, &c. -	177
Grand total,	609

The increase in the size of our ships of war was unavoidable; France and Spain increased theirs, and we were compelled, in order to meet them on fair terms, to increase the dimensions of ours; many of theirs were, besides, added to the list of our navy. The following sketch will show the progressive rate at which ships of the first rate, or of 100 guns and upwards, were enlarged in their dimensions. In 1677 the first rates were from 1500 to 1600 tons. In 1720 they were increased to 1800 tons. In 1745 we find

them advanced to 2000 tons. During the American war they were raised to 2000 tons. In 1795 the Ville de Paris, of 110 guns, measured 2350 tons. In 1804 the Hibernia, of 110 guns, was extended to 2500 tons; and in 1808 the Caledonia, carrying 120 guns, measured 2616 tons, and here we stopped; but since then, the Nelson, the Howe, the St Vincent, the Britannia, the Prince Regent, the Royal George, and the Neptune, have been built, or building, all nearly of the same dimensions, and from the same draught—nine such ships as the whole world beside cannot produce. The French had one ship larger than any of these, called the Commerce de Marseilles. She was taken by us in Toulon, but broke her back in a gale of wind.

The following are the comparative dimensions of the Caledonia and the Commerce de Marseilles:

	Length of Gun-deck.		Length of Keel.		Extreme Breadth.		Depth of Hold.		Tons.
	feet.	in.	feet.	in.	feet.	in.	feet.	in.	
Commerce de Marseilles,	205	0	170	9	53	8	23	2	2616
Caledonia, - - -	208	4	172	0	54	9½	25	0½	2747

The following is the armament of the Caledonia: On the gun-deck she carries 32 guns, 32-pounders; middle-deck 34 24-pounders; upper deck 34 24-pounders, carronades; quarter-deck 10 32-pounders, and 6 12-pounders, carronades; fore-castle 2 32-pounders, and 2 12-pounders, carronades. Her complement of men 875.

At the commencement of the *third period*, we have a somewhat more precise account of the armament of our ships of war. On the 16th May 1677, a Committee of the Navy Board, Ordnance, and certain naval officers, recommended to his Majesty the following scheme for arming and manning the 30 new ships of the line ordered to be built by act of Parliament.

Guns.	1st Rates.	2d Rates.	3d Rates.
Cannon (supposed 42 prs.).	No. 26		
Demi-cannon (32 prs.),		26	26
Culverins (18 prs.),	28	26	
Twelve pounders,			26
Sakers, upper-deck,	28	26	
Fore-castle,	4		4
Quarter-deck,	12	10	10
Three pounders,	2	2	4
	100	90	70

For the 1st rate, 780 men.  
For the 2d do. 660 do.  
For the 3d do. 470 do.

The rates of ships immediately after the Revolution were reduced, the 1st being turned to 2d rates, 2d rates to 3d, &c., and the size of each class more equalized. But from this time forward it was found impossible to preserve any thing like uniformity in the several classes. So many ships captured from the French, Dutch, and Spaniards, were added to

our navy, and so many new ones built after the models of ships taken from these maritime powers, that the various descriptions of ships of which our navy was composed became a very serious evil.

In the year 1745, a committee, composed of all flag officers unemployed, of the commissioners of the navy, who were sea-officers, under the presidency of Sir John Norris, and assisted by the master shipwrights, were ordered to meet, to consider, and propose proper establishments of guns, men, masts, yards, &c. for each class of his Majesty's ships; and, according to their recommendation, the rates, armaments, and complements of his Majesty's ships were to be as follows:

Rate.	Guns.	Men.
1	100	850 or 750
2	90	750 or 660
3	{ 80	650 or 600
	{ 70	520 or 460
4	{ 60	420 or 380
	{ 50	350 or 280
5	44	280 or 220
6	24	160 or 140

But this establishment was very soon departed from; for, on the 3d of February 1747, the Board of Admiralty acquainted his Majesty, that the French ship Invincible, lately captured, was found to be larger than his Majesty's ships of 90 guns, and 750 men; and suggested that this ship, and all other prizes of the like class, and also his Majesty's ships of 90 guns, when reduced to two decks and a half, and 74 guns, should be allowed a complement of 700 men. And it further appears, that, at the latter end of the reign of George the Second, the rates of ships had undergone a very material alteration, for they consisted as under:

1st Rate, 100 guns.  
2d Rate, 90 guns.

Navy.

3d Rate, 80 guns, 74—70—64 guns.  
 4th Rate, 60 guns, 50  
 5th Rate, 44 guns, 38—36—32 guns.  
 6th Rate, 30 guns, 28—24—20 guns.

The scales for measuring the ships were as various as their rates; and the evil was further increased by the varieties, which it was found necessary to introduce in the rigging and arming the ships of war. The masts, yards, rigging, and stores, were of so many and various dimensions, as to be not only highly inconvenient, but extremely expensive. When Lord Nelson was off Cadiz with 17 or 18 sail of the line, he had no less than *seven* different classes of 74 gun ships, each requiring different sized masts, sails, yards, &c. so that, in the event of one of these being disabled, the others could not supply her with such stores as could be appropriated to her wants.

#### *Present Rating of the Navy.*

To remedy the many inconveniences resulting from the irregularities above mentioned, the Lords of the Admiralty suggested, by their Memorial to the Prince Regent, which, by his Order in Council, of the 25th November 1816, was ordered to be carried into effect, that the ships of the navy should for the future be rated as under:

The 1st rate to include all three-deckers, in as much as all sea going ships of that description carry 100 guns and upwards.

The 2d rate to include all ships of 80 guns and upwards, on two decks.

The 3d rate to include all ships of 70 guns and upwards, and less than 80 guns.

The 4th rate to include all ships of 50 and upwards, but less than 70 guns.

The 5th rate to include all ships from 36 to 50 guns.

The 6th rate to include all ships from 24 to 36 guns.

And that the complements of men be established as under:

1st Rate,	900 — 850 or 800 men
2d do.	700 or 650
3d do.	650 or 600
4th do.	450 or 350
5th do.	300 or 280
6th do.	175 — 145 or 125.

Of sloops the complements established according to their size, to consist of 135, 125, 95, or 75 men. Brigs (not sloops), cutters, schooners, and bombs, with 60 or 50 men.

Thus stands the rating and manning of the navy at present; but another war, or a new administration of the affairs of the navy, will, in all human probability, make new regulations in these respects. It is, however, of the utmost importance, with a view to convenience and economy, that the size and dimensions of the several rates should be kept as nearly as possible equal, in order that one description of stores may be applicable to every ship of the same rate. To this end, the commissioners of naval revision have recommended, "that the ships of each class or rate should be constructed in every particu-

lar, according to the form of the best ship in the same class in our navy; of the same length, breadth, and depth; the masts of the same dimensions, and placed in the same parts of the ship, with the same form and size of the sails."

Navy.

#### *Improvements in Construction.*

If we look back to the days of Elizabeth, when the chain-pump, the capstan, the striking of the top-masts, the studding sails, top-gallant-sails, sprit-sails, &c. were first introduced into the navy, one can scarcely conceive how they contrived to keep the sea for any length of time; but these improvements, important as they were, are trifling when compared with those aids and conveniences which have gradually been introduced since her reign, and which a ship of war now enjoys. When Sir Anthony Deane, in 1664, raised the lower ports of a two-decker four and a half feet out of the water, which had before been scarcely three feet, and made a ship of this class to stow six months' provisions instead of three, it was justly considered as a most important improvement; not less so, when the breadth of a ship of this class was carried to 45 feet. "The builders of England," says Pepys, "before 1673, had not well considered that breadth only will make a stiff ship." It must be confessed, however, that as far as the form of a ship's bottom depends on scientific principles, we have copied our best models from the French, sometimes with capricious variations, which more frequently turned out to be an injurious alteration than an improvement.

The first essential alteration in the form of our ships of the line was taken from the *Superbe*, a French ship of 74 guns, which anchored at Spithead, on the model of which, as already stated, the *Harwich* was built by Sir Anthony Deane in 1674; since which time we have constantly been copying from French models; improving or spoiling, as chance might determine. "Where we have built exactly after the form of the best of the French ships that we have taken," say the commissioners of naval revision, "thus adding our dexterity in building to their knowledge in theory, the ships, it is generally allowed, have proved the best in our navy; but whenever our builders have been so far misled by their little attainments in the science of naval architecture, as to depart from the model before them in any material degree, and attempt improvements, the true principles on which ships ought to be constructed (being imperfectly known to them) have been mistaken or counteracted, and the alterations, according to the information given to us, have, in many cases, done harm:" while, therefore, they add, "our rivals in naval power were employing men of the greatest talents and most extensive acquirements, to call in the aid of science for improving the construction of ships, we have contented ourselves with groping on in the dark, in quest of such discoveries as chance might bring in our way."

On these grounds, and by the recommendation of the commissioners, a school for a superior class of shipwright apprentices has been established in Portsmouth Dockyard. It consists of twenty-five young men of liberal education; whose mornings are passed in the study of mathematics and mechanics, and in their

Navy.

application to naval architecture; and the remainder of the day under the master shipwright in the mould loft, and in all the various kinds of manual labour connected with ship-building, as well as in the management and conversion of timber, so as to make them, at the same time, fully acquainted with all the duties in detail of a practical shipwright.

If, however, we have hitherto been inferior to the French in the scientific principles of ship-building, in the constructive part we have left them behind beyond all comparison; and notwithstanding the narrow prejudices which have been more remarkably adhered to among shipwrights, than among almost any other class of artisans, various alterations and improvements have from time to time been introduced into the mechanical part of naval architecture, which have added to the strength, the stability, the comfort, and convenience of our ships of war, and rendered them, in every point of view, superior to those of any other nation. The application of iron where wood was formerly used, and of copper for iron, have added considerably to the durability of ships; and the sheathing their bottoms with copper, to their celerity; giving them, at the same time, a protection against the worm and those marine insects which were wont to adhere to them; yet, it is remarkable, how strong the prejudice was against this practice before it obtained a due degree of credit. In the fleet of Sir Edward Hughes in India there was but one coppered ship, and Rodney's squadron in the West Indies had but four that were coppered in the year 1779; but these were enough so completely to establish their superiority over the others with wooden sheathing, that, in the year 1782, the whole British navy was coppered.

System of Diagonal Bracing.

But the greatest of all improvements in the construction of ships of war, as tending to their strength and durability, is the system of diagonal bracing, introduced a few years ago by Mr (now Sir Robert) Seppings, surveyor of the navy, and now universally adopted in all ships of the line and frigates; a system that may be said to have established a new era in naval architecture. Of all large machines destined to undergo severe shocks, a ship is perhaps the least skilfully and artificially contrived. Her several parts are put together on a principle so much opposed to that which constitutes strength, that if a ship, on the old construction, should be put upon wheels, and drawn over a rough pavement, the action of a day would shake her in pieces; but being destined to move in an element that closes upon her, and presses her equally on all sides, she is prevented from falling in pieces outwards, and her beams and decks preserve her from tumbling inwards. Whoever has observed a ship *in frame*, as it is called, on the stocks, that is, with only her timbers erected, must forcibly be reminded of the skeleton of some large quadruped, as of a horse or ox, laid on its back; the keel resembling the back-bone, and the curved timbers the ribs, which is, in fact, the name by which they sometimes go. These ribs, issuing at right angles from the keel, consist, in a 74 gun-ship, of about 800 different pieces, the space between each rib seldom exceeding five inches. These ribs are covered with a skin or planks of different

thickness within and without, also at right angles to the ribs, and fixed to them by means of wooden pins or tree-nails. In the inside three or four tier of beams cross the skeleton from side to side, at right angles to both planks and ribs. These beams support the decks. At right angles to the beams are pieces of wood called carlings, and at right angles to these other pieces called ledges, and upon these the planks of the deck are laid in a direction of right angles to the beams, and parallel to the planking of the sides. From this sketch it will be perceived, that all the parts of a ship are either parallel or at right angles to each other. The ribs form a right angle with the keel, the planks inside and out are at right angles to the ribs, the beams at right angles to these, the carlings to the beams, the ledges to the carlings, and the planks of the decks to the ledges, the beams, and the ribs.

Now, it is well known to every common carpenter that this disposition of materials is the weakest that can be adopted. Thus, if five pieces of wood be pinned together in the shape of a parallelogram, it will require but little force to move them from the rectangular to the oblique or rhomboidal shape, as

But place a cross-bar, as in the figure Z, as carpenters are accustomed to do on a common gate, and it is no longer moveable on the points of fastening.

The strongest proof of a ship's partaking of this weakness in the old construction, is afforded on her being first launched into the water, when it is invariably found that the two extremities, being less water-borne than the middle, drop, and give to the ship a convex curvature upwards, an effect which, from its resemblance to the shape of a hog's back, is usually called *hogging*. In very weak or old ships this effect may be discovered in all the port-holes of the upper-deck, by their having taken the shape of lozenges declining different ways from the centre of the ship to each extremity.

Navy.

Navy.

To obviate this great defect, Seppings tried the experiment of applying to the ribs or timbers of the ship, from one extremity to the other, and from the orlop-deck downwards to the keelson, that well-known principle in carpentry, called *trussing*; being, in fact, a series of diagonal braces disposing themselves into triangles, the sides of which give to each other a mutual support and counteraction. These triangles were firmly bolted to the frame; and in order to give a continuity of strength to the whole machine, and leave no possible room for play, he filled the spaces between the frames with old seasoned timber cut into the shape of wedges; but recently with a prepared cement, thus rendering the lower part of the ship or floor one solid complete mass, possessing the strength and firmness of a rock.

The same principle of trussing is carried from the gun-deck upwards, from whence, between every port, is introduced a diagonal brace, which completely prevents the tendency of ships to stretch, or draw asunder their upper works. The decks, too, are made subservient to the securing more firmly the beams to the sides of the ship, by the planks being laid diagonally in contrary directions, from the midships to the sides, and at an angle of 45° with the beams, and at right angles with the ledges.

In frigates and smaller vessels, iron plates, lying at an angle of 45° with the direction of the trusses, are substituted for the diagonal frame of wood in ships of the line.

By this mode of construction, the ceiling, or internal planking, is wholly dispensed with, and a very considerable saving of the finest oak timber thereby effected; and what is more important, those receptacles of filth and vermin between the timbers, which were before closed up by the planking, entirely got rid of. This is not the least important part of the improvement, either as it concerns the soundness of the ship, or the health of the crew. It is stated, that a ship, which had been three years in India, on being laid open, exhibited a mass of filth, mixed up with dead rats, mice, cockroaches, and other vermin, which was taken out in cakes, not unlike in appearance the oil-cake with which certain animals are fed; that the stench was abominable, and the timbers with which it was in contact rotten. No such filth can find a lodgment in ships of war as they are now built.

The first ships on which the new principle was tried were those rebuilt or repaired in docks, from which they were quietly floated out without any shock from launching; but several of them sustained severe gales of wind, without showing the least symptoms of weakness, but quite the contrary, not even a crack appearing in the white-wash with which their sides within were covered. If these experiments were not satisfactory, the launching of two of the largest ships in the navy, established the fact of superior strength beyond the possibility of a doubt—the Nelson and the Howe. The Nelson, constructed on the old principle, was probably, in every respect, the best built ship in modern times; the timber sound and well seasoned; the workmanship admirable; and no pains were left unemployed by Mr Sison, the builder, to have her as perfect as she could be made; and her motion, when launched from

Navy.

the stocks, was slow, easy, and majestic, without a shake or a plunge; yet the Nelson was found to have arched, after launching, no less than 9½ inches. The Howe is a sister ship to the Nelson, but built on the new principle; and after launching, she was found to have arched only three inches and five-eighths. The St Vincent, built on the old principle, and the same in every respect as the Howe, likewise hogged on launching nine inches and a quarter; and the whole fabric, in both cases, was found, on examination, to be greatly disturbed; whereas the Howe exhibited no such symptoms. The Plate No. CI. will show the mode of trussing ships of the line according to the plans of Sir Robert Seppings, now universally adopted in the British navy.

It has been a subject of discussion among ship-builders, whether tree-nails or metallic fastenings are to be preferred. The objection to iron bolts is, their rapid corrosion from the gallic acid of the wood, the sea-water, and perhaps by a combination of both; in consequence of which, the fibres of the wood around them become injured, the bolts wear away, the water oozes through, and the whole fabric is shaken and deranged. This corrosion of iron fastenings was most remarkable when the practice of sheathing ships with copper became general, and when iron nails were made use of to fix it: by the contact of the two metals and the sea-water, both were immediately corroded. Mixed metal nails are now used for this purpose; and copper bolts are universally employed below the line of flotation, though it is found that in these also oxidation takes place to a certain degree, and causes partial leaks. Various mixtures of metals have been tried, but all of them are considered to be liable to greater objections than pure copper. It would appear, then, that tree-nails, if properly made, well seasoned, and driven tight, are the least objectionable, being seldom found to occasion leaks, or to injure the plank or timbers through which they pass. This species of fastening has at all times been used by all the maritime nations of Europe. The Dutch were in the habit of importing them from Ireland, it being supposed that the oak grown in that country was more tough and strong than any which could be procured on the Continent, and in all respects best adapted for the purpose. "Under all circumstances," says Mr Knowles, "it appears that the present method of fastening ships generally with tough well seasoned tree-nails, with their ends split, and caulked after being driven, and securing the butts of each plank with copper bolts well clenched, is liable to fewer objections, and more conducive to the durability of the timber, than any other which has been tried, or proposed to be established."

The rounding the form of the bow, in ships of the line, is considered, by nautical men, of great utility and importance. The plan was first proposed by Seppings in 1807, and has since been generally adopted. The removal of the head railing, and the continuing of the rounded form, give not only great additional strength to the ship, but also much more comfort and convenience to the crew, and security in that part of the ship when in action.

Fastenings.

Round Bows  
to Ships of  
the Line.

Navy.  
 Scarphing a Substitute for Compass Timber.

The scarcity of compass or crooked timber was, for some time, attended with serious injury to those ships of war, while on the stocks, into which it was considered necessary to be introduced. The difficulty with which it was procured, the length of time which a ship sometimes remained on the stocks waiting for a few pieces of compass timber, the green wood, when found, being immediately added to the seasoned timber in other parts of the frame, gave to the ship different periods of durability; though, in the long-run, the seasoned parts became affected by the green wood with which they were in contact, and a premature decay of the whole fabric was the consequence. Seppings, therefore, proposed a plan in 1806, which, by uniting short timbers according to a method called *scarphing*, enabled him to obtain every species of compass-form that could be required from straight timber. Since that period, the whole frame of a ship can be prepared at once, without waiting for particular pieces, and thus every part of it be made to undergo an equal degree of seasoning.

Plan for rendering Frigate Timber applicable to Ships of the Line.

By the same ingenious and indefatigable surveyor of the navy, a plan was proposed and adopted in the year 1813, by which ships of the line were built with timber hitherto considered as applicable only to the building of frigates, and that which had been deemed only fit for inferior uses was appropriated to principal purposes. The *Talavera* was the first ship built on this principle, and the expence of her hull is stated to have been about a thousand pounds less than that of the *Black Prince*, a ship of similar dimensions built on the old principle. The method by which the timbers were united was found, on trial of the *Talavera* with the *Black Prince*, while in frame, to give so much additional strength to the former, that it furnished the ground-work of the present mode of framing the British navy, by the introduction of the same union of materials in the application of the large, as was practised in that of the small timber; and from which both strength and economy have been united.

Use of Chocks abolished.

The building of the *Talavera*, and the great strength of her frame, led to the practice of putting together the frames of ships of the line from timbers of reduced lengths, and dispensing altogether with the chocks used for uniting their extremities, or, as they are technically called, their heads and heels. These chocks are of the form of an obtuse wedge, as A, and they are used to unite the two pieces of timber, as B and C, by firmly bolting the piece A to the two timbers B and C.

It generally happened, however, that, in the operation of thus fixing this chock, its two extremities split, and the surfaces of the chock and timbers not being in perfect contact, the moisture and air were admitted, and occasioned, as they always do, the dry-rot to a greater degree in those parts of the ship than in most others; and as there were from four to five hundred of these chocks in a 74 gun-ship,

it will readily be conceived what mischief was done to the whole fabric, if the greatest care was not taken by the workmen to prevent their splitting, and to bring their surfaces immediately into contact. It is obvious, also, that a great deal of timber must have been cut to waste in making these chocks; and, in fact, they consumed timber in each ship, when it was at a high price, to the value of from L.1500 to L.2000, besides a considerable expence in workmanship; and when the ship came to be repaired, not one chock in six was found to be in a fit state to be used again. It is not easy to conceive how this practice of uniting the timbers of a ship's frame came to be introduced so generally into the British navy, more especially as it is unknown in any other nation; it was probably first done to preserve the length of some particular timbers, one of whose ends might be defective, and the unsound part cut away in the manner we see it, and the sound chock introduced to fill up the vacancy; but it is quite surprising how a practice should have become general which creates a waste of timber, an increase of workmanship, and sows the seeds of premature decay. To obviate these disadvantages, Sir Robert Seppings brought the butt ends of the timbers together thus,

and kept them together by means of a round dowel or coak, as C, just as the felines of a carriage wheel are fastened together. He justly observes, that the simplicity of the workmanship, the economy in the conversion of timber, and the greater strength and durability, although of considerable moment, are of trifling importance when compared with the advantage of rendering timber generally more applicable to the frames of ships, which had heretofore been but partially so.

Another great improvement in the construction of ships of war, introduced by Seppings, is the round stern, which, however unsightly it may at first appear, from being accustomed to view the square stern with its grotesque carved work, is even in appearance more consistent with the termination of the sweeping lines of a ship's bottom, than the cutting them off abruptly with a square stern. But the additional strength which is thus given to a ship in that part which was hitherto the weakest, is alone sufficient to recommend the adoption of the plan, in our ships of war, particularly in those of the larger classes. The advantages gained by circular sterns are thus enumerated by Sir Robert Seppings.

1. They give additional strength to the whole fabric of a ship.
2. They afford additional force in point of defence.
3. They admit of the guns being run out in a similar way to those in the sides.
4. From the circular form and mode of carrying up the timbers, an additional protection against shot is obtained, if the ship should be raked.
5. The stern being equally strong as the bow, no serious injury can accrue in the event of the ship being pooped; and the ship may be moored, if so required, by the stern.

Navy.

6. A ship will sail better upon a wind, from the removal of the projections of the quarter galleries.

7. Ships of the line have now a stern-walk protected by a veranda, and so contrived that the officers can walk all round, can observe the set of the sails, and the fleet in all directions.

8. The compass-timber heretofore expended for transoms is substituted with straight timber, and worked nearly to a right angle, which affords a considerable saving in the consumption of timber.

9. The counter being done away by the circular stern, the danger which arose from boats being caught under it is obviated.

In fact, the circular stern possesses many other advantages not necessary to be enumerated in this place.

#### *Improvements in the Preservation of the Navy.*

Not only the new mode of construction is highly favourable to the duration of ships, but the ravages of the disease known by the name of the dry-rot, occasioned principally by the hurry in which ships were built in the course of the late war, and the unseasoned state of the timber made use of (see DRY-ROT), led to such measures as tend most effectually to the preservation of the fleet.

In the first place, various modes were put in practice for assorting and seasoning the timber, and for protecting it from the vicissitudes of the weather. The oak and fir of Canada, which had been introduced to a great extent into our dock-yards, during the time the Baltic was shut against this country, are now excluded; these woods having been found not only to possess little durability, but so friendly to the growth of fungi, that they communicated the baneful disease to all other descriptions of timber with which they came in contact. The practice of building ships under cover, introduced into our dock-yards in the course of the war, and carried to an extent so as to have roofed over almost every dock and slip in all the yards, has been destructive to the growth of dry-rot. (See DOCK-YARDS.) By filling in between the timbers masses of cement, and then injecting by forcing-pumps a mixture of oil and tar, into all the joints and crevices of the frames; and lastly, by the care and very constant attention bestowed on ships after leaving the dock-yard, and being placed in a state of ordinary, it may be said that the dry-rot has no longer any existence in the British navy.

A ship now placed in ordinary, whether new or newly repaired, is carefully housed over, so that no rain can reach her lower decks; several streaks of planks are removed from her sides and decks to admit a thorough draft of air, which is sent down by wind-sails, and which pervades every part of the ship, and these, with the addition of two small airing-stoves in which a few cinders are burned, render her perfectly dry and comfortable on all the decks and store-rooms. All the shingle ballast is removed out of the hold, which is thoroughly cleaned and restowed with iron ballast. The lower tier of iron tanks filled with pure fresh water serves to complete the ballast, and prevent her from hogging or arching. The former practice of mooring two ships together, by which the two sides next to each other,

Navy.

deprived of the sun and a free circulation of air, were generally found to be decayed, is discontinued. The lower masts are left standing, and their tops housed over; the gun-carriages and several of the stores are left on board; and such, in short, is the state of a ship in ordinary, that she may be fitted in all respects for proceeding to sea in half the usual time. "The ships," says Mr Knowles, "are frequently pumped to clear them of bilge-water; and cleanliness in every respect is attended to; the lower decks are rubbed with dry stones, commonly called holly-stones, and with sand, the use of water upon them being strictly forbidden." But that which most of all is likely to ensure the preservation of the fleet, while in a state of ordinary, is the recent regulation, which places the ordinary under the superintendence of a post-captain at each port, with several commissioned-officers under his orders, who take care that the warrant-officers and ship-keepers attend to the proper airing, ventilating, and keeping clean and dry their respective ships.

A practice has recently been introduced into the dock-yards, of steeping oak timber in salt-water for several months, and then stacking it till it becomes perfectly dry, which is said to have entirely put a stop to the progress of dry-rot, where it had already commenced, and to act as a preventive to that disease. We have heard some doubts entertained on this point. The Americans seem to place little confidence in the good effects which are said to have been experienced from the immersion of timber. Rodgers, the commissioner of their navy, states, in an official report addressed to the Secretary, that "experiments have been made to arrest the dry-rot in ships, by sinking them for months in salt-water, but without success. The texture of the wood was found to be essentially injured by being thus water soaked, and it became more subject to this disease than before it was sunk. The ships were also injured in their fastenings, and the atmosphere within them was kept in a constant state of humidity, whence, among other ill effects, proceeded injury to provisions and stores, and sickness to the crews." Now, we know that not one of these injurious effects happened to the *Eden*, which was sunk in Hamoaze, remained under water three or four months, was sent to India, and has been at sea ever since; but, from being covered with fungus before the operation, she has not showed a single symptom to dry-rot since the time of her being weighed, and continues a good sound ship. The truth is, the American timber, with the single exception, perhaps, of the live-oak, is remarkably subject to dry-rot, of which, during the late war, we had fatal experience. Mr Rodgers, however, accounts for the condition in which the oak and pine was received in England from Canada, by its immersion in water: "The Canada timber," he observes, "is brought down the St Lawrence in large rafts, continues months in water, and in that saturated state is landed and exposed to frost; every attempt to season it under cover is unavailing; its pores never close again, and when used as ship-timber, dry-rot ensues, which, when once commenced, can never be arrested, but by taking out all the pieces in any degree affected." The Russians, he says, are

By Immersion of Timber in Salt-Water.

By Prevention of Dry-Rot.

By Precautions in Ordinary.

Navy.

so fully aware of the injurious effects of soaking ship-timber in water, that it is brought from great distances down the rivers in crafts, instead of rafts. The Russian ships, however, with all this precaution, are not remarkable for durability. The ships built at Antwerp by the French were in a state of rottenness before they were launched; but whether this was owing to the bad quality of the timber of the German forests, or to its being water-soaked in rafting down the Rhine, remains doubtful. But we can have no doubt that porous timber is injured by moisture, though the solid British oak may be improved by the dissolution of its sap juices, to the fermentation of which the disease, known by the name of dry-rot, may chiefly be owing. "Water," says Lescaulier, a French writer of considerable merit on the subject, "seems to be favourable to the decomposition of the sap of timber when immersed; but it substitutes in its place another kind of moisture not less destructive, of which the timber, though afterwards exposed to the air, will not easily get rid of; besides, it weakens and destroys the grain of the wood."—"The best means," he adds, "of preserving timber, appears to be that of keeping it in well constructed and airy sheds, in a vertical position, so that the moisture which remains in the interior of the logs, by running along the fibres of the wood, may be enabled to issue from the lower extremity. Timber thus kept dry, under shelter, will preserve itself for ages." Mr Knowles, secretary to the Committee of Surveyors of his Majesty's Navy, in his *Treatise on the Means of Preserving the British Navy*, is led to conclude, from a variety of experiments, "that timber is better seasoned when kept for two years and a half under cover, than when placed for six months in water, and then for two years in the air, protected from the rain and sun; that it loses more in seasoning, by having been, during the six months of immersion, alternately wet and dry, than the whole time under water; and that the loss in moisture is greater in all cases in a given time, when the butt-ends are placed downwards." And he adds as a general principle, "that no timber should be brought into use in this country, until it has been felled at least three years."

By Roofing  
the Ships.

Next to the system of diagonal braces, and making the bottoms of ships one compact and solid mass, the roofing, thrown over them while building, and in ordinary, may be considered as the greatest of all improvements for the preservation of the navy; the utility of which is so obvious, that it is quite extraordinary such a practice should not have been earlier adopted; more especially, as at Venice, at Carlsrona, and at Cronstadt, ships of war had long been built, repaired, and protected under covered roofs. It was strongly recommended to the English ship-builders fifty years ago, but without effect; and had it not been for the extraordinary ravages of the dry-rot in the unseasoned timber-built ships of the navy, we should still have been without roofs to our docks and slips.

By other  
Means.

If the dock-yards were of sufficient capacity, there can be no doubt that the efficient plan to accomplish their durability, would be that of keeping them on the slip, when built, under cover. It was stated

by Mr Strange, when examined by the Commissioners for Land Revenue, that in the year 1790 there were 22 ships of the line under roofs, in the port of Venice, some of which had remained in that situation 59 years. Since, however, it is utterly impracticable to keep our navy on slips, or in dry docks, the next important consideration is, how best to preserve them afloat in a state of ordinary. Various expedients have been at different times resorted to in order to prevent the premature decay of ships laid up in this state during peace. The two great requisites for their preservation are ventilation and cleanliness. To promote the former, wind-sails were in general use, though, if not attended to so as to oppose the open part to the quarter from whence the wind blows, or if the weather be calm, they are of little benefit. Pneumatic machines of various kinds, as pumps and bellows, have been applied to force out the foul air, and introduce atmospheric air into the lower parts of a ship's hold. Heated air from stoves, placed in various parts of the ship, and conducted through tubes, was thought at one time to be efficacious in the preservation of the navy; but experience soon showed that the heat thus circulated was so far objectionable, as it tended to encourage the growth of fungus, where there was any moisture lodged, and in the timber which had not been thoroughly seasoned. Perhaps no better means can be suggested than those we have described to be in practice, namely, to keep them clean, to admit as much dry air as possible, and to exclude all moisture.

Finally, if we take into consideration the numerous improvements which a war, unparalleled in its duration, has been the means of introducing into the materiel of the navy, whether it regards the economy of its application, the construction of the ships, and their mode of preservation, we may safely say, that at no former period was this country in possession of such a navy as at present, in respect of the numbers, size, and good condition of the ships which compose a fleet, superior to those of the whole world besides; and it is gratifying to find, that, with all the enormous consumption of the military and mercantile navy, it does not appear that the naval resources of Great Britain are at all impaired.

#### Naval Resources.

It is of essential importance that the supply of stores for the use of the fleet should not only be adequate to the demand, but that a sufficient stock should be kept on hand to answer any sudden emergency. This is the more necessary with regard to those species of stores which are derived from foreign nations.

The principal articles of consumption required for building and equipping a fleet are hemp, canvas, pitch, tar, iron, copper, and timber. All these articles might unquestionably be produced in sufficient quantities in the United Kingdom and her colonies, if necessity absolutely required it. Hemp, for instance, might be grown to any extent in Great Britain and Ireland, were not the land more advantageously employed in raising other articles of consumption; and if it could not be cheaper imported from Russia. In the East Indies, the Sunn hemp

Navy.

Princip  
Naval  
Stores.  
Hemp

**Navy.** (inferior it is true to Russia hemp) might be procured to any extent, and other plants, both there and at home, might be substituted for the making of cordage and canvas. For pitch and tar, recourse might be had to the pitch lake on the island of Trinidad, and the coal tar, of which an inexhaustible supply may be had at home. The lake is about four miles in circumference, and many feet in depth of solid pitch; and it is stated that, when mixed with oil or tallow, it is rendered fit for all the purposes to which pitch and tar are usually applied. It has the advantage of securing ships' bottoms against the attack of the worm, which is very active in the neighbouring Gulf of Para; and it does not corrode iron. The coal tar of home manufacture, from some prejudice or other, was refused a fair trial till very lately; and it is now deemed not inferior for many purposes to the common tar. For painting or tarring over wood work of every kind, it is said to stand exposure to the weather even better than the common tar; and it is used for injecting in large quantities between the timbers of ships, as a preservative from the dry-rot; its powerful smell having also the good effect of driving rats and other vermin out of the ships on which it is employed.

**Pitch and Tar.**

**Copper and Iron.** In the two important articles of copper and iron, our own resources may be considered inexhaustible. Formerly it was deemed indispensable that certain articles should be made of Swedish iron, but of late years our own has been manufactured in every respect equally good; and the extensive application of this metal in bridges, barges, dock-gates, roofs, rafters, floors, &c. has been equally progressive in most naval purposes. Iron knees and other modes of binding the beams to the side timbers of ships, are now substituted for those large and crooked pieces of timber which were once deemed absolutely necessary. Our cables, rigging, buoys, and tanks for holding water, are now of iron; and we understand that hollow masts of iron are actually constructing as an experiment, which, if successful, will do away the necessity of depending for a foreign supply of that most expensive and not very plentiful article, mast-timber.

**Timber.** But the most important article of demand for the use of the navy is timber, principally oak; concerning the supply of which from our own territories, different opinions have been entertained. A deficiency in other articles may readily be supplied. A failure in the importation of hemp, for instance, in any one year, might be remedied the next, by an extended cultivation of that article; but it requires a whole century to repair any defalcation of oak timber, and to render us independent of other nations. Nor has the subject been sufficiently elucidated, so as to form a just opinion, by the several Committees of the House of Commons; the evidence produced being almost always loose, and generally contradictory. The committee of 1774, which was directed to inquire into the state of oak timber throughout the kingdom, either from a disagreement of opinion, or defect of evidence, or a wish to avoid giving alarm, prayed the House to discharge that part of its order which required them to report their opinion. The Commissioners of Woods and Forests, however, in their

port laid before Parliament in 1792, appeared to establish the fact of an alarming scarcity of oak timber in general, but more particularly of large naval timber, both in the royal forests, and on private estates. And if such was really the fact in 1792, it will readily be conceived what the state of timber fit for naval purposes must have been at the conclusion of the Revolutionary war, when the amount of private shipping had increased from 1,300,000 tons to 2,500,000 tons, or nearly doubled; that of the East India Company, in the same period, from 79,900 tons to 115,000 tons; and that of the navy, from 400,000 to 800,000 tons, to say nothing of the vast consumption of oak timber in all kinds of mill-work and other machinery, in the barrack and ordnance departments—in mines, collieries, and agriculture—in docks, and dock-gates—in piers, locks, and sluices—in boats, barges, lighters, bridges, and a great many other purposes to which this timber is applied. From these, and many other causes, the diminution of oak timber was infinitely greater than the commissioners had calculated upon, and yet they recommended that 100,000 acres, belonging to the crown, should be set apart and planted, as necessary for the future supply of the navy. A bill to this effect, relating to the New Forest, passed the Commons, but was thrown out by the Lords.

On the departments of the Surveyor-general of the Land Revenue, and the Surveyor-general of the Woods and Forests being united, the Board of Commissioners made their first report, which was printed, by order of the House of Commons, in June 1812. In this report, it is stated, that, taking the tonnage of the navy in 1806 at 776,087 tons, it would require, at  $1\frac{1}{2}$  load to a ton, 1,164,085 loads to build such a navy; and supposing the average duration of a ship to be fourteen years, the annual quantity of timber required would be 83,149 loads, exclusive of repairs, which they calculate would be about 27,000 loads, making in the whole about 110,000 loads; of which, however, the commissioners reckon may be furnished 21,341 loads as the annual average of prizes: and of the remaining 88,659 loads, they think it not unreasonable to calculate on 28,659 from other sources than British oak. "This," they observe, "leaves 60,000 loads of such oak as the quantity which would be sufficient annually to support, at its present unexampled magnitude, the whole British navy, including ships of war of all sorts, but which may be taken as equivalent together to twenty 74 gun ships, each of which, one with another, contains about 2000 tons, or would require, at the rate of a load and a half to the ton, 3000 loads, making just 60,000 loads for twenty such ships."

Now, it has been supposed, that not more than 40 oak trees can stand on an acre of ground, so as to grow to a full size, fit for ships of the line, or to contain each a load and a half of timber; 50 acres, therefore, would be required to produce a sufficient quantity of timber to build a 74 gun ship, and 1000 acres for 20 such ships; and, as the oak requires at least 100 years to arrive at maturity, 100,000 acres would be required to keep up a successive supply, for maintaining a navy of seven or eight hundred thousand tons. The commissioners further observe,

**Navy.**

Report of the Commissioners of Land Revenue respecting Timber.

Quantity of Timber required for the Navy.

Navy.

that as there are twenty millions of acres of waste lands in the kingdom, a two-hundredth part set aside for planting would at once furnish the whole quantity wanted for the use of the navy.

This calculation, we suspect, is overrated by about one-half. In the first place, it supposes a state of perpetual war, during which the tonnage of the whole navy is considered as more than double of what it now actually is; and, in the second place, it reckons the average duration of the navy at fourteen years only, which, from the improvements that have taken place in the construction and preservation of ships of war, with the resources of teak ships, built in India, we should not hesitate in assuming at an average of twice that number of years; and, if so, the quantity of oak required for the navy will be nothing like that which the commissioners have stated. This, we think, will appear from a statement made (apparently on good authority) in the midst of the war, when the ships of the line, built in merchants' yards, were falling to decay, after a service of five or six years.

“ Assuming 400,000 tons as the amount of tonnage to be kept in commission, and the average duration of a ship of war at the moderate period of 12½ years, there would be required an annual supply of tonnage, to preserve the navy in its present effective state, of 32,000 tons: and, as a load and a half of timber is employed for every ton, the annual demand will be 48,000 loads. The building of a 74 gun ship consumes about 2000 oak trees, or 3000 loads of timber, so that 48,000 loads will build 8 sail of the line and 16 frigates. Allowing one-fourth part more for casualties, the annual consumption will be about 60,000 loads, or 40,000 full-grown trees; of which 35 will stand upon an acre of ground. The quantity of timber, therefore, necessary for the construction of a 74 gun ship will occupy 57 acres of land, and the annual demand will be the produce of 1140 acres. Allowing only 90 years for the oak to arrive at perfection, there ought to be now standing 102,600 acres of oak plantations, and an annual felling and planting, in perpetual rotation, of 1140 acres to meet the consumption of the navy alone: large as this may seem, it is little more than 21 acres for each county in England and Wales; which is not equal to the belt which surrounds the park and pleasure grounds of many estates.”

The above calculation proceeds on the principle that every acre is covered with trees fit for naval purposes, or that it contains 35 trees, with a load and a half of timber in each. It may be doubted, however, if, on the average of plantations, we shall find more than one-tenth of that number on an acre; and as the same writer endeavours to show, that the quantity of oak timber consumed in the navy is only about one-tenth part of the whole consumption of the country, instead of 120,600 acres being sufficient for a perpetual supply, there would be required some ten or twelve millions of acres, in plantations similar to those at present existing, to supply the demand for oak timber. Whether such a quantity exists or not, the fact is certain, that, long before the conclusion of the war, a scarcity began to be felt, especially of the larger kind of timber fit for

Navy.

ships of the line; and so great was this scarcity, that if Sir Robert Seppings had not contrived the means of substituting straight timber for those of a certain form and dimensions, before considered to be indispensable, the building of new ships must entirely have ceased.

If, however, the growth of oak for ship timber was greatly diminished during the war, so as to threaten an alarming scarcity, there is little doubt, that, from the increased attention paid by individuals to their young plantations, and the great extension of those plantations, as well as from the measure of allotting off portions of the royal forests to those who had claims on them, and enclosing the remainder for the use of the public, this country will, in future times, be fully adequate to the production of oak timber equal to the demand for the naval and mercantile marine. It will require, however, large and successive plantations, on account of the slow growth of the oak. But there is another tree, of late years very generally planted on rising grounds, which bids fair to become an object of great national importance, as furnishing the best, and perhaps only substitute for oak timber. We mean the larch, which thrives well and grows rapidly in bad soils and exposed situations, the timber of which has been found to be durable, and from several experiments, not inferior in strength, toughness, and elasticity to oak. So rapid is its growth, that the Duke of Atholl received twelve guineas for a single larch fifty years old; the timber was valued at two shillings a foot. A larch of 70 years' growth produces timber fit for all naval purposes, and may be considered equal in size to an oak of double that age. The dimensions of a larch tree cut down at Blair Atholl in 1817, and then 79 years of age, were as follows: stem 82 feet; top 20 feet; total height 102 feet; girth at the ground 12 feet; at 19 feet, 8 feet 3½ inches, and at 57 feet, 4 feet 10 inches; solid contents, 252,8 cubic feet. Another larch, now growing at Dunkeld, measured, in 1819, then 80 years old, and in full vigour, as follows: height of stem 75 feet, top 14 feet; total height 90 feet. At one foot from the ground, 17 feet 8 inches in girth; at 10 feet, 10 feet 4 inches, and at 70 feet, 3 feet 2 inches; its contents 300 cubic feet, or six loads. For all kinds of mill-work, as wheels, axle-trees, &c. the utility of the large larch wood is unquestionable; and the thinnings are excellent for piling, rails, and hurdles. The value of its application for naval purposes is now under trial; two frigates of 28 guns, one built entirely of larch, from the Duke of Atholl's plantations, the other of Riga fir (which is inferior only to oak), being intended to go through the same service, precisely in the same parts of the world, in order to ascertain their comparative durability.

In addition to our resources of naval timber at IndianTeak home, we have wisely availed ourselves of those which India affords for building ships of war at Bombay of teak, a wood far superior in every respect to oak, and many times more durable; not liable to corrode iron or other metallic fastenings, not susceptible of the dry-rot, nor subject to the attack of the worm.

Navy.

Navy.

II.—PERSONEL OF THE NAVY.

The *personel* of the navy is composed of two different bodies of men—the Seamen and the Marines; each of whom have their appropriate officers.

The commissioned officers of the former consist of flag-officers, post-captains, commanders, and lieutenants. Flag-officers are divided into three ranks, and each rank into three squadrons, distinguished by the colours, red, white, and blue; as admiral of the red, white, or blue; vice-admiral of the red, white, or blue; rear-admiral of the red, white, or blue; the admiral wearing his colour at the main, the vice-admiral at the fore, and the rear-admiral at the mizen-mast-head. There is also an admiral of the fleet, who, if in command, would carry the union flag at the main. There are besides superannuated rear-admirals, enjoying the rank and pay of a rear-admiral, but incapable of rising to a higher rank on the list. There is also in the navy the temporary rank of commodore, who is generally an old post-captain, and is distinguished by wearing a broad pendant. He ranks next to the junior rear-admiral, and above all post-captains, except where the captain of the fleet shall be a post-captain, who, in that situation, takes rank next to the junior rear-admiral.

The commissioned officers of the navy take rank with those of the army, as follows :

Navy.	Army.
Admiral of the fleet,	Field-marshal.
Admiral,	General.
Vice-admiral,	Lieutenant-general.
Rear-admiral,	Major-general.
Commodore,	Brigadier-general.
Post-captain of 3 years,	Colonel.
Post-captain under ditto,	Lieutenant-colonel.
Commander,	Major.
Lieutenant,	Captain.

And all officers of the same rank command according to the priority of their commissions, or, having commissions of the same date, according to the order in which they stand on the list of the officers of the navy, except in the case of lieutenants of flag-ships, who take precedence according as the flag-officer shall think fit to appoint them.

The warrant officers of the navy may be compared with the non-commissioned officers of the army. They take rank as follows: master, second master, gunner, boatswain, carpenter. There are other warrant officers of the navy, who, though non-combatants, constitute a part of the establishment of the larger classes of ships of war. These are, the chaplain, surgeon, surgeon's assistant, purser. To which may be added, as part of the staff of a fleet or squadron, secretary to the admiral or commander-in-chief, and physician of the fleet.

The petty officers are very numerous, the principal of whom are master's mates and midshipmen. Their names or ratings will be seen in the table of the establishment of the ratings and pay in the several classes of ships of war.

By the King's Order in Council, the following regulations are established for the promotion of commis-

sioned officers of the navy. Midshipmen are required to serve six years on board some of his Majesty's ships, two of which years they must have been rated as midshipmen, to render them eligible to the rank and situation of lieutenant; or, if educated at the Royal Naval College, four years service at sea qualify for a commission as lieutenant.

No lieutenant can be promoted to the rank of commander, until he has been on the list of lieutenants for two years; and no commander to the rank of post-captain until he has been on the list for one year. Post-captains become admirals in succession, according to their seniority on the list; but if a post-captain should not have served in the course of the preceding war, when his turn arrives he is passed over, and placed on the list of superannuated and retired captains; as are those captains likewise who have accepted of commissionerships or other civil employments, provided they retain those employments, when they come within the limits of a promotion to the rank of rear-admiral.

There is also a list of superannuated rear-admirals composed of those who, not having actually served at sea in the preceding war, have been employed in regulating new raised men, or in the sea fencibles, or who have made offers of service, although not accepted. They enjoy the rank and half pay of a rear-admiral, but can never be employed as such, or be promoted to a higher rank.

No person can be appointed to serve as master of one of his Majesty's ships, who shall not have served as second master; and no person can be appointed as second master, until he has passed such examination as may from time to time be directed.

No person can be appointed gunner or boatswain, unless he shall have served one year as a petty officer on board one or more of his Majesty's ships, and produce certificates of his good conduct, and undergo the necessary examination.

No person can be appointed carpenter, unless he shall have served an apprenticeship to a shipwright, and been six months a carpenter's mate on board one or more of his Majesty's ships.

No person can be appointed purser, unless he shall have been rated and discharged the duties of a captain's clerk for two complete years, one year as captain's clerk, and been employed in the office of the secretary to a flag-officer for one other year, produce good certificates, and find such security for the honest and faithful discharge of his duty as shall be required.

No person can be appointed chaplain to one of his Majesty's ships, until he has received Priest's orders; but may be appointed to act while in Deacon's orders.

No person can be appointed surgeon to one of his Majesty's ships, until, by long and meritorious services, he has discharged the duties of assistant surgeon; and all persons applying for the situation of assistant surgeon must undergo an examination touching their qualifications before the medical members of the victualling board.

The Royal Marines consist of four great divisions. Royal Marines. 1st, Stationed at Chatham. 2d, At Portsmouth. 3d, At Plymouth. 4th, At Woolwich. They are com-

Commiss-  
ioned Offi-  
cers.

Warrant  
Officers.

Petty Offi-  
cers.

Order of  
Promotion.

Navy.

posed of 72 companies, besides 8 companies of Royal Marine Artillery, whose head-quarters are at Fort Monckton, Gosport. The 1st division has 21 companies; the 2d, 18 companies; the 3d, 20 companies; and the 4th, 13 companies. The officers of Royal Marines take rank with officers of the line in the army.

A colonel commandant, who is a general officer in the corps, is resident in London; and to each of the divisions is a colonel commandant, two lieutenant-colonels, and two majors, with a proper number of captains and subaltern officers. While on shore the marines are subject to the same regulations as the army, but, when embarked, are liable to the naval articles of war.

The staff of the marine corps, consists of a general, a lieutenant-general, a major-general, who are all flag-officers of his Majesty's fleet; and four colonels, who are post-captains, near the head of the list, and are selected from those who may have distinguished themselves by their services.

The paymaster of marines is resident in London, but each division has its paymaster, a captain in the corps; a barrackmaster, also a captain; two adjutants, and a quartermaster, who are first lieutenants; and to each division is a surgeon, and an assistant-surgeon.

There is also a retired list of officers who, in consideration of wounds, infirmities, and long meritorious services, are permitted to receive their full pay.

The commissions of officers, of every rank, in the marine corps, are signed by the King, but all commissions of officers of the navy are signed by two or more of the Lords Commissioners of the Admiralty. But the marines, whether ashore or afloat, are, as well as the officers of the navy, under the immediate direction and control of the Lords Commissioners of the Admiralty. All the appointments of commissioned and warrant officers to ships are made exclusively by the Lords of the Admiralty, or made subject to their confirmation, unless in cases of the death or dismissal of officers by sentence of Court-Martial on foreign stations, when the admiral commanding has the power to fill up the vacancies. And the duties of each rank are pointed out in a code of instructions emanating from that Board, and sanctioned by his Majesty's Order in Council.

Military  
Duties of the  
Lord High  
Admiral.

The civil powers and duties of the Lord High Admiral, or Lords Commissioners of the Admiralty, are treated of under the Article ADMIRAL in this *Supplement*. Their military powers are more extensive and important. By their orders, all ships are built, repaired, fitted for sea, or laid up in ordinary, broken up or sold; put in commission or out of commission, armed, stored, and provisioned; employed on the home or foreign stations. All appointments or removals of commission and warrant officers, with the exception of masters and surgeons, are made by them, and all instructions issued for the guidance of their commanders; all promotion in the several ranks emanate from them; all honours bestowed for brilliant services, and all pensions, gratuities, and superannuations for wounds, infirmities, and long services, are granted on their recommendation.

All returns from the fleet are sent to the Board of Admiralty, and every thing that relates to the discipline and good order of every ship. All orders for the payment of naval monies are issued by the Lords Commissioners of the Admiralty, and the annual estimate of the expences of the navy prepared by them, and laid before Parliament for its sanction. All new inventions and experiments are tried by their orders before introduced into the service; all draughts of ships must be approved by them; all repairs, alterations, and improvements in the dock-yards, all new buildings of every description must be submitted for their decision before they are undertaken. But the Commissioners of the Navy are held responsible for keeping up a proper supply of naval stores of every kind, and the Victualling Board of provisions.

All flag-officers, commanders-in-chief, are considered as responsible for the conduct of the fleet or in-Chief. squadron under their command; to keep them in perfect condition for service; to exercise them frequently in forming orders of sailing and lines of battle, and in performing all such evolutions as may occur in the presence of an enemy; to direct the commanders of squadrons and divisions; to inspect into the state of each ship under their command, to see that the established rules for good order, discipline, and cleanliness, be observed, and occasionally to inquire into these and other matters themselves. They are to correspond with the Secretary of the Admiralty, and report to him all their proceedings for the information of the Board.

If a commander-in-chief should be killed in battle, his flag is to be continued flying; intelligence to be conveyed by signal, or otherwise, to the next in command, who is immediately to repair on board, leaving his own flag (if a flag-officer) flying, and direct the operations of the fleet until the battle be ended, or the enemy out of sight.

Every flag-officer serving in a fleet, but not commanding it, is to superintend all the ships of the squadron or division placed under his orders; to see that their crews are properly disciplined; that all orders are punctually attended to; that the stores, provisions, and water, are kept as complete as circumstances will admit; that the seamen and marines are frequently exercised; and that every precaution is taken for preserving the health of their crews; for all which he is responsible to the commander-in-chief. When at sea, he is to take care that every ship in his division preserve her station, in whatever line or order of sailing the fleet may be formed; and in battle, he is to observe attentively the conduct of every ship near him, whether of the squadron or division under his immediate command or not; and at the end of the battle, he is to report it to the commander-in-chief, in order that commendation or censure may be passed as the case may appear to merit; and he is empowered to send an officer to supersede any captain who may misbehave in battle, or whose ship is evidently avoiding the engagement. If any flag-officer be killed in battle, his flag is to be kept flying, and signals to be repeated, in the same manner as if he were still alive, until the battle shall be ended; but the death of a flag-

Other Flag-  
Officers.

Navy. officer, or his being rendered incapable of attending to his duty, is to be conveyed as expeditiously as possible to the commander-in-chief.

Captain of the Fleet. The captain of the fleet is a temporary rank, where a commander-in-chief has ten or more ships of the line under his command; it may be compared with that of adjutant-general in the army. He may either be a flag-officer, or one of the senior captains; in the former case, he takes his rank with the flag-officers of the fleet; in the latter, he ranks next to the junior rear-admiral, and is entitled to the pay and compensation of a rear-admiral. All orders of the commander-in-chief are issued through him, and all returns of the fleet through him to the commander-in-chief. He is appointed, and can be removed from his situation only by the Lords Commissioners of the Admiralty.

Commodore. A commodore is a temporary rank, and of two kinds; the one having a captain under him in the same ship, the other without a captain. The former has the rank, pay, and allowances of a rear-admiral, the latter such additional pay as the Lords of the Admiralty may direct. They both carry distinguishing pendants.

Captain. When a captain is appointed to command a ship of war, he commissions the ship by hoisting his pendant; and if fresh out of the dock, and from the hands of the dock-yard officers, he proceeds immediately to prepare her for sea, by demanding her stores, provisions, guns, and ammunition, from the respective departments, according to her establishment. He enters such men as may volunteer, and be fit for the service (in time of peace), or which may be sent to him from some rendezvous for raising men, in time of war; and he gives them the several ratings of petty officers, able-seamen, ordinary, or landsmen, as their apparent qualifications may entitle them to. If he should be appointed to succeed the captain of a ship already in commission, he passes a receipt to the said captain for the ship's books, papers, and stores, and becomes responsible and accountable for the whole of the remaining stores and provisions; and to enable him to keep the ship's accounts, he is allowed a clerk of his own appointing.

The duty of the captain, with regard to the several ship's books and accounts, pay-books, entry, musters, discharges, &c. is regulated by various acts of Parliament; but the state of the internal discipline, the order, regularity, cleanliness, and the health of the crews, will depend mainly on himself and his officers. In all these respects, the general printed instructions for his guidance are particularly precise and minute. And for the information of the ship's company, he is directed to cause the articles of war, and abstracts of all acts of Parliament for the encouragement of seamen, and all such orders and regulations for discipline as may be established, to be hung up in some public part of the ship, to which the men may at all times have access; he is also to direct that they be read to the ship's company, all the officers being present, once at least in every month. He is not authorized to inflict any corporal punishment on any commissioned or warrant officer, but he may place them under arrest,

VOL. VI. PART I.

Navy. and suspend any officer who shall misbehave, until an opportunity shall offer of trying such officer by a court-martial. He is enjoined to be very careful not to suffer the inferior officers, or men, to be treated with cruelty or oppression by their superiors. He alone is to order punishment to be inflicted, which he is never to do without sufficient cause, nor ever with greater severity than the offence may really deserve; and all the officers and the whole ship's company are to be present at every punishment; which must be inserted in the log-book, and an abstract at the end of every quarter made out and sent to the Admiralty,—a regulation which is said to have been attended with infinite benefit to the strict and just discipline of the naval service.

The lieutenants take the watch by turns, and are Lieutenant. at such times entrusted, in the absence of the captain, with the command of the ship; but he is to inform the captain of all occurrences that take place during his watch, as strange sails that may be in sight, signals from other ships in company, change of wind, &c. He is to see that the ship be properly steered, the log hove, and the course and distance entered on the log-board; and, in short, he is to see that the whole of the duties of the ship are carried on with the same punctuality as if the captain himself were present; in whose absence, the senior lieutenant is responsible for every thing done on board.

The master receives his orders from the captain, Masters. or any of the lieutenants. His more immediate duties are those of stowing the ship's hold, and of attending to her sailing qualities; of receiving and placing the provisions in the ship, so as most conveniently to come at those which may be wanted. He is to take care that the cables are properly coiled in the tiers. The keys of the spirit-room are in his custody, and he is directed to entrust them only to the master's mates. He has the charge of the store-rooms of the warrant officers, which he is ordered frequently to visit; in short, the whole of the ship's provisions, water, fuel, and stores of every description, are under the superintendence of the master; and he is also entrusted, under the command of the captain, with the charge of navigating the ship, bringing her to anchor, ascertaining the latitude and longitude of her place at sea, surveying harbours, and making such nautical remarks and observations as may be useful and interesting to navigation in general.

The warrant officers are charged with the duty of receiving on board from the dock-yards, and examining, the various stores of their respective departments, and of keeping an account of the expenditure of them.

The gunner has the charge of the ship's artillery, Gunner. and of the powder magazine; he is to see that the locks and carriages are kept in good order, and that the powder is preserved from damp; he is frequently to examine the musquetry and small arms, and to see that they are kept clean, and fit for service; and, in preparing for battle, it is his duty to take care that all the quarters are supplied with every thing necessary for the service of the guns, and, during the action, that there be no want of ammunition served out. He is frequently to exercise the men at the guns

**Navy.** and to see that they perform this part of their duty with correctness, explaining and enforcing the necessity of their pointing the guns before they fire them, of spunging them well, and of close-stopping the touch-hole immediately after firing. The armourer and his mates are under the immediate orders of the gunner, in every thing that relates to the great guns and small arms.

**Boatswain.** The boatswain is charged with the duty of receiving and examining all the stores belonging to his department, consisting chiefly of the ropes and rigging, the latter of which he is ordered to inspect daily, in order that any part of it, chafed or likely to give way, may be repaired without loss of time. He is always required to be on deck at such times as all hands are employed; he is to see that the men, when called, move quickly upon deck, and when there, that they perform their duty with alacrity, and without noise or confusion. The sail-maker and the rope-maker are under his immediate orders; and he is directed to see that both these officers perform their respective duties with diligence and propriety.

**Carpenter.** The carpenter, when appointed to a ship, is carefully to inspect into the state of the masts and yards, whether in the dock-yard, or on board the ship, to see that they are perfectly sound and in good order. He is to examine every part of the ship's hull, magazine, store-rooms, and cabins. He is every day when at sea carefully to examine into the state of the masts and yards, and to report to the officer of the watch if any appear to be sprung, or in any way defective. He is to see that the ports are secure and properly lined, and that the pumps be kept in good order, as are also the boats, ladders, and gratings. The caulker is placed under his immediate orders, and he is to see that he performs his duty in a workmanlike manner, in stopping immediately any leaks that may be discovered in the sides or decks.

**Purser.** The purser has the charge of all the ship's provisions, and the serving them out for the use of the crew. His charge is, therefore, of a most important nature; and, accordingly, he must not only produce good certificates of his conduct while serving in the capacity of clerk, but must also find two sureties for the due discharge of his trust, who are required to give bond in a penal sum, according to the rate or class of ship to which he may be appointed. The regulations and instructions for his guidance are minutely detailed in the general printed instructions, with all the various forms established for the keeping of his accounts with the Victualling Board, to which he is immediately responsible. To assist him in the performance of his arduous duties, he is allowed to employ the clerk, who, though engaged by the captain, who is responsible for the strict performance of the duties of all the officers under his orders, is, as it were, a check on the purser in many parts of his duty, as regards the slop-books, muster-books, &c. He has also a steward under his immediate orders.

**Physician, &c.** The duties of the physician to the fleet, the surgeon of a ship and his assistants, the secretary to the commander-in-chief, and the chaplain, are too obvious to require any specification.

**Midshipmen.** The midshipmen are considered as the principal petty officers, but have no specific duties assigned to

them. In the smaller vessels, some of the senior ones are entrusted with the watch; they attend parties of men sent on shore; pass the word of command on board, and see that the orders of their superiors are carried into effect; and, in short, are exercised in all the duties of their profession, so as, after six years service, to qualify them to become lieutenants.

Every ship, according to her class, has a certain number of marines serving on board as part of her complement, which are commanded by a captain, or brevet-major, from first to fourth rates inclusive, with three or two subalterns under them, and an established number of non-commissioned officers; but the party on board fifth rates, and under, is commanded by a subaltern, and in small vessels by a serjeant or corporal.

All marine-officers, of whatever rank when embarked, are to obey the orders of the captain, or the commanding officer of the watch. The marines are exercised by their officers in the use of their arms; they are employed as sentinels, and in all other duties on board of which they are capable, with the exception of going aloft. The officer commanding has the charge of the arms, accoutrements, and drums; and he is to inspect weekly, at least, into the state of the clothing of his party. The marines are treated in every respect in the same manner as the rest of the ship's company.

The long continuance of the revolutionary war necessarily created a prodigious increase of the commissioned officers of the navy. Their numbers, in the four following years of peace, were,

	1793.	1803.	1815.	1821.
Admirals, -	11	45	70	63
Vice-Admirals,	19	36	73	59
Rear-Admirals,	19	51	77	68
Post-Captains,	444	666	824	828
Commanders,	160	410	762	776
Lieutenants,	1408	2461	3211	3797

The warrant officers have increased, in each class, from the average of about 400 in 1793, to 700 in 1821.

The number of seamen and marines voted in 1792 was 16,000 (but never reduced to that number), and in 1822, 21,000.

The greatest number of seamen and marines voted in any one year during the war was 150,000.

The crew of a ship of war consists of able seamen, Ship's Company, ordinary seamen, landsmen, boys, and marines. The landsmen, boys, and marines, are always entered voluntarily, the latter in the same manner as soldiers, by enlisting into the corps, the two former at some rendezvous, or on board particular ships. A supply of boys for the navy is also regularly sent from the Asylum at Greenwich and the Marine Society. Able and ordinary seamen also very commonly volunteer to serve during the war, and always in time of peace; but the high wages given by the merchant ships to seamen in time of war, hold out such encouragement as to induce them to give

Navy. the preference to that service, though, in all other respects, their treatment is far superior on board a King's ship; having better provisions, and being subject to much less fatigue and exposure to the weather. Indeed, the excellent regulations now rigidly adhered to on board his Majesty's ships, the attention that is paid to the health and comfort of the crew, have overcome much of that reluctance which formerly was felt to the service of a ship of war.

Health of the Crew.

The state of health on board a King's ship, generally speaking, is not exceeded in the most favoured spot on shore; and that horrible disease, the sea-scurvy, may now be considered as unknown in the British navy, since the universal introduction of lemon juice, or the citric acid, without an ample supply of which no ship is permitted to sail on a foreign voyage. Sir Gilbert Blane, in a sensible little tract on the *Health of the Navy*, says, that he has never seen the scurvy resist the citric acid, and that, in the perusal of several hundreds of surgeons' journals, he has met only with two cases which seemed to resist it. Yet, though it appears to have been known as a remedy for the scurvy, far superior to all others, two hundred years ago, it seems to have lain dormant and utterly neglected till Dr Lind, more than a hundred years afterwards, revived and stated clearly the singular powers of this remedy. In 1600 Commodore Lancaster sailed from England, with three other ships, on the 2d April, and arrived in Saldanha bay on the 1st August. The commodore's crew having each had three table spoonfuls of lemon juice every morning, arrived there in perfect health; whereas the other ships were so sickly, that they were unmanageable for want of hands. We have all felt the commiseration and horror which the perusal of the narrative of *Anson's Voyage* produces. His ship, the *Centurion*, left England with 400 men, of which 200 were surviving on his arrival at Juan Fernandez, and of these eight only were capable of duty, from scurvy. Yet even this horrible catastrophe seems to have failed in rousing the nation to have recourse to a remedy so certain and efficacious. Cook was well supplied with vinegar and other acids, and found the good effects of them; but the first general supply of lemon juice to the navy was established only in the year 1795, in consequence of a trial that had been made of it the preceding year in the *Suffolk* of 74 guns. This ship left England, and arrived at Madras in September, without touching at any land. With every man's grog were daily mixed two-thirds of a liquid ounce of lemon juice, and two ounces of sugar. She lost not a man; and though the disease made its appearance in a few, an increased dose of lemon juice immediately removed it. Thus the *Suffolk*, after a voyage of 162 days, arrived without losing a man, or having a man sick of the scurvy, whereas the *Centurion*, in 143 days from the last place of her refreshment, lost half of her crew, and the other half so feeble and emaciated, as to be utterly helpless.

Nothing could more strongly point out the efficacy of lemon juice than the following fact. When Lord St Vincent commanded the fleet which blockaded Brest from the 27th May to the 26th Septem-

ber 1800, he maintained so close a blockade, that not a single day passed without reconnoitring the entrance of the harbour; yet, although the seamen of his fleet, consisting of at least 16,000 men, had no other than the ordinary ship's provisions, sixteen only, in the course of four months, were sent to the hospital. In 1780 the Channel fleet, as appears from Dr Lind, were so overrun with scurvy and fever, as to be unable to keep the sea, after a cruise of ten weeks only.

Navy.

From the official returns collected by Sir Gilbert Blane, M. Dupin, a French author, well versed in naval subjects, has drawn out the following table, which exhibits at one view the progressive diminution of sickness, death, and desertion, in the British navy, calculated on 100,000 men.

Progressive Diminution of Sickness.

Years.	Sent sick to Hospital.	Deaths.	Desertions.
1779	40,815	2654	1424
1782	31,617	2222	993
1794	25,027	1164	662
1804	11,978	1606	214
1813	9,336	698	10

From hence it would appear, that the diminution of sick and of deaths has been in the proportion of 4 to 1 nearly, between the years 1779 and 1813. The diminution of desertions from the hospital in the same period is not the less remarkable; and it affords, at the same time, the strongest proof of the progressive amelioration of the condition of seamen on board British ships of war. Indeed, whether on board ship, or in any of these noble institutions, the Naval Hospitals, which are established at all the principal ports at home, and in the colonies abroad, the attention that is paid to the sick sailor is above all praise. The seamen are sensible of this, and nothing keeps them back from volunteering their services, and from giving a preference to a King's ship over a merchantman, but the temptation of high wages offered by the latter in time of war, and that love of liberty and free scope for roving which are characteristic of seamen.

The speedy manning of the fleet, on the first breaking out of the war, is one of the most important objects that devolves on the Naval Administration, as by it alone depends the safety of our commerce and our colonies. This has been felt at all times; and, accordingly, a variety of schemes have been brought forward for this purpose, but all of them failed of success, except the compulsory mode of raising men under the authority of press-warrants, issued by the Lords Commissioners of the Admiralty, by virtue of the King's Order in Council, renewed from year to year. There likewise issues, on the breaking out of a war, a proclamation from the King, recalling all British seamen out of the service of foreign princes or states; and the instructions to the commanders of all ships of war direct them to search foreign vessels, and to take British seamen out of them.

Manning the Fleet.

The impressment of seafaring men, however anomalous under a free constitution like that of Great Britain, is defensible on state necessity, until it can be

Impressment.

Navy.

shown that the fleet, on an emergency, is capable of being manned without resorting to that measure. In consequence of some doubts being raised on the legality of the subject in the year 1676, when the affairs of the Admiralty were managed immediately under the direction of the King and the Great Officers of State, a discussion was held on this point, when it was decided by the Judges and Crown Lawyers, that the King had an indefeasible right to the services of his subjects when the state required them, and that the power of impressing seamen was indispensably inherent in the Crown, without which the trade and safety of the nation could not be secured. The first instance of impressing men in Ireland seems to have been in the year 1678, when the Lord Lieutenant received directions from the Privy Council to raise 1000 seamen for the fleet. In 1690, the Lords Justices of Ireland were directed to assist the officers of the navy in impressing men in that kingdom. In 1697, a register was taken of all the seafaring men in Ireland, which amounted to 4424 men, of whom it is noted 2654 were Catholics. On several occasions, during Queen Anne's reign, the Lords Justices of Ireland received directions to raise men to serve in the fleet.

In Scotland, the mode of raising men by the impress was unknown before the Union; but in various instances the Council of Scotland was directed to raise volunteers for the fleet, each man to have forty shillings as bounty.

In 1706, an experiment was tried for the speedy manning of the fleet, by virtue of an act of Parliament, which required the civil magistrates of all the counties to make diligent search for all seafaring men, and twenty shillings was allowed to the constables for each man taken up; the seamen to have pay from the day of delivery to the naval officers stationed to receive them; and if they deserted after that, were considered as guilty of felony. By the same act, insolvent debtors, fit for the service, and willing to enter it, were released, provided the debt did not exceed L. 30; and no seaman in the fleet was to be arrested for any debt not exceeding L. 20. The whole proceeding under this act incurred a very heavy expence, and totally failed.

In the same year, the Queen referred to the Prince of Denmark, then Lord High Admiral, an address from the House of Lords relating to the three following points:—1st, The most effectual means for manning the fleet. 2d, The encouragement, and increase of the number of seamen. 3d, The restoring and preserving the discipline of the navy. His Royal Highness submitted these points to such of the flag-officers and other commanders as could be assembled, who made a report, of which the substance was to the following effect:—1st, To cause a general register to be kept of all seafaring men in England and Ireland, for which they presented the draft of a bill. 2d, That all marines, qualified to act as seamen, should be discharged from the army, the officers to have levy money and the men's clothing returned. 3d, That not fewer than 20,000 seamen should be kept in employ in time of peace; but, they observe, that as to the restoring and preserving the discipline of the navy, no particular instance being laid before

them wherein it was defective, they could give no opinion on that head.

This registry of seafaring men has been tried more than once, but as the men themselves had no interest whatever in the measure, it always failed in producing the desired effect. The only chance of its succeeding in any prospective emergency is the measure recently adopted by the Lords of the Admiralty, under the sanction of the King in Council,—a measure which was called for on every principle of justice and humanity,—of granting provisions, on the paying off the fleet, to every man who had served fourteen years and upwards. The number thus pensioned amounted at one time to 33,000, and are still not far short of 30,000: and as there are voted for the peace establishment 16,000 men, mostly prime seamen, there is every reason for supposing that less difficulty will be found in manning the fleet, on any future emergency, than heretofore; and that on this account the evils of the impress will be greatly mitigated; for though numbers on the pension list will naturally be unfit for service at sea, most of them will be able to assist in fitting out the fleet.

In fact, there are now so many exemptions from the impress, that its severity is greatly abated. The following description of persons are protected by various acts of Parliament:

Masters of merchant ships or vessels.

First mates of such as are 50 tons or upwards.

Boatswains and carpenters of such as are of 100 tons or upwards.

Men belonging to vessels and craft of all kinds in the employ of Navy, Victualling, Ordnance, Customs, Excise, and Post Offices.

Watermen belonging to the Insurance Offices within the cities of London and Westminster.

All men of the age of 55 years and upwards.

All youths, not having attained the age of 18.

All foreigners.

Apprentices, not having used the sea before the date of their indentures, and not more than three years from the said date.

Landsmen not having served at sea full two years.

Masters, apprentices, one seaman, and one landsman, of all fishing vessels on the sea coast or on navigable rivers.

Harpooners, linc-managers, and boat-steerers of the Greenland fishery and the Southern Whale fishery, and all seamen and common mariners who have entered for the said fisheries.

And no person whatsoever can be impressed except by an officer who has been entrusted with a press-warrant.

The discipline of the navy, or the government of his Majesty's ships, vessels, and forces by sea, is regulated by the act of 22d Geo. II., usually known by the name of the Articles of War. By this act, the Lords Commissioners of the Admiralty are empowered to order courts-martial for all offences mentioned therein, and committed by any person in and belonging to the fleet and in full pay; and also to delegate the same power to admirals commanding in chief on foreign stations, which power also may devolve on his successor in case of death or recall, provided that no commander-in-chief of any fleet or

Navy. squadron, or detachment thereof, consisting of more than five ships, shall preside at any court-martial in foreign parts, the officer next in command being ordered to preside thereat.

Courts-Martial. By this act, no court-martial can consist of more than thirteen or of less than five persons, to be composed of such flag-officers, captains, or commanders then and there present, as are next in seniority to the officer who presides at the court-martial. And when there are but three officers of the rank of post-captains, the president is to call in as many commanders under that rank as will make up five in the whole.

Articles of War. This code of laws for the government of the fleet consists of thirty-six articles, of which nine award the punishment of death, and eleven death or such other punishment as the court-martial shall deem the offence to deserve. Those which incur the former are, the holding illegal correspondence with an enemy—cowardice or neglect of duty in time of action—not pursuing the enemy—desertion to the enemy—making mutinous assemblies—striking a superior officer—burning magazines, vessels, &c. not belonging to an enemy—murder—sodomy. The penalty of death for cowardice, or other neglect of duty in time of action (Art. 12), and of not pursuing the enemy (Art. 13), was by the 19th Geo. III. so far mitigated, as to authorize the court-martial “to pronounce sentence of death, or to inflict such other punishment as the nature and degree of the offence shall be found to deserve.” Under these articles thus mitigated, Admiral Byng would probably not have been condemned to death. The other eleven articles which leave the punishment to the discretion of the court, are, not preparing for fight, and encouraging the men in time of action—suppression of any letter or message sent from an enemy—spies delivering letters, &c. from an enemy—relieving an enemy—disobedience of orders in time of action—discouraging the men on various pretences—not taking care of and defending ships under convoy—quarrelling with and disobeying a superior officer in the execution of his office—wilfully neglecting the steering of ships—sleeping on watch, and forsaking his station—robbery. The remaining sixteen articles incur the penalty of dismissal from the service, or from the ship, degradation of rank, or such other punishment as the court may judge the nature and degree of the offence to deserve.

Petty Punishment. Much, however, of the internal discipline of a ship of war depends upon the captain, who being empowered to punish the men for minor offences, according to the usage of the service, courts-martial on seamen are rarely found necessary to be resorted to in well regulated ships. The principal circumstance that usually militates against the perfect good order of the crew, is the great allowance of grog served out daily to the men, as established by the King's Order in Council, and which frequently leads to drunkenness, and this to insubordination. Perhaps half the punishments in the navy are for this offence, which requires the utmost vigilance and precautions on the part of the officers to prevent.

Effects of Discipline. In other respects the discipline of a well organized ship of war is perfect; and to this discipline M. Dupin, a French writer of great sagacity, mainly ascribes the brilliant successes of the British navy,

Navy. and to the want of it, the ruin of that of France. “We have already cited,” says he, “as a model, the management of the *materiel* of the English ships. In the preservation of this *materiel*—in the stowing it away—in the arrangement of whatever may be necessary either for manœuvres or for action, the most perfect regularity is observed. At the same time, what becoming austerity is maintained by the commanding officer; what obedience among the subalterns; and, in a space so limited, considering the number of men on board, and the multiplicity of movements they have to make in obeying so many different orders, what imposing silence! It is the calmness of strength—the presiding influence of wisdom. In the midst of the most complicated operations, and even in the heat and transport of battle, one hears only the words of command, pronounced and repeated from rank to rank, with a measured tone and perfect *sang froid*. No unseasonable advices—no murmurs—no tumult. The commanders meditate in silence; the word is given, and the men act without either speaking or thinking.”

This is remarkably so in the day of battle. Every officer and man knows precisely his place, and the duty he has to perform on that day. By the general printed instructions, the captains of his Majesty's ships are required to accustom the men to assemble at their proper quarters, to exercise them at the great guns, to teach them to point, fire, &c. under all circumstances of sea and weather. Indeed, it is well known, that the preservation of the high character of the British navy essentially depends on the proper training of the seamen to the expert management of the guns, so as to be duly prepared in the day of battle; the issue of which so mainly depends on the cool, steady, and regular manner in which the ship's ordnance is loaded, pointed, and fired. Practice in these respects is much more necessary on board ships than on shore, as it can never happen that the ship is entirely steady, and has most frequently a rolling or pitching motion, for which allowances must be made, and which can only be made with effect by long practice.

If the management of the great guns of a ship of Naval Tactics. war is more difficult than the artillery of a fort, so likewise are naval tactics more difficult than those of an army; inasmuch as there is more difficulty and less dependence in placing and directing the movements of an inanimate than an animate machine. The general principles are the same; the object of both being that of bringing the greatest possible force to bear on that point which is likely to produce the greatest possible injury to the enemy. With this view, as well as to keep a fleet together in compact order, so that straggling ships may not be cut off by the enemy, it has been found necessary to preserve a certain order of sailing, whether out of sight of an enemy or in his presence; and such an order as, according to the state of the wind and weather, and the point of bearing of the enemy's fleet, may most conveniently and expeditiously be changed into such a line of battle as the commander-in-chief may deem it most expedient to adopt in the attack to be made on his opponent.

In order to do this, it is obvious, that every indi-

Navy. **vidual captain must be able to know, under all circumstances, what the ship he commands will be able to do, in order to preserve her station in the fleet; for, it is with ships as with horses, no two perhaps performing the same evolution with the same tightness of rein, or the same quantity of sail. This shows the absolute necessity of a commander-in-chief frequently exercising his fleet in naval tactics, and to observe how such and such a ship will behave under a certain quantity of canvass, and to assign her station in the line where she may appear calculated to act with the greatest efficiency.**

To facilitate these movements, the admirals commanding squadrons are considered as responsible for the movement of the ships in their respective divisions. They are to see that each captain strictly obeys the general order, and if any one is perceived to neglect his duty, whether belonging to his proper division or not, if in action, he has the power to send immediately another officer to suspend him. And in order that no confusion may arise, if, in time of battle, the admiral commanding in chief, or any of the admirals commanding squadrons, should be killed, his or their flags remain flying till the battle is decided. If the commander-in-chief be killed or severely wounded, a private signal is made to the second in command, or if a junior admiral be killed or wounded, the commander-in-chief is also acquainted by signal.

Code of Naval Signals.

This silent method of communicating what is going on is the perfection of naval tactics; indeed, it is difficult to conceive how our ancestors contrived to manage a fleet without a Code of Signals. For great and important occasions, the exhibition of a flag or flags, in some particular part of the ship, might be generally understood to imply, that the fleet should anchor, or tack, or form the order of sailing in two lines, or the line of battle, or some other great movement. The hoisting of a cask at the yard-arm might be understood to imply a want of water; or a hatchet, of wood; or an empty bag, of bread; and the tablecloth was a very significant invitation to dinner; but they had no means of interchanging freely their wants or intentions, or of conveying detailed intelligence. Even so late as the American war, there was no established code of signals in the navy. An anecdote is told of Admiral Geary, who, in the year 1780, commanded the Channel fleet, which clearly proves how little was then known or practised in the way of signals. His captain, Kempenfelt, had laboured long to improve the defective system; and having one day seen the enemy's fleet, he endeavoured to communicate the intelligence by the new code; but in the hurry of making sail and giving chase, the signals somehow or other were not understood by the rest of the fleet. Geary at last became impatient, and running up to Kempenfelt, seized him by the hand, and exclaimed with great emphasis, "Now, my dear Kempy, do, for God's sake, throw your signals over-

board, and make the old one which we all understand,—to bring the enemy to close action."

"If an admiral," says Dr Beaton in his able *Memoirs*, "cannot command all the necessary movements of his ships by signal in the day of battle, he is not upon a footing with an enemy who possesses that advantage, and even with better ships and better men, and more experienced commanders, he may be foiled in his expectations of victory, if not defeated, from his want of the means to direct, and to perform the necessary evolutions of his fleet." "In no fight," he adds, "was the insufficiency of the present system of naval signals more conspicuous than in this (Keppel's unfortunate action); and it is to be hoped that if ever a new code be adopted for the use of the royal navy, it may be so clear and comprehensive, that such fatal errors as those which have been pointed out will in future be prevented." This we may now say has been accomplished.

The idea of *numbering* the flags, and of assigning a certain number of corresponding sentences to certain combinations of these numbers, was reduced to something approaching a regular system in the fleet under the command of Lord Howe; and in the year 1798 a new signal book was issued from the Admiralty, containing about 400 sentences, expressive of certain operations of a fleet, communicated by means of flags to which the numerical characters were applied, and these, as far as they went, answered very well, but did not supersede the necessity of conveying orders by boats on many occasions. The following year Sir Home Popham suggested the idea of making the flags to represent the letters of the alphabet in combination with numbers, which not only added immensely to the means of communication, but also of making use of words by signal. From this time improvements in the modes of communicating by signals and telegraphs were rapidly introduced; particularly in the shape and the colours of the flags, according to a plan of Sir Home Popham, which has rendered signals by flags as nearly perfect as they probably ever will be.

There is, however, an imperfection in the flags themselves; as in calm weather when they do not fly out, neither their shape nor colour is visible without the use of stretchers, which are not always easily managed, and never without loss of time. Again, if the wind be parallel to the line of vision, the flag shows only its edge, and neither shape nor colour can be discerned. To remedy these inconveniencies, Sir Home Popham proposed a portable wooden semaphore in imitation of the French telegraph, to be mounted on the quarter-deck or poop of a ship.

It consists of two posts, each having a moveable Sea Tele- arm, which may be placed in four positions that can graph. never be mistaken, being at right angles to each other, as in the following figures, where the number annexed to each position is that which it conveys to the person receiving the message.

Navy.

Navy.

SEA TELEGRAPH.

Combinations.

The *left* hand of each column represents the numbers which are exhibited by the arms either singly or in combination.

The *right* hand of each column represents the characters of the telegraphic signals, which are exhibited by the positions of the arms placed opposite to them.

The *cornettes*, *triangles*, and *pendants*, are those used in the common signals, which in the book represent the letters opposite to each.

Position 1 represents .....	Flag 1

3.6 .....	I
3.7 .....	K
3.8 .....	<i>Pendant</i> L
4.5 .....	M
4.6 .....	N
4.7 .....	O
4.8 .....	<i>Finish</i> .

Auxiliary Signs.

These signs always represent the subjects placed opposite to them—for instance, when the alphabetical sign is made, the subsequent positions of the arms will represent the letters of the alphabet until the stop is made. The same with numbers, ships' names, &c. as particularly explained in the instructions of the Telegraphic Signal Book. The *Stop* and the other *Auxiliary Signs* must be placed *exactly horizontal*.

The mode of applying a Secret Key for RECEIVING and COMMUNICATING Messages is extremely simple, as for instance,

Communicating.		Receiving.	
Characters of Telegraph Book.	Positions of Arms.	Positions of the Arms.	Characters of Telegraph Book.
1	6	1	4
2	2	2	2
3	7	3	L
4	1	4	O
5	1.6	5	8
6	3.6	6	1
7	8	7	3
8	5	8	7
9	2.5	1.5	A
A	1.5	1.6	5
B	2.8	1.7	C
C	1.7	1.8	F
D	3.5	2.5	9
E	3.8	2.6	K
F	1.8	2.7	N
G	4.5	2.8	B
H	4.7	3.5	D
I	4.6	3.6	6
K	2.6	3.7	M
L	3	3.8	E
M	3.7	4.5	G
N	2.7	4.6	I
O	4	4.7	H
		4.8	Finish.

It is obvious, that, by a combination of letters and numerals, messages to any extent may be made either by a collection of certain sentences, or a vocabulary of words, or by spelling; the last mode being the least objectionable, though not the most expeditious, unless in very short sentences. For instance, if, on meeting a ship at sea, her name was asked by telegraph, and the answer was No. 8, which, on reference to the list of the navy, was the Hero, but by some mistake, owing to haze or other accident (which will sometimes happen to the best observers), the parallel position No. 4 was read off, opposite to which was the Bellerophon, there would be no possible means of correcting the mistake; but if the first name was spelled by the alphabetic signs, the very first signal, 8, being H, would be sufficient, but the remaining 5—3.5—2.6 would not require many seconds to remove any doubt, if no list of the navy happened to be on board. When signal flags are used, spelling is the more advisable, as the shape and colours of a flag are more liable to be mistaken.

A Polyglot Telegraph.

This simple machine might be made the means of intelligible communication in all the languages of Europe, and its utility thus become universal. For instance, if a French or Spaniard should see an English ship, their wants and wishes may easily be interchanged, although the master of the one should be totally ignorant of the language of the other; that is to say, provided the established telegraph book was translated into their respective languages: for example,

Position of the Arms.

Navy.

3. 6 represents, in English—man of war.  
 French—vaisseau de guerre.  
 German—kreig's schiff.  
 Italian—nave de guerra.

Position of the Arms.

4. 5 represents, in English—leak.  
 French—voie d'eau.  
 German—leck.  
 Italian—crepatura.

The encouragement afforded by Government to Improve every branch of science connected with the navy, and navigation in general, has been carried much farther by England than any other European nation; and has produced the happiest results for commercial enterprise—by determining with accuracy the precise position of ships—by shortening long voyages—and by the discovery of new lands and unexplored regions. From the commencement of the eighteenth century, when a national reward was first offered to the man of science, or the artist who should discover a method sufficiently exact to determine the longitude of a ship's place at sea, to the present time, the improvements in the construction and division of all kinds of instruments for measuring angles, in the calculations of lunar and other tables, and above all, in the manufacture and adjustments of chronometers, have continued in gradual progression; and may now be considered to have arrived at such a degree of perfection, more especially the chronometers, that the discovery of the longitude can scarcely be said to remain a desideratum. We may form an idea what the progress in the improvement of chronometers has been, when a public reward was offered by Parliament in the year 1814 to the first who should determine the longitude at sea *within a degree*, and in 1820, three chronometers, after remaining in the Arctic regions for eighteen months, returned to England without altering their rates more than a few seconds of time.

The officers of the Royal Navy are much more generally versed in the sciences of late years than heretofore. In fact, it is now necessary for a young man to be well acquainted with a certain portion of mathematical and astronomical knowledge, to enable him to pass an examination, without which he cannot be qualified for the commission of a lieutenant. The Royal Naval College of Portsmouth, for the education of a certain number of youths, has been the means of introducing a better system of naval education into his Majesty's ships of war. The examinations also of the several warrant officers and their qualifications for their respective stations, are more strictly attended to than heretofore; and the consequence is, that a much better system of discipline without rigour, is established throughout the fleet, and more comfort in every respect to every class of officers and men employed.

The encouragement given to the navy from its first regular establishment, has marked it as a favourite service in the minds of the public. The sea-pay, the half-pay, and other emoluments, have gene-

Increase of Science in the Navy.

Pay and Emoluments.

Navy. rally been superior to those enjoyed by the army, but subject to great fluctuations in every reign, and to frequent changes in the same reign. Thus King William, in 1693, gave to an admiral, L. 4 a day—a vice-admiral, L. 3—and a rear-admiral, L. 2—which, with the compensation for servants, amounted to more than their present pay; yet their allowances were still further increased in 1700, till a reduction took place, in consequence of an address from the Commons. From this time to the year 1806, very

little alteration took place, when a small addition was made to the pay of each class.

The following table will exhibit, at one view, the complete war-establishment of commission, warrant, petty, and non-commissioned officers, seamen, and marines, on board every class of his Majesty's ships, with the rate of pay granted to each, and the classes into which they are divided for the distribution of prize-money or seizures; as established by his Majesty's Order in Council of the 25th November 1816:

FLAG PAY.

Admiral of the Fleet.....	L. 6	0	0	} SEA PAY <i>per diem</i> , besides which every Commander-in-Chief receives a further sum of L. 3 <i>per diem</i> , while his Flag may be flying within the limits of his Station.

Assistant-surgeons . . .	6s. 6d. do.

Establishment of Half-Pay.

Though the navy, as we have seen, was put upon a regular establishment under the reign of Henry VIII., neither officers nor seamen had any pay or emolument in time of peace, until the reign of Charles II.; when, in 1668, certain allowances were made to flag-officers and their captains out of the L. 200,000 a-year voted for the whole naval service; and in 1674, certain other allowances were granted by Order in Council, to captains who had commanded ships of the 1st and 2d rate, and to the second captains to flag-officers, on the ground, as assigned in the preamble, that they had undergone the brunt of the war, without sharing in the incident advantages of it, as prizes, convoys, and such like, which the

commanders of the smaller classes of ships had enjoyed. But the first regular establishment of half-pay for all flag-officers, captains, first-lieutenants, and masters, was, by King William, in the year 1693, provided they had served a year in their respective qualities, or had been in a general engagement with the enemy. A regular established half-pay was further sanctioned by Order in Council of Queen Anne in 1700; the conditions of which were, that no officer should enjoy the benefit thereof who shall absent himself without permission of the Lord High Admiral or Lords Commissioners of the Admiralty, or who shall be dismissed for any misdemeanour, or by court-martial, or who shall not behave himself to the

Navy.

chains were also distributed to such admirals, and gold medals to such captains, as were particularized in Lord Howe's dispatches. The first lieutenants of each ship were promoted to the rank of commanders; and pensions of L. 1000 *per annum* were granted to Rear-Admirals Bowyer and Pasley.

For the action of 14th February 1797, Lord St Vincent was advanced to the dignity of an Earl, and a pension granted to him of L. 3000 a-year; Vice-Admirals Thompson and Parker were created Baronets; Commodore Nelson received the Order of the Bath, and Captain Calder of the Victory, the honour of Knighthood; and gold medals were distributed to the admirals and captains.

For the action of the 11th October 1797, Admiral Duncan was created a Viscount, with a pension of L. 2000 a-year; Vice-Admiral Onslow made a Baronet, and Captain Fairfax had the honour of Knighthood. Gold medals were also distributed to the admirals and captains.

For the action of the 1st August 1798, his Majesty was pleased to testify his sense of the importance of this brilliant achievement, by raising Sir Horatio Nelson to the dignity of the Peerage, by the title of Baron Nelson of the Nile; and by directing medals to be distributed to the captains. The first lieutenant of the Majestic was made a post-captain, and the first lieutenants of the other ships were promoted to the rank of commanders. And for the attack of the Danish fleet at Copenhagen, Lord Nelson was raised to the dignity of a Viscount, and on Admiral Graves was conferred the Order of the Bath.

For the ever memorable action of Trafalgar, in which Lord Nelson fell in the arms of victory, his Majesty was pleased to confer on his brother the rank of an Earl, with a pension of L. 5000 a-year; and the sum of L. 120,000 was voted by Parliament for the purchase of an estate to be annexed to the title. Admiral Collingwood was raised to the dignity of a Baron; Lord Northesk was honoured with the Order of the Bath, and Captain Hardy was created a Baronet. The captains had medals; five lieutenants were made post-captains; 24 lieutenants, commanders; 22 midshipmen were made lieutenants; and the senior captain of marines made brevet-major.

By this last act of Lord Nelson's life was annihilated the last remaining hope of the combined navies of France and Spain, and a blow given to the naval power of the enemies of Great Britain, which they never recovered during the remainder of the war.

In the minor victories of Sir John Warren, Sir John Duckworth, Sir Robert Calder, Sir Richard Strachan, Lord Gambier, and Lord Exmouth, and even for brilliant actions of single ships, appropriate distinctions have never been withheld. Exclusive of peerages and baronetcies, the honours bestowed for gallant conduct in the naval service consist of 25 Grand Crosses of the Bath, 70 Knights Commanders, and 130 Companions of the Bath.

Pensions for Wounds.

The provision which is made for officers, in the event of losing a limb, or being so severely wounded in the service, as to be of equal prejudice to the habit of body with the loss of a limb, is another encouragement for entering the naval service.

For an admiral, from L.300 to L.700 *per annum*.  
A post-captain, wounds, L.250, loss of a limb, L.300.  
Commander, do. L.150, do. L.200.  
Lieutenant, do. L.91, 5s. do. L.91, 5s.  
Marine officers the same as in the army.

Navy.

A provision is likewise made for the widows of the commission and warrant officers of his Majesty's navy, under the title of the "Widow's Charity," the management of which is vested in a Court of Assistants annually chosen, consisting chiefly of the Lords Commissioners of the Admiralty (the First Lord being President), and the flag-officers of the navy, making in the whole eighteen.

The funds arise from, 1. A deduction of three-pence in the pound from the pay, half-pay, and pensions of the commission and warrant officers of the navy. 2. The amount of the wages and value of the victuals of *one* fictitious man in every 100, borne on the books of ships in sea-pay. And, 3. Interest of the capital vested in the funds. During the late war, the amount of the revenue from these sources was from L.90,000 to L.100,000; and the amount of pensions were about L.70,000 a-year. The pensions are allowed according to the following scale, being similar in most cases to the widows of officers in the army of corresponding ranks: the latter are provided for by an annual vote of Parliament.

## Scale of Pensions.

The widow of a Flag-Officer of his Majesty's fleet.	-	L.120	0	0
----- of a Captain, superannuated with the rank of Rear-Admiral,	-	100	0	0
----- of a Post-Captain, of three years standing,	-	90	0	0
----- of a Post-Captain, under three years standing,	-	80	0	0
----- of a Commander,	-	70	0	0
----- of a Lieutenant, superannuated with the rank of Commander,	-	60	0	0
----- of a Lieutenant,	-	50	0	0
----- of a Master,	-	40	0	0
----- of a Surgeon,	-	40	0	0
----- of a Purser,	-	30	0	0
----- of a Boatswain,	-	25	0	0
----- of a Gunner,	-	25	0	0
----- of a Carpenter,	-	25	0	0
----- of a Second Master of a Yacht, or Master of a Naval Vessel warranted by the Navy Board,	-	25	0	0

And the widows of officers of the Royal Marines are entitled to the following pensions:

		<i>Per Annum.</i>		
The Widow of a General Officer,	L.120	0	0	
Do. Colonel,	90	0	0	
Do. Lieutenant-Colonel,	80	0	0	
Do. Major,	70	0	0	
Do. Captain,	50	0	0	
Do. First Lieutenant and Surgeon,	40	0	0	
Do. Second Lieutenant and Assistant-Surgeon,	30	0	0	

In addition to these pensions, there has recently

**Navy.** been established a *Compassionate Fund*, for the relief of such widows and orphan children as may appear to be objects of compassion. The sums annually required are voted by Parliament, and at present do not exceed from L.6000 to L.7000 a-year.

**Provision for Seamen.** No provision, however, had been made for the brave seamen who fought the battles of their country, excepting for such as had been wounded in fight with the enemy. In the year 1588, after the memorable defeat of the Spanish Armada, the wounded seamen petitioned Elizabeth for relief, upon which, with the advice of the Lord High Admiral and the Commissioners of the Navy, and with the consent of the inferior officers and seamen, the sum of sixpence a month was deducted out of the wages of warrant officers and seamen, for the relief and maintenance of such as were hurt or maimed in the service. The money so raised was deposited at Chatham in a chest, under the superintendence of the Yard Officers and the Warrant Officers of the Navy. As the funds increased, the management of them was transferred to certain Commissioners and Governors; and in order to do away in some measure the inconvenience of compelling seamen from the western ports to go to Chatham for their pensions, the chest was removed, by the 43d Geo. III. to Greenwich Hospital; and the power and authorities of the former trustees were vested in the First Lord of the Admiralty, the Comptroller of the Navy, the Governor of Greenwich Hospital, and the Auditor of the same hospital, all for the time being, who, by this act, are created a body politic and corporate, by the name of the *Supervisors of the Chest of Greenwich*; the said supervisors to appoint five *Directors* from the officers of Greenwich Hospital, to have the immediate management of the business.

In the course of the late war the funded property amounted to nearly L.1,000,000 in the 3 *per cents.* the monthly sixpences, medals, &c. to nearly L.70,000 *per annum*, and the  $\frac{2}{3}$  of 5 *per cent.* on the net proceeds of prizes to about L.40,000; making a net annual income of about L.130,000.

**Scale of Allowances.** The annual allowances made to pensioners were regulated according to the following scale:

Total blindness,	L.20	0	0
Loss of sight of one eye, the other impaired, according to the degree of blindness,	L.8 to L.18	0	0
Loss of sight of one eye; the other not impaired,	6	0	0
Loss of arm, taken out of the socket, each	20	0	0
Loss of arm above the elbow, each	16	0	0
Loss of arm below the elbow, each	14	0	0
Loss of leg above the knee, each	14	0	0
Loss of leg below the knee, each	12	0	0
Double rupture,	12	0	0
Single ditto, retainable by a truss,	4	0	0
Single rupture, not retainable, or very bad, according to the nature of the injury, from	L.6 to L.10	0	0
Loss of thumb, or fore finger, close to the hand,	6	0	0
Loss of thumb, or fore finger, first joint remaining,	4	0	0

VOL. VI, PART I.

**Navy.** In all cases of wounds, fractures, &c. for which no positive scale could be affixed, an allowance was made from the examining surgeon's report of the injury sustained, and a pension was granted for life, or term of years, according to circumstances.

When the wound or hurt was not thought of sufficient consequence to entitle the party to a pension, a sum of money was given as a full compensation.

Every man, at time of entry on the list, was paid the amount of half a year's pension, as present relief, which money was not deducted from growing pension.

Since the conclusion of the late war, the funds of the chest of Greenwich have been amalgamated with those of Greenwich Hospital, both of which are now under one and the same management.

The establishment of Greenwich Hospital embraced more extensive objects. The first idea of this noble institution, the glory and ornament of this kingdom, has been ascribed, with every appearance of justice, to Mary, the consort of William III. Being desirous that our gallant seamen, worn down by age or infirmities, as well as suffering from wounds, should not be left destitute, she made a grant, jointly with King William, of the Palace of Greenwich, and certain lands adjoining, to be appropriated to this purpose, in order, as stated in the King's commission, to "the making some competent provision that seamen, who, by age, wounds, or other accidents, shall become disabled for further service at sea, and shall not be in a condition to maintain themselves comfortably, may not fall under hardships and miseries, but may be supported at the public charge; and that the children of such disabled seamen, and also the widows and children of such seamen as shall happen to be slain in sea service, may, in some reasonable manner, be provided for, and educated." In 1695 the committee appointed to examine and report on the premises, recommended an additional wing to King Charles's building, which being approved by the King, Sir Christopher Wren undertook the conduct of the new erections without any pay or reward. Since that time various additions and improvements have been made to this magnificent pile of building, which was completed very nearly as it now appears, in the year 1778.

The King granted L.2000 a-year towards the carrying on, perfecting, and endowing this hospital. The great Officers of State and wealthy individuals also subscribed liberally to the undertaking. It was at the same time enacted by Parliament, that a deduction of sixpence *per man per month* should be made out of the wages of all mariners for the use of the hospital; and power was given to the Lord High Admiral to appoint commissioners for receiving the said duty, whose office is situated on Tower Hill. In 1699 his Majesty contributed the sum of L. 19,500, being fines laid by the House of Lords on certain merchants convicted of smuggling. In 1705 Queen Anne assigned to the use of the hospital the effects of Kid the pirate, amounting to upwards of L. 6000. In 1707 Robert Osboldiston, Esq. devised by will half of his estate, which was valued at L. 20,000. In the same year Anthony Bowyer gave the reversion of a considerable estate for the use of the hospital.

Navy.

By several statutes, the forfeited and unclaimed shares of prize-money were given to the hospital, and various grants, from time to time, continued to be made by Parliament. But the most substantial grant was that made by the Commons of the rents and profits of the forfeited estates of the Earl of Derwentwater, amounting at that time to about L. 6000 a-year, and at present to the gross rental of L. 60,000, of which, after payment of all expences for improvements, repairs, collections, and incumbances, the annual receipt may be estimated from L. 30,000 to L. 40,000.

Permanent Revenues.

At present the permanent revenues of the hospital consist of the following heads:

1. Sixpence *per man per month* for all seamen and marines belonging to his Majesty's naval service, and sixpence which was formerly paid to the chest at Chatham.

2. The same from all seamen employed in the merchants' service.

3. The duties arising from the North and South Foreland light-houses.

4. The rents and profits of the Derwentwater estates, including the lead mines.

5. Rents of the market of Greenwich, and of certain houses there and in London.

6. Interest of money invested in the public funds.

7. Forfeited and unclaimed shares of prize-money.

8. Fines for various offences.

It is evident that the funds of the establishment must vary considerably in times of war and peace; being lowest in the latter period, when the demands are heaviest upon it, especially for a certain number of years after the closing of a war.

The rental of the estates belonging to the hospital in the counties of Northumberland, Cumberland, and Durham, have risen from L. 23,000 in 1805, to L. 43,000 in 1816. The present gross rental of these estates and the lead mines, as above stated, amounts to about L. 60,000. The merchant seamen's sixpences amount to about L. 20,000 a-year; the naval seamen and marines to L. 15,000; the North and South Foreland lights to L. 7000; the interest of funded property to L. 50,000, making, with other contingencies, an annual revenue of about L. 150,000; the whole of which is expended on the household establishment, the clothing, maintenance, and allowances to pensioners and other attendants, repairs, taxes, and contingencies.

During the war, and for a few years after the war, the funds of the hospital were adequate to the payment of the out-pensioners, which, taken at 35,000, the greatest number they ever reached, and allowing to each, on an average, L. 11 a-year, must have amounted to the sum of L. 385,000. Their numbers may now have decreased to 30,000, and the amount of their pensions to L. 330,000, to be voted by Parliament; the funds of the hospital no longer affording a surplus beyond its own support, from which only, by law, the out-pensioners had any claim.

Hospital Establishment.

The establishment of this noble institution consists of a governor, who is a flag-officer in the navy, lieutenant-governor, four captains, eight lieutenants, all resident within the hospital. A treasurer, auditor, paymaster of pensions, secretary, clerk of the check,

two chaplains, two physicians, three surgeons, two dispensers, steward, clerk of the works, and several clerks. The number of in-pensioners is about 3000, and the number of nurses 180, all of whom must be the widows of naval seamen, and under the age of 45 years at the time of admission.

Under the naval administration of Earl Grey, the following officers were added to the out-pensions of Greenwich Hospital, to be selected by the Admiralty according to their respective claims on the service:

	Per Year.
10 Post-Captains, at	L. 80
15 Commanders, at	60
50 Lieutenants, at	50
in addition to their half-pay.	

The out-pensions to seamen were first established in 1763, by act of 3d Geo. III. ch. 16. in consequence of which 1400 out-pensioners were appointed, at L. 7 *per annum* each, after undergoing an examination at the Admiralty as to their claims.

At the close of the long revolutionary war, the applications became so numerous, and the claims of the seamen who had been wounded, or worn out in the service, so strongly grounded in humanity and justice, that it became necessary to adopt a scale of pensions, and to establish certain rules and regulations, by which seamen of his Majesty's fleet and royal marines should be remunerated for wounds or hurts, debility, and length of service. The following are the regulations:

#### For Wounds, Hurts, or Debility.

Every seaman, landman, boy, or royal marine, wounded or hurt in his Majesty's service, is to receive a sum of money from the *Chest of Chatham* in the nature of *smart money*, as heretofore; and also be entitled to a pension proportioned to his wounds or hurts, of not less than sixpence a day, and not more than one shilling and sixpence a day. For sickness or debility, after seven years' service (and under special circumstances before that period), of not less than fivepence a day, nor more than tenpence, according as he may appear capable of assisting himself. Beyond fourteen, and less than twenty-one years' service, not less than eightpence, nor more than one shilling and threepence. After twenty-one years' service, one shilling and sixpence a day.

#### For Length of Service.

Every able seaman, discharged on the reduction of the fleet, who has served faithfully fourteen years, and less than twenty-one, is entitled to a pension or one halfpenny a day for every year of such service. Twenty-one years' service entitles him to a free discharge, and a pension of one shilling a day; and if he may choose to continue in the service, one halfpenny a day in addition for every additional year of service.

Ordinary seamen and landmen, entitled to four-fifths and three-fifths of able seamen's pensions. The privates of royal marines are considered as ordinary

seamen. The principal petty officers, in addition to the above rates of pension, are entitled to one half-penny a day for the number of years' service; the inferior petty officers to one farthing.

All the above mentioned pensions may be forfeited by misconduct, by desertion, and by sentence of a Court-Martial. Also, by neglecting, or omitting, to attend at such port, or place, and at such time as shall, in time of war, or in prospect of a war, be appointed for the assembling of the pensioners, by the Lords Commissioners of the Admiralty.

To this noble institution is appended an asylum, for the maintenance and education of the children of officers and seamen of his Majesty's naval service.

Naval Asy-  
lum.

The *Naval Asylum* was originally instituted by the Patriotic Fund and private subscriptions, and afterwards established at Greenwich, by warrant under the King's sign-manual, dated January 1818, appointing the Lords Commissioners of the Admiralty to be commissioners and governors, who, with twenty-four directors, were to superintend and manage the same. The object was, the maintenance and education of a certain number of orphans and other children of the non-commissioned officers, seamen, and marines of the royal navy. As it was manifest, however, that this establishment, so contiguous to the hospital of Greenwich, could be managed without inconvenience by the commissioners and directors of that hospital, under a more effective and economical system, his Majesty was pleased, by his warrant of January 1821, to annul the former warrant, and to vest the superintendence and internal management of the said asylum in the commissioners and governors of Greenwich Hospital.

The two schools of Greenwich Hospital, and the Naval Asylum, and the funds thereof, are now therefore incorporated. The internal management is confided to the Board of Directors, and one of the captains of the hospital is intrusted with the general superintendence. A chaplain, and proper schoolmasters, schoolmistresses, matron, with inferior assist-

ants, male and female, with moderate salaries, reside in the building. The number of children maintained and educated in the Institution are :

In the Boys' Upper School,	-	-	200
Ditto, Lower School,	-	-	600
Girls,	-	-	200
			1000
		In the whole,	1000

To the upper school no boys are admitted but the sons of seamen and marines, slain, drowned, or dead; of pensioners in the hospital; of seamen disabled, past their labour, or otherwise objects of charity; of officers in the navy and marines, on the production of a required certificate of poverty. The age of admission from eleven to twelve; the continuance in the school three years, when they are bound apprentices to the merchant service. Presentations by the directors in rotation.

The boys and girls of the lower school are the children of seamen and marines of the naval service, admitted by the Board of Directors, giving a preference to orphans. The age of admission from nine to twelve years inclusive; but none to be retained beyond the age of fourteen. The boys to be sent into the navy, or merchant service, or put apprentices to some trade. The girls, at the age of fourteen, to be apprenticed to trades, or sent to service.

Thus are all the classes of officers, seamen, and marines, who have faithfully served in the navy, provided for by the state; and the children of such as may be in indigent circumstances receive an education at the public expence, suited to their condition in life.

The total expence of the whole navy, including every branch of the service, civil and military, for one whole year, in the middle of the late war, may be estimated at about L. 18,000,000  
In the year 1822, according to the estimates laid before Parliament, at about 5,000,000

NECKER (JAMES), a well known statesman and financier of France. He was born, 30th September 1732, at Geneva, of a respectable family, originally from the north of Germany. At the age of fifteen he quitted Geneva, and proceeded to Paris with a view to push his fortune in that city. He entered first into the banking-house of Vernet, and afterwards into that of Thelluson, of which he became the cashier, and at length a partner. On the death of Thelluson, he established a bank on his own account, by which he accumulated a very large fortune. After twenty years of unremitting attention to business, he married a Protestant lady of respectable family, but in reduced circumstances, the patrimonial estate having been lost in consequence of the revocation of the edict of Nantz. With this lady he appears to have enjoyed the highest degree of domestic happiness. A short time after his marriage,

he was named minister of the republic of Geneva at Paris; and in accepting of this employment, he refused the emoluments which were attached to it,—a degree of forbearance not very usual in public men, but in which he resolutely persisted during the whole course of his political life. Two works which he published, namely, *A Eulogium on Colbert*, and a treatise *On the Legislation and Trade of Corn*, had greatly spread the reputation of his political talents; and he had fortunately succeeded in adjusting some differences between the East India Company and the Crown, in such a manner as to receive the approbation of both parties,—a circumstance which added to the weight of his character.

About this time the disorder in the state of the French finances had become so alarming, that it was found necessary to break through the routine of official promotion, and to choose able men for

Necker.

the public service wherever they could be found. These inducements so far outweighed the objections to M. Necker, as a foreigner and a Protestant, that, after some private conversations with M. Maurepas, he was, in 1776, appointed Director of the Royal Treasury, and in the following year, Director-general of the Finances. The great object of M. Necker was to introduce order and economy in the public management. With this view, he found himself compelled either to suppress useless offices, or to diminish emoluments; and his retrenchments drew on him the enmity of all those who suffered by his economical reforms. A party was formed against him, chiefly composed of rapacious courtiers; and though the repeal of several oppressive imposts had conciliated the general goodwill of the people, he was daily the object of malicious libels. His severe measures of economy had also excited the dislike of the minister M. Maurepas; though others ascribe his hostility to a different cause; namely, to his disappointment at not finding in Necker that subserviency which he expected from a person of his comparatively obscure origin, and a Protestant. Whatever was the reason, the minister was among the number of his enemies, and he is charged by his daughter, Madame de Stael, with secretly instigating those libellous attacks of which M. Necker was the object. To enable him, according to Madame de Stael, the better to struggle with his opponents, he requested some signal mark of royal favour, such as a seat in the Council, which was granted. This demand on the part of Necker gave rise to new and acrimonious discussions; in the course of which he tendered his resignation, after he had been in office five years. Others give a different account of this transaction. Under the influence, it is said, of that passion for popular applause, which was the torment of his life, he published, in 1781, the well known piece on the state of the Finances entitled *Le Compte Rendu au Roi*, of which an immense number of copies were sold. Elated by this success, he made his demand for a seat in the Council, but was objected to on the ground of his religion. Being persuaded that this scruple would be abandoned, he persisted, and offered his resignation, which was accepted, and he became in this manner, as is alleged, the dupe of his presumption.

The enemies of Necker reproached him with indulging, during his short administration, his passion for popularity at the expence of the public interest. The great point which he laboured to establish in his *Compte Rendu* was, that there was no deficit in the public revenue, and that there was no necessity for additional taxes. In lieu of new impositions, he is charged with supplying the public necessities by the expedient of large loans,—postponing, in this manner, the evil day, but accumulating on posterity a progressive load of debt, which, sooner or later, must be provided for by adequate taxes,—and all this to procure a temporary popularity at the expence of his rivals. Notwithstanding these objections, he had numerous partizans, especially among the men of letters, who regarded his elevation to

power as the triumph of philosophy and liberal principles over aristocratical prejudice. Necker.

After his resignation, he retired to Switzerland, where he purchased the barony of Copet. In 1784, he published an able work, further illustrating his financial policy, entitled *De l'Administration des Finances*. This work, of which 80,000 copies were speedily sold, served to support the reputation of his plans, and also to keep together his adherents, whose numbers formed a counterpoise to the influence of his enemies at court.

In 1787, M. de Calonne convoked the Assembly of the Notables, and in his opening speech to that body, he impeached the accuracy of the statements contained in the *Compte Rendu*. It was not to be supposed that M. Necker would quietly submit to this charge. He sent a memorial on the subject to the king, with various other papers, for the purpose of proving the correctness of his calculations. His majesty having read these documents, requested that they might not be published; a proposition which by no means suited the views of M. Necker. His statements were accordingly printed, on which he was exiled, by a *lettre de cachet*, forty leagues from Paris.

M. de Calonne did not, however, remain long in power; and the Archbishop of Toulouse, by whom he was succeeded, was also obliged to resign, and to make way for M. Necker, the favourite of the people, who was reinstated in his former post in August 1788. A new and remarkable era was now about to open in the history both of France and of the world. The writings of the French philosophers and men of letters had gradually given currency to notions of constitutional freedom. The people could no longer endure, like their forefathers, the bondage of feudal privileges, by which the few acquired the power of oppressing the many. They had become jealous and discontented, and were deeply irritated at the insolence and oppression of the aristocratical body; and with those indignant feelings were mingled, in the minds of the popular leaders, the brilliant visions of speculative reform. But so long as the people wanted a legitimate organ through which their voice could be heard, it was clear that whatever might be their feelings, they could make little impression on the measures of the state. What was wanting in this respect was now about to be supplied; and the popular voice, hitherto so little considered, was, through the representative body, to become the pre-eminent influence in the government. At this period the French Government was assailed by a complication of difficulties, the chief of which was the impracticability of raising the necessary supplies, and the danger of an immediate bankruptcy. A great scarcity also prevailed at Paris, which rendered the populace unusually discontented and tumultuous. In this emergency various expedients were suggested; and the convocation of the States General, which had been long talked of, was advised by M. Necker as likely to give general satisfaction to the people. In assenting to this proposition, it was the plan of the court, that the different orders of the clergy, nobility, and commons, should vote in separate chambers, in or-

Necker. der that the deputies of the commons might be controlled by the other two bodies. But the popular leaders were by far too penetrating to allow their influence to be annihilated by this device. They determined, from the beginning, that the three orders should sit and vote together; and, as is well known, after various fruitless efforts to bring about this union, the commons resolved to form themselves into an Assembly for the dispatch of business, without regard to the other two chambers. This decisive step proved effectual, and the three chambers at length all met and voted in one house, by which the whole power was thrown into the hands of the commons.

During these transactions, Louis and his advisers pursued a weak and vacillating policy. They saw, when it was too late, the error they committed, or supposed themselves to have committed, in putting into the hands of the people the powerful weapon of a representative body. But in place of yielding to the necessity of circumstances, and conciliating this new power, which they could now no longer resist, by conceding with a good grace every just demand of constitutional right, they endeavoured to recover the ground which they had for ever lost; vainly struggling against the power of the commons, and meditating even the most violent measures for the recovery of their authority. It was in pursuance of these views that troops were drawn from the most distant parts and encamped around Paris;—a measure, the only construction that could be put upon which was, that it was intended to overawe the deliberations of the Assembly, or, perhaps, to dissolve it at once at the point of the bayonet. These violent courses M. Necker opposed, and he was accordingly dismissed on the 11th July 1789, and ordered to quit the kingdom in twenty-four hours. This order he obeyed with equal secrecy and dispatch, and had arrived at Brussels before it was generally known in Paris that he was out of office.

It is impossible to describe the consternation which prevailed in the capital when the dismissal and exile of this favourite minister was made known. The person who first communicated the intelligence was considered as a madman, and with difficulty escaped some harsh treatment; and the event was no sooner confirmed, than all the shops and places of amusement were shut up, and his bust, with that of the Duke of Orleans, was paraded through the streets, dressed in mourning. These proceedings were interrupted by a German regiment; the busts were broken in pieces; and in the course of the tumult one man lost his life, while others were wounded. Fresh troops arriving, a serious conflict ensued; and an old man being cut down in the Thuilleries by an officer of distinction, the populace were enraged to the highest pitch, and being joined by the French Guards, who deserted their officers, they at last succeeded in overpowering the Germans. New outrages and tumults succeeded; the Bastille was stormed; and the capital became the scene of bloody massacres, while the people's minds were at the same time filled with dismay at the near approach of foreign troops, from whom they apprehended nothing less than the sack of the city. In the midst of these alarms, they beseeched the As-

sembly to intercede with the king for the recal of their favourite minister. The necessity of complying with this demand was at length seen by the king, and a letter was written to M. Necker, requesting him to return.

M. Necker was at Basle when he received this letter, with the request contained in which he resolved immediately to comply. His progress to Paris was one continued triumph. He was cheered as he passed through the different towns by the acclamations of multitudes, who hailed him as their deliverer. This popularity, however, was not of long duration. Alarmed by the excesses which had already taken place, M. Necker became desirous to support the authority of the sovereign; and, without conciliating the confidence of the king's friends, he lost that of the popular party. By the Royalists he was always hated; he now became an object of suspicion to the more violent patriots, and was reproached as an aristocrat. Seeing his popularity on the decline, he resolved to retire, and he accordingly wrote a letter to the Assembly, pleading the necessity of repose for the restoration of his health. No notice was taken of this letter; and his personal safety being now in danger from the violence of the people, he quitted Paris, in a private manner, in the month of December 1790.

After the loss of power and popularity, M. Necker seems to have sunk into the greatest dejection. "I could have wished," says Mr Gibbon, who passed some days with him about this period, "to have exhibited him as a warning to any aspiring youth possessed with the demon of ambition. With all the means of private happiness in his power, he is the most miserable of human beings; the past, the present, and the future, are equally odious to him. When I suggested some domestic amusements, he answered with a deep tone of despair, 'In the state in which I am I can feel nothing but the blast which has overthrown me.'"

His mind was soon diverted from the disappointments of ambition by domestic griefs of a more poignant nature; his wife, to whom he was deeply attached, dying after a long illness, in which he attended her with great affection. He had now recourse to writing to divert his melancholy, and several works, which he published, were the fruits of his labours. He died at Copet, on the 9th April 1804, after a short but painful illness. His public character is, of course, differently estimated, according to the political views of parties. In his private and domestic relations he was amiable and affectionate, and appears to have been greatly beloved. His writings, besides those already mentioned, are the following:

*An Answer to the Memorial of the Abbe Marellet, on the East India Company, 1769. Memorials on the Provincial Administrations, 1781. Answer to the Speech pronounced by M. de Calonne to the Assembly of Notables, 1787. New Explanations on the Compte Rendu, 1788. Of the Importance of Religious Opinions, 1788. Observations on the Introduction to the Red Book, 1790. On the Administration of M. Necker, by Himself, 1791. On the Executive Power in Great States, 1791. On the*

NEPAUL, a long but narrow kingdom of Northern Hindostan, bounded on the north by the great range of Himmalaya mountains, on the south by the provinces of Bahar, Oude, and Delhi, on the east it is limited by Bootan, and the territory of the rajah of Si Kim; and previous to the late war with the British, their conquests extended to the banks of the Suttelege, the eastern river of the Punjab. The kingdom was then divided into the following provinces, viz. Gorcah, Kyrat, Morung, Muckwany, Mockwanpore, Lamjung, 24 Rajahs, Kemaon, and Almora. The valley of Nepaul proper, from whence the kingdom takes its name, is nearly of an oval figure; its greatest length from north to south being 12 miles, by 9 in the greatest breadth. On the north and south it is bounded by lofty mountains, but is more open to the east and west. This small track is very populous, and, besides the capital Catabandoo, is filled with villages. This valley, although situated between the 27th and 28th degrees of N. lat. is so elevated, that it enjoys an European climate, and the mountains, covered with snow, are in sight the whole year round. The soil is productive, and, in some places, yields two crops in the year. The mountains of Nepaul contain mines of copper and iron; and, although commerce is not encouraged, it sends to Bengal ivory, wax, honey, timber, bastard cinnamon, cardamums, walnuts, &c.; and takes in return, muslins and silks of Bengal, carpets, spices, tobacco, and European goods.

The government is despotic, and the rajah is considered as the proprietor of the soil. The natives are in general a hardy and courageous race; and during the late war gave the British much annoyance. This, however, partly arose from the seat of war being in a mountainous and cold country, to which the British sepoys had not been accustomed. The prevailing religion is the Hindoo, but many of the inhabitants are supposed to be descendants of Tartars, and reckoned impure. The tribe called Newars admit of poliandry, or rather the women are at liberty to divorce their husbands, and take others as often as they choose. The Brahmins of Nepaul are very numerous, and deeply skilled in Sanscrit lore. One of the libraries is said to contain 15,000 volumes in that language. There are five vernacular languages, but the Hindostany is pretty generally understood.—*Edinburgh Gazetteer, or Geographical Dictionary*, Vol. IV. For an account of the late war, see the Article INDIA, in this Supplement.

NETHERLANDS, a kingdom newly erected in Europe, in consequence of the fall of the French empire. It is composed of the ancient republic of the United Netherlands, usually denominated Holland, of the Austrian Netherlands, commonly called the Belgian Provinces, of the Bishoprick of Liege, and of the provinces of Huissen and Zevenaer, formerly belonging to Prussia. It is a compact do-

minion, bounded on the west by the German Ocean, on the north by the German Ocean and the Zuyder Sea, on the east by the duchy of Oldenburg, and by the Prussian provinces of Westphalia and the Lower Rhine, and on the south by France.

The erection of the kingdom of Holland by Bonaparte, and its subsequent union with France, were attended with alterations in the names and the divisions of the Provinces, or, as they were previously called, the States; and similar divisions were made in the Austrian provinces, which produced much confusion; but since the establishment of the new kingdom, such divisions have been adopted as best reconcile the ancient denominations with the novel political condition of the country.

The recent divisions of the kingdom are into the following provinces, which are arranged according to their ranks.

Provinces.	Capitals.	Population of the Capitals.
1 North Brabant	Herzogenbusch	13,340
2 South Brabant	Brussels -	72,280
3 Limbourg -	Limbourg -	8,200
4 Guelderland -	Nimmeguen	12,780
5 Liege -	Liege -	45,300
6 East Flanders -	Ghent -	44,000
7 West Flanders -	Bruges -	32,990
8 Hainault -	Mons -	18,400
9 Holland (North and South)	Amsterdam	193,180
10 Zealand -	Middleburg	20,800
11 Namur -	Namur -	15,100
12 Antwerp -	Antwerp -	62,000
13 Utrecht -	Utrecht -	33,400
14 Friesland -	Leuwarden	16,500
15 Overysseel -	Deventer -	10,100
16 Gröningen -	Gröningen -	24,600
17 Drenthe -	Assen -	1,100
18 Luxembourg -	Luxembourg	10,250

Divisions.

The other most considerable cities and their population are the following:

Alost, 10,920. Cortryk, 13,570. Delft, 13,850. Dornick, 21,300. Dort, 19,500. Gouda, 11,370. Haarlem, 20,100. Hague, 42,700. Leyden, 30,680. Lokeren, 11,940. Louvain, 18,580. Maastricht, 17,960. Mechlin, 16,090. Ostend, 10,500. Rotterdam, 33,800. St Nicholas, 10,980. Verviers, 10,070. Ypres, 15,150, and Zwoll, 13,060.

Although the duchy of Luxembourg is included in the kingdom of the Netherlands, in the view we are taking of it, yet it is in reality a part of Germany, and its capital, one of the strongest fortresses in Europe, is garrisoned by the confederates. The King of the Netherlands has, indeed, the nomination of the governor of the castle, but the consent of the Allies is requisite, before he can enter upon the command. Thus, the annexation of Luxembourg to the kingdom of the Netherlands resembles that of the duchies of Holstein and Lauenburg to the kingdom of Denmark.

The surface of this kingdom, according to the

Netherlands. most accurate calculations, amounts, in the northern provinces, to 16,588 square English miles; from which must be deducted for the Zuyder Sea, the lakes, rivers, and canals, 5205 square miles; leaving 11,383 miles. The whole extent will then be thus:

Extent.	In the nine northern provinces,	11,383
	In the eight southern provinces,	11,141
	In the duchy of Luxembourg,	2346
		24,870 square

miles, or 15,916,800 English acres.

Population. According to the census of the year 1816, the population was as follows:

The northern provinces,	2,016,159
The southern provinces,	3,249,841
The duchy of Luxembourg,	225,945

5,491,945, being somewhat more than one human being to every three acres of land; a density of population far exceeding that of any other country of Europe, with the exception of the small and highly productive duchy of Lucca in Italy. The difference in the density of population in the different provinces is very great. The most thickly peopled of them, East Flanders, contains 560 inhabitants to the square mile, or nearly one to each acre; whilst Drenthe contains only 59 to the square mile, or less than one to every ten acres. The average population of the provinces of the United Netherlands is 180 to the square mile, or about one person to three acres and a half; of the provinces of the Austrian Netherlands 296 to the square mile, or one person to two acres and a quarter; and of the duchy of Luxembourg, 66 to the square mile, or nearly one to ten acres.\*

Face of the Country. Almost the whole of this united kingdom possesses a flat surface, with scarcely a hill on the greater part of it. The level of most of the lands on the northern part is below that of the sea that bounds it, when the tide is at the highest, and is only protected from inundations by such powerful embankments called dikes, as demonstrate the patient perseverance and the wealth of the proprietors. In the southern part, the Belgian provinces are mostly level, though sufficiently above the sea not to need the protection of embankments. In the parts bordering on towards France, especially in the provinces of Liege, Namur, and Luxembourg, including a portion of the ancient forest of Ardennes, the surface is more irregular, in some parts undulating, in others hilly, approaching almost to mountainous. There are no forests, and but few trees in the northern parts, except willows, which are abundantly planted on the sides of the canals and embankments. In the ancient Belgic provinces, trees are more frequent, both on the borders of the fields and around the villages, but there are few woods except in Liege and Luxem-

Netherlands. bourg. From this description, it will be readily perceived, that no picturesque scenery is displayed; but the cleanliness and appearance of substantial comforts in all the villages and thickly planted farms, gives to the traveller pleasing sensations, and evince most powerfully the wonders which industry and perseverance can achieve.

No part of Europe enjoys such advantages for Rivers, Canals, and Lakes. dispensing abroad its more bulky productions as the kingdom of the Netherlands. Its navigable rivers, which are connected together by numerous canals, that serve the purposes both of draining and conveyance, intersect the whole of the northern and the greater part of the southern division of the kingdom. The principal of these rivers, the Rhine, is divided into two branches; the southernmost of these takes the name of the Waal, and, after receiving the water of the Merwe, assumes the name Maas, and enters the German Ocean. The northernmost branch of the Rhine is divided into two streams, one, called the Yssel, runs to the Zuyder Sea, the other, retaining its original name, after receiving the waters of the Lech and the Vecht, disappears in the sands. The Meuse, the most important river to the Belgic provinces, is navigable through the whole territory, and is the means of conveying from Liege the stone for building, which abounds in that vicinity, and of which the provinces on the coast are wholly destitute. The Sheldt, a river of a short course, but of excellent navigation, divides itself into two branches, called the East and West Sheldt, before it enters the German Ocean. The Lys, the Dender, the Dyle, the Sambre, the Lesse, the Nethe, and many others of smaller magnitude, are tributary streams to the Meuse or to the Sheldt. The Moselle, though it forms the boundary of this kingdom on its south-eastern side, and is highly beneficial to its commerce, passes through no part of it. There are few lakes in this country. The principal is that of Haarlem, extending over about 16,000 English acres, which is connected with two smaller ones, the Dollart and the Biesbosch. The interior communication by water is so great, that it employs 5700 barges of different burden, and upwards of 15,000 boats.

The climate of this kingdom, from its vicinity to Climate. the sea, and from the abundance of its rivers and canals, is peculiarly foggy. In summer the heat is excessive, but highly favourable to vegetation. In winter the frosts are usually very severe, and in some years, the rivers are so frozen as to bear the conveyance of cannon and heavy loaded waggons. Only the most scrupulous attention to cleanliness can, in any degree, protect the inhabitants from the deleterious effects of their moist atmosphere, and with all the care that is exercised, they are much subject to fevers.

The constitution of this country is a limited mo- Govern- narchy, hereditary in the House of Orange-Nassau, ment. to which the females may succeed, in case no male heir is left by the last monarch. The king can hold

\* See *Hofalmanak voor het Schrikkeljaar 1816 ins Gravenhage*; also *Staat-on aardrykkundige Beschrijving von het Koningryk der Neederlanden of de XVII neederlandische Provinzien, benever het Groot-Hertogdom Luxemburg*, van N. G. van Kampen. Harlem, 1816.

Netherlands. no foreign crown, nor remove the seat of government out of the kingdom. He is authorized to take from the treasury 2,400,000 guildens annually, for his own expenditure. He is allowed a summer and winter palace at the expence of the public, but the sum expended on them must not exceed 100,000 guildens annually. The heir apparent bears the title of Prince of Orange, and enjoys an income of 100,000 guildens. The king's minority terminates on the completion of his eighteenth year, and whilst under that age, the government is administered by a regency consisting of the members of the royal family. The executive government is vested, but with many restrictions, arising from the independent and varied constitution of the several states, in the king, who is commander of the army and navy, has the power of dispensing pardons, and whose consent is necessary both to the laws passed in the Provincial and in the General Assemblies of the States.

Each state has its assemblies, which are convoked annually, or more frequently if deemed necessary, by the monarch. The members are in two classes, viz. 1st, the nobles and knights; and, 2d, the citizens, who elect members to fill the vacancies that occur in their body. With the assembly of the citizens, or burghers, rests the local administration, and, jointly with the nobles, the power of enacting provincial laws. They appoint committees from their body to attend to the administration of justice, of the revenues, and the expenditure; which committees meet as well during the prorogation as the session of the states, and are the medium of intercourse between their several provinces, the monarch, and states-general. The levying taxes for provincial purposes is executed by this body, who carefully guard against the imposts they levy being made to fall heavier on articles produced in the other states than on those produced within their own; as, without such precaution, the consent of the king to the enactment would be withheld. A commissary, or administrator, nominated by the monarch, is joined to each assembly of the provincial states, and has considerable powers for superintending the execution of the laws. The police is managed jointly by this officer and the provincial states, and is generally conducted with judgment, economy, and great attention to the liberty of the subject.

The supreme legislature, or States-General, meets either at Brussels or the Hague. It is divided into two chambers. The upper house consists of not less than forty, nor more than sixty members, who are nominated by the king, and hold their seats for life, but do not transmit them to their heirs. The lower house consists of one hundred and ten members, who are nominated by the provincial assemblies of the different states. The members of these two bodies are chosen both from the Dutch and Belgian provinces; and, as in the latter, the French language is used by all but the peasantry, their debates are conducted in either the Dutch or the French tongues, according to the part of the kingdom of which the speaker is a native.

Judicial Administration. The judicial administration is in an imperfect state at present, owing to the different provinces having different systems of law. The legislative body has

been sedulously employed in forming a general code Netherlands. which shall embrace the whole kingdom, but, from the various usages and rights of ancient establishment, which they wish to protect, it has been found to be attended with almost insurmountable difficulties.

In the meantime, the securities for the personal liberty of the subject are of more practical efficacy than are to be found in any other country of Europe, except in Great Britain. No one can be arrested without a previous communication to the judge, and the prisoner must be made acquainted with the charge against him within three days after his commitment. No one can be withdrawn from the judge of one district to be tried before that of another, without his own appeal, or at least his consent. Every judgment against an offender must specify the precise article in the law under which the punishment is awarded. In all civil causes, the reasons upon which the decision of the court is founded must appear upon the face of the judgment. Each province has its own courts, both for criminal and civil cases; besides which, there is a supreme court for the whole kingdom, denominated the *Superior Council of the Netherlands*. Equal protection is extended to every description of religious worship, and the professors of all the various sects are equally admissible to every civil, military, and judicial post, and may enjoy like civic and political dignities and privileges.

Although equal protection is granted to all religions. religious sects, yet the establishments of the two predominant confessions, whose opinions prevail in the northern and southern parts of the kingdom, give to the Catholic and the Calvinistic parties a considerable degree of preponderance. The sovereign is of the reformed or Calvinistic profession, as are the greater part of the inhabitants of the northern provinces, who adhere to the catechism of Heidelberg, and the confession of Dort, and are regulated by parochial church councils, classes, and synods. In Utrecht is a Catholic archbishop, and in Haarlem a bishop. The religion of almost the whole inhabitants of the southern provinces is the Catholic, to which they are most rigidly attached. They have one archbishop, four bishops, and more than three thousand priests; although, since these provinces were formed into one of the French departments, their number and emoluments have considerably diminished. The universal toleration which has long prevailed in the northern part of this kingdom has familiarized it to the most bigotted members of the established church; but, in the southern parts, where it has only been introduced since the dissolution of the French empire, it has been most strenuously opposed, especially by the ecclesiastics, and its establishment has caused in some places tumults, and in others great dissatisfaction, which is by no means yet removed. The practical enjoyment of religious toleration in the Belgian provinces is indeed even now rather to be wished than expected.

The inhabitants of this kingdom are descended from three different races, and even now discover Origin and Character of the People. those differences which they have derived from their origin. The people of Holland, Zealand, Utrecht, Guelderland, Overyssel, and Drenthe, are of Batavian origin, probably descended from the ancient

Netherlands. Katti, and speak a flat Deutsche, or Low German language. They are more prudent than active, their minds more exact than comprehensive. They usually reason slowly, but accurately. They are economical, prudent, and cleanly, but too eager for gain, and, by the prospect of it, can alone be stimulated to deeds of daring or adventure. The people of Friesland, Gröningen, and the islands of the ocean, and the Zuyder Sea, are descended from the Frisi. They differ from the Hollanders in their language and dress, and, unlike them, are more addicted to agriculture, to the rearing of cattle, and to the fisheries, than to navigation and commerce. The southern provinces are inhabited by the descendants of the Walloons, a branch of the great German family, whose habits they still in a great degree retain; though they have become somewhat Frenchified, and whose language is a dialect of the German, but differing materially from that spoken either by the Hollanders, or the people of Westphalia and Lower Saxony.

Few countries have, according to their extent and population, more institutions for the promotion of learning than are to be found in the Netherlands. There are six universities, viz. Leyden, Utrecht, and Gröningen, in the northern, and Louvain, Ghent, and Liege, in the southern provinces. Besides these are the atheneums of Amsterdam, Middleburg, Deventer, and Doornich, and 105 public grammar schools for classical instruction, in which is kept alive that taste for literature which formerly produced some of the best editions of the writings of antiquity. In the northern part of the kingdom, the instruction of the lower classes is amply provided for by numerous well regulated burgher schools, in which gratuitous education is extensively, almost universally, dispensed, and the new system of mutual instruction generally adopted. In the southern provinces, the education of the poor is much neglected, but the present government has pledged itself to remedy this evil, and is taking steps for that purpose.

The freedom of the press in this kingdom was, at its first establishment, without restriction; but the vicinity of Brussels to France, the great number of those Frenchmen who were dissatisfied with the restoration of the ancient monarchy that took up their residence there, and the attempts made by them to spread disaffection, on the ground that religious toleration was incompatible with the rights of the Catholic Church, compelled the Government to place the smaller works which issued from the press under several restrictions. These restrictions do not extend to works containing more than four sheets, and larger works may be published without any previous licence; but the authors and publishers are amenable to the tribunals for their contents, if they are judged to be treasonable, seditious, irreligious, or immoral.

In the most remote periods, the Netherlands were distinguished by their manufacturing skill and industry. Under the Romans, the inhabitants of Arras and several other Flemish cities were celebrated for the production of woollen cloths. At a later period, under the Emperor Charlemagne, a present of fine linen and of woollen cloth, sent to the Caliph of

Bagdad, Harun al Raschid, was deemed to display the most curious specimens of the industry and skill of the Western World. In the instructions of that monarch (*Capitular. de villis Regum Francorum*), it appears that at Liege and other cities of the Netherlands, very extensive manufactories, both from flax and wool, existed, in the dyeing of which madder and kermes berries were used, and were forbidden to be adulterated. The ancient condition of the manufactories of the Netherlands is peculiarly interesting, because it is to them that we and the rest of Europe are indebted for the first rudiments of those arts, which have since been so widely extended in England, Scotland, France, Germany, and Holland. In the time of Charlemagne, it appears from the same collection, and from the *Historia Monasterii Salmuriensis*, that iron wares, gold and silver work, embroidery, arms, horse furniture, and various other articles, were extensively manufactured. The earliest Flemish fabrics were those of linen; and as early as the year 960, free marts were established in several of the cities, to which great numbers of merchants from foreign countries periodically resorted. The present state of the linen manufactory is by no means flourishing; but large quantities of the finer kinds from flax, of their native growth, is supplied by the inhabitants of this kingdom, and is everywhere most highly esteemed. The finest yarn and the best bleacheries are at Haarlem; the best linen is wove at Herzogenbasch, Eindoven, and some other places; but some fine linen, spun in Westphalia, is mixed with that of those places, and when bleached in Holland, is not distinguishable from it. The curious manufactory of thread lace originated in this country, and still distinguishes it. The best is that of Brussels and Mecklin. In the former city and its vicinity it once gave employment to more than 14,000 persons; and at one period the exports of goods fabricated in Flanders, from flax of their own growth, amounted to more than L. 2,000,000 Sterling. The woollen manufactories of Flanders were in a flourishing state as early as the year 980, but were most extensive from the twelfth to the sixteenth century. In the city of Louvain, in the year 1317, there were 4000 looms for weaving woollens. Brussels and Antwerp employed an equal number. Ghent was, however, the most distinguished city for its fabrics, both of wool and flax, and at that period employed 40,000 looms. When called upon to take arms, the weavers, under the banners of their trade, mustered 16,000 men. Ypres contained 4000 looms. Bruges was the storehouse and central point for the commerce of half Europe; but the situation was changed for that of Antwerp in 1478, which continued to be one of the most flourishing cities of the world till the beginning of the sixteenth century, when the tyranny and fanaticism of Philip the Second of Spain inflicted on the Flemish provinces the most distressing sufferings. The great prevalence of goods made from cotton, the improvements that have been made in machinery for spinning thread from that substance, as well as from flax and wool, and the long war, which suspended a great portion of the export trade, have had a very injurious effect on the manufactures of this kingdom; but they still exceed, both

Netherlands. in the numbers of people to whom they give employment, and in the excellence of their productions, those of any other country of Europe, except the British dominions. Woollen goods are extensively produced in Verviers, Eupen, Hodimont, Leyden, and Utrecht, and in smaller quantities in many other places. Cotton articles are made principally in Brussels and Amsterdam. Silk, though on the decline, is worked at Haarlem. Leather of an excellent quality is produced at Liege and Maestricht. Tobacco and snuff are manufactured at Amsterdam and Rotterdam, in which places 24,000 persons are occupied in that trade. In Amsterdam are seventy sugar refineries, in Rotterdam eighteen, in Dort twelve, and several in Antwerp, Ghent, and Ostend. Iron goods are produced in many places; but the cutlery made at Namur, and the arms made at Liege, are peculiarly valued. The earthenware of Delft, formerly so celebrated, has been almost superseded by the English potteries. The quantity of pipes for smoking tobacco produced in this country is so great, that in the town of Gouda alone their fabrication employs more than 5000 persons. The breweries are both numerous and upon a large scale, but are inferior to the distilleries, which furnish a corn spirit, when flavoured with juniper berries, well known throughout the world by the name of Geneva or gin. The greater concerns of this kind are established at Scheidam, at Rotterdam, Amsterdam, and Weesp. That which is made at the latter place is said to have the peculiar property of preserving its qualities in the hottest climates, and is largely exported to the East and West Indies.

Agriculture. The agriculture of the kingdom of the Netherlands, which, even in the northern portion, that was formerly the Seven United Provinces, was more the foundation of its wealth than either manufactures or navigation, deserves the most close examination, and merits more detailed accounts than our limits will allow. As this northern part is principally a country of land redeemed from the sea, it is naturally appropriated chiefly to the growth of the various grasses whose produce affords sustenance for horned cattle, and the profit of which is derived from the butter and cheese that these cattle yield. The corn land of Holland is insufficient for its own consumption, but the productions of the dairy afford ample means for purchasing the requisite quantities of grain. The cows of this district are fine cattle; and though they do not yield, on an average, so large a quantity of milk as many of our English cows, yet, from the butter and cheese they produce, it seems to be of a better quality. The answers of Mr Van de Poes to some queries of Sir John Sinclair state, that the quantity of milk from each cow averages about three quarts daily; that the annual produce of each cow is calculated by the Committee of Agriculture of the Province of South Holland at 78 pounds of butter, and 180 pounds of cheese. During the winter months the cattle are fed with hay, turnips, carrots, grains from the distilleries, linseed oil cake, and bear meal, and are confined to their stalls. In the summer months, soiling or stall-feeding is not practised, but the cattle are grazed day and night in the meadows. The bulls are used for the purposes of pro-

pagation from the age of one year and a half to two years and a half. At reaching that age, they are no longer so employed. The whole offspring, being thus derived solely from young males, are considered to be more valuable than could be obtained by a different plan. In the management of the dairies, both from the milking the cows, and through every subsequent operation, the most scrupulous attention is paid to cleanliness, and this attention is visible in all the utensils, as well as in the temperature which is maintained in the houses, and the state of neatness exhibited in the stalls, the litter, and on the bodies of the animals. The butter of Holland is made wholly of cream; the churning is commonly performed by very simple machinery, set on motion sometimes by a horse, and often by two dogs; in the progress of making, frequent washings are used, and it is preserved solely by being well salted. The butter-milk is applied to feed calves or to fatten pigs, and the skimmed milk is converted into an inferior kind of cheese.

Although the greater part of the agricultural attention of Holland is directed to dairies, and the fattening of cattle, yet, on receding from the coast, and reaching the more elevated lands towards the German frontier, the husbandry assumes the character of that of the midland counties of England; but with such variations as are adapted to the soil, climate, and habits of the people. On the banks of the Rhine in Guelderland, as well as in the province of Utrecht, the arable husbandry is judiciously conducted. The manure is preserved with great care, the ploughing well executed, and a good rotation of crops followed. On some of the lighter soils, the land, when cleaned and manured, is sowed in May with buck-wheat. This crop is harvested in August, when rye is sown on it; and after the rye is carried, which is usually done in the succeeding July, turnips are sowed. The land thus produces three crops in two years. On the stronger soils, the usual rotation is beans, wheat, clover, and oats; and, on the most tenacious of all the soils, they precede the beans by a whole year's clean fallow. In such soils the produce of four harvests exceeds those of five harvests when the fallow is omitted. During the existence of the Continental System of Buonaparte, the cultivation of tobacco, and of beets of different kind for making sugar was introduced, and extended over large surfaces; but the return of peace, by which the ports of the Continent were opened to those productions from the western world, created a competition, which the Dutch husbandmen were unable to withstand, and the cultivators of these articles have become involved in great distress.

The agriculture of the southern division of the kingdom, formerly the Austrian Netherlands, is peculiarly interesting, and conducted upon plans replete with economy, and productive of the most uniform and beneficial results. The land of Flanders was not naturally fertile; on the contrary, the quality of it is merely such as to admit of fertilization, by a series of operations more or less expensive and laborious. Where cultivation has not been extended, the soil produces nothing but heath and fir. As the property of such lands may be acquired for a very small sum, many individuals

Netherlands. have attempted to bring portions of it into cultivation, but have almost uniformly found the expence of doing so far exceed the value of the produce that can be drawn from it. Abbé Mann, to whom we are indebted for some valuable communications on the subject of Flemish agriculture, observes, "What land is cultivated in the Campine of Brabant, is owing to the religious houses founded in it, especially to the two great abbeys of Tongerlo and Everbode. Their uninterrupted duration for five or six hundred years, and their indefatigable industry, have conquered the barren harsh sands, and rendered many parts of them highly productive. The method they follow is simple and uniform; they never undertake to cultivate more of this barren soil than they have sufficient manure for; seldom more than five or six bunders (fifteen or eighteen acres) in a year; and when it is brought, by labour and manuring, into a state capable of producing sufficient for a family to live on, it is let out to farmers on easy terms, after having built them comfortable habitations. From the undoubted testimony of the historians of the Low Countries, it appears, that the cultivation of the greatest part of these rich provinces took its rise from the self-same means, 800 or 1000 years back, when they were in a manner one continued forest." Although, from the destruction, dispersion, or diminution of the religious communities, by the French Revolution, the process of reclaiming other parts of the heaths has been suspended or rendered languid; yet the excellent agricultural practices, which a long series of years had ingrafted into the minds and habits of the sluggish peasantry, have been adhered to with a tenacity that is obviously distinguishable in all the other customs, as well as in the manners, dress, food, and religion of the people. Besides that general system of economy, which is indispensable to the success of all efforts, and which there enters into the minutest details of their husbandry, the two great objects which seem to be aimed at in all their operations, are the increase of those crops which afford sustenance for cattle, and the careful preservation of every substance that can be converted into manure, and returned again to the land, to renew its exhausted fertility.

clover. The foundation on which the agriculture rests is the cultivation of clover, which seems indigenous, since none of the most ancient records notice its introduction, but speak of it as familiarly as of hay or oats. It is probably from this country that the plant in question has been, though but recently, slowly, and hitherto partially, introduced to the adoption of the farmers of Germany, France, and Great Britain. The clover in Flanders is sowed in every sort of grain, in wheat, rye, and winter barley, in the spring of the year, when the blades of those plants have acquired a growth of three or four inches; and with oats and summer barley at the same time with those seeds. It is also often sowed with flax; and, in general, the crops grown between those plants are more luxuriant than when sowed with the cerealia. It frequently happens when sowed with flax, that clover yields a heavy crop a few months after it is sown, two still more abundant crops the next year, and sometimes even three; and

Netherlands. if, as it occasionally happens, it is suffered to stand another year, it will yield one heavy crop, and afterwards good pasture for cattle, till it is ploughed up to receive the seed of wheat, which usually follows it. The original strength of the plants which yield such abundant nourishment is due, undoubtedly, to the care taken in pulverizing the soil by frequent ploughings and harrowings, to the careful extirpation of all weeds, and to the copious stores of manure, and its complete amalgamation with the soil; but the successive harvests which the plants yield is attributed, and with apparent probability, to the top-dressings which are bestowed upon them. The top-dressings administered to the young clover consists either of rotten yard-dung, lime, pigeons' dung, or coal, or native turf-ashes, and is laid on as soon as the plants begin to extend themselves over the ground. Sometimes the plants are refreshed with a liquid manure, which will be hereafter noticed. These manures, though administered to the clovers, as far as they can be obtained, are found far inferior in powers of fertility to that substance which is most generally used, and whose effects form the theme of the praises of all who have witnessed the Belgian husbandry. The turf-ashes of Holland are sowed by hand on the clovers, in quantities varying from eighteen to twenty bushels to the English acre. This small quantity produces a most surprising, and almost magical effect. Within a few weeks after it is sown, a field where none, or but slight straggling plants are to be seen, becomes covered with a most abundant herbage. The parts of a field sowed with these ashes, at the first mowing, show their efficacy in a most striking manner, the clover being frequently a foot higher on such parts than on those where its sowing has been omitted. These ashes are found superior in efficacy to such as are made from the turf commonly used for fuel in Flanders, in so much, that one-third of the quantity is deemed to afford as great productiveness. We have no analysis of the turf-ashes of Flanders, by which we can form a comparative estimate of the proportional substances which create so vast a difference between the vegetative faculties of them and of the turf-ashes of Holland. The latter have been carefully analyzed by Mr Brande, Secretary to the Royal Society of London, who found them to contain

Silicious earth,	32 parts.
Sulphate of lime,	12
Sulphate and muriate of soda,	6
Carbonate of lime,	40
Oxide of iron,	3
	<hr/>
	93
Impurities and loss,	7
	<hr/>
	100

These ashes are brought from Holland by the canals to Brussels, from whence they are conveyed by land carriage to the different farms where they are applied. Long practice has so convinced the Flemish farmers of their benefit, that a common proverb, in the patois of the country, may be thus translated: "He that buys ashes for his clover pays no-

Netherlands, thing, but he who does it not pays double." They are frequently fetched from the canal by persons who have to carry them forty or even fifty miles by land.

Manure.

The abundance of clover produced from the soil of Flanders enables the cultivator to maintain a great number of cattle, principally cows, whose dung is managed with an attention and care that is highly worthy of imitation, and contributes to maintain, in a state of high fertility, that soil which yields the most exhausting crops. "The farmers," says the Abbé Mann, "supply the want of straw in the following manner: The peat, or sods, which are cut from the heath, are placed in the stables and cow-stalls as litter for the cattle. The ground under them is dug to a certain depth, so as to admit a considerable quantity of these peat sods, and fresh ones are added as the feet of the cattle tread them down into less compass. These compose so many beds of manure, thoroughly impregnated with the urine and dung of the cattle. This mixture produces a compost of excellent quality for fertilizing ground where corn is to be sown."

The most unique practice of the Flemish cultivators is the application of liquid manure. Under the farm buildings, large reservoirs are constructed, into which the draining of the dung, the urine of the cattle, and the contents of the privies, run. This receptacle is divided by rails, so as to prevent any more solid substances from coming into that part where the pump is placed, by which it is raised from the reservoir into the carts that convey it to the fields. The liquid in these receptacles is commonly increased in efficacy, by throwing into them, for solution, large quantities of rape-cake. This liquid manure, enriched by oil-cake in proportion to the purse, or the spirit, of the proprietor, is spread over the land, sometimes by hand; and by habit the workmen have acquired the tact of distributing it equally and in previously prescribed proportions over a whole field. More commonly it is conveyed to the fields in large casks on wheels, to the bung-hole of which is appended a wooden shoot, narrow at the top and broad at the lower extremity, which spreads the substance equally. For the flax and rape crops this manure is most liberally used. The quantity of this liquid applied to an acre of flax is commonly about 2500 gallons of English beer measure, in which about 1000 rape-cakes of three pounds each have been dissolved.

Productions.

No country in Europe provides from its soil so great a quantity of sustenance for its inhabitants, so large a surplus of food for exportation, and such valuable commodities to exchange for articles of foreign growth, as Flanders. Besides wheat, rye, barley, oats, pease, beans, and buck-wheat; madder, rape-seed, hops, tobacco, clover-seed, mustard-seed, flax, hemp, poppy-oil, and some other productions, are raised beneficially, both for home consumption and for exportation. As the inhabitants are in every thing averse to innovation or improvement, the implements of husbandry are in a rude state, and very little variation is made from the examples set by their ancestors some centuries ago. The various machines used in England for abridging animal la-

bour in husbandry are unknown, and the use of human beings in many operations is still retained there, for which horses and machinery are adopted with us. The same aversion to innovate is seen in the management of the cows, the sheep, and the pigs; the races not having been improved by crossing as in some other countries. The horses seem to have drawn more attention, and the race commonly seen is excellent for agricultural purposes, and for the road.

The mines of this kingdom form but an inconsiderable portion of its wealth. They are wholly confined to the southern provinces of Liege, Hainault, and Namur, and yield only iron, calamine, and coals. The quantity of iron annually produced is, on an average, about 1000 tons, of calamine, about 750 tons, and of coals, 2500 tons. The turf commonly used for fuel is valued at L.500,000 annually. The clay-pits in the northern provinces, from which their porcelain is made, and the stone quarries in the southern provinces, especially in Liege, are considerable sources of wealth.

The fisheries of Holland, which were in some measure the foundation of its national prosperity and naval power, have greatly declined under the political calamities which the last thirty years have witnessed, and are yet by no means restored to their former flourishing state. At the beginning of the last century, the fisheries gave occupation to about 60,000 families, and consequently supported 300,000 persons; at present, the families so employed do not exceed 20,000. At that period, 1500 busses, of 40 tons each, were annually equipped for the herring fishery, whereas, in the year 1818, their number did not exceed 200. The whale and cod-fisheries now employ not more than 60 ships; and the fishery on their coasts, which once supplied the markets of England, is much diminished, though it still employs about 6000 boats. The whole of the gross product of the fisheries is estimated, by Dutch writers, at about L.1,000,000 Sterling annually.

Although much declined from its former eminence, the foreign trade of the Netherlands is considerable, and, since the foundation of the new kingdom, has gone on gradually, though not rapidly, increasing. The period of the most prosperous condition of the foreign trade of Holland was that commencing with the first voyage to the East Indies, under Cornelius Houtman, in 1595, who seized a large portion of the possessions of Spain, or rather of Portugal, then subjected to Spain. The East India Company was established in 1602. It conquered the Molucca Islands in 1618; established at Batavia, on the Island of Java, the central point of their commerce and power, and opened a lucrative trade with Japan. From 1620 to 1650, Brazil and the West India possessions of Holland were acquired, and their establishment at the Cape of Good Hope was founded. In the middle of the seventeenth century, from 1640 to its close, the foreign trade of Holland to that of Great Britain bore the proportion of five to one. In the beginning of the nineteenth century, the trade of Holland, as compared with that of England, gradually declined, and the events which followed the Revolution in France reduced it to a very low ebb.

Netherlands. Since the union of the two countries, the Batavians have become a more commercial people than before, and, on the whole, their foreign commerce is reaching a respectable station among the European nations. Since the year 1815, the average number of vessels, under the Netherland flag, that have passed the Sound, has amounted to about 1600. At present, the commerce of the Netherlands with England amounts to about 44,000,000 Dutch florins; with France, 38,000,000; with Spain, Italy, and Germany, 30,000,000 each; with the East Indies, 36,000,000; and with the West Indies, 29,000,000. Holland requires from foreign countries more than half of its bread corn, salt, wine, fuel, and metals; the former is, indeed, in some measure supplied from the southern parts of the newly established kingdom. The principal articles of export are cheese, butter, madder, tobacco, linen, paper, laces, cloths, leather, arms, cutlery, herrings and stock-fish, corn, spirits, whalebone, seed and fish oils, tobacco-pipes, and many articles of less note. Besides the exportation of its native commodities, this country has a considerable commerce in the valuable productions of both the Indies, which are brought to their ports, and from thence re-exported by sea to the more northern countries, or transmitted, by means of the navigable canals and great rivers, to the centre of middle Europe. This transit trade has in some years amounted to 36,000,000 pounds of coffee, 12,000,000 pounds of cotton wool, 14,000 hogsheds of sugar, 5000 pipes of rum, 100,000 pounds of cloves, 160,000 pounds of nutmegs, and 50,000 pounds of mace, besides other valuable spices.

Foreign Dominions. The foreign settlements belonging to the kingdom of the Netherlands, having been given back by Great Britain at the treaty of Paris, are, in Asia, 1st, The Island of Celebes, as far as the Dutch possessed it, viz. Macassar on the west coast, with four fortresses and several factories; Monada, under which is Gorontalo, from which the principal exports are ivory, gold, and diamonds. 2d, Banda, with nine surrounding small islands. 3d, Amboyna, whose principal productions are cloves, mace, and cinnamon. 4th, Timor, one part of which belongs to Portugal, governed by a sub-prefect. 5th, Ternate, the principal of the Moluccas, where a civil and military governor resides. 6th, Palembang, on the island of Sumatra. And, 7th, Banjermassing, on the island of Borneo. The most considerable foreign establishment is, however, on the Island of Java, where Batavia, the capital, one of the largest cities of India, is the seat of active and extensive commerce. The number of subjects of the King of the Netherlands, including all the different races on this island, are estimated at two millions and a half, and those on the other islands which have been enumerated, at one million and a half. Besides these there are some factories of the Netherlands on the coasts of Coromandel and Malabar, and some in Japan and Persia.

Netherlands. According to the statement of General Daendels, the income derived from these settlements in the year 1811 amounted to 25,890,000 florins, and the expenditure to only 21,500,000; leaving a net product of 4,390,000 florins, or 440,000 pounds Sterling, at the service of the parent state. On the coast of Guinea the Netherlands have thirteen factories with forts, and small establishments. The principal of these are Fort Nassau and Fort Elmina. The number of their subjects is estimated at about 10,000. In South America this kingdom possesses the province of Surinam in Guyana, which extends over 6400 English square miles, and contains about 300,000 inhabitants, the greater part of whom are negro slaves of the African race. In the West Indies, the Islands of Curaçoa, St Eustatia, and St Martins, have been given back by Great Britain, and are estimated to contain 40,000 inhabitants. These islands are by no means fertile, and are principally valuable as depots for commerce, especially Curaçoa, from whence large quantities of European goods used to be exported to the settlements of Spain upon the continent.

The national income of the kingdom is derived from various direct and indirect taxes, which, together, amount, on an average, to about fourteen Rhenish florins, or twenty-eight shillings Sterling, to each individual. These taxes are varied according to the exigencies of the state, as estimated in the annual budget presented to the States-General. The budget of 1818 is reduced lower than that of 1816 by about one-tenth, the whole of which is covered by taxes raised within the year, and includes the interest on the public debt. The expenditure thus covered is distributed in the following manner:—

	Rhenish Florins.
Civil List, - - - - -	2,600,000
The higher Boards of Government, - - - - -	1,170,000
Secretaries of State, - - - - -	320,000
Foreign Affairs, - - - - -	853,000
Administration of Justice, - - - - -	3,700,000
Office of Internal Affairs, - - - - -	2,000,000
Protestant Worship, - - - - -	1,325,000
Catholic Worship, - - - - -	1,875,000
Public Instruction, - - - - -	1,200,000
Department of Finances (including the Interest on the National Debt), - - - - -	25,000,000
Marine Department, - - - - -	5,500,000
Army, - - - - -	22,000,000
Water Department, for Dikes, Sluices, Canals, &c. - - - - -	4,700,000
Department of the Colonies, - - - - -	1,100,000
Reserve Fund, - - - - -	657,000
	74,000,000

Or about L. 7,500,000 Sterling. Among other causes which contribute to retard, if not prevent, a National Debt.

\* See *Staat der neederländischen oostindischen Bezittingen, onder hat bestuur, van der Gouverneur-General Herman Wilhelm Daendels, in der Jahren 1808—1811.* Gravenhage, 1814.

Netherlands. dial union betwixt the two dissimilar portions of this kingdom, the public debt is not the least considerable. This debt was almost wholly contracted by the Seven United Provinces, either during their existence as an independent government, or whilst under the yoke of France, when it was greatly augmented. It is also principally owing to the great monied capitalists of Holland. The Belgians are therefore dissatisfied with this burden, and the consequent taxes with which the Union has loaded them. The amount of the debt is as follows, viz.—

Deferred debt, on which no interest is paid,	Florins.
Active debt, bearing interest,	1,131,000,137
Belgian debt, principally contracted formerly by Austria, and assumed by the Netherland Government,	510,000,000
	34,466,679
	<hr/> 1,675,466,816

Or nearly L. 170,000,000 Sterling.

Armed Force.

The peculiar situation of this kingdom, established under the auspices of Great Britain, and designed as a check on the land side to act against any encroachments of France, renders it necessary to maintain many strong fortresses on the frontiers, and to keep up a respectable land force. A chain of strong fortifications has been planned, and in part executed, the expence of which is defrayed by the contributions inflicted on France when the Allies occupied it after the battle of Waterloo. The army of the Netherlands at present consists of about 62,000 men, formed into six military divisions. The same connection with Great Britain which induces the maintenance of so large a land force, has rendered it unnecessary to support a proportionably extensive naval armament. At present the fleet consists only of sixteen ships of the line and ten frigates, besides smaller craft. There seems no disposition to increase the number of their larger ships, but several frigates and corvettes are now building and equipping, which will somewhat augment that description of force.

Money, Weights, and Measures.

In the Belgic Provinces the French decimal system of weights and measures has been introduced, but is yet reluctantly adopted, except in the commercial cities. In the villages and small towns the weights and measures are very various, differing in almost each of them, but the decimal reckoning of money much more extensively prevails. In the Dutch Provinces accounts are kept in gilders, stivers, and pfenningers. The gilder is fifty-five kreutzers, or twelve Saxon groschen. The gold coins are, ruyders, value fourteen florins Rhenish, and ducats, five florins five stivers. Coins have recently been made of one, two, and three guilders, and of half and quarter guilders, which has been done to facilitate the decimal arithmetic in current transactions. Mints for coining these pieces are established both in Amsterdam and Brussels. The old silver coins still most commonly current are, ducatoons, three florins three stivers, rix-dollars, two florins ten stivers, and lowenthalars, forty-two stivers. The common weight of commerce is the shipspound of three hundred weight. The tonnage of ships is estimated by lasts,

consisting of two tons, and the ton is a space so large as to contain as much sea-water as weighs 2000 pounds; thus a ship of 200 tons is of such capacity as to hold, when filled with sea-water, 400,000 pounds weight.

(ww.)

NORFOLK, an English maritime county, bounded on the northern and north-eastern sides by the German Ocean; on the south and south-east by the county of Suffolk; and on the west by the counties of Lincoln and Cambridge. The shape is nearly that of an ellipsis bounded by a convex line, a little indented on the western extremity. Its greatest length is fifty-nine miles, and its greatest breadth thirty-eight. Its square contents, as calculated by the late Arthur Young, amounts to 1830 square miles, or 1,171,000 acres. It is divided into thirty-three hundreds, and contains 1 city, 30 market towns, and 722 parishes.

According to the enumeration of 1811, the number of houses was 52,807; that of families 62,815. The families employed in agriculture were 31,454; those employed in trade and manufactures 23,082; and 8279 were engaged in other occupations. The inhabitants were 291,999, of whom 138,099 were males, and 153,910 females. In the preceding year the baptisms of males were 4741, of females 4671; the burials of males were 2800, of females 2920; the marriages were 2364.

Population.

The surface of this county presents less variety than any other in England. It is generally a level plain, with few undulations, and no bold or abrupt elevations. With the exception of some recently planted districts around the seats of noblemen and gentlemen, the woody parts of the county are very inconsiderable, and there is generally a great scarcity of the more umbrageous trees. The streams have almost all a languid and sombre appearance. Though, to the traveller of taste, the sameness and uniformity is wearisome, yet to him who directs his attention to the wealth and comforts of the districts through which he journeys, few countries can be more pleasing. The number and substantial appearance of the farm-houses, and even the cottages, the condition of the roads and fences, and the high cultivation of the fields, are marks of rural prosperity that are no where more striking. Some few portions on the eastern side of the county form exceptions to this general description, but they are inconsiderable when compared with the whole.

Face of the Country.

From its exposure to the North Sea, the winters in Norfolk are usually severely cold, and the powers of vegetation are retarded to a later period of the year than in the western counties. In the hundred of Marshland the climate is not only cold, but damp,

Climate and Soil.

Norfolk. and the inhabitants are subject to intermitting fevers, which commonly attack all strangers who come to reside in that district. The soil of Norfolk is generally a light sand, or sandy loam, for though a part of the fens are within this county, and the district of Marshland consists of ooze formed by deposition from the sea, as well as a narrow tract of land on the banks of the river Waveney, yet these form but trifling exceptions to the general character of the soil of the county. Mr Arthur Young, in his *Agricultural Survey of Norfolk*, has made the attempt to classify the soils, and estimate their quantities. The difficulty of doing this with accuracy must be acknowledged by every one who considers the nice gradations which soils discover, and how various are their modifications. We give this estimate rather as an approximation to, than as absolute exactness:

Soils.	Square Miles.	Acres.
Light sand,	220	140,800
Good sand,	420	268,000
Marshland clay,	60	38,400
Various loams,	900	576,000
Rich loams,	148	94,720
Peat,	82	52,480

Agriculture. As the land of Norfolk, from the representation here given, appears to be far from being naturally of a fertile description, the great amount of its productions must be attributed to the excellent system of agriculture which has been here introduced and extended, and which, though scarcely calculated for most of the other districts of our island, is admirably adapted for the soil and climate where it is pursued. The foundation on which the whole system of its agriculture is built is the cultivation of turnips. These light soils are easily brought into a fine tilth, by repeated ploughings and harrowings, and their produce maintains so large a portion of live stock, that their manure, when carefully preserved and properly distributed, enriches the soil at every successive course more than it is impoverished by the crops of corn that are grown upon it. The land is thus in a constantly progressive state of improvement. The soil being so light, no deep ploughing is required, but such a repetition of moving it as will be sufficient to destroy the surface weeds, and to pulverize it effectually. This is easily effected by well constructed light ploughs, drawn by two horses, who are guided by reins in the hands of the man who directs the plough. In many instances a four course system of rotation is followed, consisting of turnips, barley, artificial grasses, and wheat. In some instances the artificial grasses are left two years, and then, after three or four ploughings, the wheat is sown. A very common rotation, provincially termed *the six course shift*, is wheat, barley (with or without clover), turnips, barley or oats, clover mown for hay, clover fed, and then wheat again. Both these systems, with the varieties of each, are founded on the principle that as much land shall be cultivated with green crops, which furnish sustenance for cattle, and thereby produce manure, as is destined to the growth of corn. The system of drill-husbandry is carried to a great extent, and the practice of planting or dibbling grain

of all kinds has been of late years very much and beneficially increased. By perseverance in their excellent plans, many extensive portions of this county, especially in the north-eastern part of it, which were a few years ago deemed incapable of producing a wheat crop, now yield abundant harvests of that grain. Oats are but a small object of cultivation, but barley is deemed the most appropriate grain to the soil and climate, and is consequently sowed to the greatest extent, occupying nearly one-fourth of the arable land of the county. The increase of grain varies very considerably. On the heavy soils of Marshland and Flegg the produce of wheat is frequently six quarters, and of oats ten quarters to the acre; but as these districts form but a small proportion of the whole, the average quantity of wheat in the county is about three quarters to the acre, and of barley four quarters. In no part of the kingdom have the various mechanical inventions for facilitating agricultural labour been so generally diffused as in Norfolk, and the implements used there may well serve as models for the other counties. Besides the common grains, wheat, barley, oats, pease, and beans, this county yields mustard, saffron, flax, and hemp, but none of them in such quantities as to merit especial notice.

The live stock of this county possess few peculiarly discriminative features. The horses, crossed by the breed of Suffolk, are bony, active, and hardy, and well adapted for husbandry or the road, and are almost universally used for agricultural labour, to the exclusion of oxen. The native cows were a small breed, not unlike those of Alderney and Guernsey, but have been improved by a mixture with the cows of the richer adjoining counties. The greater part of the cattle fattened in Norfolk are bought from the Scotch drovers, who bring them to the fairs about Michaelmas. They are fed on the banks of the rivers on the natural grass, or on the arable farms on turnips, till they become fit for slaughter. The number of Scotch cattle annually bought by the Norfolk farmers is estimated to vary from 15,000 to 20,000. The original sheep of Norfolk were a hardy race, with horns, black feet, and black noses, the fleece yielding about two pounds of wool of third rate fineness, and the quarters weighing, when fattened, about eighteen pounds. They were well calculated for the land when it was less highly cultivated than at present, as they were good travellers, and eat the herbage very close; but as the improved systems of husbandry have been extended, this native breed has sometimes been crossed by others, and in many instances has given place to the South Down sheep. The increase of arable farms has diminished the dairies, and consequently the pigs which were reared from them, and the practice of fattening hogs for bacon is scarcely known.

The poultry of Norfolk has been long celebrated, and vast quantities of it are conveyed to the London markets. The turkeys are most highly prized from their superior delicacy of flavour. The dry nature of the soil is deemed peculiarly favourable to the rearing of these birds, and the numbers that are sent from it to other districts amount to hundreds of thousands. No part of England is so abundantly stock-

Norfolk.

Live Stock.

Poultry and Game.

Norfolk.

ed with game, especially pheasants and partridges, as Norfolk. They are sedulously preserved by the landlords, and generally reserved in the leases, so that they have obtained the character of property, and are commonly respected as such by adjoining proprietors of estates. Great numbers of rabbits are bred on extensive warrens in many parts of the county, both for the sake of the flesh and the wool.

Manufactures.

Norfolk has been long and still continues an extensive manufacturing county. The Flemings first settled here as early as 1336, and made woollen goods at the village of Worstead, from whence the name of that place was applied to the thread made of the longer kinds of wool. Under the persecutions of the Duke of Alva, in Flanders, many more natives of that country found refuge in and near Norwich. The fabrics have indeed successively changed with the change of fashions, and the fluctuations of markets, but manufactures have been continued through many vicissitudes, to the present time. The chief goods now manufactured are bombazeens, camblots for the markets of China, and shawls of various and elegant kinds, principally for home consumption. This last article, introduced when the demand for stuffs from Spain ceased, has been highly beneficial to the city of Norwich and its vicinity. The introduction of machinery in the northern counties had destroyed the habit of spinning, which, a few years ago, universally prevailed among all the females of the peasants' families in this and the adjoining counties. Besides the manufactories of Norwich and its vicinity, in Diss, and some other parts of the county, some inferior kinds of bone lace are made, but the quantity produced is slowly and gradually diminishing.

Commerce.

Scarcely any of the goods manufactured in this county are sent to foreign markets directly; those destined for distant countries being almost wholly exported from London. The commerce is notwithstanding very extensive from the two ports of Yarmouth and Lynn. Yarmouth, in regard to the number of its ships, is the eighth port in the kingdom, having more than 300 registered vessels. It is well situated for trade, and has one of the finest quays in Europe; but the depth of water is not sufficient for ships of great draft, and the bar at the mouth of the harbour is a serious impediment. The great support of the shipping of Yarmouth is the herring-fishery. These fish are caught by the Yarmouth men, in June and July, on the shores, and in the lochs of Scotland, and at a later period on their own coasts. They are first cleaned, and then slightly salted; after which they are hung up in large appropriate houses, where, by the application of the smoke of wood fires, the preparation of curing them is completed. This fishery usually yields from 80,000 to 100,000 barrels of red herrings, each barrel containing 1000 fish. This branch of industry, besides the employment of the seamen, gives occupation to several thousand artificers of various kinds. Besides this fishery, the exports of Yarmouth as well as Lynn, and the smaller ports of Wells, Blackney, Burnham, and Clay, afford great employment to shipping by the surplus quantity of corn which the county produces and sends to London and other

ports. The imports at these towns consist of timber, hemp, wine, spirits, and foreign fruit, which, by means of the navigable rivers, are forwarded to the interior adjoining counties.

Norfolk.

The rivers are sufficiently easy of navigation to render canals unnecessary, and there are consequently none in the county, though some have been commenced, and, after languishing some time, have been abandoned without being completed. The Great Ouse is a navigable river, which rises in Northamptonshire, enters this county at Downham, and empties itself into the sea near Lynn. It has a great rise of tide; is navigable for barges twenty-four miles from its mouth, and for boats as far as Bedford; thus affording water communication with seven of the midland counties. The Little Ouse rises in the southern part of this county; at Thetford it receives the small river Thet, and from thence is navigable to its junction with the Great Ouse, on the borders of Cambridgeshire. The Waveney rises within nine or ten feet of the source of the Little Ouse, and takes a directly opposite course. It has many sinuosities, as its name denotes, becomes navigable at Bungay, receives the Yare at Burgh, and empties itself into the sea at Yarmouth. The Bure rises near Aylsham, and, after joining the Thone, near North Walsham, becomes navigable for boats. It falls into the Yare previous to its meeting the sea. The Yare rises near Attleburgh, becomes navigable at Norwich, and, after receiving the waters of the Tass and the Wensum, merges in the Waveney. The Nar rises near Litcham, has a short course to the sea at Lynn, from whence it is navigable upwards to Narborough, a distance of fifteen miles.

Interior Navigation.

The whole of the county is within the diocese of Norwich; the bishop of which see has his palace and cathedral in the city. The titles derived from the county are Duke to the family of Howard; Earl of Norwich to the Scotch Duke of Gordon, and of Yarmouth to the Marquis of Hertford, Marquis and Viscount Townsend; Viscount Thetford to the Duke of Grafton; Barons Walsingham, Calthorpe, Woodehouse, Hobart, Walpole, and Nelson. Norfolk sends twelve members to the House of Commons, viz. two for the county, and two each for Norwich, Yarmouth, Lynn, Thetford, and Castle-Rising.

This county contains few Roman antiquities, but some of Saxon date are to be seen in the cathedral, the episcopal palace, the gates of Yarmouth and Lynn, and in several piles of ruins of ecclesiastical edifices, and in some of the parish churches. Among many distinguished natives of this county, the most celebrated have been Queen Anne Boleyn, Dr Samuel Clarke, Sir Edward Coke, Archbishops Herring and Parker, Lord Nelson, Richard Porson, Sir Robert Walpole, and the Right Honourable William Windham.

Antiquities, &amp;c.

In so large a county many seats of noblemen and gentlemen are naturally expected to be found. It would far exceed the limits which the nature of this work admits to enumerate one half of them, but the most remarkable are the following:

Bickling, Lord Suffield; Binley Hall, Earl of Rosebery; Bracon Ash, T. F. Berney, Esq.; Bucken-

Norfolk  
||  
Northamptonshire.

ham House, Lord Petre; Costessey Hall, Sir Wm. Jerningham; Felbrigg, Captain Lukin; Harling, Sir John Sebright; Hethel Hall, Sir Thomas Beevor; Hillington Park, Sir Martin Folkes; Houghton Hall, Watson Taylor, Esq.; Intwood Hall, Earl of Buckinghamshire; Gunton, Lord Suffield; Kimberley Hall, Lord Woodehouse; Kirby Bedon, Sir John Berney; Melton Constable, Sir J. H. Astley; Quiddenham, Earl of Albemarle; Rainham Hall, Marquis of Townsend; Wareham, Sir M. B. Folkes; Wolterton Hall, Earl of Orford; Oxburgh Hall, Sir Richard Boddington.

bridgeshire. The whole of the county is within the Northamptonshire. diocese of Peterborough, with the exception of three parishes that are under the see of Lintcoln.

It is generally a pleasant country, with such undulations as give an agreeable variety; but, owing to the numerous inclosures, the prospects are not in general extensive, except upon the summits of the higher hills. The centre of the county is a level elevation, from which the rivers have their rise, and descending in opposite directions, take a course both to the German Ocean and the English Channel.

The towns whose population exceeds 1500 inhabitants are the following:

	Houses.	Inhabitants.
Norwich, - - -	8521	37,256
Lynn, - - -	2318	10,259
Wells, - - -	603	2,683

East Dereham, - - -	554	2,888
Diss, - - -	352	2,590
Swaffham, - - -	485	2,350
Market Downham, - - -	383	1,771
Harlestone, - - -	278	1,516

The agriculture of this county partakes so much of the nature of the several counties that border it as to be almost as various, and not to merit any particular description. The most important rural pursuit is the grazing of cattle, for which the excellent pastures are admirably adapted. These, when fattened, are sent in weekly droves to the market of Smithfield for the supply of the metropolis, where they are highly esteemed. The arable land produces excellent wheat, beans, and oats; but the soil in general is not well calculated to raise good barley. The artificial grasses, clover, trefoil, sanfoin, and rye-grass, are very extensively cultivated, and, aided by turnips, form important articles of food for the flocks and herds.

See A. Young's and Kent's *General View of the Agriculture of Norfolk*; *Topographical History of Norfolk*; *The Norfolk Tour*, 1808; *Booth's History of Norwich*; *Gough's Topography*; *Richards's History of Lynn*; *Brayley and Britton's Beauties of England*, Vol. II.

Forests. Within this county are several large forests belonging to the Crown, with two chaces, over which the King has certain rights. The largest of these is the Forest of Rockingham, in the northern part of the county; it extends over 11,000 acres. The land, in many instances, belongs to individuals; but the royal deer have, under certain restrictions, the range over the whole. Whittlewood Forest contains about 5000 acres. It is stocked with about 1000 deer; a proportion of which, according to ancient prescription, are killed annually for the royal household and for the great officers of the Government, who receive them as a matter of right, attached to their appointments. This forest contains much excellent naval timber, which is reserved for the use of the Government; but, from the reports of the commissioners, appears to be very negligently preserved, and very injudiciously managed. Salcey Forest is about 1850 acres. This tract was formerly covered with most valuable ship timber, but has furnished for the navy but a very small proportion of what it is capable of. The mixture of opposite interests in this kind of property diminishes its productiveness to all the parties interested in it. The underwood does not belong to the Crown. The individuals who own it cut it down every twenty-one years. During the following nine years it is inclosed, and for the remaining twelve is open for the deer to feed on the land. The Crown enjoys only this right of pasture and the timber trees. The pasture does not belong exclusively to it, for many of the surrounding parishes possess also a right to turn their cattle into the forests, under ancient grants and prescriptions, and with limitations, of a complex nature, which are productive of perpetual dissensions and litigations. The rangership of these forests is hereditary in the Dukes of Grafton, who have, during the last century, derived from it a very large income, whilst the revenue to the Crown has been very trifling.

Extent. NORTHAMPTONSHIRE, an inland county of England, nearly in the centre of the kingdom. It is of an irregular and very extended figure, being about 67 miles in length. In the widest part it is 30 miles, and in the narrowest not more than eight in breadth. Its contents are 965 square miles, or 617,600 acres. The land is thus appropriated; about 290,000 acres are in arable cultivation, 235,000 acres are in pasture, and about 86,000 are uncultivated, or occupied as forests and woodlands. It contains one city, eleven market towns, 301 parishes, and is divided into 1901 liberties.

Population. In the year 1811, the county was returned as containing 28,957 houses, with 30,860 families, and 141,353 inhabitants. The families employed in agriculture were 15,235, those engaged in trade and manufactures were 12,100, and those of other descriptions 3525. Of the inhabitants, the males were 68,279, and the females 73,074. In the preceding year, the baptisms of males were 1973, of females 1896; the burials were of males 1276, and of females 1323, the marriages were 1090.

Boundaries. From its oblong shape, lying obliquely across the middle of the kingdom, Northamptonshire comes in contact with, and is bounded by, a greater number of other counties than any other division of England. Proceeding from the north, on its western side, it touches upon Lincolnshire, Rutlandshire, Leicestershire, Warwickshire, and Oxfordshire; and on its eastern side, it is bounded by Buckinghamshire, Bedfordshire, Huntingdonshire, and Cam-

Northamp-  
tonshire.Rivers and  
Canals.

ling; scarcely amounting to L. 200 *per annum* on an average of the last hundred years.

The only navigable river in this county is the Nen or Nine. It rises in the western part, flows across, and then runs north, till it enters by Lincolnshire into the German Ocean. The Welland rises in the county, soon forms the boundary between it and Leicestershire and Rutlandshire, and only becomes navigable after entering Lincolnshire at Stamford. The other rivers, the Ouse, the Avon, the Leam, and the Charwell, though they have their sources in Northamptonshire, are but inconsiderable rivulets till they enter the contiguous counties. The benefits of internal navigation have been very freely bestowed here by the canals, which afford great facilities to intercourse. The Oxford Canal connects it with that city. The Grand Junction Canal, communicating on one hand with London, and on the other with Liverpool and Manchester, passes through the county. The Grand Union Canal connects it with Leicester. Thus the heavy products, especially coals, are brought to every part on very moderate terms.

Antiquities.

The remains of Roman and Saxon antiquities are very numerous. Among the former, the Watling Street Road, the Ermine Street Road, the camps of Arbury, of the Boroughs, and of Rainsbury, and the tessellated pavements at Cotterstock, at Stanwick, and at Woodford Field, have engaged the attention of Stukely and other eminent antiquarians. As there were more than sixty monasteries and other religious houses at the period of the Reformation, whose traces may now be seen, they, with the baronial castles, present a wide field for the researches of the lovers of antiquity; but the bare enumeration of them would be incompatible with the limits of this work.

Manufac-  
tures.

The manufactures of this county are chiefly of a domestic nature, and carried on in the dwellings of the workmen. Boots and shoes are made for foreign markets, and, in war, for the supply of the army. Both fine thread and silk lace are made, and afford employment to the females, who are taught the art in schools for that purpose, and attain great perfection. The principal places for collecting the lace are Northampton and Wellingborough. A large quantity of horse whips were made at Daventry, and though diminished in some degree, the trade is still continued there.

Titles, &amp;c.

The titles derived from this county are Duke of Grafton; Marquis of Northampton; Earls of Peterborough, Fitzwilliam, Spencer, and Harrington; Viscount Sackville; Barons Braybrooke and Lilford; and as second titles, Baron Burleigh to the Marquis of Exeter, Viscount Milton to Earl Fitzwilliam, Viscount Brackley to the Earl of Bridgewater, and Baron Finch to the Earl of Winchelsea. The members returned to the House of Commons are nine, viz. two for the county, two each for Northampton, Peterborough, and Brackley, and one for Higham Ferrers.

The most celebrated natives of Northamptonshire have been, Robert Browne, founder of the sect of Independents; Mrs Chapone; John Dryden the poet; Fletcher the dramatist; Fuller the historian and divine; Harrington, author of the *Oceana*; Her-

vey, author of *Meditations* and other works; Knolles the historian of the Turks; Dr William Paley; Bishop Wilkins, and Thomas Woolston.

Northamp-  
tonshire  
||  
Northum-  
berland.

The catalogue of all the noblemen and gentlemen's seats in this county would extend to a long list, and we, therefore, can only notice the most remarkable of them.

Castle Ashby, Marquis of Northampton; Aldwinckle, Lady Lilford; Althorpe, Earl Spencer; Ape-  
thorpe, Earl of Westmoreland; Brinworth, Walter Strickland, Esq.; Burleigh, Marquis of Exeter; Cannons Ashby, Sir J. E. Dryden; Cottesbroke, Sir James Lanham; Courteen Hall, Sir William Wake; Dean, Earl of Cardigan; Drayton, Duke of Dorset; Easton Neston, Earl Pomfret; Ecton, Samuel Isled, Esq.; Fawsley Park, Sir Charles Knightley; Finedon Hall, Sir William Dolben; Horton, Sir Robert Gunning; Kirby, George Finch Hatton, Esq.; Lamport, Sir Justinian Isham; Lilford, Lord Lilford; Martin's Thorpe, Earl of Denbigh; Milton Abbey, Earl Fitzwilliam; Rockingham Castle, Lord Sondes; Salcey Forest, Earl Euston; Wakefield Lawn, Duke of Grafton; Walgrave, Sir James Langham; Whittlebury, Lord Southampton.

The towns whose population exceeds 1000 are the following:—

	Houses.	Inhabitants.
Northampton,	1600	8427
Peterborough (city),	829	3674

(w. w.)

NORTHUMBERLAND, an extensive county in England, situated on its northern extremity, on the borders of Scotland, from which it is separated partly by the river Tweed, which, during the latter part of its course, flows between this county and Berwickshire, and partly by a line supposed to be drawn over the mountainous region on the west and north-west, where it meets with Roxburghshire. The other boundaries are the German Ocean on the east, Durham on the south, Cumberland on the west, and on the north two small districts called Northamptonshire and Islandshire, which, though belonging by their situation to Northumberland, form a part of the county of Durham, along with another tract, called Bedlingtonshire, on the south-east. But in a general description, it is unnecessary to attend to these

Boundaries,  
Situation,  
and Extent.

**Northumberland.** distinctions. The Tweed may, therefore, be considered as the northern boundary of the county, and, in this case, it will include the towns of Berwick and Norham. Lindisfarne, or Holy Island, on the north-east coast, which, in like manner, belongs to Durham, is situated about two miles from the mainland, opposite the mouth of the brook Lindis, and accessible to all kinds of conveyance at low water. Though about nine miles in circuit, it contains little more than 1000 acres, half of which is sandbanks. These several portions may extend to something more than 100 square miles, or about one-twentieth part of the whole. In this view, Northumberland is situated between  $54^{\circ} 51'$  and  $55^{\circ} 48'$  north latitude, and between  $1^{\circ}$  and  $2^{\circ} 27'$  west longitude from London. Its greatest extent from north to south is 64 miles, and from east to west, it varies from about 46 miles, which is its usual breadth between the river Tyne on the south and the Coquet on the north, till it terminates at Berwick, on the north, in a breadth of only five or six miles. According to the authors of the *Agricultural Report*, the extent of the whole is 1980 square miles, or 1,267,200 acres, of which nearly two-thirds may be fit for cultivation.

**Divisions.**

It is divided into six wards, namely, Tindale, Coquetdale, Glendale, Bamborough, Morpeth, and Castle, the first three comprising the western and mountainous district, and the latter three the coast lands on the east. These last, though extending over only one-fourth of the county, are by far the most wealthy and populous, owing chiefly to the great coal-works in Castle ward, near the town of Newcastle, and along the banks of the Tyne. It contains five deaneries and seventy-three parishes, all of which are in the archdeaconry of Northumberland and diocese of Durham.

**Surface.**

All the western side of this county is mountainous, from the boundary with Durham on the south, almost to the valley of the Tweed on the north; but this extensive tract, comprising more than a third of the whole area, is not all of the same character; the northern, or Cheviot hills, extending to about 90,000 acres, being mostly all green nearly to their summits, enclosing many narrow but fertile glens, and affording excellent pastures for the breed of sheep, to which they have given their name; while those to the west and south are, in general, open, solitary wastes, covered with heath, and of very little value. On the coast, from the mouth of the Tyne to that of the Tweed, and also on the north, for its whole breadth from Belford to Mindrum, the country is, with few exceptions, level and rich, with a soil, in some places, a strong clay, and in others a dry loam; but almost every where very productive, under the enlightened system of cultivation which prevails so generally throughout Northumberland.

**Rivers.**

The principal rivers are the Tyne, Blyth, Wansbeck, Coquet, Aln, and Tweed, all of which fall into the sea, carrying with them the tribute of many smaller streams. The Till, which empties itself into the Tweed, is also a considerable rivulet. The Tyne and Tweed are by far the most important, the tide flowing up the former sixteen miles, and up the latter eight or ten miles, while the navigation of the

other rivers is confined to a small distance from their mouths. Both of these have been long celebrated for their salmon-fisheries, which yield great rents, and afford a valuable article of trade with London, to which the fish are sent packed in pounded ice, by which means they are presented in the market in nearly as fresh a state as if they had been newly taken from the water.

**Northumberland.**

Northumberland has been long distinguished for its subterraneous treasures, the main source of its wealth and population. Of these, coal, which abounds in most parts of it, is by far the most important. It is of the best quality in the south-east quarter, on the banks of the Tyne, from whence those vast quantities are exported which supply the great consumption of the metropolis, as well as the coasting and foreign trade. In some years, the export from the port of Newcastle has amounted to upwards of 600,000 chaldrons of 53 cwt. each; and probably as much more has been sent from Sunderland and consumed in Northumberland and Durham,—the same coal field extending across the Tyne to the latter county. This coal is all of the kind called "caking coal," which melts and runs together in the fire, and, when of the best quality, leaves very few ashes. Calculations have been made as to the extent of this tract, the quantity which it may contain, and the period when it must be exhausted; but on this last point there is a great difference of opinion, some estimating that the supplies must cease in 300 years, some not in less than 800, while by others it is held to be almost inexhaustible. Of the coal found in Bamborough, Islandshire, and Glendale ward, the seams are, in general, thin, and the quality inferior, not caking or burning to a cinder, but yielding a great quantity of ashes. This is used only for home consumption and for burning limestone; for the latter purpose it is well adapted; and through all this district, coal and lime are generally found together. The south-east quarter, which is so rich in coal, is destitute of limestone. Lead-ore abounds in the mountains on the south-west, particularly towards the head of that branch of South Tyne called Allendale, where it has long been wrought to a considerable extent. Iron-ore is found in many parts; stone marl near Tweedside, shell marl in Glendale ward, and various sorts of sandstone, or freestone, are got in almost every quarter, some of it affording tolerable slates for roofing, and flags for floors. Excellent grindstones are raised in those sandstone quarries, of which a great many are exported from Camus and Warkworth.

**Agriculture.**

The agriculture of Northumberland is an object only second in interest and importance to its coal-works. Almost all those branches of rural economy, for one or more of which other districts are celebrated, may here be found combined into one system, and conducted upon the same farms. One finds here the Leicester sheep and the short-horned cattle of Durham and Yorkshire, both in great perfection; the turnips of Norfolk cultivated upon the drill system of Scotland; the well dressed fallows of East Lothian and Berwickshire; and that regular alternation of tillage and grazing which is, of all other courses of cropping, the one best adapted to sustain

Northumberland  
||  
Nottinghamshire.

and improve the productiveness of the soil. These remarks apply in an especial manner to the northern part of the county, where the farms are in general large, and the occupiers men of education and liberal acquirements. This quarter has been long distinguished as a school of agriculture to which pupils are sent, some of them gentlemen of fortune, from various parts;—a character for which it is eminently indebted, as well as for other distinctions, to the late Messrs Culley, who were among the most extensive and successful farmers in the kingdom. The common period of leases, at least in the northern district, is 21 years, though many are shorter, and on a few estates no leases are granted. In 1795 the rental was stated, conjecturally, at L. 605,000, in 1809 it was L. 916,857, 18s. 11½d. It is worthy of remark, that at Chillingham near Belford, the seat of the Earl of Tankerville, there is a herd of wild cattle, perhaps the only remains of the ancient race to be now found in a pure state. An accurate description of them has been given in the *Agricultural Report* of Messrs Bailey and Culley.

Wild Cattle.

Manufactures.

Northumberland is not the seat of extensive manufactures; its principal establishments of this kind are derived from the coal trade, or connected with it, such as ship-building, roperies, forges, &c. On the Tyne there are a great many glass-houses, which a few years ago paid a duty of L. 180,000 yearly; and Hexham has been long noted for its manufacture of gloves.

Principal Towns, Population, &c.

The principal towns are Newcastle, North Shields, Morpeth, Alnwick, Berwick, Norham, and Wooler. The county sends two members to Parliament, and Newcastle, Morpeth, and Berwick, two each,—eight in all. Northumberland contains a great many elegant seats; but for these, and for its history and antiquities, we must refer to the *Beauties of England*, Vol. XII., and the works there enumerated.

The census of 1811 gives the following returns for this county:

Houses inhabited,	-	-	-	28,258
uninhabited,	-	-	-	1,126
Families employed in agriculture,	-	-	-	10,945
trade and manufactures,	-	-	-	16,547
All other families,	-	-	-	10,251

Total inhabitants, - - - 172,161

See Bailey and Culley's *General View of the Agriculture of Northumberland.* (A.)

NORWAY, see SWEDEN.

Boundaries and Extent.

NOTTINGHAMSHIRE, an inland county of England; bounded on the north by Yorkshire and a part of Lincolnshire; on the east by Lincolnshire; on the south by Leicestershire; and on the west by Derbyshire. It is of an oval figure, with its narrowest end towards the north. Its greatest length is about 50 miles, and its greatest breadth 27. Its circumference is estimated to be 140 miles, and its contents 776 square miles, or 496,640 acres.

Divisions and Population.

The county is divided into six hundreds, or, as they are usually denominated, wapentakes; three of which are to the north, and three to the south of the Trent. It contains 9 market towns, and 207 parishes. In the year 1811 the number of inhabitants

was 162,900, in 32,298 houses. The males were 79,057, the females 83,843. The families were 33,514, of whom 12,293 were employed in agriculture, 18,928 in trade and manufactures, and 2293 followed neither of those pursuits. In the year preceding the census the baptisms of males were 2407, of females 2386; the burials of males were 1791, of females 1787; and the marriages were 1372. The towns, whose population exceeds 1500 inhabitants, are the following:

	Houses.	Inhabitants.
Nottingham,	- 6801	34,253
Newark,	- 1492	7,236
Mansfield,	- 1453	6,816
Worksop,	- 756	3,702
Greysley,	- 597	3,673
Radford,	- 725	3,447
Sutton in Ashfield,	- 679	3,386
Arnold,	- 710	3,042
Basford,	- 573	2,940
Southwell,	- 557	2,674
East Retford,	- 469	2,030
Bulwell,	- 560	1,944
Hucknall-Torkard,	- 317	1,793
Clareborough,	- 356	1,531

The face of the county is generally level, with moderate undulations; and its beauties are of a mild description, somewhat picturesque in the vicinity of Sherwood Forest, but displaying neither the striking features of the adjoining county of Derby on its western side, nor the flat insipidity of the plains of Lincolnshire on its eastern side. From its position between these two descriptions of country, and from its moderate elevation, it enjoys a milder climate than either; partaking neither of the raw air of the one, nor the moist atmosphere of the other. The dryness of the climate is favourable to early vegetation, and is supposed to be the cause of the seed-time and harvest in Nottinghamshire commencing at the same period as in the more southern counties.

The soil of this county is very various. On the borders of Derbyshire is a stripe of land with coal and limestone, partly in wood, but mostly under arable culture. Parallel to it is a broader track including Sherwood Forest, whose soil is chiefly sandy and gravelly, which, though naturally sterile, has in some degree been brought into a productive state by the extensive cultivation of turnips, and the maintenance of considerable flocks of sheep. The track which adjoins is a clayey soil, extending to the banks of the river Trent. It is chiefly arable land, but varied with woods and meadows, and highly productive of wheat, oats, beans, and, in some parts, of hops. The lands on the banks of the Trent are very fertile, mostly devoted to pasture, on which many oxen are fattened, and some of the dairies are extensive. The arable land of this district is celebrated for both the quantity and the quality of the oats that it produces. The beautiful Vale of Belvoir in the south-easternmost part of the county enjoys some of the best soils both for pasture and arable husbandry of any part of this island. The farms are in general small, and commonly held by tenants at will; the rents from whom were generally moderate, and a

Nottinghamshire.

Face of the Country and Climate.

Soil and Rural Economy.

Nottingham-shire. very great proportion of the land is free from the burden of tithes. The spirit of agricultural improvement has not proceeded so far as in many other counties, though it has made considerable progress of late years. Neither the breeds of cows and sheep, nor the modes of cultivation, differ so much from those of the adjoining counties as to deserve any especial notice.

Mines. There are no mines except those of coal, which are exclusively confined to a narrow district bordering on Derbyshire; these are of good quality, very abundant, and, by means of internal navigation, diffused through the whole county. Excellent stone for building is raised in many parts, some of which has the peculiarly valuable quality of improving by exposure to the weather. Many parts of the county abound in veins of gypsum. In the parish of Gotham, it is found in strata of the thickness of three feet. At Beaconhill, near Newark, are large quarries of this substance. Although it has been much praised as a manure, the trials of it that have been made in its vicinity have not been attended with such beneficial results as to induce the continued use of it for that purpose.

Sherwood Forest. The Forest of Sherwood, formerly celebrated as the scene of the exploits of Robin Hood, whose deeds amused our nursery days, is mostly an open heathy plain, bordered with recent plantations, and upon which the plough has made very extensive encroachments. The boundaries of the forest are extensive, it being twenty-five miles in length, and from seven to nine in breadth; but a great portion of it is become the property of private individuals, and is enclosed in farms and parks; in the latter of which alone are to be found the deer with which this forest was once most abundantly stocked. The trees of most ancient date are those now remaining on the estates of the Duke of Newcastle and Lord Manvers.

Manufactures. Nottinghamshire is, for its population, one of the greatest manufacturing countries. The frames for making hosiery were the discovery of a clergyman of this county named Lee, in the reign of Queen Elizabeth, who, finding but little encouragement in England, repaired to Paris, and commenced his work under the auspices of Henry the Fourth. The murder of that monarch having deprived him of a patron, he died in France of chagrin, and the workmen returned home, when, after many fluctuations, the machinery was introduced in this county. The making stockings, caps, pantaloons, and other similar articles, has long given employment to the great mass of the labouring population; and of late years, the making of lace, upon a similar principle, has been introduced, and created additional employment. Although the riotous conduct of the workmen, under the denomination of *Luddites*, has driven some of the large capitalists to other parts of the kingdom, yet the hosiery business is by far the most important means of employment throughout the whole county. The spinning of cotton-yarn, from its natural connection with hosiery, has been introduced, and very widely extended; and the establishments at Nottingham, at Mansfield, at Newark, at Southwell, and several other places, are upon an extensive scale. There are also several large manufactories for spinning worsted yarn. Malting and brewing are carried

on to a considerable extent; and the beer of Nottingham and of Newark rivals that of Burton upon Trent. There are potteries at Sutton Ashfield; starch is made near Southwell; and sailcloth and candlewick at Retford.

The foreign trade of this county is mostly conducted by the mercantile houses of London and Liverpool; but some of the larger manufacturers export their own goods, both to the Continent of Europe, and the more distant parts of the world.

Rivers and Canals. The river Trent, the fourth in magnitude of the English streams, passes across the county, and is navigable for barges through the whole of it; but its deficiencies of water and its shoals are such great impediments, that a canal by the side of it, ten miles in length, is found of great use to the intercourse. The other rivers are not navigable, but are beneficial for the purposes of irrigation. They are the Erwash, the Soar, the Maun, the Meden, the Wollen, the Worksop, the Idle, the Lene, and the Dover or Dare. These all discharge their waters into the Trent. The canals are the Nottingham, the Grantham, the Idle, and the Chesterfield. The last of these is about forty miles in length; the others about ten. By means of these and the Trent, the intercourse by internal navigation is extended to almost every district of the county.

The titles derived from this county are, Marquis of Granby; Earl of Mansfield; Viscount Newark; and Barons Pierrepont and Carrington. Eight members are returned from it to the House of Commons, viz. two for the county, and two each for the boroughs of Nottingham, Newark, and East Retford. The whole county is in the diocese of York.

The remains of Roman and Saxon antiquities are numerous. Amongst the former are the camps at Barton hill, at Combes farm, at Gringley, at Hexgrave, and Wenny hill, and a Roman villa near Mansfield: among the latter are the Castle of Newark; the Abbeys of Newstead, Rufford, and Welbeck; the Priors of Mattersey and Worksop; and the Churches of Bingham, Blythe, Southwell, and Balderton.

The most distinguished natives of this county have been, Archbishop Cranmer, Dr Erasmus Darwin, Sir Martin Forbisher, Denzil Lord Holles, Ireton, the son-in-law of Cromwell, Lady Mary Wortley Montague, Paul Sandby, Archbishop Secker, Gilbert Wakefield, and Bishop Warburton.

The seats of noblemen and gentlemen of the first class are as numerous as in any county of England; of which the most remarkable are the following, viz. Annesley Hall, J. W. Chaworth, Esq.; Babworth Hall, Honourable J. B. Simpson; Bunney Park, Lord Raneliffe; Clifton Grove, Sir Gervas Clifton; Clipstone Park, Duke of Portland; Clumber Park, Duke of Newcastle; Colwich Hall, John Musters, Esq.; Grave, A. H. Eyre, Esq.; Holme Pierrepont, Earl Manvers; Hurgarton Hall, G. D. L. Gregory, Esq.; Kelham House, J. M. Sutton, Esq.; Langold, H. Gally Knight, Esq.; Lenton Priory, William Stretton, Esq.; Muskham, J. Pocklington, Esq.; Newstead Abbey, late Lord Byron (lately sold to Major Wildman); Norwood Park, Sir Richard Sutton, Bart.; Osberton, F. F. Foljambe, Esq.; Ossington Hall, J. Denison, Esq.; Rufford Abbey, Honourable J. L.

## ORGANIC REMAINS, FOSSIL.

THE occurrence, in rocks of various kinds, of remains of animals and vegetables, more or less altered, is so remarkable and striking a fact, that it could not fail to attract the notice of mankind, even at an early period. Xenophanes of Colophon is said to have described the remains of fossil fishes found in the stone quarries of Syracuse, and in the deep marble rocks of Paros. Not long after, in the fifth century before Christ, Herodotus mentions fossil shells as occurring in the rocks of Egypt, and states this as a proof of that country's having been formerly an arm of the sea, like the Red Sea. We find some allusions to fossil organic remains even in the poets of antiquity. The following passage from Ovid is an example of this kind:

Vide ego, quod fuerat quondam solidissima tellus  
Esse fretum, vidi factas ex aequore terras,  
Et procul a pelago conchæ jacuere marinæ.  
Et vetus inventa est in montibus anchora summis.  
*Metamorph. Lib. XV. v. 62.*

But our author confounds true organic remains with the accidental occurrence of an anchor in soil. Not long after the commencement of the Christian era, attempts were made to connect these phenomena with the Deluge of Noah; and in the writings of Tertullian, there are passages that refer to this supposed connection. This opinion afterwards became general, particularly towards the beginning of the eighteenth century, when it was attempted to prove, or at least to illustrate, the truths of revelation by appeals to natural history. Thus Büttner, in his *Zeichen und Zeugen der Sundflut*, published at Ulm, in 1710, and Scheuchzer, in several of his works, as in his *Homo Diluvii Testis, Piscium Querelæ et Vindicta, Herbarium Diluvianum*, &c. enumerate many facts, and state numerous reasons in illustration of the accumulation and deposition of fossil shells, plants, and animals, during a great flood, which they maintain to have been that described in the *Old Testament*. But the non-occurrence of the remains of man along with those of other animals came to be considered as inimical to this opinion, and by the time of Knorr it was nearly abandoned. Another speculation was soon started in its place, by which it was attempted to show that these remains were not truly organic, but merely efforts of nature to produce organic beings; and, therefore, that these bodies, although exhibiting the organic form, had never been animated. This fancy was

combated by the supporters of the diluvian hypothesis, and the result was, the addition of many new facts, and the total abandonment of both hypotheses. The discovery of remains of elephants, rhinoceroses, &c. in Europe and Northern Asia in a fossil state, gave rise to a new opinion, that these, and many other fossil animals found along with them, had been floated hither from the tropical regions. Forster, Pallas, and others, who advocated this opinion, brought together a host of facts in support of it; and, in this way, contributed, in an eminent degree, to our knowledge of fossil organic remains, and to a more accurate investigation of their various characters and relations. But their speculation, with all its plausibilities, was soon supplanted by that which is at present considered as the most consistent with facts—namely, that the various fossil organic remains, contained in rocks of different kinds, belong to animals and vegetables that formerly lived in the countries where these remains are at present met with. The facts which have been brought to light by the collision of opposite opinions, and by the careful and successful investigations of many naturalists who were contented to view these fossil remains, not as connected with any general geological hypothesis, but as interesting additions to zoology and botany, and important contributions to our knowledge of the physical and geographical distributions of animals and vegetables, are so interesting, even to the general reader, that we shall attempt to give a short account of them, in the following order:—

1. Different kinds of fossil organic remains.
  1. Animal remains.
  2. Vegetable remains.
2. State or condition of these remains.
3. Geognostical situations.
4. Formation of the strata in which these remains are contained.

### I.—DIFFERENT KINDS OF FOSSIL ORGANIC REMAINS.

#### I.—FOSSIL REMAINS OF ANIMALS.

1. *Fossil Remains of the Human Species*.—When the diluvian controversy was keenly agitated, many descriptions were published of fossil remains of man, said to have been found in secondary rocks of different kinds; but all these, without exception, proved to be remains of the lower animals. Thus the famous

Organic Remains. — "homo diluvii testis" of Scheuchzer was found to be a gigantic fossil salamander. The fossil bones of Cerigo, so confidently described by Spallanzani as human, were determined to belong to quadrupeds. The remains of the human species, therefore, do not occur in the secondary strata; but the following facts prove their occurrence in fissures of rocks and in post-diluvial strata. Human bones, and even whole skeletons, have been found in clay in fissures of rocks, being the remains of bodies that had fallen into them; in other cases, human bones and skeletons have been met with, and occasionally more or less mineralized, in old deserted galleries in mines. Some years ago, human skeletons were discovered in a compact calcareous rock in the Island of Guadaloupe. A mass of this rock, inclosing a pretty well preserved human skeleton, but without the head, and wanting the right arm (represented at fig. 1, F, Plate CII.), was sent by Admiral Cochrane to Lord Melville, and afterwards by him deposited in the British Museum. The rock, on examination, proved to be a mere alluvial mass, formed of pieces of coral, that appear to have been thrown up on the shore by the sea, and afterwards united together by water impregnated with calcareous matter. M. Moreau de Jornes thinks these skeletons are remains of persons who had perished by shipwreck. Human bones have lately been found in alluvial soil at Köestritz in Germany, and in such a situation as to render it probable that they are of great antiquity. The absence of human fossil remains from diluvial formations has excited surprise; but this will cease when it is recollected that, probably, at the period of the deluge, the human race had not extended into the countries where fossil organic remains have been examined, and, therefore, are only to be looked for in those regions where man is known to have lived when that event took place.

## CLASS I.—MAMMALIA.

Order I.—*Quadrumana*.

Hitherto no fossil remains of apes, baboons, monkeys, or other tribes of the order *Quadrumana*, have been met with; although it is probable that they will be found among the alluvial strata of those regions where these animals now live.

Order II.—*Chiroptera*.—*Bat*.

It is probable that fossil species of the larger bats will be found in the alluvial strata of the warmer regions of the earth, and that remains of the smaller European species will be discovered in some of the European formations. The only fossil remains of the animals of this order with which we are acquainted are those represented, fig. 5, Plate CII. These are contained in a slab of limestone from Eichstädt, and belong to a species which must have measured six or seven feet from the tip of one wing to the tip of the other. The remarkable fossil tribe named *Ornithocephalus*, to be described after-

wards, in general aspect bears a striking resemblance to bats. Organic Remains.

Order III.—*Marsupialia*.

Two species of this order, both belonging to the genus *Didelphis*, or *Opossum*, have been met with in a fossil state; the one was found in the gypsum of Paris, the other in the calcareous oolite slate of Stonesfield in England.

Order IV.—*Glires*, or *Gnawers*.

Fossil remains of an animal resembling the *Cavia porcellus*, or Guinea-pig, have been detected in the limestone of Oningen; remains of an animal resembling the *Lagomys alpinus*, a species at present confined to the higher parts of Siberia, were found in the fissures of the rock of Gibraltar; two species of *Lepus*, one nearly resembling the *common rabbit*, and the other one-third less, were found in the limestone rocks of Cette; three species of *Mus* have been met with in a fossil state, one nearly resembling the *Mus terrestris*, occurs in limestone in Bohemia, and also in the limestone-conglomerate of Corsica, and two others, one referred to the *Mus arvalis*, and the other to the *common water-rat*, in the rock of Gibraltar: fossil remains of the *common beaver* have been met with in alluvial strata in Perthshire and Berwickshire in Scotland, and in similar situations on the Continent; and another species, named *Castor trogontherium*, was found on the shores of the sea of Azof.

Order V.—*Bradypoda*.—*Sloth*.

The fossil species of this order, although not numerous, are remarkable for their magnitude and singular organization. Hitherto only two species have been discovered, and apparently both belong to the same genus: the one is the *Megatherium*, and the other the *Megalonyx*, of authors. We might assume *Megatherium* as the generic denomination, and name the South American species *Megatherium Australe*, and the *Megalonyx*, or North American species, *Megatherium Boreale*; but our present view will be answered by describing them under their common names.

*Megatherium*.—A complete skeleton of this colossal species was found in diluvial soil near Buenos Ayres, and sent to Madrid; afterwards another was discovered near Lima, and a third in Paraguay.\* The splendid specimen in Madrid is fourteen feet long, and seven Spanish feet in height. The skeleton of this *Megatherium* is so rude and unshapely, that the clumsy skeleton of the elephant and rhinoceros, and even the massive and rugged bones of the hippopotamus, appear, when placed beside it, slender and light. It is one of the largest and most massive of all the fossil quadrupeds hitherto discovered. Judging from its structure, its motions seem to have been slow and dragging, and, with exception of its long claws, appears to have been more defenceless than any of the other large quadrupeds. The form of the

\* Remains of the *Megatherium* have been lately found in limestone caves in Brazil.

teeth shows that it lived on vegetables, and its long claws are supposed to have been used for digging up the roots on which it is conjectured to have fed. Plate CIII. exhibits a correct representation of this animal from the specimen in the museum at Madrid.

*Megalonyx*.—This species is smaller than the megatherium, being only the size of the ox. The general form and arrangements of the skeleton are the same as in the megatherium, and the agreement is so considerable, that some naturalists conjecture, although without sufficient ground, that it is a young variety of the megatherium. It appears also to have been herbivorous, and hitherto its remains have been met with only in limestone caves in Virginia.

#### Order VI.—FERÆ.—RAPACIOUS ANIMALS.

##### *Ursus*.

Several fossil species of this tribe have been met with in different parts of Europe. The following are enumerated by naturalists:

1. *Ursus Spelæus*.—It is the largest species, and is distinguished from the Polar bear, to which it bears a close resemblance, by its more inclined brow, and the want of the anterior small grinding tooth.
2. *U. Arctoides*.—The skull smaller than the preceding, and the small anterior grinding tooth also wanting.
3. *U. priscus*.—Not larger than the brown bear; the cranium the same shape, and provided with the same teeth.

These fossil species occur in limestone caves in Germany and Hungary.

##### *Canis*.

Fossil remains of a species of *canis* resembling the dog, and of another nearly allied to the common fox, and bones of the common wolf, have been found in post-diluvial and diluvial soils, and in caves in England, Germany, and France.

##### *Hyæna*.

Fossil remains of a species nearly allied to the common hyæna have been found in caves in limestone in Yorkshire. In these also dung was found, proving that these caverns had been the residence of the hyæna. Remains of the same species occur in caves in Germany. Another species, resembling the *H. crocuta*, was found in Hanover, in marl, along with bones of the lion and elephant.

##### *Felis*.

One species of this tribe, and nearly resembling the jaguar of South America, has been found in a fossil state in limestone caves in Germany; another species, nearly allied to the tiger, is found in diluvial soil, along with fossil remains of the elephant, rhinoceros, hyæna, and mastodon.

##### *Mustella*.—Weasel.

Two species of this genus occur in the German limestone caves. The one is allied to the common pole-cat (*Mustella putorius*), and the other to the zorille, a pole-cat, native of the Cape of Good Hope. Another species, allied to the *ichneumon* of Egypt, but nearly double its size, occurs in the gypsum quarries around Paris.

#### Order VII.—*Solidungula*.

*Equus Adamiticus*—*Equus Caballus*.—Fossil teeth of a species of horse are found in diluvial soil, associated with those of the elephant, rhinoceros, hyæna, mastodon, and tiger. These teeth are larger than those of the present horse, and, to all appearance, belong to a different species, which inhabited the countries where they are now found, as Great Britain, along with elephants, rhinoceroses, hyænas, bears, wolves, &c.

#### Order VIII.—*Bisulca*.

Many fossil animals of this order occur in a fossil state. We shall enumerate the principal of these.

##### *Bos*.—Ox.

Four species of this genus occur in a fossil state. 1. *Bos aurochs* or *urus*.—This species is considered as distinct from the common ox, being much larger. Horns and bones are found in this country, and also on the Continent of Europe. It occurs likewise in alluvial soil in the district of Ohio in North America. 2. *Common Ox*.—The fossil skulls of this species differ from those of the present existing races in being larger, and the horns having a different direction. They are considered as belonging to the original race of the present domestic ox. The remains are of frequent occurrence in our peat-bogs, also in a similar situation in Ireland. 3. *Large Buffalo of Siberia*.—Skulls and bones of a large species of ox are found in Siberia, which Cuvier maintains to be distinct from any of the present species; and as it occurs in the same situation as the elephant and rhinoceros of Siberia, he considers it to have lived at the same early period. 4. *Fossil Ox, resembling the Musk Ox of North America*.—The bones of this species resemble in many points those of the musk ox, but the marks of difference are so considerable as to show that it is a distinct species. This species has hitherto been found only in Siberia.

##### *Cervus*.—Deer.

The following are the fossil species. 1. *C. elephas*, or *Red-Deer*.—Horns and skulls of a deer, agreeing in almost every particular with the common red deer, are occasionally met with in strata of different descriptions. Some of these have been found in the newer secondary formations, in supposed ancient volcanic tufas, and in diluvial strata, with remains of the elephant, rhinoceros, &c. and lastly in our common peat-mosses. The horns and crania found in our peat-bogs are of the same species with our present red deer, but it is not equally certain that those found in the older formations are of the same description. 2. *Roe-Deer*.—Bones of this species are met with in our peat-mosses, and in beds of shell marl, but never in any of the diluvial strata. 3. *Fossil Roe of Orleans*.—This species, nearly allied to the roe, but different as a species, is remarkable on account of its geognostical position, its remains occurring in a new secondary limestone, along with bones of the palæotherium. It occurs near Orleans in France. 4. *Fossil Fallow-Deer*.—This species is found in peat-bogs and in marl pits in Scotland, England,

and in different parts on the Continent of Europe. The antlers are in general larger than those of the present varieties. 5. *Fossil Deer of Etampes*.—This species appears nearly allied to the rein deer, but much smaller, not exceeding the roe in size. The bones were found near Etampes in France, in a sand, the geognostical relations of which have not been determined. 6. *Cervus giganteus, Irish Elk, or Elk of the Island of Man*.—This gigantic and magnificent species, now apparently extinct, occurs in a fossil state in Ireland, Isle of Man, England, Germany, and France. The most perfect specimen of the skeleton of this species hitherto met with is that which was found in the Isle of Man, and now preserved in the Museum of the University of Edinburgh. In Plate CIV. we have given an accurate representation of this remarkable specimen. It is six feet high, nine feet long, and in height to the tip of the right horn, nine feet seven and a half inches. It was dug up in the parish of Kirk Balaff, and fortunately secured for the Museum by his Grace the Duke of Atholl. It was imbedded in a loose shell marl, in which were numerous imbedded branches and roots. Over the marl was a bed of sand, above the sand a bed of peat, principally composed of small branches and rotten leaves, and over the peat the common soil of the country.

#### Order IX.—*Multungula*.

Several of the largest and most remarkable of the fossil species of quadrupeds belong to this order, and of those the following are the most interesting :

##### *Rhinoceros*.

Of this genus four fossil species have been determined. 1. *Rh. tichorinus*.—In this species the nostrils are separated by a thick osseous plate. It is the largest of the fossil rhinoceri, and is that which is found in England, France, Italy, Germany, Siberia, &c. One specimen was found in the year 1770 with its skin on, imbedded in ice, on the banks of the Wilhoui. It appeared to have had very long hair on its feet, an arrangement, according to Cuvier, probably connected with the climate which it inhabited. 2. *Rh. ptorhinus* (from  $\lambda\epsilon\pi\tau\omicron\varsigma$ , *thin*).—In this species the nostrils are not provided with an osseous septum, the bones of the nose are thinner, and the skeleton less massive than in the preceding species. It is found in Italy. 3. *Rh. minutus*, of a diminutive size.—Found in diluvium in the village of St Laurent, near to the town of Moissac, in the department of the Tarn, and the Garrone. 4. *Rh. incisorus*, provided with incisor teeth. It is the size of the common rhinoceros, and is found in Germany.

##### *Hippopotamus*.

Only one living species of this tribe is known to naturalists, but four fossil species have been de-

termined by Cuvier. 1. *H. magnus*. It is very nearly allied to the present living species, and is of the same size. It is found in England, France, Germany, &c. 2. *Middle-sized Hippopotamus*, is smaller than the former, being the size of a hog, and is found in France. 3. *Small Hippopotamus*.—Found in France; is less than the second species. 4. *Least Hippopotamus*.—Found in France, and appears to have been the size of the hog of Siam.

##### *Elephant*.

Of this interesting tribe of animals two living species, the Asiatic and African, and one fossil species, named *Mammoth* by the Russians, are known to naturalists. The fossil elephant or mammoth differs from the living species in the following particulars: The alveoli of the tusks are much larger, and the zygomatic arch of a different form. The vacuity between the branches of the jaws at the fore part is wider than in the Asiatic and African species; and the lower jaw, in place of terminating in a kind of pointed apophysis, as in the living species, is rounded off. The grinders of the fossil species differ from those of the living, and the tusks, although of the same magnitude, appear to be more curved than in either the Asiatic or African species. Single bones and teeth, or even perfect skeletons, are found, and one instance is on record of the whole animal being found preserved in ice. This specimen was discovered in the year 1799 in Asiatic Russia. The flesh, skin, and hair, were completely preserved,—even the eyes were entire. It was provided with a long mane, and the body was covered with hair. This hair was of different qualities. There were stiff black bristles, from twelve to fifteen inches long, and these belonged to the mane, tail, and ears. Other bristles were from nine to ten inches long, and of a brown colour; and, besides these, there was a coarse wool, from four to five inches long, of a pale yellow colour. This latter is the wool which lies next the skin in all the inhabitants of cold countries; and hence, Cuvier thinks it probable that the northern fossil elephants, or those of Siberia, Russia, &c. were inhabitants of cold countries.\* Its remains have been found in Iceland, Norway, Scotland (in Ayrshire and West Lothian), England, and in many places throughout the Continent onwards to the Arctic Ocean. But they are more abundant in Siberia than in other countries; for Pallas informs us, that there is scarcely a spot from the Don to Kamtschatka where they have not been met with. They also occur in North America, even as far north as Churchill, Hudson's Bay; this latter being the locality of a specimen sent to us from that country; and teeth and bones of a fossil elephant have been found in South America.†

##### *Mastodon*.

This remarkable genus of fossil multungular ani-

\* The wide distribution of this fossil species, and its occurring amongst with remains of numerous large feline animals, &c. would seem to show, in opposition to the above inference, that the climate of the countries it inhabited had a tropical character.

† There are in the Ashmolean Museum at Oxford, some vertebræ and leg bones of an elephant of vast size, probably sixteen feet high, found in gravel near Abingdon. Mixed with these were bones of the rhinoceros, hippopotamus, horse, dog, ox, and a species of deer.

Organic Re-  
mains.

mals, first systematically arranged by Cuvier, was named by him Mastodon (from *Μαστος*, *mamilla*, and *ὀδός*, *dens*), in reference to the mamillary or tubercular processes on the grinding teeth. The following are the species at present known to naturalists: 1. *Great or Gigantic Mastodon of the Ohio*.—This species appears to have been as tall as the elephant, but with longer and thicker limbs; probably provided with a proboscis or trunk, and had tusks like those of the elephant. It appears to have lived on roots and fleshy parts of plants, and hence this kind of food attracted it to soft and marshy places, where its fossil remains are principally found. It is more common in North America than in any other part of the world, although its remains have also been found in Siberia. 2. *Mastodon with Narrow Grinders*.—It is smaller than the great mastodon, and the grinders are narrower in proportion to their length than in the great mastodon. It is found in Europe, and also in North America. The teeth and bones of this species when of blue colour, from mineral impregnation, are named Animal Turquois. Besides the great mastodon and the species with narrow grinders, remains of four others have been met with, but their characters are not well known. Two of them are from America; the one is named *Mastodon of the Cordilleras*, and the other *Mastodon of Humboldt*; the other two are European, and of these one is named *Small Mastodon*, the other the *Tapir-like Mastodon*.

#### Tapir.

The tapir was long held as peculiar to America, but the late discovery of a species in Malacca shows that it also extends to the Old World. The living species are different from those in a fossil state. These latter are found in the same diluvial strata as afford the fossil elephant and mastodon. Two species have been determined. The one, named *Gigantic Tapir*, about eighteen feet long and twelve feet high, thus equalling in magnitude the great mastodon of America and the great elephant, has been found in France, Italy, and Germany: The other is smaller, but still a formidable animal, and occurs in the same countries.

#### Lophiodon.

This is a newly discovered fossil genus, nearly allied to the tapir, and named from the eminences on its teeth. Twelve species have been ascertained by Cuvier, and one of them, the largest, is of gigantic dimensions. All of them are found in what is called a fresh water formation, of the same nature with that which contains the remains of the palæotherium and anoplotherium, and hitherto they have been met with only in France and Germany.

#### Elasmotherium.

Of this newly discovered fossil genus but one species has been found, and that in Siberia. It appears from the few fragments in the Museum at Moscow, and described by Fisher, to be nearly allied to the rhinoceros and horse, and that probably it forms an intermediate tribe between these two. It is the size of the rhinoceros.

#### Palæotherium.

This genus, like the two preceding, is entirely fossil.

Its generic character, as given by Cuvier, is as follows: *Organic Re- mains.* Dentes quadraginta quatuor; scilicet, Primores utrinque sex; laniarii quatuor, acuminati paulo longiores, tecti; molares viginti octo; utrinque septem; quorum superiores quadrati, inferiores bilunati. Nasus productior flexilis. Palmæ et plantæ tridactylæ. In general osteological arrangement it resembles the tapir. Like that tribe, it appears to have had a lengthened snout, or short proboscis, and there can be little doubt that the form of the body was nearly the same as that of the tapir. Ten species are described by Cuvier, and these vary in magnitude from that of the rhinoceros to the hog and sheep, and all of them appear to have been herbivorous. None of the species have been hitherto found in this country, and those described by Cuvier occur in new secondary and diluvial strata in different parts of France, particularly in the vicinity of Paris.

#### Anoplotherium.

This also is a fossil genus of extinct herbivorous animals. It bears some resemblance to the camel, and the tail is of equal length to the body, if not longer, being at the same time very thick and strong. There are but five species known, and all of these, as far as we know, are found only in the new secondary rocks around Paris. The following is the character of this genus, as given by Cuvier. Dentes quadraginta quatuor, serie continua. Primores utrinque sex; laniarii primoribus similes, cæteris non longiores; molares viginti octo, utrinque septem; anteriores compressi; posteriores superiores quadrate; inferiores bilunati. Palmæ et plantæ tridactylæ, ossibus metacarpi et metatarsi discretis; digitis accessoriis in quibusdam.

#### Sus.—Hog.

Bones and teeth of the common hog occur in peat-mosses, and similar remains of a dubious species of hog in loam, along with remains of the elephant and rhinoceros.

#### Order X.—Palmata, Palmated Quadrupeds.

Under this head we include those tribes provided with four paws somewhat resembling fins, and sometimes provided with clawed toes.

1. *Phoca, or Seal*.—Two fossil species of this genus have been found in France, in the coarse marine limestone of the formation above chalk. One of them appears to have been three times as large as the common seal, and the other of rather smaller dimensions.

2. *Trichecus, or Sea Horse, or Walrus*.—No well marked fossil remains of this genus have hitherto been met with.

#### Order XI.—Sirenia.

*Lamantin, or Manatus*.—Several bones of an unknown species of this genus have been discovered in the coarse marine limestone formation in the department of the Maine and Loire.

#### Order XII.—Cetacea.—Whale.

Mr Parkinson says that two teeth of the narwal, or *Monodon monoceros*, were found on the coast of Es-

Organic Re-  
mains.

sex, in the London clay, and that one specimen was found in the limestone of Bath. Fossil remains of dolphins and whales are mentioned as occurring in the new secondary formations of Italy; and we know that a skeleton of the common whale was found near Airthry in Stirlingshire, imbedded in alluvial soil formed by depositions from a river in a marine estuary.

## CLASS II.—ORNITHOLITES, OR FOSSIL BIRDS.

Fossil remains of birds are of rare occurrence, and the few specimens hitherto found afford results much less satisfactory than those obtained by the study of the fossil bones of quadrupeds. The best information on this subject is furnished by Cuvier, who has also communicated some obvious characters for assisting in the determination of this class of organic remains. Among others, the following are enumerated:—The foot in birds has a single bone in place of the tarsal and metatarsal bones of quadrupeds; birds, too, form the only class in which the toes all differ as to the number of joints, and in which this number, and the order of the toes which have them, is nevertheless fixed. The great toe has two; the first two, reckoning on the outside, three; the middle five, and the outermost five. The crocodile has the same number of phalanges; but, as these have a tarsal and metatarsal bone, they cannot be confounded. By attention to these and other characters, fossil remains of species of the following genera have been determined, viz. *owl*, *buzzard*, *starling*, *ibis*, *quail*, *curlew*, *tern*, and *pelican*. These occur in the limestone and gypsum of the Paris formations, and, it is said, also in an older formation, viz. that into which the Stonesfield slate enters as a member.\*

*Ornithocephalus.*

This genus, which is entirely fossil, is so remarkable in its structure, that naturalists are not agreed as to its place in the system. Some, as Cuvier, refer it to the Amphibia; others, as Blumenbach, to the birds; Collini described it as a fish; while Sömmering arranges it with the Mammalia, and near to the bats. In this state of uncertainty, it is of little consequence where we place it. The skull is very large in proportion to the size of the skeleton, the jaws themselves being longer than the body, and furnished with sharp slightly incurvated teeth. In general form, the head of the *O. longirostris* resembles that of the curlew tribe, while the *brevirostris* more nearly resembles the bat, particularly the *Vespertilio murinus*. The orbits of the eyes are disproportionably large, and hence it is probable that, like the bat, it was a nocturnal animal, while, from the size of its jaws, it is likely that it fed on small flying insects. There are four legs, the hinder ones being of considerable length. There are no tarsal bones, only metatarsal bones and claws. There is a distinct tail. Two species are described by Sömmering, the largest, which is about a foot long, is named *O. longirostris*; while the other, which is less, is named *O. brevisrostris*. They are re-

presented in Plate CII. Both species occur imbedded in the limestone of Eichstädt.

Organic Re-  
mains.

## CLASS III.—AMPHIBIA.

*Testudo.*

Several species of this tribe have been detected in formations of different descriptions. In England they have been met with in the lias limestone near Bristol, in the oolite of Stonesfield, but most perfect in the London clay, as it is termed, in the vale of Sheppey. Cuvier and other naturalists enumerate different species of land, marine, and fresh water fossil testudines found in France, Germany, and Italy, but all of them apparently extinct species.

*Crocodile.*

Two species were found in a blue clay (resembling that below chalk) in the neighbourhood of Honfleur and Havre. They cannot be referred to any of the present species. In England, one specimen was obtained from the Purbeck stone, and another was found in the cornbrash rock at Gibraltar, in Oxfordshire. These are distinct from the first French species, but perhaps may agree with the second. Vertebræ, apparently of that species, are found in clay near Weymouth, and in chalk in Sussex.

*Mosasaurus of Conybeare.—Lacerta Gigantea of Sömmering.*

This tribe contains those fossil amphibia which differ from crocodiles in some important characters, and is considered as an intermediate genus between those animals of the lizard tribe with a short tongue, and whose palate is furnished with teeth, and those where the tongue is long and forked. The gigantic species found in the soft limestone of Maestricht has long excited the attention of naturalists. The length of the skeleton appears to have been nearly 24 feet. The head is a sixth of the whole length of the animal, a proportion approaching very near to that of the crocodile. The tail must have been very strong, and its width at its extremity must have rendered it a most powerful oar, and have enabled the animal to have opposed the most agitated waters.

Fossil remains of an animal of the same kind, found in Bavaria, are described by Sömmering, under the name *Lacerta gigantea*; all the known parts of which are represented in Plate CV. "When it is considered," says he, "that this gigantic lizard was 24 feet long, we are forcibly reminded of the dragons so much spoken of in fable. At least, the fact that, at one period of the world, there existed animals of the lacerta, or dragon tribe, more than 20 feet in length, is more astonishing than all that is recorded in ancient tradition respecting monsters, which even the wildest fancy did not amplify to such enormous dimensions."

*Ichthyosaurus.*

This is a marine oviparous animal, closely agreeing in the whole osteology of the head, and sternum,

\* Cuvier has lately found in Montmartre an ornitholite, in which the head, neck, wings, tail, thighs, and even the trachea arteria, are well preserved.

Organic Remains.

with the saurian tribe, except that the bones are usually, as in fish, united by squamous sutures, and approximating to fish in some parts of the structure of its vertebral column, and, in others, being *sui generis*. From these double analogies the name (fish-like lacerta) is derived. The extremities terminate in four swimming paws, or paddles, composed of a series of flat polygonal bones, greatly exceeding in number, not only the phalanges of quadrupeds, but also the phalangeal cartilages of the fins of fish. Three distinct species, distinguished from each other by their teeth, are found in the lias limestone in England.

*Plesiosaurus.*

From *πλησιος*, approximate to, and *σαυρος*, a lizard.—This newly discovered fossil animal appears to be intermediate between the crocodile and ichthyosaurus, but whilst the ichthyosaurus recedes from the forms of the lizard family, and approaches those of fishes, the new animal approximates, in these respects, more nearly to the crocodile; the plesiosaurus is, therefore, a marine animal, intermediate in structure between the ichthyosaurus and crocodile. It also occurs imbedded in lias limestone in England.

*Megalosaurus.*

From *μεγαλος*, great, and *σαυρος*, a lizard.—This is a species nearly allied to the monitor in the mode of its dentition. It is found in the calcareous slate of Stonesfield, in England. The animal must, in some instances, have attained the length of forty feet, and stood eight feet high. The gigantic lizard of Sömmering appears diminutive when contrasted with this stupendous being.

*Monitor.*

Fossil remains of animals that appear to belong to some of the numerous species comprised by Linnæus under the name *Lacerta monitor*, and of *Tupinambis* by Daudin; animals which frequent marshes and the shallow beds of rivers, occur in bituminous marl slate in Thuringia.

*Salamandra.—Salamander.*

Scheuchzer's famous *Homme fossil*, which is considered to be an extinct species of salamander, was found in the limestone of Cœningen.

*Bufo.—Toad.*

Fossil remains of this animal occur in the slate limestone of Cœningen. It is not the common toad, but one nearly allied to the *Rana calamita*.

*Coluber.*

Several accounts have been published of the occurrence of fossil serpents in rocks of different formation, but all of them, with exception of the notice of Cuvier, are so loose and unsatisfactory, as to be undeserving of notice. In the notice alluded to, we are informed the bones of a snake, resembling the *Coluber natrix*, were found in the calcareous conglomerate of Montpellier.

CLASS IV.—FOSSIL FISHES.

Fossil remains of fishes occur in considerable abundance in formations of particular descriptions, but hi-

Organic Remains.

therto, owing to the difficulties attending the investigation, the determination of the genera and species has been far from satisfactory. Even the attempts that have been made to divide these fossil fishes into fresh and salt water species have generally failed, and the whole geognostical history is in such a state, as to require a complete revisal. The fish, in some specimens, are found nearly entire, with the soft parts, and even the scales, preserved by mineralization. In others, all the parts are removed, except the skeleton, and this is more or less perfect, and frequently only the hardest parts remain, such as the palates and teeth. Fossil fishes are found in a variety of geognostic situations in Great Britain, and the following genera are mentioned by authors as occurring in this island: *Balistes*, *Xiphias*, *Diodon*, *Anarchichas*, *Salmo*, *Esox*, *Zeus*, *Muraena*, *Squalus*, but of this latter only the teeth, and of the *Raia* only the bony tongue and palates.

*Fossil Vertebrae.*—Many figures, and some descriptions, have been published of the fossil vertebrae of fishes. Most of the specimens appear to have belonged to large species of fishes, and some authors have confounded, under this name, the caudal vertebrae of cetacea, which, however, are always easy to determine, as they do not present any traces of the deep and regularly disposed foramina, which present themselves at the surface of the vertebrae of fishes.

*Fossil Teeth, or Ichthyodonta.*—These are the parts of fishes that occur most frequently in the bowels of the earth, on account of their being less subject to decay. They are divided into two groups, the *glossopetra*, or more or less flattened teeth, which have belonged to fishes of the shark tribe, &c. and the *bufonites*, *batrachites*, &c. or more or less rounded teeth, which have been generally considered as belonging to certain species of sparus or of anarchichas. 1. *Glossopetra*, or *Petrified Tongues.*—This denomination has its origin from the idea that was formerly entertained of the form of the tongue of serpents, and especially from the notion that the Apostle Paul, on going to Malta, had destroyed all the serpents of that island, and that the fossil teeth of sharks, which occur in great abundance, originated from them, and were nothing else than their tongues converted into stone. 2. *Bufonites*, or *Batrachites.*—We find figures, or rather descriptions, by authors under this name, derived from *bufo*, because it was imagined, we cannot say how, that there were engendered in the head of toads a great number of fossil bodies, of a more or less rounded shape and shining surface, which are evidently nothing else than portions of the teeth of fishes. Many of them are true teeth implanted in the maxillary bones, while others are maxillary plates.

CLASS V.—CRUSTACEA.

1. *Fossil Crustacea, or Crabs.*

The description of fossil crustacea presents more difficulties than might at first be imagined. The greater number of them are in such a state of mutilation, or so inclosed in the rock, that very often there is nothing to be seen but a part of the upper

Organic Remains. surface of the body, or of the thorax; while the under surface, composed of the numerous pieces of the plastron, or sternum, giving attachment to feet composed of many articulations, and presenting also the external parts of the mouth, is found completely fixed in the substances which inclose it. The antennæ and feet, besides, are most commonly broken and separated from the body; which may be readily conceived, when we recollect with what facility these latter parts are detached from living crustacea, which lose them when fighting with one another, or even when executing some violent motions. The general want of the antennæ and feet in the fossil specimens, induced Desmarest to restrict the distinctions to characters obtained from the shell or the thorax. On examining the thorax, it results that the various prominences which it exhibits are not irregular and accidental; on the contrary, in all the genera of crustacea, the disposition of these inequalities is constant, and subjected to certain laws. Reflecting, besides, that the crustacea have their principal internal organs situated immediately under the shell or thorax, Desmarest was led to inquire if there existed marked relations between the place occupied by these viscera and the distribution of the internal inequalities of the shell. We have been the more inclined, he remarks, to admit these relations, that it is known that at a certain period of the year all the crustacea, after having lost their old solid envelope, are covered with a delicate skin, which hardens in its turn, and at the end of a few days changes into a crust equally resisting with that which it substitutes; and we might presume, that in the first moments the new skin moulded itself to a certain point upon the internal organs, and that its ossification was subsequently influenced by the motions peculiar to these organs, or by the greater or less developement of each of them. It is easy to prove that the relations which we have just mentioned exist; for, if the shell of a crab of the most common species on our coast, the *Cancer mænas*, Lin. be removed with care, we observe, fig. 1, Plate CVI. behind the inter-orbitary edges, a membranous vesicular stomach, having two large lobes, *a a*, before, and two small ones, *â â*, behind, supported in the middle by a slender transverse bone in the form of an arch, *h h*, and having above, between the two great lobes, and on the middle line, two longitudinal muscles, *i i*, which are attached on one side to the anterior edge of the shell, and on the other to the transverse bone. If we make a comparative examination of the thorax, which is detached, fig. 2, we perceive on it, *1 1*, the indication of the two anterior lobes of the stomach with a depressed central line, which corresponds with the interval that separates the two muscles mentioned.

Behind the stomach whitish sinuous bodies present themselves, fig. 1, *g g*, in the form of intestines, and making many circumvolutions. These are preparatory organs subservient to generation, the spermatic vessels in the males, and the ovaria in the females. They project beneath in different places, but above they occupy the same place in both sexes. With reference to the shell, fig. 2, these organs appear to us to occupy the space, *2*, which is circumscribed by sunk lines, and which is seen behind the one corresponding to the stomach.

Organic Remains. Still farther back, fig. 1, in a pretty deep hollow, we find the heart, *d*, which is depressed above, and which occupies its whole extent; this organ is easily distinguished by its pulsations. Each lateral edge of the cavity, *ff*, in which it is placed, is solid and much elevated, and formed by a vertical septum which proceeds from the sternum to the shell, and which contributes to its solidity, by being fixed between these two surfaces, much in the way of the supporter between the two tables of a violin. This septum also gives support to other transverse partitions, which are equal in number to the separations of the sternal pieces, and in the interval of which are situated the muscles which move the feet. The shell, fig. 2, 3, shows the place of the heart well defined, in the same situation in which this organ is found in the crab when laid bare, and on each of its sides we observe two small sunk lines, which belong to the point of attachment of the two bony partitions between which the heart is situated.

On the right and left of the preparatory organs of generation and of the heart, there are two large spaces, fig. 1, *ee*, where the branchiæ are arranged and extended on two oblique osseous tables, which shut up above all the compartments in which the muscles of the feet are fixed. These branchiæ are five in number on each side, and each of them presents a double row of small transverse branchial laminae; this point of attachment is externally, and all their extremities are directed toward the line which separates the preparatory organs of generation from the heart. The shell, fig. 2, 5, 5, presents, above these parts, on each side of the body, a bulging space, which, in its extent, agrees perfectly with the place occupied by them beneath it.

Lastly, on both sides of the stomach, and before the branchiæ, we find the liver, fig. 1, *bb*, which is very large; it is of a soft consistence and yellowish colour, and its surface presents a multitude of small vermiform parts. This liver passes beneath the viscera which we have described, and is prolonged posteriorly, as far as the base of the tail to *e*, so that it is seen still behind the heart. At this point it has the same aspect and structure as in the anterior part of the body, and is divided into two lobes, which, besides, are in close contact. In the shell, the parts which cover the places where the liver is visible, when it has been removed, fig. 2, 6, 6, and 4, are less bulging than the others, and are distinct on account of this want of protuberance, especially the anterior ones.

The same relations have been found in the *Cancer pagurus*, and many other species. In some, however, many of the indications were wanting, as in certain *Leucosiæ* for example; but in this case, the shell is altogether smooth, and no other furrow indicated divisions which did not correspond with those which we have mentioned.

In some others, the surface of the shell is, on the contrary, marked with an infinity of furrows, and with numerous asperities (*Cancer variolosus*, and *C. incisus*); but the principal divisions have always the same arrangement.

We have found it convenient to give the name of Regions to the different parts of the shell which cover the internal organs, and to distinguish these

Organic Remains.

regions by particular designations, which bear reference to the relations existing between them and the organs, thus:

The *gastric region* (région stomacale), or that which covers the stomach, is median, or anterior, fig. 2, 1.1.

The *genital region* is median, and situated immediately behind the gastric, 2.2.

The *cardiac region* (région cardiale) is median, and placed behind the genital, 3.

The *hepatic regions* are three in number; two *anterior*, situated one on each side of the gastric, and before the branchial, 6.6; a *posterior* median, placed between the cardiac and the posterior edge of the shell, 4.

The *branchial regions*, two in number, one on each side, are placed between the cardiac and genital regions on one hand, and the lateral edges of the shell on the other, 5.5.

Desmarest describes, according to the plan just detailed, twenty genera, and a considerable number of species from different parts of Europe, Asia, and Africa. Many species occur in Great Britain, but principally in England, where they appear in the chalk formation, and also in the plastic clay of Sheppey.

In Plate CVI. we have given, from Brongniart, representations of a *Limulus* and of a *Cancer*, both of them genera of the Crustacea.

## 2. *Trilobites*.

Upwards of an hundred years ago, there was found in England, near to Dudley, in beds of limestone, organic bodies of a very singular form, and different from all the petrifications which had been previously seen, as well as from every organized body known to exist at the surface of the earth. There was no hesitation, however, in referring them to the animal kingdom; but for a long time it could not be determined to what class they belonged; and Linnæus himself, on placing them with the insects, found their form to be so very different from that of the animals of this class, that he gave to the particular species which he has described the name of *Entomolithus paradoxus*.

Notwithstanding the considerable differences which exist between many of the bodies to which the name of *Entomolites* was at first given, and afterwards that of *Trilobites*, we nevertheless discover between them points of resemblance sufficient to characterize a very natural family.

Their body, as in the greater number of insects and in some crustacea, may be divided transversely into three principal parts. But the principal general characteristic, and what essentially distinguishes them from all known animals, is their longitudinal division into three parts, or lobes, by two deep furrows parallel to the axis of the body; this remarkable structure has excited the attention of all observers. At first the tails were only observed, and from their being considered as shells, the name of *Concha triloba* was given them. Afterwards this designation was transferred to the entire animals, by naming them *Trilobites*, a denomination first given by Knorr, and afterwards employed in a systematic manner by Brünnich and Blumenbach.

Organic Remains.

The *Trilobites* appear to form a distinct family in the great division of animals named articulated, which may be included in the class Crustacea. It exhibits the following characters:

Their body, as Brongniart remarks, is divided into three parts, which are more or less distinct; the anterior part, which is named the *scutum* (bouclier), (the head, Walch, &c.), appears to present the union of what, in insects, is generally called the head and thorax; the middle part of the body, which is divided by very distinct transverse articulations, may be considered as the *abdomen*, or trunk of Walch, Brünnich, Wahlenberg, or the union of the belly and back; the posterior part, often distinctly separated from the middle division, though sometimes nearly blended with it, and which is divided by less distinct articulations, or transverse folds, may be called the *post-abdomen*. The name of *tail* has been universally applied to it by naturalists, from its analogy with the part in crustacea, to which the same name is given with equal impropriety; it is traversed by the intestinal canal, but as there is, besides this part, a true tail, it would be improper to allow the name to remain. At the extremity of this prolongation of the abdomen, we find, in many species, an elongated appendage of a coriaceous, or crustaceous nature, either without articulations, as in the limulæ, or composed of several plates arranged in the form of a fan, as in the lobsters; this appendicular part, which does not contain any viscus, should bear the name of *tail*.

These two abdomens are divided longitudinally in all the trilobites by two deep grooves, into three longitudinal parts, or lobes, of unequal breadth; the middle one is generally the narrowest and the most distinctly articulated; the lateral ones, which are broader, even sometimes extend under the form of nearly membranous expansions, which appear to be supported by hard and costiform sides, or appendages, proceeding from the abdomen and the post-abdomen. We shall follow M. Audouin in giving the name of sides (or ilia, or latera) (*flancs*) to these lobes, or lateral parts: we have said that this forms the essential character of the trilobites; it is never wanting in any species, and does not occur so distinctly marked in any known living animal.

The scutum (bouclier) is always divided into three more or less distinct parts; a middle one, which, by Walch, is named the *frons* (front), and two lateral ones which may retain the name of *cheeks* (joues), employed by the same author.

We observe upon this frons, or middle part of the scutum, two or more tubercles; and, often upon the two lateral parts, two other projecting tubercles very different from the first, which have been compared to eyes.

The similarity of these parts, in regard to position, general form, and reticular structure, to the reticulated eyes of insects, and especially of the crustacea, scarcely leaves any doubt regarding the analogy which may be established between these tubercles and eyes. The articulations of the abdomen and post-abdomen are sometimes prolonged laterally into projecting appendages.

Sometimes the tail does not exist at all, sometimes

Organic Re- it is formed of a membrane which terminates in a  
mains. point, or with a crustaceous subulate appendage.

Lastly, no naturalists have ever seen any thing which could be compared to antennæ or feet.

The trilobites are all marine animals; their constant association in the same rocks with shells and other marine productions can leave no doubt on this point. It would appear that they have been capable of multiplying prodigiously, judging from the manner in which certain formations are crowded with them, insomuch that these rocks appear to be entirely composed of them.

The following are the generic names and characters given to these fossil animals by Desmarest :—

Genus I.—CALYMENE. (That is, obscure or hid.)

*Body*, contractile, nearly semicylindrical.

*Scutum*, having several tubercles or folds, *two reticulated oculiform tubercles*.

*Abdomen* and *post-abdomen*, entire at the margin, the abdomen divided into twelve or fourteen joints.

Point of the *tail* prolonged.

C. Blumenbachii. Dudley Fossil. Auct.

*Clypeo rotundato, tuberculis sex distinctis in fronte; oculis in genis eminentissimis; corpora tuberculata.*

Abundant at Dudley in Worcestershire. Plate CVI. Three other species are described by Brongniart, and two of these are figured in Plate CVI.

Genus II.—ASAPHUS. (That is, difficult to determine.)

*Body* broad and pretty flat; middle lobe projecting, and very distinct.

*Sides*, or lateral lobes, each twice the breadth of the middle lobe.

Submembranous *expansions* extending the arches of the lateral lobes.

*Scutum* semicircular, with two *reticulated oculiform tubercles*.

*Abdomen* divided into eight or twelve joints.

A. Debuchii.

Corpore ovato, antice obtuso: pars caudæ membranacea ad marginem longitudinaliter striata. Plate CVI.

Is one of the species found in Wales. Four other species described by Brongniart, and one of these the A. Cornigerus, is figured in Plate CVI.

Genus III.—OGYGIA. (That is, of the greatest antiquity.)

*Body* much depressed, in the form of an elongated ellipsis, not contractile.

*Scutum* marginate; a shallow longitudinal groove proceeding from its anterior extremity.

No other tubercles than the *oculiform ones*.

*Oculiform protuberances* little protruded, not reticulated; posterior angles of the scutum prolonged into a point.

*Longitudinal lobes* little protruded.

*Abdomen* with eight articulations.

Two species of this genus, but none of them British, described by Brongniart.

Genus IV.—PARADOXIDES.

*Body* depressed, not contractile.

*Sides* much broader than the middle lobe.

*Scutum* nearly semicircular; three oblique wrinkles on the middle lobe.

No *oculiform tubercles*.

*Abdomen* with twelve articulations.

*Arches* of the abdominal and post-abdominal *sides* more or less prolonged beyond the membrane which sustains them.

Five species, no British, described; and one of these, the P. spinulosus, is figured in Plate CVI. The fossils described by Linnæus under the name *Entomolithus paradoxus* belong to this genus.

Genus V.—AGNOSTUS. (That is to say, unknown.)

*Body* ellipsoidal, semicylindrical.

*Scutum* and *sides* with the edges a little elevated.

*Middle lobe* presenting only two transverse divisions, each of a single piece.

Two glandular tubercles at the anterior part of the body.

Of this genus but one species, and that found in Sweden.

CLASS VI.—INSECTA.

From their perishable nature, the animals of this class rarely occur in a fossil state; and when they do appear, they are generally very imperfect. Supposed larvæ of the genera *Libellula* and *Ephemera* occur in the marl slate of Eningen and Pappenheim; and the elytra of coleopterous insects in the Stonesfield slate. Insects well preserved, and of extinct species, occur in amber. Schweigger describes a piece of amber containing a perfect scorpion, but different from the common species of that genus. The ants inclosed in amber appear to be the same with the present species; so that we have the same arrangement in this substance as in rock formations, viz. known and unknown species together.

CLASS VII.—MOLLUSCA.

FOSSIL SHELLS.

Fossil shells are amongst the most abundant of the organic remains met with in the strata of which our globe is composed. They exhibit not only great variety in form, but also in magnitude, having a range from the colossal ammonite, several feet in diameter, to the microscopic nautili, and other shells of the same description. They are divided into *univalve*, or those composed of one valve or piece, *bivalve*, with two valves, and *multivalve*, with more than two valves.

1. *Univalve Fossil Shells.*

These univalve shells are again divided into those with one chamber, termed *unilocular*, as the common patella or limpet; and those with several chambers, named *multilocular*, as the nautilus. Upwards

Organic Re-  
mains.

of seventy genera of unilocular shells occur in a fossil state, and many of these include numerous species. The multilocular genera are not so numerous, their number amounting to about twenty-two, but their internal structure is so interesting as to deserve from us some notice. The nautilus, which is one of the best known of these, like all the other genera of this division, has its shell formed into a number of chambers, divided by a perforated septum. The animal which inhabits it, and which is of the sepia or cuttle-fish tribe, resides in the largest and last formed chamber; an elastic tube (siphunculus) proceeds from the animal, and passes through the perforation in the septa and the different chambers, and terminates in the first or smallest. It is conjectured that part of the shell is enveloped by the animal, independent of the connection it has with it by means of the siphunculus. The tube is membranous, and it is probable that it is dilatible and compressible, so as to be capable of rendering the animal buoyant or otherwise at pleasure, as the air-bladder does in fishes. The cells or chambers seem to answer no other purpose than that of containing air, as the animal leaves the last formed one in succession as it forms a new one, keeping up with them no other communication than what is preserved by the siphunculus. Thus, as the animal increases in size and occupies a new chamber, the last in order, and, in the same way, all the preceding ones, are left empty, so that the gravity of the shell is not much more than that of the water of the sea, and hence the addition of a small portion of air, by means of the siphunculus, may render it buoyant, and the expansion of the air, and probably the addition of water, may cause it to sink. Of these nautili some are known to live in the present waters of the globe, but are of rare occurrence, while the fossil species are numerous and abundant. Hence has arisen a question as to the cause of the great disproportion between the number of fossil and of recent shells of this tribe. Some are of opinion that the fossil genera have become extinct, while others maintain that they still live at the bottom of the sea, out of the reach of our observation. But the structure of the shell, as already explained, proves that so far from their inhabitants having been destined to live always at the bottom of the sea, they possess the power of rising up to and remaining at the surface of the sea. Supposing them still to live, they would occasionally, as the present nautilus, be seen at the surface; but not a single instance being known of a shell of these genera having been thus seen, their existence may be reasonably doubted.—(Parkinson's *Introduction*.)

*Ammonites*.—This is another tribe of multilocular fossil shells, remarkable not only for its beauty and variety, but also on account of its vast abundance and wide distribution in the mineral kingdom. They are the petrified serpents of the vulgar; by some considered as the original type of the volutes of architecture, and have also an interesting mythological meaning. Three hundred different species have been described.

*Nummulites*.—Another of the concamerated fossil genera, of a discoidal form, and which has been confounded with seeds. It is so very abundant, that some-

times whole tracks of country are principally composed of it. The pyramids of Egypt are partly built of a limestone almost entirely made up of nummulites. Our limits will not allow of any details in regard to the Orthoceratite, Belemnite, Bacculite, and other genera of this remarkable division, which, in general character and economy, agree with the nautilus, already particularly noticed.

Organic Re-  
mains.

### 2. *Bivalve and Multivalve Fossil Shells.*

The bivalve fossil shells are so numerous and varied in their forms, that we must refer for descriptions of them to the numerous treatises and works on fossil conchology. The multivalves are of comparatively rare occurrence.

## CLASS VIII.—RADIARIA.

### *Echinus, or Sea Urchin Family.*

This extensive division of the echinodermata exhibits great variety in form, and although not met with in the older secondary rocks, is abundant in several of the newer. Some of the species resemble those at present met with in our seas, but none of them, as far as we know, are identical with the recent ones.

### 2. *Asterias, or Sea Star Family.*

The animals of this series, from the delicacy and frailness of their structure, speedily decay, and hence are rarely met with in a fossil state.

### 3. *Crinoidea, or Encrinite Family.*

The animals of this order appear, from their internal structure and external form, to belong to a series allied to the Radiaria, and therefore cannot be arranged with the simple class of polypi. They abound in many strata, and in vast abundance, but very rarely in a living state,—a fact which shows the great difference between the animal world of the former and present period. Blumenbaeh first conjectured their affinity to the Radiaria; Schweigger describes them as pediculated and fixed asteriæ; and Miller, in his late excellent work on the Crinoidea, has removed every doubt as to their true place in the system. All the Entrochites and Encrinites of authors belong to this family.

## CLASS IX.—POLYPI.

Under this head we include all the different kinds of simple animals named polypi, with their coverings, termed *polyparia*. All the corals popularly so called are polyparia of this class, and many of these occur in a fossil state, as will appear from the following enumeration:—*Astrea*, some species fossil. *Porites*, none fossil. *Madrepora*, few fossil. *Explanaria*, none fossil. *Hydnophora*, some fossil. *Meandrina*, some fossil. *Agaricia*, some fossil. *Pavonia*, none fossil. *Fungia*, some fossil. *Cyclolites*, entirely fossil. *Turbinolia*, entirely fossil. *Caryophyllia*, several fossil. *Favosites*, a fossil genus. *Orbulites*, some fossil. *Alveolites*, nearly all fossil. *Flustra* and *Echara*, sometimes fossil. *Gorgonia* and *Antipathes*, not fossil. *Corallina*, not fossil. *Coralium*, rarely fossil.

The most simple of all the animal productions

Organic Remains.—hitherto found in a fossil state are the alcyoniums and sponges.

The *alcyonia* in the fresh state are nearly as soft as sponge, but have stellular openings on the surface, through which polypi project. They occur sometimes fossil, and frequently in flint.

Sponges are composed of horny fibres connected together by means of an animal jelly, but hitherto no distinct polypi have been detected in them. They occur in a fossil state, and are abundant in the flint of the chalk formation, and in the chalk itself.

## II. FOSSIL REMAINS OF PLANTS.

### *Casts and Impressions of Trees and Ferns.*

Vegetable remains occur in great abundance, and in considerable variety, in different formations, particularly in the coal formation. In some coal mines they appear well preserved, and thus afford many facilities for the determination of their characters; whilst in others they are so much changed, as to render it nearly impossible to make out the classes and orders to which they belong. In Plates CVII. CVIII. we have given representations of several casts and impressions of the fossil vegetables met with in our coal fields, partly from original drawings, partly from the plates of Sternberg.

1. *Lepidodendron*.—Stem squamous, the scales in perfect specimens, with attached leaves, which are arranged in a spiral manner around the stem. Specimens of four species are represented by fig. 1, 2, 3, Plate CVII., and fig. 7, Plate CVIII., and all of them from the coal formation of the river district of the Forth. Mr Allan, in the *Transactions of the Royal Society of Edinburgh*, has given a figure of a *Lepidodendron*, with several circular flowers.

2. *Variolaria*.—Stem scutelar, or verrucose, and the centre of the scutæ affording a point of attachment to leaves. This tribe bears some resemblance to arborescent *Euphorbia*, and to some *Cacti*. In Plate CVIII., fig. 8, is a drawing of the *Variolaria ficoides*, with attached leaves. Fig. 4, Plate CVII., is another specimen without leaves, and both from our neighbouring coal fields.

3. *Calamitæ*, so named from their general resemblance to the *calamitæ* of the ancients. One species is represented by fig. 5, Plate CVII. Fig. 9, Plate CVIII., is another figure of the same genus, but probably a different species.

4. *Syringodendron*.—Of this tribe, one species is figured, fig. 6, Plate CVII.

5. *Rhytidolepis*—Is so named on account of the thick wrinkles with which the back is marked. In coal formation, England. Fig. 7, Plate CVII.

6. *Flabellaria*.—A tribe which resembles the palms, fig. 8, Plate CVII., *F. borassifolia*, from the coal formation near Burntisland.

7. *Noeggerathia*.—Fig. 3, Plate CVIII. A representation of one of the species of this fossil genus.

8. *Rotularia*.—So named from its resemblance in form to a wheel. Appears to be a cryptogamous plant, probably peculiar to marshy places or water and forms a particular genus. Fig. 6, Plate CVIII., is one of the species from the coal formation.

9. *Schlotheimia*.—Stem jointed, contracted at the joints, leaves verticillated. Fig. 1, Plate CVIII., *S. tenuifolia*; leaves sessile, awl-shaped, and rigid. Is the *hippuris* of some authors. From the coal formation near Burntisland.

10. *Annularia*.—Leaves disposed in a verticillate manner, and inserted in a ring which surrounds the stem. Fig. 2, Plate CVIII., is *A. spinulosa* from the coal formation.

11. *Osmunda gigantea*.—Fig. 5, Plate CVIII. Occurs in the bituminous shale of the coal formation near Burntisland. The species figured differs from any of the recent species. It is indeed very difficult, in general, to form an opinion as to the ferns found in rocks; for the leaves of ferns of the present creation, even of different genera, are so alike, that they are easily confounded, when we have not an opportunity of examining their seeds, and particularly when we do not attend to the nicer distinctions known to the experienced botanist. How, then, can we determine in a satisfactory manner the impressions in rocks where the seeds are so rarely visible, and the parts so often altered? Smith, Brown, Link, and other eminent botanists, on examining these impressions in slate clay and bituminous shale, thought some resembled a *Pteris*, another a *Dicksonia*, others *Polypodium*, *Adiantum*, *Osmunda*; and in all these cases, the individuals they most resembled were natives of tropical climates,—but not a single instance occurred of an impression of any known and recent species.\*

### 2. *Leaves of Plants.*

Impressions of leaves occur in rocks of different descriptions. Fig. 4, Plate CVIII., is the representation of a leaf of a tree, intermediate between a *Platanus* and *Lyriodendrum*. Some impressions resemble *Spiræa*, others the *Tilia Europea*, *Betula alnus*, *Betula fruticosa*, *Salix caprea*, *Acer pseudo-platanus*, *Populus nigra*, *Acer campestre*, *Rhamnus frangula*, *Salix myrsinites*. These impressions are found in some of the rocks of the Paris formation. Leaves are also sometimes found in amber, and some are of opinion that these belong to the *Aloexylon agallachum*, and the amber itself is conjectured to be an exudation from that tree.

### 3. *Impressions of Flowers.*

Beautiful specimens of aster-like flowers are sometimes met with in a lepidodendrous tree in the coal formation near to Edinburgh; and one of these, as already mentioned, has been figured in the *Transactions of the Royal Society of Edinburgh*.

Schlotheim describes the impressions of a flower

\* Schlotheim has lately published descriptions and figures of impressions of sea plants, fuci, found in a coal formation connected with a limestone which rests upon the new red sandstone formation. Similar impressions occur in the coal field near Burntisland.

Organic Re-  
mains.

of a ranunculus from a metalliferous bed near Frankenberg in Hessa; also impressions of an aquatic Ranunculus or Trollius in the limestone of Oeningen. In Blumenbach's *Spec. Arch. Tellur.* and in Karg's *Essays*, there are observations on this subject.

#### 4. Fossil Seeds and Fruits.

Fossil seeds and fruits of plants occur in different formations, but usually in such a state as renders it nearly impossible to determine the tribes to which they belong. Faujas St Fond found fossil fruits in the brown coal of Liblar, which, he said, bore a strong resemblance to areca nuts; an opinion in which he was not supported by the after examinations of Jussieu, Desfontaines, Lamarck, and Thouin. They probably belong to some palm. The fossil seeds that occur in bituminous wood, in which amber also is found, cannot be referred to any known plants. In the Island of Sheppey there are accumulations of seeds, some of which are like those of the palm, others the chesnut, cocoa, but none identical with any of these.

#### 5. Plants in Calcedony, Siliceous Sinter, and Calc-Tuff.

The early observations of Daubenton, and the later ingenious investigations of Dr Macculloch, seem to prove the existence of various cryptogamic plants in calcedony, particularly in that variety named *mocha stone*. The included vegetables are referred to the tribes Jungermannia and Hypnum of botanists. The siliceous sinter of Iceland, sometimes confounded with calcedony, we find also to contain occasionally plants of different descriptions. Calc-tuff, in some districts, as at Burgtonna, contains well preserved specimens of the *Chara vulgaris*, and *Ch. hispida*. *Confervæ* have also been found in a preserved state in compact calc-tuff. Some of the gyrogonites of Lamarck, found in calc-tuff, are certainly seeds of the *chara* tribe.

#### 6. Petrified Woods.

Trunks, branches, and roots of trees occur in rocks of different kinds, or even loose, more or less impregnated or petrified with mineral matter. The structure and external form are sometimes well preserved, and in other cases both are nearly obliterated. Some of these, belonging to the palm tribe, are therefore monocotyledonous; others, and the greater number, present concentric rings and other internal arrangements which characterise dicotyledonous trees. Hitherto no accurate descriptions have been published of the internal structure of these petrifications, and consequently the names given to them are not to be depended on. Thus it is said that oak, birch, pine, box, elm, willow, hazel, ash, occur petrified in the form of wood-stone and wood-opal; but our own experience does not go to confirm these determinations.

## II.—STATE OR CONDITION OF FOSSIL ORGANIC REMAINS.

Fossil organic remains occur either unchanged,

or more or less altered from their original state or condition, by the removal of some of their constituent parts, their bituminisation, or owing to impregnation with various mineral substances. Shells, bones, teeth, vegetables, of various descriptions, in some alluvial soils, are scarcely at all altered, and remains of quadrupeds have been found well preserved in ice in polar countries; and in peat-mosses, human bodies remain uncorrupted for a long series of years. Shells are sometimes found in a nearly unaltered state in solid rocks, as limestone. The beautiful fire marble of Carinthia contains unaltered shells of ammonite, with their pearly lustre, and rich tints of the most beautiful colours. Shells and bones occur in other alluvial strata, more or less bleached, being dry and fragile, owing to the removal of a portion of their animal matter. In fossil fishes, sometimes not only the bones, but also the soft parts, and even the scales, occur more or less perfectly preserved. Fossil vegetables occur, either nearly unaltered, or more or less bituminised or carbonised, in alluvial strata, also in the brown-coal formation, and in some sandstones. In other cases, the animals or vegetables have disappeared, and only their casts, or impressions, remain to attest their former presence. This change is more frequent with vegetables than animals. In particular situations, the organic body, whether plant or animal, is simply coated, or incrustated, with the mineral matter, and but slightly impregnated with it. The incrusting matter is most frequently calc-tuff and calc-sinter, less frequently volcanic tuff. But the most durable state of fossil organic remains is the *petrified*, when they are more or less completely impregnated with mineral matter.

### I. PETRIFIED VEGETABLES.

*Wood Petrified with Hornstone.*—Trunks, branches, and roots of trees and shrubs are sometimes impregnated with hornstone, forming what is called wood-stone, or ligneous hornstone, and this is one of the most frequent of the petrified woods. The wood appears, in some cases, to have been in a rotten state when petrified, and such varieties appear light coloured and shivery; in other cases, it appears first to have been bituminised, so that it is both bituminous and siliceous together, in which case it is of a dark brown or black colour, and of a more compact texture. In our Cabinet, we have several specimens to show the combination of siliceous matter and bituminous wood in its different stages of bituminisation. Lastly, in other cases, the wood appears to have undergone no change, and then, the wood, or at least part of the ligneous matter, remains in the petrification, while, in others, the whole has disappeared, leaving nothing but its form behind. It is probable, however, that many wood-stones, in collections, are not real petrifications, but portions of trees in which a great secretion of silica has taken place. In the Museum of the University of Edinburgh, there is a large mass of wood-stone, said to have been obtained from the centre of the trunk of a teak tree, which may be viewed as a portion of the wood highly im-

Organic Re-  
mains.

Organic Remains. — pregated with silica by the living powers of the tree. \*

2. *Calcedonic Wood and Jasper Wood.*—In some cases the wood is petrified with calcedony, and in others with jasper; the first has usually a yellowish white colour, and resembles decayed wood, while the latter exhibits great variety of colours. In some rare varieties of Heliotrope a fibrous and probably vegetable structure occurs.

3. *Opaline Wood.*—Wood, when impregnated with opal, forms the most beautiful variety of petrified wood. It is distinguished from the others by resinous lustre, conchoidal fracture, inferior hardness, and lower specific gravity. Hungary is the chief country of this beautiful fossil remain.

4. *Calcareous Wood.*—Wood is sometimes more or less completely petrified with carbonate of lime, in the form of calcareous spar or of limestone. In some cases the wood appears to have been bituminous before petrification, in others rotten, and in some not altered. It occurs in alluvial soil and in various limestones in different parts of England.

5. *Aluminous Wood.*—Some woods are petrified with aluminous matter, but generally along with it there is a considerable intermixture of iron pyrites.

6. *Wood petrified with Iron Pyrites.*—Fossil wood of this description soon decays on exposure to the influence of the weather. Seeds are sometimes in this state, as is the case in the Island of Sheppey.

7. *Wood and other Parts of Trees and Plants petrified with Carbonate and Hydrocarbonate of Iron.*—Wood and fossil vegetables in this state are not of rare occurrence, and are the most indestructible of the woods impregnated with ores.

8. *Wood impregnated with Copper Pyrites.*—This variety of mineralized wood generally contains, besides pyrites, blue and green malachite, which stains it with their beautiful colours.

9. *Wood impregnated with Galena or Lead-Glance.*—Some specimens of this description occur in old mines, thus proving the comparative newness of their formation, while others of a more ancient date occur in brown coal.

## 2. PETRIFIED ANIMAL REMAINS.

The remains of quadrupeds, birds, and amphibious animals are seldom impregnated with mineral matter, and when this takes place, it is generally their harder parts which are petrified. The horns of deer are sometimes impregnated with clay iron ore, and bones of quadrupeds occur penetrated with lead-glance and iron pyrites, and have superimposed crystals of the same minerals. The fossil fishes in the bituminous marl slate of Thuringia are often entirely bituminised, and, according to Werner, the bituminous impregnation of the

slate is derived from these fishes. Sometimes the fishes in the marl slate are also impregnated with copper pyrites, and also with lead-glance and iron pyrites. Crustaceous animals are petrified with calcareous spar, or with iron pyrites. The Echini, or Sea Urchins, are petrified with calcareous spar, with flint, and seldom with iron pyrites. The various tribes of shells and corals are often petrified with calcareous spar, less frequently with clay iron ore, and rarely with flint or calcedony, and with sulphur. And lastly, the Alcyonia and Sponges, the lowest of the animal world met with in a fossil state, are usually penetrated or impregnated with flint.

## III.—GEOGNOSTICAL SITUATIONS OF FOSSIL ORGANIC REMAINS.

When fossil organic remains first engaged the particular attention of naturalists, it was believed that they were irregularly distributed throughout the different formations of which the crust of the earth is composed, and that the whole had been deposited from the waters of the Deluge. It was soon, however, ascertained, that some rock formations never contain petrifications; a fact which gave rise to the opinion, that fossil organic remains were confined to one set of rocks, the secondary, in which they were jumbled together in an irregular manner, while they were entirely wanting in the formations of the primitive class. The more accurate investigations of geologists, particularly those of the geognostical school of Werner, not only proved the insufficiency of former views, but gave a new and interesting character to the whole subject. It was shown by these inquiries, 1. That petrifications, or fossil organic remains, do not occur in primitive rocks, but first appear in rocks of the second, or Transition class. 2. That these organic remains are, in general, more altered, or mineralised, in the older than in the newer formations; so that they appear much changed in transition rocks, and scarcely at all altered in the rocks of the newest, or alluvial class. 3. That these remains are so arranged in the bowels of the earth, that those of the more simple animals and plants appear first, or in the oldest rocks; that in rocks of a middle age, the remains are of animals higher in the zoological and botanical scales; and that in the newest rocks, the fossil organic remains are of the more perfect animals, even reaching to man.† 4. That the fossil organic remains in transition, secondary, and diluvial formations, are in general different from those of the present creation; but that, in the post-diluvial formations, the remains are of recent species of animals and vegetables. 5. And lastly, that although these fossil animals and plants, in general, differ from those of the present world, we observe

\* Workmen remark that mahogany, plane tree, and other woods, are sometimes harder than usual; and also, that they occasionally contain grains of sand. The hardness may be partly owing to secreted silica, and the sand would appear to be silica, secreted by the powers of the plant, therefore resembling that in the teak wood, the rush, and the bamboo.

† The terrestrial rock formations, or those which have been formed on the land, are still so imperfectly known, that, in some cases, it is not easy to determine their age in relation to those which have originated under the water of the ocean.

Organic Re-  
mains.

that they approach nearer and nearer, in appearance, to those of the recent tribes the newer the formation in which they are contained; so that, as already mentioned, in the newest formations there is an absolute identity of character, proving that the fossil species are the same as those of the present creation. A full statement of all the facts on this very interesting subject would extend this article much beyond the limits prescribed; and, therefore, we must rest satisfied with the following account of the distribution of petrifications as they occur in different rock formations, particularly as observed in Great Britain.

Primitive rocks, as already mentioned, contain no organic remains, and, therefore, are supposed to have been formed before animals and vegetables were called into existence. They first appear in the rocks of the second great class or the Transition.

### I. FOSSIL ORGANIC REMAINS IN TRANSITION ROCKS.

The rocks of this class which afford organic remains are limestone, greywacke, and clay slate; but of these limestone is that which affords the greatest number and variety. All the remains, nearly, are of animals, and of tribes occupying a comparatively low rank in the zoological scale; none of them ranging higher than the class Mollusca; and most of the species, and some of the genera, occur only in the transition series, disappearing entirely in the rocks of the succeeding formations.

The following tribes of corals are met with, and generally in the limestone, *Caryophyllia*, *Tubipora*, *Favosites*, *Astrea*, *Madrepora*, and *Stylina*. The last mentioned genus is, with the exception of one recent species found in the South Sea, entirely fossil, and confined to the transition class. This is one of many instances, of the occurrence of fossil animals along with those of the earliest creation, no traces of which have been seen in any of the subsequent formations, but which are now found in a living state in the seas of the opposite hemisphere. No fossil Echini, or Asteriæ, occur in the rocks of this class, but several tribes of the nearly allied family Crinoidæ are met with, such as the *Cyathocrinites* from Shropshire; *Platicrinites* in limestone, Dudley; and *Rhodocrinites*, also at Dudley. The *Trilobite* tribe, so nearly allied to the Crustacea, occurs abundantly in the rocks of this class, but principally in the limestone. When the crustacea begin to appear in the newer formations, the trilobites have disappeared, if not altogether, at least almost so. Fossil shells occur in greater numbers and variety than is generally imagined. Of these the multilocular univalves are the most characteristic in a geognostical sense, and the following are the genera met with, viz. *Ammonites*, *Orthoceratites*, *Nautilites*, and *Conularia*. Unilocular univalves are *Euomphalus*, *Helecites*, *Patellites*, *Bucrinites*, and *Bucardites*. Bivalves are *Anomites*, *Terebratulites*, and *Pentamerus*. The vegetable remains are of rare occurrence, and their peculiar cha-

racters have not been determined. The corals, or-  
thoceratites, and trilobites are the most charac-  
teristic petrifications of this class. Organic Re-  
mains.

### II. FOSSIL ORGANIC REMAINS IN SECONDARY ROCKS.

#### 1. First Sandstone, or Old Red Sandstone.

Occasionally, remains of plants, shells, and corals, occur in this formation, but hitherto they have not been determined with the requisite accuracy.\*

#### 2. First Secondary Limestone, or Mountain Limestone.

This formation, which, in a general view, rests upon old red sandstone, and sometimes alternates with the rocks of the coal formation, is more abundant in petrifications than the transition rocks. Of the tribe of corals, it contains species of the genera *Caryophyllia*, *Turbinolia*, and *Flustra*: of the unilocular univalve shells, *Euomphalus*, *Planorbis*, and *Cirrus*: multilocular univalve, *Orthoceratites*, *Nautilites*, *Ammonites*, *Ellipsolites*, *Nautellipsites*, *Conularia*, and *Amplexus*. Of the bivalve genera, the following are met with, viz. *Productus*, *Pentamerus*, *Spirifer*, *Terebratulites*, *Gryphites*, and *Cardites*. It is worthy of remark, that many of the univalves and some of the bivalves that occur in this and the transition limestone, possess that particular kind of structure, rarely met with in the shells of the present creation, which enabled their inhabitants to rise and sink in the water. The curious structure of *Spirifer*, and the multilocular arrangement of *Productus*, *Pentamerus*, *Amplexus*, and *Conularia*, as Mr Parkinson remarks, imparted, in all probability, to their inhabitants, a power of a similar kind. Sowerby mentions a shell resembling the *Helix* found in mountain limestone; but Parkinson is of opinion, that it belonged to a distinct genus, and probably possessing the same power as *Janthina* (formerly considered as a *helix*), that of sinking and rising in the water. Hitherto, no remains of *Asteriæ* or *Echini* have been met with in this formation, but the *platicrinites* of the Crinoid family, is not unfrequent. No true crustacea occur, but several members of the family *Trilobites* are found in the mountain limestone of England and Ireland. Some obscure traces of fossil fishes are rarely met with. As examples of these may be mentioned the supposed spinous radii of a *Balistes*, and imperfect remains of what resembled the snout of the *Xiphias*, or sword-fish.

#### 3. Coal Formation.

This formation is principally remarkable on account of the numerous fossil remains of plants which it affords. Several of the principal tribes are represented in the plates attached to this article. All the species, and most of the genera belong to plants different from those of the present creation; many of them, and those the predominating ones, resemble cacti, palms, reeds, and ferns; thus intimating the general state of the earth's surface when they flourished.

\* The petrified woods in old red sandstone are often in the state of woodstone.

Organic Remains.—The bituminous shale and slate clay sometimes contain *Orthoceratites*, *Terebratulites*, *Ammonites*, and some species of the genera *Lingula* and *Unio*.

Organic Remains.—shell *Trochus Anglicanus* of Lister, not, perhaps, met with in any of the succeeding strata; a shell of the genus *Helicina*, and the first simple unilocular shell having a turricated form, met with in a fossil state, being a species of the genus *Melania*. Several species of *crustacea* occur. Spines, teeth, and other parts of *fishes* also occur, but in general in an imperfect state. Bones and palates of *turtle* have been found in this formation; but it is particularly distinguished by its containing remains of two very remarkable extinct genera of oviparous quadrupeds, belonging to the same class with the natural order *Lacerta*, but yet differing in structure from all the genera at present known to exist, and in such particulars as must have fitted them to live entirely in the sea. These are the animals already mentioned under the names *Ichthyosaurus* and *Plesiosaurus*.

#### 4. Second Secondary Limestone, or Magnesian Limestone.

The fossil organic remains of the magnesian limestone, which, in the general succession, rests immediately upon the coal formation, have not hitherto been much studied. Some *Flustræ* and *Crinoidea* are mentioned as occurring in it; and also species of the genera *Donax*, *Arca*, *Anomia*, and *Unio*; and lastly, remains of a fish, of the genus *Chælodon*, were found imbedded in this formation near to Sunderland.

The limestones named *Bituminous Marl Slate* and *Zechstein*, are associated with this magnesian limestone, and, therefore, are considered as belonging to the same general formation. The bituminous marl slate often forms the lower part of the series of magnesian limestone, and contains numerous petrified *fishes*; which some naturalists are inclined to consider as principally fresh water species; a few only appearing to them to have been inhabitants of the ocean. In this limestone also there occur remains of an animal of the genus *Monitor*, of the class *Amphibia*; but petrifications of vegetables are rarely met with. We sometimes meet with branches of plants analogous to the *Lycopodium*, and more rarely of *ferns*, and of plants allied to the genus *Phalaris*. Amongst these fresh water productions, various remains of marine animals, such as *Gryphites*, *Trilobites*, and *Crinoidea*, make their appearance.

The *Zechstein* is particularly distinguished by the great abundance of the *Gryphites aculeatus* it contains; *Ferns* and *Lycopodiums* resembling those of the coal formation; and it is said, also remains of *Lepidodendrous plants* are found in it.

#### 5. Second Sandstone, or New Red Sandstone Formation.

Very few organic remains have hitherto been found in this formation, and those met with are *fossil trees and shells*.

#### 6. Third Secondary Limestone, including the Lias, and Oolite.

##### a. Lias Limestone.

This limestone rests on the new red sandstone. It abounds in fossil organic remains, of which the following list contains several of the more interesting:

Corals are of rare occurrence; species of one tribe only, the *Turbinolia*, having been met with. Several species of the genus *Pentacrinite* are met with; and also remains, more or less perfect, of *Echini*. The fossil shells in this rock differ considerably from those of the mountain limestone and other preceding formations; only a few species of some of the multilocular univalves, as *Ammonites*, *Nautilites*, and *Belemnites*, and of the *Terebratulas*, being here discoverable. The fossil shells found in this formation chiefly consist of bivalves of the genera *Ostrea*, *Gryphæa*, *Plagiostoma*, *Plicatula*, *Avicula*, *Mya*, and *Cardita*, with the single univalve

##### b. Oolite, &c.

In the strata above the lias belonging to the oolite, including also the rocks named *Cornbrash*, *Coral Rag*, &c. many genera of organic remains are met with, which we shall now enumerate in the usual manner, beginning with those of the lowest or least perfect animals.

1. *Lower Oolite*.—Traces of *Alcyonia*, and the following genera of corals, are met with, viz *Explanaria*, *Astrea*, *Caryophyllia*, *Fungia*, and *Cyclolites*. The interesting *Crinoide* family affords the *Pentacrinites Caput Medusæ*, and *Subangularis*; species, sometimes well preserved, of the genera *Conulus*, *Cidaris*, *Echinus*, and *Clypeus* of the *Echinus* family, are met with, and rarely fragments of *Crustacea*. Shells of the following genera are abundant, viz *Pecten*, *Ostrea*, *Terebratula*, *Modiola*, *Tellina*, *Unio*, *Lutraria*, *Trigonia*, *Trochus*, *Belemnites*, *Nautilites*, and *Ammonites*. Remains of vertebral animals are of rare occurrence, the only instance known being of vertebræ, supposed to belong to the marine *laccæ*.

2. *Cornbrash, Stonesfield Slate, Forest Marble, and Great Oolite*.—The following is a general enumeration of the organic remains met with in this part of the oolite series, which, in the regular succession, rests on the lower oolite.

Species of *Millepore*, *Tubipore*, *Cyclolite*, and *Caryophyllia*, occur in this part of the oolite series, and the *Encrinital* family appears in considerable variety; species of *Echini*, and two or three varieties of *Crustacea* also occur. The fossil shells are of the following genera: *Terebratula*, *Lima*, *Avicula*, *Pecten*, *Ostrea*, *Cardium*, *Trigonia*, *Modiola*, *Scrpula*, *Voluta*, *Turbo*, *Turritella*, *Ampullaria*, *Ammonites*, and *Nautilus*. Teeth, vertebræ, and palates of *fish* are met with; and also several species of *Tortoise*. Several oviparous quadrupeds have been found; one is a well characterized *Crocodile*, and remains of a *Megalosaurus*, forty feet long, were found at *Stonesfield*. But the most singular fact is, the occurrence of bones of a species of *Didelphis*, or *Opossum*, in the *Stonesfield slate*. Fragments of *fossil wood* are met with; and the *Stonesfield slate* exhibits beautiful impressions, chiefly of *ferns* and *reeds*, many of which resemble those of the coal formation.

Organic Re-  
mains.

3. *Coral Rag*.—This limestone lies above the preceding, and is also a member of the Oolite series. It abounds in *corals*,—contains many different species of the tribe *Echinus*, and considerable variety of bivalve and univalve shells, and among the latter are species of *Ammonites*, *Nautilites*, and *Belemnites*. The remains of vertebral animals are rare, and of these the most remarkable are the vertebræ of the *Ichthyosaurus*.

4. *Kimmeridge Clay*.—Under this head we include a series of clay beds, higher in the series than the preceding, but still belonging to the oolite formation. It contains both bivalve and univalve fossil shells, and of these the most characteristic is the *Ostrea deltoidea*. It also contains remains of the *Ichthyosaurus* and bones resembling those of the whale.

5. *Portland Oolite*.—The most characteristic shells in this Oolite are the *Ammonites triplicatus*, and *Pecten lamellosus*.

6. *Purbeck Beds*.—This limestone contains beautiful impressions of *fish*; also bones of *turtle*, and heads of *crocodiles*. Its shells have not been well examined.

#### 7. *Third Sandstone Formation, or Green Sand Formation*.

In this formation the organic remains, whether of animals or vegetables, are often in a siliceous state. All the *wood* found in this formation is silicified, but none of it has hitherto been referred to any even of the most general divisions of the botanical system. Numerous silicified *Alcyonia* are met with, and also a good many fossil species of the family *Echinus*. *Corals*, and also species of the *Crinoid* family, rarely occur. *Shells* occur in vast abundance, and in great variety; but, with the exception of a few teeth of *fish*, no remains of vertebral animals have hitherto been met with.

#### 8. *Fourth Limestone Formation, or Chalk Formation*.

##### a. *Chalk Marl*.

The lower part of this formation, named *chalk marl*, affords considerable variety of fossil organic remains;—fossil *Corals*, *Sponges*, *Echini*, *Crustacea*, *Encrinurites*, and *bivalve* and *univalve shells*; and of these the most abundant and interesting are those of the multilocular division. The species of the multilocular genus *Hamites* are numerous and abundant, and are highly characteristic of this part of the chalk formation. *Fossil wood* is sometimes met with.

##### b. *Chalk*.

This formation contains many organic remains of animals, from the sponge to the alligator. The families of *Alcyonium* and *Spongia* occur in great variety of form, but their characters are still much involved in obscurity. *Madrepores* occur, and but little changed from their original state; also several genera of the *Crinoidea*, and the species often in a high state of preservation. Several species of the *Asterias*, or star fish, are described as occurring in chalk; but of all the organic remains, those of the tribe *Echinus* are the most numerous, abundant and characteristic of the formation. Of the fossil shells probably the only genera peculiar to the chalk

are the *Crania* and *Magas*. Of the multilocular genera the following are met with; viz. *Ammonites*, *Scaphites*, and *Belemnites*. The first occurs rarely in the upper chalk; the second only in the lower. The remains of several tribes of fishes are met with, which are alleged to belong to the following genera; viz. *Squalus*, *Diodon*, *Balistes*, *Muraena*, *Anarhichas*, *Salmo*, *Esox*, and *Zeus*. The remains are chiefly different sulcated palates, teeth, detached vertebræ, and irregular masses, with the scales of fishes. The teeth are generally referable to different species of shark or *Squalus*; the bony tongues and palates to different species of *Raia*.

#### 9. *Brown Coal Formation*.

This formation, which rests upon chalk, is almost entirely composed of extinct species of plants; and in some countries, as Switzerland, it is associated with vast accumulations of a conglomerate named *Nagelfluhe*.

#### 10. *Paris Formation*.

Under this head we comprehend all the different secondary rocks newer than the brown coal or chalk formations. In this group of rocks the number and variety of organic remains is great, and in general they are in a higher state of preservation than in the preceding formations, and also approach much nearer to the organic beings of the present creation. The members of this series, as it occurs in England, are as follows, reckoning from below upwards. 1. Plastic clay. 2. London clay. 3. Fresh water formations. 4. Upper marine formations.

1. *Plastic Clay*.—In this clay, which reposes immediately either on brown coal or chalk, there are *Ostreae*, *Cerithiæ*, *Turritellæ*, *Cyclades*, &c. together with the teeth of *fish* and portions of *coal*.

2. *London Clay, the Calcaire Grossier of the French*.—Few *corals* occur; the *echinites*, so common in chalk, are very rare in this formation, and very few of the *encrinurite* family have yet been discovered. *Crabs* and *lobsters* are frequent; for in the British Museum there are preserved thirty different species of crabs from the London clay in the Island of Sheppey. *Fossil shells* are numerous and well preserved, often retaining nearly the appearance of recent shells. There are but few genera of recent shells that do not occur in this formation, but the species are generally different; on the other hand, few of the extinct genera, so common in the older formations, occur in this. No multilocular or bivalves of complicated structure occur in this clay. About thirty-two genera of bivalves have been found in the more ancient strata; and only five or six new genera have been found in the London clay; but, on the other hand, the more ancient strata have been found to contain only twelve or fourteen genera of simple turbinated univalves, whilst the London clay and its accompanying sands and crag have afforded thirty-two genera of turbinated shells; twenty-five of which, with about sixteen other genera not known to have existed in a mineralised slate, inhabit the present waters of our globe. *Petrified fishes* of great beauty are

||  
Orkney and Shetland.

sometimes met with; also *crocodiles* and *turtles* in a more or less perfectly mineralised state. It frequently contains portions of *fossil wood*, and vast variety of fruit or ligneous seed-vessels. Seven hundred different seed-vessels have been collected, and few of them agree with any known kinds.

3. *Fresh-water Formations*.—These are so named from their containing principally shells resembling those of fresh-waters. The following genera occur here, viz. *Lymneus*, *Planorbis*, *Cyclostoma*, and *Helix*. And these are associated with seeds, and with parts of coleopterous insects.

4. *Upper Marine Formation*.—It is remarked of this formation by Parkinson, "A few shells only, which may be placed among those which are supposed to be lost, or among those which are the inhabitants of the distant seas, are here discoverable; the greater number not appearing to differ specifically from the recent shells of neighbouring seas." Besides these shells, there rarely occur *palates of fish*, and fossil *sponges*, and *alcyonia*; and, it is said, *fossil bones* of some unknown animal, and teeth of the *mammoth*.

III. FOSSIL ORGANIC REMAINS IN ALLUVIAL ROCKS.

In the *diluvial* members of this class are found the fossil remains of *elephants*, *hippopotami*, *rhinoceri*, &c. already enumerated; while the *post-diluvial* soils contain, principally, the remains of animals and vegetables of the present creation.

IV.—FORMATION OF THE STRATA IN WHICH FOSSIL ORGANIC REMAINS ARE CONTAINED.

Our limits do not permit us to enter into any particular discussion on this branch of our subject, which is, indeed, the less to be regretted

from its vague and dubious nature. We shall, therefore, conclude with a very few observations. The primitive rocks, as already mentioned, appear to have been formed before the organic kingdom was called into existence; because they contain neither animal nor vegetable remains. It is in the transition rocks that organic remains first make their appearance; showing, that at their formation, and not earlier, animals and vegetables began to exist; and thus nearly establishing one of the most remarkable and striking facts in the whole range of geological science. For a long period, the organic productions of the earth appear to have been principally marine; as in all the formations extending from the transition class, to the chalk, inclusive, corals, shells, encrinites, echinites, fishes, and marine oviparous quadrupeds, are the predominating fossil animals; and hence the different rocks of those formations must have been formed under the waters of the ocean. But the strata of the coal formation contain, besides marine organic remains, land plants and land shells, and the bituminous marl slate, already mentioned as lying over the coal formation, principally fresh water fishes; facts which lead to the conclusion, that fresh or land water was concerned in their formation. The formations extending from chalk to the alluvial series, from their containing abundant remains of both marine and fresh water animals, show that the waters of the land and the ocean assisted in the formation of these rocks. And lastly, in the diluvial formations containing the remains of so many extinct quadrupeds, &c., we have sufficient evidence of their formation by a great rising of the waters of the ocean, or of a flood; which appears to have been that described in the Bible; while the post-diluvial clays, and sands, and gravels, with their fossil remains of known plants and animals, are formations daily taking place upon the land, and under the sea.

Organic Remains

Orkney and Shetland.

(MMM.)

Situation.

ORKNEY and SHETLAND, or ZETLAND, two groups of islands in the North Sea, belonging to, and forming together one of the counties of Scotland. The Orkney Isles, which are separated from Caithness by the Pentland Frith, a strait from six to twelve miles broad, are situated between 58° 47' and 59° 20' north latitude, and between 20° 24' and 3° 23' west longitude from Greenwich. Between these, and what properly form the Shetland group, are the two isles of Fair Isle and Foula; the former lying about 24 miles to the south of the mainland of Shetland, and the latter, supposed to be the Thule of Tacitus, about 20 miles to the west: both of them fall under the general denomination of Shetland. With these exceptions, the Shetland Isles may be placed between 59° 48' 30" and 60° 52' north latitude, and between 52' and 1° 57' west longitude. In clear weather they can be distinctly seen from Orkney, from which Fair Isle is only

about 36 miles distant. The Orkney Isles have been computed to contain 384,000 acres, which is probably above the truth; and of this, 300,000 are said to be waste, or covered by water. Those of Shetland may be about twice as large as Orkney; of which only about 20,000 acres are supposed to be cultivated. But the very irregular form of the islands, penetrated by arms of the sea in all directions, render those estimates, in the absence of any accurate survey, nothing more than approximations. Orkney is divided into seventeen parishes, composing three presbyteries and one synod; and Shetland into twelve, here called *ministries*, making one presbytery, which is invested with synodical powers. Together they constitute one sheriffdom or stewardry, under the jurisdiction of a sheriff-depute and two substitutes, whose courts are held at Kirkwall in Orkney, and at Lerwick in Shetland. Orkney alone sends one member to Parliament; the landholders of

Extent.

Divisions.

Representation.

Orkney and  
Shetland.

Shetland, owing to their peculiar tenures, or the want of a separate valuation of their estates, having no vote in the election. Kirkwall, the only royal burgh, joins with Dingwall, Tain, Dornoch, and Wick, in electing a member for the Scottish burghs. Of the land-tax payable for the county, two-thirds are levied from Orkney, and one-third from Shetland. The valued rent is L. 57,786 Scots; and the real rent, as returned to the property-tax in 1811, was, for the lands of Orkney, L. 9495, 3s. 6d. Sterling, and for the houses L. 2138, 14s. 6d.; for the lands of Shetland L. 6741, 6s., and for the houses L. 1408; the land rent of both being thus L. 16,236, 9s. 6d. Supposing the extent to be a million of acres, this gives a rent of not quite 4d. the acre; but the land-owner derives a profit from the labour of the tenantry, which, though considerable, being indefinite in its amount, and difficult to be ascertained, was not probably included in this rental.

Rental.

Orkney Isles.

The number of the ORKNEY ISLES, besides insulated rocks which bear little or no herbage, here called *skerries*, is 67; of which only 28 or 29 are inhabited; the others, known by the name of *holms*, being employed only as grazing grounds for sheep and cattle. Of the inhabited isles the most southerly is South Ronaldshay, supposed to contain 24 square miles, with a population of upwards of 1600, partly employed in agriculture; much of this island being good arable or grass land; and partly in the manufacture of kelp. To the north-west of this is Hoy, an island of twice the extent, but containing only about a third of the inhabitants, the greater part of it being high land covered with heath. Burray, situated north from South Ronaldshay, from which it is separated by a channel about a mile broad, has an area of only three square miles, but produces grain, green crops, and good pasture, and has a valuable rabbit warren. Farther north is the largest island of the group, called Pomona, or Mainland, extending at least 30 miles from east to west, and containing upwards of 200 square miles. The towns of Kirkwall and Stromness are in this Island; the former having about 2000 inhabitants, and the latter 1400. The harbour of Stromness, to which the entrance is from the south, by a passage only a quarter of a mile in breadth, is particularly safe and commodious, though somewhat difficult of access. Shapinsha and Rousa, each containing from 10 to 12 square miles, partly arable and partly pasture, lie to the north of the Mainland. Beyond these are Stronsa, to the north-east, about 16 square miles; and Eda, north-west from Stronsa, not quite so large; both of them containing a considerable proportion of productive land; the former having two good harbours, and the latter carrying on the manufacture of kelp on such a scale as to afford employment to a great part of its inhabitants. Still farther north lie Sanda on the east, and Westra on the west. Sanda, though only about 19 square miles, has about 1800 inhabitants, being naturally a productive territory, and yielding about a fifth of all the kelp made in Orkney. Both from this and Westra, fishing is carried on to some extent. North Ronaldshay, the most northerly of all the Orkneys, lies about two miles north from Sanda, and upon an area of from four to six square miles, has a

Mainland.

Towns.

population of about 500. If the extent of the Orkneys be only 440 square miles, the estimate given in the *General Report of Scotland*, the population in 1811 would be nearly 53 per square mile.

Of the SHETLAND ISLES, the number altogether is about 100; of which upwards of thirty are inhabited, and some of these last are very small. The first to the south is Fair Isle, only about two or three square miles in extent, the inhabitants of which are chiefly employed in the cod fishery. To the north, and a little to the east of this, is the Mainland, or largest of the group, about sixty miles long, and from two to seven miles and upwards broad; having the promontories of Sumburgh-head and Fitful-head on the south, and stretching from thence northward in a form very irregular on all sides. Arms of the sea, here called *voes*, penetrate the land in all directions, so much so, that no part of the island is said to be more than two miles from the sea; and at one place, the isthmus of Mavis Grind, the breadth is less than one hundred yards; and it is surrounded at no great distance by a great many holms and skerries, which give to the landscape, if it may be so called, a singularly wild and romantic appearance, when viewed from the high grounds, which here occupy a much greater proportion of the surface than in the Orkneys. Mainland contains Lerwick, the capital of the Shetlands, having about 1300 inhabitants; and a little to the south-west, Scalloway, the only other town, which now consists of but a few scattered houses, though a place of some antiquity, and formerly distinguished for its castle, and for being the seat of justice. Between this island and Bressay, on the east of Lerwick, is Bressay Sound; so celebrated for being the resort of vessels employed in the fisheries. It is upwards of three miles in length, and from one to two in breadth, and affords safe anchorage to ships of any burden. St Magnus Bay, on the north-west of the Mainland, with an inlet from it called Hammersvoe, also presents a secure retreat for shipping in the most tempestuous weather. On the east of this island, which in extent is greater than all the others put together, the principal islands from south to north are Bressay and Whalsey, and on the west Burra, Papa Stour, and Muckle Roe, and at a distance from these Foula. Bressay and Whalsey contain each about sixteen or eighteen square miles, but the others are much smaller. North from the Mainland is Yell, the next largest of the Shetland isles, about twenty miles long, and eight broad. East from Yell lies Fetlar, consisting of good arable and pasture land. Unst, the most northerly, about two miles from Yell, in extent about forty square miles, also contains much good land, fit for either tillage or grazing. It was here that the French philosopher Biot, in 1817, and in the following year Captain Kater, prosecuted their experiments for the purpose of determining, in this high latitude, the variation in the length of the seconds pendulum. The former has given an animated picture of the country and its inhabitants, in his *Notices sur les Operations*, &c. read to the French Institute in 1818. Assuming the extent of these islands to be 880 square miles, or twice that of the Orkneys, the population in 1811 was at the rate of only twenty-six

Populat

Orkney and  
Shetland.

*per square mile.* But, if the productive land be little more than 20,000 acres, much of the subsistence of the inhabitants, small as the number is, must be drawn from other sources than their own soil.

Climate.

The climate of these islands is exceedingly moist, and the winters long; yet the cold is not intense, and snow seldom lies more than a few days. The thermometer in the Orkneys commonly ranges between 23° and 68°, and in 1811, a rainy year, the quantity of rain was 29.05 inches. In Shetland, during the summer of 1808, the thermometer was for a few days at 75°, the medium temperature of July and August being about 70°; and it seldom falls 10° below the freezing point. According to Dr Edmondston, the medium temperature of the winter months may be taken at 38°, and of the summer at 65°. On the shortest day of the year the sun is above the horizon five hours and twenty-five minutes. From the middle of May to the end of July it is never dark, the short absence of the sun being supplied by a bright twilight. Yet all these islands are much exposed to high winds, which often destroy the crops, as well as occasion great losses at sea; while, surcharged as the atmosphere commonly is with moisture, the sensation of cold is often greater than what is indicated by the thermometer.

Soil.

Of the arable or productive land, the soil is in general sandy, or a light loam, of no great depth, sometimes upon limestone, but frequently sandstone, and in the latter case it is often much injured by wetness. But by far the greater part of the surface is covered with moss and moor, and exceedingly sterile. Among the minerals are iron, lead, and copper, none of which are wrought at present. In 1817 Dr Hibbert found the chromate of iron in the island of Unst. Marl is very common in Orkney, but much neglected, and also limestone. Beds of limestone occur in almost every parish of Shetland. There is no coal, but peat is every where so abundant, that the inhabitants do not suffer from want of fuel.

Rural Economy.

The rural economy of these islands presents several peculiarities, to which we can only advert very shortly. The proprietors of Orkney derive a greater income from the kelp manufactured on the shores, and those of Shetland from the fisheries on the coast, than from the soil itself; and to obtain a sufficient number of hands for these employments, the land is, in general, divided into very small farms, of which most of the rent is paid in produce and in services;—in Shetland chiefly in butter, and in fish sold to the landlord at a price below that of the market. In Orkney land is let by the *mark*, or merk, an indefinite measure, and not by the acre; and in Shetland, where the same practice prevails, the marks are divided into different classes, such as sixpenny, ninepenny, and twelpenny marks; terms which, whatever they may have denoted originally, do not now define either their relative extent or value; a sixpenny mark being often as large and productive as a twelpenny one. Both in Orkney and Shetland nearly all the estates are freehold, though the *udal* tenure was formerly general in the latter country; but they are burdened with feu-duties and rents, formerly paid to the Crown and Bishop of Orkney, and now to Lord Dundas, the grantee, or lessee of the

Crown. Tithes are drawn in kind, and in Shetland are said to be very oppressive. Most of the small tenants hold their possessions only from year to year, having no leases.

Orkney and  
Shetland.

Oats, bear, or big, and potatoes, are the principal crops; yet the soil and climate are in general well adapted to turnips and clovers, which are now to be found cultivated upon a small scale in many of the islands. All their implements are rude, and, as we should think, ineffective; in many parts the spade is almost the only one in general use. Their native horses, cattle, and sheep, are all diminutive animals, stunted by hunger and cold, particularly those of Shetland; but better breeds are now found in Orkney. The late Mr Malcolm Laing (the well known historian of Scotland), who introduced a flock of Merinos into Orkney in 1808, found them to thrive well, and their wool not to deteriorate, but rather improve. The Shetland horse seldom reaches the height of eleven hands, or the cow the weight of 3 cwt., and the milk which the latter yields, on the common pastures, does not exceed three English quarts *per day*. In Orkney, the number of sheep has been computed at 50,000, and in Shetland at from 70,000 to 80,000. The wool of many of the latter is very fine, and might probably be much improved, as well as the animal itself, by proper treatment. But at present, the sheep depasture promiscuously without being herded; neither shelter nor food is provided against the rigour of a long winter, and disease, when once introduced into the flocks, makes the most cruel ravages. A great many swine are bred in these islands, particularly in the Orkneys. The hair, or rather wool, with which they are covered is made into ropes, “and it is not uncommon for a man who sells his pig to bargain to have his wool returned.”—(Shirreff's *Agricultural View*.) Rabbits are found in most of the Orkneys; and geese are reared in great numbers as an article of export.

Live Stock.

Of the manufactures of this county, by far the most important is kelp, of which the quantity produced in the Orkneys yearly is about 3000 tons, but in Shetland only from 400 to 600 tons; the precipitous shores of the latter islands being less favourable to the growth of the sea-weeds from which it is made than those of Orkney. During the late war, it has been computed that about L.40,000 a year was received by the landholders for the kelp made in Orkney alone; and the people whom it employs, for eight or ten weeks in summer, include a great proportion of the inhabitants. But since peace, the price has fallen so much, that this important branch of industry will perhaps cease to be profitable; and the repeal of the duties on Scotch salt, in the last session of Parliament, which may lead to the production of soda from that article, has filled the proprietors with apprehension that it may soon be annihilated. Before the late war, the linen manufacture was carried on to a considerable extent in Orkney, but has decreased since. Straw-plaiting has been introduced both into Orkney and Shetland, and employs from 1200 to 1400 people, chiefly females. Shetland has been long celebrated for its hosiery. Stockings are knit upon wires in almost every family, and of such different qualities, that while some

Orkney and Shetland. are valued at L.2 a pair, others are so low as 5d or 6d.

The fisheries are to Shetland what kelp is to Orkney, the great source of employment and revenue to its inhabitants; yet cod and lobsters are caught in great quantities among the Orkney isles, and carried alive to the London market, and the dog and coal-fish, for the use of the inhabitants; the former affording oil, and the latter an agreeable article of food. But the fisheries of Shetland are far more considerable. About 600 boats and 3500 men are employed from the 20th May to the 12th August in fishing for ling, cod, and tusk, called the *white fishing*, at from twenty to forty miles from the coast. The principal stations, or *haafs*, are in the parish of Northmaven, in the north-west quarter of the Mainland. The spacious bay of St Magnus, which is on the south side of this parish, leads to the harbour of Hillswick, where there is good anchorage in from seven to twenty fathoms; and on the beach, which is large and commodious, there are warehouses and salt and fish cellars, with every other necessary accommodation. Another great station is at the *Out Skerries*, east from the Mainland. As the fishermen are also small farmers, it is commonly stipulated that these three kinds of fish shall be delivered to their landlord at so much *per cwt.* of wet fish, the landlord curing them, and taking all further risk upon himself. Two tons and a half of wet fish make only one of dry; of which the quantity annually cured by the landholders was, a few years ago, upwards of 1000 tons; and the price in Shetland was 18s. 6d. the cwt. This was before the discovery of the Cod-bank, which we shall notice immediately. But there is a number of what are called *free* fishers, especially in the two islands of Burra, who being at liberty to sell to whom they please, receive a higher price than the small tenants, and the quantity caught by them is not included in the above. Besides these kinds of fish, halibut, skate, and several others, are got at the same time, all of which belong to the fishermen, without any claim on the part of the landholders; and this is the case also with what is caught on hand-lines during winter and spring. Of these *winter fish*, the annual export is about 65 tons. The herring-fishery was formerly prosecuted by the Dutch to a great extent among these islands. "Some old men," says Gifford, who wrote his *Description of Shetland* in 1733, "say that they have seen in Bressay Sound, at one time, 2200 busses." Since peace, these industrious people have begun to resume their labours, though upon a much smaller scale. But the quantity of herrings caught by the Shetland fishermen on the coast is comparatively trifling; and notwithstanding the encouragement afforded by Parliament, it does not appear that they have embarked to any extent in the deep sea fisheries. One of the most ancient and beneficial branches of the Shetland fisheries is that of the coal-fish, known, according to its age, by the names of *sillock*, *piltock*, and *sethe*. These form a principal article in the subsistence of the lower classes.

In the summer of 1818, an extensive cod-bank was discovered to the west of the Shetland Isles. According to the fishermen, it lies from 25 to 30 miles west from Foula. They refer to the west of the island of Westra, one of the Orkneys, as its origin, and from thence it is continued in a direction nearly north by west, having been variously entered upon in steering from the east, as far as about 20 miles north-west of Shetland, a distance of about 140 miles. The breadth is reported to be from 18 to 45 miles, and the depth of water from 28 to 50 fathoms. The great productiveness of this bank has been fully established. About double the weight of fish was caught on it in 1819 that had been formerly taken by vessels of the same burden in other parts.

The nature of the trade of these islands may be anticipated from what we have said of their products. Orkney exports kelp, linen cloth and linen yarn, skins, goose feathers and quills, and a few other articles; and the imports are wine, spirits, groceries, &c. Oatmeal and bear or big appear both among the imports and exports; but it is understood that this range of islands, in ordinary seasons, grows corn enough for the consumption of its inhabitants. The chief exports of Shetland are fish, kelp, oil, butter, and hosiery; and the imports the same with those of Orkney, with the addition of corn, of which it does not raise nearly a sufficiency. The money brought into Shetland by such of the natives as engage themselves as seamen in the whale vessels is computed to amount to no less a sum than L.15,000 yearly.

There is no poor rate in this county. It is the practice of the island to board the poor upon the tenantry, in proportion to the extent of their possessions; each pauper having a certain number of families assigned to him, with whom he lives in succession, and who are said to treat him with kindness. The wages of labour cannot be accurately expressed in money, as they are paid partly in produce, and vary much at different seasons, owing to the demand for kelp-making and the fisheries. In Shetland a man-servant will seldom engage for more than nine months in the year. The provisions obtained from their own soil and from the fisheries are sufficiently moderate, but such as must be imported are proportionally high priced. The condition of the labouring classes is understood to have been much improved since the introduction of kelp-making; but it is alleged, that the practice of connecting this kind of industry, and that of the fisherman, with the occupation of land, is incompatible with agricultural improvement. The population of the county, in 1801 and 1811, will be seen in the annexed abstract.

ORLEANS, NEW. See UNITED STATES.

ORME (ROBERT), the Historian of British India, born at Anjengo in Travancore, was the son of Dr Alexander Orme: his mother was a Miss Hill, a sister of Mrs Robert Adams.

He was sent to England at the age of two years, and placed under the care of Mrs Adams, who lived in Cavendish Square. His literary education commenced very early, for he went to Harrow at six, having been previously, for a twelvemonth, under the private tuition of a clergyman in the neighbourhood. For seven or eight years he applied to his classical studies as a schoolboy with great diligence; and when he was thirteen, he was placed in the office of the Accountant of the African Company, in order to gain some practical knowledge of the principles of commerce.

In 1742 he went out to Calcutta, and was there engaged in a mercantile house of respectability: he made a voyage to Surat in their concerns, and on his return, in 1743, he received from England the appointment of a writer. Five years afterwards he was promoted to the rank of factor in the Company's service. In 1752, having been desired to give his opinion on the regulation of the Police of Calcutta, he drew up a memorial on the subject, which did great credit to the accuracy and profoundness of his views of the manners, the habits, and the interests of the country.

He returned to England in 1753, upon a visit to his aunt, and he was much consulted, during his stay in London, by Lord Holderness, then Secretary of State, with regard to the policy to be observed towards the French Government respecting the affairs of India. He went out again in 1754, and took his seat as a member of the council at Fort St George. He had here an opportunity of effectually serving

the Company by the vigour of his political conduct, and of greatly contributing to the establishment of the decided preponderance of the English interest in India. After the well known affair of the Black Hole of Calcutta, he was particularly active in promoting the appointment of Colonel Clive to the command of the expedition destined to punish the cruelty of the tyrant who was the author of that outrage: although his friendship with Colonel Clive did not continue uninterrupted through life. Mr Orme's exertions on this and other occasions were so highly appreciated by the Directors, that he was nominated as eventual successor to the government of Madras: but he did not stay long enough to profit by the appointment. In the capacity of Accountant-General, he became intimate with Mr Alexander, afterwards Lord Caledon, who was his deputy, and with Mr Dalrymple, the hydrographer, to whom he showed many civilities from a conviction of his merits. Mr Benjamin Robins, the historiographer of Anson's *Voyage*, had also been one of his early friends, that is, during his first residence in India; for this singularly active person died in 1751.

Mr Orme's situation in India was extremely favourable for the acquisition of historical information, which it was the delight of his life to collect; but his health requiring a change of climate, he sailed for Europe on board of the *Grantham* in 1758. The ship was, however, captured in January 1759, off the Cape of Good Hope, and carried to the Mauritius: after having been detained here for some time, Mr Orme was allowed to proceed to the Cape, and thence to France. He landed at Nantes in the spring of 1760: he paid a visit to Paris, where he amused himself for some months with the literature and the theatres of the day: and his biographer has preserved some interesting remarks that

Orme.

they suggested to him. In October he arrived in London, and engaged a house which had lately been built in Harley Street.

He employed himself for the two succeeding years upon his Military History; sparing no pains nor expence to complete the collection of materials, which he had begun to form in India, and to prepare the work, with all possible care, for the press. The first volume appeared in 1763, and was received with great approbation. The Company not only granted him free access to their Records, but gave him also the appointment of their historiographer, with a salary of L. 400 a year. After this time, he resumed some of his classical studies which he had discontinued so long, as to have forgotten almost all that he had learned: but he soon recovered his knowledge of the ancient languages, and added to them afterwards such of the modern ones as he found likely to be subservient to his pursuits. His hours of leisure were chiefly passed in the enjoyment of literary society: he became a Fellow of the Society of Antiquaries in March 1770; he was intimate about the same time with Lord Sandys, and with Sir James Harris. Sir William Jones, Dr Robertson the historian, Dr Pemberton, Dr Wilson, Athenian Stuart, and Nourse the bookseller, were also among his particular friends; as well as Mr Rouse Boughton, afterwards Sir Charles Rouse Boughton, Bart., to whose urbanity and thorough acquaintance with the Persian language he was indebted for several of his historical documents. He obtained additional information for the completion of his History from the French General de Bussy, who had been much concerned in some of the transactions narrated in his first volume, and who was so much satisfied with his candour and impartiality, that he invited him to his house in the country, and entertained him there, in 1773, with great kindness and hospitality.

After the publication of the second volume of his History, he had ample leisure to amuse himself with literary pursuits of a more general nature: but in 1784, he suffered a severe affliction from the loss of his nephew, Mr Hosea, who was shipwrecked, with his wife and family, upon their return from India, on board of the Grosvenor. In 1792, he retired to Ealing, where he continued to reside till the time of his death, which happened on the 13th January 1801.

Good sense and sound judgment were the principal features of his character: his works are more distinguished by simplicity, clearness, and precision, than by any very powerful eloquence, or a very nice discrimination of character. He was not, however, deficient either in command of language or in poetical feeling. Sir William Jones and Dr Robertson paid him some very high compliments, in their private correspondence, for the elegance and purity of his style: the former of these writers has also characterized him, in his third Discourse, as possessing "an exquisite taste for every fine art." We find also, among a few miscellaneous poems collected by his biographer, a remarkable little Address to the Moon, written at Madras in 1757, which is manifestly the original of a well known Greek epigram and a Latin ode of Sir William Jones: and

certainly the compliment of having been "set to music, and much admired," must be considered as far inferior to that of having been repeatedly imitated and translated by a poet of a judgment so correct and a taste so refined, and having been called the production of "a man of great talents, and a particular friend of the translator."

1. Of his works, the earliest, in its origin, was his *General Idea of the Government and People of Indostan*. It was principally written in 1752, and finished during his return to England in the next year. A part of it was prefixed to his Military History, and it is printed in its entire state among his posthumous works.

2. *History of the Military Transactions of the British Nation in Indostan, from the year 1745*. Vol. I., extending to 1756. 4to. Lond. 1763. Ed. 3, with an excellent index, 1781. A Dissertation on the Mahomedan Conquests and Establishments in Indostan is prefixed to this volume. "No historian," says the author of the *Annual Register* for 1764, "seems to have been more perfectly informed of the subject on which he has undertaken to write: and very few have possessed more fully the talent of impressing it, in the clearest and most vivid manner, on the imagination and understanding of his reader."

The *Second Volume*, published in 1778, carries the history down to the peace of 1763.

3. *Historical Fragments of the Mogul Empire*, from the year 1659. 8vo. Lond. 1782. First published anonymously, but acknowledged and reprinted in 4to in 1805; together with the *Origin of the English Establishment at Broach and Surat*, the *General Idea of the Government and People of Indostan*, and a *Life of the Author*. The Historical Fragments is a work of considerable research, making a sort of episode to the Military History, to which it affords some additions and corrections: it relates principally to the sanguinary Arungzebe and his immediate successors, and to his contemporary, Sevagi the "Morattoe," the professed descendant of Porus. The Essay on the Trade of Surat is a fragment which was left unfinished by the author.

4. Several hundred volumes of Mr Orme's manuscript collections, together with some scarce printed tracts, relating to Oriental history, are carefully preserved in the library of the East India Company.

[*Life* prefixed to the *Historical Fragments*. Jones, *Poeseos Asiaticæ Commentarii*.] (L. 1.)

OXFORDSHIRE, an inland county of England, chiefly celebrated on account of its capital, which is the principal seat of learning in the British dominions, and from which city it has derived its name. It is bounded on the east by Buckinghamshire; on the south, south-west, and south-east, by Berkshire; on the north-east by Northamptonshire; and on the north-west by the county of Warwick. The river Thames (called sometimes the Isis till it reaches Oxford) is the line of demarkation on the whole of its southern boundary; running between this county and Berkshire with various, and in the latter part of its course most beautiful, sinuosities. The county is of a most irregular figure. Near the centre, in which the city of Oxford stands, it is not more than seven miles in breadth, and at no great distance to

Orme  
||  
Oxfordshire.

Herefordshire. the north it is thirty-eight miles. Towards the north it resembles a cone, and to the south it is similarly contracted. Its extreme length is fifty miles. The extent is estimated at 742 square miles, or 474,880 English acres. It contains one city, twelve market towns, and two hundred and seven parishes, and is divided into fourteen hundreds.

This county is by no means uniformly beautiful. On the north, the absence of hedges, which are supplied by stone walls, gives a dreary appearance to the face of the country. In the centre, it is generally flat and woody, affording few pleasing prospects, though its trees and verdure give it the semblance of wealth. The southern part, from the beauty of its rivers, the gentle swelling of its hills, the verdant meadows between them, and the number of highly embellished residences of rich proprietors, is a district abounding with rural charms. The Chiltern Hills, the highest range in England south of the river Trent, form a part of this portion. They are in many parts adorned with beech woods, and in every interval of these woods cultivated quite to their summits.

The climate of the county varies according to the elevation and exposure. In the north, where no hedges impede the winter winds, the cold is somewhat severe, and the Chiltern Hills are frequently enveloped in damp fogs, especially in the more woody parts of them. Mr Arthur Young, in his *Agricultural Survey of Oxfordshire*, has formed a classification of the soils in the different districts of the county, which, like all similar estimates, must be received with hesitation, or at least with many exceptions. The red soil, found chiefly in the north, and by far the most fertile, he estimates at 79,635 acres. The land, provincially called *stone brash*, found in the centre, and whose surface is often covered with stones, amounts to 164,023 acres. The Chiltern lands, whose soil is a loam resting everywhere on a bed of chalk, and covered with flint stones, are 64,778 acres. To these are added 166,400 acres under the description of miscellaneous, which comprehends all sorts of soil, from loose sand to the heaviest clay, and includes the rich meadows on the banks of the rivers.

Though this is wholly an agricultural county, and though much progress in improvement has been made of late years, yet the general practices are by no means equal to the average of those of the rest of England. The most beneficial husbandry is founded upon the valuable water meadows on the banks of the different streams. These are naturally so fertile, that they appear to have prevented that care which would render them still more productive. Little attention is paid to draining, and still less to irrigation, though the good effects of both these practices are obvious, and their accomplishment easy in many circumstances. Some few oxen are fattened, and butter and cheese made in the dairies, but the facility of navigation induces the farmers to make more hay than is consumed by their stock, and to send it to distant and higher markets than their own—nearer to the metropolis. On the arable fields, especially on the stony lands near Burford, the use of oxen for the plough is very common, and the

Herefordshire breed is generally preferred for that purpose. The practice of paring and burning the surface prevails in many parts of the county, and in the newly inclosed lands the application of lime as a manure is highly beneficial, whilst on the Chiltern lands it is not found to produce a good effect equal to the expence which attends it.

Where the soils are so various, the rotation of crops must necessarily vary with them. On the red soils, the most usual course is, 1st, turnips; 2d, barley, or spring-wheat; 3d, clover; 4th, wheat; 5th, peas, or beans; and, 6th, oats. On the stone-brash lands, the usual rotation is, 1st, turnips; 2d, barley; 3d, clover, to stand two years; 4th, wheat; and, 5th, oats, peas, or sometimes, but rarely, beans. On the Chiltern lands, the rotations are the same, with only slight variations. On both these last tracts of country, the cultivation of sanfoin is very extensive; on most farms occupying from one-seventh to one-eighth of the whole. This valuable artificial grass produces heavy crops. When it was first introduced, it would remain productive for fifteen or sixteen years; but since it has become more familiarised to the soil, it seldom lasts more than seven years so as to be fit to make hay, but yields food for sheep for one or two years afterwards. The sheep, which were formerly almost all of the Berkshire breed, have of late years been superseded by the race of the South Downs.

Oxfordshire is not a manufacturing district. Witney was celebrated for its blankets, and they still retain their superiority; but the cheapness with which similar goods are made by machinery in the northern counties has reduced the demand; and though machinery has been introduced, the trade is still on the decline. On the eastern side of the county, some females find occupation in making bone lace, but that, too, is on the decline. At Banbury there is a manufactory of plushes, hair-shaggs, and some bindings, and other haberdashery wares; and at Woodstock, the making of gloves gives employment to many of the inhabitants. There are no minerals and no coals found in this county.

The rivers all empty themselves into the Thames. They are formed by the numerous small springs which are everywhere to be seen; and before they join the Thames are called the Windrush, coming from Burford and Witney, the Evenlode, from Wichwood and Charlbury, and the Cherwell, from the vicinity of Banbury. The Thames, composed of the stream of that name and the Isis (on which a strange confusion has arisen), is navigable from near one of its sources, not far from Letchlode, to the sea. The barges navigating it are from seventy-five to one hundred tons burden, but the larger ones ascend no higher than Oxford. From the frequent recurrence of shoals, from the floods in winter, and the scarcity of water in summer, it is a dilatory navigation; so that frequently the passage from America to London occupies less time than from Letchlode to that city. The scarcity of fuel was severely experienced till within these last few years; but the completion of a canal, which connects the city of Oxford with the collieries of Staffordshire, has removed the evil, and proved high-

Oxfordshire ly profitable to the proprietors of that important work.

||  
Paley.

⏟  
Oxford City.

We forbear to say any thing of that which is the glory of this county and of this kingdom—the city of Oxford. It is described in the *Encyclopædia* in a moderate compass, and a farther expansion of that description, by enumerating the works of art and the repositories of everything valuable in literature, would be incompatible with the limits prescribed to this work.

**Antiquities.** The antiquities of this county have been accurately described, and are deserving of the closest inspection. Among them are the traces of the various roads formed by the Romans, whose principal station was at Dorchester, many funereal mounds, and the Vallum called the Devil's Ditch. The Priory of Godstow, and the ruins of many other religious houses, exhibit the architecture of different and remote ages.

**Population.** The population of this county had increased, between the years 1801 and 1811, by 9536 individuals. In the last mentioned year, the numbers were, 119,204; of whom the males were 59,140, and the females 60,064. The number of houses were 21,598, inhabited by 24,749 families. Of these persons, 36,409 were employed in agriculture, 17,946 in trade and manufactures, and 64,849 derived their subsistence from neither of these employments. The towns and their population are as follows, viz.—

Oxford city,	12,931
Henley-upon-Thames,	3,111
Banbury,	2,840
Witney,	2,722
Thames,	2,328

Bicester,	2,114

||  
Paley

The county is in the diocese of the capital city, which gives the title of Earl to the family of Harley. The members returned to the House of Commons are nine, viz. two from the county, two each from the city and university of Oxford, two from Woodstock, and one from Banbury.

The most distinguished residences are, Blenheim Castle, Duke of Marlborough; Blandford House, Duke of Beaufort; Brightwell, W. Lowndes Stowe, Esq.; Cuddesdon Palace, Bishop of Oxford; Crowsley Park, John Atkins Wright, Esq.; Ditchley Park, Lord Dillon; Grey's Court, Lady Stapleton; Heythorp, Earl of Shrewsbury; Kirtlington Park, Sir H. W. Dashwood; Middleton Stoney, Earl of Jersey; Mongewell, Bishop of Durham; Mapledurham, Michael Blount, Esq.; Nuneham Park, Earl of Harcourt; Rycot Park, Earl of Abingdon; Shiplake, Lord Mark Kerr; Shelswell, ——— Harrison, Esq.; Shirburn Castle, Earl of Macclesfield; Thane Park, Miss Wykham; Wroxton, Earl of Guildford; Wood Eaton, John Weyland, Esq.; Waterstock, W. H. Ashurst, Esq.; Wormsley, John Fane, Esq.; Wheatfield, Lord Churchill.

See *The Agricultural State of Oxfordshire*, by Arthur Young; *Pott's Oxfordshire*; and Brewer's *Account of Oxfordshire*, in the *Beauties of England and Wales*. (w. w.)

## P A L

PALEY (WILLIAM), D. D., was born at Peterborough in July 1743, where his father was then minor canon of the cathedral church. His father afterwards removed to Giggleswick, being appointed head master of the school at that place. Here his son was trained under his immediate inspection, and discovered a solidity of understanding, and a studiousness of disposition, which gave a fair earnest of his future eminence.

In November 1758, at the age of fifteen, he was admitted a sizar of Christ's College, Cambridge; and in October 1759, he became a resident member. When he left home, his father could not refrain from expressing to his friends the anticipations he entertained of the figure which his son was destined to make. "He'll turn out a great man—very great. He has by far the clearest head I ever met with."

Shortly after his removal to Cambridge, he obtained three scholarships. He was not at this time a close or laborious student; he spent much time in com-

pany, and improved himself rather by observation and reflection than by reading. When he appeared in the public school to make his first *act*, the spruceness of his dress presenting a striking contrast to the habitual carelessness of his appearance, attracted very particular notice, and, aided by a singularity in his gestures and manner, occasioned much mirth among the spectators; but the uncommon success with which he acquitted himself had the effect of drawing crowds on all future occasions when he was expected to dispute. His eminent abilities created on one occasion some degree of apprehension, when he proposed to argue against the eternity of future punishments. One of the heads of the college insisted on his relinquishing that question. Dr Watson, then Moderator, and afterwards the celebrated Bishop of Llandaff, protected, on this occasion, Paley's independence. The latter, however, was averse to give offence; and at the suggestion of Dr Watson he retained the subject, but took the opposite side. He

Paley. came off with much eclat, his talents having received the best scope for display from the high ability of his opponent, Mr Frere.

After obtaining, with great honour, his bachelor's degree in January 1763, he accepted of the situation of second assistant and Latin teacher in an Academy at Greenwich, chiefly resorted to by young men intended for the army and navy.

In 1765, Mr Paley gained the first senior bachelor's prize by a Latin dissertation on "a comparison between the Stoic and Epicurean Philosophy in their influence on morals;" taking the side of the Epicureans, as a sect friendly to rational pleasures, and not (as their enemies supposed) indulgent to vicious excesses; while he condemned the affected austerity of the followers of Zeno, and showed, from facts, that it was compatible with the most flagitious crimes. It is a remarkable circumstance, as illustrative of the formality which often presides in university matters, that this dissertation narrowly escaped rejection, because the Latin text was accompanied by *English Notes*, for the purpose of aiding philosophical accuracy where the Latin appeared liable to ambiguity.

Being ordained deacon at the proper age, he officiated as curate to Dr Hinchcliffe, Vicar of Greenwich, where he continued to reside, though he gave up his situation in the Academy.

Mr Paley was elected a fellow on the foundation of Christ's College in June 1766; returned to reside in the University; took the degree of Master of Arts; and engaged in the business of private tuition. He took priest's orders in December 1767, and in 1768 he was appointed tutor of Christ's College, along with his friend Mr Law, already a distinguished scholar. The talents and assiduity of these two quickly raised the celebrity of their college to an unprecedented height. Paley's intimacy with Law was productive of much mutual improvement, and introduced the former to the acquaintance of his friend's father, the eminent Dr Edmund Law, who was soon after Bishop of Carlisle, but continued to reside in the university as master of Peterhouse. Mr Paley was at this time held in the highest esteem, and among his particular friends were numbered Dr Plumtre, Professor of Casuistry, Dr Waring, Lucanian Professor of Mathematics, who was in his department eminent beyond his contemporaries, and the accomplished Mr Jebb. He figured as a lecturer on mathematics, morals, and the *Greek Testament*, and afterwards on divinity. His method of lecturing was singularly happy; the result of a diligent study of the art of teaching. He soon discovered that, in moral disquisitions, more pains are required to make young minds perceive the difficulty than to make them understand the solution; and that some curiosity must be raised before an attempt is made to satisfy it. The discourses which he delivered at this time contained the germ of the principal works which he afterwards published on morals and theology.

The controversy on the propriety of requiring a subscription to articles of faith, as practised by the Church of England, was at this time much agitated at the two universities. At Oxford the High Church party was triumphant, and scarcely any in-

dividual ventured a whisper of opposition; but at Cambridge talents and ingenuity were exercised on both sides of the question. Paley favoured the claims of the reforming party; but, from motives of prudence, declined signing a petition for relief at that time drawn up; not entertaining such expectations of ultimate success as to be induced to take a public step so obnoxious to those on whom his future prospects depended. He told one of his friends in jest, that "he could not afford to keep a conscience;" a confession which will, no doubt, lay him open to the animadversions of those who reserve their censures for the subdued struggles of a mind of limited moral strength, while they excuse or applaud the oppressive system by which its efforts are overawed. Paley, however, soon after wielded his pen in a decided tone in the cause of freedom. Dr Law, the Bishop of Carlisle, published an able and moderate pamphlet against the imposition of the Church Test. An answer appeared at Oxford from the pen of Dr Randolph. To this Paley published, anonymously, a reply, entitled, *A Defence of the Considerations on the Propriety of the Church Test*.

His well merited reputation induced that great constitutional lawyer, the late Earl of Camden, to offer him the situation of tutor to his son, but his other engagements led him to decline the offer.

In 1775, he was inducted to the rectory of Musgrove in Westmoreland, worth about L. 80 a-year, presented to him by the Bishop of Carlisle. He now married Miss Hewit of Carlisle, and took a small farm to improve his income; a speculation which he soon after gave up as unproductive. Next year, he was inducted to the vicarage of Dalston in Cumberland.

In 1777, he was inducted to the vicarage of Appleby, worth about L. 200 a-year; and while in this situation he published a small volume, entitled, *The Clergyman's Companion in Visiting the Sick*; in which he both evinced his personal attention to the spiritual wants of his own flock, and conferred an obligation on his brethren, which has been acknowledged by the numerous and large editions which it has undergone. In June 1780, he was installed a prebendary of the fourth stall, in the Cathedral of Carlisle, worth about L. 400 a-year; and in August 1782, on the promotion of his friend Mr Law to the see of Clonfert, he was raised to the dignity of archdeacon of the diocese.

A report was long in circulation, that Mr Paley, being appointed to preach before the University of Cambridge when Mr Pitt made his first appearance at St Mary's after his elevation to the premiership, chose the following passage for his text: "There is a lad here who hath five barley loaves and two fishes, but what are they among so many?" That was not the fact; but the joke originated with Paley, who said to a friend that, had he been asked to preach on the occasion, he would have chosen this text.

Now in possession of a competent income, and sufficient leisure, he prepared for the press his great work *On the Principles of Moral and Political Philosophy*, which first appeared in 1785. In conse-

Paley.

quence of the well known merit of his lectures on the subject of that work, high expectations were formed of it; and his admirers were not disappointed. Its most obvious feature was that of being all directed to the practice of life in cases which hourly claim the attention of well meaning minds. Most other scientific works on morals were mere speculative treatises, which pleased the reader by unfolding the principles of right and wrong, in cases in which he has been previously satisfied about the practical rule and its application; while they embarrassed conscientious inquirers with hair-breadth distinctions, instead of conveying satisfactory principles. Dr Paley's work happily unites a due regard for practical duty with rational information on those points on which the mind is most anxious to obtain satisfaction. It soon established the reputation of its author. Some of his doctrines met with opposition; but he never was provoked to write any reply; and it is further remarked by his biographer, Mr Meadley, that, in the subsequent editions, he made no alterations materially affecting the sense. Had there been a few such alterations, however, he would have more fully merited the character of a liberal inquirer.— Among his elucidations of the foundations of virtue, he certainly fails in his definition of "the nature of obligation." He acknowledges that the subject had embarrassed his own mind; yet he ultimately reposes in a solution founded on a confusion of terms, which laid him fully open to the animadversions of the Reverend Mr Pearson, who published *An Examination of his Theory*. Dr Paley's doctrine is, that "a man is under moral obligation when he is urged by a violent motive resulting from the command of another." He thus resolves obligation into an effectual inducement. According to this statement, a man is under no moral obligation unless he feels, acknowledges, and acts upon it. Had such a hypothesis occurred in the writings of an author who made the purity of practice to depend on the reception of peculiar theories, it might have created great laxity of principle in the minds of some persons and distress in those of others. But his masterly elucidation of the rule of morals, and the paternal benignity with which his efforts are uniformly accompanied, set his reader at rest from all hurtful anxiety on practical topics.

His exposition of the rule of morals, as founded in utility, is ably managed. He demonstrates the superiority of this rule to every other, and the subordinate rank of all those mental suggestions and impressions, which some moralists have represented as essential parts of the foundation of morality. Many such feelings are valuable provisions of the Author of our nature; but they do not deserve the authority of guides. Their whole claim to our obedience is derived either from their coincidence with some express command of the Deity, or their conduciveness to utility. The difficulties attending inquiries into this conduciveness in particular instances do not generate uncertainties so great as those attached to the other supposed natural tests of moral truth. A man may be mistaken respecting the useful or hurtful *tendency* of a particular line of conduct; but he is equally liable to be led

Paley.

astray by feelings venerated as moral suggestions; and under that influence, he is deprived of an equal possibility of correcting himself by subsequent reflection. When authors declaim on the danger attached to the doctrine of utility, they borrow their arguments from that doctrine itself. They merely set up utility in its extensive application against such utilities as are partial and delusive. Dr Paley, therefore, dwells strongly on the necessity and importance of *general rules*; and by taking them for his guides, obviates all the serious objections brought against his leading theorem, "that the method of coming at the will of God concerning any action, by the light of nature, is to inquire into the tendency of that action to promote or diminish the general happiness."

On our duties to ourselves his observations are short, at which we cannot be surprised when we find that in his definition of virtue these duties are excluded. In the excellent casuistical *Observations on Self-Defence, Drunkenness, and Suicide*, of which this portion of his work entirely consists, he regards the tendency of personal conduct and habits only as they affect society around us. Had he paid more respect to the maxims of the stoical authors, and studied them in their most favourable meaning, he would have been more disposed to point out the importance of maintaining mental composure as an ultimate object of individual efforts. On our duties towards God he also treats briefly. The simplicity attached to our knowledge of their great Object divests them of variety as a separate subject, without detracting from their sublimity.

In the political part of this work, we find the exertions of a manly understanding employed with some success in exposing the dark bigotry and the gratuitous king-worship by which political knowledge had in past ages been disgraced. His efforts, however, are exempt from those headstrong tendencies which minds liberated from unfair control sometimes betray, to run into schemes incapable of being applied without compromising the happiness of society. That happiness he keeps steadily in view, as the only legitimate object of all government, as well as the only legitimate object of opposition to existing practices and institutions. Some of his admirers consider him as going too great lengths in vindicating the execution of a subscription to the Thirty-nine Articles. His chapter on subscription has been assailed with equal asperity by the strenuous adherents of the established church, and by the scrupulous advocates for Protestant freedom. His biographer, Mr Meadley, calls it "the last effort of an ingenious mind to soften, by interpretation, the rigour of a practice of which he could not seriously approve, and so to enlarge the pale of conformity to liberal and conscientious men."

The answer which he gives to the arguments for passive obedience as founded in Scripture is particularly worthy of attention. Through the whole he displays a candour of the most conciliating kind. None of his strictures on existing systems had the slightest tendency to give offence to any, except to persons actuated by downright prejudice, or the most corrupt motives.

Paley. On the death of Dr Law, Bishop of Carlisle, which happened in 1787; Mr Paley published a short *Memoir* of the life of that venerable prelate. Soon after he wrote two tracts in favour of "the abolition of the slave trade;" a subject on which he had expressed his sentiments with decision in his *Principles of Moral and Political Philosophy*, before it began to excite general interest.

In 1790 he published his *Horæ Paulinæ, or the Truth of the Scripture History of St Paul evinced, by a comparison of the Epistles which bear his name, with the Acts of the Apostles, and with one another*. The object was to show, by a copious selection of references and reciprocal allusions, the strong evidence of their genuineness derived from their undesigned coincidence. This able treatise possesses more novelty of interest, and greater originality of idea, than any of his other works.

During the political ferment which led to the French Revolution, Dr Paley published a short tract, entitled, *Reasons for Contentment, addressed to the Labouring Classes*; and he republished, in a separate form, his chapter *On the British Constitution*, from his *Principles of Moral and Political Philosophy*. He was censured by the violent partisans on both sides, as he went the full lengths of neither; but his style of reasoning had the best tendency to guide and satisfy those minds which were not obstinately and unreasonably prepossessed.

In May 1791, Mrs Paley died, leaving a family of four sons and four daughters.

Early in 1794 he published his *View of the Evidences of Christianity*. This work, with regard to manner and effect, follows a happy medium between that learned prolixity which deters the reader, or tires out his patience, and that abrupt brevity which is apt, with some minds, to beget an unfortunate impression of some imperfection in the argument. He contends for the substantial truth of the history connected with the Christian revelation; and, not undervaluing, as some have injudiciously done, the internal evidences, he exhibits, in primitive simplicity, and without the least oratorical exaggeration, the superlative value of those doctrines in which all Christians are agreed, and gives an animated view of the morality of the gospel. The work, considered as addressed to doubting minds, was well fitted to interest the attention of all who are duly impressed with the importance of the question at issue.

Hitherto his preferment in the church had been slender, considering his singular merit and the opulence of the ecclesiastical establishment. The boldness of his reasonings on political subjects had given deep dissatisfaction. To the favourers of power, it was not welcome doctrine, that "governments may be too secure;" that "the obligations of subjects and sovereigns are reciprocal;" and "that the divine right of Kings rests on the same foundation with the divine right of Constables." But when he stood forth as the successful defender of the Christian revelation, at a time when the interests of the church were supposed to be in danger, his services met with more marked attention. Dr Porteus, Bishop of London, conferred on him the desirable situation of prebend of St Pancras in the cathedral of St Paul's, to which he was in-

stituted in August 1794. He was in a few months after promoted to the sub-deanery of Lincoln by Dr Prettyman, Bishop of that diocese, and took his degree of D. D. at Cambridge.

Before leaving this place, he had the agreeable surprise of a letter from Dr Barrington, Bishop of Durham, offering him the valuable rectory of Bishop-Wearmouth, worth about £. 1200 a-year, into which he was soon inducted. A few months after he married Miss Dobinson of Carlisle, and, from this period to his death, divided his time between Bishop-Wearmouth and Lincoln; being obliged to reside three months in the year at the latter place. Now that he enjoyed a handsome independence, we find his company courted by many distinguished characters, and his life spent in a series of the most useful labours, while all his secular transactions were so well conducted, as to shed a lustre on his character, and to exhibit a most instructive example to all around him. Both his parents lived to witness his high reputation and success in life. His mother died in 1796, and his father in 1799.

In 1800, Dr Paley was attacked by a disease in the kidneys, accompanied with a species of melæna, which obliged him to suspend the discharge of his professional duties. He had a second attack in the following spring, and a third about the end of 1802.

During the progress of this fatal disease, he was engaged in preparing for the press his last important work *On Natural Theology*. His literary labours were frequently interrupted by severe paroxysms of pain, but on the first respite, he always resumed them with cheerfulness. Under these circumstances, he wrote his excellent remarks on the alleviations of pain, in his chapter *On the Goodness of the Deity*.—This work had been undertaken at the suggestion of the Bishop of Durham, that he might, by theological exertions in his closet, make up for the unavoidable suspension of his public ecclesiastical labours. In none of his writings does his candour appear to such incontestible advantage as in this. We never find him brow-beating the adversary, or attempting to push his conclusions a single step farther than his premises evidently warrant. We do not find him with many others advancing the metaphysical position, "that every thing which exists must have a cause," so glaringly open to the query, "why should the world have a cause more than its Creator?" Mere existence cannot authorize the inference of owing that existence to a higher source. He rests his argument on far better ground,—the character of the fabric of nature, or rather of various objects in it which offer themselves to our observation. Nor does he, with some, assume the doctrine, that matter is essentially inert, and that, therefore, its motions must be induced by an extraneous and spiritual cause. He more wisely turns his attention to the proofs of *design* which so many objects in the world exhibit. These are so selected and arranged, as to appear in the most interesting and satisfactory point of view. Where the phenomena are apparently inconsistent, we find no straining to reconcile them; no reluctance to take a full view of unfavourable appearances; no inclination to draw the same inferences from opposite facts. His argument is not

Paley  
||  
Pallas.

suspended on a chain of metaphysical reasoning, which would have subjected it to the risk of destruction as soon as one of the links gives way. He directs the attention of his reader to numerous columnar supports of the existence of a God, each of which is adequate to the whole office. Each instance adduced is decisive of the point at issue; and though his instances are numerous as well as beautiful, they are evidently only partial exemplifications of a species of evidence which is boundless in extent.

In the present state of the learned world, this is the most important of Dr Paley's works; as possessing the best tendency to reclaim persons wandering in the mazes of scepticism to that state of thought which is most favourable to the true improvement of the human character; and to the establishment of that state of mental peace after which a sense of our weakness naturally leads us to aspire.

After its publication, Dr Paley continued to take a lively interest in the literary and scientific discussions of the day; especially such as bore directly on the great interests of society; but in May 1805, he was subjected to a violent attack of his complaint, in which all remedies proved ineffectual; and, with great tranquillity, he breathed his last at Bishop-Wearmouth, leaving a family of four sons and four daughters in possession of a competent fortune, saved by a systematic, though by no means a niggardly economy.

He wrote several sermons and other minor productions, less known than those above enumerated. They are all collected in a uniform edition of his works, and will be found, on examination, worthy of his fame, and successfully directed to the same valuable ends with his more celebrated productions.

(R. R.)

PALLAS (SIMON PETER), a distinguished naturalist and geographer, born 22d September 1741, was the son of Simon Pallas, a surgeon in the Prussian army, and Professor of Surgery at Berlin.

He received the early part of his education in his father's house, and his instructors bore ample testimony to the rapidity of his progress. At the age of fifteen he began to attend medical lectures, and he applied so closely to practical anatomy, that in 1758 he was found qualified to deliver a course of public lectures on that science. In the same year he went to Halle, and became the pupil of Segner, continuing also his studies of zoology, and in particular of entomology, with great assiduity. In 1759 he removed to Gottingen, where he made a variety of experiments on poisons, and on other active medical substances, and commenced his observations on parasitical animals. In July 1760 he went on to Leyden, in order to attend the lectures of Albinus, Gaubius, and Musschenbroek, and at the end of the same year he took his degree of Doctor of Physic. The following summer he proceeded to England, principally with the view of completing his medical education, although he devoted the greater part of his time to the active pursuit of natural history, being assisted and encouraged by the friendship of Peter Collinson, and of some other British naturalists, which procured for him a few years afterwards the distinction of having his name inserted in the list of the Foreign Members of the Royal Society, at the early age of

twenty three. He visited several parts of the coast of England, in order to examine its marine productions, and his love of natural history enabled him to profit in a similar manner by an accident which detained him some time at Harwich, on his return to the Continent, in the spring of 1762.

Having paid a visit to his native city, he went again to the Hague, and established himself as a resident there under the patronage of Gaubius. On occasion of the publication of a miscellaneous work on zoology, which he dedicated to the Prince of Orange, he proposed a plan for an expedition to the Cape of Good Hope, and to the Dutch East Indies, which he offered to conduct in person; but although the project was encouraged by Gaubius, and approved by the Prince, his father's interference prevented its execution, and obliged him to return to Berlin. His filial affection, however, was not strong enough to induce him to refuse the invitation of the Empress Catharine to Petersburg, where he accepted, in the year 1767, the appointment of Professor of Natural History in the Imperial Academy of Sciences.

The first few months of his residence at St Petersburg were employed in preparing his *Zoological Gleanings* for publication, and in making catalogues of some collections of natural history. It was now that the more active career of his public life was about to commence, and in 1768 he undertook, in common with Falk, Lepcehin, and Guldenstädt, the conduct of an expedition sent out by the Empress for the joint purposes of observing the transit of Venus, and of investigating the natural history and geography of Siberia, and the neighbouring countries. The object of their researches for the first summer was the province of Kasan, and the winter was passed at Simbirsk; the next year they examined the shores of the Caspian, and the borders of Calmuc Tartary; they returned through Orenburg, and passed the winter at Ufa. In 1770 Pallas crossed the Uralian mountains to Catharinenburg, and, after examining the mines in that neighbourhood, proceeded to Tobolsk. The next year he went to the Altaic mountains, traced the course of the Irtish to Kolyvan, went on to Tomsk, and observed the natural freezing of quicksilver at Krasnoyarsk, on the Yenisei, in latitude 56 $\frac{1}{2}$ <sup>o</sup> north. He proceeded in March 1772 by Irkutsk across the Lake Baikal, as far as Kiatka, and returned to Krasnoyarsk. In 1773 he visited Tara, Astracan, and Tzaritzin, on the Volga, and returned to St Petersburg in 1774, after an absence of six years. About ten years later he was made a member of the Board of Mines, with an additional salary of L. 200 a year, and he was complimented with the title of a Knight of St Vlodymir. The Empress purchased his collection of natural history for a price one third greater than his demand, and allowed him, at the same time, to keep it in his possession for the remainder of his life.

In 1794 he took a journey into the Crimea, and was captivated with the beauty of the country and its productions; the climate also appearing to be such as his health was supposed to require, he obtained from his munificent patroness not only permission to establish himself there, but a grant of a large and fertile estate, and a sum of 10,000 rubles

Pallas. to assist him in his outfit. He was thus enabled to build a little palace, rather than a country house, in which a traveller from the North of Europe was sure to receive the most obliging hospitality, as Dr Clarke has made well known to the English reader. It appears, however, that the air was not altogether exempt from the miasmata, which are the causes of paludal fevers; and some other circumstances, besides the distance from all civilized society, seem to have made the old age of Pallas more cheerless than he had anticipated to find it, in the independence and tranquillity of his patriarchal establishment at Akmetshet. About ten years after the period of Dr Clarke's travels, he undertook a journey to Berlin to pay a visit to his brother, and died there in September 1811.

Linné the younger has given him a genus, *Pallasia*, in his *Supplementum Plantarum*; a compliment to which his unremitting labours, in every department of natural history, had amply entitled him. His collection of dried plants was purchased by Dr Clarke's fellow traveller, Mr Cripps, and is now in the possession of Mr Aylmer Bourke Lambert.

The general character of Professor Pallas's acquirements appears to have been that of extent and variety, together with fidelity. He was not the author of any new theories, or improved systems; and it has sometimes been observed, as by Murray in his *System of Vegetables*, that his descriptions were somewhat defective from the omission of correct specific distinctions; but this omission is of such a nature as to affect a compiler, or a book-maker, more than an actual student of natural history, who is studying for his own improvement only, and who is capable of entering into a detailed examination of the objects concerned. To such a detail the principal part of Professor Pallas's works have related; and it is impossible to enumerate the whole of his memoirs without making a pretty extensive catalogue of the productions of the various kingdoms of nature.

1. His *Dissertatio Inauguralis de Infestis Viventibus intra Viventia*, 4. Leyd. 1760; containing a systematic account of intestinal worms, is said to have been previously published in another form at Gottingen, a short time before he went to Leyden. 2. We find in the *Philosophical Transactions* for 1763, p. 62, a short note *On the Cold observed at Berlin* the preceding winter. 3. In the volume for 1766, p. 186, a description of the jaculator fish, or *Sciaena jaculatrix* of the Indian Ocean, which catches insects by darting drops of water at them; this description is repeated in the *Spicilegia Zoologica*, Fasc. 8. 4. *Elenchus Zoophytorum*, 8. Hague, 1766; containing near three hundred species; *Dutch* by Boddaert, with figures, 8. Utrecht, 1768. 5. *Miscellanea Zoologica*, 4. Hague, 1766; consisting of descriptions and dissections. 6. *Spicilegia Zoologica*, 4. Berl. 1767-1780. Of this valuable collection of memoirs, intended for the description and illustration of new or little known species of animals, there appeared in the whole 14 fasciculi; some of them were published by Professor Martin, during the author's absence in Siberia. We find, among other articles, an interesting account of the *musk deer*, of various species of the *antelope*, and on the different varieties of *sheep*, both wild and tame; the latter has been published in Eng-

lish; *On Russian and Tartar Sheep*, 8. Edinb. 1794. 7. In the *N. Act. Acad. Nat. Cur.* III. p. 430, *Phalaenarum biga*; an account of two species of moth, of which the females are without wings, and spontaneously fertile. 8. A variety of miscellaneous papers, by Pallas, appeared in the *Stralsund Magazine* which began to be published at Berlin in 1767; they chiefly relate to the *Winter Residence of Swallows*, Vol. I. p. 20; to *Hydatids* found in the abdomen of ruminant animals, and supposed to be a species of *tænia*, p. 64; to the *Birds of Passage of Siberia*, p. 145; from Heller's *Notes*; to Firmii's supposed discovery of the *Origin of the Belemnite*, p. 192; to some *Peculiarities of Insects*, p. 225; to a *Poison* supposed to be prepared in Siberia from the *Sitta* or nuthatch, p. 311; to the *Elk or Moose Deer*, p. 382, from Heller's papers; and to the use of the *Sphondylium* in Kamtshatka, p. 411. 9. *Collections relating to the Mongol Tribes*, published in 1776, and showing that they are distinct from the Tartars.

10. Professor Pallas's contributions to the *Memoirs* of the Imperial Academy of St Petersburg are also very numerous, and on miscellaneous subjects. In the *Novi Commentarii* we find an account of the *Tubularia Fungosa*, Vol. XII., observed near Woldemir; *Lepus pusillus*, and *Fossil Bones of Siberia*, Vol. XIII.; *Quadrupeds and Birds observed in 1769*, Vol. XIV. i.; *Remains of Exotic Animals in Northern Asia*, Vol. XVIII., especially the skulls of the rhinoceros and the buffalo; *Tetrao arenaria*, *Equus hemionus*, and *Lacerta apoda*, Vol. XIX.; the last also in *Geneesk. Jaerboek*. II. In the *Acta* for 1777, ii., *An Account of the Teeth of an Unknown Animal*, like those which have been found in Canada; *Observations*, from Camper's Letters, on a *Myrmecophaga*, and a *Didelphis*; and *Equus asinus*, in the wild state. In the volume for 1779, ii., a *Description of Plants peculiar to Siberia*; *Capra Caucasica*, also in Lichtenberg's *Magazin*, II. For 1780, Part i., *Galeopithecus vitans*; Part ii. *On the Variations of Animals*; and *Didelphis brachyura*. For 1781, Part i., *Felis manul*, a new Asiatic species of Felis; ii., *On some Species of Sorex*. In the volume for 1783, *New Species of Fishes*; and 1784, *On some new Marine Productions*.

11. The *Observations sur la Formation des Montagnes, et les Changemens arrivés au Globe, particulièrement à l'égard de l'Empire Russe*, published separately, 4. Petersb. 1777, were also inserted in the *Acta* of the Academy for 1777, having been read at a public sitting before the King of Sweden. A translation of this discourse is inserted in Tooke's *Russian Empire*, and some remarks on it are found in the *Journal de Physique*, Vol. XIII.

12. The most considerable of the separate publications of Pallas was the account of his travels, entitled *Reise durch verschiedene provinzen des Russischen Reichs*, 3 vols. 4. Petersburg, 1771-3-6; *French*, 8vo, 8. Par. 1803; *English*, 2 v. 4. London, 1812; a work of the highest authority in geography and natural history. 13. It was in the course of these travels that Pallas observed in Siberia an insulated mass of *native iron*, which he described in a paper, addressed to the Royal Society of London, and printed in the *Philosophical Transactions* for 1776, p. 523; a substance which has become the

Pallas  
||  
Panorama.

subject of many discussions, from its resemblance to some of the specimens of well ascertained aerolites: the author mentions also the remains of an unmineralised rhinoceros, which had been found in the same country.

14. In the *Beschäftigungen Naturforschenden Freunden*, published at Berlin about 1777, we find a letter on the *Acipenser ruthenus*, or *Sturgeon*, Vol. II. p. 532, and *An Account of a Monstrous Horse*, Vol. III. p. 226. 15. Some *Mineralogical Observations*, addressed to Born, are published in the *Böhmische Abhandlungen*, Vol. III. p. 191. 16. In the Swedish *Handlingar* for 1778, we have the *Alanda Mongolica*, and the *Sturnus Daauricus*; the *Anas glaucans*, in 1779.

17. *Novæ species Glirium*, 4. Erlang. 1778. 18. *Icones Insectorum, præsertim Rossicæ Sibiricæque*, 4. Erlang. 1781. 19. *Enumeratio Plantarum Procopii a Demidoff*, 8. Petersb. 1781.

20. Another channel, in which a number of Pallas's most valuable essays appeared, is the work entitled *Neue Nordische Beyträge*, which he published at St Petersburg and Leipzig, in 1781 and the following years. The most remarkable of the subjects of these are, *A great Exotic Animal found in Kasan in the year 1776*; *On the Migration of the Water Rat on the Volga*, and *Observations on Tania*, Vol. I.; *Further Remarks on Tania*; *On American Monkeys, bred at St Petersburg*; *On the Ardea helias*; *On the Culex lanio, sometimes fatal to Cattle*; *On the Phalangium, or Scorpion Spider*; and *On Copper Island, in the Sea of Kamtschatka*, Vol. II.; *On Two Birds*; and, *On the Labrador Stone*, Vol. III.; *On a Cross of the Black Wolf with the Dog*; *On a Mine*; *On the Oriental Turquois*; and, *Mineralogical Novelties from Siberia*, Vol. V.

21. In the *Physische Arbeiten* of Vienna, we have a geological *Essay on the Orography of Siberia*, Vol. I. i.

22. *Flora Rossica*, f. Vol. I. Petersb. 1784; II. 1788, published at the expense of the Empress.

23. *Tableau Physique et Topographique de la Tauride*, 4. Petersb. 1795; German in *N. N. Beyträge*, VII. A work derived chiefly from the observations made by the author in his travels of 1792.

24. A *Monography of the Astragali* is mentioned by some of his biographers.

25. He edited also Guldenstädt's *Reisen durch Russland und in den Caucasischen gebirgen*, 2. v. 4. Petersb. 1787-1791. 26. He also compiled and arranged the two first and most valuable of the four volumes of the *Vocabularia Comparativa*, 4. Petersb. 1787; in which he attempted to make some improvements in the Russian orthography. See LAN-  
GUAGES.

[*Coxe's Travels*; *Clarke's Travels*; *Tooke's Russian Empire*; *Halleri Bibliotheca Anatomica*; *Aikin's General Biography*, Vol. X. 4. Lond. 1815. *Chalmers's Biographical Dictionary*, Vol. XXIII. 8. Lond. 1815. *Dryander, Bibliotheca Banksiana.*]

(I. S.)

PANORAMA.—A Panorama is a picture drawn on the interior surface of a large cylinder, representing the objects that can be seen from one station, when the observer directs his eye successively to every point of the horizon. A picture drawn on a vertical plane in the usual way includes

only that portion of the sphere of vision that can be seen from one point opposite to the picture, without turning the eye; this portion may comprehend about 60 degrees of the horizon. There are compositions, comprehending the visible hemisphere, and sometimes nearly the whole sphere of vision; in these compositions, one connected scene is represented on the interior surfaces of a polyhedron, or of a curved solid, the point of sight being in the centre of the polyhedron, and the eye being turned round on its centre, to each of the surfaces, in order to view the whole scene. Of this kind are the gnomonic projection of the sphere on the interior surfaces of a cube, and several pictures, in which one connected subject is represented on the ceiling and the sides of a room; such as the picture of Jupiter fulminating the Giants, by Julio Romano, on the walls and hemispherical ceiling of a round room in the Palazzo del T, at Mantua; or the architectural representations and ornaments in Raphael's loggia in the Vatican. Objects are also sometimes projected on the interior surface of a sphere, the eye being placed in the centre; as in a large hollow sphere with the constellations, which was constructed at Pembroke College, Cambridge. These projections, where the eye, remaining in the point of sight, is turned round on its centre to view the different parts of the picture, are formed on the same principle as the panorama.

The cylindrical surface is the most convenient for panoramas of landscapes; and the specific employment of a large cylindrical surface for representing the landscape of the whole circle of the horizon, is the invention of Mr Barker, who brought the panorama into use, and still continues to exercise his art. The cylinder on which the panorama is painted is commonly about 60 feet in diameter. The projection or perspective of a panorama is formed by imaginary lines drawn from different points of the surrounding objects, to the point of sight in the axis of the cylinder. The intersections of these lines with the cylindrical surface form the corresponding points in the panoramic picture. Where the picture is projected on a plane, as in common perspective, and in the gnomonic projection of the sphere, the cones formed by imaginary lines or rays passing from the point of sight to the different objects, are cut by the plane of the picture; consequently, the sections being formed by a plane, are curves, of which the curvature is always simple. In the perspective of the panorama, where the picture consists of the intersection of the cones of rays by a cylinder, these intersections are, in many of the cases, doubly curved curves. When the picture of a straight line, which is neither parallel to the horizon nor to the axis of the cylinder, is drawn on the cylinder of the panorama, the picture of the line is part of an ellipse, because the oblique section of a right cylinder, by a plane passing through the axis, is an ellipse; when the cylinder is developed and unrolled on a plane surface, this ellipse becomes the curve called the sinical curve. The projection of lines on the interior surface of a cylinder is also employed in drawing Mercator's charts. But in the projection of the panorama, the field extends only a few degrees above and below the horizon, whereas, in the projections

panorama of the sphere, the field extends many degrees on each side of the plane, which is at right angles to the axis of the cylinder. In drawing a panorama, as well as in drawing a picture on a plane, the horizontal angles between different objects may be observed by a plane table or theodolite; and the elevation of the objects above the horizon, or their depression, may also be observed by the theodolite: the horizontal angles are to be laid down by setting off on the graduated horizon of the cylindrical picture the number of degrees observed; the vertical angles on the cylinder are the tangents of the angles observed, the radius being the semidiameter of the cylinder.

(Y.)

PANTOGRAPH, an instrument contrived for the purpose of copying drawings, so that the copy may either be of the same size, of a greater, or of a less size than the original. It consists of four moveable rulers fixed together by four pivots, and forming a parallelogram. At the extremity of one of these rulers prolonged is a point, which is drawn over the lines of the original drawing, whilst a pencil, fixed at the end of another branch of the instrument, traces on paper the lines of the copy. The pencil is placed in a hollow cylinder, and a weight is added on the top of the pencil; by this means, the point of the pencil is made to press on the paper with the force requisite for drawing the lines. The improvements in the construction of different parts of the pantograph described in the *Memoires de l'Academie des Sciences*, 1743, have been generally adopted. The pantograph, however, is not found convenient in practice; and, for the purpose of copying maps, plans, and other designs, artists most commonly employ the method of dividing the original design into a number of squares, and the paper on which the copy is to be made into the same number of squares. When this is done, they copy the lines contained within each square of the original, so as to form a similar figure within the corresponding square of a reticula which covers the copy. When the drawing consists of straight lines, a reduced copy is accurately made by means of an isosceles triangle, in which the base is to the side as any line of the copy is to the corresponding line in the original. By setting off with the compasses any line of the original drawing on the sides of the triangle, the base which completes the triangle is the length of the corresponding line to be laid down on the copy. The same operation is performed by the sector.

If a drawing is to be copied, of the same size as the original, without diminution or enlargement, engravers usually trace the copy on oiled paper laid over the original, or on the transparent *papier de guimauve* (marsh-mallow paper), made in France.

A pantograph has been made, consisting of a rod, placed vertically, and turning round a fixed point in its length, situated between its upper and lower extremity: the upper end of the rod being a point which is conducted by the hand over the lines of the original drawing; the lower end of the rod being the pencil which traces the copy on paper. An instrument upon this principle is sometimes used for drawing the profile of the face, in order to form small portraits or silhouettes.

The instrument called Micrograph and Prosopa-

graph in Puissant's *Geodesie*, does not differ in principle from the common pantograph.

(Y.)

A very ingenious instrument for copying drawings, either upon a reduced or enlarged scale, has been lately invented by Mr Wallace, Professor of Mathematics in the University of Edinburgh. Of this instrument, which may be fitly introduced under the present head, though differing in name, we have been favoured with the following description.

It is a fact well known, that artists of various descriptions, who have frequent occasion to imitate original designs, have long felt the want of a convenient mathematical instrument, by which a copy may be made with neatness and expedition, that shall have any given proportion to the original. The *Pantograph* is the only instrument that has been hitherto employed; but although correct and plausible in theory, in practice it is found to be so very imperfect, that the artist hardly ever thinks of making use of it.

A consideration of the essential service that would be rendered to the graphic art, by a copying instrument, which should be at once simple in its theory and easy in its application, induced Mr Wallace to turn his attention to the subject; and, in the summer of 1821, he produced the model of a copying instrument, which he has denominated an EIDOGRAPH (from *ειδος* and *γράφω*). The instrument, and its application to the copying of a great variety of subjects, has been shown to engineers, engravers, and other competent judges in London and in Edinburgh, and their opinion of its utility has been such as to leave no doubt of its completely fulfilling the views of the inventor.

The instrument is represented in this figure:

Pantograph  
||  
Park.

The *beam*, A B, which is made of mahogany, slides backward and forward in a *socket*, C: the socket turns on a vertical axis, supported by the *fulcrum* D, which stands on a table. There is a slit in the beam, through which the axis of the socket passes, so that, when the beam slides in the socket, a portion of it passes on each side of the axis. There are two equal wheels, E, E, below the beam, which turn on axes that pass through pipes fixed at A, B, near its extremities; and a steel chain passes over the wheels as a band, by which a motion of rotation may be communicated from the one to the other. There are two *arms*, F, F, which slide in sockets along the lower face of the wheels, just under their centres: at the extremity, G, of one arm, there is a metal *tracer*, with a handle attached to it, by which its point may be carried over the lines in any design; and at H, the extremity of the other arm, there is a black-lead *pencil* fixed in a metal tube, which is ground to fit so exactly into a pipe, as just to slide up or down. In using the instrument, the pencil, in its tube, is raised by a thread which passes over a pulley, and it descends again by a weight with which it is loaded.

From the perfect equality of the wheels, it is easy to see that, if the arms attached to them be placed parallel in any one position, they will retain their parallelism, although one of the wheels, and consequently both, be turned on their centres. Supposing, now, that BC and AC, the parts into which the axis is divided at the centre, have any proportion whatever to each other, if the distances of the tracing point G, and pencil point H, from the centres of their wheels have the very same proportion, then it follows, from the elements of geometry, that the tracing point G, the centre C, and the pencil point H, will be in a straight line; and further, that C G and C H, the distance of these points from the centre, will have to each other the constant proportion of C B to C A, or of E G to A H. Such being the geometrical property of the *Eidograph*, if any subject to be copied be fixed to the table on which the instrument stands, and the tracing point be carried over every line of the design, the pencil point will trace a copy in all respects similar to the original. To facilitate the adjustment of the instrument, so that the copy may have any given ratio to the original, there are scales of equal parts on the beam and the two arms: By these and verniers, both halves of the beam, and equal lengths on the arms, are each divided into 1000 equal parts, and at certain intervals corresponding numbers are marked on them. By means of the scales, when any ratio is assigned, the adjustment is made without the least difficulty.

To avoid any derangement by the chain slipping on the wheels, there are *clamps* at K and K, which hold it fast to the wheels at points where it never quits them. They are slackened when the instrument is adjusted.

The inventor has committed its construction to Mr R. B. Bate, philosophical instrument-maker, Poultry, London, from whom it may be obtained.

PARK (MUNGO), the most illustrious traveller of the present age, was born at Fowlshiels, near Sel-

kirk, upon the 10th of September 1771. His father occupied the farm of Fowlshiels, under the Duke of Buccleugh. He appears to have bestowed uncommon attention on the education of his children. He even employed a tutor to reside in his house, an expence which then especially was supposed to exceed the resources of an ordinary farmer. Young Park made a good figure at school. His general demeanour was reserved and thoughtful; yet occasional sparks of ambition broke forth, indicative of that adventurous spirit which lay concealed under a somewhat cold exterior. This thoughtful disposition led his friends to consider the church as the profession best suited to his character; but as he himself preferred the medical line, his wishes were acquiesced in; and he spent three years at the University of Edinburgh, in the studies necessary to that profession.

At Edinburgh, Park studied with ardour and success; and he in particular imbibed a fondness for botany, which served strongly to give the colour to his future life. It strengthened his natural connection with his brother-in-law, Mr James Dickson, who, notwithstanding many disadvantages, attained such skill in that science, that, on going as a gardener to Hammersmith, he obtained a large share of the patronage and favour of Sir Joseph Banks. This connection induced Mr Park to repair to London. He was introduced to Sir Joseph, who was so much pleased with him, that he obtained for him the appointment of assistant-surgeon to the Worcester East Indiaman. In this capacity Mr Park made a voyage to Bencoolen, where he made some collections and observations in botany and natural history, which were submitted to the Linnean Society, and an account of them printed in the third volume of their *Transactions*.

The African Association were now anxiously looking for a successor to Major Houghton, their unfortunate missionary, who had perished in the attempt to penetrate to the Niger and Tombuctoo. This opening, though foreign to any of Mr Park's former pursuits, except that of natural history, was immediately embraced by him with an ardour which showed how congenial it was to the character of his mind. Without hesitation, he offered himself for this arduous and perilous service, and being supported by the recommendation of Sir Joseph Banks, was at once accepted.

Park spent about two years in and near London, acquiring the qualifications necessary for his mission. In May 1795 he set sail, and on the 21st of June following arrived at Jillifree, near the mouth of the Gambia. After spending some months with Dr Laidley at Pisania, in acquiring the Mandingo language, he, on the 2d December 1795, departed on his grand expedition. It would be very superfluous to enter here into a detail of events so generally known, and which excited so deep an interest, as his captivity among the Moors—his almost miraculous escape—his discovery of the course of the Niger—of the African capital of Sego—his journey through Bambarra, and the train of peril and difficulty through which he effected his return. He arrived, after the length of his absence, and the

Park.

Park.

want of intelligence respecting him, had nearly extinguished all hopes of his safety. Reaching London early in the morning of Christmas 1797, he went to pass the time before breakfast in the gardens of the British Museum, where, by a singular chance, he met Mr Dickson, who embraced his friend as one returned from the grave. An extraordinary interest in his adventures was immediately excited among the African Institution, its friends, and the public in general. Major Rennell drew up an important Memoir, showing the new light thrown by his journey upon African geography, which, with an abstract of his Narrative, by Mr Bryan Edwards, was speedily offered to satisfy the curiosity of the public. In the spring of 1799 Mr Park presented the public with a full Narrative from his own pen. Major Rennell's Memoir was appended, and a considerable part of Mr Edwards's abstract was incorporated *verbatim*; upon which circumstance alone seems to have been built the rumour of that gentleman having been the actual writer of the volume. The work was read with an avidity proportioned to the novelty and importance of the information contained in it, and to the interesting and agreeable manner in which the events were narrated.

Having finished this task, Mr Park seems to have resolved to retire into domestic and professional life. In 1799, he married Miss Anderson of Selkirk, daughter of the gentleman with whom he had served his apprenticeship as a surgeon. In October 1801, he embraced an opportunity which offered of commencing a professional career at Peebles, and soon found himself in respectable practice. His situation seemed now sufficiently comfortable, being happy in domestic life, possessed of competence, and surrounded by a respectable society; but his active mind was not to be so satisfied, and was secretly panting after a higher sphere of exertion.

Important as were his discoveries, their effect had been, not to satisfy, but to excite still farther, the public curiosity. The course of the Niger through the unknown and central parts of the continent could not fail to excite peculiar interest. This was strongly felt, not only by the scientific world, but by some intelligent members of administration, who, on the conclusion of the peace in 1801, determined to fit out an expedition on a great scale to effect the discovery of the termination of this great river. In autumn 1803, Lord Hobart, now Earl of Buckinghamshire, who was then Colonial Secretary, offered the command of it to Mr Park, who, though he asked a short interval to consult his friends, seems never in his own mind to have hesitated as to its acceptance. To those who represented to him the dangers to be incurred, he urged, that the hardships attendant on the

Park.

obscure exercise of his profession, his journeys to distant patients, his long and solitary rides over "cold and lonely heaths," and over "gloomy hills, assailed by the wintry tempest," would tend as effectually to shorten life as the journey now in contemplation.

Mr Park, in this new undertaking, was amply supplied with every thing which could ensure success. Thirty soldiers, and nearly the same number of carpenters and artificers, were placed under his command; arms, beasts of burden, commodities to trade with, were amply supplied; and he was empowered to draw upon the Treasury to the extent of L. 5000. Every thing, therefore, seemed to augur a still more brilliant issue to his present than to his former journey. But a dark destiny impended over it, and rendered abortive all human means and efforts.

It would be superfluous to enter into a detail of that afflicting train of events, with which the public are already but too well acquainted.\* That Park perished in his voyage down the Niger, may be now considered as fully established; and we need not swell our pages with the rumours that have been circulated respecting an event no longer doubtful.

Park has been pronounced by some the first of modern travellers, and he does not seem unworthy of that high appellation. The problem of the course of the Niger, which he had the fortune to solve, was one which had involved in error almost all former geographical systems on Africa. D'Anville, indeed, had stated it correctly; but as he had not communicated the grounds upon which his conclusion rested, the opposite opinion, which represented the Niger as flowing westward, and joining the ocean by the channel of the Senegal, continued still prevalent. This point, finally decided, fixed the geographical character of the continent. In Bambarra, also, a name as yet scarcely heard of by Europeans, Park found a kingdom much farther advanced in populousness and civilization than was yet supposed to exist in the heart of Africa.

Mr Park's literary, though not equal to his active qualifications, were yet respectable. Notwithstanding his knowledge of botany, he cannot be considered as a scientific traveller. We see not in him that varied and splendid science which, in Humboldt, illustrates and adorns, though it sometimes overlays the main subject. But with regard to the general aspect of nature, and the forms of human society, his observations are careful, accurate, and judicious. Nothing can be more lively than the idea which we receive from him of the African forests and deserts, the cities of Bambarra, the stream of the Niger, and the regions watered by it. The spirit, joined to the unpretending simplicity of his narrative, has rendered

\* The Narrative of this journey was published in 1815, in 4to, with a very interesting biographical Memoir and Preface, by Mr Wishaw. It may not be amiss to notice here a singular oversight in Park's Journal, lately observed by M. Walckenaer. A 31st day is counted in April (p. 7); and as all the days before and after are accounted for, there can be no doubt that all the following dates are one day behind. This, as Mr Bowdich has shown, is not so trifling an error as it at first sight appears; for a false declination being thus taken, an error, greater or less, and sometimes not inconsiderable, is committed in the calculation of all the subsequent latitudes.

Park  
||  
Pauw.

his work one of the most popular of its kind in the English language.

Mr Park's bodily frame was well fitted for the arduous enterprises which he undertook. He was six feet high, his limbs well proportioned, and his whole frame active and robust. His countenance was prepossessing, and his manners retained always their native plainness and simplicity. This was combined with a natural coldness and reserve, which rendered his conversation less interesting than was expected by those who considered his general talents and extensive opportunities of observation. His conduct in all the relations of private life was highly exemplary. He left a widow, three sons, and a daughter.

(B.)

PAUW (CORNELIUS DE, sometimes called NICOLAS), a moral philosopher and historian, born at Amsterdam in 1739, is better known as the uncle of the revolutionist Anacharsis Cloutz, than by the ancestors from whom he was descended: they are, however, reported by his nephew to have distinguished themselves in the revolutions of Holland in the sixteenth century.

It appears, upon the same authority, that his name was Cornelius, and not Nicolas, but that he was not related to Cornelius de Pauw, the critic, and the rival of Dorville; and that it was upon the marriage of his sister to Cloutz's father, that he obtained, through the interest of his brother in law, a Catholic canonicate at Xanten, in the territory of Cleves. He was afterwards appointed reader to Frederic King of Prussia, perhaps as an advocate of the new doctrines and principles which that sovereign was disposed to patronise; but he is said to have declined the offer of the place of an academician of Berlin, and a bishopric at Breslau. His attacks on the Jesuits, whom he accused of gross misrepresentation and exaggeration in their historical and geographical memoirs, made him unpopular with the Catholic clergy, though his learning and talents commanded a certain portion of their respect. He was simple in his manners, and somewhat negligent of his appearance; the close of his life was embittered by a tedious and painful disease, and he died the 7th of July 1799.

1. His principal publications are his *Recherches sur les Américains*, 2 v. 8. Berl. 1770; ed. 2, 1772; a work intended to show the "degraded state of the savage Americans," and forming a contrast to the speculations of some contemporary writers of celebrity. 2. *Défense des Recherches*, 8. Berl. 1771.

3. *Recherches sur les Egyptiens et les Chinois*, 2 v. 8. Berl. 1773. *Philosophical Dissertations on the Egyptians and Chinese*, translated by Captain J. Thomson, 2 v. 8. London, 1795. The investigation was undertaken, he observes, to show that "no two nations ever resembled each other less than the Egyptians and the Chinese;" and it must be admitted that he has sufficiently established his proposition. There is, indeed, one argument that he has employed, which appears to be founded on a mistake of the Greek historians of Egypt, who have asserted that the Egyptians had long been in the use of alphabetical characters; and the want of any alphabet among the Chinese, is stated by M. de

Pauw as affording a marked distinction from the Egyptians. There is, however, scarcely a shadow of resemblance in the particular hieroglyphical characters employed by the two nations, though the general system of beginning with a representation of a visible object, and departing, more and more, by degrees, from the fidelity of the delineation, must necessarily have been common to both. But it so happens, that out of about 70 Egyptian characters, which are compared by the Jesuits and Dr Morton with the Chinese in the *Philosophical Transactions* for 1769, there are about 20 of which the sense has been ascertained with tolerable accuracy in the Article EGYPT of this *Supplement*; and of these there is only one that happens to have been rightly determined by the comparison with the Chinese, excepting two or three which are obviously mere pictures, as the Moon and a Bow. There is also a figure of a chain, among the old Chinese characters, which agrees remarkably in its form with the Egyptian hieroglyphic employed as a copulative conjunction; and there is a still more striking coincidence, which M. Jomard has noticed, between the Egyptian and Chinese characters for a thousand, both of which he derives from the seed vessel of the lotus, as containing a multitude of seeds; and if the older Chinese characters be found to preserve this resemblance as perfectly as they ought to do, it must be confessed that the suspicion of a common origin will be much strengthened by the argument. Both the Egyptians and the Chinese were condemned, M. de Pauw observes, "to an eternal mediocrity;" and the weight of this observation is certainly not diminished by any thing that has lately been inferred from the study of the hieroglyphics of the stone of Rosetta.

4. There are several papers of M. de Pauw on antiquarian subjects in the *Memoirs of the Society of Cassel*, and one in particular *On the Temple of Juno Lacinia*, Vol. I. 1780.

5. *Recherches sur les Grecs*, 2 v. 8. Berl. 1787. *Philosophical Dissertations on the Greeks*, translated by Thomson, 2 v. 8. Lond. 1793. The work is principally devoted to the Athenians, among whom their boasted liberty is shown to have been confined to a very small number of citizens, who tyrannized over the rest of the inhabitants of their country. The Lacedæmonians, the Aetolians, the Thessalians, and the Arcadians, are separately discussed, but considered as comparatively contemptible; the Lacedæmonians in particular, and their successors, the Maimotes, are treated with great severity, as a worthless race of dishonourable vagabonds. The athletic education of the Athenians is, however, highly applauded, from a visionary theory of the importance of the physical perfection of the body to the operations of the mind. An edition of the author's three principal works appeared at Paris, in seven volumes octavo, 1795.

Peebles-shire.

Situation.

Extent and Divisions.

Surface, &c.

Veget.

Climate.

PEEBLES-SHIRE, or TWEEDDALE, a county in Scotland, situate between 55° 24' and 55° 50' north latitude, and between 2° 45' and 3° 23' west longitude from Greenwich. It is bounded on the north by Mid-Lothian or Edinburghshire; on the east by the county of Selkirk; on the south by Dumfries-shire; and on the west by Lanarkshire. Its greatest extent from north to south is about 30 miles, and its greatest breadth from east to west about 22; the contents being 229,778 English acres; of which only about a tenth part is fit for cultivation. It is divided into sixteen parishes, twelve of which form the presbytery of Peebles, and four belong to that of Biggar, all under the synod of Lothian and Tweeddale.

which injure the potatoe and other crops; while the winters are frequently so severe as to destroy turnips, and the snow lies so deep and so long as to occasion great loss among the flocks.

Peebles-shire, in 1811, was divided into about 80 estates, many of them large, but not valuable in proportion. The valuation of the whole is L. 51,937, 13s. 10d. Scots; and the real rent, as assessed to the property-tax that year, was, for the lands, L. 57,382 Sterling, and for the houses L. 2568. Two-thirds of the estates are valued under L. 500 Scots; a sum which may indicate pretty nearly their present yearly value in Sterling money, and little less than two-thirds of the whole is entailed. In the same year the number of freeholders entitled to vote in the election of a member for the county was 39. Many of the proprietors, among whom, there were lately five noblemen, have seats distinguished either for their antiquity or their beauty; but the Earl of Traquair is the only nobleman who now resides in the county. Of the other seats the most considerable are Darnhall, Lord Elibank; Drummelzier, Hay; Magbiehill, Montgomery; Neidpath Castle, the heirs of the late Duke of Queensberry; and Whim, Montgomery.

As this is almost exclusively a pastoral country, the farms are in general large, most of them from 1000 to 4000 acres. On the arable land they are small, the greater number below 100 acres. These are in general held on leases for 19 years, as in other parts of Scotland. Taking the extent and rental as before stated, the average would be nearly 5s. the English acre. This is chiefly derived from live stock, especially sheep, of which there may be about 120,000. Most of these are still of the black-faced heath variety, sometimes called Tweeddale sheep, from the name of the county, or Linton sheep, from the name of a village on the north side of the district, where great fairs are held for the sale of them. The Cheviot breed, however, which bears a much more valuable fleece, has established itself on many of the lower hills. The crops are the same as in other parts of Scotland, except that wheat is cultivated only upon a very small scale. A variety of oat, called the *red oat*, and sometimes the *Magbiehill oat*, from its being first cultivated here on that estate, is well adapted to high and exposed situations; both because it ripens earlier than the common kind, and is less liable to be beat out by wind, while on good land it is found to be highly productive.

Peebles, a royal burgh, containing, in 1811, about 2200 inhabitants, is the only town in the county. The villages are Linton, Skirling, Eddlestone, Broughton,—at all of which fairs are held, chiefly for the sale of live stock, and for the hiring of servants, —and Innerleithen, where a woollen manufactory has been established. There is no other manufacture within the county, if we except that of stockings, carpets, and flannels, all upon a small scale, carried on in the town of Peebles, where there is also an extensive brewery. Peebles-shire, therefore, has little to offer in exchange for the commodities which it requires but its raw produce; chiefly sheep and wool.

The county sends one member to Parliament, and

The surface of this county is hilly, and towards the south mountainous, several of the high grounds in that quarter, such as Hartfield, Harstane, Broadlaw, and Dollarlaw, being from 2800 to nearly 3000 feet above the level of the sea. The general elevation of the pasture lands is about 1200 feet; yet, with few exceptions, the hills are covered with green herbage, heath being almost confined to a few of the highest ridges on the south-east. On the banks of its streams are many pleasant and fertile spots; but from the want of wood, the general appearance is naked and uninteresting, except about the seats of the proprietors, where considerable plantations have been made, extending in all to more than 2000 acres. The soil of the cultivated land, lying chiefly on the sides of the lower hills and the banks of the streams, is, for the most part, a light loam, with clay, moss, and moor, on the high grounds. Coal and limestone abound in the parishes of Linton and Newlands, on the north side of the county, and in the latter, ironstone; in the same quarter red and white sandstone is wrought for sale, and the parish of Stobo, on the Tweed, has long furnished a good kind of slate, much of which is carried to the adjacent counties. The river Tweed, from which this district is often called Tweeddale, rises from a well of the same name, in the parish of Tweedsmuir in the south-western extremity of the county, about 1500 feet above the level of the sea, and flowing first north-east and then east, dividing the county into two nearly equal parts, passes into Selkirkshire at Gatehaup-burn, after a winding course of about 36 miles. The Annan and the Clyde have their source in the same quarter. Of the other streams, here called *waters*, the most considerable are Biggar, Lyne, Peebles or Eddlestone, Leithan, Mannor, and Quair, which fall into the Tweed; and the North and South Esks, which pursue their course into Mid-Lothian. The lakes or lochs are St Mary's, Waterloch, and Slipperfield. These, as well as the rivulets, abound in the common fresh-water fish, and most of the streams are occasionally frequented by salmon; but salmon are not found in such numbers, even in the Tweed within the bounds of this county, as to afford a fishery that will pay rent.

The climate of Peebles-shire, owing to its elevation and want of shelter, is perhaps more rigorous than that of the other southern counties of Scotland. Cold easterly winds prevail in spring, which greatly retard vegetation; and frosts often occur in summer,

Extent and Boundaries.

PEMBROKESHIRE, a maritime county of South Wales. It forms a peninsula at the south-west corner of the principality, and is surrounded by the sea every where but on the eastern side, where it is bounded by Carmarthenshire, and by Cardiganshire. Its shape is very irregular, which makes it difficult to ascertain its exact extent. Its extreme length is thirty, and its extreme breadth twenty-seven miles. Its area is estimated, but with no decided accuracy, at 575 square miles.

Face of the Country.

It is generally an undulating country, composed of plains, with hills of no great elevation, except in the northern part, where a range of mountains is stretched out to the extent of nine or ten miles; the loftiest points of this group are Precelly Top, 1754 feet, and Brennin-Vaur, 1285 feet above the level of the sea. Few of the hills in the other parts of the county attain a greater height than 290 feet. As the greater part of the country is destitute of woods, it has a bare and bleak appearance, except in the valleys, where the numerous brooks that flow through them impart a pleasing verdure to the bordering meadows.

Bays, Rivers, and Estuary.

The most considerable rivers are the Eastern Cleddaus, which forms at first the dividing line between this county and Carmarthenshire; and the Western Cleddaus, which traverses a considerable portion of Pembrokeshire. These two rivers unite, and form the admirable estuary of Milford Haven, which is considered to be the best harbour in the British islands. It is sufficiently capacious to contain the whole navy of England; is so completely sheltered as to be secure from all winds; has good holding ground, and competent depth of water. These natural advantages have induced the Lords of the Ad-

miralty to establish a dock-yard on its banks, where ships of the line and frigates are built, and where the town of Haberstone has in a few years sprung up, and grown to considerable importance. It is the place whence the packets for the south part of Ireland sail, and to which, on that account, numerous passengers resort. The other rivers are of inconsiderable note; namely, the Newgall, the Solva, the Alan, the Gwayn, the Nevern, the Cuch, and the Teivi. Besides Milford Haven, St Bride's Bay and Fishguard Bay deserve notice, as affording secure anchorage for large ships, and possessing good landing-places. This circumstance induced the government of France, in the year 1797, to land some troops from two frigates under General Tote, which in a few days surrendered to the inhabitants, who hastily collected with such arms as presented themselves. It was generally supposed that the men were criminals of the worst description, whom the French took this extraordinary method of discharging from their prisons.

The soil of the county is generally a red loam, in many parts resting on a calcareous subsoil, and admirably adapted for the growth of corn. In some places the surface is covered with porous stones, which are supposed to imbibe and retain the salt from the saline air, and to render the land highly prolific. The principal grain consists of wheat, barley, and oats, but in some parts of the county rye is extensively cultivated. The modes of cultivation are commonly the same as prevailed in remote ages in this island; that is, growing wheat, barley, and oats in succession, till the land was so exhausted as to yield no increase, when it was suffered to return to its natural state, under the idea of recovering itself by rest.

Pembroke-shire. Very little attention is given to the preservation of manure; the barns and farming erections are very badly constructed, and the agricultural implements, especially the ploughs, are of a rude and antique form. Such is the description of the greater part of the agricultural state of the country, but there are splendid exceptions, affording specimens of improvement that would have been more extensively followed, but for the general depression of agriculture, which has been experienced within the last few years. The size of the farms varies from fifty to five hundred acres; the average extent of them is estimated to be about two hundred: some of the occupiers are annual tenants, but many hold from the lords of manors by leases for three lives at an agreed rent, but without any fine on the renewal of a life, as is customary in England, and on the lands in Pembroke-shire belonging to the church.

attle. The black cattle of this county are of an excellent race, and are annually distributed over the south of England in droves, which travel from fair to fair, till the whole are sold. They are commonly sent to market when they are in calf the first time. Some valuable horses are bred here. The sheep are small, and yield little wool, but the mutton is very highly esteemed.

erals. At no very remote period, silver was found in the parish of St Elwys, or St Bride's Bay. The mine, which was discontinued in the reign of Queen Elizabeth, was resumed a few years ago, but not with such success as to induce perseverance. Some excellent lead ore is found on the banks of the Tave, but the mines are not worked with any degree of spirit. The most important production of the mines is coal. It is confined to a district of narrow extent on the southern side of the county. The veins lie near the surface, and the quality is not very good. The inhabitants use the small coal mixed with clay, and formed into balls; it is sulphureous, and highly offensive to strangers.

Manufactures and Commerce. The manufactures of this county are very inconsiderable. Some speculators, indeed, were induced, by the excellent streams of water, to erect mills for spinning cotton, and for making tin plates; but these schemes, though conducted with much spirit, were found to be unprofitable, and finally abandoned. The principal commerce of the county is a coasting trade, and the conveyance of coals from Tenby to the opposite shores of Somerset, Devon, and Cornwall, where they are principally used for burning lime, and drying malt. Under the auspices of the late Honourable Charles Greville, and with the sanction of a special act of Parliament, some American fishermen formed an establishment at Milford for the purpose of carrying on the southern whale fishery, upon the plan of the crew being sharers with the owners in the result of the fishing, as is practised in the United States. The concern was conducted with success for several years, but has been recently abandoned from various circumstances, none of them connected with the local position, which was ascertained to be favourable.

Language. The inhabitants are of two distinct races. If a line be drawn through the whole county, cutting

through the centre of the town of Haverfordwest, it will be found that on one side of the line nothing but English is spoken, and on the other side only Welsh. This is so definite, that in the town of Haverfordwest, the one language is spoken in the upper and the other in the lower part of it; and there are two markets, one frequented by the English, the other by the Welsh peasantry. The part where the English live, called commonly "Little England, beyond Wales," was originally peopled by a colony of Flemings, who have kept themselves distinct since the first colonization. They are allowed to speak the English language with more purity than is to be found among the lower classes in any other part of the island.

Two members are returned to Parliament from Pembroke-shire; one for the county, and one for the boroughs of Pembroke, Tenby, and Wiston. The divisions are into seven hundreds, which contain one cathedral, one hundred and forty-five parishes, and several chapelries.

St David's. St David's, the see of a bishop, is a miserable collection of cottages, in the midst of traces of ancient, extensive, and numerous buildings. The object deserving of most notice is the cathedral, whose antiquity is very great, having been originally built about the year 1180, and enlarged in 1280 and 1328. This venerable pile has been much repaired and improved by the prelate who at present fills the see. The bishop's palace is a magnificent pile, not far from the cathedral, on the opposite side of the river Alan. It was originally a quadrangular building of great extent, of which at present only one side remains entire.

Antiquities. Among the ancient buildings in this county, the most remarkable are, Carew Castle on a creek of Milford Haven; Manorbeer, the mansion of the Barri family, of which Giraldus Cambrensis was a member; and Killgarran, on the river Tyvy, whose massy towers and fragments of bastions present a most imposing spectacle.

Seats. The picturesque beauties of this county, and the mildness of the air, have induced many gentlemen to select it as the place of their residence, and the number of their seats is considerable; among them are Picton Castle, Lord Milford; Hen Gastell, Thomas Stokes, Esq.; Slebeck Hall, N. Phillips, Esq.; Oriclton, Sir John Owen, Bart.; Johnston, Lord Kensington; Trecoon, J. F. Barham, Esq.; Fynonean, John Colby, Esq.; Stockpool Court, Lord Cawdor; Begelty Hall, James Child, Esq.; Lawrenny, Hugh Barlow, Esq.; Tal y Bort, John Meares, Esq.; Payston, (the late) General Picton; Plas Newydd, Sir Watkin Lewis; and Pentree, Dr Davies.

Population. The population of the county, by the census of 1811, was 60,615 persons, viz. 27,453 males, and 33,162 females; the militia are not included. The principal towns are Haverfordwest, with 3093 inhabitants; Pembroke, 2415; St David's, 1816; Tenby, 1176; Fishguard, 1608; Newport, 1487, and Hubberston, 754.

## P E N D U L U M.

*Pendulum.* **W**HEN a solid and heavy body of any form and description is suspended from an axis fixed horizontally, and round which it can turn with freedom, or at least with a very slight degree of friction; if we withdraw it, however little, from the position of equilibrium at which it naturally places itself when at rest, and then abandon it to itself, the force of gravity, which is now no more destroyed by the resistance of the axis of suspension, brings back the body towards its primitive position of equilibrium with a velocity continually accelerated. When it reaches this position, the accelerating force ceases for a moment to act on it, but the body continuing to move in consequence of the velocity already acquired, rises on the other side of the vertical line, and continues rising until the constantly increasing force of gravity destroys its velocity—then it stops for an instant, and again yielding to the continued action of gravity, to which there is now no more any opposition, it again falls with a motion exactly similar to that which it had when it began to descend from the opposite side of the vertical. It returns then, in the same manner, to its primitive position of equilibrium, passes it, and reascends on the opposite side of the vertical to the point where its velocity is destroyed anew; after which it again begins to descend, and again to remount; and the oscillatory motion which results from these alternations only ceases in consequence of the resistance of the air and the friction of the axis, which gradually reduce it to nothing.

An apparatus of this kind is termed a *pendulum*. The oscillations of pendulums can be calculated completely, and with perfect rigour, by the principles of mechanics, when they are supposed to take place in a vacuum, and round an axis, which presents no friction. The results in regard to this imaginary case are so much the more important to be known, as in the real experiments we always endeavour to approach it as near as possible, by combining to the utmost every circumstance which can tend to prolong the duration of the pendulum's motion. These are the results, then, which it is proper to present first in order, as they exhibit a first approximation to every motion of this kind, which can be realized.

In this simple case, whatever be the form of the body which constitutes the pendulum, provided that it remains invariably constant, all the successive oscillations have equal amplitudes, and are also of equal duration among themselves, so that the motion, once begun, never ceases to go on. In the case of oscillations with different amplitudes, the duration is in general unequal, but this inequality diminishes in proportion as the amplitudes become less, and it ceases altogether at the limit where they become infinitely small; so that all the oscillations made with amplitudes, which, in a physical sense, may be reckoned infinitely small, are sensibly of equal duration.

In regard to the nature of the motion in each oscillation, it is absolutely the same for every body, whatever be its form, and we may always consider it as identical with that of a pendulum formed by a material gravitating point suspended at the extremity of a thread, supposed to be inflexible and without weight. Let  $l$  (Plate CIX. fig. 1) denote the ideal length of such a pendulum, which is called a *simple pendulum*. Let  $m$  be the mass of an oscillating body with which we wish to compare it, and which we shall call, in opposition to the other, a *compound pendulum*. From the centre of gravity of this body, denoted by  $G$ , conceive a perpendicular  $SG$  drawn to the axis of suspension, and call  $h$  the length of this line. If we multiply each element of the mass  $m$  by the square of its distance from the same axis, and denote the sum of the whole by  $C$ , the product  $C$  thus formed will be what is called in mechanics the momentum of inertia of the body  $m$  relatively to the axis in question. In order that the motion of the simple pendulum  $SP$  be exactly isochronous with that of the body  $m$ , it is sufficient that we have the equation  $l = \frac{C}{mh}$ , and be-

sides this, that the lines  $SP$  and  $SG$  have at any one instant an angular velocity equal at the same distance from the vertical. This last condition will be fulfilled if, for example, at the beginning of the motion the lines,  $SP$ ,  $SG$ , are equally distant from the vertical, and that the simple and compound pendulum be then abandoned together to the action of gravity, or be driven with equal velocities in the plane of their oscillations. The simple pendulum will then accompany the compound one in all its successive excursions, and its direction will always coincide with the line  $SG$  drawn from the centre of gravity of the body  $m$ , perpendicular to the axis of suspension. The length  $l$  being ascertained by this formula, we can lay it off on the line  $SG$ , setting out from the axis of suspension  $S$ , and the point  $P$ , where it terminates, is called the *centre of oscillation* of the body  $m$ .

The initial conditions above stated can be always established, and the analytical value of  $l$  is also always real. For every given compound pendulum, then, we can always assign a simple pendulum, which is isochronous with it, and of which the motion is absolutely similar to that of the line  $SG$ . By means of this substitution, we have nothing more to consider or to compare, but the different lengths of the simple pendulums, and it then only remains to ascertain the mode in which such pendulums perform their oscillations.

To do this in the simplest manner possible, let us conceive that the arc  $ZP$  (Plate CIX. fig. 2) is half the extent of the oscillations round the vertical  $SZ$ , and suppose that the pendulum arrived or placed in this position is there abandoned to the sole action of gravity without any initial velocity of impulsion. Call  $\alpha$

pendulum. the angle PSZ, and denote by  $g$  the intensity of gravity measured by the double of the space which heavy bodies describe at the place where the experiment is made, when they fall freely in a right line during the unity of time. Then denoting always by  $l$  the length of a simple pendulum SP or SZ : the time T of its whole oscillation in the arc PZP' or PP' will be expressed by the following series :

$$(1.) \quad T = \pi \sqrt{\frac{l}{g}} \left\{ 1 + \left(\frac{1}{2}\right)^2 \sin^2 \frac{1}{2}\alpha + \left(\frac{1.3}{2.4}\right)^2 \sin^4 \frac{1}{2}\alpha + \left(\frac{1.3.5}{2.4.6}\right)^2 \sin^6 \frac{1}{2}\alpha + \dots \&c. \right\}$$

$\pi$  being the ratio of the circumference of the circle to its diameter, or 3.14159.

If, besides, we denote the velocity of the pendulum in any point of its oscillation by V,  $\theta$  being its angular distance from the vertical, we have

$$(2.) \quad V^2 = 2gl (\cos \theta - \cos \alpha)$$

or, what comes to the same thing,

$$V^2 = 4gl \sin \frac{1}{2}(\alpha + \theta) \sin \frac{1}{2}(\alpha - \theta).$$

These formulæ will still serve if the pendulum, instead of falling freely from the extremity of the arc, receives there an initial velocity expressed by  $V'$ , provided always this velocity is within the limits which permit the oscillatory motion to take place. If this be the case, indeed, it will be sufficient to consider the pendulum as setting out with an initial impulse from another angular distance,  $\alpha'$ . Then it will be necessary that this unknown distance  $\alpha'$  satisfy instead of  $\alpha$ , the general equation of the velocities, and that  $\alpha$  becomes in it  $\theta$ , which gives

$$(3.) \quad V'^2 = 2gl \left\{ \cos \alpha - \cos \alpha' \right\}$$

The half amplitude  $\alpha'$  of the oscillations being the only unknown quantity in this equation, will be thus determined, and their duration will be then obtained by the equation (1), but putting in it  $\alpha'$  instead of  $\alpha$ . This same substitution made in the equation (2) will give

$$V^2 = 2gl (\cos \theta - \cos \alpha')$$

for the velocity in any point whatever of the oscillation. But these transformations are only possible when the equation (3) gives for  $\alpha'$  a real arc, and consequently for  $\cos \alpha'$  a value comprehended between +1 and -1. We may easily conceive, that, when the  $\cos \alpha'$  exceeds these limits, it is because the velocity of impulse  $V'$  exceeds the greatest velocity of the fall which the pendulum can acquire in a circle of a radius  $l$ , even supposing it to fall from the very summit. It is evident, indeed, that the oscillatory motion can then no more produce such a velocity, and we know also that, in that case, it will change into a continued motion of rotation. If we exclude this circumstance, the formulæ (1) and (2) will determine generally every particular regarding oscillatory motions. When the amplitudes of the oscillations become so small that we can, in the series (1), neglect all the powers of  $\sin^2 \frac{1}{2}\alpha$ , compared with the unity which precedes

them, we will have simply  $T = \pi \sqrt{\frac{l}{g}}$ .

Now, the angle  $\alpha$  entering no more into the value of T, it appears that its value will have no influence on it; that is to say, that for the same pendulum moved in a vacuum, all the oscillations which are performed with amplitudes infinitely small, are of equal duration.

In actual experiment, the oscillations can never be altogether infinitely small, but we may take care, at least, to confine them within amplitudes so limited, that the angle  $\alpha$  has a very small value. We have then an approximation perfectly sufficient in limiting the series to the term which contains the square of the  $\sin \frac{1}{2}\alpha$ . We may then, in the same order of approximation, substitute  $\frac{1}{4}\sin^2 \alpha$  for  $\sin^2 \frac{1}{2}\alpha$ ; and the series (1) being thus limited to its two first terms, gives

$$T = \pi \sqrt{\frac{l}{g}} \left\{ 1 + \frac{1}{16} \sin^2 \alpha \right\}$$

$\alpha$  being always the half amplitude of the oscillation.

We have seen above, that, by supposing the simple pendulum  $l$  isochronous with the compound pendulum of the mass  $m$ , we have

$$l = \frac{c}{mh},$$

$c$  being the momentum of inertia of the mass  $m$ , relatively to the axis of suspension. But if we call  $c'$  the momentum of the same mass, relatively to an axis parallel to the preceding, and passing through the centre of gravity G, we find, by mechanics, that the quantities  $c, c'$  have between them the following relation :

$$c = mh^2 + c'.$$

This value of  $c$  being substituted in the expression of  $l$ , gives evidently

$$l = h + \frac{c'}{mh}.$$

Now, when  $h$  is given, this expression only furnishes one value of  $l$ ; that is to say, a single length for a simple pendulum isochronous with the mass  $m$ . But if  $l$  be given, then there are two values of  $h$ , which give the same value to  $l$ ; and these are deducible from the preceding equation, by taking  $h$  in it as the unknown quantity. If we denote these two values of  $h$  by  $h'$  and  $h''$ , it is easy to see that their sum is  $l$ , and that thus the first being SG (fig. 1), the second will be PG. If, then, after having placed the axis of suspension in S, we place it in P, that is, in the centre of oscillation itself, preserving it always parallel to its first direction, the oscillations performed round the axis P will be of the same duration as those performed round the axis S, provided always that in both cases the amplitudes of the oscillation, as well as the initial velocities, are equal. This remarkable theorem we owe to Huygens.

It is easy to extend it to one much more general. In all solid bodies, whatever be their figure, we may draw through the centre of gravity three rectangular axes, termed in mechanics *principal axes*, and which possess several properties extremely remarkable. Let the momentum of inertia of the mass  $m$  relatively to these axes be denoted by A, B, C. Then, if we consider any axis of suspen-

*Pendulum.* sion of which the distance from the centre of gravity is expressed as above by  $h$ , and which forms with the preceding certain angles,  $X, Y, Z$ ,—it is shown, in mechanics, that the momentum of inertia  $c''$ , relatively to this axis, can be expressed in the following manner :

$c'' = mh^2 + A \cos^2 X + B \cos^2 Y + C \cos^2 Z$  ;  
and this value being substituted in  $l$ , instead of the letter  $c$ , gives

$$l = h + \frac{A \cos^2 X + B \cos^2 Y + C \cos^2 Z}{mh}$$

If, now, the axis of suspension be given along with the distance  $h$ , this expression gives but a single value for  $l$  ; but if we regard  $l$  as given, and constant, then there arises between the angles  $X, Y, Z$ , and the distance  $h$ , a simple relation, which we can satisfy in an infinity of different ways, so that there result as many different axes of suspension, which are all isochronous with each other. To be sensible of the extensive application of such solutions, let us transform the preceding relation into one with rectangular co-ordinates. Let  $x, y$ , and  $z$ , be such co-ordinates directed rectangularly, according to the three principal axes of the mass  $m$ , and having their common origin at the centre of gravity of this mass, the axis of suspension relatively to these co-ordinates will have its equations of the form

$$(4.) \quad x = az + a \quad y = bz + \beta,$$

$a, b, \alpha, \beta$ , being four constant indeterminate quantities, depending on their position in space. We have, besides, by the well-known theorems of analytical geometry,

$$\cos X = \frac{a}{\sqrt{1+a^2+b^2}}, \quad \cos Y = \frac{b}{\sqrt{1+a^2+b^2}}$$

$$\cos Z = \frac{1}{\sqrt{1+a^2+b^2}}, \quad \text{and, lastly, } h = \frac{\sqrt{a^2+\beta^2}}{\sqrt{1+a^2+b^2}}.$$

By substituting these values in the general expression of  $l$ , it becomes

$$(5.) \quad l = \frac{\sqrt{a^2+\beta^2}}{\sqrt{1+a^2+b^2}} + \frac{Aa^2+Bb^2+C}{m\sqrt{a^2+\beta^2}\sqrt{1+a^2+b^2}}.$$

By supposing  $l$  constant, this relation, combined with the equation (4), will characterise the isochronous axes : but as this combination only furnishes three equations, while there are four constant indeterminate quantities  $a, b, \alpha, \beta$ , in the position of the axis, it hence appears that we may still assume at pleasure an additional condition among the quantities themselves, after which, by eliminating them, we shall have in  $x, y, z$ , the equation of a surface on which will be found the isochronous axes fitted to satisfy the condition prescribed.

Having thus made known the laws of oscillatory motion, in a vacuum and round an axis altogether free from friction, let us now consider them in a feebly resisting medium like air, and supposing a slight degree of friction round the axis, such as is invariably the case in the experiments.

In the first place, whatever be the nature of the physical process by which the two causes operate, their definite effect will always be to retard the pendulum, according to a certain function of the velocity. But whatever be the form of this function,

*Pendulum.* provided it be such as to become nothing when the velocity is nothing, which is an essential condition of the kind of obstacles it is designed to express, we may always assign a simple pendulum which, moving with the same laws of friction and resistance, will be exactly isochronous with the compound pendulum we are considering ; and what is very remarkable, the length of this simple pendulum is exactly the same as it would be if the oscillations were performed in a vacuum, and consequently the same as that of which we have given the expression above. Thus the centre of oscillation of solid bodies such as we have defined it, has in each of them a situation independent of the medium in which they move, and of the resistances of every kind which their motions may suffer. This important proposition was first demonstrated by Clairaut.

Now, for the simple pendulum, as well as for the compound one which accompanies it, the resistance of the air and the friction of the axis diminish continually the extent of the arcs in which the successive oscillations are performed ; but it happens, from a circumstance well worthy of remark, that when this retarding force is very slight, and acts with continued and equal effect on both sides of the vertical, the duration of the oscillations are not altered on this account. For, although the resistance which the pendulum suffers must retard, no doubt, its fall, and consequently prolong its duration in each half-oscillation in descending ; yet in each half-oscillation, in ascending, this same cause accelerates the extinction of the velocity, and rather brings on the instant when this half-oscillation is terminated. And whatever be the mathematical law of the motion thus performed, if the amplitudes of the successive oscillations diminish very slowly, which always takes place when the body put into oscillation has a very considerable density relative to that of the air, and if we make it perform vibrations only of very small extent, and round an axis of suspension so worked as to present but a slight degree of friction, then the motion of the pendulum presents a succession of velocities almost exactly similar in each descending half-oscillation, and in the ascending half which follows it. The alterations produced in these velocities by the friction and the resistance of the air, are then almost equal, so that their effects are almost exactly compensated in the actual observations. Hence it follows that the isochronism of small oscillations, though altered in each particular half-oscillation, is still found to subsist in the total oscillations, notwithstanding of the friction of the axis, and the resistance of the air, provided always that these two forces are rendered so feeble as to have but a very gradual influence on the motion. This is at least proved by experiment ; for, when a compound pendulum of any form whatever oscillates in the air round a suspension, so free that the decrease of its vibrations goes on with great slowness, if we observe the amplitudes of these vibrations at intervals so near each other, that their absolute diminution is inconsiderable, and apply to the number of oscillations performed during this interval, the reduction

pendulum. of amplitude calculated according to the mean value of the arcs thus observed ; the number of oscillations corrected and reduced in this manner to the case of amplitudes infinitely small, is also found invariably the same for the same pendulum, at least with all the degree of exactness admitted by physical experiments ; which shows that the correction of the amplitude is the only one which the oscillations require in order to reduce the motion of the pendulum to a uniformity quite mathematical. This spontaneous compensation, which is produced in the effects of the resistance of the air on the two descending and ascending half-oscillations, had first been remarked and pointed out by Newton in his *Principia*, Lib. II. Prop. XXVII. Theor. XXII. Coroll. 2. He even gives a rigorous demonstration of it in Prop. XXVI. and XXVII. for the case of a resistance proportional to the two first powers of the velocity—the motion being then in the cycloid. M. Poisson has given the analogous demonstration for a circular motion in the seventh volume of the *Journal de l'Ecole Polytechnique*. These demonstrations, however, only apply to that part of the resistance which arises from the direct impulse with which the moving body strikes the aerial particles, supposing these particles quite removed after the stroke, and consequently without regard to the peculiar agitation which their displacement produces in the medium itself. But, as Newton remarks in the corollary above cited, the descending half-oscillation, which is performed with a motion continually accelerated, must, on this account, excite a resistance in a slight degree stronger than the half-oscillation ascending, which goes on with a motion continually retarded ; because, in this second case, the aerial particles struck by the pendulum may fly from it, and withdraw themselves from its action more easily than in the former. This diminution of the resistance in the second half of the oscillation must cause it to last a little longer than it would have done without this circumstance, and thus the time of the whole oscillation must be a little augmented. Fortunately this cause, it appears, becomes insensible in the most important experiments to which the pendulum is applied ; for, in these the observations are never made but with very small amplitudes, which produce very small velocities, and these cannot excite any sensible resistance except by the direct impulse communicated to the ambient medium.

But, independent of its resistance, the air, by its mere presence, floating round the oscillating body, produces on the motion another effect, which may be called *statical*, and which must be attended to, in order to compare the observations made in different states of this fluid. As a gravitating medium, in fact, it deprives the oscillating body of a part of its weight equal to that of the volume of air which the body displaces, so that the latter, in reality, only gravitates in consequence of the difference between these two quantities. To calculate the resulting effect on the oscillations, call P the absolute weight of the body in vacuo, Δ its density, compared with that of the air in the circumstances under which we are operating. The weights of bodies of equal

volume being proportional to their densities, the weight of the air displaced by the body will be

$P \cdot \frac{1}{\Delta}$ , thus the apparent weight of this same body,

during its oscillations, will be  $P - \frac{P}{\Delta}$ , so that it

will be to its absolute weight as  $1 - \frac{1}{\Delta}$  to 1. The

effect, then, will be the same as if the absolute weight P were acted on, not by the actual gravity itself, but by a force diminished in this ratio. We have only, therefore, to reduce the elements of this correction to terms that we can compare together. For this purpose, suppose that at the temperature of freezing, and under an atmospheric pressure measured by a column of mercury of 0.76 metres in height, D represents the density of the substance of the pendulum, that of the air being taken as unity. If we denote the cubic dilatation of this substance for a change of temperature equal to a centesimal degree, by *c*, its density at *t* degrees will become very nearly  $D(1+ct)$ , and if *p* is the atmospheric pressure at this temperature, the corresponding density of the air, according to the known law of the dilatation of this fluid, will be

$$\frac{p}{0.76(1+t.00375)}$$

Then denoting the absolute intensity of gravity, as it is exerted on the body in vacuo by *g*, and the apparent force with which it really moves the body in the air by *g'*, we shall have

$$g' = g \left\{ 1 - \frac{p}{0.76(1+t.00375)(1-ct)D} \right\}$$

To illustrate the use of this correction, let *l'* represent the length of a simple pendulum, which performs its oscillations in the time T', under the influence of the apparent gravity *g'*, and, with the amplitude 2*α'*, we shall have,

$$T' = \pi \sqrt{\frac{l'}{g'}} \left\{ 1 + \left(\frac{1}{2}\right)^2 \sin^2 \frac{1}{2} \alpha' + \dots \&c. \right\}$$

In the same manner, if we call *l* the length of a simple pendulum, which makes its oscillations in the time T, under the influence of gravity *g*, and, with the amplitude 2*α*, we shall have,

$$T = \pi \sqrt{\frac{l}{g}} \left\{ 1 + \left(\frac{1}{2}\right)^2 \sin^2 \alpha + \dots \&c. \right\}$$

If now we wish the two pendulums to oscillate with equal amplitudes, we have only to make  $\alpha = \alpha'$ ; if we wish, also, to have their times of oscillation equal, we have only further to suppose  $T' = T$ , then the two preceding expressions being equal to each

other, we obtain  $\frac{l}{g} = \frac{l'}{g'}$ , and  $l = l' \cdot \frac{g}{g'}$ , from which we

can calculate *l*, when we know from observation *l'* and  $\frac{g}{g'}$ .

Pendulum. As the density of the solid mass of the pendulum is usually very great, compared with that of the air,  $D$  is a very considerable number, so that this correction is always very small. Bouguer appears to have been the first philosopher who made use of it, as appears by his work on the figure of the earth. But before him Newton was well aware of the necessity of paying attention to it, as we may conclude even from the enunciation which he gives to the propositions regarding the resistance of the air above alluded to. For he there compares the motion of the pendulum, affected by this resistance, to that which would take place in a *medium of the same specific gravity, and which would present no resistance.*

Having thus explained in general the mathematical laws of the motion of the pendulum, whether in the air or in vacuo, we shall now describe the principal applications which have been made of them in physical science. These are, 1st, The measurement of time. 2d, The estimating of the resistance of fluid media. 3d, The comparison of the intensities of gravity on different parts of the surface of the terrestrial spheroid, from which certain positive conclusions have been drawn regarding the figure of a spheroid, as well as the arrangement, and the density of the strata of which it is formed.

The first idea of employing the pendulum as a measure of time is due to Galileo; and it occurred to him when he was observing the apparent isochronism of the small oscillations of suspended bodies. But the variation in the length of these oscillations, in proportion as the resistance of the air diminishes their amplitude; the necessity of frequently renewing, by a new impulse, the motion which this resistance was destroying; and, lastly, the tedious necessity of following, and counting directly the oscillations one by one, during the whole interval that is to be measured, these proved serious obstacles to a practical and certain use of the instrument. Huygens had the merit of surmounting all these difficulties, by employing the pendulum in clocks to regulate the motions of a system of wheels, acted on by a constant power which tends continually to make them revolve; the pendulum determining the rate of their gradual rotation, by acting on them at equidistant intervals. The pendulum carries at its upper extremity a piece in the form of an anchor, which is termed the escapement, and of which the two ends, carried successively from right to left, and from left to right, by the oscillatory motion, are alternately engaged and disengaged with the teeth of a principal wheel, whose rotation they thus serve to check, and which, in its turn, serves as a similar alternate check to the other wheels. These now turn more or less slowly, according to the relation of the number of their teeth to that of the principal wheel. By applying, then, to their axes one or more indices, which turn on a dial-plate divided on the outside, we obtain by their indications so many unities of different kinds, the amount of which shows the number of oscillations that have been made. These unities of time are *hours, minutes, and seconds.* Great care is taken in the construction, as well as in the application of the wheels, so that their motion may be as easy as possi-

ble, and that they may always obey, with equal facility, to the intermitting impressions of the pendulum. The body of the pendulum itself is constructed with particular precautions. It is formed of a rod, or system of rods of metal, terminated below by a mass also of metal, and very heavy; generally of a lenticular form, which, as the edge lies in the direction of the plane of oscillation, possesses the advantage of diminishing the effect of the air's resistance. Besides this, as the dilations and contractions of the metal, by the changes of temperature, would lengthen or contract the pendulum, and thus cause it to alter the duration of its oscillations, the stalk of the pendulum is composed of a number of slips of different metals, which are so combined, that the centre of oscillation of these slips, and of the lenticular weight, remains constantly at the same height.

Such is, in general, the mode of applying the pendulum to clocks, which we owe to Huygens, and which, by the exactness it has introduced in the measurement of time, is one of the finest and most valuable presents which the sciences have ever received from the hands of genius.

The second application of the pendulum, namely, its use in determining the resistance of fluid media, we owe to Newton, who has explained it, with much detail in the sixth section of the first book of the *Principia*. The intensity, and the law of the resistance, is estimated from the progressive diminution of the amplitudes, determined by observation. We may see in that part of the work above referred to, the profound nature of the theory on which this deduction is founded, as well as the experiments themselves to which Newton applies it. The pendulums which Newton made use of were, in general, spheres of wood, or of metal suspended by threads. Besides the law, also, of resistances, several important points in physics depend on this sort of observation. Newton, for example, made use of it to establish the fact, that the action of terrestrial gravity upon all bodies is proportional to their mass; and also to inquire if these bodies, when in motion, suffer any sensible resistance by the presence within them of subtle media, which have been supposed to spread throughout the whole universe.

Lastly, it now remains to consider the use of the pendulum in measuring the intensity of gravity on different parts of the terrestrial spheroid; and we have kept this application for the last, on account of the delicate nature of the experiments which it requires, and which are now really performed. It would be of no use to enumerate here all the methods which have been successively employed, and successively abandoned, as experiments of greater exactness came to be required. Even the results of these first attempts, though they may have been at the time very useful, cannot now be any more employed; so much do the limits of the errors which they admitted exceed those which are allowed by our actual processes. These can be reduced to three principal methods; two of them give the absolute measure of the pendulum; the one is due to Borda, the other to Captain H. Kater; the third gives merely the relations of the lengths of pendulums in different places, and deduces these, by comparing the number

pendulum. of oscillations performed in the same interval of time by the same compound pendulum, supposed to be of an invariable form, and which is carried successively to the different places of observation.

### I.—BORDA'S METHOD.

The method used by Borda was originally described in a memoir, inserted in the third volume of the work which Delambre has published, under the name of *Base du Systeme Metrique Decimal*. The same memoir includes a detailed account of a very great number of experiments performed in this manner by Messrs Borda and Cassini, to determine the length of the seconds' pendulum at the Observatory at Paris. The method of Borda has been since simplified by the French astronomers, so that, without losing any of its original exactness, it has been rendered more easy of execution in travelling, and in places where the observer can only reckon upon the resources he carries with him. Under this new form, this method has been employed on a great number of points of the terrestrial arc, comprehended between the Pithiuse Islands and the Shetland Islands. The description of these modifications, and of the results thus obtained, will be found in a volume which forms a sequel to that of Delambre, and which has been published by Biot and Arago. It is from thence that we shall take our general account of this method, the description of which will serve also for the explanation of the others; these having many points in common with it.

The fundamental principle of this method consists in employing for a pendulum, a system of bodies which approaches the nearest possible in its properties to the simple pendulum, and which we can reduce to this ideal case by corrections equally simple to calculate, and exact in their application. The pendulum is formed by a ball of platina, suspended to a metal wire. (Plate CIX. fig. 3.) The under extremity of the wire is screwed into the bottom of a spherical cap of copper, of the same radius as the ball, and which being applied on its surface with a little tallow, adheres to it in consequence of the pressure of the atmosphere, and of the perfect contact resulting from its sphericity. The other end of the wire is attached to a suspended knife (fig. 4), which oscillates on a plane of agate (fig. 5), furnished with adjusting screws, by which it can be brought perfectly horizontal; a circumstance which is ascertained by placing on this plane a glass spirit level without its frame. The mass of the knife is previously adjusted, so that its oscillations may be very nearly isochronous with those of the clock, by which the whole pendulum must be regulated. This is done by the motion of a small ring of metal A, which screws round a metal rod T T fixed to the knife, and which, by screwing and unscrewing, approaches to, or recedes from, the plane of suspension, giving to the momentum of inertia of its mass a greater or less influence on the motion of the system of the knife and its rod. When the isochronism of the oscillations of the knife and of the clock is as perfect as can be obtained by this method, we suspend from the knife the wire and ball; giving to the wire such a length, that the oscillations of the whole system

may differ but little from those of the clock, consequently from those of the knife itself. It can then be shown, as well by calculation as by experiment, that the mass of the knife exerts no sensible influence on the length of the pendulum; which arises from its centre of gravity being then excessively near the plane of suspension. The whole system of the knife, the ball, and the wire, has only now to exert an effort infinitely small, to complete the exact regulation of the oscillations of the knife, and to make them agree with those of the whole system.

The pendulum is inclosed with the clock in a glass case, where it is exempt from the agitation of the air. Behind the wire, at a very small distance, is fixed horizontally a scale of equal parts, which serves to measure the amplitudes of the oscillations. Two sensible thermometers, carefully adjusted, are fixed near the wire, the one at the height of the plane of suspension, the other at the height of the ball, in order to indicate, at every instant, the temperature of the air around the wire. But as the wire, on account of the smallness of its mass, receives the impressions of temperature much more rapidly than the most sensible thermometer, the experiment is made in a room so large and sheltered, that the temperature of the air in it may change very slowly. The state of the thermometers is observed through the glasses of the case without ever opening it during the period of the oscillations.

Every thing being thus disposed, we place, at the distance of seven or eight metres, a telescope fixed horizontally, and the eye-glass of which has a wire fixed vertically before it. We direct this wire upon that of the pendulum, when in a state of rest, and we then place in the same direction, on the ball of the clock, also at rest, a small circle of paper to serve for an index. These preparations being made, the clock is set to oscillate, and is no more stopped. When its rate of going has become very steady, we cause the pendulum also to oscillate, and shutting the door of the glass case, we proceed to observe it from without with the telescope. If it should move exactly at the same rate with the clock, it would always be found in the same position in relation to the index in all its consecutive oscillations. But this never happens, and the pendulum goes always quicker or slower than the clock. If it goes quicker, it only coincides for an instant with the index, after which it passes it, recedes from it, returns to it in the opposite direction, passes it anew, and, after having receded from it again, returns to coincide with it a second time, and follows its motion of oscillation for an instant. The telescope which serves to observe these separations and these coincidences, magnifies the arc described by the pendulum, and by the clock—augments their apparent velocity, and thus enables us to judge of the instants of coincidence with singular precision. Between two consecutive coincidences, the pendulum gains or loses two oscillations upon the clock, and a simple proportion determines how much it must gain or lose in 24 hours of the clock, if it be sexagesimal, or in ten hours if it be decimal. If we suppose N to denote the interval between two coincidences, in clock time, it follows, that while the clock makes N oscillations,

Pendulum. the pendulum makes  $N \pm 2$ . The sign  $+$  being employed, if the pendulum goes quicker than the clock, and the sign  $-$  if it goes slower. Thus, during any number of oscillations of the clock, denoted by  $J$ , the number of oscillations of the pendulum will be proportionally  $J \left\{ \frac{N \pm 2}{N} \right\}$  or  $J \pm \frac{2J}{N}$ , a result which we may represent in an abridged form by  $J \pm n$ .

If the clock be sexagesimal, the number  $J$  of its beats in 24 hours is 86,400. If it be decimal, this number is equal to 100,000. Both these systems have been employed by the French observers. Whatever may be the one which we adopt, we regulate the length of the wire of suspension in such a manner that the coincidences of the pendulum with the clock may not be very near to each other, which would multiply unnecessarily the trouble of the observer. But neither must they be made too distant, because, in that case, the pendulum and the clock detaching themselves too slowly from each other, the precise instants of each coincidence become more difficult to observe. A few trials will soon point out a convenient medium between these extremes. Then the difference in the diurnal rate

$\pm \frac{2J}{N}$ , or  $n$  between the pendulum and the clock

always forms a very small number of oscillations. But the extent of the arcs described by the pendulum, diminishing always by the effect of the resistance of the air, while the clock, having its motion restored by the action of its weight, preserves always the same amplitude, it hence always happens that the intervals between the successive coincidences of the same pendulum vary with the time, which alters the value of the number  $n$ . During this inevitable change, the period when the coincidences are observed with the greatest precision is that where the amplitudes of the oscillations of the pendulum and of the clock are equal to each other; so that, if we are obliged, by any consideration, only to observe a small number of coincidences, we must regulate the primitive range of the pendulum, so as to approach as near as possible this condition of equality.

The difference in the rate  $\frac{2J}{N}$  or  $n$  corresponds

with those oscillations of the pendulum, which are performed between the coincidences which we compare together, that is to say, with an amplitude of arc varying from  $2\alpha$  at the beginning of the interval to  $2\alpha'$  at the end of it. The duration of these oscillations is larger than if the oscillations had been performed with the same pendulum, but with amplitudes infinitely small; and, therefore, to render the results comparable with each other, they must be reduced to this latter case. For this purpose, at the moment of each coincidence, we observe, through the fixed telescope, the point of the horizontal scale at which the wire stops in its excursions on each side of the vertical. This furnishes sufficient data to calculate the angular deviation of the pendulum from

the vertical, at the instant of the coincidence, since we know the distance of the scale from the plane of suspension at which the centre of rotation lies. We mark also the state of the interior thermometers, and that of the barometer at the same instant. If the arcs  $\alpha$  and  $\alpha'$  are both very small, as it is usual to make them, we may, without sensible error, suppose all the oscillations made with the mean amplitude  $\alpha + \alpha'$ . Then, after what has been shown above, each of them expressed in oscillations infinitely small, will be

equal to  $1 + \frac{1}{16} \sin^2(\alpha + \alpha')$ , which we may express in

an abridged form by  $1 + \mu$ , and consequently the  $J + n$  oscillations of the pendulum supposed to be made in this arc, will be equal to a number of oscillations infinitely small, expressed by

$$(J + n)(1 + \mu) \text{ or } J + n + \mu(J + n)$$

a result which we may represent in an abridged form by  $J + n'$ . The number  $n'$ , according to what has been above established, never being any way considerable.

If the arcs  $2\alpha$ ,  $2\alpha'$  differ more than in a slight degree from each other, as, for example, when the interval between the coincidences which we compare is large enough for permitting the resistance of the air to have a considerable effect in modifying the first of these arcs, it will then be no more sufficiently exact to suppose all the oscillations made with the mean amplitude  $\alpha + \alpha'$ . But this inconvenience may be remedied, by observing experimentally the law of the gradual decrease of the amplitudes. This law is in geometrical progression when the number of oscillations increases in arithmetical progression, that is, if we begin with the instant when the half-amplitude was  $\alpha$ , and represent by  $\alpha_n$  the amplitude, which

takes place after  $n$  oscillations, we find  $\alpha_n = \frac{\alpha}{K^n}$

or because  $\alpha$  and  $\alpha$  are supposed very small  $\sin. \alpha_n = \frac{\sin \alpha}{K^n}$ .  $K$  being a coefficient, which, in the same

state of the air, is constant for the same pendulum, and depends on its length, its shape, and its other physical qualities. This law, first remarked by Borda, and since confirmed by the other French observers, is a necessary consequence of the smallness of the amplitudes, and of the feebleness of the resistance, which alters each amplitude in succession, proportionally to its extent. But however this may be, it is enough that it really subsists, to enable us to calculate by it the exact sum of the squares of the half-amplitudes in the successive oscillations, a problem which is reduced to the summing of a geometrical progression of  $n$  terms, of which the ratio is  $\frac{1}{K}$ . This sum is simplified when we consider the extreme minuteness of the arcs which we compare, and by then pushing the approximation to their second power inclusively, which is the limit of the correction necessary for each individual amplitude. We thus find

pendulum.

Pendulum.

$$\mu = \frac{\sin(\alpha + \alpha') \sin(\alpha - \alpha')}{32 M \left\{ \log \sin \alpha - \log \sin \alpha' \right\}}$$

M being the modulus of the tables of common logarithms, or 2.30258509. If we suppose the arcs  $\alpha$  and  $\alpha'$  so small, that in the development of their series and of their logarithms, we may limit ourselves to their first power, this expression of  $\mu$  becomes what we have already obtained by our first approximation.

By these calculations we ascertain the rate of the relative going of the pendulum on the clock, which serves to measure the intervals between the coincidences. We know that it performs  $J+n'$  infinitely small oscillations, while the clock makes  $J$  of them. Suppose now that the latter advances during the mean solar day, a number of oscillations equal to  $h$ , that is, that it performs  $J+h$  oscillations during the same time that a clock, exactly regulated by mean time, performs the exact number  $J$ , we shall evidently obtain this proportion;  $J$  oscillations of the clock are to  $J+n'$  infinitely small oscillations of the pendulum, as  $J+h$  oscillations of the clock, or a mean solar day are to the number of oscillations of the pendulum during a mean solar day. The latter number is

thus found equal to  $\frac{(J+n')(J+h)}{J}$  or  $J+n'+h+\frac{hn'}{J}$ ,

the quantity which, for simplicity, we shall represent by  $J+n''$ . With the apparatus so disposed as we have described, if the clock is not very far from mean time, so that  $h$  denotes a small number of oscillations, the correction expressed by the last term, the only one which demands a calculation, will be of an extreme minuteness, and easily obtained with great precision.

It now remains to measure the length of the pendulum from the plane of suspension to the bottom of the ball of platina. For this purpose we place beforehand, under this ball, a small plate of metal, well polished, perfectly horizontal, and which can be made to sink or rise vertically by means of a screw, of which the threads being very fine, permit the smallest motion. (See Plate CIX. fig. 6.) When the coincidences are finished, we open the glass case, and we raise gently this plane until it comes in contact with the ball of platinum. We must be equally careful to avoid raising it too much, which would raise the ball, and make the pendulum too short, or not raising it so high as the contact, which would give a pendulum too long; but if we take for an index the disappearance of a thread of light between the plane and the ball, at their common point of contact, we may then succeed, by a little skill, in fixing this contact with the utmost degree of rigour. This,

however, is never done at the first attempt, for the entry of the observer into the glass case, however short, always elevates in a slight degree the temperature of the air contained in it, and consequently that of the wire, which acquires this temperature in the same instant, from whence arises a small increase of its length, which we ought to be aware of. On this account, instead of establishing a perfect contact between the plane and the ball, in that accidental state of the wire which the interior thermometers, less sensible than it, do not perhaps indicate with sufficient exactness, it is better to confine ourselves at first to the mere preparing for the operation, by making the little plane approach extremely near the ball, without, at this time, actually touching it. We observe now the point where the index of the screw that moves the ball stops, and then coming out of the glass case, we shut it until the temperature within, and the thermometers which measure it, have had time to return to a state of rest. We then open the case anew, and finish in an instant the operation of contact, which is easily done, as we have only to give to the plane of contact a very slight degree of motion, and such as we are previously quite prepared for. At this moment, or rather before entering the glass case, we mark the temperature of the thermometers within, and consider this as the temperature of the wire at the instant of contact.

The distance of the plane of suspension from the bottom of the ball is now fixed, and in such a manner, that it is henceforth invariable, or at least we may suppose it such during a long interval of time. For, the supports of the plane of suspension being fixed in the wall itself, and those of the plane of contact being cemented to a large stone resting on this wall, or sunk into the ground, the accidental variations of temperature cannot alter the distance which separates them, excepting in a very slow degree.\* It remains then to measure this interval by means of a divided rod of metal; but to determine the length of such a rule, its extremities must be quite free; and how can we, in that case, apply its summit exactly on a level with the plane of suspension? Borda has very happily resolved this difficulty, by adapting to one of the extremities of the rule a knife of suspension, which is fixed to it, so as to touch it on its edge. (See fig. 7.) Suppose we wish first to measure the length of the rule, we take off the knife, and apply the rule itself to the apparatus intended for that object. If we wish then to measure the length of the pendulum, we replace the knife, and suspend the rule, thus armed, on the plane of suspension, in place of the pendulum itself. In our experiments, the knife is adapted to the rule by means of a metal case; the rule is inserted into this case until it touches the knife, when it is fixed

\* Considering the indispensable necessity which there is of preserving rigorously this quantity invariable, it appears to be of extreme importance, that the ground may not yield when the observer approaches to complete the measurement. The only means of avoiding, beyond suspicion, this possibility, is to construct round the pendulum a platform, supported on certain points of the ground, at a distance from the stone which carries the little plane with which we effect the contacts of the ball, so that this apparatus may become quite independent of the motions of the observer.

**Pendulum.** in this position by means of a strong pinching screw, denoted by  $V$ , and which is screwed by an iron key. It only remains to alter the length of this rule in such a manner as to render it exactly equal to the actual distance which is found between the bottom of the ball and the plane of suspension. For this purpose, in the experiments of Borda, the rule carried, on its under part, a divided tongue, having a free motion. When the observations of the coincidences were finished, the pendulum was removed, and for it was substituted this rule, of which the tongue was let down until it fell upon the little plane which had touched the ball of the pendulum. Then by reading, with a magnifying glass, the divisions of the tongue, it is easy to know the distance between the bottom of the ball and the axis of suspension.

In Borda's experiments, the pendulum was twelve feet long. A rule of such a length could not have been carried in travelling, or even in stations of difficult access, without the risk of serious errors, resulting from the bending which it must have received. On this account the French observers, who were entrusted with such experiments, thought it necessary to modify in this point the apparatus of Borda, and they confined themselves to pendulums much shorter; as are those which swing mean sexagesimal or mean decimal seconds. This enabled them to make use of rules much shorter, more portable, and which they could also make larger and more solid without increasing too much their weight; but then it became indispensable to introduce a still greater degree of precision than before into the determination of the length of the rules; into that of the divisions traced upon the tongues which were fixed to them; and, lastly, into the measurement of the variable parts of these tongues, which were used in each experiment, in order to adapt them to the different lengths of the pendulum which they were intended to measure. All these elements were obtained with unexpected exactness, by employing for their determination the apparatus already used with such success for the comparison of metrical scales, under the name of *comparateur*. All the details of this application may be seen in the work of Biot and Arago, above referred to.

By means of the operations above described, we find the total length of the pendulum from the plane of suspension to the bottom of the ball of platina; such at least as it is at the instant of contact of the latter with the little plane. But this length may not be, and is not in general, the same which the pendulum has when it began to oscillate; because the temperature which modifies almost instantaneously the length of the wire cannot have been the same at the time of the contact of the plane, and during the observation of the coincidences. But it is to this state that we must evidently reduce the length that we have attained. For this purpose, let it be denoted by  $\Delta$ , and suppose  $t'$  the temperature of the wire in degrees of the thermometer at the instant of contact,  $t$  being its mean value, during the coincidences; then if  $R'$  represent the radius of the ball of platina at the temperature of  $t'$  when the contact was produced, the length of the wire at that instant was  $\Delta - 2R'$ ; so that, calling  $K$

the lineal dilatation of the matter of the wire, for a difference of one degree in the temperature, the length of the wire at the time of the oscillations must have been  $(\Delta - 2R') \{1 + K(t - t')\}$ .

In the same manner, if  $K'$  be the lineal dilatation of the substance of the ball, its diameter, at the time of the oscillations, will be  $2R' \{1 + K'(t - t')\}$ , and adding

this quantity to the length of the wire, we obtain  $\Delta + \Delta K(t - t') + 2R'(K' - K)(t - t')$  for the distance of the plane of suspension from the bottom of the platina ball during the actual time of the oscillations. By deducting from this length the radius of the ball, such as it was at the same instant, that is,

$R' \{1 + K'(t - t')\}$ , we shall have the distance of the centre of the ball from the plane of suspension, a distance which we shall call  $h$ . This being determined, if the wire which sustains the ball, and the cap which fits upon its surface, were both without weight, or if their weight could be altogether neglected in comparison with that of the ball, the length  $l$  of the simple pendulum isochronous with the compound one thus formed would be obtained

by the above formula, and would be  $l = h + \frac{c'}{mh}$ ,  $m$

being the mass of the ball, and  $c'$  its momentum of inertia relative to an axis drawn through its centre. But calling  $\rho$  the density of the mass of the ball, and  $R$  its radius, at the temperature at which the pendulum oscillates, its mass  $m$  is equal to  $\frac{4}{3} \pi \rho R^3$ , and

the value of  $c'$  is  $\frac{8}{15} \pi \rho R^5$ . Substituting these values, we have  $l = h + \frac{2R^2}{5h}$ ; hence it appears, that it

would be easy to calculate  $l$ , since  $R$  and  $h$  are known. But, in truth, the weight of the wire and that of the cap can never be absolutely nothing. They are only very small, relatively to the weight of the ball; so that the preceding value of  $l$  is but an approximation, which, to become quite exact, requires a small correction, depending on the relation of these masses. This correction being rather complicated in its expression, we shall not repeat it here, but refer to the memoir of Borda, or the work of Biot and Arago, already mentioned, and represent it by  $Q$ ; as it is always negative, the length  $l$  of the simple pendulum isochronous with the pendulum observed, will become  $l' = h + \frac{2R^2}{5h} - Q$ . Now we

have seen, that, in these experiments, the apparent gravity which impels the pendulum is less than the real gravity which operates in vacuo, on account of the statical effect of the ambient medium; but for a simple pendulum of the length  $l$  moved by the force of gravity  $g$ , the time  $T$  of its infinitely small oscillations is expressed by  $\pi \sqrt{\frac{l}{g}}$ ; and if we wish to obtain oscillations of equal duration with different forces of gravity, we must vary the lengths in proportion

pendulum. to these forces, so that the relation  $\frac{l}{g}$  may remain

constant. Now, after what we have before seen, if we denote by  $D$  the density of the substance of the pendulum at the temperature of freezing, and under the atmospheric pressure of  $0^m.76$ , that of the air being 1, if, besides, we denote by  $c$  the cubic dilatation of this same substance, the relation of the apparent gravity in air to the gravity in vacuo, under the pressure  $p$ , and at the temperature  $t$ , will be

$$\text{expressed by } 1 - \frac{p}{0^m.76(1+t.0.00375)(1-t)D},$$

which, for simplicity, may be represented by  $1-\gamma$ . Then, to obtain the length  $l''$  of the simple pendulum, which, making its oscillations in vacuo under the influence of the gravity  $g$ , would be isochronous with the actual pendulum  $l'$ , going in the open air,

we must take  $l'' = \frac{l'}{1-\gamma}$ , which, on account of the

smallness of  $\gamma$ , may be reduced to  $l'' = l' + \gamma l'$ . We have denoted above by  $J+n''$  the number of infinitely small oscillations performed by the actual pendulum in a mean solar day. Such, then, is also the rate of the pendulum  $l''$ . If we wish, in fine, to obtain the length  $l'''$  of a pendulum which would move exactly to mean time in vacuo, under the influence of the same power of gravity as  $l''$ , we have only to consider that, according to the preceding expression of  $T$ , the lengths  $l'''$  must be directly proportional to the squares of the times of their oscillations, and therefore reciprocally, as the squares of the number of oscillations made in equal times. We must take, then,

$$\frac{l'''}{n''} = \frac{(J+n'')^2}{J^2}, \text{ whence we obtain } l''' = l'' + \frac{2n''l''}{J} + \frac{n''^2l''}{J^2}.$$

The length  $l'''$  thus obtained is now free from all the variable elements, which depend on particular circumstances of their observations. This constitutes what we should properly call the absolute length of the simple pendulum in the place of observation.

The experimental method which we have described, when it is employed with all due care, gives results which, in the same place, are perfectly comparable with each other. For, with various lengths, such as the sexagesimal pendulum, for example, or the decimal pendulum, the deductions from particular experiments do not differ generally from each other more than in the thousandth parts of a millimetre. To establish, however, completely the theoretical certainty of this method, it is necessary to examine more particularly some of the circumstances which form a part of it.

Our first remark relates to the extensibility of the wire to which the platina ball is suspended. It is clear, that, during the period of each oscillation, the wire is impelled in the direction of its length by two forces of different kinds, and of different intensities; of which the one is the varying traction, acting on it every instant by the weight of the ball de-

composed into its direction; and the other is the centrifugal force, which the motion of oscillation generates. It may evidently be a question, whether this double action has not on the oscillations a sensible influence, which, disappearing in the measurement of the length taken when the pendulum is at rest, would alter the result which we have obtained. M. Poisson has submitted this question to calculation in the eighth volume of the *Journal de l'Ecole Polytechnique*, and he has found, first, that the symmetry of the oscillations on each side of the vertical is not altered by the extensibility of the wire; at least if we suppose them to be performed in vacuo, a circumstance which it was easy to anticipate from the symmetry itself of the mode of action of this force. But he has found that their duration is affected with a periodical inequality, in consequence of which the successive oscillations are not isochronous among themselves. When the total extension, however, suffered by the wire is very small, which is generally the case in experiments where the wires are formed of metallic substances, the effect of this inequality neutralises itself in the mean duration of a great number of oscillations; only this mean period is a little longer than if the wire had been altogether inextensible. Let  $l$ , for example, be the lineal length which the wire would naturally have if left to the sole attractive action of its particles on each other; and suppose that, by suspending the platina ball at its lower extremity, it lengthens by a small quantity  $\lambda$ . This being the case, if the half-amplitude of the oscillation is denoted by  $a$ , M. Poisson finds that limiting the results to the square of  $a$ , the mean duration  $T$  of the whole oscillations will be,

$$T = \pi \sqrt{\frac{l}{g}} \left\{ 1 + \frac{1}{16} \left( 1 + \frac{11\lambda}{l} \right) \sin^2 a \right\}.$$

If we wish to suppose the wire inextensible, we have only to make  $\lambda$  equal to nothing, and it hence appears that the extensibility only modifies the correction of amplitude, already in itself so small, and alters it by a quantity which, from the small extensibility of the metals, cannot in general produce any effect that could be detected by observation.

A second circumstance, which deserves equally to be examined, is the probable influence of the motion of rotation of the platina ball round the direction of the wire, and any twisting which the wire may suffer during the oscillations. M. Poisson has examined, by a calculation in the *Connaissance des Temps* for 1815, the effect of such a motion; and he has found that, in the ordinary disposition of the pendulum of Borda, it is rendered in a manner insensible by this circumstance, that the momentum of inertia of the ball, and of the whole pendulum, relatively to an axis drawn through the direction of the wire, is a very small quantity. Let  $R$  be the radius of the platina ball,  $h$  the distance of its centre from the axis of suspension,  $\alpha$  the angle which the rotation of the ball makes each of the points of its surface describe during the period of an oscillation, this angle being measured in a circle of a radius equal to 1,  $T$  the time of an infinitely small oscillation of the same pendulum, in the case when the rotation is nothing;

Pendulum.

Pendulum. M. Poisson finds that the real duration of the oscillations will be  $T \left\{ 1 - \frac{\alpha^2 R^4}{50h^4 \pi^2} \right\}$ ,  $\pi$  being always as before the relation of the circumference to the diameter, or, what is the same thing, the semi-circumference, of which the radius is 1. In regard to the effect of the torsion communicated to the wire by the rotation of the ball, M. Poisson proves that it can have no influence on the duration of the oscillations. In the shortest lengths of pendulum which have been observed by the above process,  $R$  was less than  $0^m.02$ , and  $l$  nearly equal to  $0^m.74$ . Adopting these numbers, and supposing, besides, that the ball describes two whole circumferences for each oscillation, which would be a very rapid motion of rotation, we shall then have  $\frac{R}{h} = \frac{1}{37}$ ;  $\frac{\alpha}{\pi} = 4$ , and consequently  $\frac{\alpha^2 R^4}{50h^4 \pi^2} = \frac{1}{5856569}$ , whence it appears that

the time of the oscillation would be diminished only by a quantity altogether insensible, even on the above suppositions. But it is far from being the case that a rotation so rapid as we have supposed really takes place in the experiments; on the contrary, when we set the pendulum in motion, we take great care to avoid every movement of this kind; we also pay particular attention to let fall the ball without any lateral impulse, so that its oscillation may be performed as exactly as possible in a vertical plane, which we also take care to verify by observation, when the pendulum is in motion. It would be useless to attempt to obtain this condition in a manner more exact; for it is known by the calculation of conical oscillations, that when these take place in an orbit much flattened, their duration is almost exactly the same as if they were quite plain.

The last object to be considered, and of which the discussion is as important as it is delicate, is the influence which the form of the suspending knife may have upon the oscillations of the same pendulum. Comparing, indeed, the motion of the pendulum to that which would take place round an axis of suspension perfectly rectilinear and mathematically straight, we suppose, or, at least, seem tacitly to suppose, that the edge of the knife forms such an axis, which is physically impossible, since the most perfect art cannot give it any other form than that of a round surface, the breadth of which is sensible to the microscope, and which even there appears always like a saw indented with teeth more or less deep. Now, if this surface were a circular cylinder, a simple calculation, which was first made by Euler, shows that the durations of the oscillations will be the same as if they were performed round a rectilinear axis placed *under* the surface of the cylinder, and at a distance equal to the radius of its curvature; and in the case of very small oscillations, this result may be extended to a knife of any form, if we take for its curvature that of its osculating circle. Hence it follows, that in order to have the true length of the simple pendulum in this circumstance, we must subtract the radius of this circle from the length calculated on the hypothesis of a

rectilinear axis, according to the oscillations observed. But such a correction would throw great uncertainty upon the results; for the osculatory curvature of the knife cannot be measured, or even appreciated by any process, and it must vary considerably, either by the difference of workmanship in different knives, or by the inevitable wearing which the edge of the knife undergoes, when the weight suspended from the wire presses it against the plane of suspension. Fortunately, the extent and the variability itself of the effects which this cause should produce, serve to prove that it has no action whatever in experiments; for, in the first place, by loading successively the head of the same knife with several weights very different among themselves, in order to observe if these different systems, previously according with the same clock, would have an influence on the length of the pendulum; now Borda has found that this influence was absolutely insensible, although the curvature of the edge, to which he did not pay attention, was then undergoing very different modifications under the unequal compressions to which they were subject. Secondly, The length of the simple pendulum, beating seconds at the Observatory of Paris, which Borda had deduced from a pendulum of 12 feet long, has since been found as exactly the same as the difficulties of the operation would permit, by employing, with the same knife and the same ball, wires four times shorter, which gave a much greater influence to the alterations of length which the curvature of the knife could produce. Lastly, By observing successively, at the same place, with the same ball, and the same length of wire, but with knives whose edges presented an extreme diversity, from the highest possible finish, to the greatest coarseness in the execution, M. Biot has obtained, at Leith Fort in Scotland, such lengths for the simple pendulum, between which no sensible difference could be observed, although no correction whatever was made for the curvature of the knife. These proofs of different kinds, but all agreeing in their consequences, seem to show evidently that in the process of Borda the shape of the edge of the knife has no sensible influence on the results, and that it is unnecessary, therefore, to pay any attention to it; and yet, as the theory of oscillations round cylindrical axes cannot be questioned, we must either conclude that in this circumstance the oscillation is really not performed on a cylinder of sensible dimensions, but upon the ideal axis of insensible dimensions, formed by the asperities which still exist in the grain of metal of which the knife is composed; or that the agreement previously established between the proper motion of the knife and the total motion of the pendulum, compensates physically the effect which the curvature of the knife would have upon the oscillations, if it consisted really of a simple cylinder without mass attached to the wire.

## II.—METHOD OF KATER.

The method employed by Captain Kater to measure the length of the pendulum is founded upon this theorem of Huygens, that whatever be the form of the oscillating body, the centre of oscillation

pendulum. and the centre of suspension are reciprocals to each other, a theorem of which we have already given the demonstration. To realise this disposition, Mr Kater chose a body of such a form, that it was easy to determine by calculation the approximate position of its centre of oscillation for a given position of the axis of suspension. These two points being thus known, he fixes there immoveably two knives parallel to each other. In the space which separates them he then adapts to the body a moveable weight, and having first placed it at random, he makes the system oscillate successively upon the one knife and upon the other. If, as it almost always happens in the first trial, the oscillations performed in the two cases are of unequal duration, he moves the intermediate weight, so as to bring them nearer to an equality; then, comparing these anew by observation, he finds necessarily a less disparity between them, which he again reduces, until at last, after a few trials, the duration of the oscillations performed round the two axes become exactly equal. The justness, as well as the rapidity of these reductions, are favoured by the form which Mr Kater has chosen for his oscillating body. This form is a simple rectilinear bar of copper, towards the two extremities of which are placed two known weights; the one of which is immoveably fixed, and the other being moveable, but, at the same time, capable of being fixed in a similar manner, serves first, by its motion, to establish between the two knives, not exactly, but approximately, that reciprocity between the oscillations to which it is desired to bring up the system. This reciprocity is then rendered rigorously exact, by the much more delicate motion of a third smaller weight placed between the knives, in that part of the rod, where we know, by calculation, the effect of its displacement will have the least sensible influence upon the oscillations, which is found to be towards the middle of the rod, in the division of the weights adopted by Mr Kater. A divided scale, engraved upon the bar of the pendulum itself, serves to measure the displacement of this latter moveable weight. In the experiments of Mr Kater, this scale was divided into 12ths of an inch, and a displacement of 12 parts produced a difference of about four seconds in the diurnal rate of the system, reckoning sexagesimally; whence we may be able to appreciate the extreme delicateness of this mode of regulation. The bar, with its weights, is represented fig. 8, Plate CIX. Fig. 9 shows its disposition during the observations.

It is then, as appears, placed before a clock, with which it is compared, by means of a fixed telescope, after the method of coincidences of Borda. But the mode of experiment employed by Kater, requiring the oscillations round the two axes to be observed in a state of rigorous equality, it becomes necessary to avoid, in their comparison, every change of temperature, and thus it is necessary to make the results independent of the variations of this kind, which inevitably arise in the atmosphere. That could only be obtained by rendering the series of coincidences very short, and multiplying the successive inversions of the apparatus. But then, to obtain the same exactness, it is necessary to fix the coincidences with much greater precision than in the method of Borda, where the

Pendulum. little influence which they have is one of the principal advantages. Mr Kater has attained this object, by fixing upon the lentil of his clock a white disc, traced upon a black ground, and of such a size, that it is exactly covered, and no more, by the interposition of the bar of the pendulum, when this is at rest in the situation of the vertical. This same occultation, being then observed during the motion of the clock and of the pendulum, serves to fix the instant of the coincidence; and Mr Kater finds, that in this manner there cannot be any error greater than a second on the instant to which each coincidence belongs.

The rest of the details of the observation are the same as in Borda's process. The amplitude of the arc of oscillation is observed at each coincidence, as well as the state of the barometer and thermometer; and these are employed in the same manner, to reduce the oscillations to what they would have been, if they had taken place in vacuo, and with amplitudes infinitely small, at the observed mean temperature of the oscillating body.

It still remains to obtain the length of the simple pendulum corresponding to this rate of going. After an equality has been obtained in the oscillations round the two knives, this length is equal to the distance between the edges of the knives, at the moment of the oscillation of the pendulum, at least if we consider these edges as lineal axes. It would be evidently impossible to observe the distance in question during the actual motion of the pendulum; but this defect may be supplied by determining it first for some known temperature, and reducing it by calculation to the value which it ought to have during the coincidences, according to the temperature at the time these took place, and the dilatation of the substance of the pendulum, which is also known. It is thus that Mr Kater operated, and he has obtained the true distance between the knives, in comparing it by a microscopic process, with the metal rule which he employed as a standard of measure. In order that this operation may be put in practice, the two edges of the knives must be very exactly parallel. Mr Kater accordingly disposed them in this manner before the experiments, employing the measure itself of their distance to determine and to prove the accuracy of their position, to which they were gradually brought by means of adjusting screws, which allowed each knife to move by very small displacements. He also took advantage of this method, to render their direction quite perpendicular to the length of the bar. Lastly, as the distance between the knives, which we are seeking to determine, is that which took place when the pendulum was in a vertical situation, Mr Kater, during the measurement, applied to the bar, now horizontal, a force of longitudinal traction equal to what it exerted on itself by its own weight, and in a state of oscillation. In calculating the influence which the curvature of the knives, supposing it to be circular, can have upon the length of the simple pendulum, deduced from the oscillations of a similar apparatus, M. La Place has found it to be equal to nothing, and that this length was always rigorously equal to the distance between the edges of the knives. This theorem is only true, on the sup-

**Pendulum.** position that the two edges are of the same curvature ; but whatever precaution may be taken to render them identical, even making them together, and with a single piece of steel, it will be impossible to be assured, that there may not be found differences, not merely very small, but very considerable in the radii of curvature of their osculatory circles ; since these circles are the result, not of any measured and geometrical operation, but of a work of reducing and polishing necessarily vague and irregular. It would appear then by this, that the results of this method would still be subject to the same uncertainty in theory as the results of the others are ; but these uncertainties are dispelled in both cases, by the experimental proofs already described, that, in the process of Borda, the figure of the edge of the knives has no influence upon the length of the simple pendulum, deduced from their oscillations. In short, what completes the proof, that these two methods do not include in themselves any source of inaccuracy, is the surprising and almost ideal coincidence of the results which they afford, notwithstanding the diversity of the two processes. We shall have occasion to give a striking proof of it at the conclusion of the ensuing paragraph.

### III.—PENDULUMS OF COMPARISON.

The two methods which we have been explaining make known the *absolute* lengths of the simple pendulum in every place where it is observed. Both of them, therefore, require to be absolutely determined, on the spot, in lineal measures, and this cannot be done with sufficient exactness but by a process of extreme delicacy, the practice of which implies numerous preparations. But when we wish merely to determine the ratios of the lengths of the simple pendulum to each other, for different places on the earth, we may obtain this without any absolute measurement ; and by the mere comparison of the oscillations made in these places in equal times by a compound pendulum of any form. To demonstrate this, suppose, first, that the figure of the mass of this pendulum is quite invariable, and that it suffers neither dilatation nor contraction, by the changes of temperature ; or, what comes to the same thing, suppose the observations are always made during temperatures exactly equal ; in this case, according to the formulæ laid down in the beginning of this article, the length  $l$  of the simple pendulum isochronous with that compound pendulum, may be expressed by  $\frac{C}{mh}$ ,  $m$  being the mass of the oscillating

body,  $h$  the distance of its centre of gravity from the axis of suspension, and, lastly,  $C$  its momentum of inertia, that is to say, the sum of all the elements of its mass, multiplied by the squares of their respective distances from the axis of suspension. This length  $l$ , then, will be the same in whatever place we observe it, since its analytical expression depends only on the figure of the oscillating body, and the density of its parts ; but in no respect on the intensity of the gravitating force which impels it ; so that, if we take any compound pendu-

lum of any form whatever, but having its mass and figure constantly the same, and make it oscillate successively in different parts of the earth, it is the same thing as to cause a simple pendulum oscillate successively in the same places. But, supposing the oscillations performed in vacuo, and with infinitely small amplitudes, or, what is the same thing, supposing them reduced to these conditions by calculation, the durations,  $T'$   $T''$ , of the oscillations of the same simple pendulum, whose length is  $l$ , are connected with the intensities,  $g'$   $g''$ , of the gravitating force, which impels them by the following relations,

$$T'^2 = \pi^2 \frac{l}{g'}; \quad T''^2 = \pi^2 \frac{l}{g''}; \quad \text{whence we obtain, } \frac{g''}{g'} = \frac{T'^2}{T''^2},$$

that is to say, that the intensities of the gravitating forces are reciprocally as the squares of the times of the oscillations ; or, what is the same thing, they are directly proportional to the squares of the numbers of oscillations made in equal times. For let  $N'$ ,  $N''$ , be these numbers, and  $T$  the total time which corresponds with them, then

$$T' \text{ will be equal to } \frac{T}{N'} \text{ and } T'' \text{ equal to } \frac{T}{N''}; \text{ so that,}$$

by substituting their values, the preceding relation will become  $\frac{g''}{g'} = \frac{N'^2}{N''^2}$ . By such experiments, then,

made with the same compound pendulum, we may be able to determine the relative forces of gravity in the different places of observation. But we may, with equal facility, deduce from them the ratios of the absolute lengths which it would be necessary to give to two simple pendulums in the same places, for making them bear an equal number of oscillations in a given time ; for example, to beat the mean second. For let  $\lambda'$ ,  $\lambda''$ , be these unknown lengths, since the corresponding times of oscillation are each one second, we shall have by our general

$$\text{formulæ } 1''^2 = \frac{\pi^2 \lambda'}{g'}; \quad 1''^2 = \frac{\pi^2 \lambda''}{g''}, \text{ whence we obtain}$$

$$\frac{\lambda''}{\lambda'} = \frac{g''}{g'}, \text{ that is, that the lengths required are pro-}$$

portional to the intensities of gravity in the two places. But we have seen, that the ratio of the gravitating forces may be deduced from the observations made with the same compound pendulum ; and introducing this determination into the preceding expression, we obtain  $\frac{\lambda''}{\lambda'} = \frac{N'^2}{N''^2}$ . Hence, when

we have observed the numbers of infinitely small oscillations made in two different parts of the earth, by the same compound pendulum, of a constant form, the ratio of the squares of these numbers will be equal to the ratio of the lengths of the simple pendulums, which swing seconds in the same places. All these results suppose, as we have seen, that the mass and form of the compound pendulum are rigorously the same at the two stations. To obtain a degree of permanency in the mass, we form the pendulum of metal, cast in one piece, to which we adapt for suspension a knife edge made by a process which ensures the firmness of the connection, and we take

every precaution possible to prevent any physical or chemical alteration from modifying it during the carriage. But the permanency in its dimensions and figure is much more difficult to be obtained, because the inequalities of temperature in the different places of observation, and the accidental variations of natural heat, even in the same place, tend perpetually to disturb it. It is physically impossible to prevent the effects of these alterations in any other way, than by preserving constantly round the pendulum the same artificial temperature; a method which has been really employed, but which requires very great precautions to render the temperature round the pendulum uniform, and a constant attention to manage the sources of cold and of heat in order to maintain it at the same fixed degree. It is on this account more simple, and perhaps more accurate, when the thing is possible, to dispose the experiment so as to have only very slow changes of temperature; then to allow the pendulum to partake of these changes, and to correct this effect on its form by calculation, from the observation of the temperature, and the knowledge of the proper dilatation of the substance of which it is composed. This correction is extremely easy; for if we resume

the expression  $l = \frac{C}{mh}$ , which expresses the corresponding length of the simple pendulum, the momentum of inertia  $C$  is of the same order as the mass, multiplied by the square of the dimensions of the oscillating body, and the denominator  $mh$  is the product of this same mass by a single dimension; whence it is easy to conclude, that if the dimensions should vary in the same proportion in every direction, which really happens in changes of tempera-

ture, the quantity  $\frac{C}{mh}$  will vary according to this simple proportion. Hence, if we name  $l$  the length of the simple pendulum, isochronous with the compound pendulum, when the latter is at the standard temperature  $t$ , and denote by  $l'$  the analogous length when the temperature is  $t'$ , representing also by  $K$  the lineal dilatation of the mass of the pendulum, for a change of one degree of the temperature, and for a length equal to unity, we shall evidently have

$$l' = l \left\{ 1 + K(t' - t) \right\} .$$

Suppose now the pendulum  $l'$  has made a number  $N'$  of oscillations, in a given interval of time, for example, a mean solar day, it will be easy to calculate how many the standard pendulum  $l$  would have made in the same time, if it had been acted on by the same force of gravity; for the squares of the numbers of oscillations made in equal times being reciprocally as the length of the pendulums which perform them, the square of the number sought will then be

$$\frac{N'^2 l'}{l}, \text{ or } N'^2 \left\{ 1 + K(t' - t) \right\} .$$

Hence we obtain for this number itself  $N' \sqrt{1 + K(t' - t)}$ ; or reducing the radical into a series, and limiting it to the first power of  $K$ ;  $N' + \frac{1}{2} N' K(t' - t)$ . This approximation is always sufficient, because the co-

efficient  $K$  of the lineal dilatation is always very small in solid bodies, and the difference  $t' - t$  of the natural temperatures in the places of observation can never exceed a small number of degrees. Captain Kater, for example, has operated with a similar pendulum, made of brass, the observed lineal dilatation of which was 0.00000982 for one degree of Fahrenheit. In an experiment made in London, this pendulum was found to perform a number of oscillations equal to 86051.32, the temperature being 71°.6. If we wish to reduce this experiment to the standard temperature of 62 degrees, which was adopted by Mr Kater, we shall have  $N' = 86051.32$ ;  $K = 0.00000982$ ;  $t' - t = +9°.6$ , whence we obtain, for the correction of the temperature,  $\frac{1}{2} N' K(t' - t) = +4''.04$ , that is to say, four oscillations, and four hundred parts, added to the number of oscillations observed. By operating in the same manner in every other case, we can reduce all the observations to the constant temperature once fixed as a standard.

But one of the indispensable elements in this reduction is the actual temperature of the pendulum during the experiments, and some precautions are necessary to obtain it with exactness. For the pendulum being always very large compared with the thermometers, which we can place by the side of it, it partakes much more slowly than them of the variations of temperature, so that it ought always to be a little colder than the thermometers when the temperature of the air is rising, and a little warmer when it descends. It would be impossible to estimate these differences of state; but we can render their effect insensible, by operating in a room, so large and sheltered from the sun, that the temperature remains in it nearly constant, or at least suffers such slow variations, that the mass of the pendulum has time to partake of them. For in that case the thermometers will point out the state of this mass in indicating that of the ambient air; or if there remains some difference between both, the effect of this will disappear by compensation in a series of experiments sufficiently repeated.

We have mentioned above, that the corrections relative to the amplitude of the arcs and the density of the air, are made in every place for the compound pendulums, the same as in the experiments with the absolute pendulum. The duration of the oscillations may also be determined in the same manner by the method of coincidences, comparing the experimental pendulum with a clock that is actually regulated by astronomical observations. Thus in applying this process, and these corrections, we shall obtain the numbers of oscillations which a compound pendulum would have made at the different stations, if it had oscillated in vacuo, and at a temperature always constant. Whence we may then deduce the relation of the intensity of gravity at these stations, or the ratio of the lengths of the simple pendulum, swinging the same fixed number of seconds in a given time.

To give an example of this deduction, we shall relate the following result, obtained in 1818, by Captain Kater, with the same compound pendulum the dilatation of which is stated above. The numbers of

**Pendulum.** oscillations expressed in the last column are reduced by calculation to the case of amplitudes infinitely small, the pendulum in vacuo, and the temperature being the standard of 62° Fahrenheit.

Names of the Places.	Latitudes of the Stations.	Number of Oscillations of the Compound Pendulum in 24 mean Solar Hours.
London, .	51° 31' 8"	86061" .30
Leith Fort,	55 58 37	86079 .22
Unst, . . .	60 45 25	86096 .84

From other experiments previously made by means of the method of inversion, Captain Kater had determined the length of the absolute second pendulum at London, precisely at the same place, and in the same room, where he since made his compound pendulum oscillate. This length expressed in English inches, on Sir George Shuckburgh's scale, was found to be 39.13908 inches. If then we call this length  $\lambda$ , and  $\lambda', \lambda''$  the analogous lengths for the two other stations of Leith and of Unst; also  $N, N', N''$  the number of oscillations of the portable pendulum in these three stations, we shall have, according to the formulæ

$$\text{above laid down, } \lambda' = \lambda \cdot \frac{N^2}{N'^2}; \lambda'' = \lambda \cdot \frac{N^2}{N''^2}, \text{ which will}$$

give for the length of the simple pendulum, at the station of Leith, 39.15538 inches, at the station of Unst 39.17141 inches. Now, by comparing, by methods of extreme precision, the scale of Sir George Shuckburgh, with a metre of platina, executed under the directions of the Board of Longitude of France, and verified by a commission of several members of this body, Mr Kater has found that the metre, taken at its own standard temperature, which is that of melting ice, is equal to 39.37079 inches of the scale of Sir George Shuckburgh, taken also at its own standard temperature, which is 62 degrees Fahrenheit. Hence, it follows, that any length  $l$  expressed in inches of this scale, taken at its standard temperature, is equal

$$\text{in millimetres to } \frac{1000.l}{39.37079}. \text{ The preceding}$$

lengths of the simple pendulum, both at Leith and Unst, being already reduced to this standard state, we may apply to them directly this formula, and deduce in millimetres the following values, which are set down, compared with those of Biot, obtained by the method of Borda, from observations made with great care, the preceding year, in the same stations of Leith and Unst, where Captain Kater has since gone.

Names of the Stations.	Lengths of the Simple Pendulum according to Kater.	Lengths of the Simple Pendulum according to Biot.	Differences of Kater's Measurement.
	<i>m m</i>	<i>m m</i>	<i>m m</i>
Leith Fort,	994.528685	994.524453	+0.004232
Unst,	994.935840	994.943083	-0.007243

The differences of the results, it will be seen, are excessively minute, for they consist only in some thou-

sand parts of a millimetre, which is equal to  $\frac{39}{1,000,000}$  of an English inch; and they are besides affected with contrary signs at Unst and at Leith. We may reasonably conclude then, that they fall within the limits of that uncertainty to which all physical results are subject; and it may therefore be inferred, that the method of Borda and that of Captain Kater are equally precise, and give both, with exactness, the absolute measure of the pendulum.

In attempting to carry compound pendulums on distant journeys, or when we are obliged to observe them in places where the apparatus cannot be fixed to solid buildings, this must necessarily be modified, so as to be complete in itself. To do this, we may prepare for the pendulum a support of metal, made from a single casting, the feet of which spreading out, can be firmly fixed in the ground, while they allow the pendulum, at the same time, to oscillate at freedom between them. The upper part of this support must consist of a plate having a longitudinal opening in it, to allow the stem and knife of the pendulum to pass through. On this is fixed, with long screws, a polished plate pierced with a similar opening, and which can be set horizontal with a spirit-level before fixing it; and it is on this plane that we place the knife of the pendulum. A divided scale, unconnected with the pendulum, is placed horizontally, immediately under the lower extremity of its stem, which being furnished with a point, indicates, by its excursions upon this scale, the amplitudes of the oscillations. In order, now, to determine the rate of the pendulum's going, it is not always possible to procure the necessary facilities for employing the method of coincidences. In that case, we may substitute for it the comparison of the pendulum with an adjoining clock, or else with a chronometer, counting as Bouguer did, the whole oscillations which the pendulum performs during a given time, and determining the fractions of oscillations, by observing the part of the amplitude with which the point of the stalk corresponds at the commencement and termination of the interval of the time observed. But in making use of this last process, which is indispensable for fixing the extreme terms of each compared interval, we can dispense with the counting of the oscillations one by one; for, it will be sufficient to follow them with a counter, the rate of which is adjusted very nearly to that of the experimental pendulum, and which we take care from time to time to regulate according to it; accelerating or retarding its motion by an impulse given to its lens before it has lost or gained a whole oscillation. This last part of the proceeding has been suggested by M. Arago, and employed by Captain Freycinet in his voyage round the world. Then it only remains to fix, by observation, the position of the stem upon the arc of amplitudes at the periods of comparison with the chronometer or the clock, and from thence to deduce the fractions of oscillations which the counter could not indicate. These fractions may be obtained from the mathematical law which regulates the motion of the pendulum in each oscillation. If we call  $2\alpha$  the whole amplitude with which the pendulum oscillates,

Pendulum and T the total time which it takes to describe it, also  $\epsilon$  the arc which it describes, during the time  $t$ , in falling from the extremity of this amplitude, the law of the descent, limited to small amplitudes, gives

$$\epsilon = 2\alpha \sin^2 \left\{ 90^\circ \cdot \frac{t}{T} \right\} \text{ so that, by representing the}$$

half-amplitude  $\alpha$  by 1000 parts, and supposing  $t$  successively equal to  $\frac{1}{10}, \frac{2}{10}, \frac{3}{10}$  of T, or of the duration of a whole oscillation, we obtain for  $\epsilon$  the following values :

Values of $t$ in 10ths of the whole Oscillation.	Portions of the Half-Amplitude described.
1	48.9
2	191.0
3	412.2
4	691.0
5	1000.0

It would evidently be of no use to push the calculation of these numbers beyond a half-amplitude, since they must be symmetrical on each side of the vertical, when the values of the time  $t$  are reckoned, as they always can be, from the extremity of the half-oscillation in which the pendulum actually is. This being understood, the use of the table is easily explained; for the immediate observation gives the demi-amplitude  $\alpha$  at the period of the comparison with the chronometer; it gives also, at this instant, the value of the arc  $\epsilon$ , according to the division on the scale of amplitudes to which the stem of the pendulum corresponds. Dividing  $\epsilon$  by  $\alpha$ , the decimal fraction which will hence result being multiplied by the number 1000, may be compared with the numbers contained in the second column of the above table; and the first column will immediately give, either directly or by interpolation, the fraction of time corresponding to this position of the stem, a fraction which must be added to the whole number N of the preceding oscillations, if the pendulum is on its descent towards the vertical, and subtracted from N+1 if the pendulum is on its ascent towards the end of the oscillation.

The experiments on the variation of gravity at different places on the earth were not at first made with a free pendulum such as we have now described, but with a pendulum adapted to a clock. It was in this manner that Richer discovered the existence of this phenomenon in 1672, in a voyage which he made to Cayenne by order of the Academy of Sciences, for the prosecution of various researches in physics and astronomy, among the number of which was the measurement of the pendulum. On his arrival at Cayenne, Richer remarked that his clock, the weights of which had not been altered since his departure, had a diurnal rate of going of 2' 28" slower than at Paris; and not only did this observation prove the fact of the diminution of gravity, in going from the pole towards the equator, but if we had known the details, particularly in regard to the relative differences of temperature, we might then probably deduce a more certain and exact measure of this di-

minution than what can be drawn from the absolute length of the equatorial pendulum, determined by the same Richer at Cayenne, with the imperfect methods which were then in use. We shall not dissemble that this assertion requires some proof; for the mode of observing by clocks appears necessarily subject to great uncertainty; the pendulum's own motion being constrained or modified by the motion of the wheels. But this influence is not, perhaps, in reality so great as one would be led to suppose; in fact, it is not the pendulum, but the weight applied to the clock, which makes the wheels move; the pendulum merely regulates the intermittances in the fall of this weight by its oscillations, which stop it and set it free by turns; and this alternation is performed by means of the escapement which now disengages itself from the teeth, and then lays hold of them again. When it is disengaged, the action of the weight which turns the wheel excites it, and accelerates its fall in its descent. But, in the ascending half-oscillation, which follows, the same action confines the pendulum and retards it; so that these two contrary efforts, which both operate with very slight degrees of friction, appear like the resistance of the air, and every other constant friction to balance their mutual influences on the motion, in each whole oscillation, and merely to limit the amplitude of the arcs in which this oscillation takes place; a limitation which we can easily take into account, by observing the amplitudes, and reducing all the oscillations, by calculation, to the case of their being infinitely small. It would be curious to make experiments on this subject, and it would be easily done; for it would be sufficient to vary the weight applied to a clock, and to see if the variations of amplitude which would result are such that, in paying attention to them, the clock may be brought back to its original rate. Some observations already made indicate the exactness of this restitution, or at least the very near approach to it.

In the travels in Lapland, for example, undertaken by the French academicians in 1736, an excellent clock by Graham was carried out to be employed for determining the variation of gravity. This celebrated artist had constructed it for this purpose, and had done so with very particular care. In order to render it more steadily comparable with itself, he had adapted to it a pendulum, formed of a simple verge of copper, to the bottom of which was affixed a lenticular mass of a constant weight; and he had provided pieces which raised the rod up during the voyage, and kept its summit free from all contact, so that the knife edge could not be altered by any friction against the plane of suspension, although the rod was always at liberty to follow the dilatations and contractions produced by the changes of temperature. Now, in the account of the labours connected with this operation, which Maupertuis has published under the title of *Figure de la Terre Determinée*, we find, that with the action of the weight, usually applied to this clock, it made, at Paris, 86394".4, during a revolution of the fixed stars, in describing arcs of 2' 10' on each side of the vertical, while, with a weight twice as small, it made 4" more, that is,

Pendulum.  $86398''.4$  in the same interval, describing arcs of  $1^\circ 15'$ . Now, if we apply here the correction relative to the amplitude of the arcs, which is  $\frac{1}{16} N \sin^2 \alpha$ ,

calling  $N$  the number of oscillations, and  $\alpha$  the demi-amplitude, we shall then find, that in the first case it is necessary to add  $7'' 711$  oscillations, and in the second,  $2'' 563$ , to reduce each of them to the case of amplitudes infinitely small, which gives  $86402.1$  and  $86401.0$  for the total number of oscillations infinitely small in the two cases. These quantities only differ by  $1.1$ , and as the observations at this period were not carried to a greater exactness than this difference, it would be of no use to look for a more perfect agreement between them. We have still the example of a similar proof made by Graham himself, upon another clock, which he had constructed to determine the variation of gravity between London and Jamaica; an object for which it was really employed; its rate having been observed for this purpose by Graham in London, and at Jamaica by C. Campbell, a skilful observer, and the friend of Bradley. In the account of this operation, which has been given by Bradley himself, in No. 431 of the *Philosophical Transactions*, it appears that Graham having taken away the weight from this clock, which was  $12\text{lb. } 10\frac{1}{2}\text{oz.}$  and having replaced it by another of  $6\text{lb. } 30'$ , the amplitudes of the oscillations, which were at first  $3^\circ 30'$ , were reduced to  $3^\circ$ , and the diurnal rate of the clock slackened by  $1\frac{1}{2}''$ . Now, if we reduce each of these rates to the case of amplitudes infinitely small, in taking successively for  $\alpha$ ,  $1^\circ 45'$  and  $1^\circ 15'$ , we find for the reduction in the first case  $5''.03$ , in the second  $2''.6$ , of which the difference is  $2''.4$ , instead of  $1''$ , which Graham had observed; and as this able artist had not had any other end in view than to prove the small alteration in the diurnal motion by a change of weight so considerable, it is possible that he may not have taken the same pains in determining the temperature and other details of the observation, which he would have done if he had been seeking to determine an element of correction with a perfect accuracy. It appears very probable then, by these examples, that in clocks constructed in this manner, the action of the weight, transmitted by the wheels, accelerates the proper motion of the pendulum, during each descending half-oscillation, as much nearly as it retards it in the ascending half-oscillation which follows. So that these opposite modifications seem to compensate each other, at least with a sensible equality, in each complete oscillation. Whence we may conclude with equal probability, that the greater or less facility in the motions, and the various energies of friction produced by the unequal tenacity of the oil, at different periods, and at different temperatures, can have but a very small influence on the proper motion of a pendulum, and which must become quite insensible by employing an oil of tried permanence of constitution; and above all, by producing artificially, at all the stations, the same fixed temperature as was done by the French academicians in 1736, in their journies in Lapland, and also by the intrepid English mariners in 1820, in their memorable voyage to the North Pole. But admit-

ting the constancy of the results obtained at the same place by this mode of observation, which, we repeat, still wants to be completely proved by new experiments, it is clear that no other method could be more convenient. For it would be sufficient in every place to prepare the clock; to set it up, with every precaution in levelling, which can place it in a state and situation similar to itself; then to compare its rate of going with the diurnal motion of the heavens, either with a small transit instrument, or even by means of a simple telescope, firmly fixed to some immovable mass, and directed towards a star, the diurnal return of which could be observed with fixed wires, stretched in the focus. Messrs Breguet have begun on this subject a series of experiments, but as the processes for determining results of this nature cannot be too severely scrutinized, we sincerely wish that other observers would make similar attempts, and publish the results deducible from them.

#### USE OF THE PENDULUM IN DETERMINING THE OBLATENESS OF THE EARTH, AND THE INTENSITY OF GRAVITY AT DIFFERENT LATITUDES.

According to the theory of universal attraction, if we consider the earth and the planets as having been originally masses in a fluid state, endowed with a motion of rotation round themselves, they must have taken the form of a spheroid, flattened at its poles; and the force of gravity, which is observed at their surfaces, would then be the result of two distinct forces, of which the one is the general attraction, exerted upon each point of the surface by all the particles of matter in the spheroid, according to their masses and distances; and the other is the centrifugal force, excited at the same point by the motion of rotation. But the intensity of the attraction, exerted upon different points of the surface by the whole mass, must be in general variable, as well as the centrifugal force. The union of these two causes, then, must produce in the force of gravity inequalities, which observation may discover. But we may easily rid these inequalities of the effect of the centrifugal force; for this can be calculated for each point, when we know the dimensions of the spheroid, its rotation, and the axis round which it turns. The observations thus reduced present results which are only dependant on the attraction of the spheroid upon which they are made; and they may consequently serve to determine its exterior configuration, as well as the laws of density, by which the attractive matter is distributed through its interior. The remarkable discovery of these relations, between the force of gravity at the surface of the heavenly bodies, and their form, as well as their internal constitution, we owe to Newton; and this great man, in following them out, determined even the value of the oblateness which the terrestrial spheroid ought to have, supposing it elliptical and homogeneous, in order to be in equilibrio with its actual velocity of its rotation. He thus found, that denoting by  $\varphi$  the observed ratio of the centrifugal force, to the force of gravity at the equator, the oblateness of the spheroid must be  $\frac{5}{4}\varphi$ ; and as  $\varphi$ , from observation, may be

Pendulum.

estimated for the earth at  $\frac{1}{289}$ , or at 0.00346031,

there results the oblateness  $\frac{5}{4}\phi = \frac{1}{231}$ , or 0.004325,

a quantity much superior to the observed value, 0.00326; which shows that the terrestrial spheroid is not homogeneous. But, as this element of measure had not as yet been determined in the time of Newton, he could not draw this consequence. He confined himself, therefore, to the determination of the variations of gravity in the case of the supposed homogeneity, and he found it, as it is in fact, proportional to the square of the sine of the latitude. But he erred in endeavouring to extend these determinations to the case of any ellipsoid, composed of concentric strata of unequal density. For, finding that the observations of the pendulum gave the actual variation of gravity in proceeding from the equator to the pole, greater than the calculation established for the case of homogeneity, he thought that the oblateness ought to increase at the same time with this variation, although the real measures of degrees have since pointed out the inverse of this result; for they agreed in giving a slighter oblateness than 0.004325, with a more considerable variation of gravity. Clairault, in his admirable work on the figure of the earth, was the first to point out this error which had escaped Newton; and he demonstrated at the same time this remarkable theorem, that, in all the hypotheses, the most probable that can be formed regarding the density of the interior parts of the earth, which must always be supposed most dense towards the centre, there is always such a connection between the fraction which expresses the difference of the axes, and that which expresses the diminution of gravity from the pole to the equator, that, if the one of these two fractions exceeds 0.004325, the second will fall short of it by the same quantity; so that their sum must be always equal to the double of 0.004325, or to 0.00865. In this case, also, the length of the seconds pendulum varies from the equator to the pole, in proportion to the square of the sine of the latitude. Thus, calling  $\lambda$  this length at any latitude  $L$ , and  $A$  the length at the equator itself, we have in general  $\lambda = A + B \sin^2 L$ ,  $B$  being a constant coefficient, to be determined by observation. It must be remarked, however, that this result supposes the lengths of the pendulum, to be observed, at the very surface of the terrestrial spheroid; for, in receding from this surface, although at the same latitude, the intensity of gravity diminishes nearly in proportion to the square of the distance from the centre, and consequently the length of the pendulum must diminish according to the same law. Reciprocally, then, if we have observed this length at any height  $h$  above the terrestrial surface, and that we have found for it a value expressed by  $l$ ;  $a$  being the radius of the earth at this latitude; the

length reduced to the level of the sea will be  $\frac{l(a+h)^2}{a^2}$ ,

or  $l + \frac{2hl}{a} + \frac{lh^2}{a^2}$ . But this reduction may be simpli-

Pendulum.

fied, by considering that, on account of the small height

to which we can rise above the earth's surface,  $\frac{h}{a}$  is al-

ways a fraction so excessively small, that the first power of it is sufficient to be used. So that, limiting ourselves to this order of approximation, the reduced length

will become  $l + \frac{2hl}{a}$ . The term  $\frac{2hl}{a}$  forms then the

correction which the experiments require that they may be reduced to the level of the sea, and thus rendered comparable with each other. Such is, in fact, the mode of reduction generally employed; but we must remark that it is itself subject to uncertainty. For the mountains on which we ascend attract the pendulum by virtue of their own mass; in consequence of which, it becomes necessary to pay attention to this attraction, that the reductions may be made rigorously exact, instead of applying the bare formula, which supposes the observations to have been made in the open atmosphere. But this is an inconvenience which is unavoidable; for it is impossible to calculate exactly the peculiar attraction of the masses on which we operate, since this would require the knowledge of their relative density, and even of the arrangement of the materials which enter into their composition. But, as we cannot avoid this uncertainty, we must endeavour to render it as small as possible, by making our observations as near the level of the sea as we are able. We must then recollect, that, by ascribing at the highest station the whole of the force of gravity to the sole and distant action of the earth, we suppose it to be more powerful than it really is. So that, by reducing it on this hypothesis, to what it would really be if it had been observed at the level of the sea itself, we commit a double error; the mountain's own attraction tending, in this second case, by its contrary direction, to weaken the effect of gravity, which it had before augmented. Fortunately, the excessive smallness of the highest mountains, compared with the mass of the globe, must diminish extremely their relative influence, and render equally minute the errors which may arise from neglecting it.

To determine, now, the coefficients  $A$  and  $B$  of the general formula, we shall employ the oblateness

0.00326, or  $\frac{1}{306.75}$ , which M. La Place has obtained

by submitting to a general and profound discussion, the measures of the terrestrial degrees, and the lunar equalities depending on the oblateness of the earth. We shall join to it the length of the simple pendulum of sexagesimal seconds, found by Biot at the station of Unst, a length which, we think, may be considered as one of the most certain that has been observed. *First*, because having been the last of the observations made by Borda's method, it must have been taken with all the precautions suggested by preceding experiments. *Secondly*, on account of the great number of series from which it results, these being 56 in number, and made with different rules, and pendulums of unequal lengths, which all agreed in assigning for the definitive result values differing excessively little from each other. And,

*Pendulum.* Lastly, from the perfect agreement which is found between it and the results of the observations of Captain Kater. This single absolute length, together with the oblateness 0.00326, will suffice for determining the two constant quantities A and B of the general formula, which expresses the length of the pendulum at any latitude. Now, according to this formula, the length of the pendulum at the equator, where L is nothing, is equal to A, and at the pole, where L=90°, it is A+B. So that  $\frac{B}{A}$  is the relation of the total variation of the pendulum to its absolute length at the equator; a ratio which is the same as that of the increments of gravity to the absolute force of gravity itself. Adding, then,  $\frac{B}{A}$  to the oblateness 0.00326, we shall have, by the theorem of Clairault, the following condition,  $\frac{B}{A} + 0.00326 = 0.00865$ , whence we obtain B=A.0.00539, and, consequently,  $\lambda = A(1 + 0.00539 \cdot \sin^2 L)$ . Now, we have seen above, that at the station of Unst, in latitude 60° 45' 25", the length of the sexagesimal seconds pendulum determined by the observations of Biot, was 994.943105. The height of this station was only 9<sup>m</sup> above, the

level of the sea, which gives for the reduction  $+0.0002818$ . Whence there results, at the level of the sea, the height 994.945923. Putting this value, then, and that of L in the formula, the coefficient A, is determined, and we find A=990.879660. consequently B=5.340843; which gives for any latitude L,  $\lambda = 990.879660 + 5.340841 \sin^2 L$ . If we wish to reduce this formula in English inches, all the terms must be multiplied by  $\frac{39.37079}{1000}$ , and then  $\lambda = 39.0117150 + 0.2102732 \sin^2 L$ . Finally, if we wish to reduce it to the decimal pendulum employed by the French observers in their calculations, we must multiply the terms by  $\left(\frac{864}{1000}\right)^2$ , the ratio of the decimal to the sexagesimal pendulum. We then have  $\lambda = 739.687686 + 3.986917 \sin^2 L$ . If we calculate from this last formula, the lengths of the decimal pendulum, for the stations where the French observers have operated, from Formentera to Unst, and compare them with their results, we obtain the following table.

Names of the Places.	Names of the Observers.	North Latitudes.	Length of the Decimal Pendulum at the Level of the Sea,		Excess of Calculation.
			By Calculation.	By Observation.	
Unst, . . .	Biot	60° 45' 25"	<i>mm</i> 742.723136	<i>mm</i> 742.723136	0.000000
Leith Fort, .	Biot, Mudge	55 58 37	742.426416	742.413435	+0.012981
Dunkirk, . .	Biot, Mathieu	51 2 10	742.098066	742.077030	+0.021036
Paris, . . .	{ Biot, Mathieu, Bouvard }	48 50 14	741.947360	741.917490	+0.029870
Clermont, . .	Biot, Mathieu	45 46 48	741.735412	741.705180	+0.030232
Bourdeaux, .	Biot, Mathieu	44 50 26	741.670048	741.608720	+0.061328
Figeac, . . .	Biot, Mathieu	44 36 45	741.654181	741.612280	+0.041901
Formentera, .	Biot, Arago, Chaix	38 39 56	741.243950	741.252000	-0.008050

The progression of the deviations contained in the last column of this table shows, in proceeding from the north to the south, a progressive decrease of gravity, greater in a slight degree than the elliptical figure requires; a result which had already been remarked in regard to Scotland and England by Captain Kater. It may be observed here, that the absolute value of this variation for Unst, Leith, and Dunkirk, agrees exactly with that which Captain Kater has found, or what could be deduced from his experiments. But the same effect is observed to continue throughout France, being most sensible at the station of Bourdeaux. It becomes less even at Figeac, situated more inland, and on a more solid base. It again becomes nothing at Formentera, where the deviation of the formula compared with observation is  $\frac{8 \text{ mm}}{1000}$  in a contrary direction, which would seem rather to indicate a slight local excess in the intensity of gra-

vity. This singular anomaly, which is so stated, in regard to the force of gravity, throughout the terrestrial arc which extends over all this part of Europe, is, without doubt, owing to peculiarities in the geological constitution of the countries which are situate on it; and it appears by this example, how well the observations of the pendulum are adapted for pointing out the irregularities of this constitution. But, for this purpose, the observations must possess so great a degree of exactness that the peculiar uncertainties to which they are liable may be, as we may suppose they were in those which we have employed, much smaller than the variations of constitution which they are intended to indicate. Here it may be remarked, that the part of France, where these variations are the most sensible, are precisely the same where there were found, by Delambre's observations, the greatest anomalies in the lengths of the degrees.

**Pendulum.** From the preceding formulæ may be deduced the variation in the diurnal rate which a compound pendulum, of an invariable form, must present when carried to different latitudes. If we denote by  $N, N'$ , the number of oscillations of this pendulum at two different stations, where the lengths of the simple seconds pendulum are  $\lambda, \lambda'$ , we have shown above that  $\frac{\lambda'}{\lambda} = \frac{N'^2}{N^2}$ , whence  $N'^2 = \frac{\lambda'}{\lambda} \cdot N^2$ . Now, calling

$L, L'$  the latitudes of the two stations, the above formulæ give the values of  $\lambda$  and of  $\lambda'$ , as well as their relations; substituting, then, these values in the preceding equation, we obtain  $N'^2 = \frac{A+B \sin^2 L'}{A+B \sin^2 L} N^2$ .

An expression by means of which we can calculate  $N'$  when we know  $N$ .

The total variation of gravity from the equator to the pole is so inconsiderable, that the difference between the numbers  $N, N'$  is always very small compared with these numbers themselves. This difference, then, is the element which we must try to put in evidence in the formulæ. But nothing is easier; for, if we denote it by  $n$ , so that  $N'$  is represented by  $N+n$ , the preceding equation will become  $N^2 + 2nN + n^2 = \frac{A+B \sin^2 L'}{A+B \sin^2 L} N^2$ .

Whence we deduce

$$2nN + n^2 = \frac{B \sin(L'+L) \sin(L'-L)}{A+B \sin^2 L} N^2,$$

and resolving the value of  $N$  into a series,

$$n = \left\{ \begin{array}{l} \frac{B \sin(L'+L) \sin(L'-L) \cdot N}{2(A+B \sin^2 L)} \\ - \frac{B^2 \sin^2(L'+L) \sin^2(L'-L)}{8(A+B \sin^2 L)^2} \cdot N \dots \&c. \end{array} \right\}$$

But from the value of the oblateness which we have adopted, we have seen that  $B$  is equal to  $A \cdot 0.00539$ . Substituting this value in our series, it becomes

$$n = \left\{ \begin{array}{l} \frac{0.00539 \cdot N \cdot \sin(L'+L) \sin(L'-L)}{2(1+0.00539 \sin^2 L)} \\ - \frac{0.000029 \cdot N \cdot \sin^2(L'+L) \sin^2(L'-L)}{8(1+0.00539 \sin^2 L)^2} \dots \&c. \end{array} \right\}$$

The second term will be almost always insensible, and it will be quite needless to take in any of the following ones.

To show the use of this formula, we shall apply it to the following observations, which belong to the most distant countries on the earth.

Names of the Observers.	Names of the Stations.	Longitudes, reckoned from Greenwich.	Latitudes.	Number of Oscillations performed by the Compound Pendulum in a Sidereal Day, or in a Mean Solar Day, at the same Temperature.	Variation of the Diurnal Rate, by Observation.	Variation of the Diurnal Rate, by Calculation.	Excess of Observation.

The experiments of Captain Sabine were made with two pendulums applied to two different clocks, the results of which have agreed very well in their relations. We have only stated here the mean of these results. The observations of Maupertuis, Clairault, and Lemonnier, were made by a process of the same kind, but with a single clock by Graham. In these two expeditions the observers produced artificially at the second station the same temperature as at the first. In the operation by Campbell, the same

pains were not taken; but in Bradley's computations, an allowance was made according to the indications of the thermometers. The experiments of Captain Freycinet were made on detached pendulums, the rate of which, first determined by Arago, Mathieu, and himself, at the Royal Observatory of Paris, was compared in the voyage with well regulated chronometers, making allowance, by calculation, for the changes of temperature. The smallness and the irregularity of the differences which are found be-

*Pendulum.* tween the results of these different experiments, and the numbers given by the formula, show that the latter is the general expression of them, modified only by the accidental variations which may be occasioned in each place by small differences of density in the neighbouring strata of the surface of the earth. The formula being grounded upon the oblateness 0.00326,

or  $\frac{1}{326.75}$ , its agreement with the facts proves that

this value of the oblateness, if not rigorously exact, is at least a very near approximation, and is, besides, common to the two hemispheres of the globe, since the observations of Captain Freycinet in the southern hemisphere, at the Cape of Good Hope, are as correctly represented by it as the observations made in the northern hemisphere. This puts an end, then, to the notion entertained after the measurement of the degree by Lacaille in this part of the globe, that the southern hemisphere was more oblate than the northern; a notion, however, already much weakened by the agreement of the oblateness observed in this latter hemisphere with that which was deduced from the inequalities of the moon; since the motion of this satellite must be influenced by the mean of the two ellipticities if they were different; but it was nevertheless of consequence to see this suspicion wholly extinguished, as it is now by Freycinet's observations.

The general experiments on the length of the pendulum which we have above described, being verified by the different observations by which we have compared them, will serve to determine the intensity of gravity, whether absolute or relative, on any of the places of the terrestrial globe. For, calling  $\lambda$  the length of the simple pendulum, which makes its oscillations in a second of time in a given place, and denoting by  $g$  the double of the space which gravity makes bodies describe in their fall in the same place, and during the same interval of a second, the fundamental formula of oscillations, infinitely small, gives  $1'' = \pi \sqrt{\frac{\lambda}{g}}$ , consequently  $g = \pi^2 \lambda$ ,  $\pi$  being

the ratio of the circumference to the diameter, or 3.14159. But we have already given for any latitude the value of  $\lambda$  expressed in millimetres and in English inches, taking for the unity of time either the decimal or the sexagesimal second. Multiplying these expressions by the square of  $\pi$ , we shall have the value of  $g$  for the same latitude, and the same kind of unity of time which may be chosen.

It may be objected, that we have not made use of the lengths of the simple pendulum observed under the equator by Bouguer, and detailed in his work on the figure of the earth. The reason is, that, notwithstanding of the ability of Bouguer, as a philosopher and an observer, and the infinite pains which he took in his measurements of the pendulum, it appears to

us, on account of the nature of the processes he made use of, that they are too inexact to be employed with advantage. The method of Bouguer consisted in forming a sort of simple pendulum, with a very small weight suspended to a stem, the other extremity of which was attached to a pincer fixed into a solid wall. He made this little pendulum always of the same length, by comparing it with an iron rule, which served him for a standard; after which he determined the value of its oscillations by comparing its rate with that of a clock regulated by the heavens. But M. La Place has justly remarked, that the bending of the stem at the point of suspension, where it is inserted into the pincer, must produce the same effect on the oscillations as a contraction in the wire; so that the length, measured in a state of repose, must be too great, and would appear to give the pendulum too long. This effect, indeed, must have been produced on all the lengths given by Bouguer, since they were all observed in the same manner. From that it would seem that these observations might at least be employed in comparison with each other, and in that case, give exact ratios. But the process by which Bouguer judged of the length of his little pendulum, and compared it with his standard rule, appears to us not accurate enough for giving a sufficient certainty in his results. For it consisted in laying this rule close to the pendulum, placing its upper end in contact with the point, and judging of its equality by the eye, in comparing it with the pendulum at its lower extremity. But no one, by such an operation, can answer for an exactness greater than  $\frac{5}{100}$  of a line. Now  $\frac{5}{100}$  of a line being equal to  $\frac{1}{10}$  of a millimetre, such an error, with the methods now actually employed, would be accounted gross, and such indeed as, with the least attention, it is quite impossible to commit. These results cannot then be compared with the observations which are made now; and, unfortunately, the same remark applies with equal justice to the measurements of the absolute lengths of the pendulum which were made about the same period, as well in France as in various other parts of the globe. We think it extremely probable, that to the want of exactness in the methods employed at that time may be ascribed, at least in a great measure, the strange anomalies observed by Grischow in the lengths of the pendulum, in the neighbourhood of Petersburg, between stations very little distant from each other; anomalies so much more justly suspected, since the different instruments employed by Grischow to establish them are far from agreeing with each other. Nevertheless, for removing entirely all suspicion with regard to a point so important, it would be a useful undertaking to repeat these experiments in the same places where Grischow's observations were made; employing for this purpose our present much more accurate methods. Perthshire. PENITENTIARIES. See PRISON DISCIPLINE.

**Situation, Extent, and Divisions.** PERTHSHIRE, a county in Scotland, having the shire of Inverness and Aberdeen on the north; Angus or Forfar, Fife, and Kinross, on the east; Clackmannan and Stirling on the south; and Dunbarton and Argyle on the west; contains, according to the latest authorities, 2638 square miles, of which 50 are occupied by lakes; or, in all, 1,688,320 English acres; being, next to Inverness-shire, the largest county on the mainland of Scotland. It is situated between 56° 7' and 56° 35' north latitude, and between 3° 6' and 4° 47' west longitude, from Greenwich. Its greatest extent, from east to west, is about 77 miles, and from north to south 68. It was anciently, and is still, popularly divided into eight districts: Atholl on the north, Stormont on the north-east, Perth Proper and Gowrie on the east, Strathearn on the south, Monteith on the south-west, Breadalbane on the west, and Rannoch on the north-west. It is under the jurisdiction of one sheriff, who has substitutes in the towns of Perth and Dunblane, and is divided into seventy-nine parishes.

**Surface.** In a general view, this extensive county may be divided into Highlands and Lowlands; the former occupying a space so much greater than the latter, that not quite so much as a third part of the whole is fit for cultivation. This last portion is chiefly, though not without considerable exceptions, situated on the eastern and southern extremities, which contain some of the richest tracts in Britain; and in the great plain of Strathmore which has the Grampians on the north-west, and the Ochils and Sidlaw Hills on the east; varying in breadth from ten to fifteen miles, and extending through this and the contiguous counties, from sea to sea, a distance of 100 miles. To the west, where the Grampians, at first rising gently, rear their rocky or heath-covered summits to the height of 4000 feet, and for almost the whole breadth of the county, the high grounds are penetrated by straths and glens, some of them of considerable extent, each traversed by its own mountain streams, and diversified by numerous lakes, many of which, having their wild and lofty banks covered with natural wood, present scenes singularly romantic and beautiful. At least seven of these mountains are upwards of 3000 feet high: the three highest being Benlawers, on the west side of Loch Tay; Benmore, south-west; and Schehallion, north-east: the latter noted as the station chosen by Dr Maskelyne, Astronomer Royal, to make observations on the attraction of mountains. The most considerable lakes are—Loch Tay, almost in the centre of the Highland district, about fifteen miles long, and one broad, with a depth varying from fifteen to one hundred fathoms; Loch Erich, on the north-west, extending into Inverness-shire, still longer, but not so broad; Loch Rannoch, south-east of the former, twelve miles long; Loch Earn, south from Loch Tay; and Lochs Vennachar, Achray, and Katrine, on the south-west: the last of which, with the wild mountain scenery around it, called the Trosachs, has acquired deserved celebrity, from Sir Walter Scott's *Lady of the Lake*. Most of the streams either have their source in these lochs, or receive,

as they flow through them, a great accession to their waters. The rivers are the Tay, the Forth, the Earn, the Teath, and the Isla; of which the two first are by far the most considerable, though the Forth does not attain its full size till it has left this county. The Tay, the largest river in Scotland, and the Earn, belong exclusively to Perthshire. The Tay, under the name of the Dochart, has its source on the western confines, and soon after entering Loch Dochart, flows from thence north-east till it falls into Loch Tay. After leaving Loch Tay, from which it now takes its name, it pursues first a north-easterly and then a southerly course towards Dunkeld, from which it proceeds eastward, and then south, through a very rich country, till it falls into the Frith of that name, a little below the town of Perth; having been joined by the Almond and many other streams in its course, which, with all its windings, is not less than ninety miles. The salmon fishery on this river yields a rent of about L. 7000 a-year. South of Loch Tay is Loch Earn, where the river of that name has its source, and which, flowing east and south, through Strathearn and by the town of Crieff, after a course of twenty-four miles, falls into the Frith of Tay at Rhind. On the banks of this river, near its confluence with the Tay, is the village of Pitcaithly, long celebrated for its mineral springs, which have lately found a rival at Dunblane, on the southern side of the county.

**Climature.** The climate of this extensive district, so different in elevation and exposure, varies considerably. In the central parts, the winters are stormy and very severe, the snow lying long, attended with keen frost; and on the banks of the rivers in this quarter, hoar-frosts are frequent in summer, and very injurious to the crops. On the east, the climate is mild and salubrious. At Longforgan, in the Carse of Gowrie, on the banks of the Frith of Tay, the thermometer, on an average of twelve years, stood at 50°, and the mean annual quantity of rain was 24.496 inches; and at Belmont, in Strathmore, for a period of ten years, the average height of the thermometer was 46.35, and the yearly quantity of rain during thirty years' observation 30.40 inches.

**Minerals.** Perthshire, as far as yet known, does not abound in useful minerals. There is no coal but at Culross, on a small detached tract lying on the Forth, south-east from the rest of the county; and, for want of coal, limestone, which is found in many parts, is of little value, though it is sometimes imperfectly calcined by means of peat. Some years ago, a machine was erected for pounding limestone, with the view of employing it in that state as a manure; but the experiment was not persisted in. In the higher grounds, the prevailing rock is granite, and in the lower sandstone. Slates are found in many parts of the Highlands, but none in the low country. Copper, lead, and ironstone, occur in some parts; and mines of the two former were once worked, but are now abandoned. Shell marl, which has been long used as a manure, abounds in Stormont and Strathearn, on the east side of the county.

**Soil.** On so great a variety of surface, every description of soil occurs that is found in Scotland. That which distinguishes this district, though it is not peculiar to

Perthshire.

it, is the alluvial soil on the banks of the rivers, which is of considerable extent, and in many parts of the richest quality. The Carse of Gowrie, in particular, a tract of about 18,000 acres, lying along the north and north-west banks of the Frith of Tay, has been long celebrated for its fertility. Here there are upwards of twenty orchards, of all sizes, from one to twenty-four acres each. Perthshire has all the kinds of game common in other parts of the Highlands of Scotland, with red and fallow deer, and roes, rabbits, pigeons, and poultry.

Estates and Seats.

The territory of Perthshire was divided, in 1811, into 755 estates, of which 621 were under L. 500 Scots of valuation, and 95 above L. 2000; the valuation of the whole being L. 339,892, 6s. 9d. Scots, the highest of any of the Scottish counties excepting Fifeshire. The real rent, as returned under the Property-Tax Act in 1811, was, for the lands, L. 460,738, 13s. 11d. Sterling, and for the houses, L. 36,697, 19s. 7d. This land-rent, which is more than that of any of the other counties by almost one-third, is equal to about a tenth part of the rent of all Scotland; yet it is only at the rate of about 5s. 6d. the English acre. In the same year, the number of freeholders entitled to vote in the election of a member for the county was 178. There are more oak-woods, and these of a greater value, here than in all the rest of Scotland, and very extensive plantations of all sorts of trees, particularly larch, have been made within the last 50 years; of which, those of the Duke of Atholl are of great extent, and now of immense value. The county is much ornamented by the numerous seats of the proprietors, of whom 12 or 13 are noblemen. Among these are Blair Castle and Dunkeld House—Duke of Atholl; Taymouth—Earl of Breadalbane; Scone—Earl of Mansfield; Dupplin Castle—Earl of Kinnoul; and Dunira—Lord Melville.

Farms.

The general size of the farms in the Lowlands is from 100 to 300 acres. In the Highlands, the same system prevails that we have adverted to in describing the other Highland counties of Scotland; though here, as elsewhere, it is slowly giving way to one better adapted to the present times. In the crops, live stock, and general management of farms, we find nothing peculiar, except, perhaps, that flax is cultivated to a greater extent than in the southern counties of Scotland. On the Carse of Gowrie, the

highest rented land of the same extent in Britain, Perthshire. if we except the immediate neighbourhood of a few great towns, the order of cropping, after a plain fallow is—wheat, beans, and pease, barley with seeds, hay, and oats; and under this course, some of the best land yielded, so far back as 1795, a money-rent of 31s. with three bushels of wheat, and about four and a half bushels of barley—altogether, at the prices during the late war, equal to four guineas the Scots acre.

This county has only two royal burghs, Perth the county town, and Culross. Perth is a place of great antiquity, formerly the usual residence of the Scottish sovereigns, who were crowned at Scone in its vicinity, and the seat of parliaments and courts of justice. Some of the most important events in Scottish history, both of a religious and military description, occurred here. (See the article PERTH in the *Encyclopædia*.) It is now a well built thriving town, containing (in 1811) about 17,000 inhabitants. About 70 other towns and villages are scattered over the county, the most considerable of which have been already described in the *Encyclopædia*.

The manufactures of Perthshire are linen, cotton, leather, paper, and a variety of minor articles. It has extensive bleachfields, printfields, and cotton-mills, with mills for extracting oil from the seeds of flax and rape, and for the spinning of flax and wool. Its exports are corn, linen and linen-yarn, cottons, boots and shoes, salmon, with coals from the ports of Kincardine and Culross on the Frith of Forth; and it imports some of the materials of its manufactures, line in great quantities, and articles required for domestic consumption. In 1806, there belonged to the port of Perth 35 vessels, of 2635 tons in all, with 153 seamen.

The county of Perth sends one member to Parliament; and the towns of Perth and Culross have a share in the election of other two for the burghs; Perth being classed with St Andrews, Cupar Fife, Dundee, and Forfar; and Culross with Stirling, Dunfermline, Inverkeithing, and Queensferry.

The population, according to the census of 1801 and 1811, is exhibited in the following abstract.

See the general works quoted under the former Scottish counties, and Robertson's *General View of the Agriculture of Perthshire*.

## P E R U.

THE name of this country has been so long associated, in the minds of Europeans, with the idea of prodigious wealth, that it has created an interest very far beyond its real importance, either as a colony of Spain, or as the future theatre of a great independent state.

The early history of the conquest of Peru by Pizarro and his associates, the vast plunder which was shared amongst them, the dissensions which prevailed after the extirpation of the family of the former sovereigns, and the ultimate tranquillity into which the country settled under the colonial administration of Spain, have been fully narrated in the *Encyclopædia*; and there only remains in this *Supplement* the duty of communicating such statements of the more recent and actual state of Peru, as shall bring down to the present period the account given of it in that work; and to correct those errors which a paucity of materials, in general circulation, were likely to produce.

When Peru was first reduced to the obedience of the Crown of Spain, it was the largest of any of the governments founded in America. It has since been reduced, at two periods, in order to give such extension to other provinces, as should entitle them to the rank of viceroyalties. In the year 1718, the province, or, as it is sometimes called, the kingdom of Quito, was separated from Peru, and added to the government of New Granada. In the year 1778, when the Court of Madrid had resolved on erecting the province of Buenos Ayres into a viceroyalty, the province of Potosi, the district surrounding it, the cities of La Paz, La Plata, and the fertile district of Cochabamba, were separated from Peru, to form a part of the newly extended government. As, during the civil wars, which have raged from 1810 to the present time, those provinces have been wrested from the dominion of Spain, they are likely, in future, to appertain to that division of South America which will be included in the territories of Buenos Ayres or La Plata, rather than to that which will include either Peru or Chili.

The present boundary of Peru to the north is the small river Tumbez, in latitude 3° 26' south, and longitude 80° 6' west from Greenwich; which river divides it from New Granada. To the south the boundary is the chain of mountains of Vilca-Nota, which terminates at the river Loa in latitude 15°. The extent of the coast of Peru is thus about 700 geographical miles, but as the sinuosities of the shore are

considerable, the whole frontage to the ocean is upwards of 1000 miles. The eastern boundaries of Peru are not clearly defined. They extend to the vast plains claimed by Portugal, as a part of Brazil, denominated the *Pampas del Sacramento*, and farther north to Colonna, or the Land of the Missions, inhabited by unreclaimed Indian tribes. The medium breadth is about 80 leagues, according to Humboldt, who estimates the whole area of Peru to be 30,000 square leagues.

The lands of Peru may be divided into three First Dis- classes, according to their height above the sea. A tract. narrow strip of sandy plain bounds the whole western coast, with intervals of many leagues between the different towns and cities, in which neither inhabitant nor any traces of vegetation are visible. It is only where the torrents from the high lands form rivers, which are few in number, and of short course, that any agricultural productions are raised. Under this sandy soil, however, springs are in general to be found, whilst the surface is most strongly impregnated with nitre. As far as the cultivation of this district extends, it is powerfully aided by a species of manure which is peculiar to the coast of Peru, whose fertile qualities seem to be derived from the singular circumstance of no rain falling there. On the islands, which are the resting-places of millions of aquatic birds, their dung has accumulated in the course of ages, so as to form hills of more than 100 feet in height, close to the shore; from whence it is conveyed by small vessels to the parts of the mainland where cultivation is practised. The dung thus collected, not having its salts washed by rain, and being but slightly affected by the rays of the sun, has retained, as appeared by the analysis of Sir Humphrey Davy, a greater portion of ammonia than any substance that has been applied to the purposes of manuring land. The quantity that is administered by the Peruvians is minutely small, and unless diluted, never suffered to come in contact with the roots of the plants which are designed to be raised. Its fructifying powers, as described by those who have witnessed its effects, especially when applied to the different species of *capsicums*, which form the chief food of the more numerous classes, exceed every thing that has been related of any other stimulant.

On the track of land we are describing, varying in breadth from six to about twenty leagues, little or

Peru.

no rain ever falls, and thunder and lightning are unknown. The lofty mountains to the eastward intercept the clouds from the Atlantic Ocean, and the constant winds from the south drive the clouds that collect in the Antarctic Circle beyond the limits of Peru before they discharge their waters. Although no rain falls in this district, commonly distinguished as "Lower Peru," the dew that descends during the night is very heavy, and uniform. The constant evaporation that is thus going on produces a haziness in the atmosphere, and the sun seldom appears with that brilliancy which it displays in the higher levels. The heat is seldom so intense as to prevent the labourers from working in the open air, and the thermometer rarely rises to above 75 degrees. The medium height through the year, in which there is little variation, is about 64°.

In this district are produced most of the tropical plants. The plantain, banana, pine-apple, sugar-cane, vine, cocoa, olive, coffee, and cotton, as well as the most delicious fruits, some, such as the chiremoya and the frutilla, peculiar to the country, arrive at great perfection.

Second District.

The next division of Peru consists of that range of the Andes nearest to the Pacific Ocean, commencing generally with hills of moderate elevation, but in some parts with bold projecting and abrupt precipices. The sides of these hills are covered with forests, rendered almost impenetrable by the numerous parasitical plants which twine round the lofty trees; and whilst, by their verdure, they give beauty to the scenery, prevent the access of visitants until a path is cut by severe labour. These forests afford acacias, mangle trees, arborescent brooms, and ferns; aloes and other succulent plants; cedars, cotton, or Cuba trees of gigantic magnitude, many kinds of ebony, and other useful woods, many species of palms, and the maria, a tree of enormous size, used in ship-building. The valleys between these hills afford most of the trees which are natives of the tropics; few of them are well calculated for the purposes of building.

The district called Higher Peru, commencing at the termination of the sands on the shore, continues increasing gradually in height towards the eastward, till the ridge of the Andes or the Cordilleras is attained.

The line of perpetual snow is about 14,000 feet above the level of the sea, and from that line upwards vegetation necessarily ceases; below it the plants, by regular gradations, display the nature of the climate, and its adaptation to the various families of vegetables; and, in different parts, exhibit every species of production which can be found from the dwarf plants of Lapland, to the odoriferous spices of Sumatra.

This portion of Peru contains the sources of those vast rivers which traverse the whole continent of South America. Their streams, for the most part, run to the Atlantic Ocean. The few that run to the Pacific are of short course, and do not yield copious supplies. It has been said, with what degree of accuracy it would be difficult to determine, that the river Thames conveys to the sea a greater supply of water than is emptied into the Pacific by all the rivers of Peru. The rivers, on the other hand,

which empty themselves into the Atlantic, are the greatest on the face of the globe. The Magdalena, the Meta, the Orinoco, and the Amazons, commence in this portion of the Andes, take varying and most tortuous courses in descending from the heights, and, having collected in their progress augmented supplies, at length reach the vast plains through which they flow to the Carribean Sea and the Atlantic Ocean.

Though many of the plains in this mountainous district possess most fertile soils, and climates admirably adapted to raise food for man; yet, from the difficulty of access to them, and the consequent expence of conveyance, they are merely cultivated to a sufficient extent to provide food for the inhabitants of their immediate vicinity. Although Lower Peru is nearly destitute of wheat, and deficient in other grain, instead of drawing the supply it needs from the more temperate regions of the vice-royalty, it is chiefly fed with corn sent by sea from Chili.

This mountainous district is the chief seat of the mineral wealth of Peru. The mines are, for the most part, situated at great elevations, and consequently in a climate so severely cold, as to be unfavourable both to the health of the labourers, and to the raising food for their subsistence. The most abundant silver mines, those of Pasco and Huancavelica, are between 13,000 and 14,000 feet above the level of the sea.

The third district of Peru commences on the eastern summit of the Andes, and proceeds eastward till it reaches the territories of Portugal, towards their northern part; and the provinces of La Plata, or Buenos Ayres, towards the south. The descent from the Andes, on the eastern, is much more abrupt than on their western side. They terminate in vast plains called sometimes *Pampas del Sacramento*, or more usually, collectively, *Colonna*, or the *Land of the Missions*. The Jesuits succeeded in collecting in villages many of the rude inhabitants of this country; and, according to the relation of one of that body, Father Girval, the tribes are numerous, small, and scattered; with as many various languages as tribes, and differing much from each other in the degree of civilization to which they had attained. These Pampas are represented as being covered with trees and verdure, and yielding balsams, oils, gums, resins, cinnamon, cocoa, cascarilla, and many valuable drugs, spices, and other rare productions. The trees are lofty, and form impenetrable forests, in which wander all the animals peculiar to the torrid climate of America. The heat is excessive, and accompanied with such humid fogs, as to be a most miserable residence for these missionaries, whose zeal for the conversion of the natives led them to penetrate into such wilds.

Amidst the various circumstances which distinguish Peru, there are some, of the most calamitous and terrific nature, of which all parts partake, and in a long series of years in almost equal degrees. The whole country is subject to the most violent convulsions of nature. Earthquakes are frequently felt in every part; and are sometimes accompanied with most extensive and fatal effects. The lofty chain of the Andes is a collection of volcanos, some in constant activity, others occasionally ejecting inflamma-

Peru. ble substances; while there are many whose fires, in the lapse of ages, seem to have been burnt out. The annexed TABLE, taken from an ecclesiastical

census, contains a view of the population of Peru, and of the classes into which it is divided; exhibiting also the proportions of the sexes.

This table is confirmed by one returned to the Viceroy in 1803; as the difference does not amount to more than 850 souls. Although the number of Spaniards is stated at 136,311, nearly one-eighth of the whole population; it must be considered, that in this number is included those who, after five mixtures with the white race, acquire the privileges of whites, though their complexions are as dark as those of the Indians or Negroes. Of those denominated Spaniards, it is not estimated, that one-tenth are natives of Europe. The great mass of the population consists of the original Peruvians, usually called Indians by the Spaniards; and of the descendants of their females by white fathers, called Mustees. The former of these, for the most part, live in towns or villages by themselves, or when they are established in the larger places, have separate quarters assigned to them. They have magistrates, and usually clergy of their own race. They are not subject to the Inquisition, pay none of the taxes to which the other inhabitants are liable, nor have any duties imposed on them, except that of furnishing a certain number of labourers for the mines; for which they are so well paid, that the employment is rather an object of desire than aversion; and those who are once destined to it, most commonly become constant miners. They pay, indeed, a small capitation tax, which exempts them from all other imposts, and is considered rather as a mark of distinction betwixt those settled among the Spaniards, and those unreclaimed tribes who are denominated *Indios infideles*. The average net amount of the Indian tribute is about 520,000 dollars, a little more than L.100,000 annually.

The Peruvians seem to have degenerated since their subjection. They appear timid, dispirited, and melancholy in their temperament, but severe and rigid in the exercise of their authority; wonderfully indifferent to the general concerns of life, and neither anxious nor careful to avoid death. They stand

in awe of their white masters, but secretly dislike and shun their society. They are reputed to be of a distrustful disposition, and though robust, and capable of enduring great fatigue, excessively indolent. Their habitations are miserable hovels, destitute of every convenience and accommodation, and disgustingly filthy. Their dress is poor and mean; their food coarse and scanty; and their greatest gratification seems to be an excessive indulgence in the use of spirituous liquors. They observe with docility the external rites and ceremonies of the Catholic worship, though it is said they indulge in secret an attachment to the ancient superstitions of their nation.

The language of Peru is still retained by this the greater portion of the inhabitants, who discover so strong an aversion to that of their conquerors, that the clergy and the other Spaniards settled among them learn and commonly use their dialect, with the addition of such Castilian words as signify things not known in Peru at the period of the conquest. The language, called the Quichan, or language of the Ineas, is said to be harmonious, and its grammar as variegated and artificial as that of the Greek, though the sounds b, d, f, g, and r, are not to be found in it. A grammar of the tongue has been composed for the instruction of the clergy who are destined to labour in their conversion.

The numbers of the Peruvians had been gradually declining from the period of the conquest till within a few years. The introduction of the small-pox, and the free use of spirits, had a desolating effect; but it is said that their numbers have somewhat increased, especially since the practice of vaccination has been extended to the whole of them.

The agricultural productions of Peru are barely sufficient for the subsistence of its inhabitants. In the interior, corn is grown to feed the population; but on the coast, the supply has been in a great measure drawn from Chili. Sugar, cocoa, coffee, rice, maize,

Productions.

Peru.

and the various fruits, suffice for the consumption; but there is no surplus, nor any stimulus to produce it, since in all the countries to which the Peruvians can have access the markets can be as well, if not better, supplied from their own soils. Nearly as much wine is produced as is needed, though some is imported from Chili. Oil, brandy, and rum, are made. The former is, however, generally rancid, from the olives being suffered to become too ripe before they are expressed. The spirituous liquors are strong, fiery, and impure, being distilled in the rudest manner. The various kinds of capsicums are cultivated with more attention and skill than any other plants; and, dressed in various ways with garlic, form the most important article of food to the greater portion of the inhabitants. The common beverage is from the leaf of a plant called *matte*, the tea of Paraguay, an infusion of which, as hot as it can be borne, is drank, or rather sucked through a pipe, by all classes of the inhabitants. As a substitute for drink, the Indians make use of the leaf of a very pungent plant, called *coca*. A small portion of quicklime is wrapped up in it, and carried in the mouth. The pungent qualities of these two substances excite a most abundant flow of saliva, and serve to allay the thirst of those who travel over the mountains, or the vast plains of sand, where, for days in succession, no water can be obtained. The natives are so much attached to this mode of allaying thirst, and have such confidence in the general salubrious effect of the plant, that they will not commence the labours of mining till they are satisfied that their employers have in store a quantity sufficient for their use.

The demand for animal food is but small, and hence but little attention has been paid to the breeding, and none to the fattening, of cattle. Neither cows nor sheep are numerous: what are found in the country are the progeny of those brought originally from Europe. In the mountainous districts, between Guamanga and Cuzo, both butter and cheese are made; but in the lower country, oil is the universal substitute for the former. Pigs are bred in great numbers in the more hilly districts. The whole coast is well stored with fish of every kind. The natives of the Indian villages on the shore are very dexterous in catching them; and with the addition of capsicum and garlic, they form the chief part of their subsistence.

Mines and Minerals.

The chief riches of Peru have been derived from its mines, especially those of silver. Since the separation of Potosi and La Paz from this viceroyalty, the quantity they have yielded has been gradually diminishing; and, especially since the year 1810, when the civil war with Buenos Ayres and Chili, on one side, and with New Grenada on the other, commenced, the annual produce, both of gold and silver, has most rapidly declined. The mining in Peru has been much injured by the competition of Mexico, where capital is more abundant, where more skill in the operations of extracting and amalgamating is exercised, where provisions, and consequently labour, are cheaper, and where the mines are situated in a much more salubrious climate than those of Peru. Another cause to which the declension of the silver mines may be attributed is the difficulty of procuring mercury; for, having within the viceroyalty, at Guancavelica,

Peru. mines of that indispensable mineral, too much dependence has been placed on their produce, which is found insufficient for the consumption. Whilst care has been taken to supply Mexico with quicksilver from the mines of Spain and of Istria, the mother country has overlooked their more remote mining possessions on the shores of the Pacific Ocean.

The quantity of gold produced in Peru arises partly from some mines in the province of Tarma, where it is found in veins of quartz traversing primitive rock, and partly from washings established on the banks of the rapid mountain torrents. These last, like the washings in Brazil, have been found to yield less return for the labour employed on them than the common operations of husbandry, and have, in consequence, in many instances, been abandoned. On an average of several years to the year 1800, the produce of silver was 321,165 marks of Castile, each being nearly eight ounces, and of gold 6793 marks. On the average from 1800 to 1810, the silver yielded was 444,229 marks, and the gold 4255 marks. Since that period, the decline is generally asserted to be very great; and from 1810 to 1820, the supply is estimated to fall short by more than one-half of the quantity yielded in the ten preceding years.

Cobalt, antimony, and especially rock salt, abound in Peru; but as they are, except the latter, chiefly found in the mountainous districts, the distance, and the want of roads, render their conveyance too expensive for them to be advantageously carried to any market of consumption. There are a few mines of copper and of lead, which, from the same causes, are worked on a very contracted scale.

The manufactures of Peru are inconsiderable, and consist chiefly of those homely articles which are required by the poorer classes of the community. On the high land, where warm clothing is necessary, the want is chiefly supplied by a species of long-woolled baize, made from the fleeces of the aboriginal sheep, and in some instances from the wool of sheep of the European breed. In the valleys, and on the coast, where the heat forbids the use of woollens, cotton cloths are made; but of a very inferior texture, from there having yet been no gins introduced, which effectually clear the cotton wool from the seeds of the plant. In dyeing the cloths, whether of woollen or cotton, the natives make use of plants that are scarcely known in Europe, or at least have not been applied to the same purpose. They have a root called *reilbon*, resembling madder, but with a smaller leaf, an infusion of which dyes a good red. A plant called *poquel*, a kind of female southernwood, with green chequered leaves, is used for dyeing yellow, as is also the stem for dyeing green, both of which are fast colours. A wild indigo yields them a blue dye, and the *panque* a good black. The dress of the natives is very simple; consisting of a square cloth, with a hole in the centre, through which the head is thrust, and which falls before and behind so as to defend the whole body. The head is generally covered with a hat made of the straw of the maize, which is as large as, and serves the purpose of, an umbrella.

The commerce of Peru, as may be seen by the small surplus of its productions, is very inconsider-

Peru.

able. With the province of Buenos Ayres a trade was carried on by exchanging for the matte or tea of Paraguay, coined dollars, some brandy, and a few of the coarse woollens made in Cuzo. By the same channel some few European goods arrived, as well as the small number of negro slaves that were needed for domestic servants, in which capacity they are chiefly employed. By sea, a trade was carried on with Chili, which consisted in exchanging the wheat, wine, and copper of that country, for sugar, coffee, cotton, and silver. A vessel or two arrived from Manilla with the productions of the East Indies, for which silver only was paid. The luxuries for the few of the richer class were drawn chiefly direct from Spain, or by a contraband intercourse with English or North American traders. The annual imports from Spain, on an average of years, amounted to 4,180,000 dollars; of which about 1,950,000 consisted of Spanish, and 2,230,000 of foreign productions. The annual exports from Peru, in the same period, consisted of money, silver, and gold, amounting to 4,962,700 dollars, and other commodities amounting only to 726,800. The chief exports of goods were Peruvian bark and cocoa, the latter of which had been previously imported from Guyaquil. The ships from Europe that have sailed to the ports of Peru have found no productions there which would pay any return freight; and they have almost uniformly, after discharging their outward cargoes, proceeded to the port of Guyaquil, where a return cargo of cocoa could be generally obtained on such moderate terms as to pay a profit in Spain, where the demand for that commodity is very extensive.

Navigation.

The Pacific Ocean is by no means favourable to commerce. On the whole extent of coast in Peru there is no harbour except that of Callao, the port of Lima, which can be entered by a vessel of such a size as is fit for the navigation from Europe round Cape Horn. As the wind constantly blows from the southward, varying only as the coast trends, wherever there is a high projecting headland there is shelter, and sometimes good anchorage to the northward of it; as at Ylo, Iqueque, and some other parts. On every part of the shore, the uninterrupted swell from the sea causes such a tremendous surf on the beach, that no communication can be had with the shore, by any such boats as are carried by European ships. The natives have long ago contrived a means of passing this surf, on what is called a *Balsa*, whose buoyancy is such as to carry them over the most terrific breakers in perfect security. It is constructed of two skins of the largest sized seals, which are inflated and lashed side by side. On a small platform fixed on them, the native sits, with a pipe made of the entrails of the seal, communicating to each of the inflated skins, with which he fills them by his breath, as frequently as the evaporation of the wind makes it necessary. On these contrivances, which resemble two enormous bladders, the natives fear no waves or breakers, and frequently proceed to such a distance as to lose sight of land. By the assistance of a paddle, and occasionally of a small sail, these vessels become perfectly manageable at sea, and they have the advantage of being easily car-

ried to their own habitations when not employed on the ocean.

Peru.

A species of vessels, called by the same name, is used for longer voyages. These consist of an unequal number of trees of light wood, merely squared, and securely lashed together, but so loosely as to admit the action of the waves between them, like the catamarans at Madras. The centre tree is longer than the others, and serves the purpose of a prow. These vessels, some of which are more than 100 feet in length, have huts constructed upon them for the crew, and pass with security from the shores of Peru to the ports of Guyaquil and Panama. The deficiency of stores for naval equipment on the shores of the Pacific is such, that substitutes are used, which alarm a European sailor till he becomes familiar with the smooth surface and uniform winds that prevail on that sea. Instead of water casks, jars are fastened in the hold to contain that necessary element. The rigging is made of white rope, as the only tar they have burns the hemp, and is only fit to be applied to the bottoms of ships. The sails are made of narrow strips of cotton cloth, very clumsily fastened together. With such equipment, however, they make secure voyages; but not with much celerity when proceeding to the north, and with a most protracted delay when, on returning to the south, they are under the necessity of tacking.

Although, in the present unsettled state of Peru, the amount of its revenues, and the armed force which it maintained, become matters of but little importance, yet it may be noticed, that, under the colonial government of Spain, the revenues of the crown amounted *communibus annis* to about 6,000,000 dollars, and the expenditure to about 3,200,000; the balance was annually remitted to the parent state. The armed force consisted of the regulars, who were 2200, including 280 cavalry and 40 artillery. The disciplined militia were 8000 infantry, 2280 cavalry, and 490 artillery. Besides these there were 85 regiments, known as provincial militia, amounting to 21,700 men; but these had no arms, were rarely mustered, and then exercised only with sticks instead of muskets, and were of little use except as the means of gratifying the vanity of the natives by conferring on them the military titles of colonels, majors, captains, &c., as is said, to the great emolument of the Viceroy and the officers of his establishment.

The intendancy of Lima is chiefly remarkable for containing within its limits the capital of the viceroyalty, from which it derives its name, and the excellent port of Callao, the chief mart for the commerce of Peru. The capital is situated in latitude 12° 2' 25" south, and in longitude 77° 7' 15" west from Greenwich. The inhabitants amounted to about 54,000, of whom 19,000 are proprietors of estates or mines, clergy, lawyers, physicians, civil and military officers, and various traders; the remainder are slaves, domestics, or labourers. The city is surrounded with walls, but they scarcely merit the name of fortifications. The buildings are spacious but low, having but one story; they are built of wooden frame work, interlaced with canes, plastered over with clay, and painted to imitate stone. This

Revenues  
and Forces.Intendancy  
of Lima.

Peru.

mode of building prevails, from the frequency of earthquakes, whose force, such erections are more capable of bearing than solid buildings of stone or brick. It is supplied with fresh water by a rapid stream that passes through it, which is received into reservoirs and fountains in various parts of the city. The Viceroy's palace, the cathedral, the town-house, and archiepiscopal palace, form a square, and are said to be magnificent piles. In former times, the entrance of a new Viceroy was celebrated by a display of ingots of silver, with which one of the streets was completely paved; and the quantities of the precious metals displayed in the churches, and in their religious processions, are said to have exceeded what was to be seen in any of the Catholic countries of Europe. The country immediately around the city, being well irrigated, is fruitful in tropical productions; the sea supplies abundance of fish, and, as the elevated mountains approach near to it, the varieties of climate which their different elevations create, allow of cultivating most of the plants of the temperate zone, and of producing good meat and poultry.

Lima is the seat of the Royal *Audiencia*, or Chief Court of Justice. It is the see of an archbishop, whose income was 30,000 dollars, and who has four bishops under his superintendence within the viceroyalty, viz. Traxillo, Gumanga, Cuzco, and Arequipa, and four others, within the limits of New Granada, viz. Panama, Quito, Maynas, and Quenca.

Callao, formerly called Bellavista, is the port of Lima, and, as has been before mentioned, the only good harbour in Peru. It is defended from the winds, which blow always from the south, by the Island of St Lawrence; to the north of which, in smooth water, is good anchorage, under the protection of the guns of the strong forts. The depth of water is sufficient for the largest ships; the means of loading and discharging them are easy; and as the river Rimac empties itself into the sea at this place, the shipping easily obtain a supply of fresh water. As there is but little rise of tide, there are no docks; and vessels that need repair can only be careened. It is in south latitude  $12^{\circ} 3' 42''$ , and west longitude from Greenwich  $77^{\circ} 14'$ .

The other towns are Guara, Chancay, Canete, Ica, Pisco, and Nasca, none of which, except Ica, contain more than 1500 inhabitants, of all descriptions. There are few mines in the intendency of Lima that are worked; the chief is that of Conclapatu, in the mountains of Guarachiri, which yields some silver, and which would also, if the roads would allow of it, supply the capital with coals. Antimony and cobalt are likewise to be found in the same district.

The intendency of Cuzco lies on both sides of the Andes, and partakes of that great variety of climates which is produced by the different elevations and aspects of that prodigious range of mountains. Though the cold is so intense as to forbid human residences on the summits, or cordilleras, yet the chief places which are inhabited enjoy a mild and temperate climate. It is bounded on the north by the great river Apurimac, on the east by unreclaimed countries, on the west by the provinces of Tarma, Guancavelica, and Gumanga, and on the south by Arequipa and the viceroyalty of La Plata. This is

the chief seat of what manufactures of woollens and of leather exist in Peru; as both sheep and cows are here more abundant than in any other part of it. The district of Cannas is celebrated for breeding mules; of which animals more than 30,000 are annually sent to the towns on the coast. The agricultural productions generally partake rather of the character of those of the temperate than the torrid zone; wheat, barley, and other European grains, forming the chief articles of cultivation. There are many silver mines, and some few washing places for gold. The principal of the former are at Carahuasi, near the capital, in the district of Cotabamba, in Condonoma, Aymaraez, and especially in the province of Lampa.

The chief city of the intendency, Cuzco, was the seat of the Peruvian monarchy when visited first by Europeans, and the situation of it, as well as its climate, were well chosen. It is in south latitude  $13^{\circ} 25'$ , and west longitude  $71^{\circ} 15'$ . It is surrounded by the mountains of Sanca on its north and west sides, and has a beautiful plain to the south, through which the river Guatanay, which passes the city, runs. On the mountain to the north of the city are the remains of the fortress of the Incas, intended to be rendered impregnable by the height of the wall, and the steepness of the passes which it was designed to defend. The internal works are in ruins, but a great part of the wall is still standing. Some of the stones prepared for this work are of such a size, as to create wonder in what manner they could have been moved by people so unacquainted with powerful machinery, as the Peruvians certainly were. Though the palace of the Incas has been destroyed, yet a subterraneous passage, communicating between it and the fortress, may still be traced. Cuzco is at this time a large city, containing 32,000 inhabitants, three-fourths of whom are Indians, who are industriously employed in the manufactures of woollen baize, of cotton, and of leather. The number of Spanish families is small, and they have of late declined as compared with the Indians and Mustees. It is the see of a bishop, whose revenues amounted to 20,000 dollars, of a Royal *Audiencia*, a mint, a university, and of a college, specially appropriated for the education of the children of the Caziques. The cathedral is a noble pile of building, of stone, and there are also six parish churches, nine convents, and four nunneries. The church belonging to the Dominican Convent stands on the identical spot which was formerly covered by the Temple of the Sun, and is built of the stones which composed that edifice. The high altar fills the place in which once was fixed the image of that luminary which was the object of worship to the idolatrous aborigines. The dwellings of private individuals are substantially built of stone, and if not furnished with much attention to comfort, are decorated in a costly manner. The other towns are very small, as most of the inhabitants lead a rural life, occupied in cultivation and in breeding cattle. The chief of those towns are Abancay, Urcos, Calca, Cotabanibas, Tinta, and Lampa, none of which contain so many as 1500 inhabitants. The difficulty of communication between these places is such as to forbid much intercourse. The rapid streams descending from the Andes have worn such

Peru. numerous and such deep ravines, as are only to be crossed, with great risk, by bridges of ropes; and frequently are passed by suspending the travellers in large baskets from cables stretched across fissures, along which they descend from the higher to the lower banks of the tremendous precipices.

Intendancy of Arequipa. Arequipa is an intendancy stretching along the borders of the Pacific, but extending sufficiently inwards to contain a large mountainous district within its limits. Its southern boundary is the inhospitable desert of Atacama, the passage over which to Chili has proved fatal to many travellers. Few of the provinces of South America contain within them a greater portion of vegetable and mineral wealth than Arequipa. Its plantations yield maize, sugar, and coffee. The vineyards are extensive, especially those of Moquehua, which produce a delicious red wine, and the brandy distilled in this district supplies an extensive circle of the mountainous countries. The most celebrated of the silver mines are situated on the southern part of this intendancy; those of Huantajaya, near the small port of Yquique, are surrounded with vast beds of rock salt, in a district totally destitute of water, and where provisions are scarce, but as the silver is found in native masses, it has produced usually about 100,000 marks annually. The district of Caylloma contains several mines of silver, but they are very imperfectly worked. They are in a very high elevation, and consequently in a climate most intensely cold. The surrounding country produces but few means of subsisting the labourers; and though there is an office for distributing quicksilver to the miners, the situation has proved an impediment to successful operations, and the expence has equalled, and, in some instances, exceeded the amount of the metal that has been produced.

In Condesuyos are mines both of gold and silver, though slightly worked; as many of the inhabitants have found more profitable labour than mining, by raising silk-worms, and by breeding the cochineal insect.

The city of Arequipa, the capital of this intendancy, is situated in the beautiful valley of Quilca, about 60 miles due east from the port of Atranta. It is in  $16^{\circ} 16'$  of south latitude, and  $71^{\circ} 58'$  west longitude. The buildings are substantially constructed of stone. The public edifices are a cathedral, six convents, a college, a hospital, and revenue office. It is well watered by the river Chile, which serves extensively the purpose of irrigating the surrounding lands. The climate is healthy, and though frosts are sometimes experienced in the night, they disappear as soon as the sun rises. The inhabitants amount to about 24,000, one-third of which are said to be Spaniards. This city has been repeatedly laid waste by earthquakes, and once by an eruption of the volcano Guayna-Patina, which is in its immediate vicinity. The other towns of most consideration are Camana, Ocana, a small bad port, Caylloma, Moquehua, Arica, and Tacna, none of which are either populous or rich, and are chiefly inhabited by Indians.

Intendancy of Truxillo. The intendancy of Truxillo is the most northern, as well as the most extensive, division of Peru. It is chiefly remarkable for being the first port in which Pizarro and his followers landed. The face of the

greater part of the district has all the predominant features of the Arabian desert. From Tumbez, the boundary, to the capital of its department, Piura, a distance of more than 200 miles, there is but one small Indian village. No water is to be found in any other place, and that indispensable article must be conveyed in skins, on mules, for the use of travellers. In this sandy desert, the most experienced guides sometimes lose their way, and the bodies of passengers are occasionally buried under the waves of shifting sand. There are, however, some spots within the intendancy that enjoy a high degree of fertility; of this description is the district of Caxamarca, situated between two ridges of the Andes. Corn of all kinds, various fruits, and esculent vegetables, are abundantly produced, as well as cows, sheep, and hogs, in the latter of which, salted, a considerable trade is carried on with the warmer districts. At this place are the remains of the ancient Palace of Atahualpa, from whence Pizarro directed his operations, and where that monarch was killed. It is situated on the western declivity of the Andes, about 9000 feet above the level of the sea, 70 miles from the Pacific Ocean, in latitude  $8^{\circ}$  south, and longitude  $76^{\circ} 10'$  west from Greenwich. A family descended from the Incas, reduced to a state of comparative indigence, occupies this ancient residence of their royal ancestors. In the vicinity of Piura, and around the city of Truxillo, the tropical productions, sugar, coffee, and cotton, are cultivated; there are also some vineyards which afford wine and brandy.

The chief mines within the intendancy are those of Chota, near the limit of perpetual snow, being 13,800 feet above the level of the sea; of Micui-pampa, 12,000 feet; and some at Pataz which yield both gold and silver.

There are two cities in the intendancy. Truxillo, the capital, is the see of a bishop, and the seat of the courts of justice. The inhabitants are about 6000, principally rich Spaniards, who indulge in considerable show and luxury. Piura contains about 7000 inhabitants, chiefly Indians. The other towns, Tumbez, Lechura, Payta, Lambayeque, scarcely contain 1000 inhabitants each, who are in a low state of indigence.

Guamanga, or Huamanga, is an intendancy wholly internal, surrounded by other parts of Peru. From its elevation on the sides of the Andes, it enjoys a mild and temperate climate. It is much intersected with streams, or rather torrents, which have worn deep chasms in the friable soil, and prevent easy communication between its several districts. It yields excellent corn and fruits, and the wool of the sheep is here made into baize for clothing the inhabitants of the colder districts. In the mountains are found herds of huanucos, or Peruvian camels, employed as beasts of burden in the colder regions, and whose wool is used in the manufactories. There are also many cows and sheep of the European breeds, reared within the district. It is the chief country for the growth of the coca, which serves to the natives of Peru the same purpose as the betel does to those of the East Indies. There are mines of lead, gold, and silver; but their working has declined of late years, so that the supplies from them are dwindled to very insignificant.

Peru.

Intendancy of Guamanga.

Peru.

nificant quantities. The capital, Guamanga, situated in south latitude  $12^{\circ} 50'$ , and west longitude  $77^{\circ} 56'$ , is a well built city, of considerable extent. Its population amounts to about 26,000, of whom the greater part are Indians. It is the see of a bishop, contains a cathedral, a university, well endowed, and several churches and convents. There is no other place in the intendency meriting the name of a town, as three-fourths of the inhabitants are either occupied in cultivation or in pasturage.

Intendency of Guancavelica.

The whole of the intendency of Guancavelica, or, as it is sometimes spelt, Huancavelica, is situated in the mountains in a climate severely cold, which may account for the paucity of its population. The chief value of this intendency is derived from the important mines of quicksilver which it contains, and which, if properly conducted, would make the mines of silver in Peru equal in their product to those of Mexico. The celebrated mine of Santa Barbara is 13,800 feet above the level of the sea. In the process of excavating it, three stories of galleries, one over the other, have been constructed, which penetrate the mountain in different directions, according as the veins of the mineral are found to run. The lowest of these was found to contain red and yellow sulphureted arsenic, which, proving fatal to many of the labourers, was forbidden to be worked. The chief produce of the mine has been obtained in the form of cinnabar, from which, by distillation, the mercury is extracted at the rate of one pound of mercury from every fifty pounds of cinnabar. The upper of the three stories, called the *brocal*, furnished by far the largest part. This branch, however, has been nearly destroyed, either from the negligence or the avidity of the managers. The roof of the mine was supported by pillars, left at intervals, which consisted of the ore. As the ore became rather scarce in the interior of the mine, these pillars were gradually thinned away till they became incapable of sustaining the weight that rested on them; they gave way at length to such an extent as to fill the mine with masses of the superincumbent rubbish, which has intercepted all communication with the interior. Some ineffectual attempts have been made to remove the impediments, but the silver mines are chiefly supplied with their mercury from small veins in the same chain of mountains, which yield an insufficient quantity, and at a dear rate. The capital, which gives name to the intendency, is in south latitude  $12^{\circ} 45'$ , and west longitude  $74^{\circ} 46'$ . It was, when the mine was actively worked, a populous place, but at present contains only 5000 inhabitants. It is built almost wholly of tufa, which is found in abundance in its vicinity. The surrounding country is highly picturesque, abounding in torrents and cascades; but the climate is prejudicial to the human constitution, from the great and sudden changes of the temperature. There are scarcely any places that deserve to be called towns; as the few inhabitants are scattered at great distances from each other in thinly peopled villages or hamlets.

Intendency of Tarma.

The intendency of Tarma is chiefly situated on the Andes, and generally partakes of the severity of climates which lofty elevation creates. The small portion of it which is on the plain yields wine, but the great portion of the inhabitants are supplied with

animal and vegetable food from the mountainous regions, which, at a moderate height, produce corn and potatoes, and at a greater elevation breed considerable flocks and herds. The mines most productive of silver are within this intendency. The most eminent are those of Lauricocha, or, more properly called, collectively, the Mines of Pasco. Nearly one-half of the silver which Peru yields is extracted from these mines. They are at an elevation of 13,000 feet above the sea. The veins of the mineral are near the surface, the shafts being only from 90 to 400 feet in depth; below that water is found, the expence of clearing which is the chief drawback from the profit of the proprietors. The metalliferous bed is stated to be more than 15,000 feet in length, and upwards of 7000 in breadth, and is capable of yielding more silver than any even of the mines of Mexico.

The favourable circumstances attending these mines, and the belief, that, if the water could be cleared by a steam-engine, the profits would be immense, induced a party of Englishmen to convey a powerful engine to the spot. After many interruptions and much delay, it at last reached these mines; but the country was in too turbulent a state to admit of the operations being carried on; which, with the unpopularity attached to the undertaking, from supposing it would lessen the employment of labourers, has caused it to miscarry, and the water hasso gained, that the produce has declined very much since the commencement of the civil wars. There are many other mines in different parts of this intendency, of which the greater part are neglected, or very feebly worked. The greatest portion of the gold found in Peru is taken from the mines of Patash and of Huilias in this province. Tarma, the city which gives its name to the intendency, is in  $11^{\circ} 35'$  south latitude, and  $75^{\circ} 17'$  west longitude. It contains about 5500 inhabitants, some of whom find employment in making baize. No other place contains as many as 1000 people.

No country, perhaps, ever enjoyed so long a period of freedom from hostilities as Peru has experienced. Though occasionally, when at war with England, a few places on the coast have suffered from predatory attempts, and the navigation may have been interrupted by our cruisers, yet, in the interior, tranquillity has been undisturbed during the whole period that elapsed between the suppression of the revolt of Gonzales, by Pedro de la Gasca, in 1548, till the year 1781, when an Indian insurrection of a most alarming kind suddenly burst forth.

Jose Gabriel Condercanqui was a descendant of the last sovereign of the Peruvian race. He had been carefully educated by his father, and exhibited considerable talent. The title of Marquis of Oropesa had been conferred on one of his ancestors. On the death of his father, he petitioned to have that title renewed in him, but being refused, he retired to the mountains, and announced himself by the name of Tupac Amaru, which the last of the Incas had borne, as the true sovereign of Peru. The Indians flocked to him in crowds, the sacred fillet was bound on his brow, and he was proclaimed emperor, by the title of Tupac Amaru the Second. An overwhelming army was speedily collected by him, which subdued the country and invested Cuzco. At the com-

Peru.

Recent History of Peru.

Peru.

mencement of his reign, though he declared vengeance against every native of Old Spain, he professed to favour equally the ecclesiastics, and all of the white race who were born in America. Adhering to this system, he continued to prosper, but his followers, elated with the success that everywhere attended them, and being in an undisciplined state, commenced a war of extermination against all who were not of the Peruvian race; which was attended with scenes of the most horrid barbarity. Diego his brother, and Andres his nephew, favoured the cruel disposition of the Indians, and perpetrated deeds which Jose Gabriel vainly strove to prevent. The insurrection continued two years, and extended over most of the districts around Cuzco; but the proceedings against the Whites, Mustees, Mulattoes, and Negros, at length united these casts against the Indians. Jose was surprised, and, with his family, taken prisoner; and shortly after, the whole were executed in the city of Cuzco. So great was the veneration in which this Tupac Amaru was held by the Peruvians, that, when he was led to execution, they prostrated themselves in the streets, and uttered the most piercing shrieks and execrations, whilst the last of the Children of the Sun was torn to pieces by his executioners. With this event terminated the struggles of the Peruvians for independence; and on late occasions they are reported to have shown more disposition to adhere to the government of Spain than to the newly created independent states that have sprung up around them.

Wars with  
New Granada.

During the period in which the surrounding dominions of Spain in South America were torn by intestine wars, Peru, though engaged in hostilities, has not been the theatre in which the contest was conducted. Allegiance to Spain was maintained through all her changes of government, and the Viceroy of Peru continued to exert himself to subdue the other countries that had revolted from it. When the revolution in New Granada began, the first steps were such as threatened no disturbance to the neighbouring provinces; but its spirit at length approaching the confines of Peru, the Viceroy dispatched an army towards Quito, under the command of General Molina, who had been nominated President by the Junta of Cadiz. As the revolutionists were divided among themselves, he easily gained that city; but practising some most cruel measures, according to the accounts of the insurgents, and we have no other, the army was compelled to retreat before the different partisans, who were previously at variance, but who had united in their operations against the Peruvians. After a bloody contest, they were driven from the viceroyalty of New Granada by the republican general Marino; but as his attention was strongly engaged in watching the events in the north, he could not follow up his victory by pursuing the royalists; who, on their part, had such calls for their exertions towards the frontiers of Buenos Ayres, and in Chili, that, without any formal treaty, hostilities ceased between Peru and New Granada in 1814, and have not been since renewed.

Wars with  
Buenos Ayres.

As soon as the inhabitants of Buenos Ayres had formed an independent government, an army of 5000 men was marched to invade Peru, under the command of General Balcarce. He was opposed be-

fore he had reached the frontiers by Goynèche, a royalist commander. Before hostilities were begun, a treaty for an armistice was made, but soon broken, when the Peruvians repulsed their invaders, became invaders in their turn, and overrun the country as far as Salta; having in their possession, in 1812, the rich mining countries of Potosi and La Paz; while the republicans, being embroiled among themselves, and invaded by the Portuguese, had no means of recruiting, till early in the year 1813, when their general Belgrano attacked the royalists near Salta, and gained a complete victory, which compelled them to abandon their conquests, and retire within their own territory. In November of the same year, the Peruvians, being reinforced, fought another battle on the frontiers, near Potosi, with such decided success, that they again occupied those rich districts, which, in the early part of the year, they had been compelled to abandon. The unfortunate republican general Belgrano was, in 1814, superseded by the celebrated San Martin, who collected the fugitives, organized a new army, formed various corps of Guerillas, and compelled the royalist general Pezuela once more to retreat from the contested country, and concentrate his forces in High Peru. In the year 1815, the contests among the different parties of republicans having weakened their army on the frontiers, Pezuela again attacked them, on the 14th November; gained a hard-fought battle at Sipe-sipe; and, in consequence of it, the mining districts of Buenos Ayres, for the third time, came into the hands of the royalists. The calls on the Viceroy of Peru for troops to maintain the royal cause in Chili weakened his frontier forces at the time that San Martin was collecting his army to invade that country on the part of the republicans. By the course of events, the theatre of the war thus became changed. The republicans kept up a small force to watch the motions of the royalists, whose troops and stores were so much diminished, that they ultimately withdrew from the conquered countries; which, by the operations of the remorseless contest, had become reduced to the extreme of misery, and the mines, once so highly productive, had nearly ceased to be worked.

Chili had thrown off the government of Spain, and declared its independence. It was torn by factions, violently irritated against each other, and a civil war had commenced. The Viceroy of Peru thought the occasion favourable for bringing it again under the royal authority. A force of 4000 men, under General Paneja, was dispatched to that country. He landed at Talcahuano early in the year 1813, and took possession of Concepcion and Chillan. The Spanish troops appear to have remained in the positions they occupied, in a state of great inactivity; whilst the Chilians, divided into rancorous factions, were exhausting their means, and impoverishing their country. The Spanish commander availed himself of the circumstances to make an attempt on the capital, in the beginning of March 1814; but, not succeeding, entered into a treaty for evacuating the country. Before the treaty was concluded, General Osorio arrived, as commander from Lima, with considerable reinforcements. This changed the face of affairs. The Chilians were wearied with the evils they had experienced; the forces of the King gave them confidence;

Peru.

Peru.

and after a few skirmishes, rather than battles, with the different parties, who never ceased hostilities towards each other, the whole country submitted to Osorio, who entered the capital in October 1814. The royalists were in quiet possession of Chili till the beginning of the year 1817. The fugitive republicans had retreated over the Andes, and found an asylum in Mendoza. There others joined them, in the following years. The government of Buenos Ayres supplied them with stores, and at length General San Martin, with the addition of some tolerably disciplined troops, was appointed to the command. This force passed the Cordilleras in January 1817, and descended towards the level country; and, after a most complete victory over the Peruvian army at Chacabuco, in which their commander was made a prisoner, and his troops dispersed, occupied, with little difficulty, the whole of Chili. The government there having assumed a more consistent and regular form than before, became a collecting point to which adventurous spirits, from Europe and from America, resorted. Armaments were equipped there, both naval and military. The former were successful in making prizes, and, in combination with the latter, Valdivia, the only remaining fortress in Chili, under the command of the Viceroy of Peru, and ultimately Lima itself was captured.

Expedition  
of Lord  
Cochrane  
and San  
Martin.

The conquest of Peru seemed to be indispensably necessary to the preservation of that independence, and those republican institutions which the inhabitants of Chili had established. It had early attracted their regards, and the project for achieving it, which was widely circulated, drew to them many of those military adventurers who, by the peace in Europe, were deprived of occupation. Among others, Lord Cochrane and several English officers who had distinguished themselves in the naval service, found employment in the fleet which was speedily equipped, and which, in discipline, though not in force, soon attained such a superiority over the navy of Spain as to give it the command of the navigation of the South Sea. Being to windward of the Spanish ports, it was easy at any time to choose the point of attack. An army of 5600 men was formed, under San Martin, which, with the fleet, consisting of one ship of 64 guns, one of 50, one of 36, and one of 32, besides some corvettes and transports, sailed from Valparaiso, in the latter end of 1820, and reached Lima in February of the following year. The troops were landed to the north of Callao, and continued, without any great exertion, till May, when the garrison of Lima being much straitened, an armistice was concluded.

Pezuela, then the Viceroy of Lima, was opposed by the Audiencia and the Municipality, who censured him for not adopting measures sufficiently energetic to repel the invaders. The same disposition to censure prevailed among the officers of the army; and at length they resolved to depose Pezuela. He made no resistance, but quitting the government and country, the command was placed in the hands of Don Jose de La Serna on the 29th January 1821.

The troops of La Serna were not much superior to the invaders numerically, but some of them having gone over to San Martin, gave the latter a supe-

riority. Lima continued to be straitened by the general, and Callao to be blockaded by Lord Cochrane, who performed one of those acts of desperate valour which struck astonishment into the Spaniards. With the boats of his little squadron he entered the port of Callao, and, under the guns of its tremendous batteries, boarded, captured, and carried off one of their largest ships of war, with more men on board than were in all the boats that attacked her.

Peru.

After some months had elapsed, a convention was agreed on, when La Serna with his army marched out, and San Martin with his forces entered Lima. A garrison was, however, left by the royalists in Callao. The protracted operations had given time to remove the most valuable property, which, with the females of the best families, and the non-combatants, reached the mountainous districts. San Martin, in the possession of Lima, was in the same condition as La Serna had been for some months before; with many mouths besides those of his army to fill, and his intercourse with the country that furnished provisions intercepted; but he had the advantage of naval superiority, and could draw supplies from the coast, though, till Callao was taken, the difficulty of landing made the arrival of such supplies precarious. At length the garrison of Callao agreed to evacuate, on being allowed to join La Serna, which was effected. San Martin was thus in full possession of the capital and its port, when a dispute between him and Lord Cochrane, about the division of the insignificant plunder, caused the latter to sail to some unascertained destination, and leave the commander of the land forces to secure his conquest. He there assumed the sovereignty, and acted the part of an absolute monarch, uniting in himself the legislative, judicial, and military power.

La Serna, after uniting with the garrison of Callao, retired towards the mountains, where he intercepted all communication between Lima and the mining districts, and drew supplies of men and stores from the countries in his rear. The whole of the treasure captured in Lima did not exceed 300,000 dollars, not a tenth part of what was usually to be found in that city. Cochrane having carried away the money, his coadjutor was soon compelled to have recourse to violent measures to subsist his army. He stamped paper dollars to pay his troops, and issued decrees commanding the inhabitants to take them in payment. A civil war is thus existing, which, as far as the latest intelligence reaches, leaves it doubtful if the conquerors or the conquered are in the worst condition. Whatever may be the ultimate issue, it must probably be a long time before tranquillity can be restored, to such a degree as to give that security to property which is more essential to mining than to any other of the operations of human industry. In whatever manner the present contest may terminate, it is not possible to conceive, that in future Peru, or any part of South America, will be subjected to the condition of a Spanish colony.

## PHYSICAL GEOGRAPHY.

**PHYSICAL GEOGRAPHY.** THE object of Physical Geography is to describe the external structure, form, and appearance of the globe, and the relations subsisting between it and the various classes of animated and organic beings which inhabit its surface. It ought to comprehend a description of the solid parts of the globe, with their magnitude, position, and the progressive changes they have undergone,—of the fluid parts, consisting of seas, lakes, and rivers, with their extent, motions, and general physical qualities,—of the atmosphere, with the phenomena it presents, including the variety of climates and seasons in different regions. Lastly, it should embrace a general view of the various tribes of animals and vegetables, with the order of their geographical distribution, in the ocean, the atmosphere, or on the land. Physical geography has but recently begun to assume the form of a science, and, like other branches of knowledge depending on extensive and multiplied observations, it can only be improved by slow degrees. To render it perfect, it would be necessary that we should know the true geographical position of every point of the earth's surface, its height above the sea, its mean temperature for every month, the prevailing winds, the annual and monthly depth of rain, the rate of evaporation, the nature of the rocks, the heat of springs, the peculiarities of the soil, with the animals and vegetables which can find nourishment upon it, and are adapted to the climate. We should know also for each part of the ocean, its depth, temperature, general and particular motions, and other physical properties, with its peculiar vegetable productions, and classes of living inhabitants. And to raise this knowledge to the rank of philosophy, effects should be traced to their causes, and the infinite variety of phenomena connected by a small number of general principles, by the help of which we might be able, from the knowledge of a few facts, to form certain conclusions respecting a multitude of others. Though physical geography is still far from this degree of perfection, writers upon the science have already collected, and to some extent generalised, a great number of interesting facts. To exhibit a systematic view of these is our object in the following pages; but we think it necessary to state, that we must necessarily confine ourselves within limits which will preclude extensive details upon any part of the subject.

**Magnitude.** The earth is one of eleven spherical bodies, denominated planets, which revolve round the sun. Its distance from that luminary is 93,595,000 English miles, and its mean diameter is 7912. It completes its diurnal revolution in twenty-four hours, and its annual revolution in 365<sup>d</sup>. 5<sup>h</sup>. 48' 51". One satellite, or attendant body, the moon, 2180 miles in diameter, revolves round the earth in 29<sup>d</sup>. 12<sup>h</sup>. 44', at a mean distance of 475,000 English miles. The relations of these bodies to the sun and the other planets, and

the laws which regulate their motions, belong properly to astronomy. (Playfair's *Outlines of Nat. Phil.* II. 86, 125, 126, 225.) The earth is not a perfect sphere in its form, but an oblate spheroid, or sphere flattened at the poles. The amount of this compression is such, that the equatorial diameter exceeds the polar diameter, or axis, by twenty-five miles; or the one is to the other as 312 to 311. The centrifugal force arising from the revolution of the earth round its axis, which evidently tends to dilate the equatorial parts, led Newton to infer the oblate or compressed figure of the globe before it was known by experiment. He calculated the ellipticity, from theory, at  $\frac{1}{230}$ , which is about one-third greater than the truth. A homogeneous fluid body of the mean density of the earth, and making its diurnal revolution in the same time, would, in fact, have the proportions which Newton supposed; and the ellipticity in this case would be a maximum. But if the revolving body, instead of being homogeneous, increase in density towards the centre, the compression is not so great. Now, the experiments made at Schehallien show that the mean density of the earth is nearly double of that of the rocks at its surface, and, of course, the density of the central parts must be still higher than the mean. Mathematicians have demonstrated, that, were the density to increase so as to be infinitely great at the centre, the ellipticity, in that case a minimum, would be no more than  $\frac{1}{78}$ . The structure of the globe as to density, so far as our knowledge extends, is intermediate between these extreme conditions; and since its ellipticity of  $\frac{1}{230}$  is also intermediate between the maximum and minimum, the circumstance affords a strong presumption that its form approaches very nearly to that of a spheroid of equilibrium, and in all probability coincides with it entirely. (Playfair's *Outlines*, II. 60, 302, 304.)

This conclusion is strikingly confirmed by the phenomena presented by those planets, in which the supposed cause of the ellipticity exists in the greatest degree, Jupiter and Saturn. As each of these bodies has a diameter ten times greater than that of the earth, and revolves round its axis in less than half the time, the centrifugal force ought to be far more powerful, and produce a much greater dilatation of the equatorial parts. Accordingly, in Jupiter, the ellipticity is one-fourteenth of the longer diameter, and, in Saturn, where the effect of the centrifugal force is aided by the attraction of the ring, the ellipticity amounts to one-eleventh. (Playfair's *Out.* II. 179.)

We have good reason to conclude, that whatever causes gave this oblate figure to the globe, they have acted upon the solid as well as the fluid parts. Though the land and water are unequally distributed over the two hemispheres, the soil, in a general point of view, is as much elevated at the equator as towards the poles. But since the equatorial regions are about

Physical  
Geography.  
Form.

Physical  
Geography.

twelve miles farther from the centre than the parts at the pole, it is evident, that, had the sea only been subject to the action of the centrifugal force, the torrid zone must have been completely submerged, and the polar regions left entirely dry, and rising many miles above the level of the waters. The ocean must, in fact, have formed a broad and deep zone round the equator, separating the two continents encircling the poles; of which continents a very small part only would have been habitable in consequence of the elevation of the soil. The figure of the globe affords, therefore, evidence of considerable weight in favour of its original fluidity, and it negatives the idea, that the earth, at the period of its consolidation, had a different axis from what it has at present.

Density.

The precession of the equinoxes, and the nutation of the earth's axis, indicate, in the opinion of Laplace, that the density of the globe increases towards the centre. Mr Cavendish, from some experiments with leaden balls, estimated the mean density of the earth at 5,48. (*Phil. Trans.* Vol. LXXXVIII. 469.) But the calculation most to be depended on is that founded on the experiments at Schehallien, which gives the mean density equal to 4,71 (*Playfair's Out.* II. 320), that is, about  $4\frac{3}{4}$  times the weight of an equal bulk of water. As the density of the rocks at the surface, which does not exceed 2,5 or 2,7, is much lower than the mean, it follows, that the density of the central parts must be much higher. If, for instance, the exterior rocks with which we are acquainted should form a shell of 500 miles in thickness, the parts within this shell would require to have an average specific gravity of 5,8 to produce the mean density of 4,7 for the whole mass. Laplace thinks, however, that the change in density is not sudden but progressive, and that it is probably the effect of concentric and elliptical beds, of increasing density, disposed symmetrically round the centre of gravity. (*Daubuisson, Traité de Geognosie, Chap. I.*) This disposition would naturally take place in a mass simultaneously fluid. And, in fact, the lowest rocks with which we are acquainted have generally a greater specific gravity than those which lie above them. The only considerable class of mineral substances known to us, which have the high density inferred to exist in the central parts of the globe, are the metals and their ores. This circumstance may, perhaps, authorize a conjecture, that these substances occupy the interior of the earth, and that the metallic repositories found in the outer crust consist of minute portions, separated and cast up from the central mass.

Geological  
Structure.

It would be foreign to our purpose to enter into the disputes which divide geologists. Conceiving that the principles of geology, at the present day, are to be considered as little better than provisional, we shall recur to them as sparingly as possible. Of the central nucleus, as already stated, we can know nothing but by inference. The outer crust, however, lies exposed, in part, to our view, and the materials of which it is formed, so far as we are acquainted with them, consist of four great classes. 1. Those rocks which neither contain any animal nor vegetable remains themselves, nor are intermix-

ed with rocks which do contain them, and are therefore termed primitive, or *primary*, as having been formed before the existence of organized beings. These are granite, gneiss, mica slate, and clay slate, which occur abundantly in all regions of the globe, with quartz rock, serpentine, granular limestone, &c. which occur more sparingly. These rocks never contain organic remains, and, till lately, were supposed never to cover rocks containing them; but a larger experience has shown, that this circumstance does not hold true entirely, even of granite itself. (*Daubuisson, II. 226.*) 2. Rocks containing organic remains, or generally associated with other rocks in which such substances are found, and which, as having been formed posterior to the existence of organized beings, are termed *secondary*. These are greywacke, sandstone, limestone, and gypsum of various kinds, slate clay, with certain species of trap, and they are found lying above the primary, or older rocks. 3. Above these secondary rocks, beds of gravel, sand, earth, and moss are found, which have been termed *alluvial* rocks or *formations*. 4. The name of *volcanic formations* has been given to beds of lava, scorix, and other matter thrown out at certain points of the earth's surface by subterranean fire.

A very distinct arrangement can be traced among these rocks, though they present a confused appearance to the eye on a first view. Where those of the primary and secondary classes are exposed together, the granite, which generally exists in unstratified masses, is found almost invariably under all the others; and yet it also occupies the highest points of the earth's surface. The gneiss, which is merely a stratified granite, lies next it, then the mica slate, then the clay state. The primary limestone, trap, serpentine, &c. lie in occasional beds intermixed with these. And above all, the primary formations are greywacke, sandstone, and other secondary rocks. Farther, the primary rocks are in general highly crystalline in their structure, and at the points where they are exposed to view, are found standing on their edges, or inclining to the horizon, seldom at a less angle than 45°. The secondary rocks again have rather the appearance of mechanical deposits; they occupy a more horizontal position; and their upper edges, or *outgoings*, are generally found at a lower level than those of the primary class. On these facts, geologists have founded certain general conclusions. From the oblate spheroidal figure of the globe, and the arrangement of its superior mineral masses in beds, or strata, they assume that the whole, or at least the outer crust, was at one time in a fluid state. That the central nucleus, of which we know nothing, is encompassed round and round by a coat or shell of granite, which, crystallising from a fluid state by the force of a strong affinity, has assumed a very irregular figure, shooting up into elevated cones or ridges at some points, which form the naked summits of mountains, and sinking into vast cavities many miles, or dozens of miles, below the present surface at others. That the gneiss crystallizing next in order was deposited above the granite, covering all the lower parts, but leaving the most elevated points of the granite bare. That the mica and clay slate

Physical  
Geography.Arrangement  
of  
Rocks.

Physical  
Geography.

were deposited in a less perfect state of crystallization above the gneiss, and in beds rather less inclined; that the older class of secondary rocks of a composition more mechanical than chemical, were then deposited above the mica and clay slate; the newer secondary rocks again above the older, in a position approaching more and more to the horizontal, as their structure became less crystalline, and occupying a lower and lower level; so that the edges, or outgoings, of the older rocks are always found rising above one another, as you advance from low plains to the summits of mountains. It is thus supposed, that the gneiss and other stratified primary rocks are found in beds nearly vertical, because we see them only at those points where, resting on the elevated crests of the fundamental granite, they break through the secondary formations; but that, if we could penetrate through the masses of sandstone, limestone, &c. which cover them in level situations, we should find them there also, and lying in horizontal positions above the granite. Farther, we see how the deposition of the different formations brought the earth nearer and nearer to the state in which we find it. The deposition of the granite, we may suppose, left the surface divided into profound cavities bounded or broken by ridges or pinnacles with steep sides, on which few orders of animated beings would have existed. The stratified primary rocks, deposited on the bottom and sides of these cavities, filled them in part, the older secondary rocks, falling down in less inclined strata, reduced the inequality still farther; and the newer secondary rocks, subsiding mechanically in strata nearly horizontal, made the surface assume a tolerably even and regular appearance. Last of all, the masses of gravel, sand, earth, marl, and other alluvial matter, filling up the smaller crevices and hollows left by the newest rocks, smoothed the surface, and prepared the earth for the nourishment of vegetable substances, and the habitation of animated beings.

We give this outline of the structure of the globe according to the principles of Werner; because, though it cannot be easily reconciled with all the facts now known, it explains the general disposition of the parts of the earth's surface, better than any other that can be given in a small compass. Of the modifications lately suggested, the following is worthy of notice. The great space which the stratified primary rocks occupy, compared with granite, and the fact, that the former sometimes preserve the same direction and dip unaltered on both sides of a granite mountain, have led some to consider the latter not as the fundamental rock, but rather as existing in large kernels or isolated masses, which are stuck in among the strata of the primary schistus, without affecting their dip and direction. The schistus again, instead of being in coats wrapped round the granite, is supposed rather to affect a *squamose* structure, or to be disposed in a continued order like the scales of a fish. Gneiss, mica slate, and clay slate, may be conceived, on this hypothesis, to be disposed in strata standing out edgewise, and alternating with one another, all round the globe. The large hollows left in the surface by the irregularity of the crystallization, or produced by the wearing

Physical  
Geography.

away of the softer rocks (the mica and clay slate, the more destructible rocks, being generally found in the lowest situations, and the more enduring gneiss, with its kernels of granite, in the highest), are filled up by newer formations, sometimes in conformable positions, but more frequently lying over the ends of the older strata. In this place, it is enough to have mentioned these opinions, without attempting to discuss their merits.

The phenomena of geology show, that the original formation of the rocks has been accompanied, in nearly all its stages, by a process of waste, decay, and recombination. The rocks, as they were successively deposited, were acted upon by air and water, heat, &c. broken into fragments, or worn down into grains, out of which new strata were formed. Thus the disintegrated materials of the older rocks, reunited by a cement, constitute those strata of greywacké, conglomerate, and old red sandstone, which skirt the primary mountains; the debris of the secondary rocks are found aggregated in the same way into beds of breccia, tufa, and newer conglomerate; a large portion of the spoils of the slate and trap rocks, both old and new, in a state of great comminution, are spread over the surface in beds of clay; and a still larger portion of the spoils of the quartz rocks, form those immense beds of sandstone and loose sand which cover so great a portion of the dry land and the bottom of the sea. Even the newer secondary rocks, since their consolidation, have been subject to great changes, of which very distinct monuments remain. Thus, we have single mountains, which, from their structure, can only be considered as remnants of great formations, or of great continents no longer in existence. Mount Meisner in Hesse, six miles long and three broad, rises about 600 yards above its base, and 700 above the sea, overtopping all the neighbouring hills for 40 or 50 miles round. The lowest part of the mountain consists of the same shell limestone and sandstone which exist in the adjacent country. Above these are, first, a bed of sand, then a bed of fossil wood 100 feet thick at some points, and the whole is covered by a mass of basalt 500 feet in height. On considering these facts, it is impossible to avoid concluding, that this mountain, which now overtops the neighbouring country, occupied, at one time, the bottom of a cavity in the midst of higher lands. The vast mass of fossil wood could not all have grown there, but must have been transported by water from a more elevated surface, and lodged in what was then a hollow. The basalt which covers the wood must also have flowed in a current from a higher site, but the soil over which both the wood and the basalt passed has been swept away, leaving this mountain as a solitary memorial to attest its existence. Thus, also, on the side of Mount Jura, next the Alps, where no other mountain interposes, there are found vast blocks of granite (some of 1000 cubic yards) at the height of more than 2000 feet above the Lake of Geneva. These blocks are foreign to the rocks among which they lie, and have evidently come from the opposite chain of the Alps; but the land which constituted the inclined plane over which they were rolled or transported, has

Changes on  
the Surface.

Physical  
Geography.

been worn away, and the valley of lower Switzerland with its lakes now occupies its place. Transported masses of primitive rocks, of the same description, are found scattered over the north of Germany, which Von Buch ascertained, by their characters, to belong to the mountains of Scandinavia; and which, therefore, carry us back to a period when an elevated continent, occupying the basin of the Baltic, connected Saxony with Norway. (Daubuisson, *Geog.* I. 230.)

At the present day, we see rocks worn away by the action of rivers and the sea, or crumbling down by the agency of air, heat, moisture, and frost; we see sands thrown up by the ocean at other points, and carried by winds over the face of the continent; we find new lands forming at the bottom of lakes and the mouth of rivers; we find beds of solid matter thrown out by volcanoes, loose sand agglutinated into hard rock on the shores of the sea; and new stony deposits forming by calcareous solutions. Can we attribute the great changes of which we see traces, to the same causes which operate these effects under our eyes, or have mightier agents been employed? These are questions which geologists have not yet been able completely to resolve, and into which it is not necessary here to enter.

Organic Re-  
mains.

But the most interesting memorials of the past history of the globe are supplied by those myriads of remains of organised bodies which exist in its outer crusts. In these, we find traces of innumerable orders of beings, existing under different circumstances, and succeeding one another at distant epochs, varying through multiplied changes of form, yet, even in their most dissimilar appearances, exhibiting a constant analogy to one another, and to the organised bodies which still exist. What is not less interesting, the varieties in the character of these extinct beings are not capriciously distributed, but correspond pretty distinctly with the order of their position. Thus, as we pass from the oldest secondary formations to the newest, we find the forms of the animal and vegetable remains approaching more and more to those of the living bodies which now exist on the surface; so that, while the most ancient are but faintly allied by a few general characters to the present animal and vegetable tribes, the most recent can scarcely be distinguished from them.

If we examine the secondary rocks, beginning with the most ancient, the first organic remains which present themselves are those of aquatic plants and large reeds, but of species different from ours. To these succeed madrepores, encrinites, and other aquatic zoophytes, living beings of the simplest forms, which remain attached to one spot, and partake, in some degree, of the nature of vegetables. Posterior to these are orthoceratites, ammonites, and other mollusci, still very simple in their forms, and entirely different from any animals now known. After these some fishes appear, and plants, consisting of bamboos and ferns, increase, but still different from those which exist. In the next period, along with an increasing number of extinct species of shells and fishes, we first meet with amphibious and oviparous quadrupeds, such as crocodiles and tortoises, and some reptiles, as serpents, which show that dry land

now existed. As we approach the newest of the solid rock formations, we find lamantins, phocæ, and other cetaceous and mammiferous sea animals, with some birds. And in the newest of these formations, we find the remains of herbivorous land animals of extinct species, the paleotherium, anaplotherium, &c. and of birds, with some fresh water shells. In the lowest beds of loose soil, and in peat bogs, are found the remains of the elephant, rhinoceros, hippopotamus, elk, &c. of different species from those which now exist, but belonging to the same genera. Lastly, the bones of species which are apparently the same with those now existing alive, are never found except in the very latest alluvial depositions, or those which are either formed in the sides of rivers, the bottoms of ancient lakes and marshes now dried up, in peat beds, in the fissures and caverns of certain rocks, or at small depths below the present surface, in places where they may have been overwhelmed by debris, or even buried by man. (Cuvier's *Essay*, S. 29, Daubuisson, I. 362.) Human bones are never found, except among those of animal species now living, and in situations which show that they have been, comparatively speaking, recently deposited.

Physical  
Geography.

From these phenomena we are led to infer, that rocks now buried at a great depth, constituted, at one time, the surface of continents, and the seat of organic life; and that many orders of beings have been called into existence, and afterwards destroyed by great revolutions, which introduced new classes of mineral deposits, accompanied with new tribes of organic beings; we see farther, that among the variety of vegetable and animal forms which peopled these successive continents, aquatic plants and animals, which appear the earliest, show that the surface was long covered with water. The appearance of amphibious animals and reptiles at a later period indicates the first existence of dry land; but long posterior to these, and among the newest of the solid rocks, we find herbivorous quadrupeds, which shows, so far as our present knowledge extends, that it was only at a late period, speaking geologically, that the earth's surface was clothed with herbage, and rendered in other respects analogous to what it is at present. We find also, that, since the surface assumed this form, it has been subjected to at least two great catastrophes, apparently by irruptions of the waters. Thus the fossil remains of the herbivorous animals found in the Paris gypsum (the paleotherium, &c.) are covered by deposits containing sea-shells, and are not found again in any beds nearer the surface. Hence the waters, after the irruption which destroyed these animals, had again retired; and upon the new continent thus left dry, we find the remains of a different race of herbivorous quadrupeds (the elephant, rhinoceros, &c.), of species which are also extinct, but allied to the existing races in their generic characters. These animals are again covered by loose soil, intermixed with marine substances, which shows that a new irruption of the sea had occasioned their total or partial destruction; and when the waters retired once more, the land had been left dry, as it now exists; for the only class of animal remains above those in question belong to the species now

Geological  
History.

living on the surface, and are found in situations where their appearance is easily accounted for. It is among these last that the remains of the human species are found; and no vestiges of any being analogous to man in structure have ever been discovered among older deposits.\*

From an attentive consideration of the phenomena now referred to, we are led to conclude, that the appearance of man upon the face of the globe is, geologically speaking, a very recent event; before which the earth had been inhabited for thousands of years, by various families of plants, and tribes of animals, which had been destroyed and renewed in a long series of successions. Farther, the researches hitherto made favour the supposition that the tribes of living beings existing at each epoch were not a remnant of those destroyed by the preceding revolution, retaining the same forms, or changed and modified by external causes, but rather a new creation, adapted, we may presume, to the altered situation of the surface. It is possible, but rather improbable, that the present races of animals may have existed along with the mastodon of America and the mammoth of Russia; but we are almost certain that they did not exist, at least in this part of the globe, with the preceding order of beings, the paleotherium, anaplothorium, &c. The continual approaches which the newer orders of fossil animals make in their forms to those now living can, therefore, only be regarded as a proof that the climate, soil, and circumstances to which the nature of the extinct species was adapted, approached more and more to those under which animal life exists at the present day.

As new orders of beings have been introduced at each change, and the most perfect have appeared the last, have we any reason to believe, from the consideration of these phenomena, that some future convulsion of nature may bury the present races of men and animals, and usher in a new creation, of a still more perfect kind, over which some intelligent being, of a higher class than man, may preside? We think not. The great revolutions, which have so often overwhelmed and new-peopled the face of the globe, seem to have been continually decreasing in the magnitude of their effects, from those which deposited the vast masses of the primitive rocks, to those which left behind them the Paris gypsum and other superficial beds, like a slight sediment in the cavities of preceding formations. They may be compared, in fact, to the motions of a pendulum, which describes a smaller arc at each vibration, till it ultimately settles in a state of rest. The progressively diminishing extent of these successive changes give us reason to believe, that the system of our globe has nearly reached this state of repose. Perhaps, without an improper licence of conjecture, we may explain the phenomena which the past history of the globe presents, by supposing that the Deity, having deemed that state of the earth's surface which we

now witness the best adapted for man, and having considered a long series of changes, such as geology reveals to us, the fittest means of bringing it to this state, did, from the impulse of that benevolence which has peopled every leaf with sentient beings, create tribes of living creatures at each successive epoch, adapted to the existing order of things, and terminating with it. Nor is there any thing in this conjecture inconsistent with revelation. It has been allowed, that the word "day," in the Mosaic account of the creation, may mean a period of indefinite length; and nothing more is necessary to remove every essential difficulty. Cuvier deduces, from certain progressive changes on the earth's surface, as well as from the concurrent traditions of many nations, that the first appearance of man on the face of the globe, or at least the renewal of the human race after some great catastrophe, cannot be referred to a period farther back than about 5000 or 6000 years from the present time. (*Essay*, Sect. 34.) The researches of science in this respect afford a striking confirmation to the testimony of the sacred historian.

The earth's surface may be divided into dry land and submarine land. The dry land consists of high country, that is, of mountains and hills, with the elevated valleys between them; and of low country, or the extensive plains which lie at the foot of the mountains. The sea has also its plains, mountains, and valleys. High or Alpine country sometimes descends to the sea by a succession of valleys below one another, sometimes by one large plain. Elevated and extensive plains, however, with opposite declivities, do not terminate in one another, but are almost always divided by land of a mountainous character.

Single detached mountains are rare, except in volcanic districts, and in those where trap rocks abound. Mountains are generally found in elevated bands, consisting either of one central chain, with branches running off at right angles, or of several chains or ridges running parallel to each other; and in both cases often accompanied by subordinate or dependent chains, of a smaller elevation. Thus the Cevennes, Jura, Vosges, with the mountains beyond the Danube, are considered as dependencies of the Alps. Mountain chains have generally a great length, compared with their breadth. The ends or extremities of a chain and the outer ends of its branches seldom decline gradually into the level country, but rather terminate abruptly. In principal chains, the highest point is generally near the middle; but in dependent chains, the highest part is that which is nearest the principal. Peaks or elevated summits, rising far above the other parts of the mountain, such as Mount Blanc, in the Alps, are generally placed on the principal ridge, or that which parts the waters, and at the point where two opposite branches join. To this, however, there are exceptions. *Cols* or necks, which are the lowest parts of ridges, and serve as passages from one country to another, are al-

\* Some human bones are said to have been found in loam in gypsum caves, associated with the remains of the rhinoceros and fossil horse. Jameson's *Manual of Mineralogy*, p. 445.

Physical  
Geography.

most always placed at the joining of two opposite valleys. The Col de Brenner, the lowest of those in the great Alpine chain, is 4680 feet above the sea. The other four principal passages through the great chain are from 6500 to 8000 feet high. The lowest passage in the chain of the Pyrenees is about 3400, and in that of the Andes of Quito 12,200, feet above the sea. The summits of great chains sometimes present a sharp ridge, like the Swiss Alps; sometimes a level track, like Mount Langfield in Norway, which is ten or twelve leagues broad; sometimes a vast plain, like the table land of Mexico in North America, 150 leagues broad, and bounded by valleys with steep sides. Where many chains run parallel to each other, the steepest sides of the outer chains are generally turned towards the central chain; and in the dependent chains, the steepest sides are turned towards the principal. In general, also, mountains that surround lakes or basins present their steepest sides to the water. Thus the scarps of the hills which surround the Basin of Bohemia are turned inward; those of the hills which surround the Lakes of Geneva and Constance face these lakes; those of the mountains round the Mediterranean also generally face that sea; and the high lands which extend along the coasts of Africa, Asia, and America, from the Cape of Good Hope to Cape Horn, have their steepest sides to the great basin which forms the Indian and Pacific Ocean. (Daubuisson, I. 60—99.)

Valleys.

The form and arrangement of valleys correspond to those of mountains. A great mountain chain sends out branches at right angles to itself, which are called lateral chains; these lateral chains send out other smaller branches at right angles to themselves, and parallel to the great chain, and which are called subordinate chains; and sometimes these last send out others still smaller. The valleys which separate one principal chain from another, such as the valley of the Rhone above Geneva, are called "principal valleys;" those which separate one lateral chain from another are called "lateral valleys;" and those which divide the subordinate chains from one another are called "subordinate valleys." The subordinate valleys open into the lateral, the lateral into the principal; the whole forming a connected system, in the order of trunk and branches. Valleys often contract and enlarge their breadth, as if they formed a series of basins rising above each other towards their sources. Lakes are most abundant at the upper extremities of valleys. A vast number of small lakes exist along the ridge of the Pyrenees, some of them at an elevation of 8000 feet; and along that of the Andes, where they are also numerous, there are some as high as 13,000. In the Alps there are also many; but the largest, such as those of Constance, Geneva, Como, lie at the foot of these mountains, and at elevations from 650 to 1600 feet above the sea. Some of the basins, formed by the contraction of the valleys, have obviously been lakes at one period, though now dry. But more frequently the sides of valleys, instead of alternately contracting and receding, preserve a very striking parallelism, salient angles on one side being opposed to re-entering angles on the other. Nor is this the consequence of inflections in

the dip and direction of the strata; for these rarely correspond with the declivities of the surface. On the contrary, we find the lateral and subordinate valleys in the sides of mountains cutting distinctly through the strata; so that, when the width is not very great, we can generally trace the same beds in the same order at the opposite sides. In short, the aspect of a mountainous region, on the great scale, is very similar to that of a hillock of soft clay or earth which has been cut and worn away by heavy rains. The furrows made by the water, ramifying into others smaller and smaller, with the little ridges of earth between them, present a very accurate image of an Alpine track, with its system of valleys, its crests and pinnacles, its long chains, and its lateral and subordinate ridges. Had the mountainous district, with some slight original inequalities of surface, been subjected, for a long series of ages, to the agents which act upon it at present, or what is more probable, to agents of the same kind, but of greater power, we have reason to believe that the configuration of the surface would have ultimately been very similar to what we see. It does not follow, however, that mountains have really received their form from such causes. (Daubuisson, I. 85—94, 245.) On the other hand, a *debacle*, or great current, such as some geologists have supposed, sweeping over the globe, or a particular district, could not scoop out valleys which are almost universally shut at one extremity.

Hills are less regular in their direction and form than mountains. They exist more frequently in groups than chains, and often appear as the last undulations of the mountainous surface. (Daubuisson, I. 108.)

Volcanoes occupy but a small portion of the earth's surface; but, in consequence of the grandeur of the phenomena they present, they have always arrested the attention of mankind. About 205 are known, including only those that have been active within a period to which history or tradition reaches. Europe contains thirteen or fourteen, and of the whole number, it is computed that 107 are in islands, and 98 on the great continents. Very few of these are in constant activity; the greater number sleep for long periods, and some of them for ages. In general their activity is in the inverse ratio of their size, and of those that are active, very few throw out lava, the greater number only emit smoke, or smoke and ashes.

In a volcano that has been in a state of repose, smoke appears before an eruption; subterranean noises are heard; the earth shakes; then ashes, sand, stones, are thrown out; at last, the melted lava runs over the crater, or bursts through the sides, after which the earthquake ceases. The columns of smoke consist chiefly of aqueous vapour, with carbonic sulphuric or muriatic gas. The ashes, which seem to be lava in a state of very minute division, have been known to be carried by the wind fifty or an hundred leagues. When deposited in great quantities, and impregnated with moisture, they form a volcanic tufa, which is sometimes solid enough to serve as building stone. The sands which form the major part of the ejected matter, and the

Physical  
Geography.

principal mass of some volcanic mountains, consist of minute portions of lava which congeal in the air, or of the finer scoriæ. They are mixed with crystals of augite and felspar. The scoriæ consists of larger portions of the same matter, and has the appearance of the slag of forges. Along with these and the lava are often thrown out unfused fragments of the rock, which forms the walls of the volcano. The velocity of projection is thought to equal that of a cannon-ball, and the force is prodigiously great. Vesuvius throws up large stones 1200 yards above the crater, and Cotopaxi has launched a fragment of an hundred cubic yards (weighing not less than 200 tons) to a distance of three leagues.

The lava which flows out of volcanoes is a dark stony substance, resembling basalt, compact or porous, or with imbedded crystals. It is seen lying in the bottom of the crater in a state of incandescence, like melted metal in a furnace. It has a motion like boiling; and is seen to swell up from time to time twenty or thirty feet; as it rises, bubbles, some feet in diameter, form on its surface, and explode with a noise like a clap of thunder, bursting into a thousand fragments, which are accompanied with smoke and sparks. It then sinks in silence, to rise again in a little time. These alternate swellings and subsidings are evidently produced by the disengagement of elastic fluids. The force of the fluids, however, is rarely sufficient in the large volcanoes to raise the lava to the surface; and hence, in such cases, it generally happens that the flank of the mountain is burst through by the pressure of so vast a column, and the lava escapes laterally. Of ten eruptions of Mount Etna, nine have been by the flank, but Vesuvius, and other small volcanoes, habitually throw out their lava by the crater. On the other hand, the gigantic volcanoes in the Andes, having their sides compressed by the immense mass of the Cordilleras, are never known to throw out lava now in either way, though lava is found in the country. Scoriæ and ashes, however, are still ejected. The current of lava descends in general slowly, but sometimes with a velocity of five or six miles an hour. The surface cooling first, forms a sort of tube or tunnel, under which the liquid mass is sometimes seen to flow upwards, in consequence of the pressure of the column behind. These tubes, and inclosed portions of gaseous fluids, often form caverns. When the lava first issues out, it is very fluid, but becomes more viscous as it cools. By means of its solid crust, however, it preserves its heat an astonishing length of time. Spallanzani saw a piece of wood take fire in lava three years and a half after it was thrown out, and at a distance of two leagues from the crater. It has been seen flowing ten years, and smoking twenty-six years, after its ejection. The currents are of various magnitudes. At Vesuvius one was observed eight or ten yards thick, from 100 to 400 broad, and four-fifths of a mile long; but there have been others much larger. In Iceland, in 1783, there was a current twenty leagues in length, by four leagues in breadth. So vast is the quantity of ejected matter in some instances, that the mountain of Jorullo, in Mexico, 1600 or 1700 feet high, standing

on ground which was formerly a plain, was thrown up by an eruption in 1759.

Currents of water, accompanied with mud, sometimes descend from volcanoes. The water is believed to proceed generally from heavy rains falling on the exterior of the mountain, and occasioned by the sudden change of temperature round the crater; sometimes, however, from reservoirs in the interior; sometimes also, as indicated by the fish thrown out, from the water of brooks finding its way into the bowels of the mountain. Spallanzani thinks that part of the tufas of Italy owe their origin to eruptions of mud. In Cotopaxi, which rises above the line of perpetual frost, the melting of the vast masses of snow, when ignition takes place, produces most destructive torrents, one of which swept away a village thirty leagues from the crater.

The name of *Air or Mud Volcanoes* has been given to certain spots where gaseous fluids, or mud, or water (generally salt), issue out of the earth, but these have no connection with subterraneous fire. At Macalouba, in Sicily, large bubbles of gas, consisting chiefly of hydrogen, formed at some depth, rise to the surface, where they explode, and scatter the soft mud in which they are generated round the opening. Near Modena, there are a number of cones from which, at times, hydrogen gas issues, with explosions which resemble small earthquakes, while stones of several hundred weight are launched to the distance of some yards, and currents of mud are vomited forth 1000 yards in length. In some cases, the gas issues pure from chinks or caverns, and, taking fire, exhibits columns of flame 100 yards in height. The fire-worshippers in Persia built their temples over these fountains of flame; and the Chimera, with many other fables of the Greeks, had their origin in the same natural phenomena. Eruptions of mud and gaseous exhalations have been observed in the Crimea, in Java, in the American province of Carthage, and many other places.

In the district of the Cevennes, in the south of France, there exist above 100 conical hills, which are known to be volcanic by their form and composition, consisting of mixed masses of lava, scoriæ, and volcanic stones, and exhibiting in many places very distinctly the appearance of a crater. But they have never been in a state of ignition within the periods to which history reaches, and are therefore considered as extinct volcanoes. Many mountains in other countries present the same volcanic character, though they have never been known to produce eruptions.

Recent observations strongly favour the opinion that many of the trap rocks are the productions of subterraneous fire. But if we confine our view to those mineral masses which are recognized as volcanic at present, they form but a very trifling part of the outer crust of the globe. Their formation is obviously posterior to that of the other solid rocks, for they are always found at the surface, and never enter into the frame-work of the earth. Vesuvius has, perhaps, covered with its ejected matter twenty square leagues, and Etna one hundred. The 200 existing volcanoes, estimated according to this scale,

Physical  
Geography.

besides elevating their respective cones, may have spread a coat of lava and scorix, probably an hundred yards thick, over 20,000 square leagues, that is, over the twelve hundredth part of the surface of the globe. It may, therefore, be safely held, that volcanoes, as they now exist, have exercised no general influence on the state of the globe.

Theory of  
Volcanoes.

A satisfactory theory of volcanoes is yet wanting; but some progress has been made in generalizing the phenomena and circumstances connected with them which, when fully known, will certainly conduct us to the knowledge of their causes. First, water seems to be a necessary agent in the production of volcanic fire. Columns of aqueous vapour ascend from volcanoes; currents of salt water sometimes flow out of them, and heavy rains increase their action. It is only extinct volcanoes, like those of Auvergne, that are found far inland; the others are always at no great distance from the sea; the most active are in its immediate vicinity, and some are actually submarine. The matter which feeds them does not seem to be universally diffused, but rather collected in particular spots. Hence, they almost always exist in groups. Thus, Sicily and the south of Italy present us with one group, Iceland with another, the Archipelago with a third, the Canary Islands a fourth, and the great cones of Cotopaxi, Tungurahua, and Pinchincha, in Quito, a fifth. This proximity of situation in the members of the same group seems to arise, not from any subterraneous communication, but from the matter which feeds them being distributed over the space they occupy, and accompanied with the presence of the agents that excite combustion. Thus, the action of one of the volcanoes belonging to the same group, such as Etna, Vesuvius, Stromboli, is found to be entirely independent of that of the others, one being asleep while another is active, and eruptions of one producing no change in the others. The arrangement of some of these groups is perhaps most consistent with the supposition of the matter being disposed in beds; but that of others, such as the volcanoes of Mexico, and the extinct volcanoes of Auvergne, which are ranged in strait lines, rather suggest the idea of the matter being lodged in veins. The distance of some volcanoes from the sea or from large lakes, with which analogy leads us to conclude that they have a necessary connection, the length of time they have burned, and their being the focus of earthquakes, which are felt over a great extent of surface, show that the fire is seated at some distance under the surface; on the other hand, we have every reason to believe, that wherever the source of the heat may be, the erupted matter does not come from a very great depth in the bowels of the earth. The quantity of lava is too trifling to be thrown up by a central fire, or to restore the equilibrium of nature, after it has been disturbed by convulsions so dreadful as those which precede an eruption must be, if their seat is really at a very great depth in the solid mass of the globe. Neither the supposition of beds of coal, nor of pyrites, in the interior of the volcano, explain the origin of the carbonic generated so abundantly and maintained so long. Perhaps the violent heat produced in some chemical processes,

as when the pure metallic bases of potass and soda, are brought into contact with oxygen, chlorine, or water, may give us an idea, though only in the way of analogy, of the source whence subterraneous fire is derived. (Daubuisson, I. 160, 192, 208, 218.)

Physical  
Geography.

In an article like this, we cannot attempt a detailed description of the physical features of each country, and must therefore restrict ourselves to a very general survey of the two great continents, the old and the new.

If we consider the old continent attentively, we shall find that its general form, the declivity of its surface, and the course of its rivers, are chiefly determined by one great zone of mountains which traverses it from one extremity to the other, at the mean latitude of 40° north. This Alpine girdle has its origin on the shores of the Atlantic between the parallels of 30° and 42°, from which, in several chains, under the names of Atlas, on the south, and the Pyrenees, Alps, Mount Hemus, on the north, it passes into Asia; and there, under the names of Taurus, Caucasus, and Elbourz, it is continued eastward to the 70th degree of longitude. At this meridian it divides into two branches, one of which, the Himalayah range, takes a direction south-eastward, and terminates within 400 or 500 miles of the Gulf of Bengal; the other, Mount Altai and Yablounoy, passes north-eastward till it strikes the Pacific Ocean at the latitude of 55°. Its entire length to east longitude 140 is 8000 miles. Its breadth varies from 500 miles to 2000. The Pyrenees, Alps, and Mount Hemus, ought evidently to be considered as members of one great group with Mount Atlas. They rise under the same meridian, and have a corresponding direction; they are not separated by open plains, but by a long and narrow inland sea, which, from its steep shores, and great but irregular depth, has exactly the character of one of those profound lakes that occupy the bottom of valleys between the parallel ridges of the same mountain chain. The Sierras of Spain, the high ridge of Corsica and Sardinia, the Italian Appenines continued through Sicily, and the mountains of Southern Greece, form so many transverse branches connecting the great southern and northern chains of the band. Perhaps most of these transverse branches, where they meet the waters, are continued by submarine ridges. At least this is the case with the connecting branch of the Appenines and mountains of Sicily; for, though the Mediterranean generally is too deep for soundings, there is no more than 100 fathoms anywhere between Sicily and Cape Bon. Through the mountains of the Morea, and Crete, and Mount Rhodope, the African and European chains are connected with Mount Olympus and Taurus. The Carpathians and Erzegebirge are dependant chains of the Alps. Mount Taurus, reinforced by the chain of Lebanon, turns north-eastward round the sources of the Euphrates, where it unites with the lofty group of Caucasus. From this the principal chain passes round the bottom of the Caspian Sea, under the name of Elbourz, including the high peak of Demawend. A collateral branch passes south-eastward, along the basin of the Tigris,

General  
View of Old  
Continent.

Physical  
Geography.

the north side of the Persian Gulf and Indian Sea, till it sinks into the sandy plains at the mouth of the Indus. Between these two run various ridges in different directions, but generally with a certain degree of parallelism to the outer chains, the whole of which give the character of table land to the surface of Persia. About 70° of east longitude the great band parts into two branches, one of which, in several chains, runs south-eastward, forming a lofty barrier to Hindostan on the north, and giving birth to the Indus, the Ganges, and the Burrampooter. The other, the Altai branch, proceeds north-eastward to the sea of Otchosc, sending off several small branches on both sides. From Uda, in latitude 55°, it skirts the sea to Behring's Straits. These two great branches support the high plateau of Thibet, within or near which all the largest rivers of Asia have their source.

eight.

The height of this great Alpine zone is various. Mount Atlas, according to Chenier, is covered with eternal snow, and must therefore exceed 10,000 feet in elevation. The Sierra Nevada, in the south of Spain, is 11,660 feet high; the loftiest summit of the Pyrenees is 11,283 feet, of the Alps, 15,646 feet, of the Carpathians, 8640 feet, Mount Etna, 10,963 feet, Mounts Orbelus, Olympus, and Parnassus in Greece, from 6000 to 9000 feet.\* With regard to the Asiatic mountains, very few of their heights have been measured. We know generally that Mount Taurus, in the south of Asia Minor, Mounts Caucasus, Ararat, and Demawend, reach the limits of perpetual snow, and must therefore have an altitude exceeding 9000 feet. But the most elevated part of this mountain band is the Himalayah, the loftiest summits of which, according to the estimate of Captain Blake, rise to the height of 25,000 and 28,000 feet above the level of the sea, and are therefore the most elevated land on the globe. (*Edinburgh Philosophical Journal*, No. X. 408.) The Altai chain is but little known. Various circumstances show that it does not generally rise to a great height above the surrounding country, but it stands upon a very elevated base, and the extreme rigour of the climate proves that its absolute height is very great. Taking the whole Alpine band together, we shall probably not err far, if we reckon its mean height in Europe from 4000 to 9000 feet, and in Asia from 5000 to 14,000.

Apart from this principal system of mountains, we have two small and separate chains in the northern part of the old continent. These are the Dofrines, 1000 miles long, with a mean height from 4000 to 6000 feet, and of which the mountains of Scotland and England may be considered a detached portion; and the Urals, 1400 miles long, and of a moderate but unknown height. Both of these chains run south and north, or nearly at right angles to the grand central band. The Dofrines have a system of declivities and rivers dependent on them, embracing the whole peninsula of Scandinavia. The Urals seem to produce almost no effect on the general direction of the surface and of the rivers in the great northern plains.

Physical  
Geography.

This great Mediterranean band of mountains may be considered as the spine of the ancient continent. It determines the direction and elevation of the surface, over nine-tenths of Europe and Asia, and one-fifth of Africa, the course of all the great rivers in the old world, except the Nile and the Niger, and in some measure the climate of the different regions. It incloses within its extreme branches Spain, Barbary, Italy, Switzerland, Southern Germany, Hungary, the Mediterranean Isles, Turkey in Europe and Asia, Persia, Bucharía, Thibet, and Chinese Tartary, all of which countries consist either of table land, or of valleys placed between the different chains. The surface of this mountainous zone occupies a space of 5,000,000 square miles, and embraces Persia, Phœnicia, Assyria, Asia Minor, Greece, and Italy, all the early seats of civilization. Spain consists of a succession of valleys from 500 to 2500 feet high, divided by ridges, and in the central parts, especially in the basin of the Douro, approaching to table land. Southern Switzerland and the Tyrol present us with profound valleys from 1000 to 3000 feet above the level of the sea. Northern Switzerland, Wirtemberg, Bavaria, and Austria, consist chiefly of irregular plateaux from 1000 to 2000 feet high, broken by mountain ridges. Italy embraces merely the declivities of the Appenines, Barbary those of Mount Atlas. Greece consists of narrow littoral declivities, and basin-shaped valleys; and the Mediterranean Isles are merely the summits and sides of marine mountains. Bohemia is a circular valley, the bottom of which is probably 500 or 600 feet high; and Hungary a still larger and more level plain, whose bottom, according to Humboldt, is not more than 200 or 250 feet above the Black Sea. Asia Minor is an irregular elevated plateau, fenced on the south by Mount Taurus, and declining generally to the north. Persia, according to Olivier, is also a high plateau, supported on all sides by mountains, and depressed in the middle, so that the waters never penetrate the external barrier, but flow inwards, and stagnate, or disappear by evaporation. Thibet is a plateau of the same kind, but still more extensive and more elevated, forming, in truth, the summit of the Asiatic plains, and the most extensive and lofty range of table land on the globe. From a single fact respecting its climate, Humboldt has inferred that the height of this great plain is from 9000 to 10,000 feet above the sea. Thibet, with the desert of Shamo, which is merely its continuation to the north-east, are supposed to comprise a surface of 1,500,000 square miles. From the little that is known respecting these regions, they are believed to consist of level sandy or stony plains, diversified by mountains of moderate height, and by pastures with inconsiderable streams, which generally lose themselves in salt lakes or marshes. In the eastern part, the country of the Kalkas, though it rises perceptibly from China, the elevation cannot be nearly so great as Mr Barrow supposes, for some of the

\* Notes to Leslie's *Geometry*. Articles EUROPE and GREECE, in this *Supplement*.

Physical  
Geography.

hills in latitude  $45^{\circ}$  and  $50^{\circ}$  are covered with wood, which does not grow on Caucasus (in a corresponding latitude) at more than 6400 feet of absolute height.\*

Great  
Northern  
Plain.

The region on the north, exterior to this great mountain zone, but subordinate to it, is remarkably simple and uniform in its character. Commencing from the eastern shores of the North Sea and the Baltic, it extends in one vast plain, unbroken by a single chain of mountains, except the Urals, to the North Pacific Ocean. This plain, the largest on the globe, including generally the whole space between the 50th and 70th parallels, has an average breadth of 1400 miles, and a length of about 6000, and comprehends an area of 6,500,000 square miles, or rather more than one-fourth of Europe and Asia. It embraces the western part of France, all Holland, Northern Germany, Prussia, and the whole of Russia. Of its western division, that part which comprises France has considerable inequalities of surface, coasts generally rocky, and a good soil, which declines to the west. From Holland to Jutland it is chiefly a heathy or marshy *steppe*, very low and level, and with flat shores. From Mecklenburg to the Gulf of Finland, sands are more abundant than heath, the shores are flat, the surface, which is low and abounding in shallow lakes, declines to the Baltic for a breadth of 250 miles. From the longitude of  $30^{\circ}$  to the eastern extremity of Asia, a vast plain extends, one-fifth of which declines to the Black Sea and Caspian, the other four-fifths to the Frozen Ocean. Between the parallels of  $50^{\circ}$  and  $60^{\circ}$  the soil is generally capable of culture, and in many places rich, but it is intermixed with extensive sandy deserts impregnated with salt, and abounding in salt lakes. There are large forests, but the surface is, for the greater part, little wooded, presenting extensive open pastures, which are denominated *steppes*. Beyond the 60th parallel the ground is generally frozen during the whole year, and incapable of culture, but produces some low and stunted wood as far as the parallel of  $65^{\circ}$  or  $67^{\circ}$ , and grass or moss to the borders of the Frozen Ocean. The rivers eastward of longitude  $55^{\circ}$  have all their courses northward; they have little declivity, and are navigable almost to their sources, for the few weeks they are open.†

Zone of  
Sands.

South of the great central band of mountains, we have an immense zone of sandy deserts, 900 miles broad, and 4500 long, extending between the parallels of  $18^{\circ}$  and  $31^{\circ}$  north, and between the west coast of Africa, and the mouth of the Persian Gulf. But, in reality, the sandy zone includes also the eastern part of the great Alpine girdle. It is, therefore, more accurate to consider it as extending across the African continent in a band of 13 degrees in breadth. From the Red Sea it turns a little to the northward, and in the form of a truncated triangle, resting upon this sea as a basis, it reaches obliquely across the continent of Asia to the 50th degree of latitude, and the

120th of longitude; including northern Africa, Arabia, Persia, Cabul, Bucharia, Sind, Thibet, and the western part of Chinese Tartary; and embracing an area of 6,500,000 of square miles, or nearly one-fourth of the two continents through which it passes. This tract contains many mountains, and some fertile valleys, but it is characterized by vast desert plains, formed of very light moveable sands, which assume the form of waves,—by burning and pestilential winds,—by an extraordinary aridity and want of rivers,—and by an abundant formation of salt, sometimes deposited like a crust on the surface, sometimes mixed with the inferior soil. Except the Indus and the Oxus, there is not a river of any size within this immense region, which is twice as large as Europe. The Sahara, or western desert of Africa, the peninsula of Arabia, and the great Plateau of Thibet, present the most continued surface of sand. Oases, or fertile spots, are found wherever the springs break through the upper sandy stratum. These oases are comparatively numerous, and extensive, in the eastern part of Africa; while in Persia, Cabul, and Bucharia, the surface is diversified with green mountains, which give birth to fertilizing streams. Of the whole sandy zone, however, it is probable that three-fourths consist of irreclaimable deserts.

Physical  
Geography.

South from the Sahara in Africa lies a comparatively fertile tract, the basin of the Niger, the Senegal, the Gambia, and the upper basin of the Nile. This is bounded on the south by the ridge of Jebel Kumra, a mountain of moderate height behind the coast of Guinea, but rising to the region of the perpetual snow in Abyssinia, if the two are really parts of one chain. Little is known of the great southern extremity of Africa, extending from these mountains to the Cape of Good Hope. From the elevation of the coast, and the smallness of the rivers, it may be conjectured to consist chiefly of table land, and to be distinguished by its aridity.

From the head waters of the Ganges, a low and level tract extends to its mouth, and from this to Cambodia, a series of long valleys opening into marshy plains at the shore. The triangular peninsula of India, and the rich country of China on the opposite sides of this tract, are covered by considerable mountains, and have the character of table land. The group of islands which extend from China and Malacca to New Holland are in general full of elevated mountains, many of which are volcanic. New Holland has some of its shores low, and some elevated, but it is not known to possess any very high mountains, or any large rivers. Of the innumerable small isles scattered in the Pacific, the greater part are merely the summits of coral reefs.

The New World forms two great continents, united by a neck of high land. South America consists of one vast expanse of surface of small elevation, everywhere protected on the west by the great

\* See Barrow's *Travels*. Gerbillon's *Journies in Histoire Generale de Voyages*, Tom. IX.

† Walckenaer, *Cosmol.* 408, 412. Sauers's *Narrative*. Pallas's *Travels*.

Physical  
Geography.

rampart of the Andes. These mountains, which pass along the western coast, at the distance of from 50 to 150 miles from the sea, rise, in one of their summits, to the height of 21,440 feet, and in Peru have a mean elevation of about 12,000 feet. There are three small transverse ridges, one in Caraccas, at the latitude of 8° or 9° north; another, which divides Guiana from the basin of the Amazon; and a third, which parts from the Cordilleras in south latitude 18°, proceeding eastward, and spreading out into a range of table land as it approaches the eastern coast. All these transverse chains are of small elevation. The low region of this continent is divided into three great plains, which form the basins of the three principal rivers, the Orinoco, the Amazon, and the Plata. In the basin of the Orinoco, the eye is fatigued by the unvaried aspect of a boundless level, uniform as the surface of the ocean, without a plant, or any object a foot in height, to break its monotony. Except on the borders of the rivers, these plains are destitute of trees. After the annual rains, they are clothed with a luxuriant herbage, which, during the heats of the dry season, is reduced to dust, and disappears. The soil then presents the aspect of a parched desert, in the chinks and fissures of which, the alligator and the great serpent remain buried amidst the dry mud, till they are awakened by the first showers. The Pampas of La Plata, which extend from 18° to 40° of south latitude, are plains of the same description. But the zone which divides these open plains, and forms the basin of the Amazon, extending from 6° or 7° of north, to 18° of south latitude, is one vast and continued forest. On the eastern side of the continent, this forest extends as far south as latitude 25°, and altogether embraces a surface of 20,000 square leagues. This middle region is also the highest, but so low are all the three, that, if the sea were to rise 50 fathoms at the mouth of the Orinoco and Plata, and 200 at the mouth of the Amazons, it would wash the eastern foot of the Andes, and submerge more than one-half of South America. The Llanos and Pampas afford pasturage to millions of cattle, and are, in truth, *steppes* like those of Southern Russia. There are no real deserts in South America, except a narrow tract of rock and quicksands on the coast of Peru between Coquimba and Lima, on which no rain ever falls. (Humboldt, *Pers. Nar.* IV. 292, 311.)

North Ame-  
rica.

The North American continent, like the South, is distinguished by one great chain of mountains, which traverses it from south to north nearly through its whole extent, leaving a large open level region to the east, and presenting a steeper and narrower declivity to the west. The chain of the Rocky Mountains, which ascend considerably above the inferior limit of perpetual snow, at latitude 46°, has probably an elevation of 8000 or 9000 feet. In a general point of view, these mountains determine the declivities of the soil, and the course of the rivers over nearly the whole continent. On the west side of the chain the slope is rapid, and the rivers, so far as they are known, flow directly to the Pacific Ocean, passing through a high, broken, interrupted chain,

Physical  
Geography.

which skirts the coast. On the east side, they bend their course to the nearest sea, over a surface little inclined, flowing to the north-east, and north in the northern parts, and to the south-east and south in the southern parts. On looking attentively at the rivers in the map, it will be perceived that the chain of lakes above Lake Erie, the upper Mississippi, the Missouri, the Arkansaw, and Red River, all point in one direction, to the south-east, that is, at right angles to the general line of the coast, reckoning from Nova Scotia to the north-west corner of the Mexican Gulf. But, as if the barrier of the Alleghanies had been thrown up subsequently to the general level of the surface being settled, we find the St Lawrence and the Mississippi, after running nearly parallel till they were within 500 miles of the coast, suddenly deflected from their south-east course, and proceeding to the sea in directions almost exactly opposite. The mean height of the Alleghanies is from 2000 to 3000 feet.

The woods are thickest on the eastern side of the Alleghanies. In the basin of the Ohio, which occupies the western declivity of these mountains, extensive tracts, called prairies, destitute of trees, but covered with herbage, occur. The declivities of the rocky mountains from the Mississippi to the Pacific Ocean are generally bare of wood, except along the rivers, and within twenty leagues of the sea-coast. In truth, the whole of this vast region consists of open steppes or savannahs, of a rich soil, and affording excellent pastures, but mixed with stony and sandy tracts, especially towards the Mexican frontiers. Salt springs are numerous, and in some districts the surface is incrustated with a saline efflorescence. The whole of the region east of the Rocky Mountains, from the 50th parallel to the Arctic Sea, is generally low, abounds in lakes, and is scantily wooded as far as the 60th degree of latitude, beyond which trees cease to grow. From the Gulf of Mexico to the mouth of Coppermine River, in latitude 67°, the country may be considered as one great plain, the summit of which, about the 50th parallel, is probably not 1000 feet high. The mean height of the great basin of the Mississippi and Missouri, Humboldt thinks, does not exceed from 500 to 800 feet. The interior of the country between Mackenzie's River and Behring's Straits, and between Hudson's Bay and the coast of Labrador, is entirely unknown; but the former is probably fertile and tolerably wooded, as the whole of the region west of the Rocky Mountains has a mild and humid climate. The late discoveries of Captain Parry and Captain Franklin have rendered it probable that the northern limits of the American Continent run generally along the 67th or 68th parallel, and that the space between this and the latitude of 78° or 80° is occupied by a numerous group of islands, of which Greenland may be considered a part. The isthmus which connects the two American continents consists of a prolongation of the chain of the Andes, of moderate height, and which, about the latitude of 18° north, spreads out into a vast plateau of table land, about 7000 feet above the sea. From this elevated base some detached volcanic mountains ascend

Physical Geography.

10,000, reaching an absolute elevation of 17,000 feet. (Warden's *America*, Chap. 31, 32, 33. Walckenaer, *Cosmol.* Chap. 14.)

New and Old Continents Compared.

A comparison of the great continents of the Old and New World shows that the advantages are greatly on the side of the latter. All the interior parts of both the American continents have the advantage of being nearer the sea than the interior parts of Asia and Africa. There are in America no great deserts like those of the Old World, which not only withdraw a vast portion of the soil from the use of man, but, by the burning winds they generate, render the neighbouring regions scarcely habitable, and, by the wild beasts and robbers to which they afford shelter, oppose a more formidable barrier to the intercourse of nations than stormy seas or snow-clad mountains. But the grand advantage of the New World is its immense facilities for inland navigation, in consequence of the little elevation of its surface and its multitude of noble rivers. The St Lawrence, the Mississippi, the Amazons, and the Plata, penetrate the heart of the two American continents in a manner to which there is nothing analogous in the Old World. By means of these great streams, and their branches, there is scarcely a district of any extent, however remote from the sea, which has not a more easy and rapid communication with the rest of the world than the countries within 200 or 300 miles of the coast in the greater part of Asia and Africa. Mexico, the only considerable region in the New World without navigable rivers, has the advantage, by the narrowness of its territory, of being everywhere near the sea. We may add, as an accidental advantage of the New World, that its aboriginal inhabitants, from the smallness of their numbers, present almost no obstacle to the establishment and growth of a civilized population; while the Old World is too thickly peopled in most of its parts to admit of being easily colonized, and by tribes who discover no aptitude for civilization themselves.

The extent of the four great divisions of the world is as follows:

	Sq. Eng. Miles.
Europe with its Isles, - - -	3,432,000
Africa with Madagascar, - - -	11,420,000
Continental Asia, - 16,890,000	} 21,090,000

Greenland (supposed), 620,000	
	51,242,000

Rivers.

Rivers are natural drains which convey to the sea that portion of the waters falling upon the earth, which does not pass off by evaporation, or go to nourish organic bodies. They invariably occupy the lowest parts of the surface of the districts from which their waters are derived, and these districts are called their basins. The basin is bounded by high lands, which are sometimes mountainous. The water descending from these collects into brooks, the brooks unite into rivulets, the rivulets united form

the main trunk or river, which conveys the waters of the whole to the sea. All these descend over inclined planes, so that the lowest point of each brook is that where it joins the rivulet—the lowest point of the rivulet that where it unites with the main stream—and the lowest point in the whole system of inclined planes, is that where the river falls into the sea. These basins form natural divisions in physical geography. Thus the basins of the Rhone, Garonne, Loire, Seine, and part of the basin of the Rhine, comprehend nearly all France; Northern Italy consists chiefly of the basin of the Po, and Bohemia entirely of the basin of the Upper Elbe.

Channels how Formed.

The form and appearance of river courses lead to the conclusion that their channels are generally the work of their own currents. We never find them flowing in cavities which retain their natural shape, but always in beds cut below the adjoining surface, and corresponding to the quantity of water; the bed of the main stream being larger than those of the great branches, and the beds of the great branches larger than those of the small. They do not accommodate themselves to the inequalities of the country, but flow near the surface in low plains, and cut through a high ridge when it comes in the way; preserving a pretty uniform rate of descent, however great may be the undulations of the superior soil. The deep ravines that have been cut through hard rocks in this way, by an agent that operates so slowly, impresses us with a conviction that immense periods of time must have elapsed since the operations commenced. Before this took place, the courses of rivers must have consisted chiefly of a series of lakes communicating by cataracts. The waters flowing down from the high grounds in one district would collect and form a lake, which would increase till the flood found a passage over the lowest part of the bounding ridge, and fell into a second cavity, in which they would again accumulate, till they were discharged by another cataract into the next natural hollow. By a twofold chain of operations these lakes and cataracts disappear. The bottom of the lake is constantly rising by the earth and gravel carried down by the torrents and spread over it, and the level of the waters is constantly sinking by the action of the stream in deepening the outlet. At length the lake becomes a dry level plain, with a gravelly bottom, and the cataract a deep cleft or ravine, through which and the plain above, the river flows with a uniform and gradual descent. Many of the haughs or holms seen on river courses have undoubtedly been lakes of this kind.

Changes in River Courses.

The surface of the globe everywhere presents traces of these changes. The celebrated passage of Ecluse has exactly the dimensions and appearance of a channel cut by the Rhone itself, and exhibits marks of the action of the water far above the present surface. Three distinct basins are observed in the course of the Rhine. The lake of Constance occupies the first, the second extends from Basle to Bingen below Mentz, and the third from this to the sea; and each of these basins is separated from the others by a narrow rocky strait. In the Danube

Physical Geography. may be distinguished the basins of Bavaria, Austria, and Hungary, from each of which the river escapes by a mountainous defile. The celebrated defile of Tempe in Thessaly, the deep and rugged clefts by which the Potowmac, Susquehannah, and Delaware, penetrate the barrier of the Alleghanies, all bear decisive marks of the action of the stream. In many cases, the subsidence of the water can be traced from one level to another by terraces of gravel left on the sides of the mountains. In the valley of the Rhine these are seen to the number of four or five, at the distance of twenty, thirty, or forty feet below one another, and from them Professor Playfair ascertained that this river had once flowed at the height of 360 feet above its present bed.\*

In the greater number of river courses we see those changes completed, but in the chain of North American lakes on the St Lawrence, we see them still in progress. On the rocky sides of some of these lakes Mackenzie observed marks of the action of the water considerably above its present level. The Niagara falls have been observed to recede about eighteen feet in thirty years, by the water's wearing away the limestone rock. This rock forms a large level platform, from the outer edge of which, six miles below the falls, the cataract has receded, and worn out a deep channel of that length by the constant attrition of its current. Had the surface of this rock dipt rapidly to the southward, the lake would have been emptied long ago. The fact is interesting in another point of view. Supposing the rate at which the rock is wasted away by the stream (eighteen feet in thirty years) to be well ascertained, and to have continued uniform, since the fall has gone backwards six miles from the position it must have originally occupied, it may be inferred, from calculation, that 50,000 years have elapsed since the waters of the St Lawrence began to flow. If we could depend upon the smaller unit—the annual waste of the rock, we should consider this as a tolerable criterion for estimating the antiquity of the present physical arrangement of the earth's surface. (Hall's *Travels*, p. 235.)

Where rivers which pass through low and level tracts are subject to annual inundation, the earth, sand, and gravel they bring down, deposited most abundantly on their banks, raise them gradually above the surrounding country, while a part of the matter carried to the sea enlarges the coast, or forms sand or mud banks which rise, by degrees, above the water. It is thus that the Ganges, Po, Nile, Mississippi, and many other rivers, flow on the top of ridges. During floods, the elevated sides are sometimes burst through, and the waters which escape either stagnate in lakes, or return into the main stream lower down, forming islands, or travel to the sea by a separate mouth, and form a delta. Hence the Amazons, Orinoco, Mississippi, Nile, Danube, Wolga, Ganges, abound in islands, and have deltas from 50 to 200 miles in breadth, at their

Physical Geography. mouths. In the tracts of new ground which are thus gained from the sea, the soil may be seen of every degree of solidity, from soft mud to firm land. In the broad plain at the mouth of the Ganges, between the Tipperah hills and Bardwan, wherever the ground is penetrated, no virgin soil is found, but an alluvial deposit of sand and mud arranged in strata. The finest soil transported to the sea renders the water muddy to the distance of twenty miles from the coast. The Mississippi is supposed to add about two leagues to the coast in a century, or 300 feet *per annum*, at the point where its main stream falls in. (Warden's *America*, II. 492.) But the increase, if equally distributed over the whole delta, would not exceed two or three feet *per annum*. Volney calculated, but on very loose data, that the Nile had advanced four miles at Rosetta, and ten at Damiat, since the time of Herodotus; a quantity far too great, amounting to sixteen feet *per annum* over the whole delta. But Girard ascertained, that the annual floods of the Nile had raised the surface of Upper Egypt about six feet four inches (English) since the commencement of the Christian era, or four inches in a century. Now, as the sea deepens on the coast, at the rate of a fathom in the mile, supposing the deposit to have been as great along the whole shore as in the Thebais, the addition would amount to no more than one mile and a quarter since the time of Herodotus. The great error in all estimates of this kind has arisen from confounding the changes that belong to geological with those that belong to historical periods. The Po, which sweeps rapidly through a rich valley, transports a vast quantity of alluvion, and is found to encroach upon the Adriatic, at the astonishing rate of 228 feet *per annum*, at its two principal mouths. Adria was once upon the sea, and a circular space of twenty miles in diameter must have been filled up with solid soil since it was built. Assuming that 2500 years have elapsed since the building of Adria, and allowing the new ground a depth of twelve feet, it follows, that the river must have deposited 45,000,000 of cubic feet annually at its mouth, exclusive, perhaps, of as much more floated away by the sea, or spread over the banks higher up. Even this quantity of alluvion is a trifle compared with that of the Yellow River of China, which is 2,000,000 of cubic feet *per hour*, if Mr Barrow's estimate may be credited. Great as these effects seem to be, they sink into insignificance when compared with the whole extent of the ocean. Assuming that the mean depth of the sea is two miles, and that each district of land, of the same extent as the basin of the Po, furnishes an equal quantity of alluvion, it may be shown that it would require 400,000,000 of years to fill up the present bed of the ocean. †

All rivers are subject to occasional or periodical floods. Those of the Nile, observed in a country where no rain falls, have been a subject of speculation since the time of Herodotus. Within the torrid

Physical Geography. zone, these floods are produced by the annual rains, and occur during the summer months; but, beyond the tropics, they occur at various seasons, and in high latitudes, chiefly in spring, when the snow and ice melts. As the season of rains at each parallel within the tropics commences generally when the sun passes the zenith of the place towards the pole, and continues till he pass it again on his return, or a little later, the floods, of course, last longer as we advance farther within the torrid zone, and at the equator are perpetual. Hence, the Amazons, which derives its waters from both sides of the equator, may be said to be always in flood; but as its largest branches belong to the southern hemisphere, its greatest inundations are during our winter months. Those of the Plata take place during the same season, but are of shorter duration. These floods cover a vast but unknown range of country. The Orinoco begins to rise in May, overflows its banks in June, and returns into its bed in September, but, like the other tropical rivers, continues to fall till March or April next year. The Nile, which is really a tropical river, begins to rise in June, reaches its maximum height of 24 or 28 feet about the middle of August, and continues to fall till May next year. Its increase is irregular, two or three inches a day at first, and sometimes, when near its height, as much as three or four feet. The long valley of Egypt, from three to four leagues broad, with the delta at its extremity, is now covered by the water, except some elevated spots, and the higher parts of the river's banks, which rise above the adjoining surface. In Northern India, where the seasons depend chiefly on the monsoons, the Ganges begins to swell in April, when the rains fall on the mountains, and increase at the rate of one, two, or three inches a day, till it reaches the height of 15½ feet before the showers have commenced in the plains. When the latter begin in July, the river rises at the rate of five inches a day, till it reaches its maximum of 31 or 32 feet, about the same period as the Nile. In the end of July, the low country, for a breadth of 100 miles, presents a wide expanse of water, whose surface is diversified by the trees that everywhere rise above it, and by the multitude of villages standing like islands, between which, the peasants are seen passing in boats. The rains cover the low tracts before the bed of the river is filled, and its banks, which rise above the rest of the country, appear like long mounds which separate the waters of the inundation from the stream of the river. The floods are computed to advance over the low region at the rate of half a mile *per* hour, and when at their height, cover a large tract of country to the depth of twelve feet. The floods of the Indus fertilize a district reaching thirty or forty miles on each side of its course. They attain their full height, like those of the Ganges, in August, but they begin rather later, end sooner, and are probably smaller. The celebrated Euphrates, which has its

Physical Geography. sources in the high mountains of Armenia, begins to swell in March, reaches its extreme height in April, and, from this period till June, during which heavy showers fall every day at noon in Armenia, it remains nearly stationary. After June it falls rapidly. Its extreme rise is twelve feet in Mesopotamia, and so level is the country, that, with this small elevation, it covers nearly the whole plain between it and the Tigris, in the latitude of Bagdad. The Mississippi is lowest in October; in some of its remote branches the floods commence in February, with the melting of the snows, but they are not much felt in the low country till March, from which time they mount rapidly till June, and then fall again till October. From the junction of the Missouri to that of Red River, the great volumes of water thrown by the Mississippi over its western banks, spread out into shallow lakes, which are dried up by the autumnal heats, and become parched and solid plains. Below Red River, where the delta commences, the ground is a wide swamp, rising very little above the level of the tide. The only soil capable of cultivation is the long stripe of elevated land which forms the bank of the river, and is dry during eleven months. Consisting of fine travelled earth, it is luxuriantly fertile. Its breadth is small, sloping downwards as it recedes from the stream, and at a distance, varying from half a mile to a mile and a half, terminating in the swampy level. In the rivers that water the northern parts of the new and old continents, the floods, which almost invariably proceed from the melting of the snow and ice, are violent but transitory; and occur in March, April, May, or June, according as the sources of the river are farther from, or nearer to the arctic circle. In some of these rivers there are three successive floods,—the first in March or April, when the thaw takes place in the low country,—the second in May, when the thaw has reached the middle regions, and heavy rains fall,—and the third near the end of summer, when the glaciers begin to dissolve. Thus in the frigid, as well as the torrid zone, the season of floods is generally the four months nearest the summer solstice.\*

As water cannot be heaped up where it is not confined on all sides, it follows that the floods in rivers will gradually sink as they approach the sea, and assume the form of an inclined plane at their upper surface. Thus the rise in the Mississippi in the height of the inundation, at the distance of 1000, 300, and 100 miles from its mouth, is 50, 25, and 12 feet respectively. The Ganges, which rises 31 feet at Cussee, rises no more than 14 at Dacca, and 6 at Luckipoor. The extreme height of the Nile, which is 24 or 28 feet at Cairo, is only 4 at Rosetta. From the great additional rapidity thus communicated, when the depth is only doubled, the discharge is often quadrupled. In the case of the Nile, where the depth is trebled, the discharge is probably augmented tenfold during the height of the flood. The

Physical Geography.

Physical Geography.

quantity of water delivered into the sea by the rivers between the equator and the parallel of 35° north, is perhaps as great in the single month of July, as during the eight months from September to April.

The following table, which we have prepared with considerable labour, exhibits some interesting calculations with regard to the most considerable rivers of the globe. The first column of figures gives their proportional lengths, measured always to their remotest branches, the length of the Thames being reckoned unity. The second column gives the area of their basins in square English miles; the third the proportional magnitude of those basins; and the fourth the quantity of water which each discharges, that of the Thames being unity. The last column, which is necessarily hypothetical, is constructed on the following basis. The fall of rain is found to bear a certain relation to the latitude, and is assumed to be equal (though it is not strictly so) along all the parts of the same parallel. It is farther assumed, that of the rain which falls, a certain fixed propor-

tion is received by the rivers. It is evident, then, that, having the extent of the river basin, its mean latitude, and the depth of rain at that latitude, we have the elements for computing the proportional discharge of the rivers. In the ingenious article *HYGROMETRY*, in the *Edinburgh Encyclopædia*, the author deduces, from data partly theoretical, the amount of rain for each 5° of latitude. But, from Cotte's Tables, Captain Parry's observations, and various facts stated by Humboldt, we have been led to conclude, that the mean depth of rain at the equator is at least 10 inches more, and at the pole considerably less than given in the article referred to. On these and other grounds we have endeavoured to connect the results of observation by an empirical rule. Assuming the annual deposit of rain and dew at the equator to be 83 inches, and at the pole 8, we find the intermediate terms by the following formula :

$$75. (\text{Rad.} - \text{Sine of Lat.}) + 8 = \text{depth of water in inches.}$$

To deduce the approximate lengths of the rivers in miles from the proportional lengths, we may multiply the latter by 180, this being pretty nearly the distance between the remotest source of the Thames, and its mouth at the Nore, following the sinuosities of the river. To convert the proportional discharge into known measures, we would multiply by 1800 to obtain the number of *cubic feet per second*, or by .4 (or  $\frac{4}{10}$ ), to find the annual discharge in *cubic miles*. It is a question of some difficulty to ascertain

what proportion of the rain, snow, and dew, which falls on the ground, passes off by the rivers. Mr Dalton, computing the annual deposit of moisture in England to be 31 inches of rain, and 5 of dew, concludes that 13 inches, or more than one-third, is drained off by the rivers. (*Manchester Transactions*, V. 359.) But this is founded entirely on a conjectural estimate, not an actual measurement, of the depth and velocity of the Thames, in the basin of which the fall of rain is only 22 or 23 inches at London and

Discharge of Rivers.

Physical  
Geography.

Oxford. Since it is shown, however, by the observations of Dr Dobson, Dr Watson, and Mr Dalton himself, that the evaporation from water is about equal to the fall of rain,—that from a grassy plot in a dry season, it is sometimes 0.7 inches in a day, or  $\frac{2}{3}$  of what pure water yields,—and that from ordinary soils, 30 inches out of 38 escape by evaporation, leaving only  $\frac{1}{4}$  for the streams, there is surely more than a presumption that the rivers cannot carry off 13 out of 36 inches for England, and still less 13 out of 26 or 28 inches in the basin of the Thames. (*Phil. Trans. Abnd.*, XIV. 137. *Manchr. Trans.* V. 359.) The Mississippi, which drains one of the largest valleys on the globe, was found by Mr Darby to have a breadth of 2400 yards not far above New Orleans, with a depth of 153 at high, and 130 at low water. (*Geog. Descrip. of Louisiana*, p. 126.) The section considered as a semiellipse is 280,000 square feet, and the discharge, with the mean velocity of one mile an hour, which he assigns to it, is 410,000 cubic feet *per second*, equal to 88 cubic miles *per annum*. As we have taken the high water level with the mean annual velocity, the difference of 23 feet may stand as equivalent to the loss of water by the bayous, or outlets, of Iberville and Atchafalaya, and the temporary lakes farther up. Now this discharge, distributed over the basin of the Mississippi, amounts to no more than four inches of water in depth. If we add one-half to it, on the supposition that his estimate of the velocity is rather low, even this will only raise the rain water to six inches upon the area of the basin. But the depth of rain corresponding to the mean latitude of the basin of the Mississippi (41°) is by the rule 34 inches, and at Cincinnati, in latitude 39°, it has been found, by observation, to be 36 inches. This is exclusive of dew, and from what we know of the climate of St Louis, and of Columbia river, we have no reason to think that the average for the whole basin can be much less. (*Warden's America*, II. 237, III. 121.) We would be entitled, from these facts, to estimate the depth of the watery deposit at 40 inches; but suppose we reduce it to 30, the proportion drained off by the rivers amounts only to one-fifth. From the nature of the basin of this great river, which avoids all extremes, having a moderate elevation, and consisting neither of a continued forest, nor of a sterile desert, but of a mixture of the most common varieties of soil, it affords probably as fair a criterion as could be obtained for deciding a question of this kind. We think, therefore, that both theory and observation warrant the conclusion, that, in the case of large rivers flowing over extensive and tolerably level surfaces, the water carried to the sea does not exceed one-fifth of what falls in rain, dew, and snow. Where the basins are small, the surfaces steep and rocky, and where heavy rains continued for months, keep the soil in a state of saturation with moisture, the discharge may be greater. In other cases, where the basin is long and flat, the water-course broad and shallow, the temperature high, and the soil sand or gravel, the loss of the river by direct evaporation, and by infiltration, through its bed and sides, may be very great, and does in some cases (as in that of the Platte) absorb the whole wa-

Physical  
Geography.

ter. The rule, of course, is not meant for extreme, but for ordinary cases. Founding then on the rate of discharge of the Mississippi, that of the Thames should be about 1800 cubic feet *per second*, or  $\frac{4}{5}$  of a cubic mile *per annum*, equal to nearly five inches on the surface of its basin. This may serve when it is considered as the unit of the scale, but, in point of fact, the discharge is probably larger, as the basin is small, and the depth of rain greater than belongs to the parallel in general.

If we estimate the mean fall of rain, not for the whole globe, but for the dry land, at  $2\frac{6}{10}$  feet, or 31 inches, it will amount to 25,500 cubic miles *per annum*, of which, according to our calculation, the sea receives, by the rivers, about 5100. Of this quantity, the Amazon discharges  $\frac{1}{10}$ , the Plata  $\frac{2}{3}$ , the Mississippi  $\frac{1}{3}$ , the Ganges  $\frac{1}{10}$ , the Danube  $\frac{1}{100}$ , and the Thames  $\frac{1}{1000}$  part. The water thus delivered into the ocean, if not counterbalanced by evaporation, would raise the level of the sea two inches in a year. It amounts to  $\frac{1}{36,000}$  part of the mass of the ocean, supposing it to have a mean depth of two miles. In other words, the water discharged by the rivers would fill the present bed of the ocean in 56,000 years. We may infer farther, that the greater part of the supply of water belonging to each region circulates between the atmosphere and the earth, suffering a loss of one-fifth every time it falls upon the latter, and receiving an equivalent addition from the vapours of the sea. The smallness of this supplementary portion, compared with the whole quantity, is a circumstance which consists well with the general regularity of the annual supply of moisture, and the stability of the order of the seasons.

As very large rivers, with numerous tributary streams, necessarily occupy the lowest situations in all countries, it follows that their courses have a very small declivity. The surface of the Amazons, at Jaen, 3000 miles from the sea, has only an elevation of 194 toises, which gives five inches *per mile* for the mean fall; and over the whole of this space, the navigation of that majestic river is not interrupted by a single cataract. In the last 200 leagues of its course, the inclination is believed not to exceed 11 feet, or  $\frac{2}{10}$  of an inch *per mile*. A series of tides, felt to the distance of 600 miles from its mouth, exists in its bed contemporaneously, following one another up the channel, and giving its surface the form of a waving line. The Ganges, reckoning its sinuosities, has only a fall of four inches *per mile*, from Hurdwar, where it leaves the Himalayah chain to the sea. Humboldt thinks the declivity in the lower course of the Mississippi is still smaller. The Wolga, from its source to the Caspian Sea, falls 957 French feet, or about five English inches *per mile*. The Nile, though it falls from a height of 10,400 feet at its head (barometer 22 inches), if Bruce may be believed, has a very small inclination in the lower part of its course. The celebrated cataracts of Syene, which were said by the ancients to produce endemic deafness, consist merely of ten successive steps of six inches each, dispersed over two-thirds of a mile, and which are capable of being passed by boats. There is still one singular phenomenon connected with large rivers, which has been little attended to.

Declivity of  
Rivers.

Physical  
Geography.

Their beds, at some places, like the lakes of mountainous regions, have a greater absolute depth than the adjoining seas. In the Amazon, above the Rio Negro, about 1000 miles from its mouth, Condamine found no bottom with a line of 103 fathoms. Now the height of its surface here could not be above 70 fathoms, and its bottom must, therefore, have been at least 100 feet below that of the sea on the coast. At a small distance above New Orleans, where the height of the surface of the Mississippi could not exceed 40 or 50 feet, Mr Darby found the depth to be 153 feet; and hence the bottom must have reached 50 or 60 feet below that of the shallow sea at its mouth. \*

Lakes.

Lakes are among those natural objects which contribute, in the highest degree, to the picturesque beauty of the earth's surface. Like the sea, they exercise a beneficial influence on the climate and soil, by moderating the extremes of heat and cold, and by diffusing humid vapours over the land. When they occur in the courses of rivers or at their fountains, they serve as back reservoirs, to equalize the discharge, and to prevent those sudden inundations which are often so destructive. Of all the great natural features of the globe which are subject to mutation, lakes are probably the least permanent. The waste of mountains, and the raising of the bed of the great ocean, are operations of which the effects can scarcely become sensible in millions of years, but in the filling up of lakes, striking changes are often produced within the lifetime of an individual; and within the periods to which history reaches, several have entirely disappeared.

Lakes are chiefly of two kinds; those which are formed in deep hollows between the ridges, or at the foot of mountains, and which are fed by springs or torrents; and those which are formed in low and level countries by the surplus water of rivers, or in consequence of the want of a general declivity in the ground. We have thus two grand systems of lakes in the old continent. The one accompanies the great Alpine girdle, and includes the lakes of the Pyrenees, Alps, Appenines, those of Asia Minor, Syria, and Persia, with the Caspian Sea, the Aral, Balkash, Baikal, and all the series of lakes found at the foot of the Altaic chain. The other begins at the low shores of Holland, and extends along the south-east coast of the Baltic and Gulf of Bothnia, and thence in smaller numbers along the Frozen Ocean to Behring's Straits. Except in central Africa, the regions south of the great mountain band, so far as they are known, contrast remarkably with those of the north, by the fewness of their lakes. A chain of lakes, but generally smaller than the mountain lakes of the old world, accompanies the Andes from their southern extremity, through the isthmus and Mexico, to their northern termination. In the level part of South America, as in the southern regions of the old world, lakes are comparatively rare; and the coincidence is no less striking in the north, where

the regions round Hudson's Bay present a multitude of lakes, corresponding in numbers, character, and geographical situation, with those which skirt the shores of the Baltic and Frozen Ocean.

Physical  
Geography.

The Caspian, which is the largest lake in the world, and has really the character of an inland sea, merits particular notice. Its length is 750 miles, breadth about 200; it embraces an area of 170,000 square miles, and receives the waters of a surface about five times as large. Its general depth is 60 or 70 fathoms, but, near the south end, no bottom has been found with a line of 380. It is salt, and, like the ocean, is subject to storms; and, either from the effect of winds, or the unequal discharge of the rivers, it is subject to irregular elevations, varying from four to eight feet. The Caspian is distinguished from all other lakes and seas in the world, by the remarkable lowness of its surface, which was found by Engelhardt and Parrot to be 334 feet beneath that of the Black Sea. The inhabitants, therefore, of Astracan, and other places on its shores, live at a lower level by 200 or 300 feet than any other people on the globe. (Tuckey, *Marit. Geog.* I. 457. *Edin. Phil. Jour.* No. VI. 408.)

Lakes are salt only when they are placed in districts where the soil contains saline matter, and their saltness is invariably greater when they have no efflux. Most of the lakes of Europe are either fresh or slightly saline; but the Caspian Sea, the lakes Aral, Baikal, and others that accompany the Altaic chain, as well as those of Persia, being situated in the midst of plains full of salt, or in regions where salt springs abound, are almost universally impregnated with this mineral. The most highly saline waters known are found in lakes which receive streams but give out none. Thus the lake Ourmiah, in Persia, and the Dead Sea in Judea, receiving continual supplies by the streams from the neighbouring soil, which is every where full of salt, while nothing but fresh water is carried off by evaporation, the mineral accumulates, and their waters are found to contain, in the one case six, and in the other eight times as much salt as those of the ocean. (*Edin. Phil. Jour.* No. IV. 356.) When the quantity carried down by the streams exceeds what the water will hold in solution, the surplus is deposited in beds at the bottom; and hence the numerous layers of salt which are found mixed with thin strata of mud at the bottom of dried up lakes. Large shallow lakes, like that near Teheran, in Persia, which is 150 miles long, often lose their waters in the heat of summer, and become salt marshes, or plains, covered with a salt crust. (*Kinneir's Geog. of Persia*, 117.)

The depth of lakes in mountainous districts is often remarkably great. That of Loch Ness, on the line of the Caledonian Canal, is 130 fathoms in some parts, which is four times the mean depth of the German Sea, and its bottom is actually 30 fathoms below the deepest part of that sea between the latitudes of Dover and Inverness. The bottom of the

\* Humboldt's *Pers. Nar.* IV. 310, 455, V. 57. *Edin. Phil. Jour.* No. V. 409. Rennell, *Phil. Trans.* 1781. *Histoire Gen. des Voyages*, Abr. XII. p. 330—380.

Physical  
Geography.

Lake of Geneva, at the depth of 161 fathoms, reaches from the high plateau which surrounds it to within 200 feet of the level of the Mediterranean. It is difficult to account for the existence of such deep lakes among mountains whose debris are spread abundantly over countries much lower; but perhaps the profound cavities discovered in the beds of great rivers, like the Amazons, may lead us to suspect that they owe their existence to the agency of debacles, or vast currents of water, at some recent geological period, but anterior to the existence of man.

Tempera-  
ture.

The temperature of deep lakes presents what we should at first view consider as an anomaly. The heat of the waters at the bottom is never that of the containing solid strata, as we should expect, but in temperate climates always much lower. In Loch Katrine and Loch Lomond, Mr Jardine found the temperature about  $41^{\circ}$  at all depths below 40 fathoms, while that of the surface was  $57^{\circ}$  or  $59^{\circ}$ , and the mean heat of the climate is  $47^{\circ}$ . The deep waters in the Lakes of Thun and Zug have a temperature of  $41^{\circ}$  and  $41\frac{1}{2}^{\circ}$ , and those of the Lake of Geneva  $42^{\circ}$ , though the mean heat of the climate is  $49^{\circ}$ . In the Lake Sabatino, near Rome, where the annual temperature is about  $60^{\circ}$ , the thermometer indicates  $44\frac{1}{2}$  at the depth of 80 fathoms. This apparent anomaly in lakes is accounted for by the physical constitution of water. As this fluid attains its maximum density at  $40^{\circ}$ , the upper strata, if cooled down to this degree, descend to the bottom; but if heated up ever so high, remain at the top. The cold impressions received at the surface are thus carried below by the internal movement of the water, while the hot impressions can travel down only by the conducting power of the fluid, which is remarkably small. The variable influence of the seasons is little felt below 15 or 20 fathoms, and disappears entirely at 40 fathoms. In all fresh water lakes, exceeding this depth, there must, therefore, be a constant tendency in the inferior waters to approach the temperature of maximum density. To a certain degree this must be controlled by the heat of the strata which form the basin, and this may perhaps account for the slight difference in the temperature of the deep waters in the Italian lakes and those of Switzerland and Scotland. (See the Art. CLIMATE.)

The Ocean.

The ocean, though it presents to the eye only the image of a watery waste, sustains a most important part in the physical economy of the globe. It is the great fountain of those vapours which replenish our lakes and streams, which dispense fertility to the soil, and clothe the surface with all the pomp and pride of luxuriant vegetation. By its salutary action on the atmosphere, it tempers the extremes of opposite seasons and of opposite climates. It affords an inexhaustible supply of animal food, and of salt, a substance of the utmost value to human life. As the great highway of commerce, it connects the most distant parts of the globe, and affords the ad-

vantages of free and abundant communication to nations which mountains and deserts seem to have separated from each other. Its shores have been in every age the great seats of civilization; in all the great continents, rudeness and barbarism grow upon us as we advance into the interior; and it requires no great sagacity to discover that the central regions of Asia and Africa, from their want of inland seas like the Mediterranean or Baltic, or navigable rivers like the Amazons, will be the last portions of the habitable globe over which the arts will extend their empire.

The ocean, with all its inland bays and seas, covers an area of 145,600,000 square English miles, or nearly three-fourths of the surface of the globe. About  $\frac{7}{12}$  of the great body of waters lie in the southern hemisphere, and  $\frac{5}{12}$  in the northern. In the one, the ocean is to the land nearly as 7 to 5, and in the other as 13 to 2. Laplace has calculated that its mean depth is but a small fraction of the difference between the axes of the earth,\* which is 25 miles. If, therefore, we suppose the mean depth to be two miles, the cubic contents will be 290,000,000 of cubic miles.

Geographers divide the entire mass of the ocean into five great basins. The Pacific, the largest, separates America from Asia; the Atlantic separates Europe from America; the Indian Ocean separates Asia and its isles from Africa; the Arctic or North Polar basin encompasses the North Pole; and the Antarctic the South.

The Pacific Ocean, 11,000 miles in length from east to west, and 8000 broad, occupies a superficial space rather larger than the whole mass of the dry land. From Cape Horn to the head of the Bay of Bengal a rampart of mountains, containing the highest chains in the world, is arranged round this sea, at a less or greater distance from its shores. But an inner and broken chain extends from Alyaska through the Aleutian Isles and Kamtschata, Japan, the Phillipines, Borneo, Celebes, and New Guinea, to New Holland; and this chain, with the Rocky Mountains and Andes, seem placed on one continued vein of igneous matter, for they include in their wide circle the most numerous and active volcanoes in the world. From the Sea of Otchosk to Cape Horn its coasts are closely girt by the great American and Asiatic chains, which leave only a stripe of low shore, too narrow to admit of deep gulfs or large rivers. But from the Sea of Otchosk southward, the great Asiatic chain recedes from the shores, and opens an extensive country, which inclines to the Pacific. Yet though this basin forms more than one-third of the whole ocean, it certainly does not receive more than one-eighth of the whole river water. On the western side and between the tropics, its surface is studded with innumerable groups of islands, all remarkably small, and consisting generally of coral reefs, rising up like a wall from unknown depths, and emerging but a very little above the

\* A determination in more precise terms would have been desirable, but we take the statement as given by Daubuisson (*Geognosie*, I. 35), not having seen the *Memoires of the Institute* for 1818, to which he refers.

Physical  
Geography.

sea. These islands are the work of myriads of minute insects, whose incessant labours are thus gradually creating new lands in the bosom of the ocean. On the western side, it communicates with the inland seas of Otchosc and Japan, the Yellow Sea, and the Chinese Sea. These and the inlets of California and Queen Charlotte's Sound we shall not stop to describe. The Pacific Ocean, in consequence of the wide expanse of its surface, is remarkably exempt from storms, except near its mountainous shores, and hence the name. Its small isles, in which the fervid heat of the torrid zone is mitigated by the presence of so vast a body of water, enjoy perhaps the most delicious climate in the world.

Atlantic.

The Atlantic basin extends from 70° of north to 35° and 50° of south latitude. Its length is about 8500 miles; its breadth, which in the latitude of 52° north is 1800 miles, and near the equator 2100, at the northern tropic spreads out to 5400, including the Mexican Gulf. It covers about 25,000,000 square miles, exclusive of inland seas, which is nearly one-half of the extent of the Pacific Ocean. Its southern division does not contain one single deep inlet, nor one island of any magnitude; while its northern division abounds in large islands, and in deep and numerous inland seas on each side, which penetrate far into both continents, and have rendered it the seat of the most extensive commerce in the world. Few large rivers fall into this sea on the east side, but on the west it receives the three largest rivers on the globe, the Plata, Amazon, and Mississippi.

Indian  
Ocean.

The Indian Ocean extends between 40° south and 25° of north latitude, and from the Cape of Good Hope to Van Dieman's Land. Its length is about 4500 miles, its mean breadth is nearly the same, and it covers a surface of about 17,000,000 of square miles. Its shores are generally mountainous; it contains many islands, two large open bays, those of Bengal and Oman, and two deep inlets, the Persian Gulf, and Red Sea. A particular system of winds, called Monsoons, prevail in the northern part of this basin.

Antarctic.

The Antarctic basin, which surrounds the south pole, joins the Pacific in the latitude of 50°, and the Indian Ocean in the latitude of 40°. It embraces an area of about 30,000,000 of square miles. This sea is generally covered with floating ice as far north as latitude 60°. The appearance of a fixed barrier of ice, filling nearly all the space within the Antarctic circle, has led geographers to infer the existence of a mass of land near the pole, but no land was seen by navigators in a higher latitude than 60°, till the discovery of New South Shetland in 1819. This country lies between 55° and 65° of west longitude, and reaches north to the 62d parallel, but how far it extends southward, and whether it is one large region, or a cluster of islands, is unknown. (See *Edin. Phil. Jour.* No. VI.)

Arctic.

The Arctic basin, or Frozen Ocean, comprises a great part of the space within the 70th parallel. The discoveries of Captain Parry, and the very recent observations of Mr Scoresby in East Greenland have gone far to prove that the tracts of land

within this polar zone consists rather of clusters of islands than of a continent. What proportion of the space the sea and land respectively occupy, it is impossible to calculate. Of the many deep gulfs which open into this basin on the north coasts of Europe and Asia, the White Sea is the only one of any importance to navigation. The rest are shut almost constantly by the ice.

Physical  
Geography.

A detailed description of all the great inland seas Mediterranean. would be out of place in this brief sketch; but the Baltic and the Mediterranean, on account of their superior importance, merit a special notice. The Mediterranean, the finest inland sea in the world, is 2350 miles long, from 100 to 650 broad, and with the Adriatic, but exclusive of the Black Sea, embraces an area very nearly of 1,000,000 of square miles. Its depth, which is generally too great to afford soundings, diminishes to 100 fathoms between Sicily and Malta, and to 30 between Malta and Cape Bon in Africa. Placed in the midst of high mountains, its shores are steep and narrow; and, if we exclude the waters of the Nile and the Black Sea, the districts whose rivers it receives do not quite equal its own surface in extent. Adding 500,000 miles for the basin of the Nile, the space which may be called the *river domain* of the Mediterranean, amounts to 1,400,000 square miles. But its inland position gives this sea a proximity to a vast range of country; and, since vapour diffuses itself by its own elasticity, independently of the winds, were each portion of the adjoining land to draw its moisture from the nearest sea, so far as the natural limits of evaporation permit, we may calculate that the vapours of the Mediterranean would be diffused over a space five or six times larger than the basins of its rivers; and that it expends probably three times as much water as it receives. Its surface, depressed by this constant drain, is said to be 34 feet lower than the Red Sea; and hence, powerful currents rush in from the Black Sea by the Dardanelles, and from the Atlantic by the Straits of Gibraltar to restore the level. Its superior saltness is also accounted for by the constant influx of salt water from the ocean, while fresh water only is carried off by evaporation. Like all inland seas, which open to the west, it has no general tides; but local tides are felt, which rise three feet at Venice and at Marsala in Sicily, one foot at Naples, one to two at Toulon, and six inches on the Syrian coast. A current circulates round the line of its coasts, entering the Straits on the south side, setting along the African shore to Syria, where it turns north-westward, and, joined by the current from the Dardanelles, it makes the circuit of the Adriatic, then of the coasts of Tuscany, France, and Spain, and ultimately returns into itself at the Straits. (Tuckey, II. 122, 355.)

Black Sea.

The Black Sea, and Sea of Azoph, are properly inland lakes (like Ontario and Erie), which discharge their surplus waters into the Mediterranean. These two seas occupy a superficial space of 170,000 square miles, and receive the waters of a surface more than five times as large as their own, or about 950,000 square miles. Hence they have a constant efflux: their waters are turbid with floating soil, and so fresh, that ice appears in the bays of the

Physical  
Geography.

Black Sea, and covers the Sea of Azoph for four months every winter, though they are placed under the same parallels with Italy and the south of France. The channel of the Thracian Bosphorus, from 600 to 2000 yards wide, has undoubtedly been excavated by the current, which flows at present with a velocity of from three to five miles an hour; and traces of a connection between the Sea of Azoph and the Caspian exist in the low sandy tract along the course of the Manitch, which abounds in salt lakes, and marine exuviae.\*

Baltic.

The Baltic, 1200 miles long, embraces an area of 175,000 square miles, including the Cattogat. It occupies the bottom of a natural basin, which extends from the Dofrines to the Erzegebirge, and the heights of Valdai, and it receives the waters of a surface nearly five times as large as its own. Hence, like the Black Sea, it has an efflux current, and its waters, which are remarkably fresh, are partially or entirely frozen over, for three or four months in its southern parts, and for five or six in the Gulfs of Bothnia and Finland. The tides advance no farther than the three passages of the Sound, and the Great and Little Belt, which have a breadth of  $1\frac{2}{3}$ , of 8 and of  $\frac{3}{4}$  miles respectively, with a depth varying from 19 to 27 fathoms. The mean depth of the Baltic is 60 fathoms. Its currents, which vary with the state of the winds, and the freshes of the rivers, begin in the Gulfs of Bothnia and Finland, and set outwards on both sides, through the Sound and Belts. At the mouth of the Baltic, as well as that of the Mediterranean, an under current has been suspected to exist in an opposite direction to the upper, and probably smaller in magnitude. The difference of specific gravity between the Atlantic waters and those of these two seas render the existence of the under current credible. (Tuckey, I. 211.)

The other most remarkable inland seas are, in Europe, the North Sea, 160,000 square miles in extent, reaching from Calais to Orkney. Its mean depth is 31 fathoms, its greatest 190. It is deeper at the north than the south end, and at the sides than in the middle, where vast sand-banks cover its bottom. In America, there are, on the west side of the Atlantic, the Gulf of Mexico, 580,000 square miles in extent, whose western shores are remarkably destitute of ports, and are covered by annually increasing sand-banks. Farther north are the Chesapeake Bay, 200 miles long; the Gulf of St Lawrence, shut in by Newfoundland; Hudson's Bay, in the same latitude with the Baltic, but twice as large, and loaded with ice even in summer: Baffin's Bay, almost constantly shut by the ice, communicating, we have reason to think, with the Polar Sea and Hudson's Bay, and surrounded chiefly by large islands.

In the Indian Ocean the only deep inland bays are the Persian Gulf, 600 miles long, with parched sandy shores; and the Red Sea, 1500 miles long, which abounds in coral reefs, and, unlike every other sea in the world, does not receive a single river. It has considerable tides, and, as might be expected, a

current inwards from the ocean. It has a particular system of winds, which blow always either up or down its channel. (Tuckey, III. 67, 88.) The inland seas in the Pacific Ocean have already been briefly noticed.

Physical  
Geography.

The temperature of the ocean, like that of the land, varies with the latitude; but the variations, whether depending on the situation or the season, are less great, less sudden, and less frequent. The diurnal heating power of the sun is spent in the one case on a sheet of water ten or twelve feet in thickness, while, in the other, it does not penetrate more than one or two inches into the land. The mean temperature of the sea at the equator, according to Humboldt, is from  $78^{\circ} 8'$  to  $81^{\circ}$ ; it is tolerably uniform for every meridian as far as  $28^{\circ}$  of latitude; and diminishes at a corresponding rate in both hemispheres as far as the 48th parallel. Beyond this the cold is greater in the southern hemisphere. From the effect of currents, however, and the want of continued registers, it is difficult to state numerically the temperature of each latitude. The recorded observations of navigators exhibit striking anomalies. In general, the temperature of the ocean at the surface does not adapt itself to temporary changes, or to the diurnal variation, but follows the mean monthly temperature of the parallel, without, however, reaching the extreme points to which this temperature goes in the opposite seasons. This may be inferred from the phenomena of insular climates. (Humboldt, *Pers. Nar.* II. p. 50, 65, 87.)

Tempera-  
ture of  
Ocean.

In the ocean, as in lakes, we find the water colder as we descend farther below the surface. This decrease of heat is neither uniform for the same parallel; nor does it bear any constant relation to the depth; nor are its variations capable of being connected with the distance from the equator or the pole. At the depth of 100 fathoms, the difference is sometimes no more than  $1^{\circ}$ , and sometimes so great as  $20^{\circ}$ ; and this, too, when the heat at the surface was about the mean annual heat for the parallel. Sometimes the coldness attains its maximum at 100 fathoms, and sometimes it increases to 400 or 500. Humboldt thinks that, on a mean, the change is about six times more rapid than in the atmosphere, or about  $1^{\circ}$  Fahrenheit in 50 feet; but the facts are too anomalous to be easily brought under any general rule. Perhaps they agree best with the supposition that strata of different temperatures and densities, preserving themselves pretty distinct from each other, move slowly in different directions in the inferior waters; while the lowest and coldest, gliding over the unequal bottom, descend to greater depths, or mount nearer the surface, according as the absolute depth of the sea is greater or less. Hence the coldness of the waters on sand-banks and shoals; and hence also the changes produced in the temperature of the sea by storms, which mingle the water of different strata. The law that connects these changes, when rightly understood, may perhaps afford a measure of the depth for parts that cannot be sounded. To the coldness of the inferior strata, however, there is one

\* Tuckey, II. 357. Pallas's *Trav. in South Russia*, I. 78, 490, 506.

Physical  
Geography.

remarkable exception. It was ascertained by Mr Scoresby, and is confirmed by the observations made in the late polar expedition, that in the Greenland sea the temperature increases with the depth. The increase of heat does not follow any determinate ratio, being from 1° to 5° in 100 fathoms; but it is constantly progressive, and at the depth of 730 fathoms (lat. 79°, long. 5½° E.), it was found to be 8°. In fact, the bottom waters at Spitzbergen, as Mr Scoresby observes, are from 16° to 20° above the mean temperature of the climate. The most plausible explanation of this anomaly is, that the westerly current from Nova Zembla, rendered specifically light by the fresh water of the great rivers of Northern Asia, may rise above the branch of the Gulf Stream which penetrates to these latitudes; and the warm waters of the latter will thus be found at the bottom. The specific gravities observed by Mr Scoresby, however, do not tend much to confirm this hypothesis.\*

Ice.

A permanent zone of ice surrounds each pole, the breadth of which varies with the seasons. On the west side of the Atlantic, the extreme point of open sea, in winter, is found on the coast of Greenland at latitude 66° or 67°; but in the longitude of 5° or 6° east, the sea remains open to lat. 76° or 79°. In summer navigators have penetrated along the margin of Baffin's Bay as high as 77°, on the coast of Spitzbergen to 81°, and at Behring's Straits to 71°. In the southern hemisphere the utmost point to which Cook was able to penetrate was 71° in summer; but navigation was very difficult beyond the parallel of 60°; floating ice overspread the sea nearly as far as 50°, and detached icebergs are carried by currents in both hemispheres as low as 40°. (Cook's *Voyages*. Scoresby, I. 262.) In a general point of view, the ice-bound seas and lands are nearly conterminous with the arctic circle in the north hemisphere, and with the parallel of 60° in the south. In the one case they occupy about one-twelfth, and in the other about one-seventh of the hemisphere.

Saltness.

The saltness of the sea is affected by currents, storms, heavy rains, the discharge of rivers, and by evaporation. Hence there is often little consistency in detached observations, but the results upon the great scale agree with theory. According to the experiments of Dr Marcet, the mean specific gravity of the main ocean is 1,02777. The Southern Ocean, which receives a less proportion of river water, is saltier than the northern. Inland seas, like the Baltic, Black Sea, and White Sea, which receive more rain water than they expend in vapour, and have an efflux current, are fresher than the ocean. On the other hand, the Mediterranean, which is a sort of natural saltern, from which the waters of the Atlantic, poured in with their salt, are drawn off fresh by evaporation, contains more saline matter than the main ocean. We may infer from theory, that the same thing holds true of the Red Sea. There is no proof that the sea is saltier under certain meridians,

or at certain depths, than at others; but in general, the sea is saltest where it is deepest and most remote from land. Salt water parts with its salt on freezing, and hence the dissolution of ice freshens the sea. The following are some of Dr Marcet's results:

(Ed. *Phil. Jour.* No. IV. 356.)

The tides are periodical oscillations in the waters of the ocean, which take place twice every twenty-four hours, and are produced by the attraction of the moon and the sun. In the open sea, they are at their height three hours after the moon has passed the meridian of the place, and the meridian opposite. They are smallest towards the poles, and greatest at the equator, where, however, they do not exceed two or three feet in the great ocean. Their greatest elevation takes place in narrow seas, where the action of the moon is aided by winds, currents, the position of the coast, &c. The highest tides known are in the Gulf of St Malo, where the flood, driven back by the coast of England, rises to the height of seven or eight fathoms. Inland seas, whose entrances face the west, have rarely any tides, because the moon acts on all their parts at once, and there are no lateral waters to flow in and produce a local elevation. (Tuckey, I. 34.)

Independently of the motion of the tides, the waters of the ocean are found to be scarcely anywhere stationary. Local or temporary currents are produced by winds, the discharge of rivers, the fusion of fields of ice, the evaporation of inland seas, and other causes. But, exclusive of these, which we shall not attempt to describe, there are certain permanent and general currents, which are supposed all to originate in two great movements,—that of the tropical waters westward round the globe, and that of the polar waters towards the equator. The movement of the tropical waters westward is ascribed to the agency of the trade winds, which, blowing constantly in one direction, must impress their own motion on the sea to a certain extent. But the resulting current is necessarily modified by the position of the great continents. The motion of the polar waters towards the equator is not so well accounted for, nor perhaps is its general existence so well ascertained. It is supposed, that the copious evaporation at the equator, reducing the level of the sea there, the more elevated waters of the polar regions flow in to supply the loss; and, farther, that the fusion of ice in these seas must produce an accumulation of water, which naturally seeks a level by moving to the equator. But it is reasonable to believe, that the loss of the equatorial seas by evaporation is balanced by the greater fall of rain; and if the melting of ice

\* Forster's *Observations*, p. 60. Scoresby, *Account of Arctic Regions*, I. 187-210. *Edin. Phil. Jour.* No. XI. 165. Humboldt, *Pers. Nar.* II. 56. Dr J. Davy, *Phil. Trans.* 1817.

Physical  
Geography.

Gulf Stream.

produce a current from the pole during one season, the congelation of the water should produce an opposite current during another.

The great tropical current which flows round the globe prevails generally between 30° north and south of the equator, and has a mean velocity, according to Humboldt, of nine or ten miles a day. In the Atlantic, it separates into two branches, one of which constitutes the well known Gulf Stream. This branch flows northward, through the middle of the Atlantic, till it reaches the Cape Verd Islands; it then turns west, passes through the Caribbean Sea and the strait between Cuba and Yucatan, winds round the Mexican Gulf, and rushes out by the Bahama Channel; then, spreading out to a greater breadth, it sweeps along the shores of the United States to Newfoundland. At this point it is deflected south-eastward by a southerly current from Baffin's Bay, and, passing the Azores and Canary Isles, returns into itself, and repeats its circumgyration. The waters of the North Atlantic between 11° and 43° thus form a continued whirlpool, performing a circuit of 3800 leagues in about thirty-four months. Its velocity is inversely as its breadth. In the Bahama Channel, its breadth is fifteen leagues, and velocity from three to five miles an hour. In its retrograde course, from longitude 50° to the Azores, its breadth is 160 leagues, and velocity seven or eight miles a day. A zone of motionless water, 140 leagues broad, separates the direct and retrograde courses. This great current sends off one branch near Newfoundland, which proceeds north-eastward, and sometimes deposits tropical fruits on the shores of the British Isles and Norway. A second branch, escaping at the Azores, enters the Straits of Gibraltar. The Gulf Stream preserves a temperature of 71° in the latitude of Boston, while that of the neighbouring waters is 63.5. It is not improbable that the westerly part of this current, involving by accident in its course the canoes of the early inhabitants of Western Africa or the Canary Isles, has hurried them to the coast of Caraccas, and thus been one means of transplanting the human race from the Old World to the New. (Humboldt, *Pers. Nar.* I. 46—60.)

The other branch of the great tropical current is supposed to set along the coast of Brazil and double Cape Horn. In the Pacific Ocean, a general current, westward, is said to carry the waters away from the coast of Peru. It is less perceptible on the west side, till it enters the Indian Ocean, when strengthened by the northerly currents there, it flows along the eastern coast of Africa, and round the Cape in a rapid stream, 130 miles broad, and 7° or 8° warmer than the contiguous waters. A current from the South Pole sets along the west side of New Holland into the Bay of Bengal. It is supposed that other portions of the general polar current deflect the great westerly current northward, after it has passed the southern promontories of Africa and America.\*

In the North Atlantic, in the space comprised be-

tween Greenland and the coasts of Britain and Norway, and between Labrador and Spitzbergen, a great body of waters, acted upon by three or four lateral currents, is supposed to perform a perpetual revolution. These waters receive their impulse eastward from a branch of the Gulf Stream, which passes from Newfoundland along the north-west coasts of Scotland and Norway. At the North Cape, a great westerly current from Nova Zembla turns the waters north-westward, along both sides of Spitzbergen. Beyond this island, being met by a current from the Pole, they turn south-westward, and pass along the coast of Greenland to Davis' Straits, where they are deflected southward by a fourth current from Baffin's Bay, and at the Bank of Newfoundland recommence their revolution. Thus two great whirlpools, connected with one another, touching at the Bank of Newfoundland (which seems to be a bar cast up by their conflicting waters), and revolving in opposite directions, occupy four-fifths of the North Atlantic. The small current which sets from the Bay of Biscay across the mouth of the English Channel, and through the Channel of St George, is most probably a branch of the Gulf Stream which parts from the revolving current about the Azores. It is reasonable to believe, that great vortices of the same description will be found in the other parts of the ocean, when they have been as minutely examined as the North Atlantic. (Scoresby, I. 206.)

The value of any part of the earth's surface to man depends not merely on its extent, position, and soil, but also on its climate, which regulates the nature and variety of its productions, the degree of its fertility, and, to a certain extent, its salubrity, and its capacities of improvement. With no essential superiority but that of climate, the small island of Ireland supports, and probably will always support, a greater number of inhabitants than the whole northern section of the plain of Siberia beyond the 60th parallel.

The climate of a country is chiefly influenced by its distance from the equator, and its elevation above the level of the sea. But it is affected in a smaller degree by the nature of the surface, the abundance or scarcity of humidity, the proximity or remoteness of the sea, of lakes, of mountains, of arid or frozen plains, and perhaps also by the internal heat of the earth.

The mean temperature of the earth at the equator, which is pretty uniform under every meridian, is estimated, by Humboldt, at 81°.5 of Fahrenheit's scale. The decrease of heat, as we recede from the equator, on either side, follows different laws in the two hemispheres, and in the same hemisphere under different meridians. On the west coast of Europe, about the meridians of London and Paris, the cold increases much more slowly upon us as we go northward from the equator, than in any other part of the world. In North America, at the meridian of 80° or 90° west from London, and in Asia at the same distance east, the increase of cold is much more ra-

Physical Geography.

pid as we approach the pole. In the northern hemisphere, generally the cold is greatest on the east side of both the old and new continents, and least on the west. Humboldt has generalised this fact, and inferred, that all continents and large islands are warmer on the west side than the east. The following table, extracted from Humboldt's admirable Essay, exhibits the different gradations of the mean annual temperature in Western Europe and North America, continuing the scale to the equator.

Mean Annual Temperature.

Lat.	Old World.	New World.	Diff.
0	81°.5	81°.5	0
20	77.9	77.9	0
30	70.7	67.1	3.6
40	63.5	54.5	9.
50	50.9	38.3	12.6
60	41.0	25.0	16.
70	33.0	0*.0	33

We have few observations for the east coast of Asia; but the following shows that the climate of this region approaches to that of Eastern America rather than Western Europe.

Europe.	Asia.	America.
Naples, } Temp. Lat. 41 } 63.3	Pekin, } Temp. Lat. 40 } 54.8	Philadelphia, } Temp. Lat. 40 } 53.4

Thus the mean annual temperature of North America is 9° lower than that of Western Europe at the latitude of 40°, 16° lower at lat. 60°, and 33° lower at lat. 70°; a similar difference obtains between the climates of Western Europe and Eastern Asia. By comparing places under the same parallel, we find that this change is not sudden, but progressive. Petersburg, on the same parallel with Upsal, is 3° colder, and Moscow is 5° colder than Copenhagen. The annual temperature of West Greenland in lat. 70°, which is 17° or 18°, according to Sir C. Gieseke, is very nearly the mean between that of the North Cape and Melville Island, as its intermediate situation would lead us to expect.—(*Edin. Phil. Jour.* No. IX. 201.) These differences are rendered more sensible when we connect the places having the same annual temperature by lines, which Humboldt has named isothermal lines. Thus the isothermal line of 59° (Fahrenheit) passes along the latitude of 43° in Europe, but descends to lat. 36° in America. The isothermal line of 41° passes from the latitude of 60° in Europe, to that of 48° in America, showing that the same annual temperature which is found at the 60th parallel on the eastern side of the Atlantic, is only found at 12° farther south on its western shores. The western coast of

North America again is warmer than the east; and hence if we were to trace the isothermal lines round the northern hemisphere, they would all have concave summits at the east sides of Asia and America, and convex summits at the west sides of America and Europe.

Physical Geography.

The difference of mean temperature between summer and winter (reckoning each to consist of three months) is nothing at the equator, and constantly increases as we approach the pole, as shown in the following table:

	Latitude.	Mean Temperature.		Difference.
		Of Winter.	Of Summer.	
Algiers,	37°	61°.5	80°.2	18°.7
Buda,	47½	34.0	70.5	26.5
Upsal,	60	25.0	60.2	35.2

The extreme difference of the seasons is smaller under the warm meridians of Western Europe than any where else, and seems to be greatest where the mean annual temperature is lowest,—near the east coasts of Asia and America.

Places on the Same Parallel.

	Latitude.	Winter.	Summer.	Difference.
Copenhagen, } Moscow, }	55½° 55½	30°.7 10.8	62°.6 67.1	31°.9 56.3
Rome, } Pekin, } New York, }	42 40 41	45.8 26.4 29.8	75.2 82.6 79.2	29.4 56.2 49.4

Places having the Same Mean Annual Temperature.

	Mean An. Temp.	Winter.	Summer.	Difference.
St Malo,	54°	42°.3	66°.0	23°.7
New York,	54°	29.8	79.2	49.4

If we draw a line on the map in a north-east direction from Bourdeaux to Warsaw, and continue it till it strike the Wolga in latitude 55°, all the places situated under this line, at the same elevation, will have nearly the same summer temperature of 69° or 70° of Fahrenheit's scale. The lines of equal winter temperature decline in an opposite direction, and deviate much farther from the plane of the parallels. Thus a straight line drawn from Edinburgh to Milan, almost exactly at right angles to the line of equal summer temperatures, would pass over places, all of which, if equally elevated, would have nearly the same winter temperature of 37° or 38°. The other lines of equal summer and winter temperatures have a direction corresponding to these, but not exactly parallel.

\* Deduced by interpolation from the temperature of Natchez, Cincinnati, Churchill Fort, and Melville Island, reckoning that of Melville Island—2 Fahrenheit.

Physical  
Geography.

On comparing the climate of the two hemispheres, we find that the southern is rather colder than the northern, but is more remarkably distinguished by the greater equality of its seasons. This last effect may obviously be referred to the influence of a greater surface of sea upon a smaller extent of land. In the southern hemisphere also, the temperature seems more uniform under different meridians. At Port Jackson, Buenos Ayres, and the Cape, all nearly under one parallel, the annual mean temperature is almost exactly the same.

Effect of  
Elevation.

The second general cause that affects the temperature of places is their elevation above the level of the sea. The following table, by Humboldt, shows that the ratio of decreasing temperature, as we ascend in the atmosphere, is not the same at different latitudes, nor is it uniform at the same place for equal successive altitudes.

Height in English feet.	Equatorial Zone from 0° to 10°.		Temperate Zone from 45° to 47°.	
	Mean Temp.	Difference.	Mean Temp.	Difference.
0	81.5	0	53.6	0
3195	71.2	10.3	41.0	12.6
6392	65.1	6.1	31.6	9.4
9587	57.7	7.4	23.4	8.2
12792	44.6	13.1		
15965	34.7	9.9		

This table shows, that, at the equator, the thermometer sinks 10° in the first thousand yards of ascent, or 1° for 310 feet. In the next thousand yards it sinks no more than 6°, or 1° for 524 feet. In the third and fourth stages, there is a remarkable acceleration. In the whole column of air to the limit of perpetual snow, at 15,965 feet of elevation, the decrease is 1° for 341 feet. Humboldt ascribes the smaller rate of decrease in the second and third stages to the large clouds chiefly suspended in this region, which intercept the radiant heat of the earth. In the temperate zone the atmospheric cold increases more rapidly. The decrease of heat for the first thousand yards is at the rate of 1° for 253 feet, but to the limit of perpetual snow (at a temperature not of 32°, but of 23°.3) it is 1° for 317 feet, or, in round number, 1° for 100 yards. Observations made, however, in the free regions of the air, may give different results from those which were made on the sides or summits of mountains. But generally in the temperate zone, of two adjacent places, if the one is 1000 yards higher than the other, it will have a climate 12° colder. For smaller heights the decrease

is proportional. In the upper regions of the atmosphere, the difference between the heat of night and day, summer and winter, is smaller than at the surface of the earth. This law of decrease explains to us the extreme cold felt in the elevated plains of Siberia, and the mild temperature enjoyed in the torrid zone, on the table land of Mexico, the plateau of Pastos, and other high lands. Humboldt calculates, that in the temperate zone, every hundred metres of ascent (110 yards) diminishes the heat as much as a change of 1° of latitude.

The temperature of countries is affected by the Local Temperature. The temperature of the sea, and the nature of the adjacent land. The extremes of temperature are always comparatively little felt in small islands, remote from continents. In the United States intense cold is experienced as often as the wind blows from the frozen plains round Hudson's Bay. (Warden's *America*, I. 154.) From high mountains, gusts of cold wind, called *snow winds* by mariners, rush down and cool the circumjacent plains. (Volney's *Trav. in Syria*, I. 340.) At Calabozzo, in Venezuela, the temperature, which was from 87° to 90° in March, rose to 104° or 105°, whenever the wind blew from the parched and dusty surface of the Llanos, or great plains. (Humboldt, *Pers. Nar.* IV. 325.) The heat accumulates to an astonishing degree, when the wind passes over extensive deserts of fine and almost impalpable sand, which rises in the air, and hangs over the surface like a fog, or mounts in whirling columns to a great height, mixing its burning particles with the mass of the atmosphere, and communicating to it an intolerable heat. (Kinneir's *Geog. Mem. of Persia*, 216, 222.) In Europe, where the proximity of the sea cools every part of the surface by the agency of the winds, the accumulation of heat never proceeds so far as in Asia and Africa. Even in low plains, sheltered on the north, the temperature scarcely ever exceeds 100°; but at Bagdad and at Bushire, where the south wind arrives, heated by the burning sands of Arabia, the thermometer sometimes stands at 120° or 125°; and on the west coast of Africa, where similar causes operate, it is said to rise to 130°. \* Though the mean annual temperature is highest at the equator, the extreme summer heat, so far as it proceeds directly from the solar action, is greatest at the tropic, and is even rather greater at the latitude of 45° than at the equator. (Art. CLIMATE, in this *Supplement*, p. 182, Table.) We may therefore conjecture that the hottest summer climate in the world is to be found in the western parts of the Sahara of Africa, under the northern tropic, where the winds blow over a zone of sandy plains 4000 miles in breadth, unbroken by any considerable mountains, or by any surface of water

\* Morier's *Journey*, II. 97. *Edin. Phil. Jour.* No. V. 197. Tuckey, II. 442. Humboldt repeatedly observed the temperature of the soil in Equinoctial America at the hottest time of the day. It varied with the nature of the mineral substance. The highest he has recorded, we think, was that of a coarse granitic sand at Magpures, whose temperature at two P. M. was 140°.5. That of a fine granitic sand at the same place was 126°.5; of a granitic rock, 117°.6. We may hence conclude, that the air, though perfectly stagnant, could in no possible circumstances be heated above 140°, and this only within two or three feet of the ground. Humboldt's *Pers. Nar.* V. 165.

Physical  
Geography.

Physical  
Geography.

except the narrow inlet of the Red Sea. At the same time, it is possible that a much narrower surface than this may suffice to communicate the maximum effect of the solar heat to the atmosphere, and the actual heat generated may depend more upon the nature of the surface and its low elevation, than upon its extent.

It appears that within the tropics seas have very little effect in tempering the accumulating heat of the land, when situated to the westward of a continent, but a great effect when situated to the eastward. In the *steppes* of Caraccas, which are open to the sea on the east, the heat rarely exceeds 99°, but even in the wooded regions of Senegambia and Guinea, much nearer the coast, it rises to 130°.\* In the temperate zones, on the other hand, it is clear that the sea exerts its influence in a direction precisely contrary. When the land lies to the eastward, the sea mitigates the extremes of heat and cold very much; when to the westward very little. This is abundantly proved by the difference of temperature already noticed between the east and west coasts of the two continents. Now, the sea can exert very little influence over the temperature of the land, except through the agency of the atmospheric currents; and the phenomena in both cases seem to be accounted for by the prevailing direction of the winds. Within the tropics, these are almost constantly from the east; but from the tropics to the latitude of 60° north (and probably much farther), the prevailing winds are from the west. † Within the torrid zone, therefore, we should expect to find the extreme summer heat constantly accumulating from the east side of continents and islands to the west; but in the temperate zones, the extremes both of heat and cold will as regularly increase from the west to the east. This is found to be the case, and whatever other causes may be conjoined with those now assigned, there can be no doubt that the latter have really a great influence.

The temperature of each zone has such a correspondence with the amount of the solar impressions, as to lead to the inference, that the heat of the globe is entirely derived from the sun; and Professor Leslie has calculated, that, upon this hypothesis, the mean heat of the interior ought to be 66°.8. Humboldt has ascertained, however, that, in latitudes above 45°, the mean heat of springs and caves generally exceeds that of the atmosphere. The difference, which amounts to 6° or 7° at the parallel of 70°, he ascribes to the covering of snow in the higher latitudes, which prevents the loss of heat during the winter months by radiation, or the contact of cold winds. But there are facts which indicate that this heat may be derived from another source. To say nothing of volcanoes, we have hot springs in all parts of the world, at all temperatures below boiling

water; and evidence still less equivocal is afforded by the high temperature of deep mines. The following are examples:

At Giromagny, in the Vosges, annual temperature at surface, 49°; at 110 yards depth, 53°.6; at 336 yards, 65°.8; at 472 yards, 74°.6.

In Saxony, in four of the deepest mines, annual temperature at surface, 46°.4; at 170 to 200 yards depth, 54°.5; at 280 yards, 58°; at 360 yards, 62°.6. (Daubuisson, *Geog.* I. 444.)

In the coal mine of Killingworth, the deepest in Britain, annual temperature at surface, 48°; at 300 yards, 70°; at 400 yards, 77°. In seven others of the deepest coal mines in Britain, a corresponding gradation was observed. (Mr Bald, *Edinb. Phil. Jour.* No. I. 134.)

In these British mines, the increment of temperature is about 1° for 15 yards of descent. In the Vosges, it is about 1° for 20 yards, and in Saxony, 1° for 22 yards. Taking 20 yards as a mean, if the increase follows the same arithmetical ratio to a considerable depth, we should find the temperature of the Bath waters (116°) at 1320 yards below the surface, and that of boiling water at 3300 yards, or nearly two miles. The frequency of hot springs from 80° to 120°, the rarity of those that approach the boiling point, and the constancy of temperature in them all, are circumstances remarkably consistent with this hypothesis. The facts, if they do not establish, at least strongly support three conclusions; 1st, That the heat of the interior of the earth is always greater than at the surface; 2d, That this heat augments progressively as we descend, in a ratio bearing some relation to the depth; 3d, That, even at moderate depths, this heat is greater than the mean heat of the globe ought to be, if entirely derived from the sun. Such an interior heat, if it exists, must be constantly diffusing itself towards the surface; and at the surface it may be kept down, so as to affect the temperature derived from the solar action very feebly, by the greater or less rapidity of its dissipation. But as it is very improbable that it should be diffused with perfect equality round the whole exterior shell of the globe, it may be the true source of some of those anomalies of climate (such as the discrepancy in the annual heat under the same parallel) which cannot be easily referred to other known causes. ‡

The atmosphere is an elastic fluid which surrounds the globe on all sides, and serves the most important purposes in the economy of nature. It sustains the life of an immense variety of organic beings, spreads the moisture of the ocean over the land in fertilizing showers, receives, dissipates, or decomposes, the innumerable mephitic vapours which are continually exhaled from the surface; and is the grand agent

crease.

The Atmo-  
sphere.

which, by its incessant motion, tempers the extremes of heat and cold, and enables man to support himself in every climate from the equator to the vicinity of the pole.

The fluid which forms the atmosphere consists of two gaseous substances, oxygen and nitrogen, united by a weak affinity, in the proportion of 21 parts of the former to 79 of the latter. The vital functions of animals and plants depend chiefly on the presence of oxygen, though nitrogen also enters into their composition. With these two are intermixed a very small quantity of carbonic acid gas; a variable portion of aqueous vapour, and in the highest regions of the atmosphere, where meteors are common, hydrogen has been supposed to exist. Air from the tropics and the polar regions, from the most healthy and the most insalubrious countries, exhibits no sensible difference in its constituent parts. A hundred cubic inches of air at the surface of the sea, when the thermometer is at 60°, weigh 30½ grains. The whole atmosphere is equal in weight to a sheet of mercury, 30 inches, or to a sheet of water, 34 feet deep, and were its density every where the same as at the surface, would reach no higher than 27,000 feet, or five miles. But its extreme elasticity causes the upper strata to expand indefinitely, and the phenomenon of meteors show that it exists in a state of extreme attenuation, at a height a hundred times greater than this. Considering the incessant currents which agitate its whole mass, there is a surprising uniformity in its pressure. The annual range of the barometer, which indicates the variation of the pressure, does not exceed from  $\frac{1}{8}$  to  $\frac{1}{2}$  inch in the torrid zone; is about two inches at Liverpool, the same at Petersburg, and was found by Captain Parry to be  $1\frac{8}{10}$  inches at Melville Island in one year.\* The extreme variation, which no where exceeds  $3\frac{1}{2}$  inches, is not greater than one-ninth part of the total pressure. It is greater in the temperate zone than at the equator or the pole, and in winter than in summer. The density of the air decreases in a geometrical ratio as we ascend, and in temperate climates is diminished to one-half at an elevation of  $3\frac{1}{2}$  miles. We are hence enabled to measure heights by the variations of the barometrical column. Changes in the atmospheric pressure, when they are great, have been observed to take place simultaneously at Edinburgh, Paris, and Geneva, and must, therefore, affect a great range of country at the same time.

Winds.

The unequal distribution of heat over the surface of the land and water necessarily disturbs the equilibrium of the atmosphere, and produces currents of air, or winds. These currents, however various, have been supposed to result from two general movements, pervading the whole mass of the atmosphere. The heavy and cold air of the polar and temperate regions having a tendency to displace the warm and rarified air of the torrid zone, generates a current in each hemisphere towards the equator. To replace the air abstracted from the higher latitudes, an up-

per and counter current flows back from the equator to the pole; and thus the atmosphere, while it performs a constant revolution, tempers the extremes of climate, by transporting the cold of the frigid zone to the equator, and carrying back the heat of the equator to the frigid zone. These great south and north currents, which are to be considered as the *primary* winds, receive various modifications. The under current, which proceeds from the polar regions, having impressed upon it the slow rotary motion of these regions, does not acquire in its journey the velocity of the parts it passes over. Instead, therefore, of proceeding directly along the meridian, it is deflected to the westward. It pursues this lateral course more and more as it approaches the torrid zone, and the impulse south and north being destroyed when the currents from the opposite hemisphere meet at the equator, the motion westward alone remains. This constitutes the well known trade wind, which blows from the east at the equator, from the north-east at the northern tropic, and the south-east at the southern. The upper and counter current again, carrying with it the rapid velocity of the equatorial regions, does not travel right along the meridian, but deviates more and more to the east as it advances; and when its progress towards the pole is stopped by the accumulation of air from the opposite meridians, the motion eastward alone remains, and it settles into a west wind. Thus a constant east wind should prevail at the equator, and a constant west wind near the poles; but the latter, being primarily an upper current, may not be invariably felt as a west wind at the surface. It does not follow, however, that the upper and under currents preserve their relative situation over all the temperate zone. From the greater accumulation of air in the higher latitudes, and from variations of temperature produced by local causes, the upper current will often be bent down to the surface, and the lower current ascend. This interchange will take place occasionally at all parts of the temperate zone. Hence, in high latitudes, storms of wind, which mingle the warm upper current with the cold air below, always produce an increase of heat, as Captain Parry found.—(*Voyage*, p. 118.) In the northern hemisphere, then, when the cold current from the pole sweeps the surface rapidly, we have a *north* wind; it becomes a *north-east* wind when its motion southward is retarded; an *east* wind when it is checked, and a *south-east* when it is deflected back, by mingling with a current from the south; all of which, except the last, are generally found to be cold winds. When the warm current from the south descends and sweeps the surface, we have a *south* wind if its motion northward is rapid; a *south-west* when its motion northward is retarded; a *west* wind when it is checked; and a *north-west* when it meets and mingles with a current from the north. All these, except the last, are generally warm winds, as experience proves. The line of division between the upper and lower cur-

Physical  
Geography.Physical  
Geography.

rents should be where the mercury stands at 15 inches, which is at the height of  $3\frac{1}{2}$  miles. This should be the region of clouds; and clouds do generally approach to this elevation.

Trade  
Winds.

This theory, upon the whole, agrees tolerably well with the facts. But the variable surface and temperature of the land greatly affect the course and velocity of the winds. In the torrid zone, within the parallel of  $25^{\circ}$  or  $30^{\circ}$ , on each side of the equator, the trade winds blow constantly from the east. From the superior warmth of the northern hemisphere, the line that separates the opposite trade winds is not the equator, but the 2d or 3d parallel north. To a certain extent, also, they follow the course of the sun, reaching a little further into the south hemisphere, and contracting their limits in the north when the sun is on the south side of the equator, and making a reverse change when he declines to the north. In a zone of variable breadth in the middle of this tract, calms and rains prevail, caused, probably, by the mingling and ascending of the opposite aerial currents. High lands change or interrupt the course of the trade winds. Thus, under the lee of the African shore, calms and variable winds prevail near the Cape Verd Islands, while an eddy or counter current of air from the south-west is generated under the coast of Guinea. The lofty barrier of the Andes shelters the sea on the Peruvian shores from the trade winds, which are not felt till a ship has sailed 80 leagues to the westward; but the intervening space is occupied by a wind from the south. In the Indian Ocean the trade wind is curiously modified by the lands which surround it on the north, east, and west. The southern trade wind blows regularly from the east and south-east, from  $10^{\circ}$  of south latitude to the tropic, but in the space from  $10^{\circ}$  south latitude to the equator, north-west winds blow during our winter (from October to April), and south-west in the other six months; while, in the whole space north of the equator, south-west winds blow during summer, and north-east during winter. The cause of these remarkable winds, which are called monsoons, has not been very satisfactorily ascertained. (Varenus's *Gen. Geog.* Chap. xxi.)

Variable  
Winds.

The region of constant winds is confined within the 30th parallel on each side of the equator. On the outer side of these limits, calms prevail pretty generally over a narrow space, beyond which the region of variable winds extends to the pole. In the open sea, where the true direction of the winds is best known, navigators have repeatedly observed that throughout this region the prevailing wind is from the west. Mr Forster observes, that beyond the tropics, the west winds are the most universal. That east winds have an ascendancy within the Antarctic circle, as he thinks, may be questioned; few observations having been made there, and those few not to be depended on, in consequence of the local influence of the ice. (*Observations*, p. 127, *et seq.*) According to the author of Lord Anson's voyage, "a westerly wind almost perpetually prevails in the southern parts of the Pacific Ocean" (he speaks of latitude  $60^{\circ}$ ), and a similar wind in the northern parts carried the Spanish galleons from Japan to Ca-

lifornia, along the parallel of  $35^{\circ}$  or  $40^{\circ}$ . (Book I. Chap. ix. II. Chap. x.) West winds prevail in Kamchatka; they blow three-fourths of the year in Hudson's Bay; the west and north-west winds predominate greatly at Melville Island; and it is a familiar fact among mariners, that, by means of these winds, the voyage eastward across the North Atlantic is generally accomplished in about half the time of the voyage westward. (Scoresby, I. 411. Parry, *Voyage*, 299.) On the west coast of Europe, too, the west and south-west winds are the most general. It is remarked also, that in our climate, south and south-east winds are the most rare; that winds between north and east are almost invariably cold; those between south and west warm; and those between north and west of a mixed character. So far the facts correspond generally with the theory, though many anomalous circumstances may be found.

The change of the seasons which affects the local temperature so much, necessarily influences the atmospheric currents. Accordingly, the most violent tempests are about the equinoxes, and in every country there are prevailing winds peculiar to certain seasons. It may be suspected that most of the winds observed on land or in confined seas are merely local eddies, or reflex currents, produced by the irregularities of the surface. Thus, while the south-west wind prevails almost one-half of the year at Dover, London, and in the west of England generally, it is scarcely felt at Liverpool, which lies in the gorge of a valley, where the western chain of hills is interrupted; and on the other hand, the south-east, so uncommon in the rest of England, is the predominating wind here. (*Manch. Trans.* IV. 601, 615.) In the long basin of the Red Sea, the wind blows in no direction but right up or down. In Lancaster Sound, Captain Parry found the wind to blow always either east or west. For ten months of the year a wind (which is probably a smaller branch of the north trade wind) blows constantly up the valleys of the Mississippi and Ohio, preserving a breadth in the latter of twelve or fifteen miles. (*Tuckey*, III. 70. *Warden's Amer.* I. 155.) In the list of *Vents Dominans* for the interior of Europe, collected by Cotte, nothing like a system can be discovered—nothing but local currents running in every possible direction, according to the position of mountains and valleys. Winds, indeed, even when strong, are often confined to a space surprisingly small. In the temperate, but still more in the frigid zone, two or three winds are often seen blowing from, or to, different points within a few leagues; nay, of two ships within sight of one another, one is sometimes becalmed, while the other is seen struggling with a storm. In the northern seas even strong gales, when they have carried a ship into frozen water, invariably desert her, or give place to a wind which blows from the ice. The effect can only be attributed to the comparative coldness of the ice, and warmth of the water, generating a local descending current over the one, and an ascending current over the other. (Scoresby, I. 403—409.)

The Mediterranean has a system of winds peculiar to itself, which we have not room to explain. All warm countries, where sandy deserts abound, give birth to pernicious hot winds. Such is the Si-

Physical Geography.

moom or hot wind of the desert, and the Sirocco, so well known in the east, and along the shores of the Mediterranean. For the description of these, as well as the sea and land breezes, and other peculiar winds, we refer to the Article METEOROLOGY.

Rain.

Rain, so essential to the fertility of the soil, is very unequally distributed to the different regions of the globe. Nature has arranged it so, that the supply of the atmospheric moisture is most abundant in those latitudes where evaporation is most rapid. Or rather the processes of precipitation and evaporation, depending partly on the same principles, and exerting a reciprocal influence, tend to adjust themselves to each other, though this tendency is perpetually disturbed by local causes. Rain is produced by the mixture of atmospheric currents of different temperatures. The power of air to hold water in solution does not increase in the same ratio with the increase of its temperature, but in a much higher ratio. Hence, when two masses of air, saturated with moisture, and of different temperatures, are mixed, the resulting compound is not capable of holding the whole water in solution, and a part of it is precipitated in rain. As the whole atmosphere when saturated is calculated not to hold in solution more water than would form a sheet of 5 inches in depth, while the mean annual deposit of rain and dew is probably 35 or 40 inches, it is obvious that the supply of atmospheric humidity must be many times renewed in the course of a year. The quantity of rain at any place is affected chiefly by three circumstances. It is greater at the equator than towards the poles,—at the sea coast than in the interior,—and on mountains or high grounds than on plains. The winds, too, exert a certain influence, which, at any particular place, depends on their temperature, and on their travelling to that place over a dry or a humid surface. Where so many causes interfere, whose effects are scarcely capable of estimation, it would be difficult to determine the depth of rain proper to each parallel, even were our observations more numerous and accurate than they are. In a former part of this article we gave as an approximation 83 inches for the equator, and 8 inches for the pole. We have since found the following estimate by Humboldt, to whose authority we readily defer in every question of this kind. Except within the tropics, it corresponds generally with that which we gave.

Lat.	Eng. Inches.	Lat.	Eng. Inches.

Rain at Sea-Coast.

Since the supply of humidity is greatest in the vicinity of the sea, the rains must be generally more abundant there than in the interior. On the other hand, we know that currents of air fraught with vapour move with great rapidity, and that the atmosphere is far from needing an entirely new supply from the ocean after each precipitation, because three-fourths probably of the rain that falls soon rises again into the air, and continues thus to circulate between the clouds and the earth. These circumstances lead us to conclude, that the difference in the annual

depth of rain, between inland places and those on the coast, is not so great as might be imagined. We find, accordingly, that a small increase of elevation compensates for a great distance from the sea. Thus 29½ inches of rain fall at Puy at the sources of the Loire, while 24½ only fall at the sea-port of Rochelle near its mouth, and at Geneva the depth is 40 French inches, while at Paris, 300 miles nearer the sea, it is no more than 19½. If we compare Toulouse, Paris, and Gottingen, inland places not far from the coast, with Buda and Prague, places in the heart of Europe, and, like the others, not much elevated, the mean fall of rain at the three former is 20.4 French inches, at the two latter 14.1. (Cotte, *Jour. de Phys.* T. XXXIX.) These facts are cited to support the idea of a decreasing scale of rain, rather than to mark the ratio of decrease. The latter is a problem for which we are yet unprovided with data. We may infer from theory, that the decrements, so far as they are affected by mere distance, will form a geometrical series. If the atmosphere, for instance, loses one-third of its moisture in the first 400 miles from the sea, it will lose one-third of what remains in the next 400; and so on.

Rain in Mountains.

The elevation of the land has a much more marked effect on the quantity of rain than its distance from the sea. Mountains precipitate the humidity of the atmosphere, not so much by attracting it to their summits, as in consequence of their rocky or grassy sides, when acted upon by the sun, heating large masses of air in the cold upper regions of the atmosphere. These warm masses of air, which abstract moisture from the aerial columns around them, stream upwards and mingle with the cold strata above, or come into contact with cold currents moving laterally, or suffer sudden and partial changes of temperature from the vicissitudes of night and day, and thus incessantly generate the circumstances which cause precipitation. It is evident that snow-clad mountains, from the constancy of their temperature, will serve much less perfectly than those whose sides are bare as nuclei for precipitating the atmospheric humidity; and that, in temperate climes, the rains will be more abundant on all mountains in summer than in winter. Along the shores of the Adriatic, and in the valley of Lombardy, the annual fall of rain is from 26 to 35 French inches; but in the Carnic and Julian Alps, it amounts to 100 inches. From the effect of this great barrier in intercepting the aqueous vapour, and producing desiccation, Feltré, on the east side of the first chain, has one-half more rain than Trent, which is higher, but on the west side; and Coire in the Grisons, 1900 feet above the sea, has less rain than the champaign cities of Vicenza and Verona. (Cotte's *Tables*.) In England it is found that Keswick and Kendal, situated among the mountains, have 67 and 59 inches of rain respectively, while places in the level interior country and on the sea-coast have only about 24 inches. But though more rain falls in mountainous than level countries, the depth is greater at the bottom of a mountain than at the top, and close to the surface of the ground than at any distance above it, in all cases.

In the torrid zone, a small thick rain falls every day on that side of the equator on which the sun is,

Rain in Torrid Zone.

Physical Geography.

but generally intermits during the night. When it ceases in the one hemisphere, it commences in the other, and is nearly perpetual in a zone of two or three degrees in breadth, which separates the two systems. When the rains begin, the heat increases, and the trade wind subsides. Yet, even in the torrid zone, there are tracts where rain seldom or never falls, such as the Sahara of Africa, the low coasts of Caraccas, and the desert shore of Peru, between 15° and 30° of south latitude. In many parts there are two wet and two dry seasons in the year; and in some regions, from the effect of mountain ranges and peculiar winds, places under the same parallel have their wet and dry seasons at opposite periods.\* Though the annual depth of rain is greatest within the tropics, the number of rainy days follows an inverse order, and diminishes as we advance from high latitudes to the torrid zone. According to Cotte, the mean number of rainy days from 12° to 43° of latitude is 78, while it is 161 from latitude 51° to 60°. More rain falls in summer than winter in all latitudes, but in the temperate zones the rains of winter are more frequent than those of summer, though less in quantity. (Cotte, *ubi supra*.)

Mr Dalton reckons the annual deposit of water in England to be 31 inches of rain, and five of dew. His estimate is perhaps rather high. The distribution of the rain through the different seasons is so much affected by local circumstances, that it is difficult to ascertain the mean result. In general, the fall seems to be least in spring, and greatest in autumn, and less in the six winter months than in the summer. The following table affords an interesting view of the connection between the phenomena of wind and rain in this country. It gives, for one year (1775), the number of days each wind prevailed at London; the quantity of rain that fell during the prevalence of that wind; and the humidity of the winds, or the relative quantity of moisture which each would deposit in the same space of time.

Winds.	Days.	Rain.	Humidity.	Winds.	Days.	Rain.	Humidity.
N.	22 $\frac{1}{2}$	0.327	11	N.W.	39 $\frac{1}{2}$	2.391	48
S.	21 $\frac{3}{4}$	0.251	9	S.E.	32 $\frac{1}{2}$	0.944	22
E.	11	0.168	12	N.E.	72	2.148	23
W.	18 $\frac{1}{2}$	1.907	82	S.W.	148	18.975	100

The whole quantity of rain for that year was 27,11 inches; of which it will be observed that two-thirds fell with the south-west wind. The prevailing winds are the south-west and north-east, the primary winds of our hemisphere. The least frequent are the east and west. The south and north winds are the driest, and the south-west and west the most humid, as might be expected. †

The geographical distribution of plants is a subject

Physical Geography.

of such extent, that our narrow limits compel us to dismiss it with a few general remarks, extracted from Humboldt's *Prolegomena de Distributione Geographica Plantarum*. Each plant has generally a determinate climate, to which it is best adapted; there are other climates, however, in which it can be raised, though less advantageously; but beyond certain limits it either ceases to grow altogether, or is supplanted by other plants better adapted to the situation. Since vertical elevation has the same effect on climate as distance from the equator, there are properly no plants which are peculiar to the frigid zone, because the mountains of the torrid zone, embracing between their base and their summits every variety of climate, either produce, or are capable of producing, all the vegetables of the temperate and polar regions. Plants are absolutely most numerous, and exhibit the greatest variety of species, and the most luxuriant growth, within the tropics, where nature has supplied most abundantly the heat and humidity which contribute chiefly to the development of their vital functions. They diminish in number, variety, and magnitude, as we recede from the tropics; and in Greenland, Spitzbergen, and the plains of Northern Russia, the wealth of the vegetable kingdom has shrunk to a very small number of mosses and stunted shrubs. The lines that limit the growth of certain plants depend on the average summer temperature, for plants which require a long and moderate heat; on the temperature of the warmest month for those which require a short but great heat; and on the temperature of the coldest month, for those which are unable to resist a considerable cold. Their growth is affected also by the foggy or serene state of the atmosphere, because the direct stimulus of the solar light is as essential to the success of many plants as a certain determinate temperature. Instead of losing ourselves in the labyrinths of general botany, we shall illustrate these principles by a few facts drawn from the history of cultivated plants.

The plantain (*Platano harton*), which furnishes a primary article of food in tropical America, requires a mean annual heat from 82° to 73°, and its proper climate is therefore from the equator to the 27th parallel. In the equinoctial zone (lat. 0°—10°) its fruit does not ripen at a greater altitude than 500 toises (534 fathoms). The sugar cane (*Saccharum officinarum*), which has nearly the same range, thrives where the mean annual temperature is from 82° to 73°, and is cultivated, but with less advantage, in the old world to the latitude of 36 $\frac{1}{2}$ °, where the annual temperature is about 67°. In North America, it is cultivated as far as latitude 31°, beyond which it does not succeed, for, though the summer heat is sufficient to ripen its produce as far as 35° or 40°, the rigour of the winter destroys the plant. It succeeds on the table land of Mexico, at the altitude of 900 toises. The cotton plant (*gossypium*) has its favourite climate between latitude 0° and 34°, where

Physical  
Geography.

the annual heat is from  $82^{\circ}$  to  $68^{\circ}$ . But it succeeds wherever, with a mean summer heat of  $73^{\circ}$  or  $75^{\circ}$ , that of winter is not below  $45^{\circ}$  or  $48^{\circ}$ . It is cultivated as high as latitude  $37^{\circ}$  in America, beyond latitude  $40^{\circ}$  in Europe, and grows at Astrakan in Western Asia, latitude  $46^{\circ}$ . (Storch, *Tableau de la Russie*, II. 250.) The date palm (*phœnix*) thrives best between latitude  $29^{\circ}$  and  $35^{\circ}$ , but on the shores of Italy, in places sheltered from the north winds, it is cultivated as far as latitude  $44^{\circ}$ . The citron (*citrus*) has nearly the same range, and is cultivated at Nice in spots 150 toises high. This tree, with the sweet orange, grows in Louisiana, under latitude  $30^{\circ}$ , but above that it is injured by the frosts. (Darby's *Louisiana*, p. 151.) The olive (*olea*) ranges in Europe between latitude  $36^{\circ}$  and  $44\frac{1}{2}^{\circ}$ . It succeeds wherever with a mean annual heat from  $66^{\circ}$  to  $58^{\circ}$ , that of summer is not below  $71^{\circ}$ , nor that of the coldest month below  $42^{\circ}$ . This last condition excludes all the North American continent beyond latitude  $34^{\circ}$ , though the olive thrives  $10\frac{1}{2}^{\circ}$  farther north in Europe. The vine (*vitis*) thrives where the mean annual heat is from  $62^{\circ}$  to  $50^{\circ}$ , or even  $47^{\circ}.5$ , providing that of winter is not below  $33^{\circ}$ , nor that of summer below  $66^{\circ}$  or  $68^{\circ}$ . These conditions are fulfilled on the sea-coast of Europe as high as latitude  $47^{\circ}$ , in the interior as high as latitude  $50^{\circ}$ , and in North America only as high as latitude  $40^{\circ}$ . But the favourite climate of the vine in the *Old Continent* is between latitude  $36^{\circ}$  and  $48^{\circ}$ , where it yields a generous and excellent wine. The *Cerealia* (wheat, rye, barley, and oats), so important to civilized life, yield profitable returns in places where the mean annual temperature descends to  $28^{\circ}$ , providing that of summer rises to  $52^{\circ}$  or  $53^{\circ}$ . In Lapland, barley comes to maturity whenever the mean temperature of the summer months rises to  $47^{\circ}$  or  $48^{\circ}$ . Barley and oats, from the rapidity with which they germinate and ripen, adapt themselves to the short summers of the north, and are found along with the potatoe as high as latitude  $69\frac{1}{2}^{\circ}$  in Lapland. In Eastern Russia, upon the Lena (longitude  $120^{\circ}$ ), grain of any kind refuses to grow beyond latitude  $60^{\circ}$ . (Sauer, p. 24, 137.) Wheat, which is a precarious crop, and little cultivated beyond latitude  $58^{\circ}$  in Western Europe, yields good returns at this part of the temperate zone, when the mean heat of the seven months from March to October is  $55^{\circ}$ ; but if it is no more than  $46^{\circ}$ , neither this grain, nor barley, oats, or rye, come to maturity. The *Cerealia* generally, which succeed only in low grounds beyond latitude  $60^{\circ}$  in Europe, are cultivated to the height of 550 toises on the sides of the Alps in latitude  $46^{\circ}$ ; to the height of 1020 toises (barley and oats) on Caucasus in latitude  $42^{\circ}$ ; and on the sides of the Andes, under the equator, the proper climate of the *Cerealia* is found between 700 and 1600 toises of elevation (4480 and 10,240 feet). *Maize* accompanies the vine in the west of Europe,

but extends farther north on the east. It is most extensively cultivated in its native soil, the New World, where it forms the chief nourishment of man and domestic animals from La Plata to the Canadian lakes. Coming to maturity in four or five months from the time it is sown, and requiring a short but hot summer, it is admirably adapted to the climate of America. There are few situations under the latitude of  $45^{\circ}$  where it will not grow, but the parallel of  $35^{\circ}$  is that to which it is best adapted. (Darby's *Louisiana*, p. 138, 144.) The oak ceases to grow beyond latitude  $63^{\circ}$  in Norway: it terminates at  $60^{\circ}$  or  $61^{\circ}$  in Finland; and at  $57\frac{1}{2}^{\circ}$  in the government of Perm. The *Pinus sylvestris* (Scots pine) reaches the height of 60 feet at the latitude of  $70^{\circ}$  in Lapland, and grows in situations 125 toises above the sea. The *Belula alba* is found under the same parallel at 250 toises of elevation. In the eastern parts of Asiatic Russia trees are very thin beyond latitude  $65^{\circ}$ ; the larch, pine, birch, and mountain ash, disappear about  $66^{\circ}$  or  $68^{\circ}$ ; willow and birch bushes, eight inches high, are found as far as  $69^{\circ}$ . At Hudson's Bay trees of all kinds terminate about latitude  $60^{\circ}$ . (Sauer's *Account*, &c. 70—91. Mackenzie's *Voyage*, p. 404.)

Let us now endeavour to make a general summary of these details, confining our view to the great continents merely, without regard to the islands. The *plantain* or *banana* we find occupies a zone of  $54^{\circ}$  in breadth on either side of the equator, which embraces about four-fifths of Africa, one-sixth of Asia, and one-third of America, and excludes the whole of Europe. The climate of the *sugar-cane*, allowing it to extend to  $30^{\circ}$  on each side of the equator in the New World, and  $35^{\circ}$  or  $36^{\circ}$  in the Old, includes the whole of Africa, nearly one-third of Asia, and two-fifths of America, and only touches Europe at its southern extremity. The climate of the *olive* consists of two zones on the opposite sides of the equator, extending from latitude  $35^{\circ}$  to  $44^{\circ}$  in the old continent, and embracing very little of the new; this tree being equally injured by the excessive heat of the tropical, and the excessive cold of the extra tropical regions in America.\* The *wine* grows as far north as  $50^{\circ}$  or even  $52^{\circ}$ , but its profitable culture in Europe does not extend much beyond  $48^{\circ}$ . In Asia it succeeds at Astrakan latitude  $46^{\circ}$ , in Bucharina, and at Hami in Chinese Tartary, latitude  $43^{\circ}$ .† It, therefore, extends, we may suppose, to lat.  $45^{\circ}$  in Asia generally, Except in islands, or elevated plains, it is probable there are few palatable wines made at a lower latitude than  $30^{\circ}$ . The vine may hence be considered as occupying a zone of  $15^{\circ}$  in breadth on each side of the equator (from  $30^{\circ}$  to  $45^{\circ}$ ) in the Old World, and two corresponding zones of  $10^{\circ}$  in breadth in the New (from  $30^{\circ}$  to  $40^{\circ}$ ). These zones embrace about one-sixth of America, one-third of Europe, two-sevenths of Asia, and one-tenth of

\* If Humboldt has accurately defined the temperature for the year, and the coldest month proper for this tree, there ought to be no part of North, and perhaps few parts of South America, where it will thrive. It has not been introduced into the territories of the United States.—Darby's *Louisiana*, p. 150.

† *Topographie des Vignobles*, 489, Paris, 1816. Pallas's *Travels*, II. 430.

Physical Geography.

Physical Geography.

Africa. Of the productions which serve for the ordinary sustenance of man, maize and the potatoe have the widest range. The culture of the *potatoe*, as Humboldt observes, extends from the extremity of Africa to Labrador, Iceland, and Lapland. *Maize* bears any natural temperature, however high, and the only circumstance essential to its successful culture seems to be a mean summer heat, not below 68° or 70°. In consequence of this advantage, its climate embraces the whole of the torrid zone, and reaches probably to lat. 48° in America, to 50°, or 52°, in Europe, and 48° in Eastern Asia. It hence includes about five-eighths of America, three-sevenths of Europe, the whole of Africa, and three-fifths of Asia. The *Cerealia* do not succeed in the torrid zone in low situations. The climate adapted to their culture, which begins about lat. 30°, extends to lat. 50° in America, to 70° in Lapland, 62° in Finland, and 60° throughout the north of Russia, generally including five-sixths of Europe, three-fifths of Asia, one-tenth of Africa, and one-fourth of America. The region of *forests*, or the climates adapted to the growth of wood, embraces the whole of the Old and New World, except a narrow zone on the north border of each, which includes one-tenth of America, one-tenth of Europe, and one-tenth of Asia. As the prolific powers of the soil depend chiefly on the stimulus of heat and moisture, it is reasonable to believe with Humboldt, that the general fertility of the earth increases as we approach the equator. (*Pers. Nar.* IV. 106.) In warm countries, the produce not only bears a much higher proportion to the seed, but the husbandman has the advantage generally of two harvests in one year. We may probably assume, then, without any great error, that, with regard to plants which grow both in the warm and temperate zones, the productiveness of the soil increases in the ratio of the annual temperature, and the depth of rain; and that for countries under the same parallels, it is generally in proportion to the duration and intensity of the summer heat. The cosine of the latitude, or the distance from the axis, as it expresses pretty nearly the proportions of heat and moisture for each parallel, may therefore be taken as an approximate measure of the relative fertility. But when we take into view the superior productiveness of vegetables which are peculiar to warm regions, such as maize, rice, and the banana, there can be no doubt that the power of the soil to sustain animal life, augments in a much higher ratio than the cosine of the latitude, and that at the equator it is at least ten times as great as at the latitude of 60° in Europe. It is scarcely necessary to qualify those statements by saying, that we speak solely of low and level regions, and of ordinary soils. There are warm valleys in the north, where the productions of southern climes will grow beyond the limits we have assigned; there are elevated tracts in the torrid zone where every plant found in cold countries can be raised; and in all the zones, there are deserts and rocks which bid defiance to the vivifying power of the sun, and the genial influence of the seasons.

the convenience of a round number. M. Malte-Brun, a late and very respectable authority, reduces the amount to 650,000,000. We think his enumeration for Asia, Africa, and America, still rather high, and without detailing the grounds of our judgment, or pretending to accuracy, where any thing better than loose approximations is unattainable, we submit the following estimate as the result of our inquiries.

Europe,	185,000,000
Asia (with Australia and Polynesia),	270,000,000
Africa,	55,000,000
America,	40,000,000
	<hr/>
	550,000,000

The diversity of colour, stature, form, physiognomical expression (and we may add language), among different portions of the human race, have at all times arrested attention; and have in many cases created, and in all inflamed, those feelings and prejudices which have made nations the enemies of each other. Philosophers have endeavoured to analyse and class the characters which produce these diversities; and since migrations and conquests have blended the distinctive peculiarities of different races, they have attempted to ascertain those primary types, from the combination of which all the other varieties have arisen. We have no room to discuss the many idle and fantastic hypotheses which have been built upon this subject, but shall merely give a brief outline of the system of the learned Blumenbach, who has prosecuted the inquiry with the aid of a profound knowledge of physiology. This philosopher has resolved the varieties of the human species into five primary classes,—the Caucasian, Mongolian, Ethiopian, American, and Malay. In the *Caucasian* race the skin is white, the cheeks red (a character scarcely found in any other race), the hair brown, running into yellow and black, soft, long, and undulating; the head symmetrical, and rather globular, the forehead moderately expanded, the cheek-bones narrow, not prominent, the face oval, the nose narrow and slightly aquiline, the lips gently turned out, the chin full and round, the facial angle large. This variety comprehends all the Europeans except the Finns, Samoieds, and Laplanders; the Western Asiatics, as far as the Oby and the Ganges, and the people of North Africa. In the *Mongolian* variety, the skin is olive, the hair black, straight, and stiff, the head almost square, the cheek-bones prominent outwards, the face broad and flat, and its parts less distinct than in the Caucasian race, the eye-brows little arched, and the space between them flat, the nose small and flat, the aperture of the eye-lids narrow. This includes the remaining Asiatics (except the Malays), the Finns, Samoieds, Laplanders, Greenlanders, and Esquimaux. In the *Ethiopian* race, the skin is black, the hair black and crisp, the head compressed laterally, the forehead receding, the cheek-bones standing much forward, the nose flat, and blending with the cheeks, the lips thick, the chin rather receding, the jaws lengthened forwards, and the under part of the face prominent. This includes all the African nations, except those of the Caucasian race in the north.

Varieties of Human Species.

Population of the World.

The number of human beings upon the globe has been variously estimated. A thousand millions have been mentioned, apparently for no other reason than

Physical  
Geography  
||  
Physiology.

In the *American* race, the skin is of a copper colour, the hair black, stiff, and straight, the forehead short, the cheek-bones and face broad, the orbits and eyes deep, the nose rather flat, but still prominent. In this are included all the American tribes except the Esquimaux. In the *Malay* race, the skin is tawny, the hair black, soft, curled, thick, and abundant, the head rather narrow, the forehead slightly arched, the parietal bones prominent, but not the cheek-bones, the nose full, broad, and bottle-shaped at the point, the mouth large, the face projecting forward in the lower part, but the features viewed in profile, more distinct than in the Ethiopian race. This variety comprehends the inhabitants of Malacca, the Marian, Philippine, Molucca, and Sunda Isles, and Polynesia. It is to be observed, that it is only in some particular tribes, or portions of each race, that its characteristics are strongly marked. None of the leading varieties are absolutely pure, and all of them may be found passing into each other by insensible gradations, from the effects of mixture.

The question has been long agitated, whether all the existing varieties have sprung from one parent stock. The arguments in favour of the affirmative appear to us to preponderate. 1. All the different races are capable of uniting with each other, and begetting offspring, which continue themselves by pro-

creation. This is held by naturalists to be one of the most decisive tests of identity of species. 2. There is no essential difference of structure in the various races. None of them have permanently a bone, a blood-vessel, or an organ of any kind, which the others want. There are no differences analogous to those of the stag and the roebuck, or the one and the two humped camel, which clearly mark a diversity of race. 3. The differences which do exist among mankind at large, such as those of complexion, stature, physiognomy, and mental capacity are analogous to those which manifest themselves in one tribe, or nation, and even in one family. We have, therefore, only to suppose that the causes which produce these minor and accidental differences are rendered general and permanent in their operation, by peculiarities of food, climate, or habits, to account for the stronger and more lasting distinctions among nations. This view of the subject is farther confirmed by the changes which climate, food, and different modes of treatment, produce upon domestic animals. 4. The affinities of language, which promise to throw much light on this subject when fully developed, have already afforded presumptive proofs of a common origin in the case of nations whom physiologists class under distinct races.\*

(B. B. B.)

## PHYSIOLOGY.

Physiology  
divisible into  
two Depart-  
ments.

**PHYSIOLOGY**, or the study of the phenomena of life, differs from all the other branches of philosophical inquiry, by its involving the consideration of the *final* as well as the *physical* causes of these phenomena. A new principle of arrangement is thus introduced, which is scarcely ever applicable in the sciences relating to the properties of inert and inorganic matter. Those sciences are formed by applying to the subjects they concern, the rules of philosophical induction. By comparing together phenomena, and uniting in one class such as are of the same kind, we arrive at the knowledge of a certain number of general facts, which we regard as laws of nature, and from which, when once established, we deduce the explanation of a multitude of subordinate phenomena, resulting from the simple or the combined operation of these laws. By a series of experiments we succeed in removing all extraneous circumstances, and in reducing each class of phenomena to its simplest conditions; and we are also enabled to vary the combinations, so as to compare the results with the appearances presented to us by nature. But the application of the same methods to the physiology of animal or vegetable life is attended with peculiar difficulty. The immense number of species of living beings, the variety and complexity of the appearances they exhibit, and the extended chains of connection that pervade every part of organic nature, are strikingly contrasted with

the simplicity, the constancy, and the uniformity of operation of those physical forces which regulate the changes occurring in the inorganic world. The extensive generalizations which have been so successfully accomplished in the sciences of natural philosophy and chemistry, can be effected only in a very limited degree among the diversified phenomena which constitute the science of physiology; and we have, accordingly, made but very imperfect approaches to the knowledge of those laws to which they are ultimately reducible. The resources of experimental inquiry are here extremely narrowed, in consequence of the close connections which subsist among the powers concerned, and which preclude us from any opportunity of studying them in a separate or isolated state, and of ascertaining distinctly their respective operations.

Amidst these obstacles which impede our progress in the direct but thorny avenues to science, we naturally turn to the more alluring, though circuitous paths, which open upon us on every side, in the contemplation of the final purposes of the changes we are examining. So strongly is the character of design impressed upon all the phenomena of organic beings, that we are irresistibly led to associate the views suggested by their relative subserviency to particular purposes, with the more strictly philosophical relation of cause and effect, by which they may also be connected. The relation of means to an end be-

\* See J. F. Blumenbach, *De Generis Humani Varietate Nativa Dissertatio*, 1795, 8vo, and Prichard's *Researches into the Physical History of Man*.

Physiology. comes thus a leading principle of association among the phenomena presented to us by living beings: it gives to the science a new aspect, and creates an interest of a different, and even superior kind to that which mere physical relations are calculated to inspire. The study of the *functions* of life, that is, of the purposes to which the actions constituting life are subservient, is generally regarded, indeed, as the principal object of physiology; and all the facts relating to it are distributed according as they tend to the accomplishment of these purposes. Dazzled by the brilliancy of these objects, physiologists have often lost sight of the essential distinction which subsists between these, and the more sober purposes of philosophical inquiry. In framing theories to explain the phenomena of life, they have most frequently satisfied themselves with pointing out their final causes, that is, the objects which are answered in the economy: and as the detection of this final cause often required the exertion of considerable sagacity, the inquiry has terminated here, and it has not been perceived that the physical theory was left in as great obscurity as before. This proneness to substitute final for physical causes has been the source of frequent delusion, by insensibly leading us to believe that we are really in possession of the physical law on which the phenomenon in question is dependant, when we have merely given it a name with reference to the intelligent agency, by which it was adjusted to its object. In our eagerness to grasp at this kind of knowledge, we have too often mistaken the shadow for the substance.

Final, mistaken for Physical Causes.

The writings of the older physiologists exhibit continual instances of this confusion of ideas. Thus the notion of an *archæus*, or *anima*, entertained by Van Helmont and Stahl, that is, of a presiding spirit, to the operation of which were referred all the vital actions, although, perhaps, naturally suggesting itself to the mind, was yet evidently an unphilosophical assumption, incompetent to explain the phenomena in question, and occasionally even at variance with those very phenomena. The *vis medicatrix nature*, to which Hoffman and Cullen so frequently appeal in their pathological reasonings, and which supplied them with ready solutions for every obscure morbid change that embarrassed them, was, in fact, nothing more than a branch of the same doctrine. Nor have the more sober theorists of modern times been sufficiently on their guard against this illusion. In the attributes which John Hunter ascribes to his vital principle, we may continually trace the same want of discrimination between that intelligence, by which the conditions of animated nature were originally adjusted to a variety of contingent circumstances, and those physical laws and agents, by the instrumentality of which the intended objects are attained. When it is said, for instance, in the language of this school, that the coagulation of the blood is occasioned by "the stimulus of necessity," it is clearly the final cause only, and not the physical cause of this phenomenon that is assigned: and it is also evident that no advance is thereby made towards the discovery of the latter. In like manner, the principle of life is represented to us as a new power, with which organized beings are endowed; a power which modifies and controls the operation of those

simpler physical laws, to which the same matter, in its unorganized state, is subjected; a power which imposes new cohesive forces on the materials of the solid structures of the body, which imparts to the fluids a new property of coagulation, which alters the order of chemical affinities between their elements, retaining them, contrary to their natural tendencies, in a certain state of equilibrium, and resisting the agency of several causes tending to destroy it; and which, lastly, produces, in a degree somewhat corresponding to the wants of the system, either an evolution or an absorption of caloric. All these, it must be acknowledged, are purposes of manifest utility; being directly conducive to the welfare of the individual, and indeed essential to its continuance in the living state. As means conducive to a specific end, the reference of all these phenomena to the same class is unobjectionable. The fallacy lies in regarding it as a philosophical generalization of effects, of a similar kind, indicative of the operation of a simple power in nature. Between many of the effects in question, considered as physical phenomena, there exists not even the remotest analogy. But it is the fundamental principle of the method of induction that similar effects alone are to be ascribed to the agency of the same principle. Judging from the observed effects, therefore, which differ much from each other, as well as from other phenomena in nature, we ought to infer the agency of several distinct principles, the concurrence of which is required to produce all the complex phenomena of life. We are unavoidably led, no doubt, to view these phenomena as conjoined, because we readily perceive that they tend to the same object, the preservation and welfare of the beings to which they relate. But the unity of design is an attribute of intellect alone, and does not necessarily imply the unity of the agent employed in their production. However natural it may be to conceive the existence of a simple principle of life, and however possible it is, that this hypothesis may ultimately be established as the true one by future discoveries, we should recollect, that, in the present state of our knowledge, it is a mere fiction of the mind, not countenanced by the phenomena themselves, in which we see so much diversity, and, therefore, not admissible as the result of a truly philosophical induction.

Bichât, who was impressed with the necessity of drawing certain lines of distinction among the powers of life, has yet perplexed his system, by taking final causes as the basis of his divisions; a principle which is incompatible with a philosophical analysis of those powers. Thus, the distinction which he labours to establish, between the muscular contractility of animal life, and that of organic life, is founded, not upon any real difference in the nature of the power concerned; for, as we shall endeavour to show in the sequel, the power which resides in the muscles of the voluntary and of the involuntary motions is in all cases the same; but upon a difference in the application that is made of this power in the economy. Dumas has been guilty of a still more palpable error, in thinking it necessary to add to his catalogue of principles, consisting of the acknowledged powers of sensibility and contractility, a third power, which he terms *force de resistance vitale*; thus as-

Physiology. sociating a final cause in the same rank with causes that are strictly physical. To multiply examples of this mistake would be endless ; for it pervades almost every physiological system that has yet been framed.

Design of this Article.

As a full account has already been given, under the head of PHYSIOLOGY, in the *Encyclopædia*, of the principal facts relating to the *functions* of the animal economy, which, as we have stated, are commonly regarded as the leading objects of that study, we shall, in this article, present an outline of what may be considered the *philosophical* department of the science, by attempting an analysis of the principal laws, or ultimate facts to which the vital phenomena are reducible. Setting aside, then, all consideration of functions, we shall examine the changes that occur in the living system, simply as physical phenomena ; and we shall endeavour to class them according as they agree or differ among themselves, without reference to the purposes which they may happen to serve in the animal economy. Thus, if we take as an example, the phenomena of the circulation of the blood, which, when viewed with relation to the function, form together so beautiful and harmonious a system, we find that, considered abstractedly, these phenomena are ultimately resolvable into such as result from a few general powers, as muscular contractility, membranous elasticity, the hydraulic properties of the blood, &c. If a similar analysis were made of the phenomena of digestion, we should find them to be the effects of the combined agencies of the muscular action of the stomach and intestines, of the chemical properties of the gastric juice, the bile, &c. of the organic powers of secretion, and so forth ; all of which concur in the production of a definite object, namely the conversion of the aliment into chyle. The processes subservient to this object constitute the function of digestion.

These analytical investigations have not been prosecuted by physiologists with the attention their importance deserves. Our knowledge of the principles of the science has, however, been considerably increased by the experimental inquiries that have recently been instituted both in this country and on the continent ; and we shall therefore avail ourselves of the present period, as affording peculiar advantages for taking a comprehensive review of the facts which bear upon these questions, and for deducing consequences that may throw considerable light upon the animal economy, and the theory of diseases.

Classification of the Vital Powers.

Of the changes which occur in the living system, some are easily referable to particular classes ; others, again, having a less distinct character, are generalized with greater difficulty. Some of the powers concerned in the phenomena of life may be recognized as being identical with those which produce changes in inanimate matter, while the rest are powers peculiar to the living state. Thus the cohesion, elasticity, and tenacity of the particles of the solids of the body ; the strength, resistance, &c. of the materials which compose them ; and the hydrostatic and hydraulic laws of its fluids, are principles upon which we may safely reason in their application to the mechanism of the living system. Many of the laws of chemistry are also applicable to its phenomena. From our knowledge of these principles we may

predict the effects which will, under given circumstances, ensue : and if experience, in any case, teaches us that the result is different, we may thence infer the operation of new causes, peculiar to the living state, and constituting other classes of phenomena.

The powers comprehended under this latter division have usually been described as reducible to two species, namely contractility and sensibility ; for it was supposed that all the phenomena might be arranged under these two heads. We shall endeavour to show that their analysis is incomplete, and to point out at least four distinct principles of which the operation may be recognized in the living body : these are Muscular Contractility, Nervous Agency, Sensorial Power, and Organic Affinity. Let us first, however, fix the meaning of these terms.

*Muscular contractility* is a power too well known by its effects to require any elaborate definition or illustration in this place. It consists in that property by which, in consequence of the impression of certain agents, the extremities of muscular fibres are made to approach each other, with a force greatly superior to the ordinary mechanical sources of motion.

By the term *nervous agency* we would be understood to mean that power which resides in the nervous system, and by which certain effects, hereafter to be described, and which for the present we shall call *impressions*, made on one part of that system of organs, are immediately succeeded by certain other effects at a remote part of the same system. The application of an irritating substance, for example, to one extremity of a nerve, will excite, in one case, muscular contraction ; in another case, sensation ; in a third, secretion ; in a fourth, it will raise the temperature ; while, in other instances, it will produce changes of vascular action, and lead to an alteration of the organic structure of parts. Since this propagation of impressions is a fact not exactly analogous to any other phenomenon in nature, we must regard it as the effect of a distinct power, concurring with the rest in producing the general result which we term life.

Another power, perfectly distinct from the former, although it also resides in a portion of the nervous system, is that from which the corporeal operations connected with sensation and volition result. Dr Wilson Philip, to whom we are indebted for having clearly pointed out this distinction, has given to this property the name of *sensorial power*. As the term seems to be sufficiently appropriate, we shall adopt it as the designation of this specific property of the nervous system. Dr Darwin had employed the same term in a more extended sense, as including the power of muscular contraction. It should be remembered that it is here limited to those physiological changes in which the mind is immediately concerned.

The admission of the powers already enumerated do not yet supply us with the means of explaining a variety of phenomena exhibited by the living system, and which are sufficiently analogous in their nature to warrant our classing them together as depending upon the operation of a common principle. The phenomena in question are those of secretion and

2. Nervous Agency.

3. Sensorial Power.

4. Organic Affinities.

Physiology. nutrition, including those of the growth, extension, and modelling of the various organic structures which compose the animal fabric. The powers by which these effects are produced exist in the vegetable as well as the animal kingdom, and appear to result from that particular arrangement of parts which is termed *organization*. These powers, when considered abstractedly from the purposes they serve in the economy, we shall denominate the *organic affinities*, by way of contradistinction from the ordinary chemical affinities to which they are so frequently opposed.

I. We shall first examine the MECHANICAL PROPERTIES of animal structures.

Organization of Animal Membrane. The basis of the organic texture of the different parts of the body is a peculiar substance, which, amidst its various modifications of cellular tissue, membrane, vessels, neurilema, visceral parenchyma, &c. may be recognized as essentially the same. The term *membrane*, which is applied more especially to a condensed lamina of this substance, may be conveniently extended to the rest, and employed as the generic term for the whole. It has been disputed whether this substance was ultimately resolvable into plates or fibres, and the microscope has been appealed to in support of both opinions; but after all that has been said about the primordial animal fibre, which was stated by Haller to bear the same relation to anatomy which a line does to geometry, the whole may possibly be more the fruit of imagination than the sober account of the real fact. Fontana had viewed it as an assemblage of cylindric fibres, which were twisted and interlaced with each other; but Monro has shown that he was deceived by an optical illusion, to which the incautious use of the microscope frequently gives rise. Bichat describes its intimate structure as composed both of filaments and of laminae, variously intermixed; and hazards a conjecture that the former are exhalent and absorbent vessels. Bordeu appears to have been the first who advanced the opinion of the homogeneous nature of the cellular tissue, which he compares to froth or glue. Quesnay considered it more as a fluid than as an organized solid. Wolff rejects entirely the idea of its being cellular, and regards it as a homogeneous and glutinous substance, without organization. Blumenbach, Platner, and Meckel, have adopted these views; a statement of the arguments in favour of which is given by Béclard in his *Additions à l'Anatomie Générale de Bichat*. The subject has already been noticed under the head of ANATOMY in this *Supplement*. Whatever weight may be allowed to the arguments in favour of the cellular tissue being a homogeneous substance, it seems, from other considerations, more reasonable to suppose that the mechanical structure of all animal substances is framed, even in the simplest cases, with a greater degree of complication than we shall ever have the means of fully ascertaining.

Mechanical Properties. Although ignorant of the arrangement of particles which constitutes the organization of animal membrane, we observe certain mechanical properties to result from it, analogous, it is true, to those that are met with in several inorganic substances, but in ge-

Physiology. neral much superior to them in degree. These are flexibility, extensibility, and elasticity. These properties, in their different degrees, are variously combined and modified in the different forms of animal substance, but exist more or less in every organ. As it is not our object to enter into any consideration of the functions to which these properties are subservient, we shall abstain from any remarks on the utility of these properties, but confine ourselves to their physical relations. In this respect, one very striking circumstance requires to be pointed out, namely, that the force of elasticity among the particles composing these animal structures is rarely found in a state of neutrality, but is kept in equilibrium by the mechanical circumstances of situation. When these circumstances are deranged, elasticity comes into play, and produces a shrinking of the substance. In other words, every part is kept upon the stretch, and retracts when set at liberty by the removal of the extending cause. This will happen when its extremities are brought nearer to one another, when the contents of the hollow parts are withdrawn, and whenever they are divided transversely. This property has long been known, though described under different names; that of *tone*, or *tonicity*, has frequently been applied to it. Bichat, who has very well described its effects, has denominated it *contractilité de tissu*, and *contractilité par défaut d'extension*, and has distinguished it from tonicity, which he regards as a vital property.

Fibrous Tissues. The mechanical properties we have enumerated are greatly modified by diversities of structure. The same substance, when in the state of greatest condensation, composes what Bichat has denominated the fibrous tissue. Chaussier has considered it as of a peculiar nature, differing from ordinary membrane, and has given it the name of *fibre albuginée*, ascribing to it the character of having a white colour, and a resplendent satin-like surface, an appearance which it owes to its great density. Of these fibres are the tendons, aponeuroses, and ligaments principally composed. Among these we may again trace a diversity of properties. Thus tendons exhibit the smallest degree of extensibility compatible with membranous texture, although they possess great flexibility. The ligaments belonging to joints are still more flexible, and somewhat more extensible and elastic. Those ligamentous structures, on the other hand, which are employed as an antagonist power to gravitation, or to muscular action, such as the ligamentum nuchæ, which counteracts the weight of the head in grazing quadrupeds, are very extensible, and possess a high degree of elasticity. A layer of the same elastic substance extends over the parietes of the abdomen in these animals, for the support of the abdominal viscera. The elastic ligaments which retract the claws of the cat, and other animals of the same tribe, exhibit the same property. Béclard considers this highly elastic substance as a separate modification of membranous structure, distinguished from the *tissu albuginé* of Chaussier by its yellow colour and peculiar elasticity. Ligaments, having the same properties, but which are white, instead of yellow, are extensively met with in the anatomy of insects.

**Physiology.** Among the physical properties of animal membrane must also be enumerated a peculiar kind of contractility, which is accompanied with a sudden corrugation and curling of its substance. This effect, which was noticed by Haller, and which Bichat designates by the term *racornissement*, is produced by the application of a certain degree of heat, and also of several chemical agents, more especially the concentrated mineral acids. Alcohol and the neutral salts effect a similar change, but much more slowly, and in a very inferior degree; and the effect continues to increase if the agent continues applied, which is not the case when acids or boiling water are used. The continued applications of these latter agents gradually effect the disorganization and solution of the animal matter. Bichat has taken considerable pains to investigate these phenomena, and we must refer our readers to his *Anatomie Générale* for the details of his experiments. He has pointed out several circumstances by which this property is distinguished from mere membranous elasticity. Although it has been thought to resemble muscular contractility, it will really be found, when strictly compared, to differ from this last property in all essential particulars; and it probably, therefore, depends on causes that are wholly different.

**Hygrometric Property.** An effect somewhat analogous to the former, although much less in degree, takes place in animal membranes by the evaporation of the water which is united to it, but which appears to be retained by a weak affinity. This constitutes what may be called the *hygrometric property*, and is very characteristic of dry membranous structures, all of which are found more or less to contract by the loss of moisture, and again to expand by its reabsorption, according to the varying states of dryness and humidity in the surrounding atmosphere. The organic tissues of vegetables exhibit this property; but in a very inferior degree compared with animal membrane.

**Vis Mortua of Haller.** The mechanical properties of membrane which we have been examining are totally independent of the vital properties that are next to come under our review. They remain some time after the complete extinction of life in all its functions, and seem to be connected with the peculiar arrangement of particles, and the chemical composition of the substance in which they reside. They appear, indeed, not to be affected until the progress of decomposition has become sensible. Hence this assemblage of powers was denominated by Haller the *vis mortua*.

**Contractility of the Muscular Fibre.** II. MUSCULAR CONTRACTILITY is one of the most remarkable of those properties which are peculiar to animal life. It is often distinguished by the name of *irritability*, which was originally given to it by Glisson. But the merit of having clearly appreciated its importance, as a separate and peculiar power, is due to Haller, who speaks of it sometimes under the title of irritability, and sometimes under that of the *vis insita*. The phenomena of muscular contraction have already been sufficiently detailed in the Article PHYSIOLOGY in the *Encyclopædia*.

This property has been established in the system as the great source of mechanical power required for

the operations of the animal machine. As in a manufactory where the force of steam is employed as the prime mover of the whole of its complicated machinery, so, in the animal system, is the muscular power resorted to on every occasion where mechanical force is required. From its vast intensity, this power appears adequate to every purpose; and though, in some instances, it may seem to have been lavished with profuseness for the sake of slight additional convenience, in others it is carefully economized; and perhaps more accurate examination would show that it is in all cases exactly adjusted to the intended effect. Before the time of Haller it was generally regarded as an extension of the nervous power; and so great was the confusion of ideas on this subject, that even Boerhaave speaks of tendon as merely a modification of muscular structure.

The occasion, or exciting cause, which gives rise to the exertion of this power, is termed a stimulus. Thus all muscular contraction implies two things, the irritability, which constitutes the power, and the stimulus, which determines the action of that power. The irritability, according to Haller, is the same in kind, wherever muscular fibres are met with; it only varies in intensity in the different muscles: but it does not in all of them obey the same stimuli. The nervous power is the natural stimulus of all those muscles which are under the influence of the will: on the other hand, the muscles of involuntary motion are affected by stimuli of different kinds, which are appropriated to their different functions, and altogether different from the nervous power. Thus the blood is the natural stimulus which excites the contraction of the heart; and the alimentary canal, the bladder, uterus, &c. are, in like manner, excited to action by their respective contents.

It is only by examining attentively the circumstances in which the muscular power is exerted, that we can hope to attain a knowledge of its nature. That a particular mechanical structure is required for its production is apparent from the regular arrangement of parallel fibres, connected into fasciculi of larger and larger dimensions by separate investments of membrane; and also from their great vascularity. Muscles are more abundantly supplied with blood-vessels than any other parts, excepting the lungs and the organs appropriated for secretion. The minute or capillary veins are more particularly numerous, forming a vascular net-work, and are provided with numerous valves. Much contrariety of evidence exists as to the intimate structure of muscular fibres. Leeuwenhoek represents them as being exceedingly minute, many thousand uniting to form one visible fibre, but that they differ considerably in diameter in different animals, without any relation to the size of the animal. He states, for example, the fibre of the frog to be larger than that of the ox. He thinks their size also varies according to the age of the animal, being smallest in the earlier periods of life. Muys, who was engaged for many years in the most laborious researches on this subject, concludes, on the other hand, that the real ultimate filaments of muscles are in all cases of the same size, even when compared among the mammalia, birds, and insects. Prochaska, again, says expressly that they are not all of the

Physiology. same diameter, but differ in different animals, and even in different parts of the same animal. Their diameter has in general been stated as less than that of the globules of the blood; but Sprengel speaks of them as being equal to the 500th of an inch in the mammalia, and the 250th in birds and fishes. Some microscopical observers have represented them as hollow tubes; but this is probably an optical deception, like that which has led to the belief that hairs are tubular. Several, such as King and Tavvry, have imagined them to be continuations of arteries; an opinion which was connected with the theory of the indefinite extension of vascularity, formerly prevalent, but since sufficiently refuted by observation as well as reasoning. Prochaska asserts, with confidence, that they are solid, and of a polyhedral, prismatic shape, generally flattened, or thicker on one side than on another, so that a transverse section presented an appearance similar to that of basaltic pillars. Hook and Swammerdam reported the fibres to be composed of a series of globules. Cooper and Stuart supposed them to be cellular, and Borelli that they were formed of a string of rhomboidal vesicles. Fontana's account of them in general agrees with that of Prochaska; but he remarks that they are furnished, at regular intervals, with transverse bands; and that they may always be distinguished by their parallel disposition from the fibres of membrane, which are more or less contorted. Sir Anthony Carlisle states, that a muscular fibre, duly prepared, by washing away the adhering extraneous substances, and exposed to view in a powerful microscope, appears to be a solid cylinder, the covering of which is reticular membrane, and the contained part a dry pulpy substance, irregularly granulated, and of little cohesive power, when dead. Mr Bauer represents them as composed of a row of globules, exactly corresponding in size to those of the blood, when deprived of their colouring matter. By long maceration in water, the cohesion of these globules is loosened, and the fibre is broken down into a mass of globules. The statement of these various opinions is sufficient to show how little satisfactory information has been gained on the subject. Whenever an observer has a favourite theory to support, the microscope is ever ready to assist him in seeing what he expects, or wishes to discover.

In the infancy of rational physiology, much labour was bestowed upon devising some mechanical arrangement of particles that might account for the phenomena of muscular contraction. With this view Borelli contrived his rhomboidal vesicles, which he supposed to be empty in the relaxed state of the fibre, but suddenly distended by the introduction of a fluid derived from the nerves, which shortened as well as swelled each vesicle, and, consequently, the whole muscle. In this hypothesis, though ingeniously adapted to the phenomena, no power is assigned for the sudden propulsion of so large a quantity of fluid into the vesicles; the resistance that would be opposed to the entry of such a fluid would be immense, and the force required to overcome it would be much greater than even that exerted by the muscle itself, which it was the object of the hypothesis to explain. The supposition, there-

fore, involves a greater difficulty than the simple Physiology. fact. Some have, in like manner, imagined they could explain the phenomena by the turgescence of the numerous arteries which are seen to cross the fibres at right angles; not recollecting that the very force which distends the arteries is itself derived from the muscular power of the heart and arterial trunks, which could not create a power greater than itself. The hypothesis of the spiral course of the ultimate fibres, a form which admitted of elongation or contraction, according to the degree of convolution, is as gratuitous as the preceding; and equally open to the objection that the original source of motion is left unexplained. Dr Fordyce states a fact which places it in a striking point of view, the circumstance of a new force being generated during muscular contraction. If the interior surface of the ventricle of the heart, detached from the body, be pricked gently by a needle introduced into its cavity, the ventricle will thereby be made to contract with such power as to force the needle deep into it. The force of the contraction of the ventricle must have been incomparably greater than the power with which it was pricked by the needle. Muscular power, indeed, bears not the least analogy to any of the other great principles in nature, which are original sources of mechanical force; and, until such an analogy can be traced, all our endeavours to explain the phenomena by mechanical hypothesis must be as fruitless as the attempts to contrive a machine for perpetual motion. Some physiologists, wishing to avoid all hypothesis, propose to explain the phenomena of muscular contraction, by saying that it arises from an increase of attraction among the particles of the muscular fibre. Dr Fordyce calls this force "the attraction of life," a term, which, if it has any meaning, is merely a statement of the simple fact under a new form of expression.

Muscular fibres differ from those of membrane Chemical Theories. in chemical composition, as well as mechanical structure; and it becomes a question how far their properties depend on a peculiar combination of chemical elements. Physiologists have, accordingly, endeavoured to ascertain whether, while the mechanical texture was unaltered, any changes occurring in the chemical condition of a muscle would be accompanied by a corresponding change in its contractile power; and, whether there was any one element in particular, the presence of which was more essential than the rest to the exertion of that power. It was long the fashion to regard oxygen as the source of this power. This theory was advanced by Girtanner, and found strenuous advocates in Humboldt, Beddoes, and Richerand. Some account of the reasonings on which they founded this opinion has been given in the *Encyclopædia*. Experiments were made to ascertain the influence which the alternate abstraction and restoration of oxygen had on irritability, of the presence of which the galvanic excitation was used as a test. The general result of the inquiry was, that a certain proportion of uncombined oxygen is essential to the maintenance of irritability. The presence of fibrin has been regarded essential to the constitution of the muscular fibre; but Fourcroy has shown that different modifications of fibrin are compatible with irri-

Physiology. **tability.** The necessity of a due supply of caloric has, in like manner, been the subject of inquiry; and, as might have been expected, the preservation of a certain temperature has been found requisite to muscular action. All that can be safely concluded, however, from these investigations, is, that a certain state of chemical composition and of temperature, is as essential as a certain mechanical structure to muscular contractility, but that these conditions admit of some degree of variation within certain limits.

In the more perfect animals, muscular contractility remains but for a short time after the circulation of the blood has ceased. A ligature on the arteries which distribute this fluid to a muscle, occasions the speedy loss of its irritability; arterial blood, therefore, supplies some material requisite for the preservation of the proper chemical state of the muscular fibre. Yet different classes of animals are very differently constituted with respect to this circumstance. The muscles of the amphibia will remain irritable long after an entire stop has been put to the circulation; and this takes place even in limbs that are detached from the body.

Cellular  
confounded  
with Mus-  
cular Con-  
tractility.

The operation of the muscular power is of so distinct and specific a character, that it appears surprising how phenomena of any other class could be confounded with it; and yet several distinguished physiologists have ascribed to different portions of the cellular substance a contractile power analogous to that of muscles. The *tunica vaginalis testis*, and its surrounding cellular tissue, are said to exhibit indications of this peculiar species of contractility, from the irritation of stimuli, or by the application of cold. "The contractions that ensue," says Bichat, "are doubtless not to be compared to that of muscles, but they certainly constitute the first degree of that power; they are the same in kind, or rather they hold a middle rank between muscular contractions and those minute and invisible oscillations which others call tonicity, &c." There does not appear to us to be any foundation in fact for this supposed gradation of the muscular power. The motions in question may partly be accounted for by the known power of elasticity, which undoubtedly varies in degree in different textures, and partly by the real but undetected presence of muscular fibres. The *vis cellulosa* of Blumenbach appears, in like manner, to be no new power, but simply the modified elasticity of the texture in which it resides. A few cases have been pointed out, which are perhaps of a dubious character, such as the motions of the iris, the muscularity of which has been often called in question, though it now appears to be sufficiently established by the microscopical observations of M. Bauer. So much importance has been attached to these apparent anomalies, that it has been thought necessary, in order to account for them, to suppose the existence of a new power, the *vita propria*; or rather, as it should be said, to invent a new term void of any definite signification.

Power of  
Spontaneous  
Elongation.

It has frequently been supposed, that, besides the power of contraction, muscular fibres had also the opposite power of spontaneous elongation, when the former ceased to be exerted. Bichat countenances this doctrine when he says, that "it appears very

probable that the dilatation of muscles is a phenomenon equally vital with their contraction." But all the facts that have been adduced in favour of this notion may, as John Hunter has shown, be completely explained by the operation of other causes; such as that of antagonist muscles, or of the natural elasticity of neighbouring parts, or of the cellular substance contained in the muscle itself; for it should not be forgotten that a muscle, in addition to its contractility, possesses all the properties belonging to animal membrane, which composes so large a portion of its structure. Many phenomena in the movements of animals, which may, at first sight, have the appearance of arising from a spontaneous power of dilatation, such as the elongation of the trunk of the elephant, of the tentacula of polypi, and the bodies of the leech and other vermes, and the extension of the feet, and other soft parts of mollusca, are, like the varied motions of the tongue, only secondary effects of the contraction of certain muscular fibres so disposed as to produce these effects. It has been said that the heart has been found to exert, during its dilatation, a positive force, but probably if the course of all the fibres composing the muscular parietes of that organ were better known, this apparent anomaly would be as easily explained as the rest.

Still less could it have been supposed possible to confound the nervous with the muscular power; and yet, prior to the time of Haller, no clear ideas were entertained of the distinction between them; and, even in later times, the subject has been involved in much perplexity. Muscular fibres used to be spoken of as only nervous fibres on a large scale; exhibiting distinctly, on account of their greater magnitude, the contractions which were presumed to take place in the ultimate fibres of the nerves during their action, but which were insensible on account of their minuteness. The retraction of divided nerves is clearly an effect of membranous elasticity.

III.—NERVOUS AGENCY, or that property of the nervous system by which it receives impressions made on one part, and transmits them to others, is manifested in several ways. First, by exciting muscular contractions. The usual mode in which this occurs is seen in the muscles of voluntary motion, the actions of which are determined by an effort of the will, which produces an impression on the nerves sent to these muscles at their origin in the sensorium; this impression is propagated along these nerves to the muscles themselves, where it appears to act upon their irritability like any other stimulus, and to produce their contraction. But the very same effect takes place quite independently of the mind, by an irritation of a mechanical or chemical nature applied at the origin of the nerves, or in any part of their course. This conducting power in the nerves may, by these means, be called into action long after the extinction of sensibility, and may be observed even in a limb removed from the body; for muscular contractions are produced in it by mechanical irritation of the ends of the nerves leading to those muscles, and still more readily by galvanic excitation. The contraction of muscles which are not under the dominion of the

Phenomena  
of Nervous  
Agency.

Physiology. will, such as the heart, are not so evidently the consequence of irritations applied to the nerves which terminate in them, in consequence of the peculiar mode of arrangement of these nerves; but as we shall hereafter show, the conducting power of these nerves is no less real than in the former. Various stimuli, operating through the medium of the nervous system, and different affections of the mind, affect the motions of the heart and arterial system, and the muscular fibres of the alimentary canal; and produce local determinations of blood, and increased vascular actions of particular parts. Secondly, there are various operations, such as secretion, conducted in the minuter textures of the body by means that entirely escape our cognizance, which are materially influenced by certain irritations propagated along the nerves. But the mode in which this influence is exerted is reserved for future discussion. Thirdly, another, and no less important effect of nervous action is the production of sensation. An impression made upon the sentient extremity of a nerve is propagated to the sensorium, when it produces other changes, immediately followed by that affection of the sentient principle, accompanied by consciousness, which we term sensation. This latter class of effects we shall refer, as already stated, to a power distinct from the nervous, and which we have called the sensorial power. Fourthly, among the effects resulting from the nervous power, those which arise from the communication of irritations to very remote parts, which are but indirectly connected by nerves, must not be omitted. They are usually comprehended under the title of the effects of sympathy. In some cases the nervous communications may be traced; in others, it appears to take place through the medium of the central parts of the nervous system, that is, the brain and spinal marrow. In proportion as the anatomy of the nervous system has been more accurately explored, the former appear to be more numerous; though there are still a great number of cases which can only be explained on the latter supposition.

Analogies  
with Elec-  
tricity.

In what way this propagation of impressions by the nerves is effected, we are wholly ignorant. The celerity with which they are transmitted along the whole line of communication, bears a greater resemblance to the transmission of the electric agency along conducting wires, than to any other fact we are acquainted with in nature: and on the strength of this analogy the nervous influence itself has often been conceived to be of an electrical nature. In those fishes which exhibit powerful electrical phenomena, as the torpedo, gymnotus, and silurus, the organs appropriated to the production of these effects, are supplied with an enormous mass of nerves, showing clearly the important part which the nervous influence plays in these phenomena. The processes of secretion are disturbed when the nervous communications between the secreting organ and the brain are intercepted by the division of the nerves; but in the case of the stomach, the natural process of digestion is resumed when galvanic electricity is transmitted through those portions of the nerves which remain connected with the stomach. As Voltaic electricity is known to produce chemical changes in the substances on which it is made to act, it was con-

ceived that the chemical changes constituting secretion were in like manner effected by electricity, of which the nerves were the conductors. Such are the principal arguments brought forward in support of the identity of the nervous and the electrical agencies; a hypothesis which was first advanced by Valli at the period when the effects of Galvanism on the muscles, or animal electricity, as it was then called, began to engage the attention of the philosophic world. We shall have occasion to revert to this theory in the sequel.

The nervous, like the other animal powers, is dependant on a certain mechanical and chemical constitution of the organs which exercise it. Anatomists are not agreed as to the minute and ultimate structure of nervous matter. Ruysch and Leeuwenhoek considered it as vascular, an opinion to which Haller subscribes; but Albinus denies the vascularity of the medullary substance, as neither apparent by the microscope, nor by the evidence of injections. De la Torre asserts that it consists of a mass of innumerable transparent globules swimming in a diaphanous fluid; and that these globules are larger in the brain than in the spinal marrow. Prochaska describes the same globular structure, which he represents as united by a transparent elastic cellular membrane, disposed in fibres. Monro first thought these fibres to be convoluted, but afterwards suspected some optical deception. Fontana found the nerves to be composed of a number of minute cylinders, seemingly composed of a pellicle, and partly filled with a transparent gelatinous humour, and with small unequal globules. Sir Everard Home describes the optic nerves of a horse as "composed of two parts, one opaque, and the other transparent, forming fibres of a peculiar kind, unlike those of any other part of the body. Their course is curious, for they appear to be constantly passing from one fasciculus to another, so as to connect all the different fasciculi together by a mixture of fibres. This is different from the course of the blood-vessels, lymphatics, or muscular fibres; the only thing similar to it is in the formation of nervous plexuses, which leads to the idea of its answering an essential purpose respecting the functions of the nerves."

Organiza-  
tion of Ner-  
vous Mat-  
ter.

Whatever be the peculiar organization from which such astonishing effects result, we may at least be assured that the following conditions are requisite for their appearance; namely, a certain continuity of nervous substance, freedom from pressure, and the continued supply of arterial blood. With respect to the first of these conditions, however, the experiments of Dr Philip and of Mr Brodie, the results of which are stated in the *Philosophical Transactions* for 1822, would seem to show that the mere division of a nerve, if the cut ends are not above a quarter of an inch asunder, is not sufficient to interrupt the transmission of that portion of nervous influence with which the secretions are concerned. It is to be hoped that the prosecution of this curious and important discovery will throw some light on the mysterious nature of nervous agency.

Conditions  
requisite for  
the Phenomena.

As the nerves, in warm-blooded animals, lose their power in a very short time after they are isolated from the rest of the system, it has been naturally

Sources of  
Nervous  
Power.

Physiology. conceived that they derive a supply of power from the large central masses constituting the brain and spinal marrow, where it may be supposed to be prepared and elaborated, in a manner somewhat analogous to the process of secretion. It has been further imagined, that this power was capable of being accumulated in the brain and spinal marrow, forming a kind of stock or perpetual source, to supply the expenditure that takes place by the several nerves, which conduct it off. Prochaska, on the other hand, thinks that the nervous power is generated throughout the whole extent of the nervous system, so that every part derives from its own nerves, taken alone, the cause of its life and movements. There are facts in favour of each side of the question, and the subject is still involved in considerable obscurity.

Phenomena  
of Sensorial  
Power.

IV.—SENSORIAL POWER is manifested in the production of sensation and volition. These effects, when they occur in ourselves, we know by consciousness, but in other animals we can only infer their presence by the voluntary actions to which they give rise; that is, by the well-marked expressions of pain or pleasure, and by the contraction of certain muscles, with the evident intentions of gratifying natural appetites, or of avoiding or removing what occasions pain. The term *sensibility* has been used by modern writers with great latitude, as expressing generally the capacity of being affected by impressions. Thus Bichat speaks of organic sensibility as contradistinguished from animal sensibility. But the extension of this term to any property that does not involve sensation attended with consciousness, is too indefinite, and tends to introduce a confusion of ideas. The nervous and sensorial powers, though in themselves perfectly distinct, had, in general, been confounded together by physiologists. Le Gallois was the first who pointed out the difference between them; but their distinctive characters have been most clearly marked by Dr Philip in his *Experimental Inquiry into the Laws of the Vital Functions*, a work which has opened new and important views in this department of physiological science. He has brought evidence to show that these two systems do not differ less from each other than they do from the muscular system. It appears from his observations, that after the destruction of the sensorial power, the nervous power is still capable of performing its other functions, although it can no longer excite sensation, because the power on which sensation depends no longer exists. This happens, as we shall afterwards have occasion to notice, at the instant of death.

Powers of  
Exciting  
Sensation.

The power of sensation is called into action by impressions conveyed along the nerves: and the nerves appear to be the only medium through which these impressions can reach those parts of the nervous system, on the changes of which sensation depends. It has, however, been asserted, that other parts, besides the nerves, are endowed with this power. It is alleged, for instance, that muscular fibres are sensible, because the sensation accompanying muscular contraction is different from that of passive impressions; and because spasms are attend-

ed with peculiar pain. But experience shows, that the power of exciting sensation is very variable in the nerves of the same part, according to the affections of that part. Increased determination of blood to any organ generally augments its sensibility. Inflammation exalts it in a still more remarkable degree, so that parts usually insensible, as the bones, tendons, and ligaments, become exquisitely sensible in many states of disease. The marrow of cylindrical bones appears, under ordinary circumstances, to possess very little sensibility, as is seen in amputations: but in other states, it becomes highly sensible; and, if irritation be applied in particular ways, as by pressure over a certain extent of marrow, the most acute pain is immediately felt. These variations will explain the difference and even contrariety of statements that have been made by different physiologists on this subject. The greater number of experimentalists have denied that it possessed any sensibility. Duverney and Bichat, on the other hand, represent it as highly sensible. Béclard remarks, that we cannot draw any correct inference from what happens in amputation, because the intense pain suffered during the section of the soft parts, has rendered the animal scarcely sensible to a lesser degree of pain immediately succeeding: but that, if the operation be suspended until this first impression has in a great measure subsided, any injury done to the marrow will be acutely perceived. It appears, indeed, that different nerves have very different powers of exciting sensation: but the consideration of this subject involves the discussion of a previous question of great interest, and on which some light has been thrown by recent discoveries.

The nervous power is manifested, as we have already stated, by the transmission of impressions. Some of these impressions, arising from the remote extremities of the nerves, are conveyed to the sensorium, and produce sensation: others originate in the sensorium, being consequent on acts of volition, and are transmitted to the muscles. With regard to these processes, which take place in opposite directions, the following questions may be asked:—Are the impressions, as far as regards the nerves, in both cases of the same kind, and modified only by the structure of the organs of sense, of that part of the sensorium with which the nerves communicate, and of the particular muscles in which they terminate: or, are the impressions modified by differences in the structure of the nerves, which are the vehicles of their transmission? Or, in other words, are all nervous filaments alike in function, merely conveying, like electric conductors, the same agent exactly as they receive it? In particular, can the same nerve, or nervous filament, transmit both kinds of impressions, namely, those of sensation and of volition: and, if they can, do these impressions, which pass in opposite directions, ever clash and interfere with one another; or do they cross one another, without collision, like the rays of light through a lens? Or, are there two sets of fibres, the one for sensation, and the other for motion, as there are veins and arteries for the transmission of blood in opposite directions? The observations which seem first to have suggested this latter notion, were taken

Differences  
in the Func-  
tions of dif-  
ferent  
Nerves.

*Physiology.* from cases of partial paralysis of a limb, in which the power of motion remains, although that of sensation is lost. Some experiments of Arnemann's, in which nerves that had been divided, and had spontaneously reunited, were found to have recovered the power of the voluntary excitement of the muscles, but to have permanently lost the power of producing sensation, showed the possibility of a separation of these two functions.

The doctrine of there being two sets of nerves appropriated to these respective offices, had been taught, in the infancy of the science, by Erasistratus and Herophilus; and Galen was inclined to adopt the same opinion, from observing that both in the tongue and in the eye, the nerves supplying these organs are of two kinds. Galen, however, accounted for the anomaly in cases of paralysis, by saying, that a greater nervous power is necessary for motion than for sensation; so that sufficient might remain for the latter, when it was inadequate to the former function. Haller and Sauvages have both subscribed to this doctrine, and the consequences deduced from it. Dr Philip thinks we must admit that the bundles of nerves going directly from the brain or spinal marrow to any part of the body, contain nerves of two descriptions, one set adapted to convey the dictates of the will, the other to convey impressions from the part to the sensorium. This, he thinks, more probable than that impressions move backwards and forwards in actually the same channels. One of these opinions must be correct. If the former is so, there is no difficulty in accounting for the feeling being lost and the power of motion remaining, and *vice versa*. Indeed, these phenomena of disease seem to go some way towards proving the former opinion. Mr Charles Bell, also, is of opinion that the nerves which we trace in the body are not single nerves, possessing various powers, but bundles of different nerves, the filaments of which are united for the convenience of distribution, but which are distinct in their office, as well as in their origin. "It is remarkable," he observes, "that an impression made on two different nerves of sense, though with the same instrument, will produce two distinct sensations; and the ideas resulting will only have relation to the organ affected. There are four kinds of papillæ on the tongue, but with two of those only we have to do at present. Of these, the papillæ of one kind form the seat of the sense of taste; the other papillæ, more numerous and smaller, resemble the extremities of the nerves in the common skin, and are the organs of touch in the tongue. When I take a sharp steel point, and touch one of these papillæ, I feel the sharpness. The sense of touch informs me of the shape of the instrument. When I touch a papilla of taste, I have no sensation similar to the former. I do not know that a point touches the tongue, but I am sensible of a metallic taste, and the sensation passes backward on the tongue." Richerand states some experiments which he made on dogs, from which it appears that the functions of the different nerves sent to the tongue are widely different. (*Elem. de Physiologie*, T. II. p. 66, 8th edition.)

That the functions of the different sets of filaments composing the spinal nerves, and which arise respec-

tively from the anterior and from the posterior fasci-  
culi of the spinal marrow, are exceedingly different, has been proved by an experiment of Mr Bell's, of which he gives the following account. Former researches had led him to suspect that the functions of these two portions of the spinal marrow were different. He found that injury done to the anterior portion convulsed the animal more certainly than injury done to the posterior portion: but it was difficult to make the experiment without injuring both portions. But on considering that the spinal nerves have a double root, and being of opinion that the properties of the nerves are derived from their connexions with the parts of the brain, he thought this an opportunity of putting that opinion to the test of experiment, and of proving at the same time that nerves of different endowments were in the same cord, and inclosed in the same sheath. On laying bare the roots of the spinal nerves, he found that he could cut across the posterior fasciculus of nerves, which took its origin from the posterior portion of the spinal marrow, without convulsing the muscles of the back; but that on touching the anterior fasciculus with the point of the knife, the muscles of the back were immediately convulsed.

In a paper published in the *Philosophical Transactions* for 1821, Mr Bell considers the nerves as distinguished, from their functions, into two classes; the one composing what he calls the original or symmetrical system, and the other the superadded or irregular system. The former are more expressly provided for the purposes of sensation and locomotion. In animals where these functions are not complicated with those of circulation and respiration by central organs, these nerves are very simple, consisting merely of two cords, running the whole length of the body, and giving off lateral branches to the several divisions of which their annulated frame is composed. This is the case with insects, and with most of the vermes. As we ascend to the higher orders of animals, we find a greater complication of functions and a greater intricacy of nervous connexions, arising from the necessity of establishing extensive links of association between the organs that perform these additional functions. Hence the second class of nerves are provided, which crossing the former in a variety of directions, and occasionally uniting with them, gives rise to the intricacy and apparent confusion, in which the anatomy of the nervous system has hitherto been involved. The nerves belonging to the first class may be distinguished in the human body as forming the original system, if abstraction be made of all the superadded nerves. The nerves of the spine, the tenth or sub-occipital nerve, and the fifth or trigeminus of the system of Willis, constitute this system. All these nerves agree in the following essential circumstances: they have all double origins; they have all ganglia on one of their roots; they go out laterally to certain divisions of the body; they do not interfere to unite the divisions of the frame; they are all muscular nerves, ordering the voluntary motions of the frame; they are all exquisitely sensible, and the source of the common sensibility of the surfaces of the body. When accurately represented on paper, they are seen to pervade every part; no part is

*Physiology.*

Original  
and Super-  
added Sys-  
tems of  
Nerves.

without them; and yet they are symmetrical and simple, as the nerves of the lower animals. On the other hand, the nerves which connect the internal organs of respiration with the sensibilities of remote parts, and with the respiratory muscles, are distinguished from the former by their not arising from double roots, and having no ganglia on their origins; they come off from the *medulla oblongata* and upper part of the spinal marrow; and from this origin, they diverge to those several remote parts of the frame, which are combined in the motions of respiration. If the nerves be exposed in a living animal, those of the former class exhibit the highest degree of sensibility; while, on the contrary, those of the second are comparatively so little sensible, as to be immediately distinguished: in so much that the quiescence of the animal suggests a doubt whether they be sensible in any degree whatever. If the fifth pair, and the *portio dura* of the seventh, be both exposed on the face of a living animal, there will not remain the slightest doubt in the mind of the experimenter, which of these nerves bestows sensibility. If the nerve of the first class be divided, the skin and cellular substance are deprived of sensibility; but the division of nerves not belonging to this class does not at all deprive the parts of their sensibility to external impression. There is also a wide distinction in their powers of exciting the muscles. The slightest touch on the *portio dura* convulses the muscles of the face, but the animal gives no sign of pain: while, by means of the branches of the fifth pair, which, if touched, give great pain, it is difficult to produce any degree of action in the muscles.

Immediate  
Seat of Sen-  
sation;

The brain has, from the earliest times, been regarded as the organ chiefly connected with the affections of the sentient and intelligent principle. Galen taught that the governing spirit resides in the brain, and is especially contained in the ventricles, where it acts upon the nerves at their origin: for, on opening them, he observes, the spirit escapes, and the animal is immediately deprived of sensation and motion. The immediate seat of sensation appears to be confined to a particular portion of the nervous system; and observation and experiment concur in showing that this portion is restricted to much narrower limits than was formerly imagined. It certainly does not extend to the great mass of the hemispheres of the brain: for these may be wounded, or even wholly removed, in a living animal, without any indication of suffering. Both Le Gallois and Dr Philip removed by successive slices the whole of the upper and anterior parts of the brain, without affecting the muscles of voluntary motion, or apparently giving any pain. The knife excited these actions only when it approached the origin of the nerves, and the spinal marrow. The part which performs the office of the sensorium, that is, whose changes are the intermediate links between the percipient soul and the material body, appears to differ in different animals. In man, and the tribes of mammalia most allied to him in structure, it is chiefly situated in the *medulla oblongata* and upper portion of the spinal marrow, at the origin of the principal nerves of the organs of sense, and of their muscles. In proportion as we descend to the inferior orders, it seems to be

more diffused over the upper portions of the spinal marrow; but in no case does it belong to any precise point, being always diffused over a certain extent of medullary matter.

It is also generally believed, and Le Gallois professes to be of this opinion, that the power of determining resides exclusively in the brain. If a salamander, says he, be decapitated at the first vertebra, it continues to live several days; but although the muscles of the trunk and limbs be moved with a force sufficient for all the purposes of progressive motion, the animal remains on the same spot, and may be left on a plate, with a little water, without risk of its escaping. On examining its movements we may perceive that they are without order, and without any apparent object. The feet move, each in different ways, without concert; so that, if any advance happen to be made in one direction, it is presently defeated by a movement in the opposite quarter. The same remark applies to decapitated frogs; they are no longer capable of leaping; or if any leaps are made, it is only by a sort of accident, when their hind legs act against any fixed obstacle. When placed on their back, they occasionally agitate their limbs, as if from a desire to change their situation, but they remain as they were placed, from their incapacity to combine the movements necessary for that purpose. But all animals under these circumstances move but little, unless they are touched; and this is readily conceivable, since of all the senses the touch is the only one that remains to transmit impressions. Decapitation is not necessary for the exhibition of these phenomena; division of the spinal marrow will present them, and afford the singular spectacle of the two portions of the same body animated by different principles of action, each having a sensorial existence independent of the other.

Yet many actions of the living trunk of an animal appear to be governed by a sort of instinct, or obscure volition. Guinea-pigs and kittens, after they have recovered from the stupor produced by decapitation, seem strongly to feel pain from the wound in the neck, as appears by the alternate motions of their hind-feet towards that part. Sir Gilbert Blane reports that he divided the spinal marrow in a kitten a few days old, by cutting it across at the neck. The hind-paws being then irritated by pricking them, and by touching them with a hot wire, the muscles belonging to them were thrown into contraction, so as to produce the effect of shrinking from the injury. The same effects were observed in another kitten, after the head was entirely separated from the body. In repeating this experiment he found that when the spinal marrow was cut through between the lumbar vertebrae and the os sacrum, the posterior extremities no longer contracted, but the tail retained its sensibility. It is very certain that birds continue not only to live, but to walk and run, for some time after decapitation. The feats of the Emperor Commodus, who amused himself with striking off the heads of ostriches while they were running across the circus, by shooting at them arrows having a cutting edge, are well known: these animals, though headless, continued to run as before, and reached the end of the area before they dropped. Many physiologists

Not confined to the Brain.

Physiology. have obtained similar results with turkeys, cocks, ducks, and pigeons. A frog will often be found, some hours after it has been decapitated, sitting in its usual posture, and extremely sensible to any injury inflicted on any part of it. This experiment, however, is somewhat fallacious; for, if care be not taken, great part of the medulla oblongata remains with the trunk, after the operation. It is well known that insects will survive for some time the loss of the head; and that the trunk in such cases shows unequivocally by its actions that it retains the powers of sensation and volition; for the brain in animals of that class is not situated in the head, but near the œsophagus. Yet in many of the vermes these indications are afforded by each portion into which the body is divided. It may be concluded from these and other similar facts, that although in the larger animals the brain appears to be the principal source and seat of the sensorial powers, yet that the exercise of these powers is not absolutely confined to that organ, but extends, in a great number of animals, to the spinal marrow, and that this is more and more the case as we descend in the scale of animals. No evidence as yet exists of the degree in which this extension takes place in man, and we are obviously precluded from ascertaining it by any direct experiment.

Unity of the sensorium incapable of proof. Although the unity of the power of perception of which we are conscious, naturally suggests the idea of some central organ in which the corresponding corporal impressions may be united, it is yet obvious that the necessity of such a union of parts does not admit of proof; and that it may be very possible to conceive the different parts of the sensorium disseminated among the organs at considerable distances from each other, and still to be capable of performing their functions, provided they were in sufficient correspondence with each other by nervous connexions.

Requisite conditions in the Sensorium. The physiological conditions of the sensorium necessary for the exercise of the sensorial powers, besides the proper organization, chemical composition, and temperature, are freedom from compression, and a due supply by circulation of blood having the arterial qualities. Galen had proved by experiment that the ligature of both carotids in animals produced but little inconvenience; the circulation being in that case kept up by the vertebral arteries. Richerand succeeded in placing a ligature around these arteries, after the carotids had been tied, in a dog. Death in a few seconds was the consequence of this total interruption of circulation in the brain. In fainting, the loss of sensibility proceeds, in like manner, from the deficiency of blood in the brain. The insensibility which supervenes on the interruption to respiration is owing to another cause, namely, the presence of venous or carbonized blood in the arteries of the brain, in consequence of the circulating fluid being prevented from undergoing the usual salutary changes in the lungs. A similar loss of power in the spinal marrow is the consequence of depriving it of its circulating blood. This is proved by an experiment of Steno's, in which the tying of the aorta at the first lumbar vertebra was soon followed by paralysis of the posterior part of the body. Le Gallois, on repeating the experiment, found that if, after this

Physiology. effect had been completely produced, the ligature be removed, the powers of sensation and motion were gradually recovered, in proportion as the circulation was restored. He found also that the nervous and sensorial powers may be preserved even in a small portion of the trunk isolated from the rest of the system, by keeping up the circulation in that part, for which purpose, the maintenance of artificial respiration, and previous decollation, are indispensable. He seems to think that each portion of the spinal marrow might thus be made a separate centre of sensation and of life. In dogs, Sir Astley Cooper found that a ligature upon the aorta produced only slight weakness in the hinder extremities.

The necessity of a renewal of blood differs considerably in degree in different classes of animals. The amphibia are well known to be remarkably tenacious of life, in all its leading features. Both the nervous and the sensorial powers remain entire, in these animals, for a considerable time after the heart has been taken out, and the vessels drained of their blood. It has been found, indeed, by Dr Philip, that an obscure kind of circulation is kept up in the capillary vessels, after their communication with the heart is intercepted; but it appears probable that even this imperfect circulation, or rather oscillation of fluids in the vessels, must be exhausted in a much shorter period than that during which we see the nervous functions still survive. Greater tenacity of life exists in the nervous systems of animals in proportion as they are young: and it appears to be greater in the smaller than in the larger mammalia. The head of a rabbit, when severed from the trunk, shows signs of sensibility by the motion of the eyes and jaws, which latter are repeatedly opened and closed, as if vainly gasping for breath. Le Gallois observed, in rabbits decapitated on the day of their birth, that these movements continued for about twenty minutes. If the operation be performed at the end of fifteen days, they do not last above three minutes: and in rabbits of a month old, they cease in one minute, or in a minute and a half. The period during which sensibility remains in the trunk is generally less than in the head: but in both it is considerably longer in young than in adult animals.

Secretion, the Effect of a peculiar Power; V.—SECRETION, and other organic changes taking place in the living body, imply a complex series of operations, which the present state of our knowledge affords us no adequate means of analyzing satisfactorily. It is conceivable that a simple mechanical process, analogous to filtration, might effect the separation of some of the simpler fluids, such as serum, from the blood; a purpose which would be answered by a finer set of vessels, admitting only the passage of the thinner portions of the blood. Such a process would, therefore, imply only the mechanical agents and forces concerned in the circulation, and the organization of some of the secreting organs appears well adapted to this simple object. The existence of minuter series of capillary vessels in these organs has been established by an experiment of Bleulaud's, who injected, through the mesenteric arteries, a mixture of two differently coloured fluids, and found that the thinner fluid had penetrated into a net-work of

*Physiology.* vessels of a different order from those admitting the thicker fluid; and their course could be traced as they arose from the minute arteries, and terminated in the veins. But this explanation can apply but to very few of the animal secretions; since by far the greater number exhibit changes of chemical composition quite independent of mechanical separation.

No anatomical examination of the minute structure of secreting organs can be expected to throw much light on the means employed in this process, because those means transcend mere mechanism. The series of vessels, which, ramifying into tubes of smaller and smaller diameter, must have the effect of subdividing the blood, as by a strainer, to a certain degree of tenuity, probably prepare it for the changes it is to undergo in that part of the process in which the real chemical change consis; but farther than this we cannot venture to speculate, since we, in most cases, know so little what are the exact changes produced, and still less what are the particular affinities which must be called into play in effecting these changes. Their operation probably takes place in the parts where the vessels terminate, and beyond the influence of the power which propels the blood; for they occur in insects, in the system of which, it is now well ascertained, no circulation of blood exists, nor can even any vessels be traced, except such as convey air.

as also  
Nutrition,  
Growth, &c.

The appropriation of the materials thus elaborated to the purposes of growth, and the reparation of the solid structures of the body, is another stage of the same mysterious process, to the solution of which no conceivable mechanical or chemical hypothesis is at all adequate. The analogy of crystallization, although referred to in the celebrated definitions of Linnæus, is far too vague and remote to engage our serious attention: the growth of an animal or a plant being a phenomenon of a totally different class from the accretion of a stone or the shooting of a crystal. The phenomena of secretion and nutrition, inexplicable as they are at present, are sufficiently allied to each other to justify our reference of them to the same general head, until the progress of discovery may enable us to establish correct distinctions between them. Bichat, who has classed them together, subdivides them into two orders, as effects of *organic sensibility* and of *insensible organic contractility*, implying a distinction for which there appears to be no clear foundation. The terms themselves are inappropriate: we have already objected to the extension of the term *sensibility* to changes of which sensation forms no part; and *contractility* is, for the same reason, improperly implied to any organic phenomena in which contractions are neither apparent nor necessarily implied. We have selected the term *organic affinities* as best adapted to express the powers which produce these organic changes. Whether the coagulability of certain animal fluids, such as the blood, ought to be ranked under this head, or be regarded as a new and specific power, might perhaps admit of discussion; but we have not room to enlarge upon this question.

and Animal  
Tempera-  
ture.

Increase of temperature is a phenomenon commonly attendant on the exercise of the organic affinities; that is, it usually accompanies the chemical

changes that are continually taking place in the living body. It is evidently, however, only a concomitant, not an essential circumstance; for in some cases the contrary takes place, and a reduction of temperature occurs. It has lately been the fashion to speak of caloric as being a secretion, and to regard its evolution as a phenomenon referable to the class of secreting processes. The chemical theories that formerly prevailed with regard to animal temperature have, no doubt, been in some measure shaken by the experiments of Mr Brodie and of Dr Philip; but they are, perhaps, not so completely overthrown as some would endeavour to persuade us.

VI.—Having thus endeavoured to trace the distinctive characters of each of the classes of vital powers, we have further to inquire into their mutual connexions and relative dependencies on each other.

Mutual Con-  
nexions of  
the Vital  
Powers.

Physiologists have endeavoured in vain to discover whether any one of these powers might be considered as the source of the rest. The evolution of the embryo has been anxiously studied with a view to this question. The first powers that appear to be called forth in the original development of parts are the organic affinities; but, long before the period to which any accurate observation can reach, the muscular and the nervous powers have both displayed their energies. Already has the *punctum saliens* vibrated to the excitements of the fluid which it urges forwards; and the spinal marrow and brain, yet in a semifluid state, have already exerted their influence on the nascent organization. Tiedemann has bestowed great pains in the investigation of the successive stages of evolution of the nervous system in the fœtus, and has surmounted many difficulties which had stopped the progress of former inquirers. The late researches of Mr Serres have also brought to light many new facts. An abstract of the labours of these anatomists is given by Béclard. The first part of the nervous system that appears to be formed, or at least that can be distinguished, is the spinal marrow, the upper extremity of which is slightly enlarged. The formation of the brain succeeds, but this organ remains long very little developed in comparison with the spinal marrow; in the more advanced periods of gestation it increases rapidly in size. The sensorial powers are evidently not developed till the others have been matured, and till the frame-work of the body has made considerable advances towards its perfect state.

Phenomena  
of Evolu-  
tion,

The origin of the vital powers being thus veiled in impenetrable obscurity, the inquiry has been directed to the order of their extinction on the approach of death. But here, also, very little satisfactory information can be gleaned. We learn, however, that the sensorial powers, as they were the last to be developed, are invariably the first to disappear; for their continuance seems to require the most perfect co-operation of the sanguiferous and nervous powers. But the nervous power survives their destruction, and is still capable of performing all its functions, except that it can no longer give evidence of conveying impressions to the sensorium, since the functions of the sensorium are abolished.

and of  
Death.

Physiology. No impression made on any part of the body is perceived, nor followed by any visible act of volition. The muscular power still remains, for if either the heart, or the muscles of voluntary motion be stimulated, they possess the power of contracting; a power which they lose only by slow degrees, a considerable time after the sensorial power has ceased to exist. It is also manifest that a certain portion of nervous power still remains; for if the nerves themselves, or those parts of the brain and spinal marrow from which they originate, be irritated, the corresponding muscles will be thrown into action—a proof that the nerves retain the power of conveying impressions. Haller made a variety of experiments to ascertain the comparative permanence of the irritability of different muscles; and a still more numerous series with the same view has been lately made by Nysten, in his *Recherches de Physiologie, et de Chimie Pathologique*. The order which he establishes is somewhat different from that of Haller; but it varies according to the mode of death, and the nature of the stimulus employed as a test. There is, however, no doubt that in the more perfect animals, the vital powers are so connected, that no one can exist long without the others. They are all, more or less, dependent for their continuance on the uniform supply of blood having the arterial qualities: a condition which involves the continuance of the circulation and of respiration; two functions, again, for the exercise of which the muscular power is essential. Thus an interruption to any one function soon reacts in a circle upon all the others, and involves in a common destruction all the vital energies; nothing remaining but those properties which the parts of the body possess in common with inert matter, and which are immediately dependent on their mechanical and chemical constitution.

Although, by this reciprocation of functions, the vital powers are intimately connected with one another, it is still very conceivable that they may all of them be essentially independent of each other: and this is perhaps the simplest hypothesis that the subject admits of. Setting out, then, with this supposition, it remains to be seen what modifications it must undergo. The sensorial power, it is evident, can never be manifested but through the medium of the nervous power; yet it may be conceived as existing separately and independently, although all proof of its separate existence is wanting. Muscular irritability, and the organic affinities are also considerably influenced by the nervous power; but it is not easy to determine the nature and extent of their connection. Prior to the time of Haller, the nervous system was considered as the general source of power in the body; and the contractile power of the muscles was regarded as derived altogether from this system, which was supposed to transmit this power to the muscular fibre in proportion as it was called for, and to regulate the quantity supplied. Haller, as we have seen, contended for the existence of a *vis insita*, or power essentially residing in the muscles themselves, independently of any condition of the nervous system, and only called into action by stimuli, of which, in the case of the voluntary muscles, the nervous influence is one, contributing, like all

other stimuli, to exhaust it, instead of furnishing any fresh supply. Meckel adopted a sort of intermediate opinion, regarding the nervous influence as one of the conditions necessary for muscular contraction, just as the due circulation of blood is one of those conditions; and, at the same time, admitting the separate existence of a *vis insita*.

Upon the Hallerian doctrine of the independence of irritability, it is easy to explain the fact that a muscle detached from the body, such as the heart, will still contract when stimuli are applied. If all the nerves supplying the limbs of a frog be divided, and cut out close to the place where they enter the muscles, the latter still retain their contractility in as great a degree as when the nerves are entire. To this it has been replied, that the stimulus may still act through the medium of the portions of nerves that must always remain attached to the muscle, however carefully we may endeavour to dissect them away; and which nervous fibres may perhaps even constitute an essential part of the muscular fibre. This objection, though often urged, was never satisfactorily answered by Haller. Dr W. Philip has endeavoured to remove it by the following experiment, made with a view to ascertain whether a similar exhaustion of irritability would arise if the excitation of a muscle were produced through the medium of the nerves, or by other stimuli. "All the nerves supplying one of the hind legs of a frog were divided, so that it became completely paralytic. The skin was removed from the muscles of the leg, and salt sprinkled upon them, which being renewed from time to time, excited contractions in them for twelve minutes; at the end of this time they were found no longer capable of being excited. The corresponding muscles of the other limb, in which the nerves were entire, and of which consequently the animal had a perfect command, were then laid bare, and the salt applied to them in the same way. In ten minutes they ceased to contract, and the animal had lost the command of them. The nerves of this limb were now divided, as those of the other had been, but the excitability of the muscles, to which the salt had been applied, was gone. Its application excited no contraction in them. After the experiment, the muscles of the thighs in both limbs were found to contract forcibly on the application of salt. It excited equally strong contractions on both sides. In this experiment the excitability of the muscles whose nerves were entire was soonest exhausted. From this experiment it is evident that the nervous influence, far from bestowing excitability on the muscles, exhausts it like other stimuli. The excitability, therefore, is a property of the muscle itself." (*Experimental Inquiry*, 2d edit. p. 99.)

While the theory of Haller so easily explains the phenomena of the voluntary motions, many difficulties lie in the way of its application to the actions of the involuntary muscles, such as the heart, blood-vessels, stomach, intestines, gall-bladder, &c. These latter organs are usually excited to contract by stimuli of a mechanical or chemical nature applied directly to them, and generally by the mere distension resulting from the accumulation of their contents.

Physiology.

Independence of Muscular Contractility.

Difficulties attending the Hallerian Theory.

Physiology. But if these were the only occasions which called them into action, what uses must be assigned to the cardiac nerves, which establish a connection between the heart and the nervous system; and how it is subject to the influence of the passions, except through the medium of the brain or sensorium, acting through the intervention of these nerves? On the other hand, it is asked, if the nervous power, derived from the brain, be essential to the motion of the heart, how is the circulation maintained in acephalous monsters; and how are we to account for the fact that the interruption of all communication between the brain and the heart does not stop the motion of the latter? The theory of Haller explains perfectly these latter circumstances, but does not accord with the former: the opposite view of the subject is consistent with the former, but is opposed by the latter set of phenomena.

Influence of the Nervous System on the Heart.

Various opinions have prevailed at different times as to the influence of the nervous system on the motions of the involuntary muscles, and especially of the heart; for an account of which we shall refer our readers to the report made to the class of Physical and Mathematical Sciences of the Institute of France, on the work of M. le Gallois, entitled, *Expériences sur le Principe de la Vie, notamment sur celui des Mouvements du Cœur, et sur le Siège de ce Principe*, and of which a translation is given in Dr Philip's *Experimental Inquiry*. Le Gallois conceived that he had proved that the power of the heart is derived altogether from the spinal marrow, and not, as formerly supposed, from the brain. The following are the leading facts from which he draws this inference. He found that, by crushing the spinal marrow, the power of the heart is so enfeebled, that it can no longer propel the blood; but that, after the removal of the brain, the power of the heart still continues, and may even be preserved a considerable time by artificial inflation of the lungs, after the whole head has been separated from the body. He was thus at no loss to explain the use of the cardiac nerves; the heart being influenced by the spinal marrow through their intervention, and being also subject to the influence of the passions, because the spinal marrow is itself influenced by the brain. Dr Philip has shown that the above facts by no means warrant these inferences, and has established satisfactorily, by direct experiment, that the brain has just as much influence over the motions of the heart as the spinal marrow has, when the circumstances of the experiment are precisely the same. The removal of the spinal marrow, like that of the brain, if the experiment be performed with caution, and by slow degrees, does not sensibly affect the motion of the heart, the animal being previously deprived of its sensibility. In these experiments the circulation ceases quite as soon without as with the destruction of the spinal marrow. Loss of blood seems to be the chief cause of its cessation; and pain would also contribute to the same effect, if the animal were operated on without being rendered insensible. The results are the same in frogs, only they are more distinct, because less immediately affected by the loss of blood. In these animals, if the head and spinal marrow be removed, the heart con-

Physiology. tinues to perform its functions perfectly for many hours, and seems not to be immediately affected by their removal. Mr Clift made a series of experiments to ascertain the influence of the spinal marrow on the action of the heart in fishes, and found that, whether the heart be exposed or not, its action continues long after the spinal marrow and brain are destroyed, and still longer when the brain is removed without injury to its substance.

On the other hand, when the brain is suddenly crushed, as by a blow, which at once destroys its texture, the power of the heart is instantly so enfeebled, that it can no longer propel the blood. The same effect takes place if a similar injury be inflicted on the spinal marrow, as happened in Le Gallois' experiments. Dr Philip reports, that when the brain of a frog was crushed by the blow of a hammer, "the heart immediately performed a few quick and weak contractions. It then lay quite still for about half a minute. After this, its beating returned, but it supported the circulation very imperfectly. In ten minutes its vigour was so far restored that it again performed the circulation with freedom, but with less force than before the destruction of the brain. The spinal marrow was then crushed by one blow, as the brain had been. The heart again beat quickly and feebly for a few seconds, and then seemed wholly to have lost its power. In about a minute and a half it again began to beat, and in a few minutes acquired considerable power, and again supported the circulation. It beat more feebly, however, than before the spinal marrow was destroyed. It ceased to beat in about an hour and a half after the brain had been destroyed." In common cases of hemiplegia, the muscles carrying on the vital functions are seldom impaired: and Dr Cheyne of Dublin relates a case in which, while one half of the body was paralyzed, the uterus performed its function perfectly, by acting so as to expel a living fetus.

It has generally been imagined that the action of the heart cannot be influenced by stimuli applied to the brain or spinal marrow; for it would seem an inconsistency to hold this opinion, and at the same time to admit that it is not influenced by the total removal of those organs. But Dr Philip found that the application of alcohol to the brain or to the spinal marrow of a rabbit, produced immediately a great increase in the action of the heart. An effect of the same kind, but in a much smaller degree, took place from the application of a watery solution of opium, and a still smaller effect from an infusion of tobacco. The increased action which had been excited was soon succeeded by a more languid action of the heart, than that which had existed before the application was made. Little or none of the debilitating effect was observed when alcohol was used, and the action of the heart, in this case, returned to its usual state. Effects in every respect similar were observed to take place, when the same experiments were repeated on frogs.

It appears, then, that there is no essential difference between the irritability of the muscles of voluntary and of involuntary motion, in as far as their independence on the nervous system is concerned; Effects of different Stimuli.

Physiology. but yet they are influenced by different stimuli, or at least by stimuli applied in different ways. Hence the laws which regulate the effects of stimuli applied to the brain and spinal marrow on the heart and muscles of voluntary motion are different. Mechanical stimuli, such as cutting instruments, applied to the brain or spinal marrow, produce no effect on the muscles of voluntary motion, unless they are applied to those parts where the nerves originate; they then excite the most violent spasmodic actions. The heart, on the other hand, is but slightly accelerated in its motion by mechanical injury done to the brain or spinal marrow, in what part soever that injury be inflicted; but the heart is affected in proportion to the extent of the parts that are injured. It is most excited when the brain is wounded rapidly in many directions. Chemical stimuli, on the contrary, such as alcohol, applied to any part of the brain or spinal marrow, produce considerable and immediate increase of the motion of the heart; while the voluntary muscles are, at the same time, not at all affected, and the animal betrays no sense of pain. The general conclusion to be deduced from these facts is, that the heart is excited by all agents applied to any considerable part of the brain or spinal marrow, while the muscles of voluntary motion are excited only by more powerful agents applied to certain definite parts of these organs. Hence we may easily derive the explanation of the apparent anomalies formerly mentioned. The heart may continue its action when removed from the body, and when no brain or spinal marrow exists, because it has no direct dependence on any part of the nervous system. It is supplied with nerves, and subject to the influence of the passions; because, although independent of this system, it is capable of being influenced through it, especially by such causes as, like the passions, affect a considerable portion of the nervous system.

The same conclusions, derived from a series of analogous experiments, are found applicable to the powers of the vascular system employed in carrying on the circulation, and even to those of the minutest vessels which can be seen by a powerful microscope. The doctrine, indeed, may be extended generally to all the muscles of involuntary motion, or those parts possessing what Bichat would call *contractilité organique sensible*. The irritability of the stomach and intestines, from whence arises their peristaltic motion, is, like that of the heart and blood-vessels, independent of the nervous system, though capable of being influenced through it. It survives the destruction of the spinal marrow, and of the brain, or of both these organs. In rabbits the peristaltic motion continues till the parts become cold; so that, when the intestines exposed to the air have lost their power, that of those beneath still remains. The effects of the passions on the alimentary canal leave no room to doubt that its muscular fibres are capable of being stimulated by the direct influence of the nerves. But, from the extreme irregularity of their movements, we cannot so well ascertain whether they are subject to the influence of the different parts of the brain and spinal marrow, as in the case of the heart and blood-vessels.

Respiration is a function which requires for its

perfect performance the combined agency of three Physiology. great classes of vital powers, the sensorial, the nervous, and the muscular. It ceases immediately on the destruction of the sensorial power; a fact which is unexplained on the hypothesis of Le Gallois, that the nervous power alone is concerned. How it happens, that, after decapitation, the movements of inspiration are the only set of actions relating to this function that are annihilated, while the rest remain, is, according to that physiologist, "one of the greatest mysteries of the nervous power, the revealing of which would throw the strongest light upon the mechanism of the functions of this wonderful agency." The difficulty vanishes, according to Dr Philip, if we admit the sensorial power as acting a part in this process, and as being necessary to call into action the nervous and muscular powers. He considers the muscles of respiration as, in the strictest sense, muscles of voluntary motion. By a certain sensation originating in the lungs, a wish is excited to expand the chest. This is an act of the sensorium, and until it takes place, the nervous as well as the muscular power, by which its expansion is affected, remain inert. It is in vain that these powers survive, if the power which calls them into action be lost. Thus we can understand why the removal of the brain, or the injury to that part of the brain where the par vagum originates, or the division of the spinal marrow above the origin of the phrenic nerves, immediately puts a stop to respiration, and the animal perishes unless the lungs be artificially inflated.

The number of muscles which have a relation to this function, and which may occasionally be called into play as auxiliaries, when, in consequence of some impediment to the natural motions, the muscles usually employed are inadequate to produce the full expansion of the chest, is extremely great. "When a post horse," says Mr Bell, "has run its stage, and the circulation is hurried, and the respiration excited, what is his condition? Does he breathe with his ribs only; with the muscles which raise and depress the chest? No. The flanks are in violent action; the neck as well as the chest is in powerful excitement; the nostrils as well as the throat keep time with the motion of the chest. It is quite obvious that some hundred muscles thus employed in the act of breathing, or in the common actions of coughing, sneezing, speaking, and singing, cannot be associated without cords of connection or affinity, which combine them in the performance of those actions: the nerves which serve this purpose I call the respiratory nerves." Some of the peculiarities in the structure of these nerves have already been noticed. The following are enumerated by Mr Bell as composing this system; the par vagum; the portio dura of the seventh pair, or respiratory nerve of the face; the spinal accessory nerve, or superior respiratory nerve of the trunk; the phrenic, or great internal respiratory nerve; the external respiratory nerve: and also, the glossopharyngeal nerve, or ninth of Willis, and the branches of the par vagum to the superior and inferior larynx. Mr Bell has deduced his theory from a great number of experiments made on animals. Thus, on dividing the portio dura on one side of the head, in an ass,

Physiology. the motion of the nostril accompanying respiration immediately ceased on that side, while the other nostril continued to expand and contract in unison with the motions of the chest; and sneezing took place only on that side. But the voluntary motions of the lips, and other parts of the face, remained on both sides, and the animal could eat without impediment. The reverse took place on the division of the superior maxillary branch of the fifth pair; no change occurred in the motion of the nostril; the cartilages continued to expand regularly in time with the other parts which combine in the act of respiration, but the side of the lip was observed to hang low, and it was dragged to the other side. When the nerves on both sides were divided, the power of elevating and projecting the lips, necessary for gathering food, was lost. The effects of partial paralysis, which affects sometimes one set of nerves, and sometimes another, strikingly illustrate the truth of Mr Bell's theory, and have been accurately traced by Mr Shaw, in his papers in the *Journal of Science*, and more recently in a Memoir published in the twelfth volume of the *Medico-Chirurgical Transactions*.

Influence of Nervous Agency on the Organic Affinities.

It remains to be inquired, whether the organic affinities which give rise to the phenomena of secretion, nutrition, and animal temperature, are in immediate subordination, or are only occasionally under the influence of the nervous power. In as far as the materials on which the observed chemical changes are produced by the operation of these powers, are furnished to the secreting organs by the blood-vessels, secretion must evidently be influenced by all those causes which affect the circulation; many of which causes, we have seen, act through the medium of the nervous system. But with regard to that part of the process, which is conducted after the fluids have passed out of the capillary vessels, it is conceivable that they may still be carried on after the circulation has ceased, and may be influenced by totally different causes. The evidence of such processes being continued after the circulation is at an end, is obscure and defective. Stories have been told of certain secretions occurring after death; and of the hair and nails continuing to grow; but they have seldom been stated on authority to which any credit can be attached. Majendie, however, reports the fact of these parts growing for several days after death; and states, that he has seen a similar phenomenon with respect to the secretion of mucus. If the power which effects secretion, be independent of the other vital powers, these facts would admit of explanation; for it might survive the destruction of the vital powers for a certain period, in the same way that muscular contractility survives for a short time, the destruction of the sensorial and nervous powers. Hunter suspected that a vital action, referable to this class, continued in the stomach for some time after death, occasioning "an action and probably a secretion in the stomach." This he inferred from the well known fact that the coats of the stomach are often found digested, when examined after death. But Dr Philip remarks that this phenomenon is evidently the effect of a chemical, and not a vital process.

Dr Philip, who has so ably supported the doc-

Physiology. trine of the independence of the muscular and nervous powers, has advanced an opinion directly the reverse of this with regard to the power of secretion, which he maintains is completely dependent on the nervous power. Such is the inference he deduces from a series of numerous experiments on the effects of dividing the par vagum on both sides of the neck in warm-blooded animals, and particularly in rabbits, in performing which, he was assisted by Dr Hastings. If this be done with proper precautions, the secretion of the gastric juice, and, consequently, the process of digestion is entirely suspended: great difficulty of breathing succeeds, and the air-cells of the lungs, with the bronchiæ, become clogged with a frothy mucus. Mr Brodie had already found that arsenic introduced into the system, after the division of these nerves, does not produce the copious secretion from the stomach and intestines, which it is found to do under ordinary circumstances; and he met with a similar result when he divided the stomachic nerves immediately above the cardiac orifice of the stomach. The destruction of any considerable portion of the spinal marrow also deranges the secreting power of the stomach. When the nervous influence is withdrawn, the capillaries continue to convey fluids to the secreting organs, because their action is independent of that influence: but the changes constituting secretion no longer take place; it is thence inferred, that the power of secretion is immediately dependent on the nervous power. Dr Alison, on the other hand, has contended, in some very ingenious essays published in the *Journal of Science*, that this is not a legitimate inference because, in the experiment of the division of the par vagum, other causes than the interruption of the influence of the brain, such as the immediate injury done to the nerves by the act of dividing them, might be assigned for the observed effects of this operation on secreting surfaces. Mr Shaw thinks, that the only inference that can be drawn from the phenomena of this experiment is, that, in consequence of the bond of connection between the stomach and the organs of respiration and circulation, being destroyed, the functions of the stomach will necessarily be more or less disturbed.

Dr Philip has been further led to conclude, that galvanism is identical with the nervous agency. This opinion is founded on the result of the experiments we have already alluded to, in which the galvanic influence, transmitted through the lower portions of the divided par vagum, restored the secretion of the gastric juice, and the digestion of the contents of the stomach, which would otherwise have ceased. The accuracy of the experiments was for a long time disputed, but has lately been satisfactorily established by their careful repetition at the Royal Institution, by Dr Philip, in conjunction with Mr Brodie. But though the fact be admitted, there appears reason to doubt whether it warrants the conclusion, which Dr Philip has boldly drawn from it, relative to the identity of the nervous and galvanic agencies. Dr Alison, in the papers above alluded to, has discussed this question with great acuteness. Our limits preclude us from entering into the arguments employed in the controversy. We shall only, therefore, add, that Dr Philip ascribes the

Physiology. evolution of animal heat to the operation of the nervous power, and endeavours to show, by experiment, that the galvanic influence occasions an evolution of caloric from arterial blood, if subjected to it as soon as it leaves the vessels, but that it produces no such effect on venous blood; and also that the destruction of any considerable portion of the spinal marrow is followed by a reduction of the temperature of the animal.

Nervous Communications by Ganglions, &c. In order that any one set of organs may be subjected to the influence of every part of another set, it is necessary that some very extensive mode of nervous communication should exist between them. Such appears to be the object of that complex system of ganglionic nerves, of which the branches of the great sympathetic compose so large a portion. All the organs which have muscles of involuntary motion, and which, as we have seen, are influenced by every part of the brain and spinal marrow, receive nerves from a chain of ganglions, to which filaments of nerves from all the parts of the brain and spinal marrow are sent. Thus the nerves issuing from those ganglions are made up of filaments from an infinite number of sources, and transmit to the organs in which they terminate the united influence of all the nerves which the ganglions have received from the brain and spinal marrow. Each ganglion may accordingly be regarded as a secondary centre of nervous influence, receiving supplies from all the parts of the brain and spinal marrow, and conveying to certain parts the united influence of these organs. On the other hand, as the muscles of voluntary motion are to be subjected to the influence of only small portions of these central parts of the nervous system, they receive their nerves directly from those parts; generally without the intervention of ganglia, and with comparatively few intermixtures of nervous filaments. The system of ganglionic nerves appears to be quite as extensive as that of nerves proceeding directly from the brain and spinal marrow. These views, developed by Dr Philip, are directly opposed to those of Bichat, who maintains that the ganglions are centres of nervous influence, independent of the brain and spinal marrow, and incapable of transmitting their influence; but they coincide with Bichat's opinion, that the great sympathetic derives its origin from the spine and not from the brain, with which it has only very slender communications.

General Conclusion. We have thus attempted to delineate the characters of those powers by which the living animal body is distinguished from those of the inert materials that enter into its composition, and of which the combined effects constitute what is called *life*; and we have further endeavoured to investigate the laws of their mutual connections and dependencies. If the views we have presented are correct, they will enable us to detect the fallacy of those definitions of the vital principle, which have been from time to time advanced, in violation of the just rules of philosophical induction. The real state of the science does not yet authorize that degree of generalization which these definitions would imply. We are not warranted by the phenomena already known, in regarding life as the effect of any single power.

Physiology. The attempts of Brown, of Hunter, and of Bichat, to reduce the science to this state of simplification are premature, and have been the means of retarding, instead of promoting, the progress of real knowledge. The error has sometimes been that of generalizing partial views; so that one class of facts has been assumed as comprehending all the rest; but most frequently it has consisted in including a variety of dissimilar phenomena under the same common principle. We may take as an instance of the former, the definition of Le Gallois, which takes cognizance only of the nervous power, as if this were the sole characteristic of life. "Life," says he, "is owing to an impression made by arterial blood on the brain and spinal marrow, or to the principle which results from this impression;"—a definition which would totally exclude the life of animals that have neither brain, nor spinal marrow, nor arterial blood, nor circulation, which is the case with so large a proportion of beings in the inferior ranks of the animal creation. As an example of the latter error, we may adduce the language of Hunter, who talks of life as the effect of a peculiar and subtle matter, the *materia vitæ diffusa*; a hypothesis analogous to those in natural philosophy, by which the phenomena of matter are attempted to be explained by the intervention of an ethereal fluid, diffused throughout all space. To pursue these speculations, would be to wander in the regions of visionary hypothesis, where fancy assumes the garb of science, and where truth is obscured by the clouds of mysticism. The attempt to reduce the vital phenomena to a single law, is as vain as would be a similar endeavour with regard to the phenomena of the inorganic world. The effects of gravitation, electricity, magnetism, cohesion, elasticity, and chemical affinity, have been sometimes regarded as modifications of a single principle of *attraction*. But this is a simplification not warranted by the facts; although future researches may possibly enable us to recognize the identity of some of these principles with others. The recent discovery of Professor Cæsted, indeed, entitles us to hope that such will ere long be the result with regard to electricity and magnetism. In like manner, the muscular, the nervous, the sensorial, and the organic powers, may be established as separate agencies in the living body; and no speculative ingenuity is able to reduce them to a single power; unless, indeed, we call to our aid another and a totally different class of relations, namely, those which they bear to the general object they concur in producing. But against such a substitution of final for physical causes, we have already entered our serious protest. The latter are the only legitimate objects of philosophical analysis, and no other can furnish a solid basis for the physical sciences. This foundation being once firmly established in physiology, subsequent inquiries will consist in the analysis of complex phenomena into the several principles from which they result; and we may then pursue with safety the more fascinating study of final causes, and trace the admirable subordination of purposes, and the skilful combination of means for attaining distant ends, which marks the whole series of phenomena presented to us by living beings. (w.)

PHYSIOLOGY OF VEGETABLES. See VEGETABLE PHYSIOLOGY.

PINDARIES. See INDIA.

PLAYFAIR (JOHN), a Mathematician and Philosopher of great eminence and celebrity; and so peculiarly a benefactor to this publication, as would have made it fit that some memorial of him should be preserved in these pages, even if it could have been surmised that it might not have been found in any other place. There are few names, however, in the recent history of British Science that are more extensively or advantageously known, or of which the few particulars that remain to be recorded will be more generally interesting. His life, like most others that have been dedicated to the silent pursuits of learning and science, does not abound in incidents or adventures; but it is full of honour, both for the individual and the studies to which he was devoted, and may be read with more profit than many more ambitious histories.

He was the eldest son of the Reverend James Playfair, minister of Benvie, in Forfarshire; in which place he was born on the 10th of March 1748. He resided at home, under the domestic tuition of his father, till the age of fourteen, when he entered at the University of St Andrews; and was almost immediately distinguished, not merely for his singular proficiency in mathematical learning, but for the extent of his general knowledge, the clearness of his judgment, and the dignity and propriety of his conduct. A remarkable testimony to this effect has been lately made public in an early Letter of the late Principal George Hill, who was, at this time, one of his fellow students, and was himself so remarkable for early talent, that we find it recorded of him, that he had privately composed an excellent sermon in the tenth year of his age! A youth of this description cannot be supposed to have been very indulgent in his estimate of the merits of his competitors; and it could, therefore, have been no ordinary measure of ability that called forth the following ingenuous avowal, in a confidential Letter to his mother: "Playfair has very great merit, and more knowledge and a better judgment than any of his class fellows. I make no exceptions; my parts might be more showy, and the kind of reading to which my inclination led me, was calculated to enable me to make a better figure at St Andrews; but in judgment and understanding I was greatly inferior to him." (Dr Cook's *Life of Principal Hill*.) It is scarcely a stronger, though undoubtedly a very different proof of his rare attainments, that when the Professor of Natural Philosophy, Wilkie, the once celebrated author of the *Epi-  
goniad*, was prevented by indisposition from delivering the regular lectures, he used generally to delegate the task of instruction to his youthful pupil. Wilkie, besides being a scholar and philosopher of no mean note, was a man of primitive benevolence and integrity, and of great vivacity in conversation; and the friendship which, in spite of the disparity of their years, was speedily formed between him and young Playfair, speaks as much for the social and moral character of the latter, as his substitution of him in the class-room does for his early

proficiency in science. On this last subject we shall mention but one fact more. In 1766, when only eighteen years of age, he offered himself, with the approbation of his instructors at St Andrews, as candidate for the Professorship of Mathematics in Mareschal College, Aberdeen, and sustained, with the most distinguished credit, an examination or comparative trial, which lasted eleven days, and embraced nearly the whole range of the exact sciences. Out of the six competitors who entered the lists against him, two only were judged to have excelled him,—the Reverend Dr Trail, who was appointed to the office, and Dr Hamilton, who afterwards succeeded to, and has long filled it with much reputation.

In 1769, he removed to Edinburgh, where his merit and modesty very soon introduced him to the friendship of Dr Robertson—Adam Smith—Dr Matthew Stewart—Dr Black, and Dr Hutton; with all of whom he continued in terms of the utmost cordiality during the whole period of their lives. In 1772, he was a candidate for the Professorship of Natural Philosophy at St Andrews, vacant by the death of his friend Dr Wilkie. There was no comparative trial on this occasion; and he was again unsuccessful—under circumstances, which have led one of the most dutiful sons of that University (Dr Cook, in his *Life of Principal Hill*) to remark, "how much it suffered in thus losing a man, by whose talents its reputation would have been so highly promoted." In the course of the same year, the death of his father suddenly devolved upon him the burden of supporting the family, and admonished him no longer to delay the final election of a profession. He had been educated with a view to the Church, and was every way qualified to accept a living on the establishment; but his decided predilection for science had hitherto made him hesitate about engaging in a vocation, the duties of which, he felt, if conscientiously discharged, would necessarily interfere, to a great extent, with the studies he was loth to abandon. In this emergency, however, he thought himself no longer entitled to indulge in those predilections—and, accordingly, made application to Lord Gray, the patron, for a presentation to the livings of Liff and Benvie, which had been filled by his father. His Lordship was too well aware of his merits to hesitate about conferring so great a benefit on the parishioners; and immediately issued a presentation in his favour, although, from some challenge of his right to the patronage, induction was not obtained till late in the year 1773.

From this period, till 1782, Mr Playfair was constantly resident at Liff, and occupied almost exclusively with the pastoral duties of his office. In this retreat, his leisure hours were dedicated to the education of his younger brothers, and to a very close and intimate correspondence with Mr Robertson (now Lord Robertson), the son of the illustrious historian, to whom he seems to have confided the remarks that occurred to him upon the different authors he perused, and the subjects of speculation which they suggested. We cannot help hoping, that some selection from this correspondence may one day be given to the public. In the year 1779, he contributed to the *Transactions of the Royal Society of London* a paper

Playfair.

Playfair. *On the Arithmetic of Impossible Quantities*, which exhibits, within a very small compass, a striking example of the rare and admirable talent of detaching the sound spirit of science from what may be termed its mysticism, and circumscribing, by the most precise and luminous boundaries, the vague and unlimited inquiries into which many mathematicians had been seduced by the nature of the instruments they employed.

In the year 1782 he was induced, by very advantageous offers, to resign his charge, and to superintend the education of the present Mr Ferguson of Raith, and his brother, Sir Ronald; an arrangement which restored him, in a great measure, to the literary and scientific society of Edinburgh, and enabled him to gratify himself by a personal introduction to several of the most eminent cultivators of science in London. He had repeatedly visited Dr Maskelyne, Astronomer Royal, while that ingenious mathematician was busied, in 1774, in making a series of observations in Perthshire on the attraction of mountains; and while sharing the shelter of his tent on the side of Schehallien, contracted with him a cordial friendship, which continued unbroken for the remainder of their lives. Under these honourable auspices, he made his first appearance in London in 1782, and was speedily introduced to all those in whom he was likely to take most interest. He seems to have kept a pretty full and correct journal of all that he observed during this journey to the metropolis; and a portion of it, which is prefixed to the late collection of his works, is, in our judgment, one of the most interesting parts of that publication. It is not only written with great elegance and accuracy, but affords, in the free, candid, and pointed observations which it contains on the different individuals with whom he comes in contact, a very remarkable proof of his quick and sagacious perception of character, and his power of selecting and turning to account, even in the fever and distraction of a first visit to such a scene, all that was really worthy of careful observation or permanent remembrance.

In 1785 he was received into the University of Edinburgh, in consequence of an arrangement between his two illustrious associates, Dr Adam Ferguson and Mr Dugald Stewart. Mr Stewart exchanged the chair of Mathematics, in which he had succeeded to his father, for that of Moral Philosophy, which had been long filled by Dr Ferguson; who, finding that the delicate state of his health would prevent him from discharging the active duties of the mathematical professor, immediately devolved them upon Mr Playfair, for whom he procured the appointment of joint professor in that department.

In 1788 he published, in the *Transactions of the Royal Society of Edinburgh*, "*A Biographical Account of Dr Matthew Stewart*," which is remarkable, not only for the ease and purity of the style, but also for containing a singularly clear and interesting account of the labours of Dr Simson in the restoration of the ancient geometry, and of the success both of him and Dr Stewart in adapting the elegant simplicity of the Greek methods of investigation to problems which had previously been regarded as inso-

luble except by the aid of the modern analysis. He also published, in the same year, a paper *On the Causes which affect the Accuracy of Barometrical Measurements*, which is written with all the perspicuity, caution, and sagacity, that constitute the great excellence and the great difficulty of such disquisitions, where scientific principles are employed to give precision to physical observations.

In 1790 he published in the same *Transactions* a paper of still greater interest and delicacy, *On the Astronomy of the Brahmins*;—a subject which had been recently recommended to the notice of the European scientific world by the curious and learned observations of M. Bailley, in his *General History of Astronomy*, but had never met with so minute and scrupulous an investigation as it now received at the hands of Mr Playfair. The whole treatise is written with a beautiful perspicuity, in an admirable spirit of candour and ingenuity, and in a style more elegant and spirited than had yet lent its attraction to subjects so recondite and abstruse. The publication accordingly attracted very general notice, both in Europe and Asia; and gave rise to much discussion and research, the final value and result of which does not seem to be yet ascertained. This was followed in 1794 by a learned and very beautiful treatise *On the Origin and Investigation of Porisms*, in which the obscure nature of the very comprehensive and indefinite theorems to which this name was applied by the ancient geometers, is explained with the most lucid simplicity; and the extraordinary merits of Dr Simson, in deducing their true theory from the very vague and scanty notices of them which had come down to his time, are commemorated with a noble spirit of emulation.

In 1795 he published his *Elements of Geometry*, for the use of the pupils attending his class; a work which has since been held in such estimation by the public, as to have gone through five editions of 1000 copies each, four of which were called for since the work ceased to be used as a class-book in the University of Edinburgh. In 1797 he composed a sequel to his first paper on the Indian Astronomy, in the shape of *Observations on the Trigonometrical Tables of the Brahmins*; and also a masterly collection of *Theorems on the Figure of the Earth*. It is also understood that he occupied himself a good deal at this time in the preparation of an *Essay On the Accidental Discoveries made by Men of Science while in Pursuit of some other Object*; although we find no portion of this curious discussion in the late collection of his works.

His excellent and ingenious friend Dr Hutton died in the year last mentioned; and Mr Playfair having undertaken to draw up a biographical account of him for the Royal Society, was first led to study his ingenious, but somewhat crude speculations on the Theory of the Earth, and afterwards to lend them the assistance of his own powerful pen in his *Illustrations of the Huttonian Theory*. This work, on which he bestowed more time and labour than on any of his other productions, did not appear till 1802; and it was not till 1803 that he presented to their associates his admirable Memoir of their departed friend.

Whatever opinion may be formed, now or hereaf-

Playfair.

ter, of the truth or soundness of the suppositions by which Dr Hutton endeavoured to explain the actual state and condition of our globe, it is impossible to doubt that Mr Playfair's illustration of that theory must always be ranked among the most brilliant and powerful productions of philosophic genius. The beautiful clearness, and captivating eloquence, with which the system itself is unfolded and explained—the spirit and force of reasoning with which all the objections to it are combated—the skill with which the infinite variety of facts which it brought into view are combined into one grand and legitimate induction—and the judgment and extent of learning by which so many large and profound views of nature are brought to bear upon the points in discussion, and blended into one large and discursive argument, uniting the utmost logical precision with the richest variety of topics, and the highest graces of composition—arc merits which have been universally acknowledged in this performance, even by those who have not been convinced by its reasonings—and have extorted, even from the fastidious critics of France, the acknowledgment that “Mr Playfair writes as well as Buffon, and reasons incomparably better.”

The biographical account of Dr Hutton is by far the best of Mr Playfair's productions in this line, and contains not only an eloquent and luminous account of the speculations in which he was engaged, but what is too often forgotten in this species of biography, a charming portrait of the individual—drawn, no doubt, by a favourable hand, but gaining far more in grace and effect than it can possibly have lost in correctness, from the softening colours of affection.

In 1805 he quitted the chair of Mathematics to succeed Professor Robison in that of Natural Philosophy. The appointment of Mr Leslie, as his successor in the chair of Mathematics, was opposed at the time by a majority of the Presbytery of Edinburgh, and made the subject of very angry discussion, as well in various publications as in the General Assembly of the Church of Scotland. From both these fields of contention the opponents of Mr Leslie retired discomfited, and in the opinion, we believe, of many of the lookers on, disgraced. Among the heaviest blows they had to sustain were those that parted from the hand of Mr Playfair. He first addressed a Letter to the Lord Provost, in which, after asserting, with infinite spirit and freedom, the dignity of the science in question, he openly imputes the new sprung zeal for orthodoxy, which had prompted the attack on Mr Leslie, to a wish or design on the part of some of the clergymen of Edinburgh to obtain for themselves a number of the chairs in that University, which had hitherto afforded sufficient occupation to the undistracted industry of laymen: and when this denunciation brought upon him a series of acrimonious and unhandsome attacks, he replied to them all in a pamphlet of greater bulk, written in a style of which

Playfair.

the high polish and elegance only serve to give a keener edge to the unsparing severity of the exposures which it conveys.\* We do not know, indeed, where to find a more perfect model of polemical or controversial writing; and much as it was to be regretted that an occasion should have arisen for employing such a pen and such a mind as Mr Playfair's on any temporary or personal theme, it is impossible not to admire the extraordinary talent and vigour with which, when the occasion did arrive, he could turn talents, exercised in far other studies, to the purposes suggested by the emergency.

In 1807 he was elected a Fellow of the Royal Society of London, and soon after presented to that learned body his *Lithological Survey of Schehallien*. In 1809 he contributed to the Edinburgh *Transactions* an excellent paper *On Solids of the greatest Attraction*, and in 1812, another *On the Progress of Heat in Spherical Bodies*.

In 1814 he published, in two volumes 8vo, for the use of his class, an elementary work of great value, under the title of *Outlines of Natural Philosophy*. For some years before this, he had been much occupied in digesting the plan and collecting the materials for a greatly enlarged edition of his *Illustrations of the Huttonian Theory*; with a view to which, he had not only carefully perused and extracted a vast body of voyages and travels, but had made various journeys, and very minutely examined almost all the places in the British dominions, the structure of which promised to throw any light on the subject of his researches. No part of the work, however, was actually written, when the preparation for it was suspended by his being induced to draw up for this publication an introductory *Dissertation on the Progress of Mathematical and Physical Science*,—a treatise which, though its author had written nothing else, would itself suffice to carry his name down with distinction to the latest posterity. The soundness of judgment—the beauty of the writing—the extent of knowledge—the candour and precision of the estimates of character, and the noble spirit of liberality and generous admiration for genius which breathes through the whole performance, give it an attraction which is rarely to be found in works of the same erudition, and renders it not only one of the most instructive, but one of the most interesting publications that philosophy has ever bestowed on the world.

In 1815 he drew up for the Royal Society of Edinburgh a very interesting Memoir of his distinguished predecessor Dr John Robison—a philosopher in whose early life there was more adventure, and in his later days more political prejudice, than we usually find to diversify the history of men of science. Nothing can be more spirited and interesting than Mr Playfair's account of the former—nothing more manly and tender than his reluctant but decided protestation against the excesses of the latter.

\* This piece is entitled, *Letter to the Author of the Examination of Mr Stewart's Short Statement of Facts relative to the Election of Professor Leslie*, 8vo, Edinb. 1806. It has not been reprinted in the recent collection of his works.

Playfair. After the general peace, in 1815, had at last opened the Continent to British inquirers, Mr Playfair, at the age of sixty-eight, undertook a long journey through France and Switzerland into Italy, and did not return for a period of nearly eighteen months. His principal attention was directed to the mineralogical and geological phenomena of the different regions which he visited, and he made many notes with a view to the great object, which he was not destined to accomplish, namely, the extension and new modelling of his *Illustrations of the Huttonian Theory*. Every object of liberal curiosity, however, had for him an attraction as fresh as in his earliest youth, and the social simplicity and benevolence of his character and manners insured him a favourable reception in every new society to which he was introduced.

On his return from this expedition, he employed himself chiefly in preparing the Second Part of the *Dissertation* to which we have alluded; and he also drew up a *Memoir on the Naval Tactics of Mr Clerk of Eldin*, which was published after his death in the *Philosophical Transactions*, though only a fragment of a projected life of Mr Clerk which he did not live to complete. His health had been occasionally broken for several years by the recurrence of a painful affection of the bladder, which appeared with increased severity in the early part of 1819, but was so far got under as to enable him to complete his course of lectures in the spring. It returned, however, in a still more distressing form in the summer, and at last put a period to his life on the 19th of July. Though suffering great pain during the last part of his confinement, he retained not only his intellectual faculties quite unimpaired, but the serenity and mildness of his spirits, and occupied himself till within a few days of his death in correcting the proof sheets of the *Dissertation*; the printing of the Second Part of which had commenced sometime before his last illness.\*

Before concluding these notices of Mr Playfair's scientific and literary labours, we have still to mention, that, from the year 1804, he was a frequent contributor to the *Edinburgh Review*, and that, though most of his articles were of a scientific description, he occasionally diverged into the field of general literature, or indulged in the refinements of metaphysical speculation. Many of his scientific articles attracted great attention on the Continent as well as at home; and several of them are written with a force and beauty that might well entitle them to a higher place than the pages of a periodical publication. There is no general account of the great facts and principles of astronomy, so clear, and comprehensive, and exact, nor *half* so beautiful and majestic in the writing, as his account of La Place's *Mécanique Céleste*, in the eleventh volume of the publication just mentioned.

In this brief sketch of the events of Mr Playfair's

life, we have purposely omitted any general account either of his personal character, or of the distinguishing features of his intellectual powers and habits; thinking it better to give those by themselves, in the words in which they were recorded, to the satisfaction, we believe, of most of those who knew him intimately, in a periodical Journal which appeared a short time after his death. The portrait there given has been pronounced by one of the earliest and most illustrious of his surviving friends, "a faithful and perfect resemblance;"† and has accordingly been allowed a place in the prefatory Memoir which his nephew has prefixed to the recent Collection of his Works.

"It has struck many people, we believe, as very extraordinary, that so eminent a person as Mr Playfair should have been allowed to sink into his grave in the midst of us, without calling forth almost so much as an attempt to commemorate his merit, even in a common newspaper; and that the death of a man so celebrated and so beloved, and, at the same time, so closely connected with many who could well appreciate and suitably describe his excellences, should be left to the brief and ordinary notice of the daily obituary. No event of the kind certainly ever excited more general sympathy; and no individual, we are persuaded, will be longer or more affectionately remembered by all the classes of his fellow-citizens; and yet it is to these very circumstances that we must look for an explanation of the apparent neglect by which his memory has been followed. His humbler admirers have been deterred from expressing their sentiments by a natural feeling of unwillingness to encroach on the privilege of those whom a nearer approach to his person and talents rendered more worthy to speak of them,—while the learned and eloquent among his friends have trusted to each other for the performance of a task which they could not but feel to be painful in itself, and not a little difficult to perform as it ought to be; or perhaps have reserved for some more solemn occasion that tribute for which the public impatience is already at its height.

"We beg leave to assure our readers that it is merely from anxiety to do *something* to gratify this natural impatience that we presume to enter at all upon a subject to which we are perfectly aware that we are incapable of doing justice: For of Mr Playfair's scientific attainments,—of his proficiency in those studies to which he was peculiarly devoted, we are but slenderly qualified to judge: But, we believe we hazard nothing in saying that he was one of the most learned mathematicians of his age, and among the first, if not the very first, who introduced the beautiful discoveries of the later continental geometers to the knowledge of his countrymen; and gave their just value and true place, in the scheme of Eu-

\* Besides the DISSERTATION, Mr Playfair contributed to this *Supplement* the valuable biographical account of ÆPINUS, and the still more valuable article on Physical ASTRONOMY.

† Letter from Mr Dugald Stewart to Dr Playfair, in the Appendix to the *Biographical Account of Professor Playfair*, prefixed to the Collection of his Works, published at Edinburgh in 1822, in 4 vols. 8vo.

*Playfair.* ropean knowledge, to those important improvements by which the whole aspect of the abstract sciences has been renovated since the days of our illustrious Newton. If he did not signalize himself by any brilliant or original invention, he must, at least, be allowed to have been a most generous and intelligent judge of the achievements of others; as well as the most eloquent expounder of that great and magnificent system of knowledge which has been gradually evolved by the successive labours of so many gifted individuals. He possessed, indeed, in the highest degree, all the characteristics both of a fine and a powerful understanding,—at once penetrating and vigilant,—but more distinguished, perhaps, for the caution and sureness of its march, than for the brilliancy or rapidity of its movements,—and guided and adorned through all its progress by the most genuine enthusiasm for all that is grand, and the justest taste for all that is beautiful in the Truth or the Intellectual Energy with which he was habitually conversant.

“ To what account these rare qualities might have been turned, and what more brilliant or lasting fruits they might have produced, if his whole life had been dedicated to the solitary cultivation of science, it is not for us to conjecture; but it cannot be doubted that they added incalculably to his eminence and utility as a Teacher; both by enabling him to direct his pupils to the most simple and luminous methods of inquiry, and to imbue their minds, from the very commencement of the study, with that fine relish for the truths it disclosed, and that high sense of the majesty with which they were invested, that predominated in his own bosom. While he left nothing unexplained or unexplained to its proper place in the system, he took care that they should never be perplexed by petty difficulties, or bewildered in useless details, and formed them betimes to that clear, masculine, and direct method of investigation, by which, with the least labour, the greatest advances might be accomplished.

“ Mr Playfair, however, was not merely a teacher; and has fortunately left behind him a variety of works, from which other generations may be enabled to judge of some of those qualifications which so powerfully recommended and endeared him to his contemporaries. It is, perhaps, to be regretted that so much of his time, and so large a proportion of his publications, should have been devoted to the subjects of the Indian Astronomy, and the Huttonian Theory of the Earth. For though nothing can be more beautiful or instructive than his speculations on those curious topics, it cannot be dissembled that their results are less conclusive and satisfactory than might have been desired, and that his doctrines, from the very nature of the subjects, are more questionable than we believe they could possibly have been on any other topic in the whole circle of the sciences. To the first, indeed, he came under the great disadvantage of being unacquainted with the Eastern tongues, and without the means of judging of the authenticity of the documents which he was obliged to assume as the elements of his reasonings; and as to the other, though he ended, we believe, with being a very able and skilful mineralogist, we think it is now generally admitted that that science does not

yet afford sufficient materials for any positive conclusion; and that all attempts to establish a Theory of the Earth must, for many years to come, be regarded as premature. Though it is impossible, therefore, to think too highly of the ingenuity, the vigour, and the eloquence of those publications, we are of opinion that a juster estimate of Mr Playfair's talent, and a truer picture of his genius and understanding, is to be found in his other writings;—in the papers, both biographical and scientific, with which he has enriched the *Transactions* of our Royal Society;—his account of Laplace, and other articles which he is understood to have contributed to the *Edinburgh Review*,—the *Outlines* of his *Lectures on Natural Philosophy*,—and, above all, his *Introductory Discourse* to the *Supplement to the Encyclopædia Britannica*, with the final correction of which he was occupied up to the last moments that the progress of his disease allowed him to dedicate to any intellectual exertion.

“ With reference to these works, we do not think we are influenced by any national, or other partiality, when we say that he was certainly one of the best writers of his age; and even that we do not now recollect any one of his contemporaries who was so great a master of composition. There is a certain mellowness and richness about his style, which adorns without disguising the weight and nervousness, which is its other great characteristic,—a sedate gracefulness and manly simplicity in the more level passages,—and a mild majesty and considerate enthusiasm where he rises above them, of which we scarcely know where to find any other example. There is great equability, too, and sustained force in every part of his writings. He never exhausts himself in flashes and epigrams, nor languishes into tameness or insipidity; at first sight you would say that plainness and good sense were the predominating qualities; but by and bye, this simplicity is enriched with the delicate and vivid colours of a fine imagination,—the free and forcible touches of a most powerful intellect,—and the lights and shades of an unerring and harmonizing taste. In comparing it with the styles of his most celebrated contemporaries, we would say that it was more purely and peculiarly a *written* style,—and, therefore, rejected those ornaments that more properly belong to oratory. It had no impetuosity, hurry, or vehemence,—no bursts or sudden turns or abruptions, like that of Burke; and though eminently smooth and melodious, it was not modulated to an uniform system of solemn declamation like that of Johnson, nor spread out in the richer and more voluminous elocution of Stewart; nor still less broken into that patch-work of scholastic pedantry and conversational smartness which has found its admirers in Gibbon. It is a style, in short, of great freedom, force, and beauty; but the deliberate style of a man of thought and of learning, and neither that of a wit throwing out his extempores with an affectation of careless grace,—nor of a rhetorician thinking more of his manner than his matter, and determined to be admired for his expression, whatever may be the fate of his sentiments.

“ His habits of composition, as we have understood, were not perhaps exactly what might have been expected from their results. He wrote rather slowly,

Playfair.

—and his first sketches were often very slight and imperfect,—like the rude chalking for a masterly picture. His chief effort and greatest pleasure was in their revisal and correction; and there were no limits to the improvement which resulted from this application. It was not the style merely, or indeed chiefly, that gained by it: The whole reasoning, and sentiment, and illustration, was enlarged and new modelled in the course of it, and a naked outline became gradually informed with life, colour, and expression. It was not at all like the common finishing and polishing to which careful authors generally subject the first draughts of their compositions—nor even like the fastidious and tentative alterations with which some more anxious writers assay their choicer passages. It was, in fact, the great filling in of the picture—the working up of the figured *west*, on the naked and meagre *woof* that had been stretched to receive it; and the singular thing in his case was, not only that he left this most material part of his work to be performed after the whole outline had been finished, but that he could proceed with it to an indefinite extent, and enrich and improve as long as he thought fit, without any risk either of destroying the proportions of that outline, or injuring the harmony and unity of the design. He was perfectly aware, too, of the possession of this extraordinary power, and it was partly, we presume, in consequence of this consciousness that he was not only at all times ready to go on with any work in which he was engaged, without waiting for favourable moments or hours of greater alacrity, but that he never felt any of those doubts and misgivings as to his being able to get creditably through with his undertaking, to which we believe most authors are occasionally liable. As he never wrote upon any subject of which he was not perfectly master, he was secure against all blunders in the substance of what he had to say; and felt quite assured, that if he was only allowed time enough, he should finally come to say it in the very best way of which he was capable. He had no anxiety, therefore, either in undertaking or proceeding with his tasks; and intermitted and resumed them at his convenience, with the comfortable certainty, that all the time he bestowed on them was turned to good account, and that what was left imperfect at one sitting might be finished with equal ease and advantage at another. Being thus perfectly sure both of his end and his means, he experienced, in the course of his compositions, none of that little fever of the spirits with which that operation is so apt to be accompanied. He had no capricious visitings of fancy which it was necessary to fix on the spot or to lose for ever,—no casual inspiration to invoke and to wait for,—no transitory and evanescent lights to catch before they faded. All that was in his mind was subject to his control, and amenable to his call, though it might not obey at the moment; and while his taste was so sure, that he was in no danger of overworking any thing that he had designed, all his thoughts and sentiments had that unity and congruity, that they fell almost spontaneously into harmony and order; and the last added, incorporated, and assimilated with the first, as if they had sprung simultaneously from the same happy conception.

Playfair.

“ But we need dwell no longer on qualities that may be gathered hereafter from the works he has left behind him. They who lived with him mourn the most for those which will be traced in no such memorial; and prize far above those talents which gained him his high name in philosophy, that personal character which endeared him to his friends, and shed a grace and a dignity over all the society in which he moved. The same admirable taste which is conspicuous in his writings, or rather the higher principles from which that taste was but an emanation, spread a similar charm over his whole life and conversation; and gave to the most learned Philosopher of his day the manners and deportment of the most perfect Gentleman. Nor was this in him the result merely of good sense and good temper, assisted by an early familiarity with good company, and a consequent knowledge of his own place and that of all around him. His good breeding was of a higher descent; and his powers of pleasing rested on something better than mere companionable qualities. With the greatest kindness and generosity of nature, he united the most manly firmness, and the highest principles of honour,—and the most cheerful and social dispositions, with the gentlest and steadiest affections. Towards women he had always the most chivalrous feelings of regard and attention, and was, beyond almost all men, acceptable and agreeable in their society,—though without the least levity or pretension unbecoming his age or condition: And such, indeed, was the fascination of the perfect simplicity and mildness of his manners, that the same tone and deportment seemed equally appropriate in all societies, and enabled him to delight the young and the gay with the same sort of conversation which instructed the learned and the grave. There never, indeed, was a man of learning and talent who appeared in society so perfectly free from all sorts of pretension or notion of his own importance, or so little solicitous to distinguish himself, or so sincerely willing to give place to every one else. Even upon subjects which he had thoroughly studied, he was never in the least impatient to speak, and spoke at all times without any tone of authority; while, so far from wishing to set off what he had to say by any brilliancy or emphasis of expression, it seemed generally as if he had studied to disguise the weight and originality of his thoughts under the plainest form of speech and the most quiet and indifferent manner: so that the profoundest remarks and subtlest observations were often dropped, not only without any solicitude that their value should be observed, but without any apparent consciousness that they possessed any. Though the most social of human beings, and the most disposed to encourage and sympathise with the gaiety and joviality of others, his own spirits were in general rather cheerful than gay, or at least never rose to any turbulence or tumult of merriment; and while he would listen with the kindest indulgence to the more extravagant sallies of his younger friends, and prompt them by the heartiest approbation, his own satisfaction might generally be traced in a slow and temperate smile, gradually mantling over his benevolent and intelligent features, and lighting up the countenance of the Sage with the expression of the

Playfair  
||  
Polar Seas.

mildest and most genuine philanthropy. It was wonderful, indeed, considering the measure of his own intellect, and the rigid and undeviating propriety of his own conduct, how tolerant he was of the defects and errors of other men. He was too indulgent, in truth, and favourable to his friends;—and made a kind and liberal allowance for the faults of all mankind,—except only faults of baseness or of cruelty,—against which he never failed to manifest the most open scorn and detestation. Independent, in short, of his high attainments, Mr Playfair was one of the most amiable and estimable of men,—delightful in his manners,—inflexible in his principles, and generous in his affections, he had all that could charm in society or attach in private; and while his friends enjoyed the free and unstudied conversation of an easy and intelligent associate, they had at all times the proud and inward assurance that he was a being upon whose perfect honour and generosity they might rely with the most implicit confidence, in life and in death,—and of whom it was equally impossible, that, under any circumstances, he should ever perform a mean, a selfish, or a *questionable* action, as that his body should cease to gravitate or his soul to live!

“ If we do not greatly deceive ourselves, there is nothing here of exaggeration or partial feeling,—and nothing with which an indifferent and honest chronicler would not concur. Nor is it altogether idle to have dwelt so long on the personal character of this distinguished individual: For we are ourselves persuaded, that this personal character has done almost as much for the cause of science and philosophy among us as the great talents and attainments with which it was combined,—and has contributed in a very eminent degree to give to the better society of this our city that tone of intelligence and liberality by which it is so honourably distinguished. It is not a little advantageous to philosophy that it

Playfair  
|  
Polar Seas.

is in fashion,—and it is still more advantageous, perhaps, to the society which is led to confer on it this apparently trivial distinction. It is a great thing for the country at large,—for its happiness, its prosperity, and its renown,—that the upper and influencing part of its population should be made familiar, even in its untasked and social hours, with sound and liberal information, and be taught to know and respect those who have distinguished themselves for great intellectual attainments. Nor is it, after all, a slight or despicable reward for a man of genius to be received with honour in the highest and most elegant society around him, and to receive in his living person that homage and applause which is too often reserved for his memory. Now, those desirable ends can never be effectually accomplished, unless the manners of our leading philosophers are agreeable, and their personal habits and dispositions engaging and amiable. From the time of Hume and Robertson, we have been fortunate in Edinburgh in possessing a succession of distinguished men, who have kept up this salutary connection between the learned and the fashionable world; but there never, perhaps, was any one who contributed so powerfully to confirm and extend it, and that in times when it was peculiarly difficult, as the lamented individual of whom we are now speaking; and they who have had the most opportunity to observe how superior the society of Edinburgh is to that of most other places of the same size, and how much of that superiority is owing to the cordial combination of the two aristocracies, of Rank and of Letters,—of both of which it happens to be the chief provincial seat,—will be best able to judge of the importance of the service he has thus rendered to its inhabitants, and through them, and by their example, to all the rest of the country.”

(G. G.)  
POLARISATION OF LIGHT. See REFRACTION, DOUBLE.

## P O L A R S E A S.

THE rapid progress which has been made within the last half century in physical science and geography, has thrown a deeper interest on whatever concerns the Polar Regions, than belongs to the mere commercial speculation in which originated the earliest attempts for discovering a passage through the North Polar Ocean to India and China. It is not here intended, however, to enter into any detail concerning the new objects of natural history, the atmospherical phenomena of temperature, electricity, and magnetism, and various other points of scientific research, which the late expeditions have been the means of collecting and communicating; but to exhibit a sketch of the various attempts which have been made to explore those regions of darkness, long supposed not only to be uninhabitable, but unapproachable; and to take a very concise view of the progressive discovery and geographical information which have resulted from those attempts.

### NORTH POLAR SEA.

We are now able to draw, with nearly geographical accuracy, the boundaries of the North Polar Sea. A very large portion of the northern shores of Europe, Asia, and America, which circumscribe it, have been visited; and the position of most of their bays, headlands, and rivers, geographically ascertained. By casting our eye over the North Polar Chart, it will be seen that the Polar Sea of that hemisphere is an immense circular basin, which communicates with the two great Oceans of the world, the Atlantic and the Pacific, by two channels, the one separating America from Europe, the other America from Asia. It will be seen, that few points of the coasts of Europe and Asia, which occupy a full half of the circumscribing circle, extend much beyond the 70th parallel of latitude; and all these points have been passed by water, though at different times and by different persons, with the single exception of the

Boundaries  
and Extent  
of the North  
Polar Sea.

**Polar Seas.** Cape Cevero Vostocknoi, which, on the charts, is made to extend to the latitude  $75\frac{1}{2}^{\circ}$ . The northern coast of America, with Old Greenland, and the two channels above mentioned, complete the circle; America extending about  $80^{\circ}$  of longitude, or just two-ninths of the whole circle; and of this portion three several points have been ascertained: Icy Cape by Captain Cook; the mouth of Mackenzie River by him whose name it bears; and of the Copper Mine River incorrectly by Hearne; and from these positions it may be concluded, that the average of the latitude of this coast is about the same as, or rather lower than, that of Europe and Asia. The extent, therefore, of the North Polar Sea may be considered about 2400 geographical miles in diameter, or 7200 in circumference.

The interior or central parts of this sea are very little known. Several islands are scattered over its southern extremities, the largest of which is Old Greenland, whose northern limit has not yet been passed; the others are, Spitzbergen, Nova Zembla, the islands of Liakhov, or, as some have been pleased to call them, New Siberia; the North Georgian islands of Parry, and those which form the western land of Baffin's Bay. Besides these, there are a number of small alluvial islands formed at the mouths of the several rivers of the two continents; but whether any, or what number of islands may exist nearer to the Pole, we must of course remain ignorant till the Polar Sea has been further explored.

For that little which is known of this sea, we are indebted to that spirit of discovery which showed itself immediately after a passage to the Indies had been effected round the Cape of Good Hope; not so much, it is true, for the sake of geographical discovery, as that of shortening the passage by sea to the eastern parts of the world. It was obvious that, if a ship could proceed from the Atlantic to the Pacific, on a great circle of the sphere, or nearly so, the distance, compared with the circuitous passage round Southern Africa or Southern America, would be prodigiously shortened. The voyage of Columbus had that object; but it was soon discovered, that, from the Straits of Magellan to the Gulf of St Lawrence, there was one uninterrupted continuity of land. Of the northern regions, the information has been scanty and discouraging for such an enterprise. One of the Scandinavian pirates had indeed been driven by stress of weather, so early as the middle of the ninth century, upon an island to the north-west, to which, from its appearance, he gave the name of Snowland, which was afterwards changed to that of Iceland by the leader of the Norwegian colonists who took refuge on that inhospitable spot; but it was not till more than a century after this that Eric Rauda discovered the southern part of Old Greenland; and there are grounds for believing that, in the year 1001, some of these colonists discovered Newfoundland and the coast of Labrador.

The colony of Iceland continued to flourish in spite of the storms and tempests, the chilling temperature, the earthquakes and volcanoes, which shook to its centre this *Ultima Thule* of the inhabitable world; but the Greenland colonies were less fortun-

ate. For some time that on the west is said to have so well succeeded as to number one hundred villages, divided into four parishes; but that, having engaged in hostilities with the natives, whom they named *Skrælings* (the same people as the present Eskimaux), the latter compelled them to abandon their settlements. The eastern colony is supposed to have shared a more deplorable fate; a stream of ice having fixed itself to the coast, about the year 1406, and rendered the whole of it, from that time to this, utterly inaccessible. The existence, however, of any such colony, has of late years been called in question; and it is now supposed that all the Danish and Norwegian settlements were confined to the western side of Cape Farewell.

The voyages and adventures of the two brothers Nicolò and Antonio Zeno in 1380, though they added but little to the knowledge of northern geography, are extremely curious, and throw considerable light on the state of Greenland, Labrador, and the Feroe Islands (Friesland), at that early period. It may be doubted, however, if any of the voyages hitherto made were undertaken for purposes of discovery and the benefit of navigation. The Portuguese have unquestionably the merit of being the first to send out expeditions with these views; and it is to their successful discovery of a passage round the Cape of Good Hope, that we owe the bold enterprise of Christopher Colon, better known as Columbus, to find out a passage to the Indies by steering directly to the west.

It was not till the year 1496 that England engaged in nautical discoveries. In that year, Henry VII. encouraged John Cabota, a citizen of Venice, to make discoveries, by granting him a patent to search for unknown lands, and to conquer and settle them. His son Sebastian, either alone or in company with his father, discovered Newfoundland, to which was given the name of *Prima Vista*, "the first seen." We say *discovered*; for although the testimonies are in favour of the Scandinavians having settled colonies on this island, no vestige then remained or has since been found of any such colonies. The object of the voyage was, as stated by himself, that, "understanding, by reason of the sphere, that if I should sail by way of north-west, I should by a shorter tract come into India, I thereupon caused the king to be advertised of my devise, who immediately commanded two caravets to be furnished with all things appertaining to the voyage." He states in his report that he reached the 56th degree, but finding no opening in the coast, he despaired of a passage, and returned.

A claim, however, has been set up for the discovery of *Terra de Bacalhaos* (the Land of Codfish), afterwards called Newfoundland, by John Vaz Costa Cortereal, a Portuguese gentleman belonging to the household of the Infanta Don Fernando, who is said to have touched at that island in the year 1463 or 1464, in an attempt to find a route to India and the Spice Islands by sailing westward round the northern extremity of America. This claim rests on the testimony of Cordeira, and on a patent commission, granting to Cortereal the Captaincy of Terceira, in 1464, as a reward for his important discovery. The

**Polar Seas.** Portuguese certainly not only fished on the banks, but formed establishments on the island of Newfoundland towards the end of the fifteenth century.

In the summer of 1500, two ships sailed from Lisbon, under the command of Gaspar Cortereal, on northern discovery. According to Ramusio, they arrived at a region of extreme cold; and in the latitude of 60° north, discovered a river filled with ice, to which they gave the name of Rio Nevado, that is, Snow River. This land was Labrador, which on an old chart is named Corterealis. In returning, he discovered the Gulf of St Lawrence. Gaspar Cortereal was so satisfied of the existence of a north-west passage to India, that he again left Lisbon, in May 1501, with two vessels, but his own was separated on the coast of Terra Verde, and never more heard of. A second brother went out the following year, but his ship was also supposed to be lost and all hands perished. A third expedition was sent out in search of the unfortunate navigators, but no tidings could be obtained of their fate.

Of Auberton  
Cartier.

The French are the only maritime people who have seen, with apparent indifference, the exertions made by other nations for the discovery of a passage to India, either by the north-east or the north-west. Auberton Cartier's voyages to Newfoundland and the Gulf of St Lawrence, between 1508 and 1534, can hardly be considered as voyages of discovery; and the subsequent voyages of Roberval and of the Marquis de la Roche had no other object than the discovery of gold, or of a desirable spot to establish a colony on the coast of America.

Of Estevan  
Gomez.

In the year 1524, the jealousy of the Spaniards would seem to have taken the alarm at the attempts which were making by other nations to discover a shorter way to China and the Indies by the north; for it appears, that a skilful navigator, who had been with Magellanes, of the name of Estevan Gomez, sailed in that year from Corunna, with the view of discovering a northern passage from the Atlantic to the Moluccas. Gaspar, the only author who has recorded this voyage, enters into no details, but it is supposed he reached no farther than the coast of Labrador, from whence he brought away some of the natives. On his return, he was asked by a friend what success he had met with? The answer was *esclavos* (slaves), which the inquirer mistook for *clavos* (cloves), and spread the report of his having made, as Purchas calls it, a "spicy discovery." It is evident, however, that his voyage was a complete failure, of which, as the voluminous compiler just mentioned observes, "little is left us but a jest."

Of the Spaniards on  
the West  
Coast of  
America.

The alarm of the Spaniards spread to the Pacific; and Cortez, the conqueror and Viceroy of Mexico, on receiving intelligence of the voyages of the Cortereals, fitted out three ships, under the orders of Francisco Ulloa, to look for the supposed Strait of Anian, through which they were to pass. In 1542, the Viceroy Mendoza sent one expedition by land and another by sea from Mexico to the northward. No discoveries were made by any of these voyages. Two years after this, the Court of Spain ordered another expedition along the western coast of America, the conduct of which was entrusted to Juan

Rodrigues de Cabrillo, a Portuguese in the service of Spain. He reached the latitude of 44° N. and gave the name of Cape Mendocino to the land, about the latitude 42° N., in compliment of the viceroy.

Polar Seas.

England, in the mean time, was not inactive. At the suggestion of Mr Robert Thorne of Bristol, King Henry VIII. caused to be sent forth "two faire ships, with divers cunning men, to seek strange regions," which left the Thames in 1527. All that Hakluyt could discover of these ships and the cunning men was, that the name of one of them was *Dominus Vobiscum*, and that a canon of St Paul's of London, a great mathematician and wealthy man, went on the expedition. One of these ships was cast away in the great opening between the north parts of Newfoundland and *Meta Incognita*, supposed to be Greenland.

At First Eng-  
lish Voyage.

In the year 1536, two ships, the *Trinitie* and the *Minion*, were set forth by Master Hore of London, "a man of goodly stature and of great courage, and given to the studie of cosmographie." Six score persons, we are told, embarked on this expedition, whereof thirty were gentlemen. They reached no higher than Newfoundland; but there is a curious account of their proceedings by Hakluyt, which he procured from Mr Oliver Dawbeny, merchant of London, who was one of the adventurers on board the *Minion*.

Second Eng-  
lish Voyage.

On the return of Sebastian Cabot to England, he was constituted Grand Pilot, and "Governor of the *Mysterie* and *Companie* of the Merchants Adventurers for the Discoverie of Regions, Dominions, Islands, and Places unknown." At his suggestion, a voyage was undertaken, in the year 1553, for the discovery of a north-east passage to Cathaia, consisting of three vessels, whose crews, including eleven merchants, amounted to 113 persons. Numerous candidates stood forward for the command of this expedition; but Sir Hugh Willoughby was appointed Captain-General of the fleet, "both by reason of his goodly personage (for he was of tall stature), as also for his singular skill in the services of warre." The fate of this expedition was most disastrous. Sir Hugh Willoughby, with his brave associates, as well as the crew of the second ship, to the number of seventy persons, miserably perished, from cold and hunger, on the coast of Lapland, at the mouth of a river called *Arzina*, not far from the harbour of *Kegor*. The third ship, under Master Richard Chancellor, had parted company, and by putting into *Wardhuys*, in Norway, escaped the fate of his companions; and in the following year, discovered the port of *Archangel*, and opened the first intercourse with Russia.

Voyage of  
Sir Hugh  
Willough-  
by.

In the years 1555 and 1556, two ships were sent out to *Archangel*, to carry Commissioners to the Court of Moscow, and having landed them to prosecute discoveries, and "to use all wayes and meanes possible to learne howe men may passe from Russia, either by land or sea, to Cathaia." Stephen Burrough, in the *Serchthrift*, proceeded easterly as far as the island of *Waygatz*, where he was stopped by the constant north-east and northerly winds, thick weather, and abundance of ice. The neighbouring

Of Stephen  
Burrough.

**Polar Seas.** country was inhabited by *Samoeds*, who had no houses, but tents made of deers' skins.

**Of Martin Frobisher.**

The rapid progress made from this time by land through Russia to Persia and India, revived the ardour for discovery by sea, and the pens of the most learned and ingenious men in the nation were employed to prove the existence, the practicability, and the great advantages which would result from the discovery of a north-west passage. Among others, Martin Frobisher had laboured for fifteen years, but without the means of setting forth an expedition, till at last, in the year 1576, by the assistance of Dudley Earl of Warwick, and a few friends, he was enabled to fit out two small barks, the Gabriel of 35, and the Michael of 30 tons, and a small pinnace of 10 tons. On the 11th July, this little squadron came in sight of Friesland, "rising like pinnacles of steeples, and all covered with snow." This Friesland, being in 61° latitude, was probably the southern part of Old Greenland. He entered a strait, which now bears his name, in latitude 63° 8' N., and had communication with the Eskimaux, whom he describes as "like to Tartars, with long black hair, broad faces, and flat noses." He brought home one of these "strange infideles, whose like was never seene, read, nor heard of before;" and Frobisher had the satisfaction to find himself "highly commended of all men for his greate and notable attempt, but specially famous for the great hope he brought of the passage to Cathaia."

**His Second Voyage.**

Some of the crew having brought home a stone which "glistend with a bright marquesset of gold," Queen Elizabeth now gave countenance to a second attempt, and added to the expedition "one tall ship of hir Majesties, named the Ayde." In this voyage they proceeded to Mount Warwick, on Resolution Island, in latitude 63½° N., from whence they sailed on their return home on the 22d August, having lost only one man by sickness, and another who fell overboard.

**His Third Voyage.**

Though Frobisher brought home neither gold nor silver, but something which had the appearance of both, the Queen and her Court pleased in "finding that the matter of the gold ore had appearance, and made shew of great riches and profit, and the hope of the passage to Cathaia by this last voyage greatly increased," determined to establish a colony on Meta Incognita; for which purpose fifteen ships were prepared, carrying 100 persons to form the settlement; with whom three of the ships were to remain, and the other twelve to bring back cargoes of gold ore. The fleet sailed on the 31st May 1578; part of it entered Frobisher's Strait, and part were driven towards the coast of Greenland. On the 30th August, the ships having re-assembled off Hatton's Headland, on Resolution Island, and all hands disheartened by the cold and tempestuous weather, they resolved to make sail for England, where they all arrived at different ports about the beginning of October, with the loss, by deaths, of about forty persons.

**Of Pet and Jackman.**

The progress made by land to the eastward in-

duced the Russia Company to fit out two ships, under the command of Pet and Jackman, to make another attempt at a north-east passage. They left Harwich on the 30th May 1580, reached Wardhuys on the 23d June, and the coast of Nova Zembla the 16th July; passed the Strait of Waygatz, but were obliged to return on account of the ice.

**Polar Seas.**

Sir Humphry Gilbert and his brother obtained from Queen Elizabeth, in 1578, a patent for making western discoveries, by which they established a corporation under the name of "The Colleagues of the Fellowship for the Discoverie of the North-west Passage." In 1583, Sir Humphry set out to take possession of Newfoundland, but the voyage was most disastrous, and on his return, his little bark foundered at sea, when he and all that were in her perished.

**Of Sir Humphry Gilbert.**

In 1585, John Davis was sent out by the merchants of London, for the discovery of the north-west passage. Two barks, the Sunshine and the Moonshine, one of 50, the other of 35 tons, were fitted out for this purpose. On the 6th of August, Davis had proceeded so high up the strait which now bears his name as latitude 66° 40', and anchored in Exeter Bay, under "a brave mount," to which he gave the name of "Mount Raleigh, the cliffs whereof were as orient as gold." On the 8th August, they returned to the southward, and arrived in Dartmouth the 30th September.

**Of John Davis.**

In 1586, Davis set sail a second time, and coasted the western shore of Greenland up to the latitude 66° 33', stood from thence across to the westward, made the land in 66° 19', and turning to the southward, along the coast and numerous islands, anchored in a bay on the coast of Labrador, in latitude 56°, and, sailing from thence, arrived in England in the month of October.

**His Second Voyage.**

A third voyage being determined on, Davis sailed from Dartmouth on the 19th May, made the land on the west coast of Greenland in latitude 64° on the 14th June, had advanced as high as latitude 67° on the 24th, and, on the 30th, was in latitude 72° 12'. From hence he crossed to the westward in an open sea, but being driven, as he supposed, by a current, found themselves, on the 19th, abreast of Mount Raleigh. After this, Davis advanced 60 leagues up the strait he had discovered on the former voyage, now called Cumberland Strait; passed through Lumley's Inlet, the same, it is supposed, which Frobisher had discovered, and known as Frobisher's Strait; and, standing to the south-east, discovered Cape Chidley, and, returning homewards, arrived in England by the middle of September.\*

**His Third Voyage.**

Of the voyage of Maldonado in 1588, and of Jan-de Fuca, 1592, it is not necessary to say any thing, the latter being at best but problematical, and the former altogether spurious.

The next attempts we find in chronological order were three voyages for the discovery of a north-east passage, undertaken by the Dutch, in which William Barentz was chief pilot. The first of these was

**Voyages of William Barentz.**

\* An interesting account of the proceedings of this able and intrepid navigator, by himself, is contained in a very rare and curious little book called *The Worlde's Hydrographical Description, 1595.*

*Polar Seas.* set forth in 1594; proceeded easterly as far as Waygatz, then along the western coast of Nova Zembla as high as latitude  $77^{\circ} 25'$ , and returned to the Texel the 16th September. On the second voyage, the following year, they did not reach Nova Zembla till the 17th August, when finding it impossible, on account of the great quantity of ice, and "the weather being misty, melancholic, and snowie," they returned to the westward, and arrived in the Maes on the 18th November.

The third voyage of Barentz is intensely interesting. The ships left the Texel in May, and on the 9th June, after sailing among much ice, they discovered Bear (since called Cherry) Island. Proceeding northerly, they discovered Spitzbergen, along the western coast of which they had advanced, on the 19th, as high as  $80^{\circ} 11'$ , opposite the point since known as Hakluyt's Headland. Returning to the southward, Barentz made for the coast of Nova Zembla; doubled the northern extremity; and then found himself compelled, by the pressure of the ice and bad weather, to seek for refuge in a small bay, which they called Ice Haven; and here they passed "their cold, comfortlesse, darke, and dreadful winter," in about the 76th parallel of latitude. The ship was wholly wrecked, and the surviving part of the crew, fifteen in number, left this spot the following year in two open boats; and after an exertion of forty days, in which they suffered the greatest fatigue, famine, and cold, and in which Barentz and two others died, they reached Kilduin in Lapland, a distance of 1000 miles and more from the bay in which they had passed the winter.

*Of George Weymouth.*

The merchants of England seem to have lost all hope of a northern passage to the East Indies, till they were once more roused by a supposed piece of information of Captain James Lancaster, that the passage was in the north-west of America, in latitude  $62^{\circ} 30'$ . Accordingly in 1602 the Muscovy and Turkey Companies fitted out two fly-boats, the Discovery and Godspeed, the command of which was given to Captain George Weymouth. This voyage, however, was a complete failure. It is difficult to make out precisely the utmost limit at which it arrived; it was not much beyond Resolution Island in Hudson's Strait; but, to use the words of a subsequent sagacious navigator, Luke Fox, "Davis and Weymouth lighted Hudson into his Straits."

*Of Hall and Knight.*

In 1605, the King of Denmark sent out an expedition of discovery, in which two Englishmen, James Hall and John Knight, were employed. The ships proceeded along the west coast of Greenland, but reached no higher than about latitude  $66^{\circ} 55'$ ; gave the names of Christian's Foord and Queen Anne's Cape; traded and quarrelled with the natives; left two malefactors among them, and returned to Elsinour.

This expedition was followed up by two others in the two following years, neither of which was productive of any discoveries; the first having advanced only to  $66^{\circ} 25'$  on the coast of Greenland, and the latter not farther than Cape Farewell.

In 1606, the merchants of London sent out the

*Of John Knight.*

Hopewell, under the directions of John Knight. In latitude  $56^{\circ} 48'$ , on the coast of Labrador, Knight, with his mate and four others, went on shore, and were supposed to be murdered by the natives, as none of them were ever afterwards heard of. The ship returned home.

Henry Hudson made no fewer than four voyages of discovery. The first, in 1607, was along the eastern coast of Greenland, when he observed, in  $78^{\circ} 56'$ , a higher degree of latitude on that coast than has since been ascended. The second, in 1608, was an attempt to the eastward, where, as in all preceding attempts, he was stopped at Waygat Strait. Of the third little is known. Its northern limits appear to have been the North Cape on one side, and Newfoundland on the other.

The fourth voyage was fatal to Hudson; but it opened the way to the coast of America in a higher degree of latitude than it had yet been approached. He left the Thames in the Discovery of 55 tons, on the 17th April 1610; and reached the Isle of Godsmercie, in the strait which bears his name, on the 6th July; on the 2d August, he discovered land, which he named Cape Wolstenholm; and near it, on a cluster of islands, Cape Digges—and here ends Hudson's narrative; for his crew having mutinied, they put Hudson, his son, and seven others, into an open boat, which was never heard of more. The ship returned to England, and, what is most remarkable, the inhuman and atrocious act does not appear to have caused any sensation, nor was any inquiry instituted into the proceedings of the mutineers.

Two of them, in fact, Abacuk Pricket and Robert Bylot, were employed under Captain (afterwards Sir Thomas) Button, appointed to prosecute the discovery of a north-west passage, in two ships, the Resolution and Discovery. Button followed the tract of Hudson, and succeeded in reaching the coast of America, where he wintered in Nelson's River, in latitude  $57^{\circ} 10'$ . The following year they stood to the northward, and discovered Southampton Island, as high up as latitude  $65^{\circ}$ ; made some discoveries of Islands, and returned to England in the autumn of 1613.

In 1612, we find James Hall employed on an expedition up the western coast of Greenland, where he was slain by one of the natives at Ramel's Point, in latitude  $67^{\circ}$ . The account of the voyage is written by William Baffin, who was pilot, in which he relates the method of determining the longitude by an observation of the time when the moon came upon the meridian; the first navigator probably who practised this method.

In 1614, Captain Gibbon was sent out in the Discovery, at the recommendation of Sir Thomas Button; he encountered much ice at the opening of Hudson's Strait, returned to the southward, and was shut up in a bay on the coast of Labrador, for five months; and returned without making any progress in the north-western discovery. To this bay the ship's company are said to have given, in derision, the name of "Gibbon's his Hole."

In 1615, the Discovery was fitted out a fourth time, and the command of her given to Robert By-

*Of Bylot and Baffin.*

*Polar Seas.* lot, who took William Baffin as his mate. They visited Button's Islands, Savage Islands, and Mill Islands, and proceeded along the east coast of Southampton Island to Cape Comfort, in latitude 65°. From hence they returned to the southward, and reached England in the month of September.

In 1616, Bylot and Baffin again set out in the bark *Discovery*, in search of a north-west passage; and, following their instructions, proceeded up Davis Strait to Hope Saunderson, the extreme point of Davis's progress, being between 72° and 73° latitude, which they reached as early as the 30th May. A little to the northward was a group of islands, to which, finding females only, they gave the name of Women's Islands. From hence they stood northerly, between the ice and the land, passing in succession Horn Sound, Wolstenholm's Islands, Whale Sound, Sir Thomas Smith's Sound, in latitude 78°, and, at the northern extremity of what has since been called Baffin's Bay; and following the direction of the land, they passed, on the western shore, Alderman Jones's Sound, and lastly, Lancaster Sound; from whence the ice compelled them to leave the land, and they therefore shaped their course homewards. This last voyage of Baffin is the most important that had yet been made; and it is quite surprising that the discovery of so many immense openings which he calls *sounds*, for want of a better word, should not have been followed up, and that not one of them should have been examined until the recent expedition under that intelligent and enterprising officer Captain Parry.

*Of Jens Munck.* In 1619, the Danes sent out an expedition under Jens Munck, who penetrated as high up on the coast of America as Chesterfield Inlet, which he named Munck's Winter Harbour, for he wintered in it, and all his people, except two, perished of cold, disease, and famine. Munck, and these two survivors, with great difficulty, fitted out the smaller of the two vessels, and reached Denmark, where they were considered as men risen from the dead. Munck is said to have received the indignity of a blow from the King, on which he took to his bed, and died of a broken heart; but there is an air of romance in the account of this voyage, which makes its authenticity doubtful.

*Of Luke Fox.* In 1631, Captain Luke Fox, who quaintly calls himself the "North-west Fox," prevailed on some merchants of London to procure from King Charles I. his countenance, and the loan of one of his ships, for attempting the discovery of a north-west passage. Fox was undoubtedly the most shrewd and intelligent of all former navigators; and if, when he reached what he calls Fox's Farthest, he had stood across to the westward, the probability is, that he would have got upon the northern coast of America, and succeeded in working his way into the Pacific, by the very route which Parry is now pursuing.

*Of Captain James.* In the same year the merchants of Bristol fitted out the *Maria* of 70 tons, the command of which was given to Captain James. In proceeding up Hudson's Strait, somewhere about Resolution Island, he got his ship entangled in the ice; and from that spot to Charlton Island, at the bottom of Hudson's Bay, in latitude 52°, he details a series of disasters

which never happened to any navigator before or since. Here he passed the winter, and returned the following year, without making the least progress in discovery.

*Polar Seas.* In 1652, the King of Denmark again set forth an expedition under Captain Daniel, to explore the eastern coast of Greenland. He stood to the northward of Iceland, but he could not approach the land on account of the ice, but the mountains were visible at least 60 miles. The most northern cape seen was in 65° 30', to which he gave the name of Cape King Frederick. From this point to Cape Farewell the ice lay between him and the shore, which in no part he could approach within 20 miles; of course, no discovery was made by him.

*Of Wood and Flaws.* After the lapse of more than a century, a paper admitted into the *Transactions* of the Royal Society of London in 1675, tended to revive the attempt at a north-east passage in England. It contained an account of a Dutch ship fitted out by a company of merchants in Holland, having passed to the north-eastward of Nova Zembla several hundred leagues, between the parallels of 70° and 80°; and the sea in that direction was found to be perfectly open and free from ice. About the same time, it was reported that Spitzbergen had been circumnavigated, and that a Dutch ship had proceeded within one degree of the Pole. Upon the strength of these reports, Captain John Wood addressed a memorial to the king, assigning *seven reasons* and *three arguments*, for the existence of a north-east passage. Accordingly, two ships were fitted out under Captains Wood and Flaws; they left the Nore in May 1676; on the 22d June, had reached the latitude 75° 79', and on the 26th got sight of the west coast of Nova Zembla. Three days after this, Wood lost his ship among the ice, and after some perils and the loss of two men in reaching the shore, they were picked up by the other ship, and returned homewards without making the least discovery; when Wood published many peremptory and ill-founded reflections on former navigators, and now found out seven reasons and three arguments *against* the passage to the north-east.

*Of Captain Middleton.* Of the voyages of Knight, Barlow, Vaughan, and Scroggs, from the Hudson's Bay Company's settlements, along the eastern coast of America, little else need be said, than that they extended not the knowledge of that coast beyond Whale Point; but their observations on the strong tide flowing down the Welcome, induced a gentleman of the name of Dobbs to press the Board of Admiralty to appropriate a ship of the navy to make discoveries in this quarter. Two ships were accordingly fitted out, the *Furnace* bomb, and the *Discovery* pink, commanded by Captain Middleton and Mr William Moor. They left England in 1741, and wintered in Churchill River in latitude 58° 56'; remained there till the 1st July; proceeded northerly to the latitude 65° 23', and entered Wager River, which they examined in an imperfect manner. They then stood to the northward as far as Cape Hope, in latitude 66° 14', longitude 86° 28' W.; and, most unaccountably, abandoned all farther search, having

seen, or fancied they saw, "a frozen strait" between them and the point round which they had to proceed to the westward. Middleton had been an old servant of the Hudson's Bay Company, who were supposed to be jealous of any discoveries in their neighbourhood, and averse from encouraging them; and he was accused of having taken a bribe from them to defeat the object of the expedition. The Lords of the Admiralty refused to approve of his proceedings, and to evince the feeling of the government, an act was passed the very year after his return, offering a reward of L. 20,000 to the person or persons, being subjects of his Majesty, who should discover a north-west passage through Hudson's Strait to the Pacific. Dobbs, turning these circumstances to the advantage of his favourite project, got up a large subscription, and in 1746, two other vessels were fitted out, and the command of them given to Captain William Moor and Captain Francis Smith. Their first examination was that of the Wager River, which was found to terminate in a broad rapid, beyond which were two unnavigable rivers. They then proceeded northerly, till they came to Captain Middleton's "frozen strait," or opening into Repulse Bay, when a difference of opinion arose among the officers, whether they were authorized by their instructions to examine this bay! The fact appears to be, that the officers and men had no taste for the business, and were under no kind of discipline. Instead, therefore, of proceeding, they began to murmur, and although only the 7th August, they urged the lateness of the season, and wished to return home. After this nothing was done or even attempted; and Repulse Bay remains unexamined to this moment; and what we see laid down in the charts under that name is wholly gratuitous.

Of Moor and Smith.

Of Phipps and Lutwidge.

No farther attempts at either passage appear to have been made by any of the maritime nations for nearly thirty years. But the Honourable Daines Barrington having, in the year 1773, presented to the Royal Society a series of papers on the practicability of approaching the North Pole, the President and Council of that Society made application to the First Lord of the Admiralty (then Lord Sandwich) to send out a ship or ships, to try how far navigation might be practicable towards that quarter. The Racehorse and Carcass bombs were accordingly prepared, and the command given to Captain the Honourable Constantine Phipps and Captain Skiffington Lutwidge. They left the Nore on the 10th June, passed along the western coast of Spitzbergen, and advanced to latitude  $80^{\circ} 48'$ , in sight of the Seven Islands; here they were beset in the ice on the 1st August, and on the 10th, after being forced through it by a north-east wind, they proceeded to the southward, and arrived at the Nore on the 25th September.

Of Cook and Clerke.

The hopes of a north-west passage were not abandoned by this failure; but it was resolved to make the attempt by a different route to any that had yet been practised; that is to say, from the Pacific to the Atlantic. Captain Cook was selected for this enterprise, and two ships, the Resolution and Discovery, were fitted out for the purpose, the latter being commanded by Captain Clerke. An amended

act was passed for granting the reward of L. 20,000 for the discovery of "any northern passage" by sea, between the Atlantic and Pacific Oceans, and also the reward of L. 5000 to any ship which should approach the North Pole within one degree. Captain Cook left England in July 1776; entered Behring's Strait on the 9th August 1779; and on the 17th August, reached latitude  $70^{\circ} 41' N.$ , and saw the highest point of America surrounded with ice; and, therefore, named by him Icy Cape, in latitude  $70^{\circ} 29'$ , longitude  $198^{\circ} 20'$ . The main body of the ice drifting down towards the ships, and the weather becoming foggy, they stood to the southward; and, as the season was far advanced, Captain Cook determined to pass the winter at the Sandwich Islands, and to renew the attempt at an earlier period the following year. By his death at this place, Captain Clerke became the commanding officer. That he should have failed in reaching as far north as Cook had done, is not at all surprising, after an absence of three years from home, and all hands, as is avowed, "heartily sick of a navigation full of danger." A small vessel had been sent, in the year 1776, up Davis's Strait, under Lieutenant Pickersgill, and the same vessel again in 1777, under Lieutenant Young, to render any assistance that might be required, in the event of Captain Cook's reaching Baffin's Bay; but neither of these officers made a progress beyond the 73d degree of latitude.

In 1786 and 1787, the King of Denmark, at the suggestion of Bishop Egede, sent out an expedition under Captain (now Admiral) Lowenorn, for the purpose of rediscovering the eastern coast of Greenland. This officer persevered for two years, but with no better success than his predecessors. They saw the coast at various points, as high up as  $66\frac{1}{2}^{\circ}$ , but could not approach it for the ice. No discovery, therefore, of importance resulted from this expedition.

Admiral Lowenorn

On the part of England, all farther attempts appeared to be abandoned after the failure of Captain Cook. One gentleman, however, the late Alexander Dalrymple, Hydrographer to the Admiralty, considering that three points of the northern coast of America had been clearly established,—Icy Cape by Cook; the north of the Copper Mine River, in 1772, by Hearne; and the mouth of Mackenzie River by the traveller whose name it bears, in 1789;—which three points were supposed to be in or about the  $70^{\circ}$  parallel of latitude, and that they comprehended within them full two-thirds of the whole of that coast; and combining these discoveries with other circumstances, was decidedly of opinion that a north-west passage did exist, and that it was practicable. On the strength of this opinion, he prevailed on the governor of the Hudson's Bay Company to employ Mr Charles Duncan, a master in the navy, on the discovery. He left England for this purpose in 1790, to join a sloop of the name of the Churchill, then in Hudson's Bay; but he soon discovered that the crew were averse from the intended enterprise, and set up so systematic an opposition to proceeding upon it, that he deemed it prudent to leave them, and to return to England. The governors of the company expressed their regret; and to prove how

Mr Duncan's Voyage.

**Polar Seas.** much they were in earnest, fitted out a strong ship called the *Beaver*, and Mr Duncan set out a second time. He wintered in Churchill River, where he remained till the 15th July, and entered Chesterfield Inlet; his crew mutinied, encouraged by his first officer, who was a servant of the Hudson's Bay Company, and thus ended his second voyage.

**Of the Russian Voyages.** We have said nothing of the Russian voyages along the northern coast of Asia. That no one person has performed the whole, either at once or by successive trials, is quite clear; but, with the single exception of one "sacred promontory," called Cape Cevero Vostochnoi, between the Yenisei and the Lena, the whole has been navigated by various persons at different times. In the years between 1734 and 1738, Lieutenants Moroviof, Malgyn, and Skurakof, succeeded in proceeding from Archangel to the Bay of Obe; and in the latter year, Offzin and Koskelef proceeded from that bay to the mouth of the Yenisei. In 1735, Lieutenant Prontshistshef set out in the contrary direction from the Lena, but was stopped by the promontory above mentioned; though some affirm that he passed it, and reached as far as Taimura. From the Lena eastward to the Kowyma, the voyage has frequently been performed, and Shalau-roff, in 1671, succeeded in reaching the Shelatskoi Noss, but could not double it; and the only instance of its having been passed is that of Deshnef, as far back as the year 1648, who sailed from the Kowyma, through Behring's Strait, to Anadyr.

**Of Lieutenant Kotzebue.** The immense distance by sea from Petersburg to Kamtschatka, and the Russian settlements on the north-west coast of America, would render the discovery of a north-west passage of infinite importance to Russia. Impressed with the magnitude of this importance, an individual of that nation, the Count Romanzoff, fitted out, at his own expence, a small vessel, named the *Rurick*, the command of which was given to Lieutenant Kotzebue. She left the Baltic in 1815, passed Cape Horn, and in 1817 entered a deep inlet on the eastern side of Behring's Strait, in which he passed the remaining part of the summer. He found no ice, neither in the strait nor the inlet, and saw nothing to prevent his proceeding up the American coast to Icy Cape but the lateness of the season; and therefore returned to the southward, with the intention of renewing the attempt the following year. An accident, however, which occurred on his second entrance of the strait, though personal only, put an end to the expedition.

**Of Ross and Parry, Buchan and Franklin.** This voyage of Kotzebue would alone have been sufficient to stimulate England to attempt once more to accomplish the almost only interesting discovery in geography that remains to be made; but other circumstances were reported in the year 1817 which determined the Government to fit out two expeditions for northern discovery. A ship from Hamburg, in the summer of that year, made the eastern coast of Greenland, which was supposed to have been shut up with ice for four centuries, in the 70th parallel of latitude, continued along it to the 80th degree, and stood along that parallel to the coast of Spitzbergen. For three years before this, the post-office packets, and other vessels crossing the Atlantic, had fallen in

**Polar Seas.** with very unusual quantities of ice floating to the southward. This breaking up of the ice was deemed favourable for the prosecution of northern discovery. For this purpose, two separate expeditions were put in preparation. One was intended to proceed by the North Pole, as the nearest route, and, if no interruption from land occurred, probably the most practicable, to Behring's Strait; the other, to attempt a passage by some of the openings leading out of Baffin's Bay. To each were assigned two ships. Those destined for the Polar passage were the *Dorothea*, of 370 tons, commanded by Captain David Buchan, and the *Trent*, of 250 tons, by Lieutenant John Franklin. Those for the north-west were the *Isabella*, of 382 tons, commanded by Captain John Ross, and the *Alexander*, of 252 tons, by Lieutenant William Edward Parry. The Polar expedition was rendered abortive by the disabling of the *Dorothea* in the ice; the other circumnavigated Baffin's Bay, and ascertained that the narrative of that able navigator whose name it bears is substantially true; and that the chart appended to the *Voyage of the North-West Fox* is, in fact, the chart of Baffin, and wonderfully correct for the time in which it was laid down. Not one, however, of the many great openings which appear in that chart, and were ascertained to exist, were examined; and the only one that was entered was abandoned in a most unaccountable manner, and on grounds which were at once suspected, and subsequently proved, to be utterly without foundation.

**Of Parry and Liddon.** Another expedition was, therefore, immediately fitted out, consisting of two ships, the *Hecla* bomb and *Griper* gun-brig, and the command of it given to Lieutenant Parry, Lieutenant Liddon being appointed to that of the *Griper*. They dropped down the river on the 4th May 1819; saw Cape Farewell on the 15th June; and by the 30th July had succeeded in crossing the ice of Baffin's Bay, and reaching the opening of Sir James Lancaster's Sound; just one month earlier than in the preceding year. To the examination of this sound Mr Parry was particularly directed by his instructions. In proceeding along it to the westward, he met with little obstruction from the ice (though he was evidently navigating through an archipelago of islands where it usually most abounds), until he came to the western extremity of what he calls Melville Island; the last that was visible on the northern side of the strait or passage through which he had proceeded. Beyond this he struggled in vain, till the 20th September, to get to the westward, when the severity of the weather made it prudent to look out for a secure spot to pass the winter; and after cutting a canal through the ice upwards of two miles in length, tracked the two ships into Winter Harbour, the crews "hailing the event with three loud and hearty cheers." The following year, when released from their icy prison, every effort was again made to pass the western extremity of Melville Island, but in vain; and, after many fruitless attempts, the ships returned to the eastward, and reached England in safety, bringing back every man who had embarked on the expedition, with the exception of one, who carried out with him an incurable complaint.

Polar Seas.

The farthest point reached by Lieutenant, now Captain, Parry in the Polar Sea, was latitude  $74^{\circ} 26' 25''$  N. and longitude  $113^{\circ} 46' 43''$  W.; a point of western longitude which, by an amended act of Parliament, dividing the sum of L. 20,000 into a graduated scale, entitled the discoverers to L. 5000.

Of Parry and Lyon.

On their return to England, there was not an officer or man in the whole expedition that was not satisfied with the practicability of a western passage from the Atlantic to the Pacific; though in some other line of direction, either to the northward or the southward of the extensive group of islands among which they had been navigating. The Lords of the Admiralty appear to have entertained the same feelings, and accordingly gave directions for two bombs, the *Fury* and the *Hecla*, to be prepared for the prosecution of the discovery. To Captain Parry was given, as was justly due, the command of the expedition, and to Captain Lyon that of the *Hecla*. They left England in May 1821, and were last heard of high up in Hudson's Strait, in open water, and with a fair wind, on the 22d July, standing for the northeastern extremity of the coast of America; the intention being to keep close along the northern coast of America, where, from experience, it is concluded a stream of water will be found between the land and the main body of the ice.

Probability of a Passage, from the information obtained.

The sketch here given of the various attempts which have been made for the discovery of a North-West, a North-East, and a Polar passage, is purely *historical*. The results have been uniformly unsuccessful; but though they have failed in the main object, it must not be concluded that they have been useless. On the contrary, they have been the means of accumulating a stock of information of the highest importance in almost every department of science, so as to entitle those who, at the expence of every personal comfort, embarked in them, to the gratitude of mankind. From the present state of our knowledge, thus acquired, a very probable conjecture may now be formed of the practicability, or otherwise, of a navigation through some part of the Polar Sea.

In the first place, it has been distinctly ascertained that human beings can winter with impunity to their health in the highest possible degree of cold which can exist in any part of the earth's surface; for there is every reason, short of actual proof, to believe, that the temperature of the atmosphere on the Pole itself is not lower (perhaps not so low) than in the parallel of  $75^{\circ}$ , where Parry wintered; the spirit in the thermometer having there descended to  $55^{\circ}$  below zero. So little, indeed, is a high parallel of latitude the sole cause of a decreased temperature, that, in  $65^{\circ}$  N., ten degrees less than Parry's winter-quarters, Lieutenant Franklin had the spirit in the tube down to  $57^{\circ}$ , two degrees lower than Parry. This officer, therefore, left England with the impression that he should experience no injury, nor much inconvenience, from passing a second winter in the Polar Sea, if it should be found necessary.

In the second place, it has now been ascertained in what situations it would be a waste of time to look for a passage, and where the only remaining

points are deserving of examination. That a communication, if not a practicable passage, does exist between the Atlantic and the Pacific Oceans, through the medium of the Polar Sea, very little doubt can remain. The three known points of Icy Cape, Mackenzie's River, and Hearne River, go far to prove it; and the distance to which Parry proceeded to the westward, considerably beyond Hearne River, strengthens not a little this position.

Another ground for concluding that a communication exists between the two oceans is, the constant current which the old navigators, Button, Fox, Middleton, and others, observed to set down the *Welcome*, and which also, in a less degree, prevails in Baffin's Bay and Davis' Strait; together with the current which as constantly sets up Behring's Strait, as appears from the journals of Cook, Clerke, Glottof, and Kotzebue. The fact of this circumvolving current, which we have no doubt contributes to those permanent movements everywhere existing in the great oceans, has been called in question, because Captain Ross found it running as much one way as the other in Baffin's Bay. Captain Ross had no further knowledge of currents than of those which agitate the surface of the sea, and which are known to change with every wind. Superficial currents, however, are not here meant, but the uniform motion of that great body of water, which, in spite both of winds and superficial currents, and in the teeth of both, carry icebergs many hundred feet immersed below the surface, and bear them along the coast of America, in direct opposition to the strongest and most extensive current that we know of, the Gulf Stream. How happens it, then, it may be asked, why none of these icebergs, so very commonly met with in the Atlantic, ever come across to the coast of Norway, or Denmark, Scotland, or Ireland, with the spray of the said currents, after reaching the banks of Newfoundland, and which brings with it so many other matters floating on the surface to these coasts? Or why do all the bottles which have been launched in Davis' Strait separate from the icebergs, and turn up on some of the above-mentioned coasts? Clearly, because there is a body of water acting on those parts of the icebergs under the surface (and which are at least thirty times the magnitude of the parts above the surface) in a contrary direction to that which is in motion above. This is so obvious as not to require another word on the subject. It is the icebergs only that are subject to this law: the field-ice, which is influenced and drifted about according to the winds and the currents on the surface, gives no indication of the direction in which the great body of water is moved.

In the same manner, we may be satisfied of the constant rush of water from the Pacific through Behring's Strait into the Polar Sea, to supply the constant stream which flows down the *Welcome* into Hudson's Bay. It is this current which, according to the observations of Kotzebue and the naturalist Chamisso, brings the great quantity of drift-wood into Behring's Strait and Kotzebue's Inlet. It is the same current by which, on the same authority, we are told, that the icebergs and fields of ice, which are formed and break up in the sea of Kamt-

*Polar Seas.* schatka, "do not drift, as in the Atlantic, to the south, but into the Strait to the north;" and the strength of this set of the sea is stated to be from two and a half to three miles an hour, and that even in the teeth of a strong northerly wind. The conclusion drawn by M. Kotzebue is this, "that the constant north-east direction of the current of Behring's Strait proves that the water meets with no opposition, and, consequently, that a passage must exist, though perhaps not adapted to navigation. Observations have long been made that the current in Baffin's Bay runs to the south; and thus no doubt can remain that the mass of water which flows into Behring's Strait takes its course round America, and returns through Baffin's Bay into the ocean. But we have still more direct and positive information. Two Russian ships doubled the Icy Cape in 1821, and proceeded some forty or fifty miles beyond the point reached by Captain Cook; and such was the strength of the current *to the eastward*, that it was with the utmost difficulty they could stem it on their return, which a want of provisions, and of every requisite to pass the winter or encounter ice, compelled them to do; but they had no doubt whatever of a practicable passage.

An idea has heedlessly been started, that the superficial current in Baffin's Bay, and those which descend along the coast of Labrador, may be owing to the melting of the ice in summer; but if so, why does not the summer current at least descend through Behring's Strait instead of perpetually ascending it? But the supposition is altogether without foundation; for the quantity of ice destroyed *above* the surface will be replaced by very nearly the same quantity rising from *below* the surface; and, therefore, the water produced by the melting of the ice will merely supply the place of the latter, and not raise the surface of the sea above its usual level, nor produce any current. Be it observed too, that, in the Arctic Regions, little or no increase of the ice is occasioned by the fall of rain or snow.

Another objection, equally frivolous, was made against a communication of the waters of Hudson's Bay and Behring's Strait, on the ground, that the continent of Asia overlapped and was united to America, making Behring's Strait to terminate in a great bay. *That* question, however, has been set at rest for ever, even with those who were disposed to doubt of the voyage of Deschreff. The Russian government has recently employed several men of science to determine points of doubtful position on the northern coast of Siberia. In February 1821, Baron Wrangel, a distinguished officer in their service, left his head-quarters on the Nishey Kolyma to determine, by astronomical observation, the position of Shelatskoi-noss, or the North-east Cape of Asia, which was found to be in latitude  $70^{\circ} 05' N.$ , considerably lower than it is usually placed on the maps. He then proceeded over the ice directly north for 80 miles, without perceiving any other object than a boundless field of ice. The supposed continuation, therefore, of Asia to the eastward, may be considered an idle speculation.

These facts being established, it may be assumed

*Polar Seas.* that a communication does exist between the two oceans; and, from the low latitude of the three known points of the coast of America, it may be inferred that this communication is a navigable one. The question then is narrowed to the direction in which it is most probable a passage will be found? The north-eastern route may be given up, were it only for the great distance (just one half of the whole circumference of the Polar Sea) that it would be necessary to navigate, more or less, among ice. The north-western, by keeping close along the coast of America, is now (1822) under trial; it is that which Captain Parry has judged to be the most feasible from the experience he had acquired along the western coast of Old Greenland, the shores of the western islands of Baffin's Bay, and the southern shores of the numerous islands between the entrance of Barrow's Strait and the western extremity of Melville Island; in all of which places a navigable channel of water was found between the land and the ice. The same thing invariably happens along the western shore of Spitzbergen, and probably along the eastern coast of Old Greenland, when once fairly in with the land. It was proved, indeed, at Winter Harbour, with what extraordinary rapidity the radiated heat of the land melted the ice on the return of summer; and as the coast of America is five degrees of latitude more southerly than Melville Island, the former has a full month more of summer than the latter. The only circumstance which militates against an uninterrupted open channel along that coast, is that of its being a lee-shore to the northerly winds, which appear to be the most prevailing in the Arctic Seas; though Parry found them drawing generally either to the eastward or westward in the direction of the strait. It is not quite certain, however, though every appearance is favourable, that the north-eastern extremity of America terminates at the head of the Welcome, in or about what is called on the charts Repulse Bay; but there is no doubt, that the Regent's Inlet on the south side of Barrow's Strait leads down upon that coast.

The tract pursued on the late voyage through Barrow's Strait, and among the islands, must obviously be given up as hopeless. The north-westerly winds had wedged in such a mass of ice among the islands which never melts, as to render all attempts to penetrate it at the western opening of the funnel impracticable; but beyond this ice, Captain Parry had no doubt there was an open sea; as it was observed whenever the wind came to the eastward, that the whole body of the ice kept moving to the westward for several days together. And this open sea is probably not inaccessible from some other quarter. There is an opening on the northern side of Barrow's Strait in the meridian of  $92^{\circ}$ , which Captain Parry has named Wellington's Channel. This "grand opening," as Parry calls it, was free from every particle of ice, as far as the eye could reach on a fine clear day, and apparently as open and navigable as any part of the Atlantic. This channel, therefore, in all probability, leads to an open sea to the northward of the archipelago of islands, which, there is every reason to believe, is

**Polar Seas.** connected with Baffin's Bay by the great inlets known by the names of Smith's Sound and Alderman Jones's Sound.

**Probability of a great portion of the Polar Sea being free from Ice.** The most important part of the question is, whether the great body of the Polar Sea is composed of water or land. The absence of icebergs in the long tract from Baffin's Bay to Melville Island, and in the seas around Spitzbergen, affords at least a strong presumption against the existence of high precipitous land rising out of a deep ocean, without which, no formation of these huge masses of ice, some of which are not far short of a thousand feet in height, can possibly take place. If, then, the Polar Sea should be free from land, it will, in all probability, be also sufficiently free of ice for the purposes of navigation; for, although it is not doubted that the deep and wide sea will freeze over, yet it is well known that, by the navigation of the water in these boisterous latitudes, the ice formed on the surface is soon broken up, heaped together, and drifted with the wind to some shore or islands, where it becomes fixed, or floated so far down to the southward as to undergo a dissolution. If this was not the case, and we were to suppose the whole surface of the Polar Sea to be once frozen over into one dense and compact mass of ice, that mass must continue to increase from year to year, till that part of the ocean become one solid and immovable body. On the whole, then, we should say, that the probability of an open sea towards the North Pole rather predominates; it is a theory which has been entertained since the days of Dr Hooke; and all the Greenland fishermen are impressed with this opinion.

**Probable Mean Temperature of the Pole.** Dr Brewster, in an ingenious and interesting paper on "the Mean Temperature of the Globe," has shown, in a satisfactory manner, by comparing the results of the late expedition with those he had drawn from a preconceived theory, "that the mean temperature of the North Pole of the globe will be about 11°," which, he says, is "incomparably warmer than the regions in which Captain Parry spent the winter." The mean annual temperature of this spot, according to a series of accurate observations for twelve months, was actually 1°, 33'; and on shore could not have been more than 1° below zero.

**Shortest Route to Behring's Strait.** But if the Polar Sea should be tolerably free from ice and islands, and it were possible to pass the barrier of ice which is usually jammed in between Spitzbergen and Old Greenland, and no doubt it is possible, in many years, as may also be the case on the eastern side of Spitzbergen in most years, the route by this way, and close to the Pole, being on a great circle, would be by far the shortest in point of distance, cutting off not less than the whole width of the Atlantic from the Shetland Islands to Cape Farewell. The accident that happened to Captain Buchan's ship is greatly to be regretted, as otherwise there was every prospect of much new information being obtained in this quarter, which is not likely to be acquired from private ships; for although the present graduated scale of rewards, which commence at the latitude 83°, would appear to encourage masters of fishing ships to avail themselves of favourable openings, which frequently occur, to run for that lati-

tude, we have little hope of a whale-fishing ship attempting it, and thereby perhaps running the risk of losing the short and precarious opportunity of accomplishing the main object of the voyage.

**Polar Seas.** The whole surrounding coast of the North Polar Sea is inhabited; the European part with Laplanders and Finns; the Asiatic shores with Ostiacks, Samoyedes, Yuckagires, Tchutskies, and Koriacks, who derive their subsistence from the rein-deer and dried fish. The Tchutskoi bordering on Behring Strait are a superior kind of Eskimaux, and are no doubt the same race which extend along the northern coast of America, the shores and islands of Baffin's Bay, Davis and Hudson's Straits, and the coast of Labrador; and as high up on the coast of Old Greenland as latitude 78°, the highest habitable spot, in all probability, on the globe. All these people, distantly as they are removed from each other, speak the same language, wear the same dress, subsist in the same manner, and in all their habits and appearance are precisely the same people. Spitzbergen has no permanent inhabitants, but English, Dutch, Danes, and Russians, have frequently wintered there; and even as high as 80° N. many hundreds, some say thousands, of graves, are met with in two or three particular spots where it was usual to extract the oil from the whale and other marine animals furnishing blubber. On Nova Zembla, the body of which is five or six degrees lower in latitude, no inhabitants are found, nor, with the exception of Barentz and his associates, have any been known to pass the winter even in the more southerly parts. Such, indeed, is the difference of climate on the same parallels, that while on the southern part of Nova Zembla, in latitude 69°, not a shrub is to be found, at Altengoord, in Norway, in latitude 70°, trees grow to a considerable size. Old Greenland, and the islands on the western shore of Baffin's Bay, of Davis Strait, and of Hudson's Bay, down to the 55th degree of latitude, are barren of trees and shrubs; while, on the western side of America, as high up as the 60th and even 65th degree, the firs and birch grow to a considerable size. Even in the short distance which separates America from Asia across Behring's Strait, Kotzebue, in passing from the former to the latter, experienced a change like that of summer and winter; in the former all was verdure, in the latter, a complete surface of ice and snow. On the south side of Melville Island, in 75° of latitude, the moment that the snow had departed, the ground was enamelled with a variety of brilliant flowers.

Nor are these dreary regions entirely destitute of **Animals of the Northern Regions.** Rein-deer are met with on the northernmost part of Spitzbergen. The polar bear, the wolf, the arctic fox, the polar hare, the ermine, the lemming or Hudson's Bay mouse, the musk-bull, and the rein-deer, were all caught on Melville Island, the first six being perpetual residents, the two last migratory. Grouse, ptarmigan, plover, and a great variety of water-fowl, frequent in vast numbers the straits and islands of the arctic seas. The following picture, drawn by the naturalist who accompanied Kotzebue, is correct and interesting: "As, on the one hand, in proportion as you advance farther on the land towards the north, the woods become less

**Polar Seas.** lofty, the vegetation gradually decreases, animals become scarcer, and lastly (as on Nova Zembla), the rein-deer and the *glives* vanish with the last plants, and only birds of prey prowl about the icy streams for their food: so, on the other hand, the sea becomes more and more peopled. The *algæ*, gigantic species of *tang*, form inundated woods round the rocky coasts, such as are not met with in the torrid zone. But the waters swarm with animal life—the *medusæ* and *zoophytes*, *molluscæ* and *crustacæ*, innumerable species of fish, in incredibly crowded shoals; the gigantic swimming *mammalia*, whales, physeters, dolphins, morse, and seals, fill the sea and its shores, and countless flights of water-fowl rock themselves on the bosom of the ocean, and in the twilight resemble floating islands.”

## SOUTH POLAR SEA.

Confined  
Knowledge  
of the South  
Polar Sea.

Of the South Polar Sea little or nothing may be said to be known. Captain Cook, in the years 1773 and 1774, crossed the Antarctic Circle in *five* places only;—in longitude  $39\frac{1}{2}^{\circ}$  E., where he advanced to latitude  $67\frac{1}{2}^{\circ}$ , and met with fields and detached pieces of ice; in longitudes  $101^{\circ}$  and  $110^{\circ}$  W., between which he proceeded to latitude  $71^{\circ} 10' S.$ , the farthest progress made by him towards the South Pole, where he was stopped, or at least deemed it prudent to return, on account of the fields and mountains of ice which were scattered over the surface of the sea; and in longitude  $136^{\circ}$  and  $148^{\circ}$  W., between which he descended to latitude  $68^{\circ}$ , and saw many floating ice islands. There are, therefore, still remaining about 340 degrees of longitude in which the Antarctic circle has not been crossed, and full half the circumference of the globe which has not been visited lower to the southward than the parallel of  $60^{\circ}$  south latitude.

There can be little doubt of the existence of high land in the South Polar Sea, though Cook discovered none beyond the Southern Thule or Sandwich Land, on the parallel of  $60^{\circ}$ . Without high precipitous land, those large icebergs which he met with floating among the fields of ice could not have been formed; the *hummocks* of ice, occasioned by the agitation of the sea and the meeting of the *fields* or *flaws* in opposite directions, seldom rise to the height of twelve or fifteen feet above the surface. The Russians, indeed, on a recent voyage of discovery, are said to have fallen in with many islands about the 70th parallel of latitude; they also circumnavigated the Sandwich Land, which was left undetermined by Cook, and conjectured that it might be a part of the great Southern Continent, which occupied so much of the attention of geographers and philosophers of the last century. This idea was renewed by the recent discovery of a very considerable extent of land to the southward of Cape Horn, in latitude  $63^{\circ}$ , and seen extending from longitude  $55^{\circ}$  to  $65^{\circ}$  W. As the eastern extremity had not been seen, and the winding of the coast was to the N. E., it was conjectured that it might unite with the Southern Thule of Cook, and form the long sought for Southern Continent. It is said, however, that the Russians have also circumnavigated this land, and that it is composed of a great cluster of islands.

The land in question has been called South Shetland, but it is no new discovery. In the account of the voyage of *The Five Ships of Rotterdam*, under the command of Jacob Mahu and Simon de Cordes, to the South Seas, in the year 1599, it is stated, that, on approaching the Strait of Magelhaens, the yacht, commanded by Dirk Gherritz, was separated from all the other ships, and was carried by tempestuous weather to the south of the strait to  $64^{\circ}$  S. latitude, where they discovered a high country, with mountains which were covered with snow, like the land of Norway. This land of Gherritz was marked on some of the old charts, but discontinued on the more modern ones, from the uncertainty of its position with regard to longitude. There can be no doubt of its identity with the modern South Shetland. It answered to the description of the mountains of Norway, covered with snow, and is wholly barren, having neither tree nor shrub of any kind. It is unnecessary to say, that it is uninhabited, there being no such people in the southern hemisphere as the Eskimaux; and it may be remarked, that no human beings are found in the Southern Ocean below the 55th parallel of latitude, and none beyond the 50th, except on Patagonia and Terra del Fuego. On the shores, the seals and sea-horses, which had remained from the creation undisturbed, were so numerous, that on the first notice of the rediscovery, a whole fleet of vessels from England and North America crowded thither on speculation; but the loss of several, from tempestuous weather and a dangerous navigation, and the destruction and alarm of the objects of their cupidity, will probably cause it, for some time at least, to remain as much a land of desolation as it had been before.

**Polar Seas.**  
South Shetland.

Since the preceding article was written, the return of Captain Franklin has completely settled the geography of the mouth of the Copper Mine River, and between 500 and 600 miles to the eastward of it. The latitude of this river, which Hearne originally stated to be upwards of  $72^{\circ}$  N., but which was afterwards reduced to  $69^{\circ}$ , is now determined to be  $67^{\circ} 48' N.$ , and longitude  $115^{\circ} 30' W.$ , which is five degrees more westerly than is usually laid down on the charts. One part of the coast, to the eastward of Hearne's River, was found to come down as low as the Arctic Circle, or  $66^{\circ} 30' N.$  Little or no ice was floating on the sea, which was deep and unobstructed, on which ships of any burden might freely navigate; and thus the theory, upon the strength of which Captain Parry is at present proceeding, is confirmed; and Captain Franklin has every reason to believe, that when once he gets upon the coast of North America, he will find no difficulty in making good his passage. Captain Franklin also found that the general current set to the eastward, as all the driftwood was found on the *western* sides of the jutting promontories. Nearly parallel to the coast, and at the distance of five or six miles from it, a range of numerous islands extended the whole length of the passage made by Captain Franklin.

(K.)

# POLITICAL ECONOMY.

Political  
Economy.

THE greater number of the subordinate parts of the science of Political Economy have been treated, in various articles of this *Supplement*, with the fulness which their relative importance seemed to require. In the present article, therefore, we shall principally confine ourselves to an attempt to define the objects and limits of the science—to trace its progress—to exhibit and establish the fundamental principles on which it is founded—and to point out the relation and dependence subsisting between its different parts. In doing this, we shall have occasion to examine the more prominent of the theories which have been advanced in this field of inquiry; our object being, not merely to lay before our readers what we conceive to be a true theory of the science, but also to present them with as full an exposition as our limits will allow of the particular doctrines advocated by the most celebrated of its professors.

## PART I.—DEFINITION AND HISTORY.

*Definition of the Science—Causes of its being neglected in Greece and Rome, and in the Middle Ages—Species of Evidence on which its Conclusions are founded—Rise of the Science in Modern Europe—Mercantile System—Progress of Commercial Philosophy in England in the Seventeenth and Eighteenth Centuries—System of M. Quesnay and the French Economists—Publication of the “Wealth of Nations”—Distinction between Politics and Statistics and Political Economy.*

Definition  
of the  
Science.

Political Economy\* is the science of the laws which regulate the production, distribution, and consumption of those material products which have exchangeable value, and which are either necessary, useful, or agreeable to man.

This definition has been framed so as to exclude all reference to such articles as exist independently of man, and of which unlimited quantities can be obtained without any degree of laborious exertion. Had such been the case with all the articles required to satisfy our wants, and to gratify our desires, this science would either have had no existence at all, or would have been cultivated only as a source of amusement, without any view to utility. Political Economy is exclusively conversant with objects which come within the observation of every man, and which are continually modified by human interference. It is, in fact, the science of values; and nothing which is not possessed of exchangeable value, or which will not be accepted as an equivalent for something else, can come within the scope of its

inquiries. It is obvious, however, that an article may be possessed of the highest degree of utility, or, as it is sometimes termed, of intrinsic worth, and yet be wholly destitute of exchangeable value. Without utility of some species or another, no article will ever be an object of demand; but how necessary soever any particular article may be to our comfort, or even existence, and however great the demand for it, still, if it be a spontaneous production of nature—if it exists independently of human agency, and if every individual has an indefinite command over it, it can never become the subject of an exchange, or afford a basis for the reasonings of the economist. It cannot justly be said, that the food with which we appease the cravings of hunger, or the clothes by which we defend ourselves from the inclemency of the weather, are more useful than atmospheric air; and yet they are possessed of that exchangeable value of which it is totally destitute. The reason is, that food and clothes are not, like air, gratuitous products: they cannot be had at all times, and without any exertion; they are obtainable only by labour; and as no one will voluntarily sacrifice the fruits of his industry, without receiving an equivalent in return, they are truly said to possess exchangeable value.

The word *value* has, we are aware, been very generally employed to express, not only the exchangeable worth of a commodity, or its capacity of exchanging for other commodities, but also to express its utility, or its capacity of satisfying our wants, and of contributing to our comforts and enjoyments. But it is obvious, that the utility of commodities—that the capacity of bread, for example, to appease hunger, or of water to quench thirst—is a totally different and distinct quality from their capacity of exchanging for other commodities. Dr Smith perceived this difference, and showed the importance of carefully distinguishing between the utility, or, as he expressed it, the “value in use,” of commodities, and their value in exchange. But he did not always keep this distinction in view, and it has been very generally lost sight of by M. Say, Mr Malthus, and other late writers. We have no doubt, indeed, that the confounding together of these opposite qualities has been one of the principal causes of the confusion and obscurity in which many branches of the science, not in themselves difficult, are still involved. When, for example, we say that water is highly valuable, we unquestionably attach a very different meaning to the phrase from what we attach to it when we say that gold is valuable. Water is indispensable to existence, and has, therefore, a high degree of utility, or of “value in use;” but as it can be generally ob-

\* *Economy*, from οἶκος, a house, or family, and νόμος, a law—the government of a family. Hence Political Economy may be said to be to the state what domestic economy is to a single family.

**Definition.** tained in large quantities, without much labour or exertion, it has, in most places, but a very low value in exchange. Gold, on the other hand, is of comparatively little utility; but as it exists only in limited quantities, and as a great deal of labour is necessary to procure a small supply of it, it has a high exchangeable value, and may be exchanged or bartered for a large quantity of most other commodities. To confound these different sorts of value would evidently lead to the most erroneous conclusions. And hence, to avoid all chance of error from mistaking the sense of so important a word as *value*, we shall never use it except to signify exchangeable worth, or value in exchange; and shall always use the word *utility* to express the power or capacity of an article to satisfy our wants, or gratify our desires.

A few words will suffice to show the necessity and importance of always distinguishing between the utility of a commodity and its value. If utility and value in exchange were identical, or if they were regulated by the same laws, it would necessarily follow, that the same circumstances which were calculated to increase the utility of any article would also increase its value, and *vice versa*. But the fact is distinctly and completely the reverse. The utility of a commodity is never increased by simply raising, but it is, in the great majority of instances, increased by lowering, its value. A deficient harvest increases the exchangeable value of corn, but most certainly it does not increase its utility. If such an improvement were to take place in the manufacture of hats as would enable them to be produced for a half of the expence it now takes to bring them to market, their value, and consequently their price, would very soon be reduced a half also. Each individual would thus be able to buy two hats for the same sum it had formerly required to buy one; and while the *utility* of no single hat would be impaired by this fall of value, it is plain that the sphere of their utility would be greatly extended, and that they would be brought within the reach of a large proportion of those whose poverty might previously have rendered them unable to obtain them. In fact, the grand object of the science of Political Economy is to discover the means by which the value of commodities may be reduced to the lowest possible limits. For, the more their value is reduced, the more obtainable they become, and the greater, consequently, is the amount of the necessaries, conveniences, and luxuries at the disposal of every individual.

**Definition**  
of the term  
*wealth*.

Political Economy has been frequently defined to be "the science which treats of the production, distribution, and consumption of *wealth*;" and if by wealth be meant those material products which possess exchangeable value, and which are necessary, useful, or agreeable to man, the definition is quite unexceptionable. But the economists who have adopted this definition have attached a different, and a much too extensive meaning to the term wealth. They have sometimes, for example, considered wealth as synonymous with "*all that man desires as useful and agreeable to him*." But if Political Economy were to embrace a discussion of the production and distribution of all that is useful and

agreeable, it would include within itself every other science; and the best Encyclopædia would really be the best treatise on Political Economy. Good health is useful and delightful, and, therefore, on this hypothesis, the science of wealth ought to comprehend the science of medicine; civil and religious liberty are highly useful, and, therefore, the science of wealth must comprehend the science of politics; good acting is agreeable, and, therefore, to be complete, the science of wealth must embrace a discussion of the principles of the histrionic art, and so on. Such definitions are obviously worse than useless. They can have no effect but to generate confused and perplexed notions respecting the objects and limits of the science, and to prevent the student ever acquiring a clear and distinct idea of the nature of the inquiries in which he is engaged.

**Definition.**

Mr Malthus has defined wealth to consist of "those material objects which are necessary, useful, and agreeable to man." (*Principles of Political Economy*, p. 28.) But this definition, though infinitely less objectionable than the preceding, is much too comprehensive to be used in Political Economy. Atmospheric air, and the heat of the sun, are both material products, and are highly useful and agreeable. But their independent existence, and their incapacity of appropriation, excludes them, as we have already shown, from the investigations of this science.

Dr Smith has not explicitly stated what was the precise meaning attached by him to the term wealth; but he most commonly describes it to be "the annual produce of land and labour." Mr Malthus, however, has justly objected to this definition, that it refers to the sources of wealth, before we know what wealth is, and that it includes all the useless products of the earth, as well as those which are appropriated and enjoyed by man.

The definition we have given is not liable to any of these objections. By confining the science to a discussion of the laws regulating "the production, distribution, and consumption of those material products which have exchangeable value, and which are either necessary, useful, or agreeable," we give to it a distinct and definite object. When thus properly restricted, the researches of the economist occupy a field which is exclusively his own. He runs no risk of wasting his time in inquiries which belong to other sciences, or in unprofitable investigations respecting the production and consumption of articles which cannot be appropriated, and which exist independently of human industry.

Capacity of appropriation is indispensably necessary to constitute wealth. And we shall invariably employ this term to distinguish those products only which are obtained by the intervention of human labour, and which, consequently, can be appropriated by one individual, and consumed exclusively by him. A man is not said to be wealthy, because he has an indefinite command over atmospheric air, for this is a privilege which he enjoys in common with every other man, and which can form no ground of distinction; but he is said to be wealthy, according to the degree in which he can afford to command those neces-

**Definition.** series, conveniences, and luxuries which are not the gifts of nature, but the products of human industry. It must, however, be carefully observed, that, although the possession of value be thus necessary to the existence of wealth, they cannot be confounded together without leading to the most erroneous conclusions. Wealth and value are as widely different as utility and value. It is plain that every man will be able to command a much greater quantity of these necessities and gratifications, of which wealth consists when their value declines, or when they become more easily obtainable, than when their value increases. *Wealth and value vary in an inverse ratio.* The one increases as the other diminishes, and diminishes as the other increases.—Wealth is greatest where the facility of production is greatest, and value is greatest where the difficulty of production is greatest.

**Importance of the Science.**

The science of Political Economy is exclusively conversant with that class of phenomena, which the exertion of human industry exhibits. Its object is to ascertain the means by which this industry may be rendered most productive of necessities, comforts, luxuries, and enjoyments, or of wealth in the proper sense of the word; by which this wealth may be most advantageously distributed among the different classes of the society; and by which it may be most profitably consumed. To enter into a lengthened argument to prove the importance of a science having such objects in view, would be worse than useless. The consumption of wealth is indispensable to existence; but the eternal law of Providence has decreed that wealth can only be procured by the intervention of industry—that man must earn his bread by the sweat of his brow. This twofold necessity renders the production of wealth a constant and principal object of the exertions of the vast majority of the human race. It has subdued the natural aversion of man to labour, given activity to indolence, and armed the patient hand of industry with zeal to undertake, and perseverance to overcome, the most difficult and disagreeable tasks. But when wealth is thus necessary, when the desire to acquire it is sufficient to induce us to submit to the greatest privations, it is plainly impossible to doubt the utility and paramount importance of the science which teaches the modes by

which its acquisition may be facilitated, and by which we may be enabled to obtain the greatest amount of wealth with the least possible difficulty. There is no class of people to whom a knowledge of this science can be considered as either extrinsic or superfluous. There are some, doubtless, to whom it may be of more advantage than to others; but it is of the utmost consequence to all. The prosperity of individuals, and consequently of nations, does not depend nearly so much on salubrity of climate, or on the fertility and convenient situation of the soils they inhabit, as on the power possessed by them, of applying their labour with perseverance, skill, and judgment. Industry can balance almost every other deficiency. It can render regions naturally inhospitable barren and unproductive, the comfortable abodes of an intelligent and refined, a crowded and wealthy population; but where it is wanting, the most precious gifts of nature are of no value, and countries possessed of the greatest capabilities of improvement, with difficulty furnish a miserable subsistence to the scanty population of hordes distinguished only by their ignorance, barbarism, and wretchedness.

But when the possession of wealth is thus necessary to individual existence and comfort, and to the advancement of nations in the career of civilization, it may justly excite our astonishment that so few efforts should have been made to discover its sources, and facilitate its acquisition, and that the study of Political Economy, should not have been early considered as forming a principal part in a comprehensive system of education. Two circumstances, to which we shall now briefly advert, seem to us to have been the principal causes of the neglect of this science. The first is the institution of *domestic slavery* in the ancient world; and the second the darkness of the period when the plan of education in the universities of modern Europe was first organized.

The citizens of Greece and Rome considered it degrading to employ themselves in those occupations which form the principal business of the inhabitants of modern Europe. In some of the Grecian states the citizens were prohibited from engaging in any species of manufacturing or commercial industry; and in Athens and Rome, where such a prohibition did not exist, these employments were universally regarded as mean, mercenary, and unworthy of freemen, and were in consequence carried on exclusively by slaves, or the very dregs of the people.\*

\* The force of the prejudices on this head may be learned from the following quotations: "Illiberales autem et sordidi," Cicero says, "questus mercenariorum, omniumque quorum operæ, non quorum artes emuntur. Est enim illis ipsa merces auctoramentum servitutis. Sordidi etiam putandi, qui mercantur a mercatoribus quod statim vendant, nihil enim proficiunt, nisi admodum mentiantur! Opificesque omnes in sordida arte versantur, nec enim quidquam ingenium potest habere officina \* \* \* Mercatura autem, si tenuis est, sordida putanda est; sin autem magna et copiosa, multa undique apportans, multisque sine vanitate impertiens, non est admodum vituperanda" (*De Officiis*, Lib. I. sect. 42.)

"Vulgaris opificum, quæ manu constant, et ad instruendam vitam occupatæ sunt; in quibus nulla decoris, nulla honesti simulatio est." (*Senecæ Epistolæ*, Ep. 89.)

A hundred similar quotations might be produced; but the one we have given from Cicero is sufficient to establish the accuracy of what we have advanced. The strength of the prejudice against commerce and the arts is proved by its exerting so powerful an influence over so cultivated a mind. For a further discussion

Causes of  
the neglect  
of Political  
Economy.

Agriculture was treated with more respect. Some of the most distinguished characters in the earlier ages of Roman history had been actively engaged in rural affairs; but, notwithstanding their example, in the flourishing period of the Republic, and under the Imperial *Regime*, the cultivation of the soil was almost entirely carried on by slaves, belonging to the landlord, and employed on his account. The mass of Roman citizens were either engaged in the military service,\* or derived a precarious and dependant subsistence from the supplies of corn furnished by the conquered provinces. In such a state of society the relations subsisting in modern Europe between landlords and tenants, and masters and servants, were unknown; and the ancients were in consequence entire strangers to all those interesting and important questions arising out of the rise and fall of rents and wages, which form so important a branch of economical science. The spirit of the philosophy of the ancient world was also extremely unfavourable to the cultivation of Political Economy. The luxurious or more refined mode of living of the rich, was regarded by the ancient moralists as an evil of the first magnitude. They considered it as subversive of those warlike virtues, which were the principal objects of their admiration, and, in consequence, they denounced the passion for accumulating wealth as fraught with the most injurious and destructive consequences. It was impossible that Political Economy could become an object of attention, to men imbued with such prejudices; or that it could be studied by those who held the objects about which it is conversant in contempt, and who spurned that labour by which wealth is produced.

At the establishment of our universities, the clergy were almost the exclusive possessors of the little knowledge then in existence. It was natural, therefore, that their peculiar feelings and pursuits should have a marked influence on the plans of education they were employed to frame. Grammar, rhetoric, logic, school divinity, and civil law, comprised the whole course of study. To have appointed professors to explain the principles of commerce, and the means by which labour might be rendered most effective, would have been considered as equally superfluous and degrading to the dignity of science. The prejudices against commerce, manufactures, and luxury, generated in antiquity, had a powerful influence in the middle ages. None were possessed of any clear ideas concerning the true sources of wealth, happiness, and prosperity. The intercourse between the different countries was extremely limited, and was rather confined to marauding excursions, and a piratical scramble for the precious metals, than to a commerce founded on the gratification of real or reciprocal wants.

These circumstances sufficiently account for the

slow progress of, and the little attention paid to this science up to a very recent period. And since it became an object of more general attention and liberal inquiry, the opposition between the theories and opinions that have been espoused by the most eminent of its professors,—a necessary and inevitable result, as we shall immediately show, of its recent cultivation, has proved exceedingly unfavourable to its progress, and has generated a disposition to distrust its best established conclusions. This prejudice is, however, extremely ill-founded; and notwithstanding the diversity of the theories that have been formed to explain its various phenomena, Political Economy admits of as much certainty in its conclusions as any science not exclusively dependent on mere relation. A brief exposition of the nature of the principles on which it is founded, and of the mode in which its investigations ought to be conducted, will evince the correctness of this statement.

Political Economy is not a science of speculation, but of fact and experiment. The principles on which the production and accumulation of wealth and the progress of civilization depend, are not the offspring of legislative enactments. Man must exert himself to produce wealth, because he cannot exist without it; and the desire implanted in the breast of every individual of rising in the world and improving his condition, impels him to save and accumulate. The principles which form the basis of this science make, therefore, a part of the original constitution of man and of the physical world, and their operations, like those of the mechanical principles, are to be traced by the aid of observation and analysis. There is, however, a material distinction between the physical and the moral and political sciences. The conclusions of the former apply in every case, while those of the latter only apply in the majority of cases. The principles on which the production and accumulation of wealth depend are inherent in our nature, but they do not exercise precisely the same influence over the conduct of every individual; and the theorist must satisfy himself with framing his general rules so as to explain their operation in the majority of instances, leaving it to the sagacity of the observer to modify them so as to suit individual cases. Thus it is an admitted principle in the science of Morals, as well as of Political Economy, that by far the largest proportion of the human race have a much clearer view of what is conducive to their own interests, than it is possible for any other man, or select number of men to have, and consequently that it is sound policy to allow every individual to follow the bent of his inclination, and to engage in any branch of industry he thinks proper. This is the general theorem; and it is one which is established on the most comprehensive experience. It is not, however, like the laws which regulate the motions of

Causes of

Economy.

Principles of  
the Science.  
Nature of  
the Evidence  
on which its  
Conclusions  
are Founded.

of the opinions of the Romans on this subject, we refer our readers to the *Dissertazione del Commercio de Romani* of Mengotti, which received a prize from the Academy of Paris in 1787, and to the *Memoria Apologetica del Commercio de Romani* of Torres, published at Venice in 1788.

\* "Rei militaris virtus præstat cæteris omnibus; hæc populo Romano, hæc huic urbi æternam gloriam peperit."—(Cicero pro *Murena*.)

Evidence on which the Conclusions of Political Economy are founded. the planetary system,—it will hold good in nineteen out of twenty instances, but the twentieth may be an exception. But it is not required of the economist, that his theories should quadrate with the peculiar bias of the mind of a particular person. His conclusions are drawn from contemplating the principles which are found to determine the condition of mankind, as presented on the large scale of nations and empires. His business is with man in the aggregate—with states, and not with families—with the passions and propensities which actuate the great bulk of the human race, and not with those which are occasionally found to influence the conduct of a solitary individual.

This distinction should be kept constantly in view. Nothing is more common than to hear it objected to some of the best established truths in political and economical science, that they are at variance with certain facts, and that, therefore, they must be rejected. But these objections very often originate in an entire misapprehension of the nature of the science. It would be easy to produce a thousand instances of individuals who have been enriched by monopolies and restrictions, and even by robbery and plunder; though it would certainly be a little too much to conclude from thence that society could be enriched by such means! This, however, is the single consideration to which the political economist has to attend;—and, until it can be shown that monopolies and restrictions are not destructive of *national wealth*, and that what is gained by the monopolist is not lost by the public, he is justified in considering them injurious. To arrive at a well-founded conclusion in economical science, it is not enough to observe results in particular cases, or as they affect particular individuals; we must further inquire whether these results are *constant* and *universally applicable*—whether the same circumstances which have given rise to them in one instance, would in every instance, and in every state of society, be productive of the same or similar results—A theory which is inconsistent with an *uniform* and *constant* fact, must be erroneous; but the observance of a particular result at variance with our customary experience, and when we may not have had the means of discriminating the circumstances attending it, ought not to induce us hastily to modify or reject a principle which accounts satisfactorily for the greater number of appearances.

The example of the few arbitrary princes who have been equitable, humane, and generous, is not enough to overthrow the principle which teaches that it is the nature of irresponsible power to debauch and vitiate its possessors—to render them haughty, cruel, and suspicious; nor is the example of those who, attentive only to present enjoyment, and careless of the future, lavish their fortunes in boisterous dissipation or vain expence, sufficient to invalidate the general conclusion, that the passion for accumulation is stronger and more powerful than the passion for expence. Had this not been the case, mankind could never have emerged from the condition of savages. The multiplied and stupendous improvements which have been made in different ages and nations—the forests

that have been cut down—the marshes and lakes that have been drained and cultivated—the harbours, roads, and bridges that have been constructed—the cities and edifices that have been raised—are all the fruit of a saving of income, and establish, in despite of a thousand individual instances of prodigality, the ascendancy and superior force of the accumulating principle.

It is from the want of attention to these considerations that much of the error and misapprehension with which the science of Political Economy has been, and still is infected, has arisen. Almost all the absurd theories and opinions which have successively appeared have been supported by an appeal to facts. But a knowledge of facts, without a knowledge of their mutual relation—without being able to show why the one is a cause and the other an effect—is, to use the illustration of M. Say, really no better than the indigested erudition of an almanack maker, and can afford no means of judging of the truth or falsehood of a general principle.

But, although we are not to reject a received principle because of the apparent opposition of a few results, with the particular circumstances of which we are unacquainted, we can have no confidence in its solidity if it be not deduced from a very comprehensive and careful induction. To arrive at a true knowledge of the laws regulating the production, distribution, and consumption of wealth, the economist must draw his materials from a very wide surface; he should study man in every different situation—he should have recourse to the history of society, of arts, of commerce, and of civilization—to the works of philosophers and travellers—to every thing, in short, that can throw light on the causes which accelerate or retard the progress of civilization. He should observe the changes which have taken place in the fortunes and condition of the human race in different regions and ages of the world. He should trace the rise, progress, and decline of industry, and he should carefully discriminate the effect of different political measures, and the various circumstances wherein an advancing and declining society differ from each other. Such investigations, by disclosing the real causes of national opulence and refinement, and of poverty and degradation, furnish the economist with the means of giving a satisfactory solution of almost all the important problems in the science of wealth, and of devising a scheme of public administration calculated to ensure the continued advancement of the society in the career of improvement.

It must always be kept in mind that it is no part of the business of the economist to inquire into the means by which individual fortunes may have been increased or diminished, except to ascertain their general operation and effect. The *public interests* ought always to form the exclusive objects of his attention. He is not to frame systems, and devise schemes, for increasing the wealth and enjoyments of *particular classes*; but to apply himself to discover the sources of *national wealth*, and *universal prosperity*, and the means by which they may be rendered most productive.

Evidence on which the Conclusions of Political Economy are founded.

Rise of the  
Science in  
Modern  
Europe.

When we reflect on the variety and extent of the previous knowledge requisite for the construction of a sound theory of Political Economy, we cease to feel any surprise at the errors into which economists have been betrayed, or at the discrepancy of the opinions which are still entertained on some important points. Political Economy is of very recent origin. Though various treatises of considerable merit had previously appeared on some of its separate parts, it was not treated as a whole, or in a scientific manner, until about the middle of last century. This circumstance is of itself enough to account for the number of erroneous systems that have since appeared. Instead of deducing their general conclusions from a comparison of particular facts, and a careful examination of the phenomena attending the operation of different principles, and of the same principles in different circumstances, the first cultivators of almost every branch of science have begun by framing their theories on a very narrow and insecure basis. Nor is it really in their power to go to work differently. Observations are scarcely ever made or particulars noted for their own sakes. It is not until they begin to be in request as furnishing the only test by which to ascertain the truth or falsehood of some popular theory, that they are made in sufficient numbers, and with sufficient accuracy. It is, in the peculiar phraseology of this science, the *effectual demand* of the theorist that regulates the production of the facts or raw materials, which he is afterwards to work into a system. The history of Political Economy strikingly exemplifies the truth of this remark. Being, as we have already observed, entirely unknown to the ancients, and but little attended to by our ancestors up to a comparatively late period, those circumstances which would have enabled us to judge with the greatest precision of the wealth and civilization of the inhabitants of the most celebrated states of antiquity, and of Europe during the middle ages, have either been thought unworthy of the notice of the historian, or have been only very imperfectly and carelessly detailed. Those, therefore, who first began to trace the general principles of the science had but a comparatively limited and scanty experience on which to build their conclusions. Nor did they even avail themselves of the few historical facts with which they might have easily become acquainted, but almost exclusively confined their attention to those which happened to fall within the sphere of their own observation.

Agreeably to what we have now stated, we find that the theories advanced by the early economical writers were formed on the most contracted basis, and were only fitted to explain a few of the most obvious and striking phenomena. The *Mercantile Theory*, for example, was entirely bottomed on the popular and prevalent opinions respecting money. The precious metals having been long used, both as a standard whereby to ascertain the comparative value of different commodities, and as the equivalents for which they were most frequently exchanged, acquired a fictitious importance, not merely in the estimation of the vulgar, but in that of persons of the greatest discernment. The

simple consideration that all buying and selling is really nothing more than the bartering of one commodity for another—of a certain quantity of corn or wool, for example, for a certain quantity of gold or silver, and *vice versa*, was entirely overlooked. The attention was gradually transferred from the *money's worth* to the money itself; and the wealth of individuals and of states came to be measured, not by the abundance of their disposable products—by the quantity or value of the commodities with which they could afford to purchase the precious metals—but by the *quantity of these metals* actually in their possession. It is on this flimsy and fallacious hypothesis that the theories of almost every writer on economical subjects antecedent to the appearance of the works of Child, North, and Locke, in England, and of Gournay and Quesnay, in France, are founded; and, what is of infinitely greater moment, it is on this same hypothesis that the different civilized countries have proceeded to regulate their intercourse with each other. Their grand object has not been to facilitate the production of the necessaries, comforts, and luxuries of life, but to monopolise the largest possible supply of gold and silver. And, as in countries destitute of mines, these could not be obtained except in exchange for exported commodities, various schemes were resorted to for encouraging exportation, and for preventing the importation of almost all products other than the precious metals. In consequence of this opinion, the excess of the value of the exports over the value of the imports was long considered as the most infallible test of the progress of a country in the career of wealth. This excess, it was believed, could not be balanced otherwise than by an equivalent importation of gold or silver, or of the only real wealth which it was then supposed a country could possess.

These principles and conclusions, though absolutely false and erroneous, afford a tolerable explanation of a few very obvious phenomena; and, what did more to recommend them, they are in perfect unison with the popular prejudices on the subject. It was natural, therefore, that they should be espoused by the merchants or practical men, who were the earliest writers on this science. They did not consider it necessary to subject the principles they assumed to any refined analysis or examination. But, reckoning them as sufficiently established by the common consent and agreement of mankind, they directed themselves exclusively to the discussion of the practical measures calculated to give them the greatest efficacy.

“Although a kingdom,” says one of the earliest and ablest writers in defence of the mercantile system, “may be enriched by gifts received, or by purchase taken, from some other nations, yet these are things uncertain, and of small consideration, when they happen. The ordinary means, therefore, to increase our wealth and treasure, is by foreign trade, wherein we must ever observe this rule—to *sell more to strangers yearly than we consume of theirs in value*. For, suppose, that when this kingdom is plentifully served with cloth,

Mercantile  
System.

Balance of  
Trade.

Mercantile  
system.

Mercantile  
System.

lead, tin, iron, fish, and other native commodities, we do yearly export the overplus to foreign countries to the value of L. 2,200,000, by which means we are enabled, beyond the seas, to buy and bring in foreign wares for our use and consumption to the value of L. 2,000,000: By this order duly kept in our trading, we may rest assured that the kingdom shall be enriched yearly L. 200,000, which must be brought to us as so much treasure; because that part of our stock which is not returned to us in wares, must necessarily be brought home in treasure.”

—(Mun's *Treasure by Foreign Trade*, orig. ed. p. 11.)

The gain on our foreign commerce is here supposed to consist exclusively of the gold and silver which, it is taken for granted, must necessarily be brought home in payment of the excess of exported commodities. Mr Mun lays no stress whatever on the circumstance of foreign commerce enabling us to obtain an infinite variety of useful and agreeable products, which it would either have been impossible for us to produce at all, or to produce so cheaply, at home. We are desired to consider all this accession of wealth—all the vast addition made by commerce to the motives which stimulate, and to the comforts and enjoyments which reward the labour of the industrious, as *nothing*, and to fix our attention exclusively on the balance of L. 200,000 of gold and silver! This is much the same as if we were desired to estimate the comfort and advantage derived from a suit of clothes, by the number and glare of the metal buttons by which they are fastened! And yet the rule for estimating the advantageousness of foreign commerce, which Mr Mun has here given, was long regarded by the generality of merchants and practical statesmen as infallible; and such is the inveteracy of ancient prejudices, that even now we are annually congratulated on the excess of our exports over our imports!

Manufacturing  
System.

But there were other circumstances, besides the erroneous notions respecting the precious metals, which led to the formation of the mercantile system, and to the enacting of regulations restrictive of the freedom of industry. The feudal government established in the countries that had formed the western division of the Roman Empire, degenerated into a system of anarchy and lawless oppression. The princes, who were of themselves totally unable to restrain the usurpations of the greater barons, or to control their violence, endeavoured to strengthen their influence and consolidate their power, by attaching the inhabitants of cities and towns to their interests. For this purpose, they granted them charters, enfranchising the inhabitants, abolishing every existing mark of servitude, and forming them into corporations, or bodies politic, to be governed by a council and magistrates of their own selection. The order and good government that was thus established in the cities, and the security of property enjoyed by their inhabitants, when the rest of the country was a prey to rapine and disorder, stimulated their industry, and gave them a vast ascendancy over the cultivators of the soil. It was from the cities that the princes derived the greater part of their supplies of money; and it was

by their assistance and co-operation that they were enabled to control and subdue the pride and independence of the barons. But the citizens did not render this assistance to their sovereigns merely by way of compensation for the original gift of their charters. They were continually soliciting and obtaining new privileges. And it was not to be expected that princes, so very deeply indebted to them, and by whom they must have been regarded as forming by far the most industrious and deserving portion of their subjects, should be at all disinclined to gratify their wishes. To enable them to obtain their provisions cheap, and to carry on their industry to the best advantage, the exportation of corn, and of the raw materials of their manufactures, was strictly prohibited; at the same time that heavy duties and absolute prohibitions were interposed to prevent the importation of manufactured articles from abroad, and to secure the complete monopoly of the home market to the home manufacturers. These, together with the privilege granted to the citizens of corporate towns of preventing any individual from exercising any branch of business until he had obtained leave from them; and the variety of subordinate regulations intended to force the importation of the raw materials required in manufactures, and the exportation of the manufactured goods, form the principal features of the system of public economy adopted, with the view of encouraging manufacturing industry, in every country in Europe, in the fourteenth, fifteenth, sixteenth, and seventeenth centuries. The freedom of industry recognised by their ancient laws was almost totally destroyed. It would be easy to mention a thousand instances of the excess to which this artificial system was carried in England and other countries; but as many of these instances must be familiar to our readers, we shall only observe, as illustrative of its spirit, that by an act passed in 1678, for the encouragement of the English woollen manufacture, it was ordered that all *dead bodies* should be wrapped in a woollen shroud!

But the exclusion of foreign competition, and the monopoly of the home-market, did not satisfy the manufacturers and merchants. Having obtained all the advantage they could from the public, they attempted to prey on each other. Such of them as possessed most influence, procured the privilege of carrying on particular branches of industry to the exclusion of every other individual. This abuse was carried to a most oppressive height in the reign of Elizabeth, who granted an infinite number of new patents. At length, the grievance became so intolerable, as to induce all classes to join in petitioning for its abolition, which, after much opposition on the part of the Crown, by whom the power of erecting monopolies was considered a very valuable branch of the prerogative, was effected by an act passed in the 21st of James I. But this act did not touch any of the fundamental principles of the mercantile or manufacturing system; and the exclusive privileges of all bodies-corporate were exempted from its operation.

In France the interests of the manufacturers were

Mercantile  
System.

Mercantile  
System.

warmly espoused by the justly celebrated M Colbert, minister of finances during the most splendid period of the reign of Louis XIV.; and the year 1664, when the famous tariff, compiled under Colbert's direction, was first promulgated, has been sometimes considered, though improperly, as the real era of the manufacturing system.

These restrictions were zealously supported by the writers in defence of the mercantile system, and the balance of trade. The facilities given to the exportation of home manufactured goods, and the obstacles thrown in the way of their importation from abroad, seemed to them to be particularly well fitted for making the exports exceed the imports, and procuring a favourable balance. Instead, therefore, of regarding these regulations as the offspring of a selfish monopolizing spirit, they looked on them as having been dictated by the soundest policy. The manufacturing and mercantile systems were thus naturally blended together. The acquisition of a favourable balance of payments was the grand *object* to be accomplished; and heavy duties and restrictions on importations from abroad and bounties and premiums on exportation from home, were the *means* by which this object was to be attained! It cannot excite our surprise that a system having so many popular prejudices in its favour, and which afforded a plausible and convenient apology for the exclusive privileges enjoyed by the manufacturing and commercial classes, should have early attained, or that it should still preserve, notwithstanding the overthrow of its principles, a powerful practical influence. Melon and Forbonnais in France,—Genovesi in Italy,—Mun, Sir Josiah Child, Dr Davenant, the authors of the *British Merchant*, and Sir James Stuart, in England—are the ablest writers who have espoused, some with more and some with fewer exceptions, the leading principles of the mercantile system.

“It is no exaggeration to affirm, that there are very few political errors which have produced more mischief than the mercantile system. Armed with power, it has commanded and forbid where it should only have *protected*. The regulating mania which it has inspired has tormented industry in a thousand ways, to force it from its natural channels. It has made each particular nation regard the welfare of its neighbours as incompatible with its own; hence the reciprocal desire of injuring and impoverishing each other; and hence that spirit of commercial rivalry which has been the immediate or remote cause of the greater number of modern wars. It is this system which has stimulated nations to employ force or cunning to extort commercial treaties, productive of no

real advantage to themselves, from the weakness or ignorance of others. It has formed colonies that the mother country might enjoy the monopoly of their trade, and force them to resort exclusively to her markets. In short, where this system has been productive of the least injury, it has retarded the progress of national prosperity; every where else it has deluged the earth with blood, and has depopulated and ruined some of those countries whose power and opulence it was supposed it would carry to the highest pitch.” (Storch, *Traité d'Economie Politique*, Tome I. p. 122.)

The greater attention which began to be paid, in the seventeenth, and in the earlier part of the last century, to subjects connected with finance, commerce, and agriculture, gradually prepared the way for the downfall of the mercantile system. The English writers preceded those of every other country, in pointing out its defects, and in discovering the real nature and functions of money, and the true principles of commerce. The establishment of a direct intercourse with India did much to accelerate the progress of sound opinions. The precious metals have always been one of the most advantageous articles of export to the East.\* And when the East India Company was established in 1600, power was given them annually to export *foreign* gold coins or bullion, of the value of L. 30,000. The Company were, however, bound to import, within six months after the return of every voyage, except the first, as much gold and silver as should together be equal to the value of the silver exported by them. But the enemies of the Company contended, that these regulations were not complied with, and that it was contrary to all principle, and highly injurious to the public interests, to permit the exportation of any quantity of bullion. The merchants and others interested in the India trade, among whom we have to reckon Sir Dudley Digges, whose defence of the Company was published in 1615, Mr Mun, who published a very able pamphlet in defence of the Company in 1621,† Mr Misselden, and more recently, Sir Josiah Child, could not controvert the reasoning of their opponents, without openly impugning some of the commonly received opinions regarding money. In such circumstances, it is easy to see, that prejudice would be forced to give way to interest. At first, however, the advocates of the Company did not contend, nor is there, indeed, any good reason for thinking that they were of opinion that the exportation of gold or silver to the East Indies was beneficial on the single ground that the commodities brought back were of greater value. They contended, that the Company did not export a greater

\* Pliny, when enumerating the spices, silks, and other eastern products imported into Italy, says, “Minnæque computatione millies centena millia sestertium annis omnibus, India et Seres, peninsulaque illa (Arabia) imperia nostro demunt.” (*Hist. Nat. Lib. XII. cap. 18.*)

† The Emperor Charles V. used to say that the Portuguese, who then engrossed almost the whole commerce of the East, were the common enemies of Christendom, inasmuch as they drained it of its treasure to export it to infidels!—(Misselden *On Free Trade*, p. 24.)

† This pamphlet, which is now become extremely rare, is printed in Purchas's *Pilgrims*, Vol. I. p. 732.

Progress of  
Commercial  
Science in  
England.

quantity of bullion than their charter authorized them to do; and they further contended, that this exportation was advantageous, because the commodities imported from India were chiefly *re-exported* to other countries, from whence a greater quantity of bullion was obtained in exchange for them.\* But even this was an immense advance in the progress to a sounder theory. *C'est toujours le premier pas qui coute.* The advocates of the Company began gradually to assume a higher tone; and at length boldly contended that bullion was *nothing but a commodity*, and that its exportation ought to be rendered as free as the exportation of any other commodity. Nor were these opinions confined to the partners of the East India Company. They were gradually communicated to others; and many eminent merchants were taught to look with suspicion on several of the received maxims, and were in consequence led to acquire more correct and comprehensive views regarding commercial intercourse. The new ideas ultimately made their way into the House of Commons; and in 1663, the statutes prohibiting the exportation of *foreign coin and bullion* were repealed, and full liberty given to the East India Company, and to private traders, to export the same in unlimited quantities.

In addition to the controversies respecting the East India trade, the discussions to which the foundation of the colonies in America and the West Indies, the establishment of a compulsory provision for the support of the poor, and the acts prohibiting the exportation of wool, and the non-importation of Irish cattle, &c. gave rise, attracted an extraordinary portion of the public attention to questions connected with the domestic policy of the country. In the course of the seventeenth century, a more than usual number of tracts were published on commercial and economical subjects. And although the doctrines of the greater number of the writers are strongly tinged with the prevailing spirit of the age, it cannot be denied, that several of them have risen above the prejudices of their contemporaries, and have an unquestionable right to be regarded as the founders of the modern theory of commerce; as the earliest teachers of those sound and liberal doctrines, by which it has been shown, that the prosperity of states can never be promoted by restrictive regulations, or by the depression of their neighbours—that the genuine spirit of commerce is inconsistent with the dark and shallow policy of monopoly—and that the *self-interest* of mankind, not less than their duty, requires them to live in peace, and to cultivate friendship with each other.

Mr Mun. | We have already referred to Mr Mun's treatise, entitled *England's Treasure by Foreign Trade.*

This treatise was first published in 1664; but there is good reason to suppose that it had been written many years previously. Mr Mun's son, in the dedication to Lord Southampton, prefixed by him to the work, says, that his father "was, *in his time*, famous among merchants," a mode of expression which he would hardly have used, had not a considerable period elapsed since his father's death: and Mr Edward Misselden, in his *Circle of Commerce*, published in 1623, (p. 36), refers to Mr Mun's tract on the East India trade, and speaks of its author as being an accomplished and *experienced* merchant. Perhaps, therefore, we shall not be far wrong if we assume, that this treatise was written so early as 1635 or 1640. At all events, it is certain, that the doctrines which it contains do not differ much from those which he had previously maintained in his pamphlet in defence of the East India Company, and some of the expressions are literally the same with those in the petition presented by that body to Parliament in 1628, which is known to have been written by Mr Mun.† The extract we have previously given, shows that Mr Mun's opinions, in so far as regards the question respecting the *balance of trade*, were exactly the same with those of his contemporaries. But, we believe, he was the first who endeavoured to show, and who has, in point of fact, successfully shown, that a *favourable balance could never be produced by restrictive regulations*:—that the exportation and importation of bullion, coin, and every other commodity, should be freely permitted;—and that violent measures will never bring gold or silver into a kingdom, or retain them in it. (pp. 27, 92, &c. original ed.) Mr Mun also distinctly lays it down, "that those who have wares cannot want money," and that "it is not the keeping of our money in the kingdom, but *the necessity and use of our wares in foreign countries, and our want of other commodities, that causeth the vent and consumption on all sides which causeth a quick and ample trade.*" (p. 43.)‡ Nor are these detached and incidental passages thrown out at random. They breathe the same spirit which pervades the rest of Mr Mun's book, and constitute and form a part of his system. His observations in answer to Malyne's, on some rather difficult questions connected with exchange, are both accurate and ingenious.

The first edition of Sir Josiah Child's celebrated work on trade (*A New Discourse of Trade, &c.*) was published in 1668; but it was very greatly enlarged in the next edition, published in 1690. There are many sound and liberal doctrines advanced in this book. The argument to show that colonies do not and cannot depopulate the mother country is as conclusive as if it had proceeded from the pen of Mr

Progress of  
Commercial  
Science in  
England.

\* Those who have not the original pamphlets may consult Macpherson's *History of Commerce*, Vol. II. pp. 297, 315, 511,—Macpherson's *Account of the European Commerce with India*, pp. 94, 104,—and Mr Robert Grant's *Sketch of the History of the Company*, p. 44, where they will find an ample confirmation of what we have stated.

† This petition, and the reasons on which it is founded, were so well esteemed, as to occasion its being reprinted in 1641.

‡ These expressions are in the petition of the Company, presented to Parliament in 1628.

Malthus; and the just and forcible reasoning in defence of the naturalization of the Jews is highly creditable to the liberality and good sense of the writer, and discovers a mind greatly superior to the prejudices of the age. Sir Josiah has also many good and judicious observations on the bad effects of the laws against *forestalling* and *regrating*; on those limiting the number of apprentices; and on corporation privileges.

When treating of the laws relating to the exportation of wool, Sir Josiah lays it down as an axiom, "That they that can give the best price for a commodity shall never fail to have it by one means or other, notwithstanding the opposition of any laws, or interposition of any power by sea or land; of such force, subtilty, and violence, is the general course of trade."

The radical defect of Sir Josiah Child's *Treatise* consists in the circumstance of its being chiefly written to illustrate the advantages, which he labours to show, would result from forcibly reducing the rate of interest to *four per cent.*; an error into which he had been led by mistaking the low interest of Holland for the principal cause of her wealth, when this low interest was in truth the effect of her comparatively heavy taxation.

It is, however, worthy of remark, that this error was very soon detected. In the same year (1668) that Sir Josiah's *Treatise* first appeared, a tract was published, entitled, *Interest of Money mistaken, or a Treatise, proving that the Abatement of Interest is the Effect and not the Cause of the Riches of a Nation*. The author of this tract maintains the same opinions that were afterwards held by Locke and Montesquieu, that the interest of money does not depend on statutory regulations, but that it varies according to the comparative opulence of a country; or rather according to the comparative scarcity and abundance of money—increasing when the supply of money diminishes, and diminishing when it increases.\* Having endeavoured to establish this principle, the author of the tract successfully contends that Sir Josiah Child had totally mistaken the cause of the wealth of the Dutch, of which he shows the lowness of their interest was merely a consequence.

In 1672, Sir William Petty published his celebrated tract, entitled, the *Political Anatomy of Ireland*. In this work, the absurdity of the act passed in 1664, prohibiting the importation of cattle, beef, &c. from Ireland into Britain, is ably exposed, and the advantage of an unconstrained internal commerce clearly set forth. "If it be good for England," says Sir William, "to keep Ireland a distinct kingdom, why do not the predominant party in Parliament,

suppose the western members, make England beyond Trent another kingdom, and take tolls and customs upon the borders? Or why was there ever any union between England and Wales? And why may not the entire kingdom of England be further canonised for the advantage of all parties?" (P. 34, ed. 1719.)

The great defect in the writings of Mun, Misesden, Child, and others, did not really consist so much in their notions about the superior importance of the precious metals, or even the balance of trade, as in their notions respecting the superior advantages derived from the importation of durable, rather than of rapidly perishable commodities, and luxuries. This, however, was an extremely natural opinion; and we cannot be surprised that the earlier writers on commerce should not have avoided falling into an error, from which neither the profound sagacity of Locke, nor the strong sense of Mr Harris, have been able to preserve them. But even so early as 1677, the fallacy of this opinion had been perceived. In that year, there appeared a small tract, entitled, *England's Great Happiness; or, a Dialogue between Content and Complaint*; in which the author contends, that the importation of wine, and other consumable commodities, for which there is a demand, in exchange for money, is advantageous; and, on this ground, defends the French trade, which was as loudly declaimed against by the practical men of that day as it is by those of the present. We shall make a short extract from this remarkable tract:

"*Complaint*.—You speak plain; but what think you of the French trade? which draws away our money by wholesale. Mr Fortrey, † whom I have heard you speak well of, gives an account that they get L. 1,600,000 a-year from us.

"*Content*.—'Tis a great sum; but, perhaps, were it put to a vote in a *wise Council*, whether for that reason the trade should be left off, 'twould go in the *negative*. For paper, wine, linen, Castile soap, brandy, olives, capers, prunes, kidskins, taffaties, and such like, we cannot be without; and for the rest, which you are pleased to style *Apes* and *Peacocks* (although wise Solomon ranked them with gold and ivory), they set us all agog, and have increased among us many considerable trades. \* \* I must confess, I had rather they'd use our goods than money; but if not, I WOULD NOT LOSE THE GETTING OF TEN POUND BECAUSE I CAN'T GET AN HUNDRED; and I don't question but when the French get more foreign trade, they'll give more liberty to the bringing in foreign goods. I'll suppose John-a-Nokes to be a butcher,

\* It has been generally supposed that Mr Hume was the first who showed (in his *Essay on Interest*) the fallacy of this opinion, and who proved that the rate of interest did not depend on the abundance or scarcity of money, but on the abundance or scarcity of disposable capital compared with the demands of the borrowers, and the rate of profit. This, however, is a mistake, the doctrine in question having been fully demonstrated in a pamphlet written by Mr Massie, entitled, *Essay on the Governing Causes of the Natural Rate of Interest*, published two years before Mr Hume's *Essay* appeared.

† Mr Fortrey's pamphlet has been much referred to. It was published in 1663, and reprinted in 1673. It contains a very good argument in favour of inclosures. The reference in the text sufficiently explains the opinions of the writer in regard to commerce.

Progress of  
Commercial  
Science in  
England.

Dick-a-Styles to be an Exchange man, yourself a lawyer, will you buy no meat or ribbands, or your wife a fine Indian gown or fan, because they will not truck with you for indentures which they have need of? I suppose no; but if you get money enough of others, you care not though you give it away in specie for these things; I think 'tis the same case."

The general spirit of this tract may perhaps be better inferred from the titles of some of the dialogues. Among others, we have "To export money our great advantage;"—"The French trade a profitable trade;"—"Variety of wares for all markets, a great advantage;"—"High living, a great improvement to the arts;"—"Invitation of foreign arts, a great advantage;"—"Multitudes of traders, a great advantage," &c. &c. But its influence was far too feeble to arrest the current of popular prejudice. In the year after its publication (1678) the importation of French commodities was prohibited for three years. This prohibition was made perpetual in the reign of William III. when the French trade was declared a nuisance!—a principle, if we may so call it, which has been acted upon to this very hour.

In 1681, a pamphlet was published in defence of the East India Company, under the signature of "Philopatris," but evidently the production of Sir Josiah Child. In the introduction to this pamphlet, the following general principles are laid down:—

"That all close monopolies (Sir Josiah contends that the East India Company does not come under this description), of what nature or kind soever, are destructive to trade, and consequently obstructive to the increase of the value of our lands."

"That silver or gold, coined or uncoined, though they are used for a measure of all other things, are no less a commodity than wine, oil, tobacco, cloth, or stuffs; and may, in many cases, be exported as much to the national advantage as any other commodity."

"That no nation ever was, or will be, considerable in trade, that prohibits the exportation of bullion." (p. 3.)

Sir William  
Petty's  
Quantulum-  
cunque.

In Sir William Petty's *Quantulumcunque*, published in 1682, the subject of money is treated with great ability, and the idea of draining England of her cash, by an unfavourable balance, successfully combated. "If some English merchants," it is said, "should be so improvident as to carry out money only, then the foreign merchants would buy up such English commodities as they wanted with money brought into England from their respective countries, or with such commodities as England likes better than money; for the vending of English commodities doth not depend on any thing else but the use and need which foreigners have of them." Sir W. denies that "a country is the poorer for having less money;" and concludes by strongly condemning the laws regulating the rate of interest; observing, that there may as well be laws to regulate the rate of exchange and of insurance. (See pp. 3, 6, 8, original edition.)

Sir Dudley  
North.

But a tract, entitled, *Discourses on Trade, principally directed to the Cases of Interest, Coinage, Clipping, and Increase of Money*, written by Sir Dudley North, and published in 1691, unquestionably contains a far more able statement of the true principles of commerce than any that had then appeared.

We regret that our limits will not permit our giving so full an account as we could have wished of this extraordinary tract. The author is a most intelligent and consistent advocate of the great principles of commercial freedom. He is not, like the most eminent of his predecessors, well informed on one subject, and erroneous on another. He is throughout sound and liberal. His system is consentaneous in its parts, and complete. He shows, that in commercial matters, nations have the same interests as individuals; and exposes the absurdity of supposing, that any trade which is advantageous to the merchant can be injurious to the public. His opinions respecting the imposition of a seignorage on the coinage of money, and the expediency of sumptuary laws, then in great favour, are equally enlightened.

We subjoin from the preface to this tract an abstract of the general propositions maintained in it:

"THAT THE WHOLE WORLD AS TO TRADE IS BUT AS ONE NATION OR PEOPLE, AND THEREIN NATIONS ARE AS PERSONS.

"That the loss of a trade with one nation is not that only, separately considered, but so much of the trade of the world rescinded and lost, for all is combined together.

"THAT THERE CAN BE NO TRADE UNPROFITABLE TO THE PUBLIC; FOR IF ANY PROVE SO, MEN LEAVE IT OFF; AND WHEREVER THE TRADERS THRIVE, THE PUBLIC, OF WHICH THEY ARE A PART, THRIVE ALSO.

"That to force men to deal in any prescribed manner may profit such as happen to serve them; but the public gains not, because it is taking from one subject to give to another.

"That no laws can set prices in trade, the rates of which must and will make themselves. But when such laws do happen to lay any hold, it is so much impediment to trade, and therefore prejudicial.

"That money is a merchandise, whereof there may be a glut, as well as a scarcity, and that even to an inconvenience.

"THAT A PEOPLE CANNOT WANT MONEY TO SERVE THE ORDINARY DEALING, AND MORE THAN ENOUGH THEY WILL NOT HAVE.

"That no man will be the richer for the making much money, nor have any part of it, but as he buys it for an equivalent price.

"That the free coynage is a perpetual motion found out, whereby to melt and coyn without ceasing, and so to feed goldsmiths and coyners at the public charge.

"That debasing the coyn is defrauding one another, and to the public there is no sort of advantage from it; for that admits no character, or value, but intrinsic.

"That the sinking by alloy or weight is all one.

"That exchange and ready money are the same, nothing but carriage and re-carriage being saved.

"That money exported in trade is an increase to the wealth of the nation; but spent in war, and payments abroad, is so much impoverishment.

"In short, that ALL FAVOUR TO ONE TRADE, OR INTEREST, IS AN ABUSE, AND CUTS SO MUCH OF PROFIT FROM THE PUBLIC."

Unluckily this admirable tract never obtained any considerable circulation. There is good reason, in-

Progress of  
Commercial  
Science in  
England.

Progress of  
Commercial  
Science in  
England.

deed, to suppose that it was designedly suppressed.\* At all events, it speedily became excessively scarce; and we are not aware that it has ever been referred to by any subsequent writer on commerce.

Mr Locke. The disordered state of the coin, and the proceedings relative to the great recoinage in the reign of William III., led to a great deal of discussion both in and out of Parliament, and contributed, in no ordinary degree, to diffuse juster notions respecting money and commerce. It was then that Mr Locke published his well known tracts on Money.† These tracts immediately obtained a very extensive circulation; and though infected with some very grave errors, they had a powerful influence in preventing Mr Lowndes's proposal for degrading the standard of the coin from being carried into effect, and in contributing to establish the true theory of money. The restoration of the currency was not, however, effected without great opposition. A large minority in Parliament supported Mr Lowndes's views; and they were also supported by a number of writers. Of these, Mr Nicholas Barbon seems to have been one of the ablest. In his tract, entitled, *A Discourse concerning Coining the New Money Lighter*, published in 1696, he detected several of the errors into which Mr Locke had fallen; and he has the further merit of having ably demonstrated the fallacy of the popular opinions respecting the balance of trade; and of having shown, that no bullion could ever be sent abroad in payment of an unfavourable balance, unless it was at the time the cheapest and most profitable article of export.

The inferences deduced by Mr Barbon from his investigations into the balance of trade and foreign exchange are:

“That a trading nation is made rich by traffic and the industry of the inhabitants—and that the native stock of a nation can never be wasted.

“That no sort of commodities ought to be totally prohibited—and that the freer trade is, the better the nation will thrive.

“That the poverty and riches of a nation does not depend on a lesser or greater consumption of foreign trade, nor on the difference of the value of those goods that are consumed.

“That the balance of trade is a notion that serves rather to puzzle all debates of trade, than to discover any particular advantages a nation may get by regulating of trade.

“That the balance of trade (if there be one) is not the cause of sending away the money out of a nation: But that proceeds from the difference of the value of bullion in several countries, and from the profit that

Progress of  
Commercial  
Science in  
England.

the merchant makes by sending it away more than by bills of exchange.

“That there is no occasion to send away money or bullion to pay bills of exchange, or balance accounts.

“That all sorts of goods, of the value of the bill of exchange, or the balance of the account, will answer the bill, and balance the account as well as money.”—(p. 59.)

It is singular, that a writer possessed of such sound and enlarged opinions respecting the principles of commercial intercourse, and who had shown that bullion differed in no respect from other commodities, should have maintained, that the value of coined money chiefly depended on the stamp affixed to it by government. This gross and unaccountable error destroyed the effect of Mr Barbon's tract; and was, most probably, the cause of the oblivion into which it very soon fell, and of its never having attracted that attention to which it was on other accounts justly entitled.

The commercial writings of Dr Davenant, Inspector-General of Imports and Exports in the reign of Queen Anne, were published in the interval between 1695 and 1711. Though a partizan of the mercantile system, Dr Davenant had emancipated himself from many of the prejudices of its more indiscriminate and zealous supporters. He considers a watchful attention to the balance of trade, and its “right government,” as of the highest importance; but he does not consider wealth as consisting exclusively of gold or silver; or that prohibitions and restrictions should be rashly imposed, even on the intercourse with those countries with which the balance is supposed to be unfavourable. But we are far from thinking, that the commercial writings of Dr Davenant deserve the eulogies that have been bestowed on them; or that they had any material effect in accelerating the progress of sound commercial science. They do not, in fact, contain a single principle that is not to be found in the work of Sir Josiah Child. Some of Dr Davenant's paragraphs are exceedingly good; but the treatises of which they form a part are remarkably inconclusive, and are for the most part founded on narrow and contracted principles. There is no evidence to show that Dr Davenant was at all aware of the effect of commerce in facilitating the production of wealth, by enabling the inhabitants of each particular country to devote themselves, in preference, to those employments for the successful prosecution of which they have some natural advantage.‡

In 1734, Jacob Vanderlint, who describes him-

Jacob Vanderlint.

\* See the Honourable Roger North's *Life* of his brother, the Honourable Sir Dudley North, p. 179.

† *Considerations on the Lowering of Interest and Raising the Value of Money*, 1691. *Further Considerations concerning Raising the Value of Money*, 1695.

‡ The progress of enlarged and liberal opinions with regard to commerce seem to have been in no small degree counteracted by the publication of the *British Merchant*. This work was written by some of the first merchants of their time, and was chiefly intended to expose the alleged defects in the commercial treaty with France negotiated by Queen Anne's Tory administration in 1713. It consists of a series of papers published weekly, and afterwards collected in three volumes. Public opinion being very much against the treaty, the *British Merchant* enjoyed a large share of popularity. Its authors appear to have

Commercial  
Science in  
England.

self as a tradesman, published his tract, entitled, *Money answers all Things*. Mr Stewart has referred to this tract in the *Appendix* to his valuable *Life of Dr Smith*, and has quoted some passages, illustrative of the advantages of commercial freedom, which, he truly says, "will bear a comparison, both in point of good sense and of liberality, with what was so ably urged by Mr Hume twenty years afterwards, in his *Essay on the Jealousy of Trade*." Vanderlint closes his pamphlet with an argument in favour of the substitution of a territorial tax in place of every other—an idea borrowed from Locke, and subsequently adopted by the French economists.

Sir Matthew  
Decker.

In 1744, \* Sir Matthew Decker, an extensive merchant, published his *Essay on the Causes of the Decline of Foreign Trade*. This essay has been frequently referred to by Dr Smith, and it deserved his notice. Sir Matthew is a most intelligent and decided enemy of all restrictions, monopolies, and prohibitions whatever. To give full freedom to industry—he proposes that all corporation privileges should be abolished; and that all the existing taxes should be repealed, and replaced by a single tax laid on the consumers of luxuries, proportionally to their incomes. The following short extracts will give an idea of the spirit and ability which pervades Sir Matthew's work:—

"In the *Memoirs of De Witt*, is it said, 'that restraint is always hurtful to trade;' the reason whereof is plain; for nature has given various products to various countries, and thereby knit mankind in an intercourse to supply each other's wants. To attempt to sell our products, but to buy little or none from foreigners, is attempting an impossibility, acting contrary to the intent of nature, cynically, and absurdly; and, as ours is a populous manufacturing country, might be prejudicial to our interests; for, could we raise all necessaries and vanities within ourselves, this intercourse designed by nature would be destroyed; and then, how is our navy, our only bulwark, to be maintained?" (p. 147.)

"Trade cannot, will not, be forced; let other nations prohibit, by what severity they please, interest will prevail; they may embarrass their own trade, but cannot hurt a nation, whose trade is free, so much as themselves. Spain has prohibited our woollens; but had a reduction of our taxes brought them to their natural value only, they would be the cheapest in Europe of their goodness, consequently must be more demanded by the Spaniards, be smuggled into their country in spite of their government, and sold at better prices; their people would be dearer clothed, with duties and prohibitions, than without, consequently must sell their oil, wine, and other commodities, dearer; whereby other nations, raising the like growths, would gain ground upon them, and their balance of trade grow less and less. But should we, for that reason, prohibit their commodities? By no means; for the dearer they grow, no more than what

are just necessary will be used; their prohibition does their own business; some may be necessary for us; what are so, we should not make dearer to our own people; some may be proper to assort cargoes for other countries, and why should we prohibit our people that advantage? WHY HURT OURSELVES TO HURT THE SPANIARDS? If we would retaliate effectually upon them for their ill-intent, handsome premiums given to our plantations to raise the same growths as Spain might enable them to supply us cheaper than the Spaniards could do, and establish a trade they could never recover. Premiums may gain trade, but prohibitions will destroy it." (p. 163.)

Sir Matthew applies the same argument to expose the absurdity and injurious effect of our restraints on the trade with France. "I allow," he says, "that Britain should be always vigilant over the designs of France, but need not be afraid of her power; her wise regulations in trade should be the objects we should keep our eyes upon, and out-do her if possible; or else, as she rises, we must sink. But it is our comfort, that our remedy is always in our own hands; nor can there be any solid reason for the nation's paying dearer to other countries for goods we could buy cheaper in France. Would any wise dealer in London buy goods of a Dutch shopkeeper for 15d. or 18d. when he could have the same from a French shopkeeper for 1s.? Would he not consider, that, by so doing, he would empty his own pockets the sooner, and that, in the end, he would greatly injure his own family by such whims? And shall this nation commit an absurdity that stares every private man in the face? — The certain way to be secure is to be more powerful, that is, to extend our trade as far as it is capable of; and as restraints have proved its ruin, to reject them, and depend on freedom for our security; bidding defiance to the French, or any nation in Europe, that took umbrage at our exerting our natural advantages." (p. 184.)

We do not know that the impolicy of restrictions on the importation of foreign corn has ever been more ably and triumphantly exposed than in the following passage: "Every home commodity, in a free trade, will find its natural value; for, though that fluctuates, as of necessity it must, according to the plentifulness or scarcity of seasons, yet, for the home consumption, every home commodity must have great advantage over the foreign, as being upon the spot, and free from freight, insurance, commission, and charges, which on the produce of lands, being all bulky commodities, must in general be about 15 per cent., and a greater advantage cannot be given without prejudice; for 15 per cent. makes a great difference in the price of necessaries between the nation selling and the nation buying, and is a great difficulty on the latter, but, arising from the natural course of things, cannot be helped; though it is a sufficient security to the landholder, that foreigners can never import more necessaries than are absolutely required;

been thoroughly imbued with all the prejudices of the mercantile sect; and the work is now only deserving of notice as containing the fullest exposition of their peculiar doctrines.

\* We quote from the edition of the *Essay* published at Edinburgh in 1756. It appears from the work itself (p. 4), that it had been written in 1740; the first edition was in 4to.

Progress of  
Commercial  
Science in  
England.

and, I presume, in such cases, they have more charity than to starve the people merely for an imaginary profit, which yet would prove their ruin in the end; for it is a fallacy and an absurdity to think to raise the value of lands by oppressions on the people that cramp their trade; for if trade declines, the common people must either come upon the parish, or fly for business to our neighbours: in the first case, they become a heavy tax on the rich, and instead of buying the produce of their lands, must have it given them; and in the second case, when the consumers are gone, what price will the produce of land bear?" (p. 56.)

Mr Hume.

Of a work so well known as Mr Hume's *Political Essays* (published in 1752) it is almost superfluous to speak. The ability with which he has combated the prejudice against the French trade, and exposed the absurdity of the dread of being deprived of a sufficient supply of bullion; the liberality and expansion of his views respecting commerce in general; and the beauty of his illustrations, cannot be too highly praised. It did not, however, enter into Mr Hume's plan to give a systematic view of the effects of commerce, nor has he instituted any analysis of the sources of wealth. Mr Harris has endeavoured to supply the latter deficiency; and his *Essay upon Money and Coins*, published in 1757, is, perhaps, on the whole, the best economical treatise that had appeared previously to the publication of the *Wealth of Nations*. We have already noticed Mr Harris's mistake of supposing that it was more profitable to import durable rather than rapidly consumable commodities; and, as a writer on commerce, he is undoubtedly very inferior to Sir Dudley North and Sir Matthew Decker. But the comprehensive and able manner in which he has treated the subject of money; the skill with which he has illustrated the effects of the division of labour in facilitating production and increasing wealth; and the near approach he has made to some of the fundamental doctrines of Dr Smith, if they do not give him a pre-eminence, certainly place him in the first rank among his precursors.

Mr Harris.

We have been induced to treat of the progress of commercial science in England at considerable

Early Ita-  
lian Writers  
on Com-  
merce.

length, partly on account of the interest and importance of the subject, and partly because we are not acquainted with any work in which it has been investigated. M. Say and some other continental writers contend, that the Italians and French were the first who discovered and established the just principles of commercial intercourse. But the details we have now given prove the indisputable priority of the English. The economical works of Davanzati, Serra, Turbolo, and Scaruffi, are almost wholly occupied with a discussion of the effects of a forced reduction of the standard of money. They deserve credit for having opposed all tampering with the currency; but the arguments they employ to show its injustice and impolicy, are stated with much greater brevity and force in Sir Robert Cotton's speech in the Privy Council in 1626. The *Discorso Economico* of Bاندini, the earliest writer on commerce whose works have been thought worthy of a place in the voluminous collection of Italian works on Political Economy,\* was published so late as 1737. Belloni and Algarotti's *Essays on Commerce*, both very inferior to the works of Sir Josiah Child or Sir Dudley North, were published, the former in 1750, and the latter in 1763.

Early Italian  
Writers on  
Commerce.

The French have still less claim than the Italians to be considered the discoverers of the true principles of commerce. There is much accurate observation, and many just, patriotic, and striking observations on the injury France sustained from the want of a free internal traffic, and from the oppressiveness of taxation, in the *Dixme Royale* of the famous Marshal Vauban, written in 1698. But Vincent de Gournay, whom the French state to be one of the earliest of their authors, who entertained comprehensive and liberal notions regarding commerce in general, was born so late as 1712. † M. Gournay published translations of the treatise of Sir Josiah Child, and of a tract of Sir Thomas Culpepper's, at Paris in 1752. So slow was the progress of economical science in France, that even Montesquieu has a chapter entitled, "*A quelles nations il est desavantageux de faire le commerce.*" ‡

Early

\* *Scrittori Classici Italiani di Economia Politica*. The publication of this collection of the works of her economical writers does honour to Italy. It was begun in 1803 and finished in 1805, in 50 volumes, 8vo.

† See Dupont's edition *Des Oeuvres de M. Turgot*, Tom. III. p. 311.

‡ Maupertuis, in his *Eloge of Montesquieu*, candidly admits that France is indebted for the science of commerce, finance, and population, or of Political Economy, to England. The passage is curious: "Comme le plan de Montesquieu," he observes, "renfermoit tout ce qui peut être utile au genre humain, il n'a pas oublié cette partie essentielle qui regarde le commerce, les finances, la population: Science si nouvelle parmi nous, qu'elle n'y a encore point de nom.—C'est chez nos voisins qu'elle est née; et elle y demoura jusque à ce que M. Melon lui fit passer le mer."

Melon's work, *Essai Politique sur le Commerce*, was published in 1734.—It is entirely founded on the principles of the mercantile system. Mr Bindon translated it into English, and published it, along with some rather valuable annotations and remarks, at Dublin in 1739.

Melon had advocated the ruinous policy of raising the denomination of the coin. This gave occasion to the publication of a very acute work by Dutot, entitled, *Reflexions Politiques sur les Finances et le Commerce*, 2 Tomes, 12mo. 1738. Dutot's work was in its turn very ably criticised by Duverney, in his *Examen des Reflexions Politiques sur les Finances, &c.* 2 Tomes, 12mo. 1740. These works contain a great deal of very curious and interesting information respecting the French finances. Duverney's account of the famous *Mississippi Scheme* is particularly good.

System of  
the French  
Economists.

writers in favour of the freedom of commerce and industry had any considerable influence on the mercantile system. Their opinions respecting the nature of wealth, and of the causes of national opulence, being confused and contradictory, their arguments in favour of a liberal system of commerce had somewhat of an empirical appearance, and failed of making that impression which is always made by arguments founded on well established principles, and shown to be consistent with experience. Mr Locke, as we shall hereafter show, unquestionably entertained very correct opinions respecting the paramount influence of labour in the production of wealth; but he did not prosecute his investigations with the view of elucidating the principles of this science, and made no reference to them in his subsequent writings. Mr Harris adopted Mr Locke's views, and deduced from them some practical inferences of great importance; but his general reasonings are merely introductory to his *Treatise on Money*, and are not illustrated with that fulness of detail, or in that comprehensive and systematic manner that is necessary in scientific works. The celebrated M. Quesnay, a physician, attached to the court of Louis XV., has the unquestionable merit of being the first who attempted to investigate and analyze the sources of wealth, *with the intention of ascertaining the fundamental principles of Political Economy*, and who gave it a systematic form, and raised it to the rank of a science. Quesnay's father was a small proprietor, and having been educated in the country, he was naturally inclined to regard agriculture with more than ordinary partiality. At an early period of his life he had been struck with its depressed state in France, and had set himself to discover the causes which had prevented its making that progress which the industry of the inhabitants, the fertility of the soil, and the excellence of the climate, seemed to insure. In the course of this inquiry, he speedily discovered that the prohibition of exporting corn to foreign countries, and the preference given by the regulations of Colbert to the manufacturing and commercial classes over the agriculturists, had been one of the most powerful obstacles to the progress and improvement of agriculture. But Quesnay did not satisfy himself with exposing the injustice of this preference, and its pernicious consequences. His zeal for the interests of agriculture led him, not merely to place it on the same level with manufactures and commerce, but to raise it above them, by endeavouring to show that it was the only species of industry which contributed to increase the riches of a nation. Founding on the indisputable fact, that every thing which either ministers to our wants, or gratifies our desires, must be originally derived from the earth, Quesnay assumed as a self-evident truth, that the earth was the only source of wealth; and held that industry was altogether in-

capable of producing any new value, except when employed in agriculture, including therein fisheries and mines.\* His observation of the striking effects of the *vegetative powers of nature*, and his inability to explain the real origin and causes of rent, confirmed him in this opinion. The circumstance, that of all who are engaged in laborious undertakings, none but the cultivators of the soil paid rent for the use of *natural agents*, appeared to him an incontrovertible proof, that agriculture was the only species of industry which yielded a net surplus (*produit net*) over and above the expences of production. Quesnay allowed that manufacturers and merchants were highly useful; but, as they realised no net surplus in the shape of rent, he contended they did not add any greater value to the raw material of the commodities they manufactured or carried from place to place, than what was just equivalent to the value of the capital or stock consumed by them. These principles once established, it followed that landlords, farmers, and labourers employed in agriculture, were the only *productive* classes in a state; and that the labour of manufacturers and traders being *unproductive*, their means of subsistence, and their wealth, could only be derived from the agriculturists. It further followed, that the expences of government, and the various public burdens, however imposed, must be defrayed out of the *produit net*, or rent of the landlords; and, consistently with this principle, Quesnay proposed that all the existing taxes should be repealed, and that a single tax (*l'Impot unique*), levied directly from the produce of the land, should be imposed in their stead.

The *economical table* of M. Quesnay—"Cette formule étonnante," says Dupont, "qui peint la naissance, la distribution, et la reproduction des richesses, et qui sert à calculer avec tant de sûreté, de promptitude, et de précision, l'effet de toutes les opérations relatives aux richesses"—was first published at Versailles in 1758.

But, however much impressed with the importance of agriculture over every other species of industry, Quesnay did not solicit for it any exclusive favour or protection. He successfully contended that the interests of the agriculturists, and of all the other classes, would be best promoted by establishing a system of perfect freedom. He showed that it could never be the interest of the proprietors and cultivators of the soil to fetter or discourage the industry of merchants, artificers, and manufacturers: for the greater the liberty which they enjoyed, the greater would be their competition, and their products would, in consequence, be sold so much the cheaper. Neither, on the other hand, could it ever be the interest of the unproductive classes to harass and oppress the industry of the agriculturists, either by preventing the free exportation of their products, or by

\* "Cherchant d'ou vient les richesses des nations, Quesnay trouva qu'elles ne naissent que des travaux dans lesquels la *Nature et la Puissance Divine*, concourent avec les efforts pour produire on faire recueillir des productions nouvelles: de sorte qu'on ne peut attendre l'augmentation des ces richesses que de la cultivation, de la pêche, et de l'exploitation des mines et des carrieres." (See the *Notice sur les Economistes*, by one of the most zealous of the sect, Dupont de Nemours, in the *Œuvres de Turgot*, Tome III. p. 312.)

System of  
the French  
Economists

System of  
the French  
Economists.

any restrictive regulations whatsoever. When the cultivators enjoy the greatest degree of freedom, their industry, and, consequently, their *surplus produce*—the only fund from which any accession of national wealth can be derived, will be carried to the greatest possible extent. According to this “liberal and generous system” (*Wealth of Nations*, Vol. III. p. 17), the establishment of perfect liberty, perfect security, and perfect justice, is the only, as it is the infallible, means of securing the highest degree of prosperity to all classes of the society.

“Ou a vu,” says the Commentator of this system, M. Mercier de la Riviere, “qu’il est de l’essence de l’ordre que l’interet particulier d’un seul ne puisse jamais etre separée de l’interet commun de tous ; nous en trouvons une preuve bien convaincante dans les effets que produit naturellement et necessairement la plénitude de la liberté qui doit regner dans le commerce, pour ne point blesser la propriété. L’interet personnel encouragée par cette grande liberté, presse vivement et perpetuellement chaque homme en particulier, de perfectionner, de multiplier les choses dont il est vendeur ; de grossir ainsi la masse des jouissances qu’il peut procurer aux autres hommes, afin de grossir, par ce moyen, la masse des jouissances que les autres hommes peuvent lui procurer en echange. *Le monde alors va de lui meme ; le desir de jouir, et la liberté de jouir ne cessant de provoquer la multiplication des productions et l’accroissement de l’industrie, ils impriment à toute la société, un mouvement qui devient une tendance perpetuelle vers son meilleur etat possible.*”—(Tome II. p. 444.)\*

System of  
the French  
Economists.

We shall have other opportunities of fully examining the principles of this theory. At present, it is sufficient to remark, that, in assuming agriculture to be the only source of wealth, because the matter of which all commodities are composed must be originally derived from the earth, M. Quesnay and his followers mistake altogether the nature of production, and really suppose wealth to consist of matter. But, in its natural state, matter is very rarely possessed of utility, and is always destitute of value. It is only by means of the *labour* bestowed in the appropriation of matter, and in fitting and preparing it for our use, that it acquires exchangeable value, and becomes wealth. Human industry does not produce wealth by making any additions to the matter of our globe ; for this is a quantity susceptible neither of augmentation nor diminution. Its real effect is simply to produce wealth *by giving utility to matter already in existence* ; and we shall hereafter show that the labour employed in manufactures and commerce is just as productive of utility, and consequently of wealth, as the labour employed in agriculture. Neither is the cultivation of the soil, as M. Quesnay supposed, the only species of industry which yields a surplus produce over the expences of production. When none but the best soils are cultivated, and when, consequently, agriculture is most productive, no rent, or *produit net*, is obtained from the land ; and it is only after recourse has been had to poorer soils, and when the productive powers of the labour and capital employed in cultivation begin to diminish, that rent begins to appear. So that, instead of being a consequence

\* That M. Quesnay is entitled to the merit of originality cannot, we think, be disputed. It is certain, however, that he had been anticipated in several of his peculiar doctrines by some English writers of the previous century. The fundamental principles of the economical system are distinctly and clearly stated in a tract entitled *Reasons for a limited Exportation of Wool*, published in 1677. “That it is of the greatest concern and interest of the nation,” says the author of the tract, “to preserve the nobility, gentry, and those to whom the land of the country belongs, at least, much greater than a few artificers employed in working the superfluity of our wool, or the merchants who gain by the exportation of our manufactures, is manifest—1. Because they are the *masters and proprietaries of the foundation of all the wealth in this nation, all profit arising out of the ground which is theirs.* 2. Because they bear all taxes and public burdens ; which, in truth, are only born by those who buy, and sell not ; all sellers, raising the price of their commodities, or abating of their goodness, according to their taxes.”—(Not being able to procure the pamphlet itself, we quote from the extract given in Mr Smith’s *Memoirs of Wool*, Vol. I. p. 254.)

In 1696, Mr Asgill published a treatise entitled *Several Assertions Proved, in order to Create Another Species of Money than Gold*, in support of Dr Chamberlayne’s proposition for a Land Bank. We extract from this treatise the following passage, breathing, as Mr Stewart has justly observed, the very spirit of Quesnay’s philosophy :—

“What we call commodities is nothing but land severed from the soil—*Man deals in nothing but earth.* The merchants are the factors of the world, to exchange one part of the earth for another. The king himself is fed by the labour of the ox : and the clothing of the army and victualling of the navy must all be paid for to the owner of the soil as the ultimate receiver. All things in the world are originally the produce of the ground, and there must all things be raised.”—(This passage has been quoted in Lord Lauderdale’s *Inquiry into the Nature and Origin of Public Wealth*, 2d ed. p. 109.)

These passages are interesting, as exhibiting the first germs of the theory of the Economists. But there is no reason whatever to suppose that Quesnay was aware of the existence of either of the tracts referred to. The subjects treated in them were of too local a description to excite the attention of foreigners ; and Quesnay was too candid to conceal his obligations to them, had he really owed them any. It is probable he may have seen Mr Locke’s treatise on *Raising the Value of Money*, where the idea is thrown out that all taxes fall ultimately on the land. But there is an immeasurable difference between the suggestion of Locke and the well digested system of Quesnay.

System of  
the French  
Economists.

of the superior productiveness of agricultural industry, rent is really a consequence of its being less productive! The opinion of M. Quesnay, that the labour of man derives no assistance from the productive powers of nature, except when employed in agriculture, is totally destitute of foundation; and, in a subsequent part of this article, we shall show that the manufacturer and merchant derive fully as much assistance from these powers as either the agriculturist, the fisher, or the miner.

Though the theory of the French economists, considered in reference to the fundamental principles of the science, was equally erroneous with that to which it was opposed, its novelty and ingenuity, its systematic and consentaneous form, the liberal system of commercial intercourse which it recommended, and the benevolent and excellent character of its founder, speedily obtained for it a very high degree of reputation. The opinions of M. Quesnay were early communicated to, and zealously espoused by, his friends the Marquis de Mirabeau, M. Mercier de la Riviere, M. Dupont de Nemours, and others; and were afterwards advocated by Turgot, one of the most distinguished statesmen of whom France has to boast; \* and by Letrosne, Condorcet, Raynal, and most of the succeeding French writers on commerce and finance. Their practical influence on the legislation of the country has also been considerable. In 1763 the free transportation of corn from one province to another was permitted; and in 1764 liberty was given to export it to foreign countries whenever the home price did not exceed 30 livres the septier (48s. the quarter). This last edict, after

being suspended in 1770, was again revived in 1778 under the administration of Turgot. But the facility given to the imposition of the *contribution fonciere*, ought certainly to be considered as the greatest practical achievement of the labours of the economists; and there is but too much reason to fear it will long continue to afford a palpable demonstration of the fallacy of their doctrines. †

But, notwithstanding the defects of their theory, there can be no question that the labours of the French economists contributed powerfully to accelerate the progress of economical science. In reasoning on subjects connected with national wealth, it was now found to be necessary to subject its sources, and the laws which regulate its production and distribution, to a more accurate and searching analysis. In the course of this examination, it was speedily ascertained that both the mercantile and economical theories were erroneous and defective; and that to establish the science of Political Economy on a firm foundation, it was necessary to take a much more extensive survey, and to seek for its principles, not in a few partial and distorted facts, or in metaphysical abstractions, but in the connection and relation subsisting among the various phenomena manifested in the progress of civilization. The Count di Verri, whose *Meditations on Political Economy* were published in 1771, demonstrated the fallacy of the opinions entertained by the French economists respecting the superior productiveness of the labour employed in agriculture; and showed that all the operations of industry really consist of *modifications of matter already in existence*. ‡ But Verri

System of  
the French  
Economists.

\* Turgot's *Reflexions sur la Formation, et la Distribution des Richesses* published in 1771, is certainly the best of all the works founded on the principles of the economists; and is, in some respects, the best work on Political Economy published previously to the *Wealth of Nations*.

† Exclusive of the *Reflexions* of Turgot, the following are the principal works published by the French Economists:—

*Tableau Economique, et Maximes Generales du Gouvernement Economique*, par Francois Quesnay, 4to, Versailles, 1758.

*Theorie de l'Impot*, par M. de Mirabeau, 4to, 1760.

*L'Ami des Hommes*, par M. de Mirabeau, 7 Tomes, 1760, &c.

*Elements de la Philosophie Rurale*, par M. de Mirabeau, 3 Tomes, 12mo, 1763.

*L'Ordre Naturel et Essentiel des Societes Politiques*, par Mercier de la Riviere, 4to, and 2 Tomes 12mo, 1767.

*Sur l'Origine et Progrès d'une Nouvelle Science*, par Dupont de Nemours, 1767.

*La Physiocratie, ou Constitution Naturelle du Gouvernement le plus avantageux aux genre humain*, par Quesnay, 2 Tomes, 1767.

*Lettres d'un Citoyen à un Magistrat, sur les vingtiemes et les autres impots*, par l'Abbe Baudeau, 1768.

‡ Alcuni benemeriti scrittori, rattristati dai gravi disordini, che soffrono i popoli per le gabelle, sono passati all'estremo de considerare ingiusto e mal collocato il tributo se non ripartito sui fondi di terra; e colla creazione di un linguaggio ascetico, hanno eretta la setta degli economisti, presso la quale ogni uomo che non adoperi l'aratro, e un essere sterile, e i mamifattori si chiamano una *classe sterile*. Rispettando il molto di vero e di utile che da essi è stato scritto, io non saprei associarmi alla loro opinione ne sul tributo, ne su di questa pretesa classe sterile. La riproduzione e attribuibile alla manifattura ugualmente, quanto al lavoro de campi. Tutti i fenomeni dell'universo, sieno essi prodotti dalla mano dell'uomo o vero dalle universali leggi della fisica, non ci danno idea di attuale *creazione*, ma unicamente di una *modificazione* della materia. *Accostare e sepearare* sono gli unici elementi che l'ingegno umano ritrova analizando l'idea della *riproduzione*; e tanto e riproduzione di *valore e di ricchezza* se la terra, l'aria, e l'acqua ne'campi si trasmutino in grano, come se colla mano dello uomo il glutine di un insetto si trasmuti in velluto, o vero alcuni pezzetti di metallo si organizzino a formare una ripetizione. Degli intieri citta, e degli stati intieri campano non d'altro che sul prodotto di questa fecondissima *classe sterile*, la di cui riproduzione comprende il valore della materia prima, la consumazione proporzionata delle mani impiegatevi, e di piu quella porzione

System of the French Economists.

did not trace the consequences of this important principle; and, possessing no clear and definite notions of what constituted wealth, did not attempt to discover the means by which labour might be facilitated. He made several valuable additions to particular branches of the science, and had sufficient acuteness to detect the errors in the systems of others; but the task of constructing a better system in their stead required talents of a far higher order.

Wealth of Nations.

At length, in 1776, our illustrious countryman Adam Smith published the *Wealth of Nations*—a work which has done for Political Economy what the *Principia* of Newton did for Physics, and the *Esprit des Loix* of Montesquieu for Politics. In this work the science was, for the first time, treated in its fullest extent, and many of its fundamental principles placed beyond the reach of cavil and dispute. In opposition to the French economists, Dr Smith showed, that *labour* is the only source of wealth, and that the desire inherent in the breast of every individual to improve his fortune and rise in the world is the cause of its accumulation. He next traced the means by which the powers of labour may be rendered most effective, and showed that it is productive of wealth when employed in manufactures and commerce, as well as when employed in the cultivation of the land. Having established these principles, Dr Smith showed, in opposition to the commonly received opinions of the merchants, politicians, and statesmen of his time, that wealth did not consist in the abundance of gold and silver, but in the abundance of the various necessaries, conveniencies, and enjoyments of human life; he showed that individuals are always the best judges of what is for their own interest, and that, in prosecuting branches of industry advantageous to themselves, they necessarily prosecute such as are advantageous to the public.\* From thence Dr Smith drew his grand inference, that every regulation intended to force industry into particular channels, or to determine the species of commercial intercourse to be carried on between different parts of the same country, or between distant and independent countries, is impolitic and pernicious—injurious to the rights of individuals—and adverse to the progress of *real* opulence and lasting prosperity.

The fact that traces of most of these principles, and even that the distinct statement of many of those that are most important, may be found in the works of previous writers, does not in the least detract from the real merits of Dr Smith. In adopting the discoveries of others, he has made them his own; he

has demonstrated the truth of principles on which his predecessors had, in most cases, stumbled by chance; has disentangled and separated them from the errors by which they were incumbered; has traced their remote consequences, and pointed out their limitations; has shown their practical importance and real value—their mutual dependence and relation; and has reduced them into a consistent, harmonious, and magnificent system. We do not mean to say that Dr Smith has produced a perfect work. Undoubtedly there are errors, and those, too, of no slight importance, in the *Wealth of Nations*. The principles to which we have just referred, and which form the basis of the work, are unimpeachable; but Dr Smith has not always reasoned correctly from them, and he has occasionally introduced others, which a more careful observation and analysis has shown to be ill-founded. But, after every allowance has been made for these defects, enough still remains to justify us in considering Dr Smith as the real founder of the science. If he has not left us a perfect work, he has, at all events, left us one which contains a greater mass of useful and universally interesting truths than has ever been given to the world by any other individual; and he has pointed out and smoothed the route, by following which, subsequent philosophers have been enabled to perfect much that he had left incomplete, to rectify the mistakes into which he had fallen, and to make many new and important discoveries. Whether, indeed, we refer to the soundness of its leading doctrines, to the liberality and universal applicability of its practical conclusions, or to the powerful and beneficial influence it has had on the progress and perfection of economical science, and still more on the policy and destiny of nations, Dr Smith's work must be placed in the foremost rank of those that have done most to liberalise, enlighten, and enrich mankind.

Wealth of Nations.

The practical part of the science of Political Economy was long confounded with that of Politics; and it is undoubtedly true that they are very intimately connected, and that it is frequently impossible to treat those questions which strictly belong to the one without referring more or less to the principles and conclusions of the other. But, in their leading features, they are sufficiently distinct. The laws which regulate the production and distribution of wealth are the same in every country and stage of society. Those circumstances which are favourable or unfavourable to the increase of riches and population in a republic may equally exist, and will have

Distinction between Politics and Political Economy.

che fa arricchire chi ha intrapresa la fabbrica e chi vi s'impiega con felice talento.—*Meditazioni sulla Economia Politica*, § 3.

\* It is of importance to observe, that Dr Smith does not say, that, in prosecuting such branches of industry as are *most advantageous* to themselves, individuals necessarily prosecute such as are at the same time *most advantageous to the public*. His leaning to the system of the Economists—a leaning perceptible in every part of his work—made him so far swerve from the principles of his own system, as to admit, that individual advantage was not always a *true test* of the public advantageousness of different employments. He considered agriculture, though not the only productive employment, the *most productive* of any. He also considered the home trade as more productive than a direct foreign trade, and the latter than the carrying trade. We shall hereafter show, that there is no foundation for these distinctions.

Distinction  
between  
Politics and  
Political  
Economy.

exactly the same effects, in a monarchy. That security of property, without which there can be no steady and continued exertion—that freedom of engaging in every different branch of industry, so necessary to call the various powers and resources of human talent and ingenuity into action—and that economy in the public expenditure, so conducive to the accumulation of national wealth—are not the exclusive attributes of any particular species of government. If free states generally make the most rapid advances in wealth and population, it is an indirect rather than a direct consequence of their political constitution. It results more from the greater *certainty* which a popular government presents that the right of property will be held sacred—that the freedom of industry will be less fettered and restricted,—and that the public income will be more judiciously levied and expended, than from the circumstance of a greater proportion of the people being permitted to exercise political rights and privileges. Give the same securities to the subjects of an absolute monarch, and they will make the same advances. Industry does not require to be stimulated by extrinsic advantages. The additional comforts and enjoyments which it procures have always been found sufficient to ensure the more persevering and successful exertions. And whatever may have been the form of government, those countries have always advanced in the career of improvement, in which the public burdens have been moderate, the freedom of industry permitted, and every individual enabled peaceably to enjoy the fruits of his labour. It is not, therefore, so much on its political organization, as on the talents and *spirit* of its rulers, that the wealth of a country is principally dependent. Economy, moderation, and intelligence on the part of those in power, have frequently elevated absolute monarchies to a very high degree of opulence and of prosperity; while, on the other hand, all the advantages derived from a more liberal system of government have not been able to preserve free states from being impoverished and exhausted by the extravagance, intolerance, and shortsighted policy of their rulers.

The sciences of Politics and of Political Economy are, therefore, sufficiently distinct. The politician examines the principles on which all government is founded, he endeavours to determine in whose hands the supreme authority may be most advantageously placed,—and unfolds the reciprocal duties and obligations of the governing and governed portions of society. The political economist does not take so high a flight. It is not of the constitution of the government, but of its *ACTS* only, that he presumes to judge. Whatever measures affect the production or distribution of wealth, necessarily come within the scope of his observation, and are canvassed by

him. He examines whether they are in unison with the just principles of economical science. If they *are*, he pronounces them to be advantageous, and shows the nature and extent of the benefits of which they will be productive; if they *are not*, he shows in what respect they are defective, and to what extent their operation will be injurious. But he does this without inquiring into the constitution of the government by which these measures have been adopted. The circumstance of their having emanated from the privy council of an arbitrary monarch, or the representative assembly of a free state, though in other respects of supreme importance, cannot affect the immutable principles by which the economist is to form his opinion upon them.

Besides being confounded with politics, the practical part of Political Economy has frequently been confounded with Statistics; but they are still more easily separated and distinguished. The object of the statistician is to describe the condition of a particular country at a particular period; while the object of the political economist is to discover the causes which have brought it into that condition, and the means by which its wealth and riches may be indefinitely increased. He is to the statistician what the physical astronomer is to the mere observer. He takes the facts furnished by the researches of the statistician, and after comparing them with those furnished by historians and travellers, he applies himself to discover their relation. By a patient induction—by carefully observing the circumstances attending the operation of particular principles, he discovers the effects of which they are really productive, and how far they are liable to be modified by the operation of other principles. It is thus that the relation between rent and profit—between profit and wages, and the various general laws which regulate and connect the apparently clashing, but really harmonious interests of every different order in society, have been discovered and established with all the certainty of demonstrative evidence.

## PART II.—PRODUCTION OF WEALTH.

### SECT. I.—*Definition of Production—Labour the only Source of Wealth.*

All the operations of nature and of art are reducible to, and really consist of *transmutations*,—of changes of form and of place. By production, in the science of Political Economy, we are not to understand the production of matter, for that is exclusively the attribute of Omnipotence, but the production of *utility*, and consequently of exchangeable value, by appropriating and modifying matter already in existence, so as to fit it to satisfy our wants, and to contribute to our enjoyments. The labour which is thus employed is the only source of wealth.\*

\* This point has been strongly and ably stated by M. Destutt Tracy—"Non-seulement," says he, "nous ne créons jamais rien, mais il nous est même impossible de concevoir ce que c'est que *créer* ou *anneantir*, si nous entendons rigoureusement par ces mots, *faire quelque chose de rien*, ou *reduire quelque chose à rien*; car nous n'avons jamais vu un être quelconque sortir du néant ni y rentrer. De là cet axiome admis par toute l'antiquité: rien ne vient de *rien*, et ne peut redevenir *rien*. Que faisons-nous donc par notre travail, par notre action sur tous les êtres qui nous entourent? Jamais rien, qu'opérer dans ces êtres des changements

Labour the  
only Source  
of Wealth.

Labour the  
only Source  
of Wealth.

ture spontaneously furnishes the matter of which commodities are made; but, independently of labour, matter is rarely of any use whatever, and is never of any value. Place us on the banks of a river, or in an orchard, and we shall infallibly perish, either of thirst or hunger, if we do not, *by an effort of industry*, raise the water to our lips, or pluck the fruit from its parent tree. It is seldom, however, that the mere appropriation of matter is sufficient. In the infinite majority of cases, labour is required not only to appropriate it, but also to convey it from place to place, and to give it that peculiar figure and shape, without which it may be totally useless, and incapable of either ministering to our necessities or our comforts. The coal used in our fires is buried deep in the bowels of the earth, and is absolutely worthless until the labour of the miner has extracted it from the mine, and brought it into a situation where it can be made use of. The stones and mortar of which our houses are built, and the rugged and shapeless materials from which the various articles of convenience and ornament with which they are furnished have been prepared, were, in their original state, alike destitute of value and utility. And of the innumerable variety of animal, vegetable, and mineral products which form the materials of our food and clothes, none were originally serviceable, and many were extremely noxious to man. It is his *labour* that has given them utility, that has subdued their bad qualities, and made them satisfy his wants, and minister to his comforts and enjoyments. "Labour was the first price, the original purchase money that was paid for all things. It was not by gold or by silver, but by labour, that all the wealth of the world was originally purchased."—(*Wealth of Nations*, Vol. I. p. 44. 8vo edit.)

If we observe the progress, and trace the history of the human race in different countries and states of society, we shall find their comfort and happiness to have been always nearly proportioned to the power which they possessed of rendering their labour effective in appropriating the raw products of nature, and in fitting and adapting matter to their use. The savage, whose labour is confined to the gathering of wild fruits, or to the picking up of the shell fish on the sea coast, is placed at the very bottom of the scale of civilization, and is, in point of comfort, decidedly inferior to many of the lower animals. The *first* step in the progress of society is made when man learns to hunt wild animals, to feed himself with their flesh, and to clothe himself with their skins. But labour, when confined to the chase, is extremely barren and unproductive. Tribes of hunters, like beasts of prey, whom they are justly said to resemble closely in their habits and modes of subsistence, are but thinly scattered over the surface of the country which they occupy; and notwithstanding the fewness of their numbers, any unusual

deficiency in the supply of game never fails to reduce them to the extremity of want. The *second* step in the progress of society is made when the tribes of hunters and fishers apply their labour, like the ancient Scythians and modern Tartars, to the domestication of wild animals and the rearing of flocks. Their subsistence is much less precarious than that of hunters, but they are almost entirely destitute of all those comforts and elegancies which give to civilized life its chief value. The *third* and most decisive step in the progress of civilization—in the great art of producing the necessaries and conveniences of life—is made when the wandering tribes of hunters and shepherds renounce their migratory habits, and become agriculturists and manufacturers. It is then, properly speaking, that man, shaking off that indolence which is natural to him, begins fully to avail himself of the productive powers of industry. He then becomes laborious, and, by a necessary consequence, his wants are then, for the first time, fully supplied, and he acquires an extensive command over the articles necessary to his comfort as well as his subsistence.

However paradoxical the assertion may at first sight appear, it is, notwithstanding, unquestionably true that the earth does not gratuitously supply us with a single atom of wealth. It is a powerful machine given by Providence to man; but without labour this machine would be altogether useless, and would for ever stand idle and unemployed. It is to labour that the products of the earth owe their *value*, and it is by its intervention that they become useful. The surface of the earth is, in its natural state, covered with fruits and game; its bowels contain an infinite variety of mineral products; its seas and rivers are stored with fish, and it is endowed with inexhaustible vegetative and productive powers; but all these powers and products are plainly of no use whatever, and have no value, until the labour of man has called the former into action, and appropriated the latter, and given them that peculiar form which is required to fit them to support his existence, or to increase his enjoyments.

The importance of labour in the production of wealth was very clearly perceived both by Hobbes and Locke. At the commencement of the 24th chapter (entitled, "Of the *Nutrition and Procreation of a Commonwealth*") of the *Leviathan*, published in 1651, Hobbes says, "The *nutrition of a commonwealth* consisteth in the *plenty and distribution of materials* conducing to life.

"As for the plenty of matter, it is a thing limited by nature to those commodities which, from (the two breasts of our common mother) *land and sea*, God usually either freely giveth, or for labour selleth to mankind.

"For the matter of this nutriment, consisting in animals, vegetables, minerals, God hath freely laid

de forme on de lieu qui les approprient à notre usage, qui les rendent utiles à la satisfaction de nos besoins. Voilà ce que nous devons entendre par *produire*; c'est *donner aux choses une utilité qu'elles n'avoient pas*. Quel que soit notre travail, s'il n'en resulte point d'utilité, il est infructueux; s'il en resulte, il est *productif*."—(*Elemens d'Ideologie*, Tome III. p. 162.)

Labour the  
only Source  
of Wealth.

them before us, in or near to the face of the earth; so as there needeth no more but the labour and industry of receiving them. Insomuch that *plenty dependeth* (next to God's favour) *on the labour and industry of man.*"

Opinion of  
Locke.

But Mr Locke had a much clearer apprehension of this doctrine. In his *Essay on Civil Government*, published in 1689, he has entered into a lengthened, discriminating, and able analysis to show that it is from labour that the products of the earth derive almost all their value. "Let any one consider," says he, "what the difference is between an acre of land planted with tobacco or sugar, sown with wheat or barley, and an acre of the same land lying in common, without any husbandry upon it, and he will find that the improvement of labour makes the far greater part of the value. I think it will be but a very modest computation to say, that of the products of the earth useful to the life of man, *nine-tenths* are the effects of labour; nay, if we will rightly consider things as they come to our use, and cast up the several expences about them, what in them is purely owing to nature, and what to labour, we shall find, that in most of them *ninety-nine hundredths* are wholly to be put on the account of labour.

"There cannot be a clearer demonstration of any thing, than several nations of the Americans are of this, who are rich in land, and poor in all the comforts of life; whom nature having furnished as liberally as any other people with the materials of plenty; *i. e.* a fruitful soil apt to produce in abundance what might serve for food, raiment, and delight; yet for *want of improving it by labour*, have not one hundredth part of the conveniencies we enjoy; and the king of a large and fruitful territory there feeds, lodges, and is worse clad than a day-labourer in England.

"To make this a little clear, let us but trace some of the ordinary provisions of life through their several progresses, before they come to our use, and see how much of their value they receive from human industry. Bread, wine, and cloth, are things of daily use, and great plenty; yet, notwithstanding, acorns, water, and leaves, or skins, must be our bread, drink, and clothing, did not labour furnish us with these more useful commodities; for whatever bread is more worth than acorns, wine than water, and cloth or silk than leaves, skins, or moss, that is solely owing to labour and industry; the one of these being the food and raiment which unassisted nature furnishes us with; the other provisions which our industry and pains prepare for us; which how much they exceed the other in value, when any one hath computed, he will then see how much labour makes

the far greatest part of the value of things we enjoy in this world; and the ground which produces the materials is scarce to be reckoned on as any, or, at most, but a very small part of it.

Labour the  
only Source  
of Wealth.

"An acre of land that bears here twenty bushels of wheat, and another in America, which, with the same husbandry, would do the like, are, without doubt, of the same natural intrinsic value. But yet, the benefit mankind receives from the one in a year is worth L. 5, and from the other possibly not worth *one penny*; if all the profit an Indian received from it were to be valued and sold here, at least, I may truly say, not  $\frac{1}{10000}$ .—'Tis labour, then, which puts the greatest part of value upon land, *without which it would scarcely be worth any thing*: 'Tis to that we owe the greatest part of its useful products; for all that the straw, bran, bread of that acre of wheat, is more worth than the product of an acre of good land, which lies waste, is all the effect of labour. For 'tis not merely the ploughman's pains, the reaper's and thrasher's toil, and the baker's sweat, is to be counted into the bread we eat, the labour of those who broke the oxen, who digged and wrought the iron and stones, who fitted and framed the timber employed about the plough, mill, oven, or any other utensils, which are a vast number, requisite to this corn, from its being seed to be sown, to its being made bread, must all be charged on the account of *labour*, and received as an effect of that. Nature and the earth furnishing only the almost worthless materials as in themselves.—'Twould be a strange *catalogue of things that industry provided and made use of about every loaf of bread*, before it came to our use, if we could trace them. Iron, wood, leather, barks, timber, stone, brick, coals, lime, cloth, dyeing-drugs, pitch, tar, masts, ropes, and all the materials made use of in the ship that brought away the commodities made use of by any of the workmen, to any part of the work; all which, it would be almost impossible, at least too long to reckon up." (*Of Civil Government*, Book II. § 40, 41, 42, and 43.)\*

Had Mr Locke carried his analysis a little further, he could not have failed to perceive that neither water, leaves, skins, nor any of the spontaneous productions of nature, have any *value*, except what they owe to the labour required to appropriate them. The value of water to a man placed on the bank of a river depends on the labour necessary to raise it from the river to his lips; and its value, when carried ten or twenty miles off, is equally dependent on the labour necessary to convey it there. All the rude products, and all the productive powers and

\* This is a very remarkable passage. It contains a far more distinct and comprehensive statement of the fundamental doctrine, that labour is the constituent principle of value, than is to be found in any other writer previous to Dr Smith, or than is to be found even in the *Wealth of Nations*. But Mr Locke does seem to have been sufficiently aware of the real value of the principle he had elucidated, and has not deduced from it any important practical conclusion. On the contrary, in his tract on the *Raising of the Value of Money*, published in 1691, he lays it down broadly that all taxes, howsoever imposed, must ultimately *fall on the land*; whereas, it is plain he ought, consistently with the above principle, to have shown that they would fall, not exclusively on the produce of land, but generally on the *produce of industry*, or on all species of commodities.

about the  
only Source  
of Wealth.

capacities of nature, are gratuitously offered to man. Nature is not niggardly or parsimonious. She neither demands nor receives an equivalent for her favours. An object which it does not require any portion of labour to appropriate or to adapt to our use, may be of the very highest utility; but, as it is the free gift of nature, it is utterly impossible it can be possessed of the smallest value.\*

“Si je retranche,” to use a striking illustration of this doctrine given by M. Canard, “de ma montre, par la pensée, tous les travaux qui lui ont été successivement appliquées, il ne restera que quelques grains de minéral placées dans l'intérieur de la terre d'où on les a tirés, et ou ils n'ont aucune valeur. De même si je decompose le pain que je mange, et que j'en retranche successivement tous les travaux successifs qu'il a reçus, il ne restera que quelques tiges d'herbes, graminées, éparses dans des deserts incultes, et sans aucune valeur.” (*Principes d'Economie Politique*, p. 6.)

It is to labour, therefore, and to labour only, that man owes every thing possessed of exchangeable value. Labour is the talisman that has raised him from the condition of the savage—that has changed the desert and the forest into cultivated fields—that has covered the earth with cities and the ocean with ships—that has given us plenty, comfort, and elegance, instead of want, misery, and barbarism.

Having established this fundamental principle—having shown that it is labour only that gives exchangeable value to commodities—it is plain the great practical problem of the science of Political Economy must resolve itself into a discussion of the means whereby labour may be rendered most efficient, or whereby the greatest amount of necessary, useful, and agreeable products may be obtained with the least quantity of labour. Wealth, as we have already shown, is always increased with every diminution of the labour required to produce the articles of which it consists. Every measure and invention that has any tendency to save labour, or to reduce the cost of producing commodities, must add proportionably to our power of obtaining wealth and riches, while every measure or regulation that has any tendency to waste labour, or to raise the cost of producing commodities, must equally lessen this power. This is the simple and decisive test by which we are to judge of the expediency of

every measure affecting the wealth of the country, and of the value of every invention. If they render labour more productive—if they have a tendency to reduce the exchangeable value of commodities, to render them more easily obtainable, and to bring them within the command of a greater portion of society, they must be advantageous; but if their tendency be different, they must as certainly be disadvantageous. Considered in this point of view, that great branch of the science of Political Economy which treats of the production of wealth, will be found to be abundantly simple, and easily understood.

Labour, according as it is applied to the raising of raw produce—to the fashioning of that raw produce, when raised, into articles of utility, convenience, or ornament—and to the conveyance of raw and wrought produce from one country and place to another—is said to be agricultural, manufacturing, or commercial. An acquaintance with the particular processes, and most advantageous methods, of applying labour in each of these grand departments of industry, forms the peculiar and appropriate study of the agriculturist, manufacturer, and merchant. It is not consistent with the object of the political economist to enter into the details of particular businesses and professions. He confines himself to an investigation of the means by which labour in general may be rendered most productive, and how its powers may be increased in all the departments of industry.

SECT. II.—Means by which the Productive Powers of Labour are increased—Security of Property—Division of Labour—Accumulation and Employment of Capital.

The most careless and inattentive observer of the progress of mankind from poverty to affluence must have early perceived, that there are three circumstances whose conjoint operation is necessary to stimulate and improve the productive powers of industry, and in the absence of which men could never have emerged from barbarism. The first, and most indispensable, is the security of property, or a well-founded conviction in the mind of every individual that he will be allowed to dispose at pleasure of the

Labour the  
only Source  
of Wealth.

Means by  
which the  
Productive  
Powers of  
Labour may  
be increased.

\* Bishop Berkeley entertained very just opinions respecting the source of wealth. In his *Querist*, published in 1735, he asks,—“Whether it were not wrong to suppose land itself to be wealth? And whether the industry of the people is not first to be considered, as that which constitutes wealth, which makes even land and silver to be wealth, neither of which would have any value, but as means and motives to industry?”

“Whether, in the wastes of America, a man might not possess twenty miles square of land, and yet want his dinner, or a coat to his back.”—*Querist*, Numbers 38 and 39.

We shall afterwards notice Sir William Petty's opinion on this subject.

M. Say appears to think (*Discours Preliminaire*, p. 37) that Galiani was the first who showed, in his treatise *Della Moneta*, published in 1750, that labour was the only source of wealth. But the passages we have now laid before the reader prove the erroneousness of this opinion. Galiani has entered into no analysis or argument to prove the correctness of his statement; and, as it appears from other parts of his work, that he was well acquainted with Mr Locke's *Tracts on Money*, a suspicion naturally arises that he had seen the *Essay on Civil Government*, and that he was really indebted to it for a knowledge of this principle. This suspicion derives strength from the circumstance of Galiani being still less aware than Mr Locke of the value of the discovery.—See *Trattato Della Moneta*, p. 39, ediz. 1780.

Security of  
Property.

fruits of his labour. The *second* is the introduction of exchange or barter, and the consequent appropriation of particular individuals to particular employments. And the *third* is the accumulation and employment of the produce of previous labour, or, as it is more commonly termed, of capital, or stock. All the improvements that have ever been made, or that ever can be made, in the great art of producing the necessaries, comforts, and conveniences of human life, are *all* resolvable into the more judicious and successful application of one or more of those means of stimulating labour, and adding to its power. To give a full exposition of the nature and influence of each would far exceed the limits of this article; and we must content ourselves with such observations as may suffice to give a general idea of their operation.

Security of  
Property.

SECURITY OF PROPERTY.—Security of property is the first and most indispensable requisite to the production of wealth. Its utility in this respect is, indeed, so obvious and striking, that it has been more or less respected in every country, and in the earliest and rudest periods of society. All have been impressed with the reasonableness of the maxim which teaches that those who *sow* ought to be permitted to *reap*—that the *labour* of a man's body and the *work* of his hands are to be considered as exclusively his own. No savage horde has ever been discovered in which the principle of *meum* and *tuum* was not recognised. Nothing, it is plain, could ever tempt any one to engage in any laborious employment—he would neither domesticate wild animals, nor clear and cultivate the ground, if, after months and years of toil, when his flocks had become numerous, and his harvests were ripening for the sickle, a stranger were to be allowed to rob him of the produce of his industry. No wonder, therefore, that the utility of some general regulations, which should secure to every individual the peaceable enjoyment of the produce he had raised, and of the ground he had cultivated and improved, suggested itself to the first legislators. The author of the book of *Job* places those who removed their neighbour's land-marks at the head of his list of wicked men; and some of the earliest profane legislators subjected those who were guilty of this offence to a capital punishment. (Gouet, *De l'Origine des Loix*, &c. Tom. I. p. 30. 4to ed.)

Dr Paley has said that the *law of the land* is the real foundation of the right of property. But the obvious *utility* of securing to each individual the produce which has been raised by his industry, has undoubtedly formed the irresistible reason which has induced every people emerging from barbarism to establish this right. The institution of the right of property is, in truth, the foundation on which all the other institutions of society rest. Until property had been publicly guaranteed, men must have looked on each other as enemies, rather than as friends. The idle and improvident are always desirous of seizing on the earnings of the laborious and frugal; and, if they were not restrained by the strong arm of the law—if they were permitted to prosecute their attacks, they would, by generating a feeling of insecurity, effectually check both industry and accumulation, and sink

all classes to the same level of hopeless misery as themselves. In truth, the security of property is even more necessary to accumulation than it is to production. No man ever did or ever will deny himself an immediate gratification when it is within his power, unless he thinks, that, by doing so, he has a fair prospect of obtaining a greater accession of comforts and enjoyments, or of avoiding a greater evil at some future period. Where the right of property is vigilantly protected, an industrious man, who produces as much by one day's labour as is sufficient to maintain him two days, does not lie idle the second day, but accumulates the surplus produce above his wants as a capital; the increased consequence and enjoyments which the possession of capital brings along with it, being, in the great majority of cases, more than sufficient to counterbalance the desire of immediate gratification. But, wherever property is insecure, we look in vain for the operation of the principle of accumulation. "It is plainly better for us," is then the invariable language of the people, "to enjoy while it is in our power, than to accumulate property which we shall not be permitted to use, and which will either expose us to the extortion of a rapacious government, or to the unrestrained depredations of those who exist only by the plunder of their more industrious neighbours."

But the security of property is not violated merely when a man is deprived of the power of peaceably enjoying the fruits of his industry; it is also violated, and perhaps in a still more glaring and unjustifiable manner, when he is prevented from using the powers with which nature has endowed him, in any way, not injurious to others, that he considers most beneficial to himself. Of all the species of property which a man can possess, *the faculties of his mind and the powers of his body* are most particularly his own. He ought, therefore, to be permitted to enjoy, that is, to use or exert these powers at his discretion. And hence the right of property is as much, or more infringed upon, when a man is interdicted from engaging in a particular branch of business, as it is when he is forcibly bereft of the property he had produced and accumulated. Every monopoly which gives to a few individuals the exclusive power of carrying on certain branches of industry, is thus, in fact, established in direct violation of the right of property of every other individual. It prevents them from using their natural capacities or powers in the manner which they might have considered best; and, as every man who is not a slave is held, and justly held, to be the best, and, indeed, the only judge of what is advantageous for himself, the principles of natural law and the right of property are both subverted when he is excluded from any employment. In like manner, the right of property is violated whenever any regulation is made to force an individual to employ his labour or capital in a particular way. The property of a landlord is violated when he is compelled to adopt any system of cultivation, even supposing it to be really preferable to that which he was previously following. The property of the capitalist is violated when he is obliged to accept a particular rate of interest for his stock, and the property of the labourer is violated whenever he is obliged

Security of  
Property.

Security of  
Property.Effects of  
Insecurity.

to betake himself, in preference, to any particular occupation.

The finest soil, the finest climate, and the finest intellectual powers, can prevent no people from becoming barbarous, poor, and miserable, if they have the misfortune to be subjected to a government which does not respect the right of property. This is the greatest of all calamities. The ravages of civil war, of pestilence, and of famine, may be repaired; but nothing can enable a nation to contend against the deadly influence of an established system of violence and rapine. It is the want of security—the want of any lively and well-founded expectation of being permitted freely to dispose of the fruits of their industry, that is the principal cause of the wretched state of the Ottoman dominions at the present day, as it was of the decline of industry and arts in Europe during the middle ages. When the Turkish conquerors overran those fertile and beautiful countries in which they are still permitted to encamp, they parcelled them among their followers, on condition of their performing certain military services, on a plan corresponding, in many important particulars, to the feudal system of our ancestors. But these possessions are not hereditary. They do not descend to the children or legatees of the present possessor, but, on his death, revert to the Sultan. Among the occupiers of land in Turkey there is, therefore, no thought of futurity. No one can feel any interest about the prosperity of an unknown successor; and no one ever executes any improvement of which he does not expect to be able to reap all the advantage during his own life. This is assigned by Lady Wortley Montague as the cause why the Turks are so extremely careless about their houses. They never construct them of solid or durable materials. And it would be a gratification to them to be assured that they would fall to pieces the moment after they had breathed their last. Under this miserable government the palaces have been changed into cottages, and the cities into villages. The long continued want of security has extinguished the very spirit of industry, and destroyed not only the power, but even the desire to emerge from barbarism.

Had it been possible for arbitrary power to profit by the lessons of experience, it must long since have perceived that its own wealth, as well as the wealth of its subjects, would be most effectually promoted by maintaining the inviolability of property. Were the Turkish government to establish a vigilant system of police—to secure to each individual the unrestricted power of disposing of the fruits of his labour—and to substitute a regular plan of taxation in the place of the present odious system of extortion and tyranny, industry would revive, capital and population would be augmented, and moderate duties, imposed on a few articles in general demand, would bring a much larger sum into the coffers of the treasury than all that is now obtained by force and violence. The stated public burdens to which the Turks are sub-

Security of  
Property.

jected are light when compared with those imposed on the English, the Hollanders, or the French. But the latter know that when they have paid the taxes due to government, they will be permitted peaceably to enjoy or to accumulate the remainder of their earnings; whereas the Turk has no security but that the next moment after he has paid his stated contribution, the Pacha, or one of his satellites, may trip him of every additional farthing he possesses! Security is the foundation—the principal element in every well digested system of finance. When maintained inviolate, it enables a country to support, without much difficulty, a very heavy load of taxes; but where there is no security—where property is a prey to rapine and spoliation—to the attacks of the needy, the powerful, or the profligate—the smallest burdens are justly regarded as oppressive, and uniformly exceed the means of the impoverished and spiritless inhabitant.

The Jews have been supposed to afford an instance of a people, whose property has been long exposed to an almost uninterrupted series of attacks, and who have, notwithstanding, continued to be rich and industrious. But when rightly examined, it will be found that the case of the Jews forms no exception to the general rule. The absurd prejudices with which the Jews have been almost universally regarded, long prevented their acquiring any property in land, and have excluded them from participating in the benefits derived from the charitable institutions of the different countries among which they are scattered. Having, therefore, no adventitious support on which to depend, in the event of their becoming infirm or destitute, they had a powerful additional motive to save and accumulate; and being excluded from agriculture, they were of necessity compelled to addict themselves, in preference, to commerce. In an age when the profession of a merchant was generally looked upon as something mean and sordid, and when, of course, they had comparatively little competition, they must have made considerable profits; but these have been very greatly exaggerated. It was natural that those who were indebted to the Jews should represent their gains as enormous; for this inflamed the existing prejudices against them, and afforded a miserable pretext for defrauding them of their just claims. There are a few rich Jews in most of the large cities of Europe; but the majority of that race have ever been, and still are, as poor as their neighbours.

Let us not, therefore, deceive ourselves by supposing that it is possible for any nation or any people to emerge from barbarism, or to become wealthy, populous, and civilized, without the security of property. From whatever point of the political compass we may set out, this is the principle to which we must come at last. Security is indispensably necessary to the successful exertion of the powers of industry. Where it is wanting, it is idle to expect either riches or civilization.\*

Rousseau and some other sentimental writers

Security of  
Property.

have made an objection to the institution of the right of property, which has been, in some measure, sanctioned by the authority of the Marquis Beccaria.\* They allow that the security of property is advantageous for those who possess it; but they contend, that it is disadvantageous for those who are poor and destitute. It has condemned, they affirm, the greater portion of mankind to a state of misery, and has provided for the exaltation of the few by the depression of the many! The sophistry of this reasoning is so apparent, as hardly to require to be pointed out. The right of property has not made *poverty*, but it has made *wealth*. Previous to the institution of this right, those nations which are now most civilized, were sunk to the same level of wretchedness and misery as the savages of New Holland and Kamtschatska. All classes have been benefited by this change; and it is mere error and delusion to suppose that the rich have been benefited at the expence of the poor. The institution of the right of property gives no advantage to any one man over any other man. It deals out justice impartially to all. It does not say, labour, and I will reward you; but it says, "*labour, and I shall take care that none shall be permitted to rob you of the produce of your exertions.*" The institution of the right of property has not made all men rich, because it could not make all men frugal and industrious. But it has done more than all the other institutions of society put together to produce this effect. It is not, as it has been sometimes ignorantly or knavishly represented, a bulwark thrown up to protect and secure the property of a few favourites of fortune. It is a rampart raised by society against its common enemies—against rapine and violence, plunder and oppression. Without its protection, the rich man would become poor, and the poor man would never be able to become rich—all would sink to the same bottomless abyss of barbarism and poverty. "It is the security of property," to use the just and forcible expressions of a profound writer, "that has overcome the natural aversion of man to labour, that has given him the empire of the earth, that has given him a fixed and permanent residence, that has implanted in his breast the love of his country and of posterity. To enjoy immediately—to enjoy without labour, is the natural inclination of every man. This inclination must be restrained; for its obvious tendency is to arm all those who have nothing against those who have something. The law which restrains this inclination, and which secures to the humblest indivi-

dual the quiet enjoyment of the fruits of his industry, is the most splendid achievement of legislative wisdom—the noblest triumph of which humanity has to boast."—(Bentham, *Traité de Legislation*, Tome II. p. 37.)

Security of  
Property.

DIVISION OF LABOUR.—The division of labour naturally divides itself into two separate branches;—  
1st, The division of labour among individuals; and  
2d, Its division among nations.

Division of  
Labour.

1. *Individual Division of Labour.*—The division of labour can only be imperfectly introduced in rude societies, and thinly peopled countries. But in every state of society—in the rudest, as well as in the most improved—we can trace the operation and effects of this principle. The various physical powers, talents, and propensities with which men are endowed, naturally fit them for different occupations; and a regard to mutual interest and convenience necessarily leads them, at a very early period, to establish a system of barter and a separation of employments. Each individual finds that he can obtain a greater quantity of all sorts of commodities by devoting himself to some particular business, and exchanging his surplus produce for such parts of the produce of other people's labour as he may have occasion for and they may be disposed to part with, than if he had attempted directly to produce all the articles which he consumes. As society advances, this division becomes more and more extended. In process of time, one man becomes a tanner, or dresser of skins; another, a shoemaker; a third, a weaver; a fourth, a house-carpenter; a fifth, a smith, and so on. Each endeavours to cultivate and bring to perfection whatever talent or genius he may possess for the species of industry in which he is employed. The national wealth and the comforts of all classes are, in consequence, prodigiously augmented. In a country where the division of labour has been carried to a considerable extent, agriculturists are not obliged to spend their time in clumsy attempts to manufacture their own produce; and manufacturers cease to interest themselves about the raising of corn and the fattening of cattle. The facility of exchanging is the vivifying principle of industry. It stimulates agriculturists to adopt the best system of cultivation and to raise the largest crops, because it enables them to exchange whatever portion of the produce of their lands exceeds their own wants for other commodities conducing to their comforts and enjoyments; and it equally stimulates manufacturers and merchants to increase the quantity and to improve the quality of their goods, that they may

ceux qui les possèdent; ce n'est que la dis-je, que les particuliers seront encouragés à se soumettre aux privations les plus dures pour compenser par leurs épargnes les retards que la profusion du gouvernement peut apporter aux progrès de la richesse national. Si l'Angleterre, malgré ses guerres ruineuses, est parvenue à un haut degré d'opulence; si malgré les contributions énormes dont le peuple y est chargé, son capital est pourtant accrue dans le silence par l'économie des particuliers, il ne faut attribuer ces effets qu'à la liberté des personnes et à la sûreté des propriétés qui y regnent, plus que dans aucun autre pays de l'Europe, la Suisse excepté." (Storch, *Traité d'Economie Politique*, Tom. I. p. 317.)

\* Speaking of theft, Beccaria calls it, "Il delitto di quella infelice parte di uomini, a cui il diritto di proprietà (terribile, e forse non necessario diritto), non ha lasciato, che una nuda esistenza."—*Dei Delitti e delle Pene*, § 22.

Division of Labour.

thereby be enabled to obtain a greater supply of raw produce. A spirit of industry is thus universally diffused; and that apathy and languor, which is characteristic of a rude state of society, entirely disappear.

But it is not the mere facility of exchanging, or the circumstance of being able to barter the surplus produce of one's own labour for such parts of the surplus produce of other people's labour, as we may be desirous of obtaining and they may choose to part with, that renders the separation of employments of such signal advantage. The introduction of barter and the division of labour not only enables each individual to betake himself in preference to those departments which suit his taste and disposition, but it makes a positive and a large addition to the efficacy of his powers, and enables him to produce a much greater quantity of commodities than he could have done had he engaged indiscriminately in different employments. Dr Smith, who has treated this subject in the most masterly manner, has classed the circumstances which conspire to increase the productive powers of industry, when labour is divided, under the following heads:—*First*, To the increase of the skill and dexterity of every particular workman; *second*, to the saving of time, which is commonly lost in passing from one particular employment to another; and, *third*, to the circumstance of the division of employments having a tendency to facilitate the invention of machines and of processes for abridging and saving labour. We shall make a few observations on each of these heads.

Division of Labour increases the Skill and Dexterity of the Workman:

*1st, Respecting the improvement of the skill and dexterity of the labourer*, it is sufficiently plain that when a person's whole attention is devoted to one branch of business, when all the energies of his mind and the powers of his body are made to converge, as it were, to a single point, he must attain to a degree of proficiency in that particular branch, to which no individual engaged in a variety of occupations can be expected to reach. A peculiar play of the muscles, or *sleight of hand*, is necessary to perform the simplest operation in the best and most expeditious manner; and this can only be acquired by habitual and constant practice. Dr Smith has given a striking example, in the case of the nail manufacturer, of the extreme difference between training a workman to the precise occupation in which he is to be employed, and training him to a similar and closely allied occupation. "A common smith," says he, "who, though accustomed to handle the hammer, has never been used to make nails, if, upon some particular occasion, he is obliged to attempt it, will scarce, I am assured, be able to make above two or three hundred nails in a day, and those very bad ones. A smith who has been accustomed to make nails, but whose sole or principal business has not been that of a nailer, can seldom, with his utmost diligence, make more than eight hundred or a thousand nails in a day. But I have seen several boys under twenty years of age, who had never exercised any other trade but that of making nails, who, when they exerted themselves, could make, each of them, upwards of two thousand three hundred nails in a day;" or nearly three times the number of the smith

Division of Labour.

Saves Time.

who had been accustomed to make them, but who was not entirely devoted to that particular business!

*2d*, The effect of the division of labour in preventing that waste of time in moving from one employment to another, which must always take place when an individual is engaged in different occupations, is even more obvious than the advantage derived from the improvement of the skill and dexterity of the labourer. When the same individual carries on different employments, in different and perhaps distant places, and with different sets of tools, it is plainly impossible he can avoid losing a considerable portion of time in passing between them. If the different businesses in which a labourer is to be engaged could be carried on in the same workshop, the loss of time would be less, but even in that case it would be considerable. "A man," as Dr Smith has justly observed, "commonly saunters a little in changing from one business to another. When he first begins his work, he is seldom keen or hearty; his mind is said not to go along with it, and for some time he rather trifles than applies himself in good earnest. The habit of sauntering and of indolent and careless application, which is naturally, or rather necessarily acquired by every country workman, who is obliged to change his work and his tools every half hour, and to apply his hand in working different ways almost every day of his life, renders him almost always slothful and lazy, and incapable of any rigorous application, even on the most pressing occasion. Independent, therefore, of his deficiency in point of dexterity, this cause alone must always reduce considerably the quantity of work which he is capable of performing."—(*Wealth of Nations*, I. p. 14.)

Facilitates the Invention of Machines:

*3d*, With regard to the effect of the division of employments in facilitating the invention of machines, and processes for abridging and saving labour, it is obvious that those engaged in any branch of industry must be more likely to discover easier and readier methods for carrying it on, when the whole attention of their minds is devoted exclusively to it, than if it were dissipated among a variety of objects. But it is a mistake to suppose, as has been sometimes done, that it is only the inventive genius of workmen and artificers that is whetted and improved by the division of labour. As society advances, the study of particular branches of science and of philosophy becomes the principal or sole occupation of the most ingenious men. Chemistry becomes a distinct science from natural philosophy; the physical astronomer separates himself from the astronomical observer, the political economist from the politician, and each meditating exclusively, or principally, on his peculiar department of science, attains to a degree of proficiency and expertness in it to which the general scholar seldom or never reaches. And hence, in labouring to promote our own ends, we all necessarily adopt that precise course which is most advantageous to all. Like the different parts of a well constructed engine, the inhabitants of a civilized country are all mutually dependent on, and connected with, each other. Without any previous concert, and obeying only the powerful and steady impulse of self-interest, they universally conspire to the same great end, and

Division of Labour.

Division of Labour Limited by the Extent of the Market.

contribute each in their respective sphere to furnish the greatest possible supply of necessaries, luxuries, conveniencies, and enjoyments.

But it is necessary to observe, that the advantages derived from the division of labour, though they may be, and in fact are, partially enjoyed in every country and state of society, can only be carried to their full extent, where there is a great power of exchanging, or an *extensive market*. There are an infinite variety of employments which cannot be separately carried on out of the precincts of a large city; and, in all cases, the division becomes just so much the more perfect, according as the demand for the produce of the workmen is extended. It is stated by Dr Smith that ten labourers employed in different departments in a pin manufactory can produce 48,000 pins a day; but it is evident that if the demand was not sufficiently extensive to take off this quantity, it would be impossible to carry the division so far. The same principle holds good in every case. A cotton mill could not be constructed in a small country which had no intercourse with its neighbours. The demand and competition of Europe and America has been necessary to carry the manufactures of Glasgow, Manchester, and Birmingham, to their present state of improvement.

The effects of the division of labour in increasing the quantity and perfection of the products of industry have been noticed by several of the writers who preceded Dr Smith, and especially by Mr Harris and M. Turgot. But neither of these writers have done what Dr Smith did. None of them have fully analysed and exhibited its various effects; and none of them have shown that the power of engaging in different employments depended on the *power of exchanging*; and that, consequently, the advantages derived from the division of labour were necessarily dependent on, and regulated by, the extent of the market. This is a principle of very great importance, and by establishing it Dr Smith shed a new light on the whole science, and laid the foundation of many important practical conclusions. "Présentée de cette manière," says M. Storch, "l'idée de la division du travail étoit absolument neuve; et l'effet qu'elle a fait sur les contemporains de Smith, prouve bien qu'elle l'étoit réellement pour eux. Telle qu'elle se trouve indiquée dans les passages que je viens de citer, elle n'a fait aucune impression. Développée par Smith, cette idée a d'abord saisi tous ses lecteurs; tous en ont senti la vérité et l'importance; et cela suffit pour lui en assurer tout l'honneur, lors même que son génie ait été guidé par les indications de ses devanciers."—(Tome VI. p. 10.)

Territorial Division of Labour.

2. *Territorial Division of Labour, or Commerce*.—Besides that sort of division of labour which enables each individual in a limited society to confine himself to a particular employment, there is another and most important branch of the division of labour, which not only enables particular individuals, but the inhabitants of entire districts, and even nations, to addict themselves in preference to certain branches of industry. It is on this *territorial division of labour*, if we may so term it, that the commerce which is carried on between different districts of the same country, and between different

countries, is founded. The various soils, climates, and capacities of production, of different districts of an extensive country, fit them for being appropriated in preference to certain species of industry. A district where coal is abundant, which has an easy access to the ocean, and a considerable command of internal navigation, is the natural seat of manufactures. Wheat and other species of grain are the proper products of rich arable soils; and cattle, after being reared in mountainous districts, are most advantageously fattened in meadow and low grounds. Nothing is more obvious than that the inhabitants of these different districts, by separately confining themselves to the particular branches of industry for the successful prosecution of which they have some peculiar *natural capability*, must produce an infinitely greater quantity of useful and agreeable commodities than they could do were they to devote their labour indiscriminately to every different employment. It is impossible to doubt that vastly more manufactured goods, more corn, and more cattle, are produced by the inhabitants of Glasgow, of the Carse of Gowrie, and of Argyleshire, respectively confining themselves to manufactures, agriculture, and the rearing of cattle, than if each endeavoured directly to supply themselves with all these various products, without the intervention of an exchange.

But it is easy to see that foreign trade, or the territorial division of labour between different and independent countries, will contribute to increase the wealth of each in precisely the same manner that the trade between different provinces of the same kingdom contributes to increase their wealth. There is a still greater difference between the productive powers wherewith nature has endowed different and distant countries than there is between the productive powers of the provinces of the same country. The establishment of a free intercourse between them must, therefore, be proportionably advantageous. It would evidently cost an infinitely greater expence to raise the wines of France or Spain in England than it would do to make Yorkshire yield the same products as Devonshire. Indeed, there are a multitude of products, and some of them of the very greatest utility, which cannot possibly be raised except in particular situations. Were it not for commercial intercourse, we should not be able to obtain the smallest supply of tea, sugar, raw cotton, raw silk, gold bullion, and a thousand other equally useful and valuable commodities. Providence, by giving different soils, climates, and natural productions, to different countries, has evidently provided for their mutual intercourse and civilization. By permitting the people of each to employ their capital and labour in those departments in which their geographical situation, the physical capacities of their soil, their national character and habits fit them to excell, foreign commerce has a wonderful effect in multiplying the productions of art and industry. When the freedom of commerce is not restricted, each country necessarily devotes itself to such employments as are most beneficial to each. This pursuit of individual advantage is admirably connected with the good of the whole. By stimulating industry, by rewarding ingenuity, and

Territorial Division of Labour.

Territorial  
Division of  
Labour.

by using most efficaciously the particular powers bestowed by nature, commerce distributes labour most effectively and most economically; while, by increasing the general mass of necessary and useful products, it diffuses general opulence, and binds together the universal society of nations by the common and powerful ties of mutual interest and reciprocal obligation. Commerce has enabled each particular state to profit by the inventions and discoveries of every other state. It has given us new tastes and new appetites, and it has also given us the means and the desire of gratifying them. The progress of domestic industry has been accelerated by the competition of foreigners. Commerce has either entirely removed, or greatly weakened, a host of the most unworthy prejudices. It has shown, that nothing can be more illiberal, irrational, and absurd, than that dread of the progress of others in wealth and civilization that was once so prevalent; and it has shown that the true glory and real interest of each particular people will be more certainly advanced by emulating and outstripping each other in the career of science and civilization, than by labouring to attain a barren pre-eminence in the bloody and destructive art of war.

Effect of the  
Territorial  
Division of  
Labour in  
Augment-  
ing National  
Wealth.

The influence of commerce in giving increased efficacy to labour, and augmenting national wealth, may be easily illustrated. Thus, in the case of the intercourse, or territorial division of labour, carried on between England and Portugal, it is plain that the superiority of the wool of England, our command of coals, of skilful workmen, of improved machinery, and of all the instruments of manufacturing industry, enables us to produce cloth at a much cheaper rate than the Portuguese: But, on the other hand, the soil and climate of Portugal being peculiarly favourable for the cultivation and growth of the grape, she is enabled to produce wine at an infinitely cheaper rate than it can be produced here. And hence it is obvious, that England, by confining herself to the manufacture of cloth, in which she has a natural advantage on her side, and exchanging it with the Portuguese for wine, will obtain a vastly larger supply of that commodity than if she had attempted to cultivate the grape at home: And Portugal, by exchanging her wine for the cloth of England, will, on her part, obtain a much greater quantity of cloth than if she had attempted to counteract the intention of nature, by converting a portion of her capital and industry from the raising of wine, in which she has an advantage, to the manufacture of cloth, in which the advantage is on the side of another.

Sophism of  
the French  
Economists  
on the Sub-  
ject of Com-  
merce.

What we have already stated is sufficient to expose the sophism involved in the reasoning of the French economists, who contended, that as an equivalent must be always given for such commodities as are obtained from foreigners, it is impossible foreign commerce can ever become a means of increasing wealth. How, they asked, can the wealth of a country be increased by giving equal values for equal values? They admitted, that commerce might be the means of making a *better distribution* of the wealth of the world; but as it did nothing more than exchange one sort of wealth for another, they denied that it could ever make any addition to that

Territorial  
Division of  
Labour.

wealth. At first sight, this sophistical and delusive statement appears sufficiently conclusive; but a very few words will be sufficient to demonstrate its fallacy. The advantage of commerce does not consist in its enabling either of the parties who carry it on to obtain commodities of greater value, than those they give in exchange for them. It may have cost as much, or more, to produce the cloth wherewith the English merchant purchases the wine of Portugal, as it did to produce the latter. But then, it must be observed, that in making the exchange, *the value of the wine is estimated by what it takes to produce it in Portugal*, which has peculiar natural capabilities for that species of industry, and *not* by what it would take to produce it in England were the trade put an end to; and, in like manner, the value of the cloth is estimated by what it takes to produce it in England, and not by what it would cost to produce it in Portugal. The advantage of the intercourse between the two countries consists in this, that it enables each of them to obtain commodities, for the production of which they have no natural capability, and which it would, therefore, cost a comparatively large sum to produce directly at home at the price which it costs to produce them in the most favourable circumstances, and with the least possible expence. The gain of the one party is not the loss of the other. Both of them are benefited by this intercourse. For both of them are thereby enabled to save labour and expence in the production of commodities; and the wealth of the two countries is not only better distributed, but it is also positively and greatly increased by the territorial division of labour established between them.

To set this important principle in a clearer point of view, let us suppose that in England a given number of men can, in a given time, manufacture 10,000 yards of cloth, and raise 1000 quarters of wheat, and that the same number of men can, in the same time, manufacture in Poland 5000 yards of cloth and raise 2000 quarters of wheat. It is plain, that the establishment of a free intercourse between the two countries would, in these circumstances, enable England, by manufacturing cloth and exporting it to Poland, to obtain *twice* the quantity of corn in exchange for a given expenditure of capital and labour that she could obtain in return for the same expenditure directly laid out in the cultivation of land at home; and Poland would, on the other hand, be enabled to obtain *twice* as much cloth in exchange for her corn as she could have done had she attempted directly to manufacture it. How ridiculous then to contend, that commerce is not a means of adding to the efficacy of labour, and, consequently, of increasing wealth! Were the intercourse between England and Portugal and the West Indies put an end to, it would require, at the very least, a hundred, or perhaps a thousand times the expence to produce Port wine, sugar, and coffee, directly in this country, that it does to produce the equivalents sent to Portugal and the West Indies in exchange for them.

“The commerce of one country with another is,” to use the words of Mr Mill, “merely an extension of that division of labour by which so many benefits are conferred on the human race. As the same

Territorial  
Division of  
Labour.

country is rendered richer by the trade of one province with another; as its labour becomes thus infinitely more divided and more productive than it could otherwise have been; and as the mutual interchange of all those commodities which one province has and another wants, multiplies the accommodations and comforts of the whole, and the country becomes thus in a wonderful degree more opulent and happy; so the same beautiful train of consequences is observable in the world at large, that vast empire of which the different kingdoms may be regarded as the provinces. In this magnificent empire, one province is favourable to the production of one species of produce, and another province to another. By their mutual intercourse, mankind are enabled to distribute their labour as best fits the genius of each particular country and people. The industry of the whole is thus rendered incomparably more productive; and every species of necessary, useful, and agreeable accommodation is obtained in much greater abundance, and with infinitely less expence."—(*Commerce Defended*, p. 38.)

To enter into a more enlarged discussion of this interesting and important subject, would be inconsistent with the object and limits of this article. In our articles on COLONIES and the CORN TRADE AND LAWS, we have examined the policy of the restrictions on the colonial trade, and on the corn trade; and in the article EXCHANGE, we have pointed out the circumstances which regulate the importation and exportation of the precious metals; and have shown, that, instead of the excess of exports over imports being any criterion of an advantageous commerce, it is just the reverse, and that it is by the excess of the value of the imports over the value of the exports that the direct gains of the merchants, and consequently of the community, are to be estimated. In the fourth book of the *Wealth of Nations*, Dr Smith has examined and refuted the various arguments in favour of the restrictions imposed on the freedom of commerce, in the most able and masterly manner, and with an amplitude of illustration, which leaves nothing to be desired. A very complete exposure of the sophisms of the French economists, on the subject of commerce, may be found in the ingenious and valuable pamphlets of Mr Mill (*Commerce Defended*) and Colonel Torrens (*Economists Refuted*), written in answer to Mr Spence's pamphlet entitled, *Britain Independent of Commerce*. The chapter on *Foreign Trade* in Mr Ricardo's great work is equally original and profound, and deserves to be carefully studied by those who wish to make themselves thoroughly acquainted with the theory of commerce.

Money.

When the division of labour was first introduced, barter was the only method by which commodities were exchanged. But according as society advanced, as the division of employments was extended, and as exchanges became more numerous, the advantage of using some one commodity as a common medium of exchange—as an equivalent for all other commodities, and as a standard by which to ascertain their relative values, soon became obvious. But this is a subject of which we have elsewhere treated at considerable length; and we beg leave to refer

our readers for a full investigation of the nature and functions of the common medium of exchange to the article MONEY in this *Supplement*, and the authorities there quoted.

Territorial  
Division of  
Labour.

ACCUMULATION AND EMPLOYMENT OF CAPITAL. Accumulation and Employment of Capital. —Capital may be defined to be "that portion of the produce of labour which is saved from immediate consumption, and employed in maintaining productive industry, or in facilitating production." Its accumulation and employment is indispensably necessary to the successful prosecution of almost every branch of industry. Without that species of capital, which chiefly consists of tools and engines, and which has been denominated *fixed*, labour could never be rendered considerably productive; and without that species of capital which chiefly consists of the food and clothes required for the consumption of the labourer during the time he is employed in the production of commodities, and which has been denominated *circulating*, he never could engage in any undertaking which did not yield an almost immediate return. An agricultural labourer, for example, might have an ample supply of carts and ploughs, of oxen and horses, and generally of all the instruments and animals used in his department of industry, but if he were destitute of *circulating* capital, or of food and clothes, he would not be able to avail himself of their assistance, and instead of tilling the ground, would have to betake himself immediately to some species of appropriative industry: And, on the other hand, supposing the husbandman to be abundantly supplied with provisions, what could he do without the assistance of *fixed* capital or tools? What could the most skilful agriculturist perform if he were deprived of his spade and his plough? a weaver if he were deprived of his loom? or a house-carpenter if he were deprived of his saw, his hatchet, and his planes? The accumulation and employment of both fixed and circulating capital is indispensably necessary to elevate any nation in the scale of civilization. And it is only by their conjoined and powerful operation that wealth can be largely produced and universally diffused.

The division of labour is a consequence of the previous accumulation of capital. Before labour can be divided, "A stock of goods of different kinds must be stored up somewhere, sufficient to maintain the labourer, and to supply him with the materials and tools for carrying on his work. A weaver, for example, could not apply himself entirely to his peculiar business, unless there was beforehand stored up somewhere, either in his own possession, or in that of some other person, a stock sufficient for his maintenance, and for supplying him with the materials and implements required to carry on his work, till he has not only completed but sold his web. This accumulation must evidently be previous to his applying himself for so long a time to a peculiar business."—(*Wealth of Nations*, Vol. I. p. 408.)

As the accumulation of stock must have preceded the division of labour, so its subsequent division can only be extended as capital is more and more accumulated. Accumulation and division act and react on each other. The quantity of raw materials which

Employ-ment of Ca-pital. the same number of people can work up increases in a great proportion, as labour comes to be more and more subdivided; and according as the operations of each workman are reduced to a greater degree of identity and simplicity, he has, as we have already explained, a greater chance of discovering machines and processes for facilitating and abridging his labour. The quantity of industry, therefore, not only increases in every country with the increase of the stock or capital which sets it in motion; but, in consequence of this increase, the division of labour becomes extended, new and more powerful implements and machines are invented, and the same quantity of labour is thus made to produce an infinitely greater quantity of commodities.

the state of the arts practised alike by civilized man and the savage, we cannot fail to be convinced that it is to the use and employment of fixed capital that we owe a very large proportion of our superior comforts and enjoyments. Consider the advantages which man has derived from the employment of the lower animals, which, in an economical point of view, are regarded only as machines! Consider the advantages that have been derived from the formation of roads, bridges, harbours, and canals—the effect they have had in facilitating the conveyance of commodities, and consequently in distributing them most advantageously, and in reducing their price to the consumer! Consider the advantages that have been derived from the construction of ships, and the improvement of navigation! But it is in vain to attempt even to glance at the numberless benefits which the employment of the fixed capital vested in tools and other instruments, has conferred on society, by cheapening and multiplying necessaries, conveniences, and luxuries. It is by their means that our fields are cultivated, our houses constructed, our clothes manufactured, our ships built, and the treasures of knowledge and of art transferred from one hemisphere to another! If we consult the history of the human race—if we trace their slow and gradual advancement from barbarism to refinement, we shall be convinced that their progress from their lowest and most abject, to their highest and most polished, state, has been always accompanied, and chiefly promoted, by the accumulation of fresh capital, and the invention and improvement of tools and engines.

Employ-ment of Ca-pital.

Besides its effect in enabling labour to be divided, capital contributes to facilitate labour, and produce wealth in the three following ways:

*First.*—It enables us to execute work that could not be executed, or to produce commodities that could not be produced without it.

*Second.*—It saves labour in the production of almost every species of commodities.

*Third.*—It enables us to execute work better, as well as more expeditiously.

With regard to the first of these modes in which we are benefited by the employment of capital, or to the circumstance of its *enabling us to produce commodities that could not be produced without it*, it is plain that the production of all such commodities as require a considerable period for their completion, could not have been attempted if a stock of circulating capital, or of food and clothes sufficient for the maintenance of the labourer while employed on them, had not been previously provided. But the employment of fixed is frequently as necessary to the production of commodities as the employment of circulating capital. It would be plainly impossible to produce a pair of stockings without the aid of wires; and, although the ground might be cultivated without the aid of the plough, it could not be cultivated without the aid of a spade or a hoe. If we run over the vast catalogue of the various arts practised in a highly polished and civilized country, it will be found that there are very few that can be carried on by the mere employment of the fingers, or tools with which man is furnished by nature. It is almost always necessary to provide ourselves with the results of previous industry, and to strengthen our feeble hands by arming them, if we may so speak, “with the force of all the elements.”

The *third* advantage derived from the employment of capital consists in the circumstance of its enabling us to execute work *better*, as well as more expeditiously, than it could be done without it. Cotton, for example, might be spun by the hand; but the admirable machinery invented by Hargreaves, Arkwright, and others, has not only enabled us to spin an hundred or a thousand times as great a quantity of yarn as could be spun by means of a common spindle, but it has also improved its quality, and given to it a degree of fineness, and of evenness, or equality, in its parts, which was never previously attained. It would require a painter months, or it might be years, to paint with a brush the cottons, or printed cloths used in the hanging of a single room; and it would be very difficult, if not impossible, for the best artist to give the same perfect identity and sameness to his figures that is given to them by the admirable machinery now in use for that purpose. Not to mention the other and more important advantages of which the invention of moveable types and printing has been productive, it is certain that the beauty of the most perfect manuscript—one on which years of patient and irksome labour have been expended—is unable, in point of delicacy and correctness, to match a well printed work, executed in the hundredth part of the time, and at a hundredth part of the expence required to copy the manuscript. The great foreign demand for English manufactured goods results no less from the superiority of the manufacture, than from their greater

3d, It enables us to Execute Work better as well as more Expeditiously.

Modes in which the Employment of Capital Facilitates Labour.

1st, It enables us to produce Commodities that could not be produced without it.

2d, It Saves Labour in the Production of Commodities.

In the *second* place, the employment of capital not only enables us to produce many species of commodities that never could have been produced without its co-operation, but it also enables us to *save labour in the production of many others*, and, by lowering their price, brings them within the reach of a far greater number of consumers. We have been so long accustomed to make use of the productive sources of the most powerful machines, that it requires a considerable effort of abstraction to render ourselves fully aware of the real extent of the advantages we derive from them. But if we compare

Employment of Capital.

The Power to Employ Labour depends on the Amount of Capital.

cheapness; and for both these advantages we are principally indebted to the excellence of our machinery.

There are other considerations which equally illustrate the extreme importance of the accumulation and employment of capital. The produce of the labour of a nation cannot be increased otherwise than by an increase in the number of labourers, or by an increase in the productive powers of the existing labourers. But without an increase of capital it is in most cases impossible to employ another workman with advantage. If capital be not augmented, and if the food and clothes destined for the support of the labourers, and the tools and machines with which they are to operate, be all required for the maintenance and efficient employment of the labourers in existence at any given period, there can be no additional demand for them. In such circumstances, the rate of wages cannot rise; and if the number of inhabitants are increased, they must be worse provided for. Neither can the productive powers of the labourer be augmented, without a previous increase of capital. It is only by a better education and training of workmen, by a greater subdivision of their employments, or by an improvement of machinery, that their productive powers can ever be materially increased. But in almost all these cases, an additional capital is required. It is only by means of an additional capital that the workman can be better trained, or that the undertaker of any work can either provide his workmen with better machinery, or make a more proper distribution of employment among them. When the work to be done consists of a number of parts, to keep every man constantly employed in one particular part, requires a much larger stock than where every man is occasionally employed in every different part of the work. "When," says Dr Smith, "we compare the state of a nation at two different periods, and find that the annual produce of its land and labour is greater at the latter than at the former, that its lands are better cultivated, its manufactures more numerous and more flourishing, and its trade more extensive, we may be assured that its capital must have increased during the interval between these two periods, and that more must have been added to it by the good conduct of some, than had been taken from it, either by the private misconduct of others, or by the public extravagance of the government."—(*Wealth of Nations*, Vol. II. p. 23.) It is, therefore, apparent that no country can ever reach the stationary state, so long as she continues to accumulate additional capital. While she does this, she will always have a constantly increasing demand for labour, and will be constantly augmenting the mass of necessaries, luxuries, and conveniences, and, consequently, also the numbers of her people. But with every diminution of the previous rate at which

capital had been accumulating, the demand for labour will decline. When no additions are made to its stock, no more labour will be, or, indeed, can be employed. And should the national capital be diminished, the condition of the great body of the people would be greatly deteriorated—for the wages of labour would be reduced, and pauperism, with all its attendant train of vice, misery, and crime, would spread its ravages throughout the largest portion of society.

Having thus endeavoured to point out the vast importance of the employment of capital, and the manner in which it co-operates in facilitating production, we shall proceed to explain the circumstances most favourable for its accumulation. Now, as capital is nothing more than the accumulated produce of previous industry, it is evident its increase will be most rapid where industry is most productive, or, in other words, where *the profits of stock are highest*.\* The man who can produce a bushel of wheat in *three* days has it in his power to accumulate twice as much as the man who, either from a deficiency of skill, or from his being obliged to cultivate a bad soil, is forced to labour six days to produce the same quantity; and the capitalist who can invest stock so as to yield him a profit of ten *per cent.* has it equally in his power to accumulate twice as fast as the capitalist who can only obtain five *per cent.* for his capital. Conformably to this statement, it is found that the rate of profit, or, which is the same thing, that the power to accumulate capital, is always greatest in those countries which are most rapidly augmenting their wealth and population. The rate of profit, or the power to employ labour and capital with advantage, is ordinarily twice as great in the United States as in Great Britain or France; and it is to this that the more rapid advancement of the former in wealth and population is entirely to be ascribed. We do not mean to say that high profits are necessarily, and in every instance, accompanied by a great degree of prosperity. Countries with every possible advantage for the profitable employment of industry and of stock, may be subjected to a despotical government, which does not respect the right of property; and the want of adequate security resulting from this circumstance may be of itself sufficient to paralyse all the exertions of those who are otherwise placed in the most favourable situation for the accumulation of capital and of wealth. But we have no hesitation in laying it down as a principle which holds good in every case, and from which there is really no exception, that, *if the governments of any two or more countries be equally liberal, and property in each equally well secured, their comparative prosperity will depend on the rate of profit.* Wherever profits are high, there is a great demand for labour, and the society rapidly augments both its population and its riches. On the

\* To avoid all chance of misconception, it is necessary to observe, that this refers to *net* profit, or to the sum which remains to the capitalist after all his outgoings are compensated, including therein a sum sufficient to ensure his capital against risk, and to make up for whatever may be peculiarly disagreeable in his business.

Accumulation of Capital.

other hand, wherever they are low, the demand for labour is proportionably reduced, and the progress of society rendered so much the slower.

But however high the rate of profit, it is evident, that, if men had always *lived up to their incomes*,—that is, if they had always consumed the whole produce of their industry in the gratification of their immediate wants and desires, there could have been no such thing as capital in the world. High profits are advantageous, because they afford the *means* of amassing capital; but something more is necessary to induce us to make *use* of these means, and this is the *accumulating principle*. The desire implanted in the breast of every individual of rising in the world, and improving his condition, has prompted mankind to save a portion of their income, or of the produce of their industry, from immediate consumption, and to set it apart as a fund, or capital, for the support of additional workmen. It is to this principle, therefore, or rather to its effect, *parsimony*, that we owe capital; and it is to capital that we owe almost all our comforts and enjoyments. Without its assistance and co-operation, labour could never have been divided; arts could never have made any progress; and mankind must have continued to shelter themselves, as in the earliest ages, in caves and forests, and to clothe themselves with the skins of wild animals. All the accumulated riches of the world—the cities which cover its surface—the ships which traverse its seas—and all the innumerable variety of improvements, owe their origin to this principle,—to the desire to rise in the world, and, consequently, to save and amass.

It has been wisely ordered, that this principle should be as powerful as it is advantageous. “With regard to profusion,” says Dr Smith, “the principle which prompts to expence is the desire of present enjoyment; which, though sometimes violent, and very difficult to be restrained, is in general only momentary and occasional. But the principle which prompts to save is the desire of bettering our condition; a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave. In the whole interval which separates these two moments, there is scarce, perhaps, a single instance in which any man is so perfectly and completely satisfied with his situation as to be without any wish of alteration or improvement of any kind. An augmentation of fortune is the means by which the greater part of men propose and wish to better their condition. It is the means the most vulgar and the most obvious; and the most likely way of augmenting their fortune is to save and accumulate some part of what they acquire, either regularly and annually, or upon some extraordinary occasions. Though the principle of expence, therefore, prevails in almost all men upon some occasions, yet in the greater part of men, taking the whole course of their life at an average, the principle of frugality not only predominates, but predominates very greatly.” (*Wealth of Nations*, Vol. II. p. 19.)

It is this principle which carries society forward. The spirit of parsimony, and the efforts which the

Accumulation of Capital.

frugal and industrious classes make to improve their condition, in most instances balance not only the profusion of individuals, but also the more wasteful profusion and extravagance of governments. The spirit of economy has been happily compared by Smith to the unknown principle of animal life—the *vis medicatrix nature*,—which frequently restores health and vigour to the constitution, in spite both of disease and of the absurd prescriptions of the physician.

We must have a care, however, lest we fall into the error of supposing, as Mr Malthus and many others have done, that public expenditure is a cause of individual accumulation. Its effect is, in every instance, distinctly and completely the reverse. The more government spends, the less remains for individuals to save. Necessity may compel a man to exert himself to pay heavy taxes; but it is *choice*, and not necessity, which makes him withdraw a portion of the produce of his industry from immediate consumption, and employ it as a stock. This distinction must be kept constantly in view. It cannot be denied that it is necessity that forces farmers and manufacturers to sell a portion of their produce to pay the taxes to which they are subjected; but when these taxes are paid, the government is satisfied, and it is plainly their own free option—their desire to improve their condition, and to rise higher in the world, and not compulsion, that induces them to accumulate *another* portion of their produce as capital. The capitals of England and of France have not increased, *because* of the vast expenditure of their governments, but in *despite* of it. Those who continued to accumulate, notwithstanding the share of their produce taken from them by government was increased, would evidently have had greater *means* of accumulation, had this share not been increased, or increased in a less proportion. But accumulation, like the other passions, increases as the means of gratifying it increase. In point of fact, the greatest accumulations are invariably made where there is the greatest power to accumulate. There are no internal taxes in America; she is possessed of vast tracts of fertile and uncultivated soil; and industry is, in consequence, extremely productive. And, agreeably to what we have now stated, America doubles her capital and population every five-and-twenty years, and is advancing in the career of wealth and civilization with a rapidity unknown in any other country.

Ambition to rise is the animating principle of society. Instead of remaining satisfied with the condition of their fathers, the great object of mankind in every age has been to rise above it—to elevate themselves in the scale of wealth. To continue stationary, or to retrograde, is not natural to society. Man from youth grows to manhood, then decays and dies; but such is not the destiny of nations. The arts, sciences, and capital of one generation become the patrimony of that which succeeds them; and in their hands are improved and augmented, and rendered more powerful and efficient; so that, if not counteracted by the want of security, or by other adventitious causes, the principle of improvement

Expenditure of Government, not a Cause of Accumulation.

Accumulation of Capital.

would always operate, and would secure the constant advancement of nations in wealth and population.

It is to this same principle that we owe the discovery and improvement of machinery. Mankind have, in every stage of society, endeavoured to increase their productive powers, and to improve their condition, by availing themselves of the assistance of natural agents, and making them contribute to the performance of tasks which must otherwise have been performed by the hand only. The savage avails himself of the aid of a club and a sling to facilitate the acquisition of game, and abridge his labour; and the same principle which prompted him to resort to and construct these rude instruments, never ceases to operate. It is always producing some new improvement; and in an advanced and refined period, gives us ships for canoes, muskets for slings, steam-engines for clubs, and cotton mills for distaffs. "The hand of man," says Colonel Torrens, "is not armed with any efficient natural instrument, such as the beak of the bird, or the claw of the quadruped, for operating directly upon the materials presented to him; but it is admirably adapted for receiving and applying artificial implements, and for employing the powers of one substance to produce the desired changes in another. Hence almost all the grand results in manufacturing industry are brought about by means of capital. Throughout the world there are no very striking inequalities in the muscular force by which direct labour is performed; and it is mainly owing to the differences in the quantity of capital, and in the skill with which it is applied, that in one country man is found naked and destitute, and that in another all the rude productions of the earth, and all the forces of nature, are made to contribute to his comfort, and to augment his power." —(*On the Production of Wealth*, p. 89.)

SECT. III.—*Different Employments of Capital and Industry—Manufactures and Commerce shown to be equally advantageous as Agriculture—Rate of Profit true test of Individual and Public Advantage.*

Different Employments of Capital and Industry.

We have, in the previous section, endeavoured to show, that the increase and diminution of capital is the grand point on which national prosperity hinges,—that if you increase capital, you instantly increase the means of supporting and employing additional labour, and that if you diminish capital, you instantly take away a portion of the comforts and enjoyments, and perhaps also of the necessaries of the productive classes, and spread poverty and misery throughout the land; and we also endeavoured to show that the increase and diminution of the rate of profit was the great cause of the increase and diminution of capital. If such be the case, it seems impossible to resist coming to the conclusion, that those employments which yield the *greatest profit*, or in which industry is most productive, are the most advantageous. But Dr Smith, Mr Malthus, and most other political economists, have objected to this standard. They allow that if two capitals yield equal profits, the employments in which they are engaged are *equally beneficial to their possessors*; but they contend, that, if one of these capitals be employed in agriculture, it

will be productive of greater *public advantage*. We believe, however, that we shall be able to show that this opinion rests on no good foundation; and that the *average rate of profit* is the single and infallible test by which we are always to judge which employment is most and which is least advantageous.

Different Employments of Capital and Industry.

A capital may be employed in *four* different ways, either, *first*, in the production of the raw produce required for the use and consumption of the society; or, *secondly*, in manufacturing and preparing that raw produce for immediate use and consumption; or, *thirdly*, in transporting the raw and manufactured products from one place to another according to the demand; or, *fourthly*, in dividing particular portions of either into such small parcels as suit the convenience of those who want them. The capitals of all those who undertake the improvement or cultivation of lands, mines, or fisheries, are employed in the first of these ways; the capital of all master manufacturers is employed in the second; that of all wholesale merchants in the third; and that of all retailers in the fourth. It is difficult to conceive that a capital can be employed in any way which may not be classed under some one or other of these heads.

On the importance of the employment of capital in the acquisition of raw produce, and especially in the cultivation of the soil, it is unnecessary to enlarge. It is from the soil, including under that term mines and fisheries, that the *matter* of all commodities that either minister to our necessities, our comforts, or our enjoyments, must have been originally derived. The industry which appropriates the raw productions of the earth, as they are offered to us by nature, preceded every other. But these spontaneous productions are always extremely limited. And it is by agriculture only, that is, by the united application of immediate labour and of capital, to the cultivation of the ground, that large supplies of those species of raw produce, which form the principal part of the food of man, can be obtained. It is not quite certain that any of the species of grain, as wheat, barley, rye, oats, &c. have ever been discovered growing spontaneously. But, although this must originally have been the case, still the extreme scarcity of such spontaneous productions in every country with which we are acquainted, and the labour which it requires to raise them in considerable quantities, prove beyond all question that it is to agriculture that we are almost exclusively indebted for them. The transition from the pastoral to the agricultural mode of life is decidedly the most important step in the progress of society. Whenever, indeed, we compare the quantity of food, and of other raw products, obtained from a given surface of a well cultivated country, with those obtained from an equal surface of an equally fertile country, occupied by hunters or shepherds, the powers of agricultural industry in increasing useful productions appear so striking and extraordinary, that we cease to feel surprise at the preference which has been so early and generally given to agriculture over manufactures and commerce; and are disposed to subscribe without hesitation to the panegyric of Cicero when he says, "*Omnium autem rerum ex quibus aliquid acquiritur, nihil est agricultura melius, nihil uberius, nihil dulcius, nihil homine, nihil libero dignius.*"

Employment of Capital in Agriculture.

Different Employments of Capital and Industry.

Different Employments of Capital and Industry.

Employment of Capital in Manufacturing Industry.

But are there really any just grounds for this preference? Are not manufactures and commerce equally advantageous as agriculture? It is plain that without agriculture we could never possess any considerable supply of the *materials* out of which food and clothes are made; but is it not equally plain, that without a knowledge of the arts by which they are converted into food and clothes, the largest supply of these materials could be of little or no service? The labour of the miller who grinds the corn, and of the baker who bakes it, is equally necessary to the production of bread, as the labour of the husbandman who tills the ground. It is the business of the agriculturist to raise flax and wool; but if the labour of the spinner and the weaver had not given them utility, and fitted them for being made a comfortable dress, they would have been nearly, if not entirely worthless. Without the labour of the miner who digs the mineral from the bowels of the earth, we could not have obtained the matter out of which many of our most useful implements and splendid articles of furniture have been made; but if we compare the ore when dug from the mine with the finished articles, we shall certainly be convinced that the labour of the purifiers and refiners of the ore, and of the artists who have afterwards converted it to useful purposes, has been quite as advantageous as the industry of the miner.

travail, on ne peut plus concevoir de véritable produit, de produit consommable et ayant une valeur réelle? La valeur du blé sur pied résulte de l'industrie du moissonneur qui recueillera, du batteur qui le séparera de la paille, du meunier et du boulanger qui le convertiront successivement en farine et en pain, tout comme elle résulte du travail du labourer et du semeur. Sans le travail du tisserand, le lin n'aurait pas plus le droit d'être compté au nombre des richesses, que l'ortie ou tout autre végétal inutile. A quoi pourrait-il donc servir de rechercher lequel de ces deux genres de travail contribue le plus à l'avancement de la richesse nationale? N'est-ce pas comme si l'on disputait pour savoir lequel, du pied droit ou du pied gauche, est plus utile dans l'action de marcher?"\*

No real Difference between Agricultural and Manufacturing Industry.

Necessity of Manufacturing Industry to the Improvement in Agriculture.

But not only is it certain that manufacturing industry, or that species of industry which fits and adapts the raw produce of nature to our use, is requisite to render its acquisition of any considerable value; but it is also certain, that without manufacturing industry this very raw produce could never have been obtained in any considerable quantity. The labour of the mechanic who fabricates the plough is as efficacious in the producing of corn as the labour of the husbandman who guides it. But the plough-wright, the mill-wright, the smith, and all those artizans who prepare tools and machines for the husbandman, are really manufacturers, and differ in no respect whatever from those who are employed to give utility to wool and cotton, except that they work on *harder* materials. The fixed capital vested in tools and machines is the product of the labour of the tool and engine manufacturer; and without the aid of this fixed capital, it is impossible that agricultural labour, or that any other sort of labour, could ever have become considerably productive.

In fact, there is not at bottom any real distinction between agricultural and manufacturing industry. It is, as we have already shown, a vulgar error to suppose that the operations of husbandry add any thing to the stock of matter already in existence. All that man can do, and all that he ever does, is merely to give to matter that particular form or shape which fits it for his use. But it was contended by M. Quesnay and the French economists, and their opinions have in this instance been espoused by Dr Smith, that the labour of the husbandman in adapting matter to our use is powerfully facilitated by the aid derived from the vegetative powers of nature, while the labour of the manufacturer has to perform every thing itself without any such co-operation.—“No equal quantity of productive labour, or capital employed in manufactures,” says Dr Smith, “can ever occasion so great a reproduction as if it were employed in agriculture. *In manufactures nature does NOTHING, man does ALL*; and the reproduction must always be proportioned to the strength of the agents that occasion it. The capital employed in agriculture, therefore, not only puts into motion a greater quantity of productive labour than any equal capital employed in manufactures, but in proportion, too, to the quantity of productive labour which it employs, it adds a much greater value to the annual produce of the land and labour of the country, to the real wealth and revenue of its inhabitants. *Of all the ways in which a capital can be employed, it is by far the most advantageous to the society.*”—(*Wealth of Nations*, II. p. 53.)

Opinion of Dr Smith respecting the Superior Productiveness of Agriculture.

“Distinguer,” says the Marquis Garnier, “le travail des ouvriers de l'agriculture d'avec celui des autres ouvriers, est une abstraction presque toujours oiseuse. Toute richesse, dans le sens dans lequel nous la concevons, est nécessairement le résultat de ces deux genres de travail, et la consommation ne peut pas plus se passer de l'un que de l'autre. Sans leur concours simultané il ne peut y avoir de chose consommable, et par conséquent point de richesse. Comment pourrait-on donc comparer leurs produits respectifs, puisque, en séparant ces deux espèces de

This is perhaps the most objectionable passage in the *Wealth of Nations*; and it is really astonishing how so acute and sagacious a reasoner as Dr Smith could have maintained a doctrine so manifestly erroneous. It is unquestionably true, that nature powerfully assists the labour of man in agriculture. The husbandman prepares the ground for the seed, and deposits it there; but it is nature that unfolds the germ, that feeds and ripens the growing plant, and brings it to a state of maturity. But does not nature do as much for us in every other department of industry? The powers of water and of wind, which

Error of this Opinion.

Nature co-operates with Man in Manufactures and Commerce.

\* See page 58 of the *Discours Préliminaire* to the second edition of the translation of the *Wealth of Nations*, by the Marquis Garnier. The same passage is in the first edition, published in 1802.

Different  
Employ-  
ments of Ca-  
pital and In-  
dustry.

move our machinery, support our ships, and impel them over the deep,—the pressure of the atmosphere, and the elasticity of steam, which enable us to work the most stupendous engines, are they not the spontaneous gifts of nature? In fact, the single and exclusive advantage of machinery consists in its having enabled us to press the powers of nature into our service, and to make them perform the principal part of what would otherwise have been wholly the work of man. In navigation, for example, is it possible to doubt, that the powers of nature—the buoyancy of the water, the impulse of the wind, and the polarity of the magnet, contribute fully as much as the direct labour of the sailor to waft our ships from one hemisphere to another? In bleaching and in fermentation the whole process is carried on by natural agents. And it is to the effects of heat in softening and melting metals, in preparing our food, and in warming our houses, that we owe many of our most powerful and convenient instruments, and that these northern climates have been made to afford a comfortable habitation. So far, indeed, from its being true that nature does much for man in agriculture, and nothing in manufactures, that the fact is nearly the reverse. There are no limits to the bounty of nature in manufactures, but there are limits, and not very remote ones, to her bounty in agriculture. The greatest possible amount of capital might be expended in the construction of steam-engines, or of any other sort of machinery, and after they had been multiplied to infinity, the last would be as powerful and as efficient in saving labour and producing commodities as the first. Such, however, is not the case with the soil. Lands of the first quality are speedily exhausted; and it is impossible to apply capital indefinitely even to the best soils, without obtaining from it a constantly diminishing rate of profit. The rent of the landlord is not, as Dr Smith conceived it to be, the recompense of the work of nature remaining, after all that part of the product is deducted which can be regarded as the recompense of the work of man! But it is, as we shall hereafter show, the excess of produce obtained from the best soils in cultivation, over that which is obtained from the worst—it is a consequence not of the increase, but of the diminution of the productive power of the labour employed in agriculture.

Employ-  
ment of Ca-  
pital in  
Commercial  
Industry.

But if the giving utility to matter be, as it really is, the single and exclusive object of every species of productive industry, it is plain that the capital and labour which is employed in carrying commodities from where they are produced to where they are to be consumed; and in dividing them into minute portions, so as to fit the wants of the consumers, is really as productive as either agriculture or manufactures. The labour of the miner gives utility to matter—to coal for example—by bringing it from the bowels of the earth to its surface; but the labour of the merchant, or carrier, who transports this coal from the mine where it has been dug to the city, or place where it is to be burned, gives it a further, and perhaps a more considerable value. We do not owe our fires exclusively to the miner, or exclusively to the coal merchant. They are the result of the conjoint operations of both, and also of the opera-

tions of all those who have furnished them with the tools and implements used in their respective employments.

Not only, however, is it necessary that commodities should be brought from where they are produced to where they are to be consumed, but it is also necessary that they should be divided into such small and convenient portions, that each individual may have it in his power to purchase the precise quantity of them he is desirous of obtaining. "If," says Dr Smith, "there was no such trade as a butcher, every man would be obliged to purchase a whole ox or a whole sheep at a time. This would generally be inconvenient to the rich, and much more so to the poor. If a poor workman was obliged to purchase a month's, or six months' provisions at a time, a great part of the stock which he employs as a capital in the instruments of his trade, or in the furniture of his shop, and which yields him a revenue, he would be forced to place in that part of his stock which is reserved for immediate consumption, and which yields him no revenue. Nothing can be more convenient for such a person than to be able to purchase his subsistence from day to day, or even from hour to hour, as he wants it. He is thereby enabled to employ almost his whole stock as a capital. He is thus enabled to furnish work to a greater value, and the profit which he makes by it in this way much more than compensates the additional price which the labour of the retailer gives to the goods. The prejudices of some political writers against shopkeepers and tradesmen are altogether without foundation. So far is it from being necessary, either to tax them, or to restrict their numbers, that they can never be multiplied so as to hurt the public interests, though they may so as to hurt their own individual interests. The quantity of grocery goods, for example, which can be sold in a particular town, is limited by the demand of that town and its neighbourhood. The capital, therefore, which can be advantageously employed in the grocery trade, cannot exceed the capital required to purchase and retail these goods. If this capital is divided between two different grocers, their competition will obviously tend to make both of them still cheaper than if it were in the hands of one only; and if it were divided among twenty, their competition would be just so much the greater, and the chance of their combining together in order to raise the price just so much the less. Their competition might, perhaps, ruin some of themselves; but to take care of this is the business of the parties concerned, and it may safely be trusted to their discretion. It can never hurt either the consumer or the producer; on the contrary, it must tend to make the retailers both sell cheaper and buy dearer, than if the whole trade was monopolized by one or two persons. Some of them, perhaps, may occasionally decoy a weak customer to buy what he has no occasion for. This evil is, however, of too little importance to deserve the public attention, nor would it necessarily be prevented by restricting their number."—(*Wealth of Nations*, II. p. 48.)

Thus it appears, that all the modes in which capital can be employed in productive industry, or, in

vantageous.

other words, that the raising of raw produce, the fashioning of this raw produce after it is raised into useful and agreeable articles, the carrying of the raw and manufactured products from one place to another, and the retailing of them in such portions as may suit the public demand, are *equally* advantageous: that is, the capital and labour employed in any one of these departments contributes equally with the capital and labour employed in the others, to increase the mass of necessaries, conveniences, and luxuries. Without a previous supply of raw produce, we could have no manufactures; and without manufactures and commercial industry, the greater part of this raw produce would be entirely worthless, and could neither satisfy our wants nor contribute to our comforts. Manufacturers and merchants are to the body politic what the digestive powers are to the human body. We could not exist without food; but the largest supplies of food cannot lengthen our days when the machinery by which nature prepares and adapts this food for our use, and incorporates it with our body, is vitiated and deranged. Nothing, therefore, can be more silly and childish than the estimates that are so frequently put forth of the comparative advantages of agricultural, manufacturing, and commercial industry. They are all intimately and indissolubly connected, and depend upon, and grow out of each other. "Land and trade," to borrow the just and forcible expressions of Sir Josiah Child, "are TWINS, and have always, and ever will, *wax and wane together*. It cannot be ill with trade but lands will fall, nor ill with lands but trade will feel it." This reasoning cannot be controverted; and on its authority, we are entitled to condemn every attempt to exalt one species of industry, by giving it factitious advantages at the expence of the rest, as being equally impolitic and pernicious. No preference has ever been given, or can be given, to agriculturists over manufacturers and merchants, or to manufacturers and merchants over agriculturists, without occasioning the most extensively ruinous consequences. Men ought, in every instance, to be allowed to follow their own inclinations in the employment of their stock and industry. Where industry is free, the interests of individuals can never be opposed to the interests of the public. When we succeed best in increasing our own wealth, we must necessarily also succeed best in increasing the wealth of the state of which we are subjects.\*

This mutual dependence of the different branches of industry on each other, and the necessity of their co-operation to enable mankind to make any considerable progress in civilization, has been ably illustrated in one of the early numbers of the *Edinburgh Review*. "It may safely be concluded, that all those occupations which tend to supply the necessary wants, or to multiply the comforts and pleasures of human life, are equally productive, in

the strict sense of the word, and tend to augment the mass of human riches, meaning, by riches, all those things which are necessary, or convenient, or delightful to man. The progress of society has been productive of a complete separation of employments originally united. At first, every man provided, as well as he could, for his necessities as well as his pleasures, and for *all* his wants, as well as *all* his enjoyments. By degrees a division of these cares was introduced; the subsistence of the community became the province of one class, its comforts of another, and its gratifications of a third. The different operations subservient to the attainment of each of these objects were then entrusted to different hands; and the universal establishment of barter connected the whole of these divisions and subdivisions together—enabled one man to manufacture for all, without danger of starving by not ploughing or hunting, and another to plough or hunt for all, without the risk of wanting tools or clothes by not manufacturing. It has thus become as impossible to say exactly who feeds, clothes, or entertains the community, as it would be to say which of the many workmen employed in the manufacture of pins is the actual pin-maker, or which of the farm-servants produces the crop. All the branches of useful industry work together to the common end, as all the parts of each branch co-operate to its particular object. If you say that the farmer feeds the community, and produces all the raw materials which the other classes work upon, we answer, that unless those other classes worked up the raw materials, and supplied the farmer's necessities, he would be forced to allot part of his labour to this employment, whilst he forced others to assist in raising raw produce. In such a complicated system, it is clear that all labour has the same effect, and equally increases the whole mass of wealth. Nor can any attempt be more vain than theirs who would define the particular parts of the machine that produce the motion, which is necessarily the result of the *whole powers combined*, and depends on each particular one of the mutually connected members."—(Vol. IV. p. 362.)

Much has been said respecting the extraordinary mortality of large manufacturing establishments. The ready communication of contagion where people are crowded together—the want of sufficient ventilation—the confinement of children—and the positive unhealthiness of some particular processes, are circumstances from which most writers have been led to infer that the mortality in manufacturing cities *must* be unusually great, without giving themselves the trouble to inquire whether the fact really was so. The returns under the population acts have shown the fallacy of these opinions. No one can doubt that Great Britain was infinitely more of a manufacturing country in 1810 and 1820 than in 1780; but, notwithstanding the vast increase during the intermediate period of what we have been in the

ments of Ca-  
pital and In-  
dustry.

habit of considering unhealthy employments, the average mortality in England and Wales in 1810 was only one in every 53, and in 1820 only one in every 58 of the existing population, whereas in 1780 it was one in every 40. It may perhaps be said, that this increased healthiness is owing to the improvements in agriculture—to the drainage of bogs and marshes, the inclosure and cultivation of commons and wastes,—and *not* to the extension of manufactures. But suppose this were admitted, still we should have to inquire *what had occasioned these extraordinary improvements in agriculture?* And a moment's reflection would be sufficient to convince us that they have principally resulted from the improvement of manufactures—from the increased demand of the manufacturing population for the raw produce of the soil. In point of fact, however, it is certain, that much of the late diminution of mortality is a *direct*, and not an indirect consequence of the improvement and extension of manufactures. Every one knows of what vast importance it is to the health of the people that they should have the *means* of providing themselves with comfortable clothes at a cheap rate. And this is one of the many advantages which improvements in manufacturing industry always bring along with them. The reduction in the price of cotton goods only, occasioned by the greater facility with which they are now produced, has enabled the poorest classes of individuals to clothe themselves in a warm, clean, and elegant dress; and has thus been productive of an increase of comfort and enjoyment, of which it is extremely difficult for us, who have so long experienced its beneficial effects, to estimate the extent.

Division of  
Labour does  
not degrade  
the Labour-  
er.

The effect of the extreme subdivision of labour in manufacturing establishments, and the exclusive attention which it requires the workman to bestow on one single operation, has been supposed to exert a most pernicious influence on his mental faculties. The genius of the master is said to be cultivated, but that of the workman to be condemned to perpetual neglect. Most mechanical arts, we are told, succeed best under a total suppression of sentiment and reason. A habit of moving the hand or the foot is said to be independent of either; and the workshop has been compared to an engine, the parts of which are men! (Ferguson on *Civil Society*, p. 303.) Dr Smith, who has given so admirable an exposition of the benefits which society has derived from the division of labour, has notwithstanding concurred with the popular prejudices on this subject; and has gone so far as to affirm that constant application to one particular occupation in a large manufactory, “necessarily renders the workman as *stupid and ignorant as it is possible to make a human being.*” Nothing can be more marvellously incorrect than these representations. Instead of its being true that the workmen employed in manufacturing establishments are less intelligent and acute than those employed in agriculture, the fact is distinctly and completely the reverse. The weavers, and other mechanics of Glasgow, Manchester, and Birmingham, possess infinitely more general and extended information than is possessed by the agricultural labourers of any country in the empire. And this is really what a more unprejudiced inquiry into the subject would have led

us to anticipate. The variety of the occupations in which the husbandman is made successively to engage, their constant liability to be affected by so variable a power as the weather, and the perpetual change in the appearance of the objects which daily meet his eyes, and with which he is conversant, occupy his attention, and render him a stranger to that ennui and desire for extrinsic and adventitious excitement which must ever be felt by those who are constantly engaged in burnishing the point of a pin, and in performing the same endless routine of precisely similar operations. This want of excitement cannot, however, be so cheaply or effectually gratified in any other way as it may be by cultivating—that is, by *stimulating* the mental powers. The generality of workmen have no time for dissipation; and if they had, the wages of labour in all old settled and densely peopled countries are too low, and the propensity to save and accumulate too powerful, to permit any very large proportion of them seeking to divert themselves by indulging in riot and excess. They are thus driven to seek for recreation in mental excitement; and the circumstances in which they are placed afford them every possible facility for amusing and diverting themselves in this manner. By working together, they have constant opportunities of entering into conversation; and a small individual contribution enables them to obtain a large supply of newspapers and of the cheaper class of periodical publications. But whatever difference of opinion may exist respecting the *cause*, there can be no doubt of the fact, that the intelligence of the workmen employed in manufactures has increased according as their numbers have increased, and as their employments have been more and more subdivided. We do not believe that they ever were less intelligent than the agriculturists; but, whatever may have been the case formerly, no one will now venture to affirm that they are inferior to them in intellectual acquirements, or that they are mere machines without sentiment or reason. Even Mr Malthus, whose leanings are all on the side of agriculture, has justly and eloquently observed, that “Most of the effects of manufactures and commerce on the general state of society are in the highest degree beneficial. They infuse fresh life and activity into all classes of the state, afford opportunity for the inferior orders to rise by personal merit and exertion, and stimulate the higher orders to depend for distinction upon other grounds than mere rank and riches. They excite invention; encourage science and the useful arts; spread intelligence and spirit; inspire a taste for conveniences and comforts among the labouring classes; and, above all, give a new and happier structure to society, by increasing the proportion of the *middle classes*—that body on which the liberty, public spirit, and good government of every country must mainly depend.” (*Observations on the Effects of the Corn Laws*, p. 29.)

Thus, then, we arrive, by a different route, at the same result we have already endeavoured to establish. The inextinguishable passion for gain—the *auri sacra fames*—will always induce capitalists to employ their stocks in those branches of industry which yield, all things considered, the *highest rate of profit*. And it is clear to

demonstration, that those employments which yield the highest profits are always those in which it is most for the public interest that capital should be invested. The profits of a particular branch of industry are rarely raised except by an increased demand for its produce. Should the demand for cottons increase, there would be an increased competition for them; and as their price would, in consequence, be augmented, the manufacturers would obtain comparatively high profits. But the rate of profit in different employments has a natural tendency to equality; and it can never, when monopolies do not interpose, continue either permanently higher or lower in one than in the rest. As soon, therefore, as the rise in the price of cottons had taken place, additional capital would begin to be employed in their production. The manufacturers engaged in the cotton trade would endeavour to borrow additional capital, and the capitalists who were engaged in less lucrative employments would gradually contract their businesses, and transfer a portion of their stock to where it would yield them a larger return. The equilibrium of profit would thus be again restored. For the additional capital employed in the production of cottons, by proportioning their supply to the increased demand, would infallibly reduce their price to its proper level. Such is the mode in which the interests of individuals are, in every case, rendered subservient to those of the public. High profits attract capital; but high profits in particular businesses are the effect of high prices; and these are always reduced, and the commodities brought within the command of a greater number of purchasers, as soon as additional capital has been employed in their production. It is clear, therefore, that that employment of capital is the best which yields the greatest profit; and hence, if two capitals yield *equal* profits, it is a plain proof that the departments of industry in which they are respectively invested, however much they may differ in many respects, are equally beneficial to the country. Nothing can be more nugatory than to apprehend that the utmost freedom of industry can ever be the means of attracting capital to a comparatively disadvantageous employment. If capital flows to manufactures or commerce rather than to agriculture, it can only be because it has been found to yield larger profits to the individual, and consequently to the state.

PART III.—DISTRIBUTION OF WEALTH.

Having thus endeavoured to trace the various methods by which that labour which is the only source of wealth may be rendered most productive, and to exhibit the mutual relation and dependence of the different kinds of industry, we now proceed to the *second division* of our subject, or to an investigation of the laws regulating the proportions in which the various products of art and industry are distributed among the various classes of the people.

SECT. I.—*Primary Division of the Produce of Industry—Value of Commodities measured in the Earliest Stages of Society by the Quantities of Labour expended on their Production.*

It is self-evident that only three classes—the la-

bourers, the possessors of capital, and the proprietors of land, are ever directly concerned in the production of commodities. It is to them, therefore, that all that is derived from the surface of the earth, or from its bowels, by the united application of immediate labour and of capital, or accumulated labour, must *primarily* belong. The other classes of society have no revenue except what they derive either voluntarily, or by compulsion, from these three classes.

But although there is no state of society in which any other class besides those of labourers, landlords, and capitalists, participates directly in the produce of industry, there are states of society in which that produce belongs exclusively to *one* only of these classes; and others in which it belongs to *two* of them, to the exclusion of the third. The reason is, that, in the earliest stages of society, there is little or no capital accumulated, and the distinction between labourers and capitalists is, in consequence, unknown; and that in all newly settled and unappropriated countries, abundance of fertile land may be obtained without paying any rent.

In that remote period preceding the establishment of a right of property in land, and the accumulation of capital or stock—when men roamed, without any settled habitations, over the surface of the earth, and existed by means of that labour only that was required to appropriate the spontaneous productions of the soil, the whole produce of labour would belong to the labourer; and the *quantity of labour* that had been expended in the procuring of different articles, would plainly form the only standard by which their relative worth, or exchangeable value, could be estimated. "If among a nation of hunters," says Dr Smith, "it usually costs twice the labour to kill a beaver that it does to kill a deer, one beaver would naturally exchange for or be worth two deer. It is natural, that what is usually the produce of two days' or two hours' labour, should be worth double of what is usually the produce of one day's or one hour's labour.

"If the one species of labour should be more severe than the other, some allowance will naturally be made for this superior hardship; and the produce of one hour's labour in the one way, frequently exchanges for that of two hours' labour in the other.

"Or if the one species of labour requires an uncommon degree of dexterity and ingenuity, the esteem which men have for such talents will naturally give a value to their produce, superior to what would be due to the time employed about it. Such talents can seldom be acquired but in consequence of long application, and the superior value of their produce may frequently be no more than a reasonable compensation for the time and labour which must be spent in acquiring them. In the advanced state of society, allowances of this kind, for superior hardship and superior skill, are commonly made in the wages of labour; and something of the same kind must probably have taken place in the earliest and rudest period.

"In this state of things, the whole produce of labour belongs to the labourer; and the quantity of labour commonly employed in acquiring or producing any commodity, is the only circumstance which

Primary Division of the Produce of Industry.

Quantity of Labour the regulating Principle of Value.

Equality of  
Wages and  
Profits.

can regulate the quantity of labour (*of other commodities*) which it commonly ought to purchase, command, or exchange for."—(*Wealth of Nations*, I. p. 70.)

Thus far there is no room for doubt or difference of opinion. When there is no class but labourers, all the produce of labour must obviously belong to them; and the *quantity of labour* required to produce commodities must form the only standard by which their exchangeable worth or value can be estimated. It is at this point, therefore, that we are to begin the investigation of the laws regulating the division of the produce of industry among the three great classes of labourers, capitalists, and landlords; and we shall do this by endeavouring, in the first place, to acquire a knowledge of the laws which regulate the *exchangeable value* of commodities in an advanced period of society, when circulating and fixed capital are employed in their production, and when land is appropriated, and rent paid. A previous acquaintance with the circumstances which determine the value of commodities, will be found to be indispensable to enable us to ascertain the principles which regulate their distribution.

SECT. II.—*Preliminary Considerations—Equality of Wages and Profits—Inquiry into the Effect of Variations of Demand and Supply on Price—Cost of Production shown to be its regulating Principle.*

Preliminary  
Considerations.

If the popular opinions on this subject were well founded, the inquiry on which we are now about to enter might be disposed of in a very few words. The exchangeable value of commodities, when compared with each other, and their value or price when compared with money, is held almost universally to depend on their *relative abundance or scarcity in the market, compared with the demand*. We believe, however, that we shall be able to show, that this opinion rests on no good foundation, and that it is the *cost of production* which is the sole regulating principle of price. But, before proceeding further, it is necessary, in order to facilitate our investigations in this and the following sections, to premise, that wherever industry is free, *the rate of wages earned by the labourers engaged in any particular department of industry, and the rate of profit derived from the capital vested in it, cannot, for any considerable period, either fall below, or rise above, the rate of wages and profits accruing to the labourers and capitalists engaged in other departments.*

Equality of  
the Wages  
earned by  
the Labourers  
engaged in  
different  
Branches of  
Industry.

With regard to the *first* of these positions, or to the equality of the wages earned by the labourers engaged in different employments, it is not meant to infer that all labourers receive precisely the same sum of money, or the same *proportional share* of the produce of their labour. Such an opinion would be equally at variance with the fact,—and with the principle it is our object to elucidate. Wages are a compensation given to the labourer in return for the exertion of his physical powers, or of his skill, or ingenuity. They must, therefore, vary according to the greater intensity of the labour to be performed, and to the degree of skill and ingenuity required. Wages would not be equal if a jeweller or engraver, for example, received no higher

rate than a common farm servant, or a scavenger. A long course of training is required to instruct a man in the business of jewelling and engraving; and if this were not compensated, by a higher rate of wages, it is evident no one would choose to learn so difficult an art; but would addict himself in preference to such employments as hardly require any training. The cost of producing artificers, or labourers, regulates the wages they obtain, precisely in the same way that the cost of producing commodities regulates their value. A man who practises a difficult or nice business, loses all the time that is spent in his apprenticeship, and generally also the clothes and provisions consumed by him during the same period. This person ought, therefore, to obtain not only the same rate of wages as husbandry labourers, and those who do not require to serve an apprenticeship, but he ought also to obtain an additional rate proportioned to the extra time and expence spent in learning his business. If he does not obtain this additional rate, it is plain he would not be so well paid as the husbandry labourers; and if he obtained *more* than what was a fair and reasonable compensation for the greater expence to which he had been put, there would be an immediate influx of labourers into that particular business, and competition would not fail to reduce wages to their proper level.

Equality of  
Wages and  
Profits.

Besides this prominent cause of apparent inequality, wages vary in amount proportionably to the ease and hardship, the agreeableness and disagreeableness, the constancy and inconstancy of employment. In the greater part of manufactures, a journeyman may, except in periods of general revulsion, generally be able to obtain constant employment. But there are several businesses, such, for example, as those of masons and bricklayers, that can neither be carried on in hard frost nor foul weather. Their earnings must therefore be able not only to maintain them while they are employed, but also while they are idle, and to make them some compensation for those anxious and depending moments which the thought of so precarious a situation must sometimes occasion. Hence, says Dr Smith, "where the daily earnings of the greater number of manufacturers are nearly upon a level with the daily earnings of the superior class of farm servants, the wages of masons and bricklayers are generally from fifty to one hundred *per cent.* higher. Where common labourers earn four or five shillings a week, masons and bricklayers frequently earn seven and eight; and where the former earn nine or ten, the latter commonly earn fifteen and eighteen."—(*Wealth of Nations*, I. p. 157.)

But these variations, instead of being inconsistent with the principle we have been endeavouring to establish, plainly result from it. The wages earned by different classes of workmen are equal, not when each earns the same number of shillings or of pence, in a given space of time—but when each is paid in proportion to the severity of the labour he has to perform, to the degree of previous education and of skill that it requires, and to the other causes of variation. So long, indeed, as the principle of competition is allowed to operate without restraint, or so long as each individual is allowed to employ himself as he pleases, we may be assured that the higgling

Equality of  
Wages and  
Profits.

of the market will always adjust the rate of wages in different employments on the principle we have now mentioned, and that it will be very nearly equal. If the rate of wages in one department were depressed below the common level, labourers would leave it to go to others; and if it were to rise above this common level, then, it is plain, labourers would be attracted from those departments where wages were lower, until the increased supply had sunk them to their just level. A period of greater or less duration, according to the circumstances of the country at the time, is always required to bring about this equalization. But all theoretical inquiries, and such as have the establishment of principles for their object, either are, or ought to be, founded on periods of average duration; and whenever such is the case, we may always, without occasioning the slightest error, assume, that the wages earned in different employments are, all things considered, *precisely equal*.

Equality of  
the Profits  
of the Capital  
employed  
in different  
Businesses.

In like manner, the profit accruing to the capitalists engaged in different businesses must always vary proportionably to the greater or less risk, and other circumstances specially affecting the capital they employ in them. It is obvious, indeed, that profits have not attained their level until they have been adjusted so as to balance these different advantages and disadvantages. None would engage in unusually hazardous undertakings, if the capital employed in them only yielded the same profit that might have been obtained by employing it in more secure businesses. No one would choose voluntarily to place his fortune in a situation of comparative danger. Wherever there is extraordinary risk, that risk must be compensated. And hence, the well known distinction between *gross* and *nett* profit. Gross profit always varies according to the risk, the respectability, and the agreeableness of different employments, while nett profit is the same, or very nearly the same, at any particular period, in them all. A gunpowder manufacturer, for example, must obtain as much profit, over and above the profit obtained from the capital engaged in the securest businesses, as will suffice to guarantee or *insure* his capital, from the extraordinary risk to which it is exposed, in a business of such extreme hazard. If the gunpowder manufacturer were to obtain *more* than this rate, additional capital would be attracted to his business, and if he were to obtain *less*, he would withdraw capital from it. The great and constantly acting principle of competition, or, which is just the same thing, the *self-interest* of every individual will never permit the wages or the profits obtained by any particular set of workmen or capitalists, taking all things into account, to continue either long below or long above the *common and average* rate of wages and profits obtained by those who are employed, or who have capital invested in other businesses. It is by this common standard that the wages and profits of particular businesses are always regulated; they can never diverge considerably from it; they have a constant tendency to equalization; and may, in all theoretical inquiries, be supposed, without occasioning any error of consequence, exactly to coincide.

The principle of the equality, or rather of the constant tendency to equality, of the wages earned by

the labourers, and of the profits derived from the capital, employed, at the same time, in all the various branches of industry, was pointed out by Mr Harris, and also by Mr Cantillon, in his work entitled, *The Analysis of Trade*, &c. published in 1759; but it was first fully demonstrated in the eighth, ninth, and tenth chapters of the first book of the *Wealth of Nations*. The establishment of this principle was one of the greatest services rendered by Dr Smith to the science of Political Economy. Nothing can be clearer, more convincing and satisfactory, than his reasoning on this subject. The equality of wages and of profits has, ever since the publication of his work, been always assumed as admitted and incontestible.

The principle of the equality of wages and profits once established, it is easy to show that variations in the demand and supply of commodities can exert no lasting influence on price. It is the *cost of production*—denominated by Smith and the Marquis Garnier *necessary*, or *natural price*—which is the permanent and ultimate regulator of the exchangeable value or price of every commodity which is not subjected to a monopoly, and *which may be indefinitely increased in quantity by the application of fresh capital and labour to its production*. That the market price of such commodities and the cost of production do not always coincide is certain; but they cannot, for any considerable period, be far separated, and have a constant tendency to equality. It is plain that no man will continue to produce commodities if they sell for *less* than the cost of their production—that is, for less than will indemnify him for his expences, and yield him the common and average rate of profit on his capital. This is a limit below which it is obviously impossible prices can be permanently reduced; and it is equally obvious, that if they were, for any considerable period, to rise above it, additional capital would be attracted to the advantageous business, and the competition of the producers would lower prices.

A demand, to be effectual, must be such as will cover the expence of production. If it is not sufficient to do this, it can never be a means of causing commodities to be produced and brought to market. A real demander must have the *power*, as well as the *will*, to purchase. A person with 20s. in his pocket may be as anxious,—nay, he may be ten times more anxious, to become the purchaser of a coach than of a hat; why then does he not obtain the one as readily in exchange for his 20s. as the other? The reason is obvious—20s. will pay the expence of producing the one, and it will *not* pay the expence of producing the other. But if such an improvement were to take place in the art of coachmaking, as would enable any one to produce a coach as cheaply as a hat, then 20s. would buy a coach as easily as it can now buy a hat. The demand for any particular commodity may become ten or ten thousand times more extensive, or it may decline in the same proportion; but if the cost of its production continues the same, no permanent variation will be occasioned in its price. Suppose, for example, that the demand for hats is suddenly doubled, that circumstance would undoubtedly occasion a rise of price, and the hatters would, in consequence, make large profits; but this rise

Cost of Production the regulating Principle of Price.

could only be of very limited duration; for the large profits would immediately attract additional capital to the hat manufacture; an increased supply of hats would be brought to market, and if no variation took place in the cost of production, their price would infallibly sink to its former level. Suppose, on the other hand, that the demand for hats is increased a thousand fold, and the cost of producing them diminished in the same proportion, we should, notwithstanding the increased demand, be able, in a very short time, to buy a hat for the thousandth part of what it now costs. Again, suppose the demand for hats to decline, and the cost of producing them to increase, the price would, notwithstanding the diminished demand, gradually rise, till it had reached the point at which it would yield the hatters the common and average rate of profit on the capital employed in their business. It is admitted that variations in the demand and supply occasion temporary variations of price. But it is essential to remark, that these variations are only *temporary*. It is the *cost of production* that is the grand regulator of price—the centre of all those transitory and evanescent oscillations on the one side and the other; and wherever industry is free, the *competition of the producers* will always elevate or sink prices to this level.

Cost of Production the regulating Principle of Price.

In certain branches of industry, such, for example, as agriculture, which are liable to be seriously affected by the variations of the seasons, and from which capital cannot be easily withdrawn, there is a somewhat longer interval than in others, before the market price of produce and the cost of producing it can be equalized. But that such an equalization will be brought about in the end is absolutely certain. No farmer, and no producer whatever, will continue to bring corn or other products to market, if they do not sell for such a price as will pay the expence of their production, including therein the common and average rate of profit on the capital employed by them.\* An excess of supply has now (January 1823) depressed the prices of corn and other farm produce below this level; and the occupiers of poor land are, in consequence, involved in the greatest difficulties; but most assuredly this glut will not continue. A part of the cultivators of poor soils will be driven from their employment. A smaller supply will be brought to market; and prices will be adjusted so as to yield the customary rate of profit, and no more, to the agriculturists who continue the cultivation of the poorest soils.—The self-interest of the cultivators will not permit prices to be permanently depressed below this level; and the self-interest of the public will not permit them to be permanently raised above it; for, if they were raised above it, then the cultivators would gain more than the common and average rate of profit, and capital would, of course, be immediately attracted to agriculture, and would conti-

nue flowing in that direction, until the natural and indestructible equilibrium of profit had been restored—that is, as we shall afterwards show, until the price of agricultural produce had fallen to such a sum as would just yield the average rate of profit to the cultivators of the worst soils, or the improvers of the best. This is the point at which *average* prices must continue stationary, or about which market prices must oscillate, until the cost of production be increased or diminished. If any great discovery were made in agriculture—such a discovery, for instance, as would reduce the cost of cultivation a half, the price of agricultural produce would fall in the same proportion, and would continue to sell at that reduced rate until the increase of population forced recourse to soils of a *decreasing degree of fertility*. Whenever this took place, prices would again rise. Why is the price of corn almost invariably higher in this country than in France? Is it because we have a greater demand for it, or because of the greater cost of production in this country?

Cost of Production the regulating Principle of Price.

A pound weight of gold is at present worth about *fifteen* pounds of silver. It cannot, however, be said that this is a consequence of the demand for gold being greater than the demand for silver, for the reverse is the fact. Neither can it be said to be a consequence of an absolute scarcity of gold; for, those who choose to pay a sufficient price for it may obtain it in any quantity they please. The cause of this difference in the price of the two metals consists entirely in the circumstance of its costing about *fifteen* times as much to produce a pound of gold as to produce a pound of silver. That this is really the case, is plain from the admitted fact that the producers of gold do not gain any greater profit than the producers of silver, iron, lead, or any other metal. They have no monopoly of the business. Every individual who pleases may send capital to Brazil, and become a producer of gold; and wherever this is the case, the principle of competition will always force the product to be sold at such a price as will just pay the expences of its production and no more. Were a gold mine discovered of equal productiveness with the silver mines, the production of gold would immediately become the most advantageous of all businesses; an immense supply of that metal would, in consequence, be thrown on the market, and its price would, in a very short period, be reduced to the same level as silver.

Reason why Gold is more valuable than Silver.

As a further illustration of this principle take the case of cottons. No one can deny that the demand for them has been prodigiously augmented within the last fifty or sixty years; and yet their price, instead of increasing, as it ought to have done, had the popular theory of demand and supply been well-founded, has been constantly and rapidly diminishing. If it is said that this is a consequence of the

Reason why Cottons have declined in Price.

\* Some of the advocates of the agricultural interest have represented this as one of the "dangerous dogmas" of the Scotch Economists! But it can boast of a much more remote origin:—"Nemo enim sanus," says Varro, "debet velle impensam ac sumptum facere in culturam, si videt non posse refici." (*De Re Rustica*, Lib. I, § 2.)

Cost of Production the regulating Principle of Price.

Cost of Production the regulating Principle of Price.

Competition of the Producers in a Civilized Society will always sink Prices to the Cost of Production.

Average Price always coincident with Cost of Production.

Influence of Monopolies.

supply of cottons having augmented in a still greater ratio than the demand, we answer that this is not enough to explain the fall of price. The supply would not and could not possibly have been brought to market, had not the constant diminution of prices, which has been going on since the invention of spinning-jennies in 1767, been balanced by an equal diminution of the cost of production. It is to this principle—to the vastly increased facility of production, occasioned by the stupendous inventions and discoveries of Hargreaves, Watt, Arkwright, Crompton, and others, that the lower price and increased demand for cottons is exclusively owing. The increased facility of production has brought them within the reach of all classes of the people; and enabled the poorest individuals in the kingdom to clothe themselves in a dress which, at the accession of George III. was fully as expensive as silk.

If you bring a set of men together from various countries who are ignorant of each other's wants, and of the labour and expence necessary to produce the commodities which each possesses, the commodities will be bought and sold according to the relative wants and fancies of the parties. In such circumstances, a pound of gold might be given for a pound of iron, and a gallon of wine for a gallon of small beer. As soon, however, as a commercial intercourse has been established, and as the wants of society and the powers of production come to be well and generally known, an end is put to this method of bartering. Thousands of sellers then enter the market. But when such is the case, it is no longer possible to sell a pound of gold for a pound of iron; and why? because the producers of iron will undersell each other until they have, by their competition, reduced its price to such a sum as will just suffice to pay the expence of its production. This is in every civilized society the pivot on which exchangeable value always turns. A civilized man might be able to obtain commodities from a savage, in exchange for toys or trinkets, which it cost infinitely less to produce; but if he tries to obtain the same advantage over his own countrymen, a very short experience will be enough to satisfy him that they are quite as clear-sighted and attentive to their own interests as he is.

Thus, then, it appears, that *no variation of demand, if it be unaccompanied by a variation in the cost of production, can have any lasting influence on price.* If the cost of production be diminished, price will be equally diminished, though the demand should be increased to any conceivable extent. If the cost of production be increased, price will be equally increased, though the demand should sink to the lowest possible limit.

It must always be remembered, that this reasoning only applies to the case of those commodities on which competition is allowed to operate without restraint, and whose quantity can be indefinitely increased by the application of fresh capital and industry to their production. When a particular individual, or class of individuals, obtain the exclusive privilege of manufacturing certain species of goods, the operation of the principle of competition is suspended with respect to them, and their price must,

therefore, entirely depend on the proportion in which they are brought to market compared with the demand. If monopolists supplied the market liberally, or kept it always as fully stocked with commodities as it would have been had there been no monopoly, the commodities produced by them would sell at their natural price, and the monopoly would have no further disadvantage than the exclusion of the public from an employment which every one ought to have the right of carrying on. In point of fact, however, the market is never fully supplied with commodities produced under a monopoly. Every class of producers naturally endeavour to obtain the highest possible price for their commodities; and if they are protected by means of a monopoly, against the risk of being undersold by others, they will either keep the market understocked, or supply it with inferior articles, or both. In such circumstances, the price of the commodity, if it cannot be easily smuggled from abroad, or clandestinely produced at home, will be elevated to the highest point to which the competition of the buyers can raise it, and may, in consequence, be sold for five, ten, or twenty times the sum for which it would be offered were competition permitted to operate in its production. The *will* and *power* of the purchasers to offer a high price forms the only limit to the rapacity of monopolists.

Besides the commodities produced under an artificial monopoly, there is another class whose quantity cannot be increased by the operation of human industry, and whose price is not, therefore, dependent on the cost of their production. Ancient statues, vases, and gems, the pictures of the great masters, some species of wines which can be produced in limited quantities only from soils of a particular quality and exposure, and a few other commodities, come under this description. As their supply cannot be increased, their price must vary inversely as the demand, and is totally unaffected by any other circumstance.

But with these exceptions, which, when compared to the great mass of commodities, are extremely few and unimportant, wherever industry is unrestricted and competition allowed to operate, the *average* price of the various products of art and industry, always coincides with the cost of their production. When a fall takes place in the market price of any commodity, we cannot say whether that fall is really advantageous, or whether a part of the wealth of the producers be not gratuitously transferred to the consumers, until we learn whether the cost of production has been equally diminished. If this is the case, the fall of price will not have been disadvantageous to the producers, and will be permanent; but if this has not been the case—if the cost of production continues the same, the fall must have been injurious to the producers, and prices will, in consequence, speedily attain their former level. It is the same with a rise of prices. No rise can be permanent except where the cost of production has been proportionably increased. If that cost has remained stationary, or has not increased in a corresponding ratio, prices will decline as soon as the ephemeral causes of enhancement have disappeared.

The extreme importance of having correct opi-

Cost of Production the regulating Principle of Price.  
Opinion of the Marquis Garnier.

nions respecting the regulating principle of price, and the discordant and erroneous opinions that are still so exceedingly prevalent with regard to it, will, we hope, be deemed a sufficient apology for the length of the previous remarks, and for the insertion of the following paragraph from the *Histoire de la Monnaie* of the Marquis Garnier, in which the doctrine we have been endeavouring to establish is enforced with equal ability and eloquence :

“ Mais les producteurs tendent continuellement à régler la quantité des productions sur la somme des demandes ; ils ne resteront pas au-dessous de ce point, sans être tentés d'accroître la masse de leurs produits ; et ils ne peuvent le dépasser sans s'exposer à perdre. Ces deux quantités, celle des produits et celle des demandes, s'efforcent donc à se mettre en équilibre l'une avec l'autre. Il existe donc un point de repos vers lequel elles gravitent chacune de son côté ; un point qui est leur niveau, et c'est ce point qui constitue le *prix naturel* de la chose vénale. Quelle est la limite au-delà de laquelle le producteur ne peut porter la quantité de ses produits ? C'est le *prix naturel* ; car, s'il ne peut obtenir ce *prix* pour tout son produit, il sera en perte. Quelle est la borne des demandes du consommateur ? C'est le *prix naturel* ; car il ne veut pas donner plus que l'équivalent de ce qu'il reçoit. Si, par une découverte, ou par un perfectionnement de l'industrie, le producteur est mis à même d'établir l'article sur lequel il s'exerce à moins de temps et de dépense, alors le *prix naturel* baissera, mais aussi la somme des demandes accroîtra dans une proportion pareille, parce que plus de consommateurs seront en état de payer ce *prix naturel*, moins élevé que l'ancien. *Le prix naturel sera toujours, pour chaque chose vénale, la limite commune au-delà de laquelle la somme des demandes de cette chose et la quantité de sa production ne devront plus faire de progrès.* Quand le *prix courant* est le *prix naturel*, le producteur et le consommateur se donnent réciproquement l'équivalent de ce qu'ils reçoivent. Quand le *prix courant* s'écarte du *prix naturel*, ou c'est la consommation qui souffre au profit de la production, ou c'est la production qui souffre au profit de la consommation. Cet état de souffrance ne peut durer, et de-là procèdent les variations du *prix courant*. Ces variations, que Smith a expliquées et analysées avec une si parfaite lucidité, ne sont autre chose que les efforts pour revenir au *prix naturel*. Tenter d'expliquer ces variations, sans reconnaître l'existence d'un *prix naturel*, ce serait vouloir expliquer les oscillations du pendule sans convenir de sa tendance vers un centre de gravitation ; ce serait supposer un effort sans but et sans mobile ; ce serait admettre le mouvement et nier le repos ; enfin, en voyant les phénomènes du cours des fluides et de l'équilibre des solides, ce serait contester les lois du niveau et de la pesanteur. Si les choses vénales n'ont point de *prix naturel*, alors les mouvemens de la circulation seront dirigés par une force aveugle et inconnue ; les *prix*

moyens ne seront plus que le résultat de chances purement fortuites ; il n'y aura plus d'équivalent réel ; les valeurs n'auront plus de mesure naturelle ; l'économie politique ne pourra plus aspirer à être au rang des sciences, puisqu'elle manquera du caractère essentiel qui les constitue telles, et que les faits dont elle traite ne seront plus fondés sur les lois immuables de la nature.”—(Tome I. *Introduction*, p. 62.)

Having thus shown that it is the *cost of production* which is the sole regulating principle of price, we shall now proceed to investigate the elements which enter into and constitute the cost of producing commodities in an advanced state of society, when a rent is paid for land, and circulating and fixed capital employed to facilitate the labour of the workman. This is, of all others, the most important, as it is the most radical inquiry in the science of the distribution of wealth ; and it is indeed impossible, without possessing accurate notions on this subject, to advance a single step without falling into errors. We shall begin by endeavouring to ascertain whether rent enters into the cost of production, or not.

SECT. III.—*Nature, Origin, and Progress of Rent—Not a Cause but a Consequence of the High Value of Raw Produce—Does not enter into Price—Distinction between Agriculture and Manufactures.*

Dr Smith was of opinion, that, after land had become property, and rent began to be paid, such rent made an equivalent addition to the exchangeable value of the produce of the soil. (*Wealth of Nations*, I. p. 75.) This opinion was first called in question in two pamphlets of extraordinary merit, published nearly at the same time, by Mr Malthus,\* and a Fellow of University College, Oxford.† These writers endeavoured to show that rent was not, as had been generally supposed, a consequence of land being appropriated and of limited extent, but of the superior productiveness of one species of land over another ; and that the annihilation of rents would not, provided the same extent of land was cultivated, enable its produce to be sold at a lower price. Mr Ricardo has illustrated and enforced this doctrine with his usual ability—has stripped it of the errors by which it had been encumbered, and has shown its vast importance to a right understanding of the laws which regulate the rise and fall of profits. But the subject is still far from being exhausted ; and we hope to be able to treat it in a somewhat different manner from what it has been treated by either of these gentlemen, and to obviate some rather specious objections which have not come under their notice.

Rent is properly “ that portion of the produce of the earth which is paid by the farmer to the landlord for the use of the *natural and inherent* powers of the soil.” If buildings have been erected on a farm, or if it has been inclosed, drained, or in any way improved, by an expenditure of capital and labour, the sum which a farmer will pay to the land-

† *An Essay on the Application of Capital to Land*, by a Fellow of University College, Oxford, 1815.

Nature and Causes of Rent.

Nature and Causes of Rent.

lord for its use will be composed, not only of what is properly rent, but also of a remuneration for the use of the capital which has been laid out in its improvement. In common language, these two sums are always confounded together, under the name of rent; but in an inquiry of this nature, it is necessary to consider them as perfectly distinct. The laws by which rent and profits are regulated being totally different, those which govern the one cannot be ascertained if it be not considered separately from the other.

to cover the cost of its production. If the price were above this level, then agriculture would be the best of all businesses, and tillage would be immediately extended; if, on the other hand, the price fell below this level, capital would be withdrawn from the soil, and the poorer lands thrown out of cultivation. In such circumstances, it is undeniably certain that no rent could enter into the price of that portion of produce raised with the capital last applied to the soil. Its price is exclusively made up of wages and profits. The proprietors of the superior lands obtain rent; but this is the necessary result of their *greater fertility*. The demand cannot be supplied without cultivating inferior soils; and to enable them to be cultivated, their produce must sell for such a price as will afford the ordinary rate of profit to *their* cultivators. This price will, however, yield a surplus over and above the ordinary rate of profit to the cultivators of the more fertile lands, and *this surplus is rent*.

No Rent paid on the first settling of any Country.

On the first settling of any country abounding in large tracts of unappropriated land, no rent is ever paid; and for this plain and obvious reason, that no person will pay a rent for what may be procured in unlimited quantities for nothing. Thus in New Holland, where there is an ample supply of fertile and *unappropriated* land, it is certain, that, until the best lands are all cultivated, no such thing as rent will ever be heard of. Suppose, however, that tillage has been carried to this point, and that the increasing demand can, in the actual state of the science of agriculture, be no longer supplied by the best lands, it is plain that either the increase of population must cease, or the inhabitants must consent to pay such an additional price for raw produce as will enable the *second* quality of land to be cultivated. No advance *short of this* will procure them another bushel of corn; and competition will not, as we shall immediately show, allow them to pay more for it. They have, therefore, but one alternative. If they choose to pay a price sufficient to cover the expence of cultivating land of the second quality, they will obtain additional supplies; if they do not, they must want them. Suppose, now, that the consumers offer such a price as will pay the expence of producing corn on soils which, in return for the same expenditure as would have produced 100 quarters on lands of the *first quality*, will only yield 90 quarters; it is plain it will then be just the same thing to a farmer whether he pays a rent of ten quarters for the first quality of land, or farms the second quality, which is unappropriated and open to him, without paying any rent. If the population went on increasing, lands which would yield only 80, 70, 60, 50, &c. quarters in return for the same expenditure that had obtained 100 quarters from the best lands, might be successively brought under cultivation. And when recourse had been had to these inferior lands, the rent of the land of the higher qualities would plainly be equal to the difference, or the value of the difference, between their produce and the produce of the worst quality under cultivation. Suppose, for example, that the worst quality under cultivation yields 60 quarters, then the rent of the *first* quality will be 40 quarters, or 100—60; the rent of the *second* quality would, in like manner, be equal to the difference between 90 and 60, or 30 quarters; the rent of the third quality would be equal to 80—60, or 20 quarters, and so on. The produce raised on the land last cultivated, or with the capital last applied to the soil, would always be sold at its *necessary price*, or at that price which is just sufficient to yield the cultivators the common and average rate of profit, or, which is the same thing,

An increase of rent is not, therefore, as is very generally supposed, occasioned by improvements in agriculture, or by an increase in the fertility of the soil. It results entirely from the necessity of resorting, as population increases, to soils of a *decreasing* degree of fertility. Rent varies in an inverse proportion to the amount of produce obtained by means of the capital and labour employed in cultivation;—that is, *it increases when the profits of agricultural labour diminish, and diminishes when they increase*. Profits are at their maximum in countries like New Holland, Indiana, and Illinois, and generally in all situations in which no rent is paid, and the best lands only cultivated; but it cannot be said that rents have attained their maximum so long as capital yields any surplus in the shape of profit.

Origin of Rent.

A quarter of wheat may be raised in the Vale of Gloucester, or in the Carse of Gowrie, at perhaps a *fourth* or a *fifth* part of the expence necessary to raise it on the worst soils in cultivation. There cannot, however, be at the same time *two or more prices* for the same article in the same market. And it is plain, that if the average market price of wheat be not such as will indemnify the producers of that which is raised on the *worst soils*, they will cease bringing it to market, and the required supplies will no longer be obtained; and it is equally plain, that if the market price of wheat exceeds this sum, fresh capital will be applied to its production, and competition will soon sink prices to their natural level—that is, to such a sum as will just afford the *common and ordinary rate of profit to the raisers of that portion of the required supply of corn which is produced in the most unfavourable circumstances, and with the greatest expence*. It is by the cost of producing this portion that the average price of all the rest must always be regulated. And, therefore, it is plainly all one to the consumers whether, in an advanced stage of society, the excess of return over the cost of production on lands of the first quality belongs to a non-resident landlord, or an occupier. It *must* belong to the one or the other. Corn is not high because a rent is paid, but a rent is paid because corn is high—*because the demand is such that it cannot be supplied without cultivating soils of a diminished degree of fertility, as compared with the best*. Suppose there is an effectual demand for

Progress of Rent.

Nature and Causes of Rent.

10 millions of quarters, and that it is necessary to raise one million of these quarters on lands which yield nothing but the common and average rate of profit to their cultivators; it is clear that the relinquishing of the rents payable on the superior lands would be no boon whatever to the cultivators of the inferior lands. It would not lessen their expences; that is, it would not lessen the quantum of capital and labour necessary to produce that portion of the required supply which is raised in the most unfavourable circumstances; and, if it did not reduce this expence, it is utterly impossible, supposing the demand not to decline, that it could lower prices. Mr Malthus is, therefore, right in saying, that although landlords were to give up the whole of their rents, their doing so would have no influence on the price of corn. Such an act would only turn farmers into gentlemen, and gentlemen into beggars. The case is, however, distinctly and completely different when the cost of production varies. If it is diminished, the competition of the producers will infallibly sink prices in an equal proportion: If it is increased, no supplies will be brought to market, unless the price be raised to a corresponding level. In no case, therefore, whether the demand be great or small—whether for one or one million of quarters, can the price of raw produce ever permanently exceed or fall below the sum necessary to pay the cost of producing that portion of the supply that is raised on the worst land, or with the last capital laid out on the soil.

Objections to this Theory.

Two objections have been made to this theory. In the first place, it has been said that, though it might hold good in a country like New Holland, where land is not appropriated, still it is true that all the lands in every civilized and appropriated country like England, always yield some small rent to the proprietor; and that, therefore, it cannot be said that the price of produce is, in such countries, determined by the cost of raising it on that quality of land which pays no rent.

Mr Mill has justly observed of this objection, that even if it were well-founded, it could not practically affect any of the conclusions we have endeavoured to establish. There are in England and Scotland thousands of acres of land which do not let for L. 20; but to cultivate them would require an outlay of many thousands; and the rent would consequently bear so small a proportion to the expences of production, as to become altogether evanescent and inappreciable. (*Elements of Political Economy*, p. 19, 1st edit.)

Land in every extensive Country which yields no Rent.

There can be no doubt, however, that there is in this, and most other extensive countries, a great deal of land which yields no rent whatever. In the United States and Russia such is unquestionably the case; and yet no one presumes to say that the laws which regulate rent in the United States and Russia are different from those which regulate it in England and France. The poorest lands are always let in immense tracts. If it were attempted to let particular portions of these tracts separately, they would bring no rent whatever; but they appear to yield rent, because rent is paid not for them, but for the more fertile spots intermixed with them. But although it were really true that every rood of land in Britain paid

Payment of Rent on all

a high rent, it would still be true that such rent did not, and could not, enter into the price of raw produce. The rent of a country consists of the difference, or the value of the difference, between the produce obtained from the capital first applied to the land, and that which is last applied to it. It would, as we have already shown, be exactly the same thing to the cultivator, whether he paid a rent of ten quarters to a landlord for land yielding, with a certain outlay, 100 quarters of corn, or employed the same capital in cultivating inferior land yielding only 90 quarters, for which he paid no rent. If it were possible always to obtain 100 quarters for every equal additional capital applied to the superior soils, no person, it is obvious, would ever resort to those of inferior fertility. But the fact, that, in the progress of society, new and less fertile land is always brought into cultivation, demonstrates that additional capital and labour cannot be indefinitely applied with the same advantage to the old land. The state of society in any particular country may be such—the demand for agricultural produce may be so great, that every quality of land actually yields rent; but it is the same thing if there be any capital employed on land which yields only the return of stock with its ordinary profits, whether that capital be employed on old or new land. That there is a very large amount of capital employed in such a manner in this and every other country, is abundantly certain. A farmer who rents a farm, besides employing on it such a capital as will, at the existing prices of raw produce, enable him to pay his rent, to obtain the average rate of profit, and to replace his stock previously to the expiration of his lease, will also employ an additional capital, if it will only replace itself, and afford the ordinary rate of profit. Whether he shall employ this additional capital or not, depends entirely on the circumstance of the price of raw produce being such as will repay his expences and profits; for he knows he will have no additional rent to pay. Even at the expiration of his lease, his rent will not be raised; for, if his landlord should require rent, because an additional capital had been employed, he would withdraw it; since, by employing it in agriculture, he got only the same profits he might have got by employing it in any other department of industry. If the capital last applied to the soil yields more than the common and average rate of profit, fresh capital will be invested in agriculture, and competition will sink prices to such a level as will just enable them to yield this rate, and no more; if the capital last applied to the soil yields less than this common and average rate of profit, it will be withdrawn, until, by the rise of price, the last remaining capital yields this common rate. In every case, therefore, whether the last quality of land taken into cultivation yields rent or not, the last capital applied to the soil yields only the common and average rate of profit; and, consequently, the price of the produce which it yields, and which regulates the price of all the rest, is totally unaffected by rent.

It has, in the second place, been objected to this account of the nature and causes of rent, that it takes for granted, that, in all extensive countries, landlords permit the farmers of the worst lands to occupy them

Nature and Causes of Rent.

Soils not inconsistent with the principle that Rent does not enter into Price.

Does not suppose the Landlords will allow Farmers to

Nature and Causes of Rent.

occupy their Lands without paying Rent.

without paying any rent. But, it is easy to show that this is a mistake. The price of raw produce is not kept down to its necessary price by the competition of farmers, but by that of the landlords themselves. Though there must necessarily be a very wide difference, in any country of considerable extent, between the best and worst soils, still the gradation from the one extreme to the other is gradual, and almost imperceptible. The best differ but little from those which are immediately inferior to them, and the worst from those immediately above them. And hence it is just as impossible to point out the precise point where the first quality ends and the second begins, or where the second ends and the third begins, as it is to point out the precise point where the contiguous colours of the rainbow differ. Now, suppose that the numbers 1, 2, 3, 4, 5, 6, 7, &c. designate the different qualities of soil in an extensive country, and suppose that the effectual demand for raw produce is such as will just afford the common and average rate of profit to those who cultivate land of the *fifth* degree of fertility, or that represented by No. 5; when such is the case, there can be no doubt that No. 5 will be cultivated; for, besides the peculiar attractions which agriculture possesses, it would be quite as advantageous to cultivate it as to engage in any other business. It would not, however, be more advantageous; for its produce would yield no surplus in the shape of rent. But suppose that a combination took place among the proprietors of Nos. 1, 2, 3, 4, and 5, to withhold a portion of their produce from market; and that, in consequence of this, or any other cause, the price of corn is raised ever so little above the expence of its production on No. 5; in that case, it is obvious that soils of the *very next* degree of fertility, or that that portion of No. 6, which, in point of productive power, differs extremely little from No. 5, would be instantly brought under cultivation; and the increased supply would infallibly sink prices to the level that would just afford the average rate of profit, and no more, to the cultivators of No. 5, or of the poorest soils which the supply of the effectual demand renders it necessary to cultivate. It is quite the same thing, therefore, in so far as price is concerned, whether a country is appropriated or not. When it is appropriated, prices are kept down to their lowest limit by the competition of the landlords. And it is by the self same principle,—the *cost of producing that portion of the necessary supply raised in the most unfavourable circumstances*,—that the price of raw produce is determined in England and France, as it is determined in New Holland and Illinois.

Does not account both for a Rise and Fall of Price in the same Way.

But then it is said, that this reasoning involves a contradiction,—that it accounts both for a rise and a fall of price in the same way, or by an extension of cultivation! In point of fact, however, it does no such thing. The market price of corn will always be low where it is cheaply produced, as in Poland; and it will *occasionally* be low where it costs a great deal to produce it, when a redundant supply is brought to market, as is the case in England at this moment. Suppose, as before, that the effectual demand for corn in Great Britain is at present such as will just enable lands of the *fifth* degree of fertility to

be cultivated; but that, owing to variable harvests, to injudicious encouragement held out by the Legislature, to the ardour of speculation, to the miscalculation of farmers, or to any other cause, lands of the *sixth* degree of fertility have been cultivated; the increased quantity of produce that must thus be thrown on the market will plainly depress prices to such an extent, that, instead of yielding average profits to the cultivators of No. 6, they will not yield them to the cultivators of No. 5. But they will yield *more* to the cultivators of No. 5 than to those of No. 6; the latter, therefore, will be first driven from their business; and when they have retired, prices will rise, *not* indeed to such a height as to enable No. 6 to be cultivated, but so high as to enable the cultivators of No. 5 to continue their business; that is, as we have already shown, to the precise sum that will enable the raisers of the last portion of the produce necessary to supply the effectual demand to obtain the common and average rate of profit. Should the demand, instead of continuing stationary, increase so that it could not be supplied without cultivating Nos. 6 and 7, the price will have to rise in proportion to the increased expence of cultivating them. But to whatever extent the demand might increase, still, if such an improvement were made in agriculture, or in the art of raising corn, as would enable the supply to be obtained from No. 1 only, the price would necessarily and infallibly fall to the precise sum that paid the expences of its cultivators, and rent would entirely disappear.

Nature and Causes of Rent.

This analysis of the nature and causes of rent discovers an important and fundamental distinction between agricultural and commercial and manufacturing industry. In manufactures, the worst machinery is first set in motion, and every day its powers are improved by new inventions; and it is rendered capable of yielding a greater amount of produce with the same expence. And as no limits can be assigned to the quantity of improved machinery that may be introduced—as a million of steam-engines may be constructed for the same, or rather for a less, proportional expence than would be required for the construction of one—the competition of capitalists never fails to reduce the price of manufactured commodities to the sum which the least expensive method of production necessarily requires for their production.

Distinction between Agriculture and Manufactures and Commerce.

Tendency of Manufactured Products to fall in Price.

In agriculture, on the contrary, the best machinery, that is, the *best soils*, are first brought under cultivation, and recourse is afterwards had to inferior soils, requiring a greater expenditure of capital and labour to produce the same supplies. The improvements in the construction of farming implements, and meliorations in agricultural management, which occasionally occur in the progress of society, really reduce the price of raw produce, and, by making less capital yield the same supplies, have a tendency to reduce rent. But, the fall of price which is permanent in manufactures, is only *temporary in agriculture*. A fall in the price of raw produce, by enabling every class to obtain greater quantities than before, in exchange for their products or their labour, raises the rate of profit, and leads, of course, to an increased accumulation of capital. But the

Tendency of Agricultural Products to rise in Price.

Nature and Causes of Rent.

industry of a nation being always in proportion to the amount of its capital, this accumulation necessarily leads to a greater demand for labour, to higher wages, to an increased population, and, consequently, to a further demand for raw produce and an extended cultivation. Agricultural improvements check for a while the necessity of having recourse to inferior soils and the rise of rents; but the check can only be temporary. The stimulus which they, at the same time, give to population, and the natural tendency of mankind to increase beyond the means of subsistence, is sure, in the end, to raise prices, and by forcing recourse to poor lands, to raise rents.

Earth compared by Mr Malthus to a Series of Machines, endowed with different Productive Powers.

Mr Malthus has, in illustrating this important distinction between agricultural and manufacturing industry, set the doctrine of rent in a clear and striking point of view. "The earth," he observes, "has been sometimes compared to a vast machine, presented by nature to man for the production of food and raw materials; but to make the resemblance more just, as far as they admit of comparison, we should consider the soil as a present to man of a great number of machines, all susceptible of continued improvement by the application of capital to them, but yet of very different original qualities and powers.

"This great inequality in the powers of the machinery employed in procuring raw produce, forms one of the most remarkable features which distinguishes the machinery of the land from the machinery employed in manufactures.

"When a machine in manufactures is invented, which will produce more finished work with less labour and capital than before, if there be no patent, or as soon as the patent is over, a sufficient number of such machines may be made to supply the whole demand, and to supersede entirely the use of all the old machinery. The natural consequence is, that the price is reduced to the price of production from the best machinery, and if the price were to be depressed lower, the whole of the commodity would be withdrawn from the market.

"The machines which produce corn and raw materials, on the contrary, are the gifts of nature, not the works of man; and we find by experience that these gifts have very different qualities and powers. The most fertile lands of a country, those which, like the best machinery in manufactures, yield the greatest products with the least labour and capital, are never found sufficient to supply the effective demand of an increasing population. The price of raw produce, therefore, naturally rises till it becomes sufficiently high to pay the cost of raising it with inferior machines, and by a more expensive process; and, as there cannot be two prices for corn of the same quality, all the other machines, the working of which requires less capital compared with the produce, must yield rents in proportion to their goodness.

"Every extensive country may thus be considered as possessing a gradation of machines for the production of corn and raw materials, including in this gradation not only all the various qualities of poor

land, of which every large territory has generally an abundance, but the inferior machinery which may be said to be employed when good land is further and further forced for additional produce. As the price of raw produce continues to rise, these inferior machines are successively called into action; and, as the price of raw produce continues to fall, they are successively thrown out of action. The illustration here used serves to show at once the necessity of the actual price of corn to the actual produce, and the different effect which would attend a great reduction in the price of any particular manufacture, and a great reduction in the price of raw produce.

"I have no hesitation, then, in affirming that the reason why the real price of corn is higher and continually rising in countries which are already rich, and still advancing in prosperity and population, is to be found in the necessity of resorting constantly to poorer land—to machines which require a greater expenditure to work them—and which consequently occasion each fresh addition to the raw produce of the country to be purchased at a greater cost;—in short, it is to be found in the important truth that *corn is sold at the price necessary to yield the actual supply; and that, as the production of this supply becomes more and more difficult, the price rises in proportion.*

"I hope to be excused for having dwelt so long, and presented to the reader in various forms the doctrine that corn, in reference to the *quantity actually produced*, is sold at its necessary price like manufactures, because I consider it as a truth of the highest importance, which has been entirely overlooked by the economists, by Dr Smith, and all those writers who have represented raw produce as selling always at a monopoly price."—(*Inquiry into the Nature and Progress of Rent*, p. 37.)

It appears, therefore, that in the earliest stages of society, and when only the best lands are cultivated, no rent is ever paid. The landlords, as such, do not begin to share in the produce of the soil until it becomes necessary to cultivate lands of an inferior degree of fertility, or to apply capital to the superior lands with a diminishing return. Whenever this is the case, rent begins to be paid; and it continues to increase according as cultivation is extended over poorer soils; and diminishes according as these poorer soils are thrown out of cultivation. Rent, therefore, depends exclusively on the extension of tillage. It is high where tillage is widely extended over inferior lands; and low where it is confined to the superior descriptions only. But in no case does rent ever enter into price. For, the produce raised on the poorest lands, or with the capital last applied to the cultivation of the soil, regulates the price of all the rest; and this produce never yields any surplus above the common and average rate of profit.

It being thus established that the circumstance of land being appropriated, and rent paid to the landlords, cannot affect the price of commodities, or make any difference whatever on the principle which regulates their exchangeable value in the earliest stages of society, we proceed, in the next place, to inquire

Exchange- into the effects of the accumulation and employment  
able Value. of capital, and of the rise and fall of wages on the value of commodities.

SECT. IV.—*Effect of the Accumulation and Employment of Capital, and of Fluctuations in the Rate of Wages on Exchangeable Value.*

It will be remembered, that the comparative quantities of labour required to produce commodities and to bring them to market, formed, in the early ages of society, and before capital was accumulated, the principle by which their comparative or exchangeable value was regulated. But capital is nothing more than the accumulated produce of *anterior labour*; and when it is employed in the production of commodities, their value must plainly be regulated, not by the quantity of immediate labour only, but by the total quantity of immediate labour and of accumulated labour, or capital, which have been necessarily laid out in their production. Suppose that an individual can by a day's labour, without the assistance of any capital whatever, kill a deer; but that it requires a day's labour to construct weapons necessary to enable him to kill a beaver, and another day's labour to kill it, it is evident, supposing the weapons to have been rendered useless in killing the beaver, that one beaver really took as much labour to kill it as was required to kill two deer, and must, therefore, be worth twice as much. The durability of the weapons, or capital of the beaver hunter, is obviously an element of the greatest importance in estimating the value of the animals killed by him. Had the weapons been more durable than we have supposed,—had they served, for example, to kill twenty beavers instead of one, then it is plain the quantity of labour required to kill a beaver would only have been one twentieth more than the labour required to kill a deer, and the animals would, of course, have been exchanged in that proportion to each other. With every extension of the duration of the weapons, the value of the deer and the beaver would obviously be brought still nearer to equality.

It appears, therefore, inasmuch as capital is nothing but anterior labour, that its accumulation and employment cannot affect the principle which makes the exchangeable value of commodities dependent on the quantities of labour required for their production. A commodity may be altogether produced by capital, without the co-operation of any immediate labour whatever, and, if so, its value in exchange will plainly be regulated by the quantity of capital, that is, of *labour* expended in its production: or it may be partly produced by capital, and partly by immediate labour, and then its exchangeable value will be proportioned to the *sum of the two*, or, which is still the same thing, to the total quantity of labour bestowed upon it. The principles we have now laid down are almost self-evident, and we are not aware that they have been disputed by any political economist of consideration; but a considerable difference of opinion is entertained respecting the effects occasioned by the employment of workmen by capitalists, and by fluctuations in the rate of wages, on value.

It does not, however, seem to us that there is much room for these differences. Suppose that a certain quantity of goods, twenty pairs of stockings for example, manufactured by independent workmen, freely exchanged for forty pairs of gloves also manufactured by independent workmen, they would necessarily continue to do so, provided the quantity of labour formerly required for their production continued invariable, after the workmen had been employed by some master manufacturer. In the first case it is true, as Dr Smith has observed, that the whole goods produced by the workmen would belong to themselves, and that, in the second case, they would have to share them with others. But it must be recollected, that in the first case the capital, or accumulated labour, made use of in the production of the commodities, *belonged to the workmen*, and that in the latter case it has been *furnished them by others*. The question then comes to be, Can the circumstance of the labourers voluntarily agreeing to give a portion of the commodities produced by them, as an *equivalent*, or compensation for the advantage and assistance derived from the use of the capital, or labour of others, afford any ground for raising the value of the commodities? It is evident it cannot. The profits of stock are only another name for the *wages of accumulated labour*. They make a part of the price of every commodity in whose production any portion of capital has been wasted. But whether the capital belongs to the labourer himself, or is furnished him by another, is obviously of no consequence. When the capital does not belong to the labourer, the commodities produced by him are divided into *two* specific portions, whereof one is the return for the immediate labour, and the other for the capital, or accumulated labour, expended in producing them. But the aggregate value of the commodities is precisely the same into how many portions soever they may be divided. A shoemaker who manufactures shoes on his own account, must obtain the same rate of profit on their sale, that would accrue to a master shoemaker were he employed by him as a workman. He must not only possess a capital adequate to maintain himself and his family until his shoes can be disposed of, but he must also be able to provide himself with a workshop and tools, to advance money to the tanner to pay his leather, and to provide for various other outgoings. If he did not, exclusive of the ordinary wages of labour, realize a rate of profit, or a compensation for the employment of his capital, equal to the profit obtained by the master shoemaker, it would obviously be for his advantage to lend it to him, and to work on his own account; and it is plain, inasmuch as his shoes could not be sold for a *higher price* than those of the capitalist, that he could not realize a greater rate of profit.

It appears, therefore, that the circumstance of the accumulated labour or capital, and the immediate labour required to produce commodities being furnished by different classes of people, makes no difference whatever on the principle which shows that their exchangeable value depends on the total quantity of labour necessary for their production. It now only

Exchangeable Value. remains to trace the effects of fluctuations in the rate of wages on price. When we have done this, we shall have exhausted the subject.

Effect of Fluctuations in the Rate of Wages on Exchangeable Value:—

1st. Effect of these Fluctuations when the Capitals employed in Production are of the same degree of Durability.

To simplify this inquiry, we shall divide it into two branches. We shall inquire, *first*, whether fluctuations in the rate of wages have any, and what effects on the relative value of commodities produced by the aid of capitals of *equal* degrees of durability; and, *second*, whether these fluctuations have any, and what effects when the capitals employed are of *unequal* degrees of durability.

I. When every class of producers employ either fixed or circulating capitals, of precisely the same degree of durability, they must be all equally affected by a rise or fall of wages. This is a principle which is equally assented to by Mr Ricardo and Mr Malthus, and which is indeed self-evident. But when such is the case, it is plainly impossible that a rise or fall of wages can occasion any variation in the exchangeable, or comparative value of commodities. To revert to our former example, let us suppose that wages, at the rate of one shilling a day, were paid by the stocking manufacturer, one pair of whose stockings exchanged for two pairs of gloves, and that, from some cause or other, the wages of his workmen have been doubled, or raised to two shillings, the question is, could he now obtain a greater quantity of gloves in exchange for his stockings? It is obvious he could not. He could not urge the circumstance of his being obliged to pay a greater amount of wages to his workmen, as a reason why the glove manufacturer should give him more gloves in exchange for his stockings; for, the latter would have it in his power to reply, that *the same rise of wages affected him to precisely the same extent*. If, therefore, one pair of stockings was previously worth two pairs of gloves, they would continue to preserve this relation to each other, so long as the quantities of labour required for their production was not varied, whatever might be the fluctuation of wages—whether they fell to a sixpence, or rose to a guinea a day. Even if the price of commodities rose, which it could not, when wages rose, that would be of no advantage to the producers. Commodities are always bought by commodities, or by labour. Of what consequence, then, could it be to a capitalist, when wages rose, to sell his commodities at an equal advance; when he, in his turn, would be obliged to give so much more for every commodity which he purchased? If wages rise 50 per cent. a producer, a farmer, for example, would be precisely in the same condition, whether he sold his corn for 50 per cent. advance, and gave an additional 50 per cent. as he would be obliged to do, for his hats, shoes, clothes, &c. &c. or sold his corn at its former price, and bought all the commodities which he consumed at the prices he had formerly given for them.

In order farther to illustrate this principle, we may be allowed to make a supposition, which, although it can never actually take place, will serve to set our doctrine in a clearer point of view. Should the quantities of labour required for the production of every species of commodities be increased in exactly the same proportion, it is plain their exchange-

able values would remain unaltered. Their real price would, however, be augmented. A bushel of corn would not then exchange for a greater quantity of muslins or of broad cloth, than it did before the increased expence of its production; but each would be the produce of a greater quantity of labour. In such circumstances, the prices of commodities would remain stationary, while the wealth and comforts of the society would be materially diminished. Every person would have to make greater exertions to obtain a given quantity of any one commodity; but as the expence of producing *all* commodities is, by the supposition, equally increased, it would not be necessary to make any greater exertions to obtain one than another, and their comparative values would be totally unaffected.

But, if a general and equal increase of the quantity of labour required for the production of commodities could not alter their relative values to one another, how is that to be effected by a general and equal increase of the wages paid for that labour? The thing is obviously impossible. If a beaver exchanged for a deer, when wages were at one shilling a day, it must do the same when they are increased to two shillings, or ten shillings, or twenty shillings. However high wages might be raised, the market-price of the beaver and deer would continue unchanged. After wages had been raised, the value of the deer would be differently divided—a *greater* share would belong to the labourer, and a *less* to the capitalist; but that would be the only effect produced. The real price of the commodities would not be in the least influenced by this rise of wages. The quantity of labour required for their production would not be increased; and it would, therefore, be equally easy to obtain them.

II. We have seen by the investigation under the preceding head, that, where the fixed or circulating capitals employed in the production of commodities are of *equal* degrees of durability, fluctuations in the rate of wages affect all classes of producers to the same extent, and have, therefore, no influence on the exchangeable value of commodities, or on their price. But when the capitals employed are of *different* degrees of durability, this is not the case. Fluctuations in the rate of wages cannot, in such circumstances, equally affect every class of producers, and the natural and indestructible equilibrium of profit could not be maintained without a variation in the relative value of their products. To illustrate this, let us suppose, that a certain quantity of goods, the produce of fixed capital or machinery fitted to last many years, freely exchange for a certain quantity of other goods entirely produced by manual labour. It is plain they could not continue to be exchanged on this footing, after a rise or fall of wages. For the proprietor of the machinery would be very little affected by such fluctuations, while the proprietor of the goods produced by manual labour would be very seriously affected by them. And, therefore, when wages fluctuate, the relative values of the goods produced by capitals of different degrees of durability must also fluctuate—that is, they must be adjusted so that they may still continue to yield the same common and average rate

Exchangeable Value.

2d. Effect of these Fluctuations when the Capitals employed in Production are of different degrees of Durability.

Exchange-able Value. of profit. Let us now endeavour to trace the mode in which this adjustment is effected.

The arguments we have brought forward, to show the impossibility of fluctuations in the rate of wages, affecting the exchangeable value of commodities produced by capitals of the same durability, were first advanced by Mr Ricardo. He, too, was the first who endeavoured to analyse and discover the precise effects of fluctuations in the rate of wages on commodities, when the capitals employed in their production were *not* of the same degree of durability. The results of his researches in this most difficult branch of the science were still more important, and more completely at variance with the universally received opinions of political economists. Mr Ricardo not only showed that it was impossible for any rise of wages to raise the price of *all* commodities; but he also showed, that in many cases a rise of wages necessarily led to a *fall* of prices, and a fall of wages to a *rise* of prices! The novelty of these opinions, and the talent and ingenuity with which they were supported, immediately recommended them to general notice; and the repeated examinations to which they have been subjected have served to confirm their truth, and to set them in a still clearer point of view. Some of the subordinate doctrines respecting value advanced by Mr Ricardo in the first and second editions of his *Principles of Political Economy and Taxation*, were opposed by Mr Malthus in his recent publication. But Mr Malthus does not attempt to invalidate the leading principles established by Mr Ricardo; and the alterations and corrections which the latter has made in the third edition of his work, have gone far to remove the objections of Mr Malthus.

Suppose a manufacturer has a machine worth L. 20,000, of a high degree of durability, and which can, without the assistance of any manual labour, produce commodities. If profits were at 10 *per cent.*, the commodities produced by this machine would sell for L. 2000, together with a very small addition to replace its wear and tear.\* Now, it is quite certain, that if, from any cause whatever, profits either rise or fall, the price of the goods produced by this machine would also rise or fall.—(Malthus's *Principles of Political Economy*, p. 92.) If profits were to rise to 15 *per cent.*, the price of the goods produced by the machine must, in order that its owner may obtain the same profit with other capitalists, rise to L. 3000; and if, on the other hand, profits fall to five *per cent.*, the price of his goods must, for the same reason, fall to L. 1000. If, therefore, it can be shown that a rise of wages reduces the rate of profits, it is plain it must also reduce the exchangeable value, or price, of all such commodities as are chiefly produced by machinery, or fixed capital of a considerable degree of durability, or by circulating capital returnable at distant periods, and *vice versa*. But it is not difficult

to show that this is really the case, and that, in point of fact, profits always fall when wages rise, and rise when wages fall. Exchange-able Value.

It is plain, from what has been previously stated, that to whatever extent wages might rise, it would be impossible for the producers of any species of commodities, whether the capitals employed in their production were returnable in a day, or week, or any other period, to obtain a larger share of the commodities produced by others of the *same class*,—that is, whose capitals were returnable in *equal periods* with their own. Suppose wages rise ten or twenty *per cent.*, that would not enable the holder of a capital returnable every month, or every twelve months, to obtain any additional value in exchange for his commodities from such of his fellow capitalists as were affected to precisely the same extent with himself by the rise of wages,—that is, whose capitals were returnable in the very same period as his own. This is as absolutely impossible as it is to change the relation of proportional numbers by multiplying or dividing them all by the same number; and, therefore, it cannot be true that a rise of wages will raise the price of any one commodity, as compared with all other commodities.

But, if a rise of wages cannot do this, it is demonstrably certain it must lower profits. Let us suppose that the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability. When wages fluctuate, the proprietors of the least durable capitals, numbers 1, 2, 3, 4, and 5, are plainly more affected thereby than the proprietors of the more durable capitals, numbers 6, 7, 8, 9, and 10. Let us suppose that wages rise, and let us endeavour to discover what would be the effect of this rise on the holder of a capital of the *tenth* degree of durability. We have already shown that whatever might be the amount of the rise—whether it were 1, 10, or 100 *per cent.*, the holder of such a capital could not possibly obtain any additional quantity of the commodities belonging to other producers whose capitals were also of the *tenth* degree of durability; and in so far, therefore, as this class of commodities is concerned, profits will be reduced to the precise extent that wages have risen. But the holders of the other capitals are all of them *more* affected by the rise of wages than the holders of No. 10; and if we took either of them as a standard by which to measure profits, they would appear to have fallen in a still greater proportion.

It is absolutely certain, therefore, that *profits vary inversely as wages*,—that is, *they fall when wages rise, and rise when wages fall*. Profits vary inversely as Wages. But owing to the different and ever varying proportions in which fixed and circulating capital and immediate labour are employed in the production of commodities, it is extremely difficult to discover the precise extent to which any given fluctuation in the rate of wages af-

\* So small a sum as two shillings and elevenpence would be sufficient for this purpose, if the machine would last for 100 years; for an annuity of two shillings and elevenpence accumulating for 100 years at 10 *per cent.*, would, at the end of that period, amount to L. 20,000.

Exchange-able Value.

Method of estimating the Effects of Fluctuations in the Rate of Wages on Profits.

fects profits. We shall, however, state three different cases which will briefly, and, we hope, satisfactorily, elucidate the manner in which fluctuations in the rate of wages always operate, and the method to be followed in estimating their influence on profits.

1. If all commodities were produced by immediate labour, or by capital employed in the payment of wages, it is obvious that every rise of wages would cause an equal fall of profits. A capitalist who employed L. 1000 in the payment of wages, must, if profits were at 10 per cent., sell the commodities for L. 1100. But when wages rise 5 per cent., or to L. 1050, he would not be able to sell his commodities for more than L. 1100; for money is itself a commodity, and as, by the supposition, all commodities are produced by immediate labour, the rise of wages would affect the producers of money in the very same degree that it affected all other producers. In this case, therefore, it is plain every rise of wages will equally sink profits, and every fall of wages will equally raise them.

2. If all commodities were produced, one-half by immediate labour, and the other half by capital, profits would only fall to half the extent that wages rose. Suppose a capitalist employs L. 500 in the payment of wages, and L. 500 as a fixed capital, when profits are at 10 per cent., the commodities produced must, as before, sell for L. 1100. If wages rose 5 per cent., the capitalist would have to pay L. 525 as wages, and would, consequently, only retain L. 75 as profits. In this case, therefore, a rise of wages to the extent of 5 per cent. would, because of the employment of equal quantities of capital and immediate labour in the production of commodities, only sink profits  $2\frac{1}{2}$  per cent.

3. If all commodities were produced by capital of a high degree of durability, the capitalists, it is obvious, would not be at all affected by a rise of wages, and profits would, of course, continue as before.

Now, suppose that commodities, instead of being wholly produced either by immediate labour, as in the first case, or wholly by equal quantities of immediate labour and of capital, as in the second, or wholly by fixed capital as in the third, are partly produced in the one mode and partly in the other, and let us see what effect this increase of 5 per cent. in the rate of wages would have on their relative values. To facilitate this inquiry, we shall distinguish these three descriptions of commodities by the Nos. 1, 2, and 3. Now, it is quite evident that the rise of wages has affected No. 1  $2\frac{1}{2}$  per cent. more than it has affected No. 2, and 5 per cent. more than it has affected No. 3. No. 1 must, therefore, as compared with No. 2, have risen  $2\frac{1}{2}$  per cent. in exchangeable value, and as compared with No. 3, it must have risen 5 per cent.; No. 2 must have fallen  $2\frac{1}{2}$  per cent. as compared with No. 1, and risen  $2\frac{1}{2}$  per cent. as compared with No. 3; and No. 3 must have fallen 5 per cent. as compared with No. 1, and  $2\frac{1}{2}$  per cent. as compared with No. 2. If wages, instead of rising, had fallen, the same

effects would obviously have been produced, but in a reversed order. The proprietors of the commodities of the class No. 1 would gain 5 per cent. by the fall; those of No. 2 would gain  $2\frac{1}{2}$  per cent., and those of No. 3 nothing; and the relative values of these commodities would be adjusted accordingly.\*

Thus, then, it appears, inasmuch as any commodity taken for a standard by which to estimate the relative values of other commodities, must itself be produced by capital returnable in a certain period, that when wages rise, all commodities produced by less durable capitals than those which produce the commodity taken for a standard, will rise in exchangeable value, and all those produced by more durable capitals will fall; and conversely when wages are reduced. Suppose, as before, that the Nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability. If a commodity produced by the least durable capital, No. 1, and which may be supposed to be wholly employed in the payment of wages, be taken for a standard, all commodities whatever produced by the other and more durable capitals would fall in value when wages rose; and if we suppose those produced by No. 2 to decline 1 per cent., those produced by No. 3 would decline 2 per cent., those produced by No. 4 3 per cent., and so on until we arrive at No. 10, which will have fallen 9 per cent. If, on the other hand, a commodity produced by the most durable capital, No. 10, and which may be supposed to consist wholly of highly durable machinery, be made the standard, when wages rise all the commodities produced by the other less durable capitals would also rise; and if those produced by No. 9 rose 1 per cent., those produced by No. 8 would rise 2 per cent., and those produced by No. 1 9 per cent. If a commodity produced by capital of a medium degree of durability, as No. 5, and which may be supposed to consist half of circulating capital employed in the payment of wages, and half of fixed capital or machinery, be taken as a standard, the commodities produced by the less durable capitals, Nos. 4, 3, 2, and 1, will rise with a rise of wages, on the former hypothesis, the first, or No. 4, 1 per cent., the second, or No. 3, 2 per cent., &c.; while those produced by the more durable capitals, Nos. 6, 7, 8, 9, and 10, will fall, the first, or No. 6, 1 per cent., the second, or No. 7, 2 per cent., &c. exactly the reverse of the other.

Hence it is obvious that the effect which variations in the rate of wages have on price will principally depend on the nature of the capital employed in the production of gold and silver. Whatever may be the proportions of circulating capital appropriated to the payment of wages, and of fixed capital employed in the production of the material of which money is made, all those commodities which are produced by the agency of a greater quantity of labour and with less fixed capital or machinery, will rise when wages rise, and fall when wages fall; but those that are produced by the agency of a less quantity of la-

\* The examples we have here given are substantially the same with those given by Mr Mill. See his valuable work entitled *Elements of Political Economy*, p. 77.

Exchange-able Value.

Exchange-able Value.

Variations of Exchangeable Value caused by Fluctuations in the Rate of Wages confined within narrow limits.

bour, and with more fixed capital or machinery, will fall when wages rise, and rise when wages fall; and those that are produced in nearly the same circumstances, or by the agency of the same quantities of circulating and fixed capital as money, will not be affected by the fluctuations of wages.

It should, however, be observed that the variations in the exchangeable value of commodities caused by variations in the rate of wages, are confined within very narrow limits, and can hardly, in any circumstances, exceed 6 or 7 per cent.\* There can be no rise of wages without a fall of profits. The produce of the land, or rather of the capital which pays no rent, and which governs the price of all the rest, is divided between the farmer and the labourer, and the more that is given to the latter, the less will plainly remain for the former. The same is the case in every other department of industry. Whenever, therefore, wages rise, profits necessarily and unavoidably fall; and this fall not only checks the rise that would otherwise take place in the price of the goods produced by less durable capitals than the medium in which price is estimated; but it also checks the fall that would take place in the price of the goods produced by more durable capitals. To exemplify this, let us suppose a manufacturer employs a capital of L. 10,000, one-half being employed as machinery, and the other half as a circulating capital appropriated to the payment of wages. If profits are at 10 per cent., the goods produced by the manufacturer must sell for L. 11,000. Now, suppose wages to rise one per cent., if the price of the goods were proportionably increased, they would have to sell for L. 11,050. But they would not be proportionably increased; for every rise of wages must lower profits. Suppose, then, that profits are reduced  $\frac{1}{2}$  per cent., the goods will still sell for L. 11,000, the increase of L. 50 caused by the rise of wages, being just equivalent to the fall of L. 50 caused by the reduction of profits. Although, therefore, a rise of wages has a necessary tendency to raise the exchangeable value of one class of commodities, and to lower that of another class, the fall of profits, which must inevitably follow every rise of wages, has a different effect, and tends to sink the price of the commodities which the increase in the rate of wages would raise, and to elevate the price of those which the same increase would sink. In the great majority of cases, these opposite effects mutually balance each other; and prices continue nearly the same, after a fall or rise of wages, as before.

"This is not the case with the other great cause of variations in the value of commodities, namely, the increase or diminution in the quantity of labour necessary to produce them. An alteration in the permanent rate of profits, to any great amount, is the effect of causes which do not operate but in the course of years; whereas alterations in the quantity of labour necessary to produce commodities are of daily occurrence. Every improvement in machinery,

in tools, in building, in raising the raw material, saves labour, and enables us to produce the commodity to which the improvement is applied with more facility, and, consequently, its value alters. In estimating, then, the causes of the variation in the value of commodities, although it would be wrong wholly to omit the consideration of the effect produced by a rise or fall of labour, it would be equally incorrect to attach much importance to it; and, consequently, in the subsequent part of this work, though I shall occasionally refer to this cause of variation, I shall consider all the great variations which take place in the relative value of commodities to be produced by the greater or less quantity of labour which may be required to produce them." (Ricardo, *Principles*, &c. p. 33.)

The universally received opinions respecting the effect of a rise of wages on the price of commodities have obviously originated from a rise in the money price of commodities being almost always confounded with a rise in their real price. But these two things are totally distinct. *Real wages*, as we shall afterwards show, depend on the proportion of the produce of industry which belongs to the labourer. They are high when this proportion is large, and they are low when it is small. It is to real wages that we always refer. And it is plain, that every inference respecting the rate of real wages, drawn from fluctuations in the rate of money wages at different periods, must be completely erroneous, if we have not estimated such money wages with reference to the relative values of money and commodities at the time when the fluctuations took place. The money wages of labour may be raised from 1s. to 2s. or 5s. a-day; and the real wages of labour may, notwithstanding, be all the while diminishing. This has been actually the case in Britain during the last thirty-five years. Money wages were in 1810 double what they had been in 1790; but, as the exchangeable value of our currency had, in the interval, been more than proportionably reduced, the price of commodities rose still faster than wages; and the proportion of the produce of industry belonging to the labourers, or their real wages, was consequently diminished. In such a case, to ascribe the rise of prices to the rise of wages would be evidently absurd. In no case, however, will it be found that a rise of real wages will raise the price of all commodities. A large class will remain stationary, after wages rise; another class will rise a little; and another class will fall a little. All considerable variations in the relative value of commodities are the consequence of variations in the quantity of labour required for their production, and not of variations in the rate at which that labour is paid.

Colonel Torrens contends, in his late valuable work on the *Production of Wealth*, in opposition to the theory we have now endeavoured to establish, that after capital has been accumulated, the relative, or exchangeable value of commodities, is no longer, as in the early stages of society, determined by the total quantities of labour required to bring them to

Variations in the Rate of Money Wages cause of the Popular Opinion.

Exchangeable Value of Commodities does not depend on the Quantity of Capital employed in their Production.

\* Ricardo *On the Principles of Political Economy and Taxation*, 3d edit. p. 33.

Exchange-  
able Value.

market, but by the quantities of capital expended on their production. At bottom, however, this theory is precisely the same with that which we have just explained. Capital is nothing but immediate labour accumulated; and to say that the exchangeable value of commodities depends on the quantity of it employed in their production, is only another way of expressing the identical proposition we have illustrated. Colonel Torrens, however, and those who agree with him, contend that the difference between the two theories is not apparent but real. "If," say they, "two capitalists employ equal stocks, the one in paying the wages of masons employed to build a house, and the other in purchasing wine after it has been put into casks, and keeping it until it has become fit for use, then, as the products of equal capitals must always be equal, the house and the wine will be worth precisely the same sum, though it is plain they are produced by very different quantities of labour." This case is very ingeniously put; and it deserves attention from the opportunity which it affords of explaining a point respecting which there has been a great deal of misconception. At first sight, it certainly seems as if both accumulated labour and immediate labour had been employed in the construction of the house, and accumulated labour only in the production of the wine. But, in point of fact, all that is done in either case is, to *change the form of equal capitals*; to transmute, if we may so speak, a certain quantity of capital, through the medium of human hands, into a house; and to transmute the same quantity of stock, through the medium of natural powers, into wine fit for drinking. The capital which is consumed by the mason in food and clothes is plainly not expended on the house, but on *himself*; and it is his immediate labour only, or the exertion of his physical powers, that forms the only labour really expended on the house. The employer of the mason paid him his wages, *not*, as Colonel Torrens supposes, in the unreasonable expectation, that he would lay out these wages, in addition to the labour of his hands, on his house, but that he might lay out the wages on himself, and give him his labour as an *equivalent* for them. The object which the builder of the house had really in view was, to convert a certain amount of capital into a house, and to accomplish this object, it was necessary that the capital should, in the first place, be exchanged for, or converted into, the immediate labour of masons. In the production of the wine, this species of transmutation was not necessary; the effect which had, in the first case, been produced by the agency of men, being, in the second case, produced by the agency

of the processes which Nature herself carried on in the casks. It is clear, therefore, that no greater quantity of labour was required to produce the house than to produce the wine. Different *agents* were employed to convert the capital into the finished commodities, but that was all. The quantity of capital which set these agents in motion was, in both cases, exactly the *same*, and, consequently, both products were brought into existence by the same quantity of labour.

Exchange-  
able Value.

The error into which Colonel Torrens has fallen, shows the necessity, in estimating the cost of commodities, of always separating between the capital, or accumulated labour, expended in the payment of wages, and the immediate labour which that capital employs. The *sum* of these two really amounts to *twice* the quantity of labour actually expended on the commodities. The capital given as wages to the labourer is merely the price, or equivalent of his labour; and the cost of producing the commodity must, therefore, be determined by the amount of wages, or of immediate labour given for these wages, taken *singly* and not together. When fixed capital is used, the cost of the commodity depends, as we have already shown, on the quantity of immediate labour, or circulating capital, and of fixed capital, necessarily expended on their production.

No one can fail to observe how naturally and beautifully these conclusions harmonise with the principles we endeavoured to establish when treating of the production of wealth. We there showed that no commodity which it did not require some portion of labour to appropriate or produce, could be possessed of exchangeable value, or become wealth; and that every diminution of the quantity of labour required to produce commodities, lowered their exchangeable value, and made them more easily obtainable by all classes: And the analysis we have now completed shows, that labour is not only essential to the existence of exchangeable value, but that it is in every stage of society, from the rudest to the most improved, *the single and only principle which enters into its composition.*\*

SECT. V.—*Profits and Wages vary inversely—Accumulation of Capital not the Cause of a Fall of Profits—The Increasing Sterility of the Soil shown to be the Chief Cause of a Rise of Wages, and consequently of a Fall of Profits—Distinction between Absolute and Proportional Wages.*

Having shown in the previous sections, that no *Profits and Wages* part of the produce of the capital last applied to the *Wages* cultivation of the land, and which regulates the price

\* Sir William Petty had stated, so early as 1667, that the value of commodities is always regulated by the quantity of labour required to produce them; but there is the same difference between his statements and the analysis and investigations of Mr Ricardo, whom we have followed in this section, that there is between the conjectures of Pythagoras respecting the true system of the world and the demonstrations of Newton. The statement of Sir William Petty is however curious, and we subjoin it:

"If," says he, "a man can bring to London an ounce of silver out of the earth in Peru in the same time that he can produce a bushel of corn, then one is the natural price of the other; now, if, by reason of new and more easie mines, a man can get two ounces of silver as easily as formerly he did one, then corn will be as cheap at 10s. the bushel as it was before at 5s. *ceteris paribus.*" (*Treatise of Taxes and Contributions*, ed. 1679, p. 31.)

Profits and Wages.

of all the rest, goes to the landlord as rent, but that it is exclusively divided between the capitalist and the labourer; and having also shown that a rise of wages does not raise the value of commodities, it follows necessarily and directly that *profits must vary inversely as wages, that is, they must fall as wages rise, and rise as wages fall.* The limits to which this article has already extended, prevent our entering into an investigation of the various circumstances which determine the market rate of wages. It is sufficient to remark, that it can never, for any considerable period, fall below such a sum as is required to support the existing labourers, and to enable them to continue their race. This is termed by Dr Smith and Mr Ricardo the *necessary* rate of wages, and forms a limit below which it is quite impossible they can be permanently reduced. But as the subsistence of the labourer must always principally consist of raw produce; and as, owing to the necessity of resorting to superior soils as society advances, its price has a constant tendency to rise, the *necessary* rate of wages must have the same tendency. Agreeably to this theory, therefore, we should expect, that in all newly settled countries, and where none but the best soils are cultivated, profits would be high; and that in all old settled and densely peopled countries, and where soils of a very inferior quality are cultivated, profits would be comparatively low—and such we find to be really the case.

We might here take leave of this part of our subject; but as the theory we have deduced from the conclusions in our previous sections is very different from the common one, we shall endeavour to set it in a still clearer point of view.

Dr Smith was of opinion, that the rate of profit varied inversely as the amount of capital, or, in other words, that it was always greatest where capital was least abundant, and lowest where capital was most abundant. He supposed, that, according as capital increased, the principle of competition would stimulate capitalists to endeavour to encroach on the employments of each other; and that, in furtherance of their object they would be tempted to offer their goods at a lower price, and to give higher wages to their workmen. (*Wealth of Nations*, Vol. II. p. 38.) This theory was long universally assented to. It has been espoused by MM. Say, Sismondi, and Storch, by the Marquis Garnier, and, with some slight modifications, by Mr Malthus. But, notwithstanding the deference due to these authorities, it is easy to see that the principle of competition could never be productive of a general fall in the rate of profit. Competition will prevent any one individual from obtaining a higher rate of profit than his neighbours; but no one will say that competition diminishes the *productiveness of industry*, and it is on this that the rate of profit must always depend. The fall of profits which invariably takes place, as society advances, and population becomes denser, is not owing to competition, but to a very different cause—TO A DIMINUTION OF THE POWER TO EMPLOY CAPITAL WITH ADVANTAGE, *resulting either from a decrease in the fertility of the soil, which*

*must be taken into cultivation in the progress of society, or from an increase of taxation.*

Mr Malthus has demonstrated, that population has a constant tendency not only to equal, but to exceed the means of subsistence. But if the supply of labourers be always increased in proportion to every increase in the demand for their labour, it is plain the mere accumulation of capital could never sink profits by raising wages—that is, by *increasing the labourer's share of the commodities produced by him.* It is true, a sudden increase of capital would, by causing an *unusually* great demand for labourers, raise wages, and lower profits: but such a rise of wages could not be permanent; for the additional stimulus it would give to the principle of population would, as Mr Malthus has shown, by proportioning the supply of labour to the increased demand, infallibly reduce wages to their former level. If, therefore, it were possible always to employ additional capital in the raising of raw produce, in the manufacturing of that raw produce when raised, and in the conveying of the raw and manufactured products from place to place, with an equal return, it is evident, supposing taxation to continue invariable, that no conceivable increase of the national capital could occasion the slightest fall in the rate of profit. So long as labour is obtainable at the same rate, and so long as the productive power of that labour is not diminished, so long *must* the profits of stock continue unaffected. Assuming, then, that the mere increase of capital has no lasting effect on wages, it must obviously be the same thing, in so far as the rate of profit is concerned, whether ten or ten thousand millions be employed in the cultivation of the soil, in the manufactures and commerce of this, or any other kingdom; provided the last million so employed be as productive, or yields as large a return as the first. But such is always the case with the capital employed in manufactures and commerce. The greatest possible amount of capital and labour may be employed in fitting and adapting raw produce to our use, and in transporting it from where it is produced to where it is to be consumed, without a diminished return. If a given quantity of labour will now build a ship of a given burden, or construct a machine of a given power, it is certain that an equal quantity of labour will at any future period be able to build a similar ship, or to construct a similar machine; and it is also certain, that although these ships and machines were indefinitely increased, the last would be equally well adapted for every useful purpose, and equally serviceable as the first. The probability, indeed, or rather, we should say, the certainty is, that the last would be much more serviceable than the first. No possible limit can be assigned to the powers and resources of genius, to the improvement of machinery, and of the skill and industry of the labourer. Future Watts, Arkwrights, and Wedgewoods, will arise; and the stupendous discoveries of the last and present age will doubtless be equalled, and perhaps surpassed, in those which are to come. It is, therefore, clear to demonstration, that if equal quantities of capital and labour could always raise *equal quantities of raw produce*, the utmost additions to the capital

Profits and Wages.

The Decreasing Fertility of the Soil Principal Cause of a Fall of Profits.

Opinion of Dr Smith, &c.

error of this opinion.

Profits and  
Wages.

of the nation could never diminish the capacity to employ that capital with advantage, or sink the rate of profit. But here, and here only, the bounty of Nature is limited, and she deals out her gifts with a frugal and parsimonious hand.

———— Pater ipse colendi  
Haud facilem esse viam voluit ————

Equal quantities of capital and labour do not always obtain equal quantities of raw produce. In raising it, man has to contend with constantly increasing difficulties. The soil is of limited extent, and of still more limited fertility. In every advancing country, the most fertile lands are, as we have already seen, speedily brought under cultivation, and recourse must then be had to lands of a less degree of fertility, or which yield *less* produce in return for the same expenditure. It is this limited fertility of the soil that is the real cause of a fall of profits. It is utterly impossible to go on increasing the price of that raw produce, which forms the principal part of the subsistence of the labourer, by taking inferior soils into cultivation, without also increasing his wages. A rise of wages is seldom or never exactly coincident with a rise in the price of necessaries, but they can never be very far separated. The price of the necessaries of life is, in fact, the cost of producing labour. The labourer cannot work if he is not supplied with the means of subsistence. And although a certain period of varying extent, according to the circumstances of the country at the time, must always elapse, when necessaries are rising in price, before wages can be proportionably augmented, there can be no question but that, in the end, such an augmentation will be brought about. Now, as rent is nothing but the excess, or the value of the excess, of the produce obtained from the best above that obtained from the very worst soils in cultivation, it is plain it does not enter into the cost of production, and can have no influence whatever on prices. Still better to elucidate this fundamental principle, let us suppose that an individual has two loaves on his table; one raised on very fertile land, the other on the very worst land in cultivation: in the latter, there will be no rent, and it will be wholly divided between wages and profits. We have already shown that it is the cost of producing this loaf which will regulate the price of all other loaves; and although it will be true that the rent which the loaf raised on the best land will afford will be equal to all the difference between the expence of growing the corn of which it is made, and the corn raised on the worst lands of which the standard loaf is made, yet it is only in consequence of this difference that any rent whatever is paid. Twenty different loaves, all selling for the same price, may yield different portions of rent; but it is one only, that which yields no rent, which regulates the value of the rest, and which is to be considered as the standard. It is demonstrable, therefore, that rent does not enter into price. Wages and profits make up the whole value of every commodity. And, therefore, when wages rise, profits must fall; and when wages fall, profits must rise. But we have shown that there is never any falling off, but a constant increase, in the

productiveness of the labour employed in manufacturing and preparing raw produce. And such being the case, it is demonstrably certain, that the subsistence of the labourer could never be increased in price, and consequently that no additions could ever be made to his *necessary* wages, were it not for the diminished power of agricultural labour, originating in the inevitable necessity under which we are placed, of *resorting to poorer soils to obtain raw produce as society advances*. The *constantly decreasing fertility of the soil* is, therefore, at bottom, the great and permanent cause of a fall of profits. Profits would never fall if wages were not increased; and, supposing taxation to continue invariable, wages would never be increased were it not for the decreasing fertility of the soil, and the consequent increase of the labour necessary to obtain corn and other raw products.

“With a permanently high price of corn,” says Mr Ricardo, “caused by increased labour on the land, wages would be high; and, as commodities would not rise on account of the rise of wages, profits would necessarily fall. If goods worth L. 1000 require at one time labour which cost L. 800, and at another time the price of the same quantity of labour is raised to L. 900, profits will fall from L. 200 to L. 100. Profits would not fall in one trade only, but in all. High wages equally affect the profits of the farmer, the manufacturer, and the merchant. There is no other way of keeping profits up but by keeping wages down.”—(*On Protection to Agriculture*, p. 43.)

It is necessary, however, to observe, that although profits depend on wages, they do not depend on wages estimated in money, in corn, or any other commodity, but on *PROPORTIONAL wages, that is, on the share of the commodities produced by the labourer, or of their value, which is given to him*. It is, indeed, easy to see that proportional wages may be increased, at the same time that wages, if estimated in corn, or any other necessary, would be found to be diminished; and, in point of fact, such is almost uniformly found to be the case when recourse is had to poor soils. Suppose that the produce obtained from a given amount of capital applied to the land last taken into cultivation in America yields 100 quarters, the labourer will perhaps receive 60 quarters, or 60 *per cent.* of the produce as his wages. But the same amount of capital, if applied to the land last taken into cultivation in Britain, would not yield more than 50 quarters; and supposing the labourer to get only 40 quarters, or 20 quarters less than in America, still his *proportional* wages, or the wages which determine the rate of profit, would be 80 *per cent.* or 20 *per cent.* higher than in America. In the early stages of society, and wherever the best lands only are cultivated, proportional wages are always low, and profits high; but these low proportional wages are always the most advantageous to the labourer, because, as labour is, in such circumstances, extremely productive, a small per-centage of its total amount gives a large supply of necessaries and conveniencies. In the advanced stages of society, on the other hand, and wherever lands of a very inferior degree of fertility are cultivated, proportional wages are high and profits low; but owing to the increased difficulty of pro-

Profits and  
Wages.

Profits de-  
pend on  
Proportion  
Wages.

**Profits and Wages.** duction, these high proportional wages afford only a comparatively small supply of necessaries and conveniences.

It is therefore on *proportional* wages that profits must always depend; and owing to the increasing difficulty of producing corn and other products, such proportional wages always increase as society advances. This natural tendency of profits to fall is occasionally checked by improvements in machinery, and by discoveries in agriculture; but the effects of these improvements are only temporary; for, by stimulating population, they never fail, in the long run, to force recourse to poor soils; and whenever this is the case, *profits must unavoidably fall*.

It has been contended, that both wages and profits are high in America, and that, therefore, the theory which we now have been endeavouring to explain, and which makes profits in every case to depend on wages, must be erroneous. But the remarks we have just made show that this objection is totally unfounded. It is by proportional quantities, and not by absolute quantities, that we are to estimate the effect of wages on profits. The American labourer receives a less proportion of the produce raised by him than the British labourer, and profits are consequently high in America; but as the American labourer cultivates none but the best soils, and which yield a very large produce, his smaller share of this large aggregate produce gives him a great absolute quantity of necessaries and conveniences, and his condition is, therefore, comparatively prosperous.

We have, throughout this discussion, been supposing taxation to be invariable. It is plain, however, that as soon as it is increased, it must have one or other of two effects—it must either lower the labourer's command over necessaries and luxuries, and degrade his condition, or it must fall on profits. There are limits, however, and those not very difficult to be attained, to the power of the labourers to pay taxes; and whenever these limits have been reached, they must entirely fall on profits. It has, therefore, been most justly and truly observed by Dr Smith, that a heavy taxation has exactly the same effects as an increased barrenness of the soil, and an increased inclemency of the heavens.

The great wealth and commercial prosperity of Holland has been confidently appealed to by Sir Josiah Child, and others, as a convincing proof of the superior advantages of low profits and interest; and seems also to have led Dr Smith to suppose that the mere accumulation of capital could sink the rate of profit. But in this instance, there can be no doubt that Sir Josiah Child mistook the effect of heavy taxation for the cause of wealth, and that Dr Smith mistook the same effect for the effect of the accumulation of capital. A country, whose average rate of profit is considerably less than the

average rate of profit in surrounding countries, may, notwithstanding, abound in wealth, and be possessed of immense capital; but it is the height of error to suppose, that this lowness of profit could have facilitated their accumulation. There is unquestionable evidence to show that the capital of Holland had been chiefly amassed when profits were comparatively high; and that the subsequent fall of profits was almost entirely a consequence of the oppressiveness of taxation, and the continued increase of the public debt. In 1580, the interest of the public debt of the province of Holland amounted to 117,000 florins, but so rapidly did it increase, that in 1655, during the administration of the famous John de Witt, the states were compelled to reduce the interest of the debt from 5 to 4 *per cent.*; and yet, notwithstanding this reduction, it amounted, in 1678, to 7,107,128 florins! (Metelercamp, *Statistique de la Hollande*, p. 203.) It was this enormous increase of the public debt, and the proportionable increase of taxation which it occasioned, and not the accumulation of capital, that was the real and sole cause of the fall of profits in Holland, and ultimately of her decline and ruin. Sir William Temple, in his *Observations on the United Provinces*, mentions that the trade of Holland was on the decline in 1668, the period when Sir Josiah Child's *Treatise* was first published; and he farther states, that the vast capitals of the Dutch merchants had been chiefly accumulated previously to the war in which the Republic had been engaged with Cromwell and Charles II., and when, of course, taxation was much lighter, and the rate of profits much higher than at any subsequent period.\*

High *proportional* wages and low profits, for they are inseparably connected, ought never to be made the subject of complaint, if they occur in the natural progress of society, under a parsimonious government, and a system of perfectly free intercourse with other countries. But if they are the result of heavy taxation caused by profuse expenditure, or by restrictions which prevent the importation of cheap foreign corn, and which, therefore, force the cultivation of inferior soils at home, they cannot be too strongly condemned. A nation placed in such circumstances must not only advance slowly, when compared with other nations which are enabled to raise their supplies of raw produce from superior soils—the power to accumulate capital must not only be diminished, but a strong temptation must be held out to transfer it to other countries. The love of country—the thousand ties of society and friendship—the ignorance of foreign languages, and the desire to have one's stock employed under their own inspection, will, no doubt, in very many instances, induce capitalists to rest contented with a *less* rate of profit in their own, than they might realise by investing their funds in other countries. But this love of

**Profits and Wages.**

Low Profits cause the Transfer of Capital to other Countries.

An Increase of Taxation reduces Profits.

Errors of Sir J. Child and Dr Smith with respect to the Low Rate of Profit in Holland.

\* For an account of the effect of heavy taxes on the industry of Holland, see the second volume of the *Traité de la Richesse de la Hollande*, pp. 39 and 179; and a memoir *On the Means of Redressing and Amending the Trade of the Republic*, drawn up from information communicated by the best informed merchants, and published by order of the Stadtholder, William IV. Prince of Orange, in 1751. This memoir was translated into English, and published in London in the same year.

Consumption of Wealth.

country has its limits. The *love of gain*—the *auri sacra fames*—is a no less powerful and constantly operating principle; and if capitalists are once assured that their stock can be laid out with equal security, and with considerably greater advantage, in foreign states, an efflux of capital to a greater or less extent will unquestionably take place.

A manufacturing and commercial country, which has wisely adopted a liberal commercial system, has no reason to be alarmed at the effects of competition in any department of industry. The production of one commodity opens a market for the exchange, that is, for the *sale* of some other commodity. What a manufacturing and commercial nation has really to fear is, that its *average rate of profit* should fall lower than the average rate of profit in the neighbouring countries. If this should be the case, its progress will, in consequence, be retarded; and it will ultimately languish and decline. Neither the skill, industry, and perseverance of artizans, nor the most improved and powerful machinery, can permanently withstand the paralyzing and deadening influence of a comparatively low rate of profit. And such a comparative reduction, it must never be forgotten, will be constantly produced by a *comparatively heavy taxation*, and by acting on a *factitious and exclusive commercial system*; for, by preventing the importation of cheap foreign corn, we necessarily *force the cultivation of poor soils, and thus by raising proportional wages, sink profits*.

#### PART IV.—CONSUMPTION OF WEALTH.

Having in the previous sections endeavoured to explain the means by which labour is facilitated, and wealth produced, and to investigate the laws regulating its distribution among the various classes of the society, we come now to the *third* and last division of the science of Political Economy, or to that which treats of the CONSUMPTION OF WEALTH.

*Definition of Consumption—Consumption the end of Production—Test of Advantageous and Disadvantageous Consumption—Error of Dr Smith's Opinions with respect to Unproductive Consumption—Error of those who contend, that to facilitate Production it is necessary to encourage Consumption—Cause of Gluts—Consumption of Government—Conclusion.*

Definition of Consumption.

We formerly showed, that, by the production of a commodity was not meant the production of matter, for that is exclusively the prerogative of Omnipotence, but the giving to matter already in existence such a shape as might fit it for ministering to our wants and enjoyments. In like manner, by consumption is not meant the consumption, or annihilation of matter, for that is equally impossible as its creation, but merely the *consumption or annihilation of those qualities which render commodities useful and desirable*. To consume the products of art or industry is, therefore, really to deprive the matter of which they consist of the utility, and consequently of the exchangeable value communicated to it by labour. And hence we are not to measure consumption by the magnitude, the weight, or the number of the products consumed, but exclusively *by their value*.

Large consumption is the destruction of large value, however small the bulk in which that value may happen to be compressed.

Consumption of Wealth.

Consumption, in the sense in which the word is used by Political Economists, is synonymous with *use*. We produce commodities only that we may be able to use or consume them. Consumption is the great end and object of all human industry. Production is merely a means to attain an end. No one would produce were it not that he might afterwards consume. All the products of art and industry are destined to be consumed, or made use of; and when a commodity is brought into a state fit to be used, if its consumption be deferred, a loss is incurred. All products are intended either to satisfy the immediate wants, or to add to the enjoyments of their producers; or they are intended to be employed as capital, and made to reproduce a greater value than themselves. In the *first* case, by delaying to use them, it is plain we either refuse to satisfy a want, or deny ourselves a gratification it is in our power to obtain;—and in the *second*, by delaying to use them, it is equally plain we allow the instruments of production to lie idle, and lose the profit that might be derived from their employment.

Consumption the end of Production.

But, although all commodities are produced only to be consumed, we must not fall into the error of supposing, that all consumption is equally advantageous to the individual, or the society. If an individual employs a set of labourers to build him a house the one summer, and to pull it down the next, their labour, or rather the capital he gave them in exchange for their labour, and which they have consumed during the time they were engaged in this futile employment, is evidently destroyed for ever, and absolutely lost both to himself and the public; whereas, had he employed them in the raising of corn, or in the production of any species of valuable produce, he would have obtained commodities of equal, or more than equal, value to the capital he gave them. *The value of the return, or the advantage obtained from the consumption*, is, therefore, the true and only test of advantageous and disadvantageous, or, as it is more commonly termed, of productive and unproductive consumption. Commodities are consumed *productively* when the advantage or benefit accruing in consequence to their possessors, or when the value of the products obtained in their stead *exceeds* their value; and they are consumed *unproductively* when the value of the advantage or benefit, or the value of the new commodities, is *less* than their value. It is on this balance of consumption and reproduction, and not, as was so long supposed, on the balance of trade, that the prosperity or decay of every nation depends. If, in given periods, the commodities produced in a country exceed those consumed in it, the means of increasing its capital will be provided, and its population will either increase, or the actual numbers will be better accommodated, or both. If the consumption in such periods fully equals the reproduction, no means will be afforded of increasing the stock or capital of the nation, and society will be at a stand. And if the consumption exceeds the reproduction, every succeeding period will see the society worse supplied; its prosperity and population will evident-

Test of advantageous Consumption.

Consumption of Wealth.

Consumption of Wealth.

ly decline, and pauperism will gradually and progressively spread itself over the whole country.

It is impossible, however, to fix on any standard by a comparison with which we may be able to obtain even a tolerable approximation to the comparative value or advantage of different kinds of consumption. This is a point on which the sentiments of no two individuals can ever exactly coincide. The opinions of each will always depend more or less on the situation in which he is placed. The rich man will naturally be inclined to give a greater extension to the limits of advantageous consumption than the man of middling fortune; and the latter than the man who is poor. And it is undoubtedly true that a man's expences ought always to bear some proportion to the magnitude of his fortune, and his condition in society; and that what might be proper and advantageous expenditure in one case, might be exceedingly improper and disadvantageous in another. It is, therefore, quite impossible to frame any system of rules on the subject of expenditure, which shall be applicable to the case of every individual; and even if it were practicable, there is no ground to think that the formation of such rules would be of the smallest utility. The state has no right whatever to control individual expenditure; nor, even if it had such a right, could it exercise it without occasioning serious injury. The public interest requires that the national capital should, if possible, be constantly kept on the increase; or, which is the same thing, that the consumption of any given period should be made the means of reproducing a greater value. But we have sufficiently proved that this cannot, in any case, or under any circumstances, be the result of a system of *surveillance* and restriction. Industry and frugality never have been, and never can be, promoted by such means. To render a man industrious, secure him the peaceable enjoyment of the fruits of his industry;—to wean him from extravagance, and to render him frugal and parsimonious, allow him to reap all the disadvantage of the one line of conduct, and all the advantage of the other. The poverty and loss of station which is the necessary and inevitable result of improvident and prodigal consumption, is a sufficient security against its ever becoming injuriously prevalent; and wherever the public burdens are moderate, property protected, and the perfect and uncontrolled freedom of industry secured, the constant efforts of the great body of the people to rise in the world and improve their condition, will ensure the continued increase of national wealth. It is idle to expect that all unproductive and unprofitable expenditure can ever be avoided; but the experience of all tolerably well governed states proves, that the amount of the produce of industry productively expended, is always infinitely greater than that which is expended unproductively.

It was long a prevalent opinion among moralists, that the labour bestowed on the production of luxuries, and consequently their consumption, was unproductive. But this opinion is now almost universally abandoned. Unless, indeed, all comforts and enjoyments are to be proscribed, it is impossible to say where necessities end, and luxuries begin. But

VOL. VI. PART I.

if we are to understand by necessities such products only as are absolutely required for the support of human life, every thing but wild fruits, roots, and water, must be deemed superfluous; and in this view of the matter, the peasantry of Ireland, who live only on potatoes and butter-milk, must be considered as contributing much more to the national wealth than the peasantry of Britain! The mere statement of such a doctrine is sufficient for its refutation. Every thing that stimulates exertion is advantageous. The mere necessities of life may be obtained with comparatively little labour; and those savage and uncivilized hordes, who have no desire to possess its comforts, are proverbially and notoriously indolent and dissipated. To make men industrious—to make them shake off that lethargy which is natural to them, they must be inspired with a taste for the luxuries and enjoyments of civilized life. When this is done, their artificial wants will become equally clamorous with those that are strictly necessary, and they will increase exactly as the means of gratifying them increase. Wherever a taste for comforts and conveniences has been generally diffused, the wants and desires of man become altogether unlimited. The gratification of one leads directly to the formation of another. In highly civilized societies, new products and new modes of enjoyment are constantly presenting themselves as motives to exertion, and as means of rewarding it. Perseverance is, in consequence, given to all the operations of industry; and idleness, and its attendant train of evils, almost entirely disappear. “What,” asks Dr Paley, “can be less necessary, or less connected with the sustentation of human life, than the whole produce of the silk, lace, and plate manufactory? Yet what multitudes labour in the different branches of these arts! What can be imagined more capricious than the fondness for tobacco and snuff? Yet how many various occupations, and how many thousands in each, are set at work in administering to this frivolous gratification!” It is the *stimulus* which the desire to possess these articles of luxury gives to industry that renders their introduction advantageous. The earth is capable of furnishing food adequate for the support of a much greater portion of human beings than can be employed in its cultivation. But those who are in possession of the soil will not part with their produce for nothing; or rather, they will not raise at all what they can neither use themselves nor exchange for what they want. As soon, however, as a taste for conveniences and luxuries has been introduced, the occupiers of the ground raise from it the utmost that it can be made to produce, and exchange the surplus for such conveniences and gratifications as they are desirous of obtaining; and, in consequence, the producers of these articles, though they have neither property in the soil, nor any concern in its cultivation, are regularly and liberally supplied with its produce. In this way, the quantity of *necessaries*, as well as of useful and agreeable products, is vastly increased by the introduction of a taste for luxuries; and the population are, in consequence, not only better provided for, but their numbers are proportionably and greatly augmented.

It is plain, therefore, that the consumption of lux-

M M

Luxury not disadvantageous.

Consumption of Wealth.

uries cannot, provided it be confined within proper limits, be justly considered as either disadvantageous or unproductive. If, indeed, a man were to consume more luxuries than his labour or his fortune enabled him to command, his consumption would be disadvantageous. But it is plain, the same thing would equally have happened had he consumed a greater quantity of *necessaries* than he could afford. The mischief does not consist in the *species* of articles consumed, but in the *excess of their value* over the means of purchasing them possessed by the consumers. This, however, is a fault which ought always to be left to be corrected by the *self-interest* of those concerned. The poverty and degradation caused by indulging in unproductive consumption is a natural and sufficient guarantee against its ever being carried to an injurious extent. To attempt to lessen unproductive consumption by proscribing luxury, is really the same thing as to attempt to enrich a country by taking away some of the most powerful motives to production.

Dr Smith's Criterion of Productive and Unproductive Consumption.

Dr Smith has given another criterion of productive and unproductive consumption; but his opinions on this subject, though exceedingly ingenious, and supported with his usual ability, appear to rest on no solid foundation. He divides society into two great classes. The *first* consists of those who fix, or, as he terms it, "realize their labour in some particular subject, or vendible commodity, which lasts for some time at least after that labour is past;" the *second*, of those whose labour leaves nothing in existence after the moment of exertion, but perishes in the act of performance. The former are said by Dr Smith to be *productive*, the latter *unproductive*, labourers. Not that, in making this distinction, Dr Smith means to undervalue the services performed by the unproductive class, or to deny that they are often of the highest utility; for he admits that such is frequently the case: but he contends, that these services, however useful, do not augment the *wealth* of the country; and, consequently, that the commodities consumed by this class are unproductively consumed, and have a tendency to impoverish, not to enrich, the society. But to avoid the chance of misrepresentation, we shall give Dr Smith's opinions in his own words.

"There is one sort of labour," says he, "which adds to the value of the subject upon which it is bestowed; there is another which has no such effect. The former, as it produces a value, may be called productive; the latter unproductive labour. Thus the labour of a manufacturer adds, generally, to the value of the materials which he works upon, that of his own maintenance, and of his master's profit. The labour of a menial servant, on the contrary, adds to the value of nothing. Though the manufacturer has his wages advanced to him by his master, he, in reality, costs him no expence, the value of those wages being generally restored, together with a profit, in the improved value of the subject upon which his labour is bestowed. But the maintenance of a menial servant never is restored. A man grows rich by employing a multitude of manufacturers; he grows poor by maintaining a multitude of menial servants. The labour of the latter, however, has its value and

deserves its reward as well as that of the former. But the labour of the manufacturers fixes and realizes itself in some particular subject, or vendible commodity, which lasts for some time at least after that labour is past. It is, as it were, a certain quantity of labour stocked and stored up to be employed, if necessary, upon some other occasion. That subject, or, what is the same thing, the price of that subject, can afterwards, if necessary, put into motion a quantity of labour equal to that which had originally produced it. The labour of the menial servant, on the contrary, does not fix or realize itself in any particular subject or vendible commodity. His services generally perish in the very instant of their performance, and seldom leave any trace or value behind them for which an equal quantity of service could afterwards be procured.

"The labour of some of the most respectable orders in the society is like that of menial servants, *unproductive of any value*, and does not fix or realize itself in any permanent subject or vendible commodity, which endures after that labour is past, and for which an equal quantity of labour could afterwards be procured. The sovereign, for example, with all the officers both of justice and war who serve under him, the whole army and navy, are unproductive labourers. They are the servants of the public, and are maintained by a part of the annual produce of the industry of other people. Their service, how honourable, how necessary, or how useful soever, produces nothing for which an equal quantity of service can afterwards be procured. The protection, security, and defence of the commonwealth, the effect of their labour this year, will not purchase its protection, security, and defence for the year to come. In the same class must be ranked some both of the greatest and most important, and some of the most frivolous professions: churchmen, lawyers, physicians, men of letters of all kinds; players, buffoons, musicians, opera-singers, opera-dancers, &c. The labour of the meanest of these has a certain value, regulated by the very same principles which regulate that of every other sort of labour; and that of the noblest and most useful produces nothing which could afterwards purchase or procure an equal quantity of labour. Like the declamation of the actor, the harangue of the orator, or the tune of the musician, the work of all of them perishes in the very instant of its production." (*Wealth of Nations*, II. p. 1.)

Such are the opinions of Dr Smith, and it will not, we think, be very difficult to show the fallacy of the distinction he has endeavoured to establish between the labour, and consequently also the consumption, of the different classes of society. To begin with the case of the menial servant:—Dr Smith says, that his labour is *unproductive*, because it is not realized in a vendible commodity, while the labour of the manufacturer is *productive*, because it is so realized. But of what, may we ask, is the labour of the manufacturer really productive? Does it not consist exclusively of comforts and conveniences required for the use and accommodation of society? The manufacturer is *not* a producer of

Consumption of Wealth.

Dr Smith's Distinction between the Different Classes of Society shown to be ill-founded.

Consumption of Wealth.

Consumption of Wealth.

matter, but of *utility* only. And is it not obvious that the labour of the menial servant is also productive of utility? If, for example, the labour expended in converting the wool of the sheep into a coat be, as it unquestionably is, productive, then surely the labour expended in cleaning and brushing the coat, and rendering it fit to be worn, must be so too. It is universally allowed, that the labour of the husbandman in raising corn, beef, and other articles of provision, is productive; but if so, why is the labour of the menial servant who performs the *necessary* and *indispensable* task of preparing and dressing these articles, and fitting them to be used, to be stigmatized as unproductive? It is clear to demonstration, that there is no difference whatever between the two species of industry—that they are either both productive, or both unproductive. To produce a fire, is it not just as necessary that coals should be carried from the cellar to the grate, as that they should be carried from the bottom of the mine to the surface of the earth? And if it is said, that the miner is a productive labourer, must we not also say the same of the servant, who is employed to make and mend the fire? The whole of Dr Smith's reasoning proceeds on a false hypothesis. He has made a distinction where there is none, and where *there can be none*. The end of all human exertion is the same—that is, to increase the sum of necessities, comforts, and enjoyments; and it must be left to the judgment of every man to determine what proportion of these comforts he will have in the shape of menial services, and what in the shape of material products. It is an error to suppose that a man is impoverished by maintaining menial servants, any more than by indulging in any other species of expence. It is true he will be ruined if he keeps more servants than he has occasion for, or than he can afford to pay; but his ruin would be equally certain were he to purchase an excess of food or clothes, or to employ more workmen in any branch of manufacture than are required to carry it on, or than his capital could employ. To keep two ploughmen when one only might suffice, is just as improvident and wasteful expenditure as it is to keep two footmen to do the business of one. *It is in the extravagant quantity of the commodities we consume or of the labour we employ, and not in the particular species of commodities or labour, that we must seek for the causes of impoverishment.*

Case of the Physician.

The same reasoning applies to all the other cases mentioned by Dr Smith. Take, for example, the case of the physician. Dr Smith tells us that he is an unproductive labourer, because he does not directly produce something that has exchangeable value. But if he does the same thing *indirectly*, what is the difference? If the exertions of the physician are conducive to health, and if, as is undoubtedly the case, he enables others to produce more than they could do without his assistance, then it is plain he is *indirectly*, at least, if not directly, a productive labourer. Dr Smith makes no scruple about admitting the just title of the workman employed to repair a steam-engine to be enrolled in the productive class; and yet he would place a physician, who had been instrumental in saving the life

of an Arkwright or a Watt, among those that are unproductive! It is impossible that these inconsistencies and contradictions could have occurred to Dr Smith; and the errors into which he has fallen in treating this important branch of the science, shows in the strongest manner the absolute necessity of advancing with extreme caution, and of subjecting every theory, how plausible and ingenious soever it may appear when first stated, to a severe and patient examination.

The amusements furnished by players, singers, and so forth, come under the description of luxuries, and have precisely the same effect on the public wealth as the introduction of a taste for tobacco, tea, or other superfluities. They create new wants, and by so doing, stimulate our industry to procure the means of gratifying them. They are really, therefore, a means of production; and while they furnish us with elegant and amusing recreation, they certainly add to the mass of useful material products.

The productiveness of the higher class of functionaries mentioned by Dr Smith is still more obvious. So far, indeed, from being unproductive, they are, when they discharge properly the duties of their high station, the most productive labourers in a state. Dr Smith says, that the results of their service, that is, to use his own words, "the protection, security, and defence of the commonwealth any one year, will not purchase its protection, security, and defence for the year to come." But this is plainly an error. We do not say that the protection and security afforded by good government is directly a cause of wealth; but it is plain that without this security and protection, the productive powers of industry could not have been called into action. Dr Smith would allow that the material products produced by the society one year, were to form the means of producing its supplies of necessities, conveniences, and enjoyments during the following year. But without the security and protection afforded by government, these products would either have not existed at all, or their quantity would have been very greatly diminished. How, then, is it possible to deny that those whose labour is necessary to afford this security are productively employed? Take the case of the labourers employed to construct fences; no one ever presumed to doubt that their labour is productive; and yet they do not contribute *directly* to the production of corn or of any other valuable product. The object of their industry is to give protection and security; to guard the fields that have been fertilized and planted by the husbandman from depredation; and to enable him to prosecute his employments without having his attention distracted by the care of watching. But if the security and protection afforded by the hedger and ditcher justly entitle them to be classed among those who contribute to enrich their country, on what principle can we reckon those public servants whose exertions protect property in the mass, and render every portion of it secure against hostile aggression, and the attacks of thieves and plunderers, be said to be unproductive? If the labourers who protect a single corn field from the neighbouring crows and cattle be productive, then surely the

Public Functionaries Productive Labourers.

Consumption of Wealth.

judges and magistrates, the soldiers and sailors, who protect every field in the empire, and to whom it is owing that every class of inhabitants feel secure in the enjoyment of their property, rights, and privileges, have a right to be classed among those whose services are supereminently productive.

That much wealth has been unproductively consumed by the servants of the public, both in this and other countries, it is impossible to doubt. But we are not to argue from the abuses extrinsic to a beneficial institution against the institution itself. If the public pay their servants excessive salaries, or employ a greater number than is required for the purposes of good government and security, it is their own fault. Their conduct is quite the same as that of a manufacturer who should pay his labourers comparatively high wages, and employ more of them than he had occasion for. But, although a state or an individual may act in this foolish and extravagant manner, it would obviously be the extreme of folly and absurdity to conclude from thence that *all* public servants and *all* manufacturing labourers are unproductive! If the establishments which provide security and protection be formed on an extravagant scale, if we have more judges or magistrates, more soldiers or sailors, than are necessary, or if we pay them larger salaries than would suffice to procure the services of others, let their numbers and their salaries be reduced. The excess, if there be any, is not a fault inherent in the nature of such establishments, but results entirely from the extravagant scale on which they have been arranged.

Consumption ought not to be encouraged for the sake of stimulating Production.

But, in showing that Dr Smith was mistaken in considering the consumption of menial servants, and of lawyers, physicians, and public functionaries unproductive, we must beware of falling into the opposite extreme, and of countenancing the erroneous and infinitely more dangerous doctrine of those who contend that consumption, even when most unproductive, ought to be encouraged as a means of stimulating production, and of increasing the demand for labour! The consumption of the classes mentioned by Dr Smith is advantageous, because they render services in return, which those who employ them, and who are the only proper judges in such a case, consider to be of greater value than the wages they pay them. But the case would be totally different, if the Government and those who employ labourers, were to do so, not in order to profit by their services, but to stimulate production by their consumption! It is a fallacy and an absurdity to suppose that production can ever be encouraged by a wasteful consumption of the products of industry. A man is stimulated to produce when he finds a ready market for the produce of his labour, that is, when he can readily exchange them for other products. *And hence the true and only encouragement of industry consists, not in the increase of wasteful and improvident consumption, but in the increase of production.* Every new product necessarily forms a new equivalent, or a new means of purchasing some other product. It must always be remembered, that the mere existence of a demand, how intense soever it may be, cannot of itself be a means of encouraging production. To become a real demander, a man

must not only have the *will*, but he must also have the *power*, to purchase the commodity he wishes to possess; or, in other words, he must be able to offer an equivalent for it. There never has been, nor is it in the nature of things that there ever can be, any limits to our wish to possess the products of art and industry. It is the *power* to give effect to our wishes, or to furnish other products in exchange for those we are desirous of obtaining, that is the real and only desideratum. The more, therefore, that this power is increased, that is, the more industrious every individual becomes, his means of offering equivalents for the products of others will be so much the more increased, and the market will be rendered so much the more extensive.

Consumption of Wealth.

Mr Sismondi and Mr Malthus have, indeed, contended, in opposition to this doctrine, that the productiveness of industry may really be carried to excess; and that, in a country where there are great facilities of production, a large unproductive consumption is necessary to stimulate industry, and prevent the overloading of the market. But if we attend to the motives which cause men to engage in any branch of industry, we shall be satisfied that the apprehensions of these writers are unfounded, and that the utmost facility of production can never be productive of a permanent glut of the market, or require to be counteracted by means of unproductive expenditure. In exerting his productive powers, every man's object is either directly to consume the produce of his labour himself, or to exchange it for such commodities as he wishes to obtain from others: If he does the first—if he directly consumes the produce of his industry, there is an end of the matter, and it is evident that the multiplication of such produce to infinity could never occasion a glut: If he does the second—if he brings the produce of his industry to market, and offers it in exchange for other commodities, then, and then only, there may be glut; but why? Not certainly because there has been any excess of production, but because the producers have not properly adapted their means to their ends. They wanted, for example, to obtain silks, and they offered cottons in exchange for them; the proprietors of the silks were, however, already sufficiently supplied with cottons, and they wanted broad cloths. The cause of the glut is, therefore, obvious. It consists not in over-production, but in the production of cottons, which were not wanted, instead of broad cloths, which were wanted. Let this error be rectified, and the glut will disappear. Even supposing the proprietors of silks to be not only supplied with cottons, but with cloth and every other commodity that the demanders can produce, it would not invalidate the principle for which we are contending. If those who want silks cannot obtain them from those who have them, by means of an exchange, they have an obvious resource at hand—let them cease to produce the commodities which they do not want, and *directly produce the silks which they do want, or substitutes for them.* It is plain, therefore, that the utmost facility of production can never be a means of overloading the market. Too much of one commodity may occa-

Unproductive Consumption not necessary to prevent Gluts.

Consumption of Wealth.

sionally be produced; but it is quite impossible that there can be too great a supply of every species of commodities. For every excess there must be a corresponding deficiency. The fault is not in producing too much, but in producing commodities which do not suit the tastes of those with whom we wish to exchange them, or which we cannot ourselves consume. If we attend to these two grand requisites, we may increase the power of production a thousand or a million of times, and we shall be as free of all excess as if we diminished it in the same proportion. Unproductive consumption is not, therefore, necessary to prevent the overloading of the market; and to maintain that it contributes to increase national wealth in any other way, is really just the same thing as to maintain that wealth would be increased by throwing a portion of it into the sea or the fire.\*

Error of Montesquieu.

Montesquieu has said, and the same sentiment has been expressed in a thousand different shapes, "*Si les riches ne dependent pas beaucoup les pauvres mourront de faim.*" (Liv. VII. chap. 4.) Montesquieu was betrayed into this error, from his being unacquainted with the nature and functions of capital. The profusion of the rich, far from being of any advantage to the poor, is really one of the greatest calamities that can befall them. It is impossible that the demand for labour can be increased without an increase of capital. When the parsimonious principle predominates, capital increases, and as capital increases, the demand for labour is increased, the existing inhabitants are better provided for, and their numbers are increased; on the contrary, wherever profusion and wasteful expenditure predominates, capital is diminished, the inhabitants are daily worse and worse provided for, and idleness, pauperism, and disease prevail. Besides, it must be remembered, that what is annually saved, is as regularly consumed as what is annually spent. The only difference is, that it is consumed in a *different* manner—consumed by those who render a great

er value in return, instead of being consumed by such as render no real value whatever. †

"By what a frugal man annually saves," says Dr Smith, "he not only affords maintenance to an additional number of labourers for that or the ensuing year, but, like the founder of a public workhouse, he establishes, as it were, a perpetual fund for the maintenance of an equal number in all time to come. The perpetual allotment and destination of this fund, indeed, is not always guarded by any positive law, by any trust-right, or deed of mortmain. It is always guarded, however, by a very powerful principle, the plain and evident interest of every individual to whom any share of it shall ever belong. No part of it can afterwards be employed to maintain any but productive hands, without an evident loss to the person who thus perverts it from its proper destination." (*Wealth of Nations*, II. p. 14.)

We have already stated the impossibility of laying down any general rules on the subject of individual consumption. What the public is really interested in is, that it should never be carried on for the absurd purpose of occasioning a demand for the products of industry, and that it should be *less* than the reproduction; or, in other words, that the capital of the country should be kept constantly on the increase. But there is no instance of any people having ever missed an opportunity to save and accumulate. And in all tolerably well governed countries the principle of accumulation in individuals has always had a marked ascendancy over the principle of expence, and the national capital, and, consequently, the riches of the country, have been constantly augmented.

But this is seldom the case with the consumption carried on by governments and their servants. Individuals are fully sensible of the value of the articles they expend. In the vast majority of instances, they are the direct result of their industry, perseverance, and economy; and they will not consume them, unless to obtain an equivalent advantage. But such is not the situation of governments. They con-

Consumption of Wealth.

\* M. Say was the first who showed, in a satisfactory manner, that effective demand depends upon production. (See his chapter *De Debouchés*.) But the principles from which his conclusions are drawn had been stated so early as 1752, in a tract of Dean Tucker's, entitled *Queries on the late Naturalization Bill*. As this tract is now become of rare occurrence, we shall subjoin the queries referred to.

"Whether it is possible, in the nature of things, for ALL trades and professions to be *overstocked*? And whether, if you were to remove any proportional number from each calling, the remainder would not have the same grounds of complaint they had before?"

"Whether, in fact, any tradesman thinks there are too many of *other occupations* to become his customers; though narrow selfish views lead him to wish there were fewer of his own trade?"

"If a particular trade be at any time *overstocked*, will not the disease cure itself? That is, will not some persons take to other trades, and fewer young people be bred up to that which is least profitable? And whether any other remedy but this is not, in fact, curing *one transient disorder by bringing on many which are dangerous, and will grow inveterate*?"

"WHETHER IT IS NOT AN INFALLIBLE MAXIM, THAT ONE MAN'S LABOUR CREATES EMPLOYMENT FOR ANOTHER?" (p. 13.)

For a farther demonstration of the same principle, see Mr Mill's *Commerce Defended*, p. 80.

† For a farther and very able discussion of the opinion of Montesquieu, see the 7th chapter of the *Commentaire sur l'Esprit des Loix* of M. Destutt-Tracy, and Tom. IV. p. 383, of the *Elemens d'Ideologie* of the same author.

Consumption of Wealth.

sume the produce of the labour of *others*, not of their own; and this circumstance prevents them from being so much interested in its profitable expenditure, and so much alive to the injurious consequences of extravagant and wasteful expenditure as their subjects. But economy on the part of government, though more difficult to be obtained, is of infinitely greater importance than economy on the part of any individual. Should a private gentleman think of acting on the principle that profusion is a virtue, and that industry may be encouraged by increasing unprofitable consumption, he will most certainly be ruined; his ruin, however, will only be *directly* injurious to the individuals in his own employment, and will have but a very slight *indirect* effect on others. But similar conduct on the part of government would most probably be productive either of revolution, or of national poverty and degradation. If, then, it is most desirable that individuals should have a correct knowledge of their real interest in the consumption of commodities; how much more so must it be that government should possess that knowledge? Economy and frugality are virtues in a private station; but in a public station their influence upon national happiness is so vast, that they are not only the first of virtues, but the most pressing of duties.

Opinion of M. Say.

“ Si les dépenses publiques,” M. Say observes, “ affectent la somme des richesses précisément de la même manière que les dépenses privées, les mêmes principes d’économie doivent presider aux unes et aux autres. *Il n’y a pas plus deux sortes d’économie, qu’il n’y a deux sortes de probité, deux sortes de morale.* Si un gouvernement comme un particulier font des consommations desquelles il doit résulter une production de valeur supérieure à la valeur consommée, ils exercent une industrie productive; si la valeur consommée n’a laissé aucun produit, c’est une valeur perdue pour l’un comme pour l’autre, mais qui en se dissipant, a fort bien pu rendre le service qu’on en attendait. Les munitions de guerre et de bouche, le tems et les travaux de fonctionnaires civils et militaires qui ont servi à la défense de l’état, n’existent plus, quoique ayant été parfaitement bien employés, il en est des ces choses comme de denrées et des services qu’une famille a consommés pour son usage.

Cet emploi n’a présentée aucun avantage autre que la satisfaction d’un besoin; si le besoin n’existoit pas, la consommation, la dépense, n’ont plus été qu’un mal sans compensation. Il en est de même des consommations de l’état;—consommer pour consommer, dépenser par système, réclamer une service pour l’avantage de lui accorder une salaire, anéantir une chose pour avoir occasion de la payer est une extravagance de la part d’un gouvernement comme de la part d’un particulier, dans un petit état comme dans un grand, dans une république comme dans un monarchie. Un gouvernement dissipateur est même bien plus coupable qu’un particulier: celui-ci consomme les produits qui lui appartiennent, tandis qu’un gouvernement n’est pas propriétaire: il n’est qu’administrateur de la fortune publique.” (Tome II. p. 268.)

Consumption of Wealth.

We have now shown how labour may be rendered most productive of wealth—how that wealth is distributed among the various classes of the society—and how it may be most advantageously consumed. We have shown the close and indissoluble connection subsisting between private and public opulence, and that whatever has any tendency to increase the former, must, to the same extent, increase the latter;—and we have shown that SECURITY OF PROPERTY, FREEDOM OF INDUSTRY, AND MODERATION IN THE PUBLIC EXPENDITURE, are the only, as they are the certain, means by which the various powers and resources of human talent and ingenuity can be called into action, and society made continually to advance in the career of wealth and civilization. Every increase of security or of freedom is a benefit, as every diminution, whether of the one or the other, is an evil. It is by the spontaneous and unconstrained efforts of individuals to improve their condition and to rise in the world, and by these efforts only, that nations become rich and powerful. The labour and the savings of individuals are at once the source and the measure of national opulence and public prosperity. They may be compared to the drops of dew which invigorate and mature all vegetable nature. None of them has singly any perceptible influence; but we owe the foliage of summer and the fruits of autumn to their combined action. (s. s.)

Conclusion

## POLYNESIA,

**Polynesia.** A NAME given by several early writers on geography, but first, we believe, by De Barros, to the numerous islands scattered over the Pacific Ocean, or, as it was usually called, the Great South Sea. It is the name which is now applied by most modern geographers to the *sixth* great division of the earth's surface; a division which will probably appear, on examination, less arbitrary than some others; for whether we consider it in a political, physical, or moral point of view, the separation from America on the one hand, and from Australasia and the Asiatic Islands on the other, is marked by strong and distinct features. A considerable portion of the two last, for instance, have, ages ago, been invaded and taken possession of by foreigners, and many of them more recently been colonized by Europeans. No colonies have yet been planted in Polynesia, with the exception of that on one of the Ladrone Islands by Spain; numbers of its islands have never yet been visited; and the rest only occasionally by passing navigators, or a few of the most inviting by some missionaries, with the sole object of the conversion of the natives to Christianity. The inhabitants have no political connection with any of the other divisions of the earth, and little or none exists between any two of its groups or separate islands, each being governed by its own chiefs, and confining its friendships or hostilities to some neighbouring group or island.

**Physically considered.** Physically considered, the line of separation is almost as distinct as their political seclusion. If a line be drawn in a south-easterly direction, along the eastern extremity of the Philippine Islands, Mindanao, Papua or New Guinea, New Ireland, and Solomon's Archipelago, and from thence continued southerly along the eastern shores of the New Hebrides and New Zealand, this line will mark with sufficient precision the separation of the Asiatic Islands (mostly to the northward of the equator) and Australasia (to the southward of the equator) from Polynesia. Besides, the geological structure of the islands which constitute the last mentioned divisions are, generally speaking, essentially different; consisting chiefly of lofty mountains, of primary or secondary formation, partaking of the same structure as those on the continent of Asia, with which some of them, indeed, may probably have once been connected, their rugged sides presenting, as it were, a broken barrier to the Great Pacific; whereas Polynesia exhibits a series of low, flat islands, scarcely rising above the level of the sea, which, with the exception of a few of the larger groups of volcanic formation, are the labours of minute sea-animals, and are usually distinguished by the name of Coral Islands or Reefs.

**Morally considered.** In a moral point of view, the distinctive character of the Polynesians is as strongly marked as the physical structure of the islands which they inhabit. In the Eastern Archipelago, or the Asiatic Islands, and in Australasia, two distinct races of men have been

traced, the *black* and the *brown*. In the Archipelago, and more particularly in the Philippine Islands, a few individual families of the Negro race were discovered by the early European visitors; in New Guinea and the Papuan Islands, the whole population appears to consist of this race. They differ in some respects from the negroes of the western coast of Africa; resembling rather those which are found on the eastern coast, particularly in the hair, which is strongly twisted into small tufts, and very different from that of the negro of Guinea.

None of these negroes have been discovered on any of the islands of Polynesia, all the inhabitants being of the *brown* race, and evidently derived from the same common stock to which the Tartars, the Chinese, the Japanese, and the Malays, owe their origin. In this opinion Sir William Jones, Dr Buchanan, Dr Hunter, Mr Marsden, and Sir Stamford Raffles, unanimously concur. This race, modified, of course, by the circumstances of climate, occupations, and habits, may thus be described: Their persons short, squat, and robust; their lower limbs large and heavy; their arms fleshy; hands and feet small; face somewhat of a lozenge shape, the forehead and chin rather sharpened, but broad across the cheekbones, which are high, and the cheeks hollow; the eyes black, small, narrow, and placed obliquely in the head, the external angle being the highest; nose broad, but not flat, and nostrils open and circular; mouth rather wide; hair harsh, lank, and quite black.

Dispersed as the Polynesians are, and rarely and purely accidental as any communication between distant islands must be, it is perfectly certain that the different dialects spoken, from the shores of India and Africa to those of America, are the derivatives of one common language, which, according to Marsden, still forms the primitive portion of the Malay language, mixed, as it now is, with Sanscrit and Arabic. "The Malayan," says this learned and accurate writer, "is a branch or dialect of the widely extended language prevailing throughout the islands of the archipelago to which it gives name, and those of the South Sea, comprehending between Madagascar on the one side, and Easter Island on the other, both inclusive, the space of full two hundred degrees of longitude. This consideration alone is sufficient to give it claim to the highest degree of antiquity, and to originality, as far as that term can be applied."

Not less remarkable is the general accordance of the Polynesians in manners, superstitions, and religious observances. The conversion of the Malays of the archipelago to Mahometanism has obliterated nearly their ancient faith, but enough still remains on some of the Asiatic Islands, and still more on the Asiatic Continent, to trace the source from whence the Polynesians have derived their notions and practices on matters of this kind.

Polynesia.  
General  
View of the  
Islands.

These preliminary observations on the physical form, features, language, and religion of the Polynesians, are made with a view to assert their common origin, and may be taken as a general description of the natives of the various groups of islands which are scattered over the surface of the vast Pacific Ocean. These groups are exceedingly different in their extent, both as to number and size as well as in their composition. Sometimes single islands are met with, surrounded by rocky reefs. These islands and reefs are dispersed, as already observed, over the whole of the Pacific Ocean, but chiefly between the thirtieth degree of northern and the thirtieth degree of southern latitude. The following classification will probably be found to embrace the greater part of those islands which are comprehended under the geographical division, Polynesia :

*In the Northern Hemisphere.*

Classifica-  
tion of the  
Islands.

1. The Marian or Ladrone Islands.
2. The Carolinas, including the Pellew Islands.
3. The Sandwich Islands.
4. The numerous reefs and coral islands scattered over the Pacific in both hemispheres.

*In the Southern Hemisphere.*

1. The Friendly Islands, including the group of the Tonga Islands.
2. The Navigators' Islands.
3. The Society Islands.
4. The Georgian Islands, including Otaheite, and the great range extending as far as Pitcairn's Island.
5. The Marquesas.
6. Easter Island.

IN THE NORTHERN HEMISPHERE.

The La-  
drones.

1. The Ladrone Islands were first discovered by Magelhaens on the 6th March 1521. This name, by which they are generally known, was given to them by the Spaniards on account of the thievish disposition of the natives. They also called them *Islas de los Velos Latinas*, in reference to the sails of their canoes. By some they were called *los Jardinas* (the Gardens), and by others *Dosprazeres* (the Delightful Islands); and, when missionaries were first sent thither in 1668, under the patronage of Mary-Anne of Austria, queen of Philip, they took the name of *las Marianes*, in honour of that lady. They consist of four larger and several smaller islands. The former are called Saypan, Tinian, Zarpan or Rosa, and Agui-gan, or rather Guahan. Saypan has a lofty peak, evidently volcanic, but the rest are of moderate height, and are surrounded by rocks of coral formation. They lie between latitude  $13^{\circ}$  and  $15\frac{1}{2}^{\circ}$  N.; longitude about  $144^{\circ}$  E. On approaching these islands, Magelhaens perceived that they were inhabited, and the natives presently came off to the ships with cocoa-nuts, yams, and rice. They were stout well-made people, of a pale yellow complexion, long black hair, and their teeth dyed red or black; an apron of the bark of a tree was their only covering; a lance pointed with a fish bone their only weapon. Their boats had latteen (shoulder of mutton) sails, with outriggers to prevent their oversetting, and they sailed with great swiftness. The captain-general was

Visited by  
Magelhaens.

so delighted with the appearance of the country, that he intended to refresh his crew among them; but such numbers of the inhabitants flocked on board his ships, and were so addicted to thieving, that, being under the necessity of driving them away by force, hostilities ensued, and several of the natives were killed. Magelhaens had one of his boats stolen, which so exasperated him, that he landed with ninety of his people, set fire to their houses, which were of wood, and carried off all the provisions he could find.

The expedition of Loyosa, commanded, after his death, by Sebastian del Cano, and at his decease by Alonzo de Salazar, touched at the Ladrone Islands in 1526, and being received in the most friendly manner, procured water and provisions in plenty for the sickly squadron. To the great surprise of the Spaniards, a countryman of theirs, named Gonzalo de Vigo, came to them from one of the islands, having deserted from one of the ships of Magelhaens; two others, he said, had deserted at the same time, but were put to death by the natives. They found no quadrupeds on the island, but plenty of excellent fruits, fish, and rice. The only birds were turtle-doves, of which the islanders appeared to be so fond, that they kept them in cages, and taught them to speak.

In 1565, the Ladrone Islands were again visited by Lopez de Legaspe. While the ships were yet two leagues from the shore, the natives came off in their canoes, but kept at a distance from the ships. The general put knives and other articles on a plank, and floated it off, and the natives showed fruits, patting their bellies, and pointing to the shore, to induce the Spaniards to land. This they did the following day on the island of Guahan, and exchanged bits of iron for provisions; but notwithstanding the regulations made by Legaspe in order to prevent quarrels, skirmishes took place, and one of the seamen, who had strolled into the woods, being found murdered, the Spaniards landed in force, set fire to their houses and canoes, wounded several of the natives, and hung up on the spot three wounded prisoners.

No kind of animal was found on the island, nor would the natives taste any other animal food except fish. "But that which caused most admiration," says Friar Gaspar, "was, that they would drink salt water, and were such expert swimmers, and passed so much of their time in the water, that, as among other animals, some are amphibious, in like manner it seemed as if these people were in their nature amphibious."

In 1588, our countryman Candish or Cavendish came in sight of the Ladrone, and sailed along the coast of Guahan, from which a number of canoes came off with fruits and vegetables, which were exchanged for pieces of iron; but the natives became so troublesome, that, in order to get rid of them, Cavendish ordered muskets to be fired at them.

In 1600, Olivier Van Noort made the Ladrone Islands, and stopped near Guahan for two days, from which island above 200 canoes came off to the ships with fish, fruits, and rice, to exchange for iron; and fowls are also mentioned, for the first time, in this voyage. In the same year, the Santa Margarita, a

Polynesia. Spanish ship, having lost her captain and many of her crew by sickness, anchored off Saypan, and was taken possession of by the natives, who killed some of the crew, and took others of them on shore, where they were kindly treated, and such as survived were afterwards taken off by a Spanish ship which had been sent for the purpose.

By Spilbergen and the Nassau Fleet.

In 1616, Spilbergen made the Ladrone Islands, and stopped two days to traffic with the natives for provisions of fruit, fowls, and fish, in exchange for bits of iron. In 1625, the fleet under Prince Maurice of Nassau refreshed at Guahan, and were supplied by 150 canoes, with immense quantities of cocoa-nuts, yams, bananas, rice, and fowls, which were of infinite service, as the scurvy had made such havoc among the crews, that in some of the ships they had scarcely strength enough to manage the sails.

Of the Spanish Jesuits.

In 1668, the Spaniards established a mission on the island Guahan, consisting of P. Servitores and five other fathers, and several lay-assistants, most of them natives of the Philippine Islands, and well acquainted with the Tagul language, the same as that spoken by the natives of the Ladrone Islands. For some time the chiefs of the islands behaved with great kindness to the Jesuits, and gave them ground for building a church. From this seat of the mission the fathers spread themselves among the other islands, where they were received with equal kindness. In short, P. Servitores says, that in the first year they had baptized more than 13,000 islanders, and instructed 20,000 in the eleven islands which they had visited. As usual, however, the imprudent zeal of the missionaries ruined their cause, by shocking the prejudices of the natives. These simple people took it into their heads that, as an infant had died shortly after being baptized, its death had been occasioned in consequence of that ceremony; and such was the terror of mothers on seeing a missionary approach, that they seized their children and ran off with them into the woods. This opinion gathered ground from the eagerness of the Jesuits to get hold of infants for the purpose of baptizing them, and more than one of these holy fathers fell martyrs to their imprudent zeal. Several murders ensued; and, as the Spaniards had taken care to strengthen the mission with a body of troops well armed, with the obvious intention of taking possession of the Ladrone Islands as an important outpost to the Philippine Islands, after a great number of the natives had been put to death, the rest submitted to the yoke of the Spaniards; though most of the missionaries suffered in the contest, and last of all Servitores, who was killed by the man to whom he had been the greatest benefactor, because the missionary insisted on baptizing his child. Thus, at the age of forty-five, this pious and good man (for such he certainly was) fell by the hand of an assassin, after having, as we are told, "established the faith in thirteen islands, founded eight churches, established three seminaries for the instruction of youth, and baptized nearly 50,000 of the islanders." From this time constant revolts and massacres, and the most inhuman cruelties, were inflicted on the unhappy islanders; so that, in 1681, the island of Guahan, which, on the first coming of the Spaniards, counted 40,000 inhabit-

ants (some accounts make them more), was so completely depopulated, that it was found necessary to bring inhabitants from the northern islands to cultivate the soil.

Polynesia.

In the year 1685, the ship of John Eaton, the Buccaneer, touched at Guahan, the crew of which quarrelled with the natives, and killed some of them. Having satisfied the Spanish governor that it was done in their own defence, "he gave us toleration," says Cowley in his narrative, "to kill them all, if we could."—"We took four of these infidels prisoners," continues the narrator, "and brought them on board, binding their hands behind them; but they had not been long there, when three of them leaped overboard into the sea, swimming away from the ship, with their hands tied behind them. However, we sent the boat after them, and found a strong man, at the first blow, could not penetrate their skins with a cutlass; one of them had received, in my judgment, forty shots in his body before he died; and the last of the three that was killed had swam a good English mile first, not only with his hands behind him, as before, but also with his arms pinioned." We are told by the late Captain Burney, that it is stated in Cowley's MS. in the British Museum, that "the boat coming up with them, our carpenter, being a strong man, thought, with his sword, to cut off the head of one of them, but he struck two blows before he could fetch blood."

Visited by the Buccaneers.

In 1686, Dampier touched at Guahan, and states the number of natives not to exceed 100. He gives a particular description of their "flying proas," with their outriggers, which, he says, "sail the best of any boats in the world;" that he tried the swiftness of one by his log, and that she ran twelve knots out before the half-minute glass was half out.—"I believe," says Dampier, "she would run twenty-four miles in an hour." Woodes Rogers, who visited the Ladrone Islands in 1710, states his opinion that one of these proas would sail at the rate of twenty miles an hour.

By Anson.

In the month of August 1742, Commodore Anson anchored before the island of Tinian. It was deserted, but cattle to the number of at least 10,000, hogs, and fowls, were running about wild. Cocoa-nuts in innumerable quantities, bread-fruit, oranges, limes, water-melons, and other tropical fruits, were in the greatest abundance. The island swarmed with rats, and the flies, mosquitoes, and ticks or bugs, were very troublesome; but it was a paradise to the crew of the Centurion, in the horrible state of scurvy in which they arrived. Though now deserted, Tinian, on the arrival of the Spaniards, is said to have contained 30,000 inhabitants. Ruins of buildings, consisting of pyramidal pillars of considerable dimensions, were met with in all parts of the island.

Commodore Byron anchored in the year 1765 before Tinian, and found the island overgrown with large trees and underwood, among which were most of the tropical fruits. He complains bitterly of the bad anchorage, break water, venomous insects, from which they suffered so severely, that "we were afraid," he says, "to lie down in our beds;" and though his crew recovered fast from the scurvy, he lost two by fevers, being the first deaths in his ship

By Byron.

Polynesia.

since leaving England. "I am, indeed, of opinion," says the Commodore, "that this is one of the most unhealthy spots in the world, at least during the season in which we were here;" yet it was in the same month when visited by the Centurion.

By Kotzebue.

The latest account of these islands is that of Lieutenant Kotzebue, who visited Guahan in 1817. No canoes nor proas, nor happy islanders, greeted his approach; the whole race of natives had long been extirpated. "We looked," he says, "in vain for a canoe or a man on the shore; and it almost seemed as if we were off an uninhabited island. The sight of this lovely country deeply affected me. Formerly these fertile valleys were the abode of a nation, who passed their days in tranquil happiness; now only the beautiful palm groves remained to overshadow their graves; a death-like silence everywhere prevailed." Soon, however, a person appeared from the Spanish governor, and piloted the ship into the harbour; and after this, Kotzebue proceeded to the town of Agana, situated on a beautiful plain, some hundred paces from the shore, in the midst of fine palm groves; some of the houses are built of coral rock, others of bamboo. It has a church and a convent, and two fortresses, one to protect the town from the seawards, the other to keep the Indians in awe. The town contains about 200 houses, and 1500 inhabitants, who derive their origin from Mexico and the Philippines. The population of the island is about 5000 souls. "There is but one man and his wife," says Kotzebue, "on the whole island of the original stock; with the death of these two people, the race of the old Ladrões will be totally extinguished."—"The present race," says Chamisso, "no longer know the sea; are no mariners, no swimmers; they have ceased to build boats. They now scarcely hollow out, without skill, the trunks of trees to fish within the breakers." All the other islands to the north of Guahan are entirely uninhabited, and overrun with wild cattle, hogs, and goats, which afford a supply to the American vessels trading to the Sandwich Islands and the north-west coast of America. Indeed, it is said that some of these people have been allowed to settle themselves in Agrigan, on condition of acknowledging their allegiance to Spain, and that they are peopling the island by kidnapping the natives of the Sandwich Islands.

The Carolinas.

2. The *Carolinas*, or Caroline Islands. In 1686, a Spanish ship, being near the meridian of the Ladrões, fell in with an island, which her Commander, Don Francisco Lazeano, named La Carolina, in honour of the King of Spain, Carlos II. This island has given the name to a very extensive chain spreading over a space of not less than six degrees of latitude, and twenty-five degrees of longitude, the western extremity being the group of the Palaos or Pellew Islands, in latitude 7° N., longitude 135° E., and the easternmost island (that of Hogolen) in latitude 9° N., longitude 155° E. The whole group, as far as is known (which, however, is very imperfectly), consists of at least 150 separate islands, and may be nearly twice as many, besides various coral reefs, with islets upon them. Yet, numerous as they

are, being somewhat out of the direct and usual route of the Spaniards in their voyages from South America to the Philippines, they had the good fortune to escape any intimate connection with them—a connection which has proved equally baneful to others, whether established by the cross or the sword; by their professions of friendship or avowals of hostility. Gobien, the historian of the desolating progress of the Spaniards in the Ladrões, says, that Quiroga, the governor, made search for the island Carolina, "wishing to extend the faith to its infidel inhabitants, and, for that purpose, sent some soldiers, and with them the chanionis (or chief), Don Alonzo Soon; but, after a fruitless search, and much pains, they returned without finding the object of their research."

Some of these islands, however, and especially those towards the western extremity of the group, had been seen by various navigators long before that of Carolina was noticed and named by Lazeano. The Portuguese, Da Rocha, fell in with islands in 9° or 10° N. latitude, in 1526, which he named Sequiera, after his pilot; and, in 1628, Saavedra, a Spaniard, in his passage to the Philippines, discovered islands in latitude 11°, which he named Los Reyes. In 1579, our countryman Drake saw some islands, to which he gave the name of the Islands of Thieves, which, from his description, have been supposed to be the Pellew Islands. In 1595, one of the islands in about 6° N. was seen by Mendana; but two proas full of people, driven by the violence of the wind from a group of islands in the east, as far as Samal, roused the attention of the College of Jesuits at Manilla, who made several unsuccessful attempts to establish missions on those islands, which the wrecked natives described to consist of thirty-two in number. In 1710, the two fathers, Duberron and Cortel, embarked in the San Trinidad, with a crew of 86 men, to establish themselves on the Pellew Islands. They landed on Sonsorol, with the quarter-master and ensign of the troops, in all sixteen persons; but the ship being driven off by the current, made for another of the islands, called Panloque, at the supposed distance of fifty leagues from the Sonsorolles. On approaching the island, several boats came off, and some of the Palaos people swam from them to the ship, and coming on board, attempted to steal whatever they could lay their hands on. In consequence of this, they were ordered away; and having reached their boats, began to shoot arrows at the ship, which were answered by a discharge of musquetry. The ship now returned to the Sonsorolles, to inquire after the two missionaries and the boat; but the strong winds and currents would not suffer them to anchor, nor could they see or hear any thing of their companions, though they stood in towards the shore within cannon-shot. A storm coming on, left them no alternative but "to return to Manilla, with the sorrowful news of what had happened." What became of the missionaries was never ascertained. The following year, however, P. Serano departed from Manilla, in a ship fitted out for the purpose, in search of the two fathers and their companions; but she foundered three days after she de-

Polynesia. parted from Manilla, and every person on board perished, except one Spaniard and two Indians, who brought back the melancholy intelligence.

In the *Lettres Edifiantes et Curieuses* is a letter and chart from P. Juan Antonio Cantova, a missionary at Guahan, addressed to the King of Spain's confessor in 1722, in which is given a more particular account of the Carolinas than any which had before, or has since, been published. It states, that, in the preceding year, a bark, with eleven men, seven women, and six children, arrived on the east side of Guahan; and that, two days after, another canoe, with four men, one woman, and child, came to the opposite side of the island. The two parties, on being brought together, recognised each other with great joy. It appeared they had been dispersed by a gale of wind, and driven about for twenty days, without knowing where they were. Cantova thus describes them: They wore a garment open at the sides, but covering the shoulders and breast, and extending down to the knees. The women had a piece of cloth round the waist, falling, like a petticoat, to the middle of the leg. Their hair was curly, the nose large, the eyes large and penetrating, and the beards of the men moderately thick. Some had the pure colour of the Indians; others apparently of a mixed breed, between Spaniards and Indians; and others between a Negro and an Indian. Cantova succeeded in learning their language, and obtained from them the following particulars respecting their islands.

The Carolinas are divided into five provinces. Beginning at the east, the first is named Cittac; the principal island, Hogolen, much larger than Guahan; its inhabitants negroes, mulattoes, and whites. There are eighteen principal islands in this province, besides a multitude of smaller ones. The second province consists of twenty-six islands, of which Uleé and Lamuree are the principal ones. The third province consists of a group of islands, of which Feis is the principal, and is very populous and fertile; but the chief of the group resides at Mogmog, and all the proas which approach this island lower their sails in token of respect to this chief. Of the fourth province, Yap is the principal island, about 120 miles in circuit, very populous, and fruitful. The fifth province is the most westerly, and is named Panleu (the Palaos, or Pellew Islands), of which there are seven principal islands. It is remarkable that the inhabitants of these islands so far differ from the Carolinians in general, and from the account given of them in the romance of Mr Keates, drawn up by that ingenious gentleman from the documents furnished by Captain Wilson, that they are represented as a most barbarous race; both men and women going entirely naked, and feeding on human flesh. We are told by the naturalist of Kotzebue's expedition, that a Spaniard, who had lived nine months on the Pellew Islands, and whom they met with at Cavité, gave him a horrible account of the natives: that they were wholly without shame; that husbands lend their wives for a mere trifle; that the women are without modesty; and that they certainly eat human flesh; a great part of which was confirmed by a native of the Carolinas, who had been at the Pellew Islands.

Polynesia. Cantova farther learned from the islanders, that to the eastward were a great number of other islands, the inhabitants of which pay adoration to the shark; that most of them are negroes, and of savage dispositions. It is supposed that Cantova returned with these islanders in the year 1722, though no account of any such voyage is on record; but, in 1731, he embarked for the islands of the third province, in company with another father, of the name of Walter, from which the former never returned. The latter, however, returned to procure certain articles of which they stood in need, was driven to the Philippines, re-embarked in 1732, and was wrecked. Walter again embarked in May 1733, with forty-four persons. On the ninth day, they approached the island, and fired cannon to inform Cantova of their arrival, but no boat appeared. Standing within a musket-shot of the shore, they observed that their former habitation had disappeared, as well as the cross which had been erected near the sea shore. Four small canoes at length approached the vessel, bringing cocoa-nuts. On inquiring after Cantova and his companions, the islanders were evidently embarrassed, and said they were gone to Yap. Being fearful, by their manner, that the good father had fallen by the hands of the barbarians, and willing to be satisfied on this head, they seized one of the islanders, upon which the rest swam ashore. After the strongest assurances that no harm should be done to him, provided he would tell the truth, he confessed that shortly after the departure of Walter, the natives put the Father Cantova to death and all his companions, fourteen in number. Cantova, it seemed, from this man's account, went, with his interpreter and two soldiers, to the Island Mogmog, to baptize, while the rest remained at Falalep. He had scarcely set his foot on shore when he was surrounded and pierced through and through with lances, the natives crying out that he was come to take away the old law, and give them a new one. They gave his body a decent burial, but the bodies of his companions were put into a canoe, which was then turned adrift upon the ocean. The same people then went over to the island of Falalep, and put to death the remainder of the companions of Cantova.

Since that time, little or no information has been procured respecting the Carolinas, with the exception of that which is contained in the narrative of Mr Keates, from the materials of Captain Wilson, who, when commander of the Antelope packet, in the service of the East India Company, was wrecked on Oroolong, one of the Pellew Islands. Whatever their general character may be, the crew of the Antelope found them a friendly, hospitable, and humane people. They were stout, well-made, rather above the middle size, and their colour approaching to a deep brown; their hair long, some wearing it loose, and others turned up. The men were entirely naked; the women contented themselves with two little aprons or fringes, made of the fibres of the cocoa-nut husk, about ten inches deep and seven wide, one of which was worn before, and the other behind. Both sexes were tattooed; the men had one ear perforated, the women both, and they wore beads, tortoise-shell, or leaves, as suited their fancy; the car-

Polynesia. tilage of the nose was also bored, and a little sprig or blossom of some plant was generally stuck in the hole; their teeth were dyed black by a paste prepared of certain herbs, which, it is pretended, caused severe sickness for five days, the time required to complete the operation.

Their Productions, and the Manners of the Natives.

Fish and cocoa-nuts are the chief articles of food, but the islands afford an abundant supply of yams, plantains, oranges, lemons, bread-fruit, carambola, and the areca nut; the sugar-cane grew wild. No quadruped, except rats, was found on the islands; of birds, the pigeon was the most abundant, and the domestic fowl ran wild in the woods. The natives were wholly unacquainted with the use of salt. Their usual beverage was the milk of the cocoa-nut. Their houses were of bamboo and plank, raised upon stones from the ground. The husk of the cocoa-nut supplied them with nets and cordage, and the tortoise-shell with hooks to catch fish. Their knives were made of mother-of-pearl, shells, or split bamboo; the cocoa-nut served them for cups, the plantain-leaf for plates, and the fibres of this plant for mats to sleep on. Their weapons were spears of wood, darts, and slings. Their boats were canoes, made of the trunks of large trees, and some of them sufficiently capacious to hold from twenty to thirty persons. In the day time they seemed to live as much in the water as on shore, and both sexes were admirable swimmers. The women mixed freely with the other sex, and their conduct was not strictly inquired into by their husbands. They seemed to have little sense of any religious duties, except in the ceremonies attending the burial of the dead, which takes place in spots set aside for that purpose, and with great solemnity; but they have some faint notion that the soul survives the body. Their graves very much resembled those in a country church-yard of England, some having earth heaped up in the same manner, and others covered with flat tombstones, and protected by fences of wicker work.

The larger of the Pellew Islands are of a moderate height, rising into beautiful hills, well clothed with forest trees. The natural history still remains unknown, but being about the same parallel, and of the same formation with the numerous group visited by Kotzebue, the plants and animals are in all probability much the same. The smaller islands are the productions of the coral-making animals, with which the larger are also surrounded to a great distance from their shores.

The Sandwich Islands.

3. *The Sandwich Islands.*—This fine group of islands in the Northern Pacific had the good fortune to escape the visits of the old navigators, and the discovery of them was reserved for Captain Cook, who first touched at them in the year 1778, and lost his valuable life there in 1779. M. Fleurieu, in his introduction to Marchand's *Voyage*, is disposed to dispute this claim, and to assign the first discovery of these islands to Mendana, for no other reason but that it appears he passed at no great distance from Owyhee (but without seeing it), on his return voyage in 1568; and because he finds an island named Mesa, laid down on the nineteenth parallel of latitude, on the obscure and unauthenticated chart of Galion de Manille. It is almost unnecessary to add,

that the name by which they are now known was given to them by Captain Cook, in honour of the Earl of Sandwich, under whose naval administration geography was enriched with many important discoveries.

Captain King makes the group to consist of eleven islands, the principal of which are Owyhee, said to contain about 150,000 inhabitants,—its extent about 6000 square miles; Mowhee, 65,000,—extent 600 square miles; Woahoo, 60,000,—extent 1800 square miles; Atooi, 54,000,—extent 1000 square miles; and Morotoi, 36,000,—extent 300 square miles. The rest are smaller, and make up a population for the whole group of about 400,000 souls. They are situated between latitude 18° 54' N. (the south point of Owyhee), and 22° 2' N. (the latitude of Orehoue), and between the longitude 199° 36' (the small island of Tahoura), and 205° 6' (the eastern extremity of Owyhee).

The island of Owyhee is described as rising majestically in grand unbroken lines from the ocean, and forming three several mountain peaks, on two of which snow lies the greater part of the year. They are as under:

	Height.
Mouna Roa (the Great Mountain),	2482 toises.
Mouna Kuah (Little Mountain),	2180
Mouna Wororai,	1687

These measurements, as given by Kotzebue, agree within a few toises with those of Marchand. The whole group is of volcanic origin, and on the summit of Mouna Wororai is an immense crater. The last eruption from the side of this mountain took place in 1801. The chain of mountains runs from the N. W. point of Owyhee, over the islands Mowee, Morotoi, and Woahoo. On Mowhee is a peak as high nearly as that of Wororai, but the latter is the only volcano in a state of activity.

These islands, though volcanic, are surrounded by coral reefs, and the plains next the sea, raised only a few feet above it, were once of the same description, and covered with water. These plains are generally naked and sun-burnt, but the valleys among the mountains are beautifully picturesque and fertile, and the sides of the hills are covered with magnificent forests. The most fertile and best cultivated of the group is Woahoo, on which is the safe and capacious harbour of Hana-rura, protected by a coral reef, through a break of which the entrance to it lies. In one of the mountains a diamond mine was supposed to exist, but the products turned out to be only quartz crystals. In the Pearl River of this island oysters have been found, containing pearls, but none of much value.

Among the indigenous plants mentioned by Chamisso, the naturalist of Kotzebue's expedition, are the acacia, metrosideros, pandanus, santalum, aleurites, dracæna, amomium, curcuma, tacca. The families of rubiaceæ, contortæ, and urticæ, predominate. From the latter, as well as from the paper mulberry (*Broussonetia papyrifera*), are made their cordage and cloths. The acacia tree used for their boats and canvas grows only in the mountains, which is the case also with the sandal-wood, the principal article of export from the islands.

Polynesia. The plants mostly in use for domestic purposes are the banana-tree, the coco-nut tree, the bread-fruit, sugar-cane, yam, batatos, and the taro root (*Arum esculentum*), of indigenous growth; besides which have been introduced the tobacco plant, the melon, and water-melon, rice, and the vine, the last of which will unquestionably thrive well on the sides of the volcanic mountains. The cultivation of the taro-root has the greatest share of attention bestowed on it; and, in fact, it constitutes a considerable portion of the food of the people. The fields or ponds in which this root is planted are inclosed with stones in the form of regular squares, from 100 to 200 feet each side; these squares are connected by sluices to convey the water from one to the other, pretty much in the same manner that the Chinese manage their rice fields. "I have seen," says Kotzebue, "whole mountains covered with such fields, through which the water gradually flowed; each sluice formed a small cascade, which ran through avenues of sugar-cane, or banana, into the next pond, and afforded an extremely picturesque prospect."

Disillation of Spirits. A convict from New South Wales has taught the people of these islands the art of distilling ardent spirits from sugar-cane, and a plant called the Tee-root (the *Dracena terminalis*). And, as every chief has now his still, it is probable that the use of the pernicious *kava* will give way to that of the almost equally pernicious use of spirituous liquors. This *kava* is the liquor or juice of a root of the pepper tribe (*Piper methysticum*), chewed and spit out into a large bowl, and then diluted with water, and this exquisite beverage is prepared for the sole use of the king and the nobles, the women being prohibited from tasting it. The baneful effects of this liquor have been noticed by most voyagers; the bodies of those who swallow it are, in process of time, covered with a white scurf, their eyes become red and inflamed, their limbs emaciated, and their whole frame trembling and paralytic.

quadrupeds. When Captain Cook first discovered these islands, the only quadrupeds upon them were hogs, dogs, and rats. They have now horses (not many), asses, horned cattle, many of them running wild in the mountains, and goats. Hogs are exceedingly abundant. "They are so large," says Kotzebue, "that the whole crew could not eat one in two days;" and the flavour, from being fed on sugar-cane, is very superior to European pork. Fowls, ducks, and geese, are equally abundant.

Progressive Civilization. The Sandwich Islands, though last discovered, have been more frequently visited by Europeans and Americans, and particularly by the latter, than any other group of islands in the whole range of Polynesia; and they have profited the most by such intercourse, though not by any means to that extent which might have been wished. Indeed, what little progress they have made towards civilization is mainly to be attributed to the personal character of the present chief or king, whose name is Tamaa-mah; and that which he has effected is more for his individual advantage than the good of his subjects. When Captain Vancouver visited these islands in 1792, the king being desirous of having a vessel of European construction, this able navigator laid down

Polynesia. the keel of one, which was speedily finished. Ten or twelve years after this, when Mr Turnbull visited the islands, he had a naval force of twenty vessels or upwards, from 25 to 50 tons, which traded among the islands. He had built a house for himself, after the European manner, with windows of glass, and he imitated the English in his dress. By means of English and American seamen and artificers, some of whom deserted from ships touching there, and others obtained regular permission to remain on the islands, most of the trades exercised in Europe have partially been introduced into the Sandwich Islands.

Most of those people having taken to themselves native wives, a new race of men is springing up, which, in the course of time, may probably be the means of hastening the civilization of these islands. It is much to be regretted, however, that hitherto no steps have been taken to bring up the new generation in the principles of morality and religion, or for instructing them in the common rudiments of education. Tamaa-mah is ready enough to imitate the Europeans in his dress and dwelling, in building forts for the protection of his islands, and in training his troops in the European mode of discipline, of whom Kotzebue saw 400 drawn out, armed with musquets. In these matters, he is willing enough to be instructed by the Europeans who have settled on the islands, who, generally speaking, are of a description not likely to convince him of the utility of intellectual acquirements. In a visit to the Morai, pointing to the large wooden statues, he said to Kotzebue, "These are our gods, whom I worship. Whether I do right or wrong, I do not know, but I follow my faith, which cannot be wicked, as it commands me never to do wrong." Such sentiments do honour to the savage; and the man who entertains them is capable of being instructed in better things.

He is very tenacious in observing the customs of the country, and says, that, although those of Europeans are better, he cannot depart from his own. Thus the women continue to be degraded and despised; and, notwithstanding the frequent intercourse with strangers, and the improvements which undoubtedly have been introduced, the sex do not appear to have gained a single step in the estimation of the men, or lost any part of the grossness of behaviour since they were first visited by Captain Cook. That "offensively conspicuous wantonness," which Vancouver deploras, and to which he found no parallel in the whole of Polynesia, appears to have suffered no abatement. When Campbell, the seaman, was on the island of Woahoo, the king's brother died, on which occasion, as part of the general mourning, a public prostitution of the women took place. The captain of a ship, then in the harbour, remonstrated with the king, who coolly observed, it was their custom, and he could not prevent it. The women, too, it seems, are more addicted to drinking than the men. The governor of Woahoo invited Kotzebue and his officers to witness a dance of the natives, at which he was not present, but sent an apology to say, that his lady was so drunk that he could not leave her. The women are also great smokers of tobacco, and continue it sometimes till they fall down senseless,

Polynesia.

Though the women are so far degraded that they cannot eat in the same house with their lords and masters, and must not taste at all of certain articles, yet if the latter be sick, they must howl and make lamentations, tear their hair, lacerate their cheeks; and if he should die (provided he be a Jerrie, Eree, or noble), the favourite wife must die with him. The victims, both men and women, who are to be sacrificed at the death of Tamaa-mah are well known, nor is it concealed even from themselves, and they glory in the distinction. "I have myself," says Kotzebue, "seen one of the devoted victims in Woahoo, a man who was always cheerful and happy." On the death of the king, these people will be led bound into the royal Morai (temple and burning place), where, after the prescribed ceremonies, they will suffer death at the hands of the priests. Chamisso, however, says, that this inhuman practice is wearing out, and that now culprits only, whose lives have been forfeited, are sacrificed to the gods on particular occasions. But though the custom of offering up human sacrifices is still retained, there are no grounds whatever for supposing, as the surgeon of Captain Cook's ship did, that they ever taste of human flesh.

To violate the sanctity of the Morai is one of the greatest crimes of which a man can be guilty. Campbell was present at the execution of a man who had committed this offence, in getting drunk and running out of the Morai during *taboo* time. He was taken back to the Morai, where his eyes were put out; in this state he remained two days, when he was strangled and his body exposed before the image of Etooah, or Eatooah, the principal deity, who, according to their belief, is the creator of the universe, and who afterwards destroyed it by an inundation that covered the whole earth except Mouna Roa; on the top of which one single pair had the good fortune to save themselves, from whom the present race of men, that is, the Sandwich Islanders, sprung. Each chief has his own peculiar deity and his own Morai, and dresses up his wooden god after his own fashion. The common people have also their own objects of worship in their houses—birds, beasts, fish, &c. just like the *fetishes* of the Africans on the coast of Guinea.

That singular superstition by which the king, the nobles, and the priests, under the name of *Taboo*, have contrived to render sacred and inviolable whatever they may wish to appropriate to their own use, and which is in universal operation through the whole of Polynesia, is practised to a great extent in the Sandwich Islands. By means of it, a whole people is contented to be robbed of their property, and to suffer any privations that may be imposed on them without murmuring. When their houses are *tabooed* they dare not enter them; when their *taro-roots* or their hogs are *tabooed*, they surrender them without a struggle; but in return, it must be owned, they are not scrupulous in appropriating to themselves whatever is not *tabooed*.

Among the customs which they inveterately retain is that of *tattooing* the body, this operation being also universal among the islanders of the Pacific. The hands and arms of the women, in particular, are mark-

ed with peculiar elegance of figure, and many of the women have the tip of the tongue tattooed. Contrary, however, to the common practice of the islanders, they do not paint their bodies, nor wear ornaments of any kind in the ears; but the women decorate their hair, which is cut short, with wreaths of flowers, and wear necklaces, bracelets, and anklets of shells, coral, and other substances. The common dress of the men is the *maro*, a piece of cloth about a foot wide, which, passing between the legs, is tied round the waist; that of the women is a short petticoat, reaching about half-way down the thigh. The chiefs, on days of ceremony, and on particular occasions, wear cloaks made of the most beautiful feathers, with an elegant shaped helmet to correspond. They are ambitious, however, to appear in the dress of Europeans, to enable them to do which, great quantities of old laced coats are carried out to the Sandwich Islands, as articles of commerce.

To whatever degree of civilization the Sandwich islanders may have attained, since the first discovery of Captain Cook, it is to be ascribed, as we said before, to the personal character of Tamaa-mah; but whether they will continue to proceed or to retrograde, on the death of this extraordinary man, is a matter of great doubt, considering the character of his son and successor. The old man, however, has caused him to be *tabooed*, or made sacred, so that nobody is allowed, on pain of death, to see him by day. This being done, he receives the appellation of *Leo-leo*, "that is," says Kotzebue, "dog of all dogs; and such we really found him."—"We entered," he continues, "a neat and small house, in which Leo-leo, a tall, corpulent, and naked figure, was stretched out on his stomach, and just indolently raised his head to look at his guests; near him sat several naked soldiers armed with muskets, who guarded the monster. A handsome young native, with a tuft of red feathers, drove away the flies from him—The dog of all dogs at last rose very lazily, and gaped upon us with a stupid vacant countenance." His age is stated to be about twenty-two, but his corpulency is somewhat enormous for one so young. This description does not certainly portend much in favour of the future happiness of the Sandwich Islands, for the vacant government of which there will probably start up many competitors. An European of talent, if such there should happen to be on the spot, might probably succeed to the government and civilization of this good humoured, and by no means untractable people.

4. *Coral Islands and Reefs*.—The number and position of the multitude of low islands, sometimes found in groups, and sometimes solitary, are by no means yet ascertained; but from the various tracts of ships, it is known that the whole of that part of the Pacific lying between the equator and the 10° of north latitude, and from the Pellew Islands, to 180° longitude, being at least forty-five degrees of longitude, is completely studded with low coral islands and reefs in countless numbers, some of them inhabited, and others not; and in different stages, from the circular reef, with islets rising upon it like the beads of a necklace, with a lagoon in the centre, to the complete consolidation into one firm island.

lands and  
Reefs.

Polynesia. About the tenth parallel, and proceeding easterly from the Carolinas, we have Button, Tindall, Watt's, and Gilbert's Islands; and about the longitude 175° east, a whole group, extending to the southward of the equator, named on some charts "Lord Mulgrave's Range," on others "Scarborough's Range;" some of the individual islands of which are Smith's, Allen's, Gillespie's, Toulmin's, Hopper's, Chatham's, Calvert's, Robertson's, Arrowsmith's, Daniel's, Marshall's, Pott's, near to which are Kingmill's Group and Byron's Island, all of coral formation.

Various accounts have been given by Cook, Forster, Flinders, and others, of the progressive formation of these low specks of land, with which the Pacific is studded; but the best and most satisfactory is that by Kotzebue and the naturalist Chamisso. They not only saw the "Lord Mulgrave's" chain of islands, which extend from 1° to 12° N., of which Gilbert's Islands form the northern, and Marshall's Island the southern, extremity, but they discovered and examined minutely many other groups and detached islands. Between the eighth and tenth degrees of north latitude, and between longitude 188° 48' and 190° 46', they fell in with no less than six distinct groups, to which they understood the natives applied the name of Radack; and they learned that to the westward were nine other groups, and three detached islands, called Ralick, besides four groups to the southward. The Radack chain is probably those which were seen by Captain Marshall in 1788, and to which he gave the name of Chatham and Calvert Islands, though Krusenstern thinks that these are the same as the Ralick chain. It is not of much importance, in a geographical point of view, whatever it might be for the benefit of navigation.

The small size of Kotzebue's vessel gave him the advantage of sailing through the openings in the circular reefs, and of examining the lagoons within them. From his account, it would seem that the coral-making animals do not commence their labours at the very depth of the ocean, as has been supposed, but on rocky shoals, the summits, in all probability, of submarine mountains, round which they lay the foundation of their extraordinary fibres, forming an united chain, irregular in shape, but generally approaching, more or less, to a circle. The greatest depth at which they are able to derive a sufficient degree of light and heat for their operations has not yet been ascertained; but we know that marine animals have been drawn up in a living state from the depth of a thousand fathoms, and from a temperature very little above that of the freezing point. The outer edge of the reef exposed to the surf of the sea is the first that shows itself above water; in process of time, it becomes indurated, breaks, and crumbles, by the action of the sea, and at length forms a sort of barrier, within the sloping sides of which the living animals are seen carrying on their operations. Those observed by Chamisso were the *Tubipora musica*, the *Millepora cærulea*, *obstichopora*, *actimas*, and various kinds of the polypus. He found the living branches of the *lythophytes* generally attached to the dead stems; many of the latter, however, crumbled into sand, which, accumulating on the inner declivity, constitutes no inconsiderable part of the surface of

Polynesia. the new islands, which rise out of this reef, and are gradually united into one island, having in its centre a salt water lake, that alternately grows up by a silent and slow progress, till what was at first a chain of islets, has become one connected mass of land. The progress towards a state fit for the habitation of man is thus described by Chamisso:—

"As soon as it has reached such a height, that it remains almost dry at low water, at the time of ebb, the corals leave off building higher; sea-shells, fragments of coral, sea-hedgehog shells, and their broken off prickles, are united by the burning sun, through the medium of the cementing calcareous sand, which has arisen from the pulverization of the above-mentioned shells into one whole or solid stone, which, strengthened by the continual throwing up of new materials, gradually increases in thickness, till it at last becomes so high, that it is covered only during some seasons of the year by the high tides. The heat of the sun so penetrates the mass of stone when it is dry, that it splits in many places, and breaks off in flakes. These flakes, so separated, are raised one upon another by the waves at the time of high water. The always active surf throws blocks of coral (frequently of a fathom in length, and three or four feet thick) and shells of marine animals between and upon the foundation stones; after this, the calcareous sand lies undisturbed, and offers to the seeds of trees and plants, cast upon it by the waves, a soil upon which they rapidly grow, to overshadow its dazzling white surface. Entire trunks of trees, which are carried by the rivers from other countries and islands, find here, at length, a resting place, after their long wanderings: with these come some small animals, such as lizards and insects, as the first inhabitants. Even before the trees form a wood, the real sea-birds nestle there; strayed land-birds take refuge in the bushes; and, at a much later period, when the work has been long since completed, man also appears, builds his hut on the fruitful soil, formed by the corruption of the leaves of the trees, and calls himself lord and proprietor of this new creation."

#### IN THE SOUTHERN HEMISPHERE.

1. *The Friendly Islands*.—The Friendly Islands, among which may also be included the Feejee Islands, were first discovered by Abel Jansen Tasman in 1643, to three of which he gave the names of Amsterdam, Middleburgh, and Rotterdam. The first of these islands is that which was afterwards visited by Captain Cook, and described by him under the name of Tongataboo; more properly, as we since learn from Mr Mariner, *Tonga*, the annexed word *Taboo*, so extensively used throughout Polynesia, being expressive only of its sacred character. From the inhabitants of this island Tasman received yams, cocoa-nuts, bananas, hogs, and fowls, in exchange for iron, nails, beads, and pieces of linen. They had also plenty of sugar-canes. Women as well as men swam off to the ship, and it was observed that all the elder dames had the little finger of both hands cut off, but the young women had not. They wore round the middle a covering of mat-work, which reached down to their knees; the rest of the body naked. None of the

Polynesia. men would taste wine, and they were ignorant of the use of tobacco; they had no arms of any kind, which led Tasman to conclude that they lived in perpetual peace and friendship.

Produce of the Islands, and the Natives.

Tasman next touched at Ammomooka, or, as he called it, Amsterdam Island, in the hope of meeting with better water than on the first, where it was bad and scanty. On landing, they perceived some sixty or seventy persons sitting quietly on the shore, who had no arms of any kind, and appeared to be a harmless and peaceable people. There were, besides, many women and children, the former clothed like those on Amsterdam Island, but they were of a larger size, and as strong in their bodies and limbs as the men. The party was shown to a piece of fresh water not a mile from the shore, about a quarter of a mile in circumference, and about a musket-shot from the north side of the island, where there was a good sandy bay. Here they watered their ships, and received abundance of provisions, the same in kind as those of the other island. The inhabitants are described as being great thieves, but very friendly. They have large vessels with masts, sails, and outriggers, as well as canoes, and on going into the interior of the island it was observed that all their plantations were laid out in neat and regular order. "In our walk," says Tasman, "we saw several pieces of cultivated ground or gardens, where the beds were regularly laid out into squares, and planted with different plants and fruits; bananas and other trees placed in straight lines, which made a pleasant show, and spread round about a very agreeable and fine odour; so that among these people, who have the form of the human species, but no human manners, you may see traces of reason and understanding." He says they have no religion, no idols, relics, or priests; but that they have their superstitions, as a man was seen to take up a water-snake, which, after placing it respectfully upon his head, he threw back into the water. Indeed, they seem averse from hurting any thing that has life, for though the flies are numerous and troublesome, they will not kill them, and one of the principal people was offended on perceiving the steersman kill a fly, though accidentally. Captain Cook bears testimony to the beauty and fertility of the Tonga Islands. "There was not," says this celebrated man, "an inch of waste ground; the roads occupied no more space than was absolutely necessary; the fences did not take up above four inches each, and even this was not wholly lost, for in many were planted some useful trees or plants. It was everywhere the same; change of place altered not the scene; nature, assisted by a little art, nowhere appears in more splendour than here." The missionaries, too, in 1797, found these islands in as high a state of cultivation and beauty as they appeared to Tasman and to Cook.

Revolution in the Government.

A woeful difference in their peaceable habits, according to Mr Mariner, has taken place since the visits of these Europeans. In 1799 a revolution took place, and from that time bloody wars and most savage slaughter have desolated these beautiful islands. They first commenced, as it would appear, by a most atrocious savage, in whom the kingly power was vested, who not only practised the most barbarous

cruelties on his subjects, but seized upon the sacred or ecclesiastical power, which had always, as in Japan, been kept separate from the secular arm. The sacred spell being thus broken, which rested solely on public opinion, a complete revolution followed, and from that hour these once happy islands have been the scene of slaughter, famine, and every species of horror and misery. We must not, however, give implicit credit to all that has been stated by Dr Martin, the writer of Mariner's account of these islands, but rather consider it as a romantic exaggeration of facts and descriptions, similar to that of the Pellew Islands by Mr Keats. There are shades of difference merely between the inhabitants of these and of the neighbouring islands.

2. *Navigator's Islands*.—To the north-east of the Feejee, Tonga, or Friendly Islands, are situated the Bauman or Navigator's Islands. The first name was given to them after Captain Bauman, of the Teinhoven, by Jacob Roggewein, by whom they were discovered in 1722; the latter name was conferred by Bougainville, who passed them in 1768. La Perouse likewise visited these islands, and is of opinion that they are not the same as Bauman's Islands, because their geographical position does not agree with that assigned to them by Roggewein. Burney, however, has no doubt that they are identical, the only difference being in their supposed longitude, which, in the time of Roggewein, was frequently set down erroneously by several degrees.

These islands form an archipelago, consisting of ten in number, according to La Perouse, of which Maoua, Oyolava, and Pola, are the largest and most beautiful. The parallel of 14° south latitude, and the meridian of 190°, pass through the centre of the group. They are said by La Perouse to be volcanic, but surrounded by coral reefs. Roggewein describes the hills and valleys as affording a delightful prospect. The natives came off in boats neatly made and carved, bringing fish, cocoa-nuts, and plantains. They are said to have white skins, but tanned by the sun, gentle in their manners towards each other, lively and good humoured; their bodies were neither painted nor marked, and they were clothed from the waist downwards; the cultivated grounds were all enclosed, and, in short, they are described by the writer of Roggewein's voyage as the most civilized and honest people they had met with among the islands of the South Sea. We may conclude, indeed, from his account, that they were equally well cultivated, and the inhabitants equally mild and peaceable with those of the Friendly Islands.

Description of the Islands and Natives.

Very different, however, is the account given of them by La Perouse. Ferocious in the highest degree, he describes them as utterly destitute of gratitude and every good moral feeling; that a look of disdain is stamped on all their countenances, and that they are eternally fighting with each other, so that their bodies are covered with scars occasioned by the blows of clubs. Tall in stature, their limbs are of colossal proportions; and their bodies are tattooed to such a degree as to make them appear clothed, though they have only a girdle of sea-weeds round their loins, which reaches to the knee. The

Navigator's Islands.

Polynesia. size of the women corresponds with that of the men, and their whole behaviour is represented as highly indecent and disgusting. They had no desire for iron, preferring their own adzes and other tools made of basalt. Their huts were made with great nicety, and all their wood-work was highly polished and carved. Their matting and cloth were exceedingly beautiful; the latter woven with thread made from the nettle, and a species of flax. The sails of their boats or canoes were made of this cloth. The islands are so intersected with creeks, that they travel from place to place almost universally in canoes, which have outriggers to prevent them over-setting.

Fertility. All the islands were clothed with trees up to the very summit of the hills, many of them laden with fruit. The villages are ranged along the margin of the streams which fall from the mountains, and are built in the midst of groves of cocoa, banana, guava, and other fruit trees common to the South Sea islands. The woods abound with wild pigeons and turtle doves, which are tamed by the natives, and kept about their houses in flocks of many hundreds. Sugar-cane grows abundantly and without culture. Their animals are pigs, dogs, and the domestic fowl; these and the fish, which they catch with great expertness, afford them an abundant supply of food.

Society Islands. 3. *Society Islands*.—The first account of these islands is given in the voyage of Jacob Roggewein, who touched at Ulitea in the year 1722; at least it is conjectured by Burney on probable grounds, that the Verquickking or Recreation Island of that navigator is the same. On sending a boat on shore, the inhabitants assembled on the beach, and advanced into the water armed with lances to oppose their landing. The Hollanders fired upon them, and having dispersed them, landed on the beach, and the inhabitants returned in a friendly manner, and brought them cocoa-nuts and other articles of food. The Hollanders then advanced up a valley towards the mountains, but some thousands of the natives coming out of the glens and crevices, made signs to them to return. The Hollanders, however, paid no regard but proceeded, upon which showers of stones were hurled at them, by which some were killed and others wounded. These volleys were answered by a discharge of musketry, which killed many of the islanders, who, nevertheless, continued the action, and finally drove the Dutchmen into their boats. Many of the latter subsequently died of the wounds they had received in consequence of the bad state of their constitutions, being severely affected with the scurvy.

Description. Captain Cook visited these islands in 1769, and again in 1777. They consist of six in number (besides small coral islets), whose names are Ulitea and Otaha (both encompassed by the same coral reef), Huaheine, Bolabola, Tubai, and Maurua. They extend from about 16° to 17° south latitude, and from 151° to 152° west longitude. The climate, the productions, and the inhabitants, resemble so nearly those of Otaheite, that the same description will apply to both. The surfaces of all the islands are uneven and hilly, but not mountainous, and the hills are finely wooded. The inhabitants, like those

Polynesia. of the Navigator's Islands, are generally of a larger stature than the Otaheitans. The late Sir Joseph Banks measured one of the natives of Huaheine, and found him to be six feet three inches and a half in height, and the women are described as generally more handsome and somewhat fairer than those of Otaheite. Bolabola differs from the rest of the islands by having a lofty double peaked mountain near its centre, apparently volcanic. In Ulitea there is a large morai, in which a number of jaw-bones are kept as trophies of war. The coral reefs which every where surround these islands form numerous safe and commodious harbours for shipping, and refreshments of hogs, fowls, plantains, cocoa-nuts, and yams, are generally to be had in great abundance.

4. *The Georgian Islands, including Otaheite, &c.* The Georgian Islands. —Otaheite is the chief island of this vast group, which extends over fifteen degrees of longitude, in the direction of south-east. The extreme point is Pitcairn's Island, lately become interesting on account of the discovery of the descendants of the mutineer Christian and some of his associates. The natives of this vast chain of islands, and particularly of Otaheite, may probably be considered as the most civilized, but, at the same time, the most sensual people in all Polynesia. It was first discovered by Quiros, in 1606, and received from him the name of Sagittaria. The natives received the strangers with great kindness, gave them cocoa-nuts and other fruits, and a general interchange of civilities and presents soon took place. This good understanding remained uninterrupted, and the Spaniards, for once, left the island without having quarrelled with the inhabitants. In their zeal, however, they committed an act which, if discovered, might have been attended with unpleasant circumstances. The place at which they first landed was uninhabited, but in passing through a wood they discovered a Morai, in which they concluded "the enemy of mankind resided;" and under this impression, cut down a tree, which they formed into a cross, and planted in the midst of the sacred building.

In 1765, Commodore Byron discovered two low islands to the northward of Otaheite, which, in honour of his Majesty, he named George's Islands, one of which, afterwards visited by Cook, is called Tiookea; the natives of these islands were very dark coloured, robust, and apparently ferocious; their bodies were marked with the figure of a fish.

In 1767, Captain Wallis touched at Otaheite, and went through the ceremony of taking possession of the island in the name of his Sovereign; but the flag was removed by the natives in the night. Various squabbles occurred between the seamen and the natives, who, however, behaved on the whole with great kindness and hospitality. Most of the quarrels were owing to the licentious intercourse of the seamen with the native women. In 1768, M. de Bougainville visited Otaheite, and was most hospitably received; in return for which, several murders were committed by the French seamen. Captain (then Lieutenant) Cook anchored in Matavai Bay in April 1769. It is from this and his several subsequent visits, together with a missionary voyage in the ship

Polynesia. Duff, commanded by Captain Wilson, 1796—1798, that Otaheite is so well known to us.

Otaheite. The island consists of two peninsulas, connected by a low isthmus, about three miles in width, covered with brushwood. The larger, Otaheite Nove, is about ninety miles in circumference, and nearly circular; the smaller, Tiaraboo, is about thirty miles; the whole nearly surrounded by a low belt of land, from a furlong to a mile in width, which is prolonged by a gradual rise to the valleys which run up to the foot of the lofty central mountain. These valleys and their intermediate ridges are beautiful, clothed with a great variety of trees to their very summits; in the valleys are mostly met with clear streams of water, which, in the rainy season, become mountain-torrents. The island being surrounded with coral reefs, is dangerous to approach, and the only safe harbour is that of Matavai, on the northern side, in latitude 17° 30' S. longitude 149° 13' W. This too is not free from danger, from December to March. The climate is delightful, the thermometer seldom rising above 80° in summer, and ranging from 62° to 72° in winter.

Productions. The island is so fertile as to produce every thing in abundance, and without toil, for the sustenance of man. The bread-fruit is here superior to that which grows on the other islands. The fruit affords them a most nutritive food, either for present use, or made into a paste called *mahie*, which will keep till the following season; the trunk supplies them with timber for their buildings and canoes; it exudes a gum, which serves for pitch, and from the inner bark is manufactured a substantial cloth. They reckon no less than thirty varieties of this most useful tree, which, with the different exposures to the trade winds, and the difference of elevation above the sea, afford to the natives a bread-fruit harvest at almost all seasons of the year. The cocoa-nut, next to the bread-fruit, supplies them with meat, drink, cloth, and oil. Of plantains, they reckon fifteen different sorts. Yams and sweet potatoes, taro-root of different kinds, and various other edible roots and fruits, are most abundantly produced; to which our missionaries have added the pine-apple, the grape, and various culinary vegetables of Europe; but the natural and spontaneous productions of the soil, and the consequent indolence of the people, are unfavourable to their success.

Animals. The animals found on the island are hogs, dogs, and rats. Several attempts have been made to introduce the horse and horned cattle, sheep and goats, but without success. The latter are so disliked for their smell and the mischief they did to their plantations, that they drove them into the mountains, where they run wild. The breed of cats has succeeded, and found to be extremely useful; and rabbits have been introduced, but we know not with what success. Common poultry are abundant, and the woods supply vast quantities of wild pigeons and parrots. The tropic-bird builds its nest in the steep cliffs, and as their long feathers are highly valued, they are taken on the nest by lowering down a man seated across a stick, by a rope, to the depth of thirty or forty fathoms; in which situation, by means of a long pole, he swings himself from side to

side, examining all the holes as he descends, in order to take the bird on her nest. The shores abound with sea fowl, and the sea with excellent fish, which they take with great expertness by hook and line, or by the net. Dolphins are caught at a distance from the shore, by baiting the hook with a real or artificial flying fish. Their fishing-tackle displays the greatest ingenuity, and can only be exceeded by their skill in using it. Their hooks are made of pearl-shells, bone, and hard wood. The coast abounds with lobsters, crabs, and various kinds of shell-fish.

Inhabitants. The colour of the natives is that of olive, or light copper. The men are above the middle size; the chiefs almost uniformly tall, muscular, and well-limbed, measuring from five feet nine inches to six feet four inches, and continue healthy and vigorous to a good old age. The women of the upper ranks are also tall, with limbs finely turned. Their skins soft and delicate; eyes black, sparkling, and full of expression; teeth beautifully white and even; their hair jet black, and generally ornamented with flowers; in their gait they are firm, but easy and graceful. From a custom of compressing the face when infants, they can scarcely be called beauties; yet, according to the account of Captain Wilson, they possess feminine graces in an eminent degree; "their faces never being darkened with a scowl, or covered with a cloud of sullenness or suspicion." They are affable and engaging; mild, gentle, and unaffected; courteous to each other and to strangers. The whole of the body to the middle of the leg is clothed; but there is a singular custom which compels a woman to uncover her shoulders and breasts in the presence of a chief, or in passing a morai, or sacred place. The lower classes have always been described as extremely licentious, but Captain Cook says they have been much calumniated. "It is too true," say the writers of the Missionary Voyage, "that, for the sake of gaining our extraordinary curiosities, and to please our brutes, they have appeared immodest in the extreme. Yet they lay the charge wholly at our door, and say the Englishmen are ashamed at nothing, and that we have led them to public acts of indecency never before practised among themselves." It must be admitted, however, that the most abandoned conduct is freely indulged by the women of the Arroy society, who, to the crime of unbounded licentiousness, add that of murdering their children the moment they are born. In recent accounts, however, it is stated, that this horrible practice has been abolished, and that Christianity is making a rapid progress among these interesting islanders.

As wives, the Otaheitan women are tenderly affectionate to their husbands and children, nursing and attending the latter with the utmost care. They never, on any occasion, strike a child. A melancholy instance of the fidelity and affection of one of these women is given in the *Missionary Voyage*. "The history of Peggy Stewart marks a tenderness of heart that never will be heard without emotion. She was daughter of a chief, and taken for his wife by Mr Stewart, one of the unhappy mutineers (of the Bounty). They had lived with the old chief in the most tender state of endearment; a beautiful little

Polynesia. girl had been the fruit of their union, and was at the breast when the Pandora arrived, seized the criminals, and secured them in irons on board the ship. Frantic with grief, the unhappy Peggy flew with her infant in a canoe to the arms of her husband. The interview was so affecting and afflicting, that the officers on board were overwhelmed with anguish, and Stewart himself, unable to bear the heart-rending scene, begged she might not be admitted again on board. She was separated from him by violence, and conveyed on shore in a state of despair and grief too big for utterance. Withheld from him, and forbidden to come any more on board, she sunk into the deepest dejection; it preyed on her vitals,—she lost all relish for food and life,—rejoiced no more,—pined under a rapid decay of two months, and fell a victim to her feelings, dying literally of a broken heart.”

The Otaheitans are generous even to a fault; they seem to be utterly unable to resist importunities, and always ready to share their last morsel with their neighbours. Poverty is no reproach, but affluence with covetousness brings contempt on the owner. Should any one, indeed, refuse to share his property in cases of distress, the chances are that it will be destroyed, and his house pulled down over his head. The office of king is hereditary in one family; the chiefs resemble our ancient barons; under them are the vassals, and below them the *villeins*, or labourers. The king and queen enjoy many privileges, one of which is, to be carried about every where on men's shoulders; and the reason of this is, that whatever soil they tread upon becomes sacred, and belongs to them; so also, if they enter a house, it is rendered sacred, and becomes their property. Their domestics and attendants are also *raa*, or sacred, and for thieving, plunder, and all manner of licentiousness, they are said to be the worst on the island.

In the *Missionary Voyage* is given an account of the ceremony of investing the new sovereign with the royal *maro*, when each chief of the island, amounting to nearly one hundred, brings one, two, or three human victims, to offer up on the occasion. They are brought before the sovereign in a lifeless state, having first been stoned to death, or knocked on the head with clubs. From each of these victims the priest scoops out an eye, and presents it to the king on a plantain-leaf, and the bodies are then carried away and interred in the *Morai*. The reason assigned for this oblation is, that the head being accounted sacred, and the eye the most precious part, it is presented to the king as the head and eye of the people. During the presentation the king holds his mouth open, as if devouring it, whereby it is imagined he receives additional wisdom and discernment. The royal *maro*, and the sacred canoes which brought the human sacrifices, are then deposited in the *Morai*. A series of feasts then begin, which continue for two months. These abominable rites, if not entirely abolished, have, in a great degree, ceased by the influence of the missionaries.

In their language and their deities may be traced their Hindoo origin; and, though their religion is a tissue of superstitions and brutal ceremonies, they never draw near to their *Eatova* with carelessness

and inattention. Captain Cook testifies to the decorous conduct of an Otaheitan on such occasions: “He is all devotion,—he approaches the place of worship with reverential awe,—uncovers when he treads on sacred ground, and prays with a fervour that would do honour to a better profession.”

On the whole, the Otaheitans are not only the most advanced in civilization, but inhabit the fairest and most fertile island of Polynesia. Taking into account, as Captain Wilson says, its amenity, the salubrity of the climate, the plenty of fine water, spontaneous productions of the earth, the rich and most romantically picturesque appearances of the country, “he felt the justice of the title given to Otaheite by one of the navigators, as the ‘Queen of Islands.’” The latest accounts received from the missionaries are most gratifying. One of them thus concludes: “Public immorality, drunkenness, and profane swearing, are unknown here. All their former sports and amusements are completely put down. Their *morais* are almost all demolished, and many of them completely obliterated; and it is a singular fact, that chapels now occupy the very ground on which many of them stood.”

With such a people is the north-western extremity of the large group of islands, and the interesting offspring of the mutineers of the *Bounty*, who still preserve their religious habits and purity of manners, on the small island of Pitcairn, at the opposite extremity, a hope may be indulged that, in the course of half a century, civilization will have made a rapid progress, not only throughout the Friendly, Society, and King George Islands, but over a very considerable portion of Polynesia.

5. *The Marquesas*.—This cluster of islands was discovered by Alvarode Mendana in 1595, and named The Marquesas. by him *Las Marquesas de Mendoca*, in honour of the Viceroy of Peru. Four only are described by Quiros the pilot, under the names of *La Dominica*, *Santa Christina*, *San Pedro*, and *La Madalena*. The Spaniards anchored in a port on *Santa Christina*, to which they gave the name of *Madre de Dios*, well protected from the trade-wind, and which has two excellent streams of fresh water flowing into it. The people are described as being an elegant race, the women in particular as remarkably beautiful, whose complexions and general appearance are said to excel those of the women of Lima. Their dress consisted of a cloth made of the leaves of a palm-tree, with which they were covered from the breast downwards; and so civilly disposed were they, that a beautiful native woman seated herself by the side of *Donna Isabel*, the wife of Mendana, and began to fan her. But the Spaniards, as usual, found means to quarrel with the natives, and to drive them with their fire-arms into the woods.

The produce of the island was hogs, fowls, fish, cocoa-nuts, sugar-canes, plantains, and the bread-fruit, described for the first time by the writer of this voyage.

Subsequent discoveries have made us nearly as well acquainted with the Marquesas as with Otaheite. Captain Cook visited them in 1774, and Captain Wilson in 1797. From these we know that they consist of eight islands in number, besides some smaller islands to the westward, which being seen by Description.

Polynesia. an American master of the name of Ingraham, he called them Washington's Islands. They had previously been seen, however, by Marchand in 1789, and may fairly be grouped as part of the Marquesas. The centre of the group may be reckoned in about the latitude  $9^{\circ} 30'$  south, and longitude  $139^{\circ} 30'$  west.

Manners.

The manners, the religious ceremonies; the nairs, and the general appearance of the natives, are so similar to those of Otaheite, that a description of them would amount to little more than a repetition of what has been said. They have all the good qualities of the natives of that island, and most of their bad ones; but owing probably to a more restricted communication with strangers, a greater degree of simplicity was observable in their manners, on the first arrival of the missionaries among them, than in the people of Otaheite. Scarcely had they anchored in Resolution Bay (Madre de Dios), than two women, though dark, swam off to the ship, in the hope of meeting a favourable reception, calling out in a piteous tone, when they found they could not be admitted on board, "*Waheené, waheené!*" We are women, we are women. The next morning the visit was repeated, and is thus described in the *Missionary Voyage*.

"Our first visitors from the shore came early; they were seven beautiful young women, swimming quite naked, except a few green leaves tied round their middle; they kept playing round the ship for three hours, calling *Waheené!* until several of the native men had got on board; one of them, being the chief of the island, requested that his sister might be taken on board, which was complied with. She was of a fair complexion, inclining to a healthy yellow, with a tint of red in her cheek, was rather stout, but possessing such symmetry of features, as did all her companions, that as models for the statuary and painter their equals can seldom be found." Captain Wilson says, that an Otaheitan woman which they had on board was far eclipsed by the Marquesan woman; but she was shocked to see a woman quite naked walking the deck, and threw over her a dress of Otaheitan cloth; but as for the rest of these females, the goats, it seems, soon stripped them of their green leaves, and left them in a state of complete nudity. On shore the women clothe themselves in decent habits.

The Marquesans are so far superior to the Otaheitans, that they sacrifice hogs only to their deities, and never men. Their houses, canoes, their dress, and the cultivation of their land, are at least equal to those of Otaheite, and they have none of those infamous *arreey* societies. Captain Porter of the American frigate *Essex*, after brutally massacring a number of these people on the most frivolous pretext, charges them with cannibalism, though, from his own account, there does not appear the slightest ground for so injurious an imputation. To all unprejudiced navigators they have appeared as an amiable people, entertaining a great respect for old age, fond of their children instead of murdering them, as on Otaheite and some other islands, and living in

peace and harmony with each other, and with their families. Polynesia.

6. *Easter Island*.—This small island, not 30 miles in length, is only deserving of notice from its solitary position, its great distance from any of the islands of the Pacific, its comparative proximity to the coast of South America, and its being inhabited by a race of men who differ no more from the rest of the Polynesians than they do from each other; having the same language, the same features, the same religious notions, and Morais constructed as they generally are in other islands; on the platforms of which are erected shapeless and uncouth masses of stone, carved in imitation of the human bust, with rude faces four or five feet long, set on trunks of ten or twelve feet in height. Kotzebue, the last visitor to this island, looked, however, in vain for any traces of these statues on the spots where they are described by Cook and La Peyrouse. Easter Island.

This island is supposed to have been discovered by the Buccaneer Davis in 1687; though some have contended for the Dutch Admiral Roggewein being the discoverer, who gave it the name of Paaschen, or Easter Island, having first seen it on the day of that feast. Its latitude is  $27^{\circ} 5'$  south, and longitude  $109^{\circ} 46'$  west.

It is not remarkably fertile; few trees are found on it, and no running stream. The natives are very industrious in raising food for their support, which consists chiefly of bananas, taro-root, sugar-canes, sweet potatoes, and yams. By some navigators they are described as a very savage people, by others as a mild and amiable race:—the fact is, that their conduct has corresponded with the treatment they have received from strange visitors. Thus their decided hostility to Kotzebue, when he attempted to land on the island, was explained on his arrival at the Sandwich Islands. An American commanding a schooner called the *Nancy* from New London, had observed a vast multitude of seals on the shores of the small uninhabited island of Massafuero, to the westward of Juan Fernandez; and thinking it might turn out an excellent speculation, if a small establishment were formed on the island, to carry on the fishing, set about the means of carrying this project into effect. His own crew was but just sufficient to navigate the vessel, and there being no anchorage off the island, could not be spared to catch seals. The brutal wretch, therefore, proceeded to Easter Island, and landing at Cook's Bay, seized and carried off twelve men and ten women to people his new colony. For the first three days they were confined in irons, and were not released till fairly out of sight of land, when the first use they made of their liberty was to jump overboard, choosing rather to perish in the waves than to be carried away they knew not whither, or for what purpose; the women, who were with difficulty restrained from following them, were carried to Massafuero, but what ultimately became of these poor creatures M. Kotzebue does not relate. No wonder then that such base and inhuman practices should drive the natives to acts of hostility against all foreign intruders. (K.)

## P O O R - L A W S .

Poor-Laws. **T**HE laws comprehended under this title, and regulating the relief, maintenance, and employment of the poor, form so important and peculiar a feature in the polity of England, as to demand a careful notice. Especially as the administration of the system, within the last twenty-five years, has been so essentially altered, as to render any previous account, in a great measure, obsolete: and the effects of the system have been so widely extended, and so sensibly felt, as to obtain a considerable degree of public attention.

We shall, therefore, under this article, explain, as briefly as possible, the laws on which the English Poor-System is founded; their practical administration; their effects political and moral; and the principal plans which have been proposed for the mitigation and ultimate removal of the evils inseparable from a system of compulsory and indiscriminate relief, involving an interference with the general concerns of a large portion of the community.

Origin of the Poor-Laws. It is not necessary to trace, particularly, the circumstances of difficulty and hardship, to relieve which the compulsory provision for the poor was first instituted. From the date of the earliest statutes, the middle of the sixteenth century appears to have been the period when the number and wants of the poor began to attract legislative attention. In 1536, 1550, 1561, and 1563, sundry statutes were passed directing that every aged, disabled, and impotent person, should be relieved and kept in the place where they were born or had dwelt three years; and in the last of the acts referred to, the justices of the peace were empowered to make the payment of assessments for these purposes compulsory. The sudden alienation of the abbey-lands, the cessation of all customary relief from the monasteries, together with the rapid increase in the money price of commodities, occasioned by the influx of the precious metals from America (estimated at 50 *per cent.* between the years 1550 and 1580), sufficiently account for the pressure on the labouring classes which these provisions were intended to remove.

However, in spite of all palliations, this evil grew, and led to the famous act of the 43d of Elizabeth, which continues to this day the fundamental and operative law on this important subject. This statute enacts, "That the churchwardens and overseers shall take order from time to time (with the consent of two or more justices) for setting to work the children of all such whose parents shall not be thought able to keep and maintain their children; and also, for setting to work all such persons, married or unmarried, having no means to maintain them, and using no ordinary or daily trade to get their living by; and also, to raise by taxation, &c., a convenient stock of flax, to set the poor on work; and also competent sums of money for and towards the necessary relief of the lame, impotent old, blind, and

such other among them, being poor and not able to work." Poor-Laws.

By this enactment, the State virtually undertook to do two things, which were never before attempted by any national or legislative provision. It became pledged to support, at the public expence, all the poor, aged, and impotent members of the community; and, far worse, to provide employment for all those who would not or could not procure it for themselves. Results of the Act of Eliz. 43.

The first of these undertakings, however humanely designed, is found by experience to eradicate some of the finest principles of human nature, and to create more distresses than it remedies.

The second, which compels the overseers to set to work all those for whose labour there is no natural demand, is in decided opposition to the known rules of political economy. The number of persons that can be employed in labour must absolutely depend upon the amount of the funds applicable to the maintenance of labour; so that, an enactment, engaging to find employment for as many as may demand it, undertakes a condition which it is not in the power of any law to fulfil.

The wonder which arises at the first view of a system like this—a system which has the radical fault of assuming, or establishing, the right of the poor, *i. e.* as it may turn out, of the whole community, to support, at the expence of the community, is, that it should have existed more than 200 years, without occasioning the complete destruction of prosperity. This, however, is no proof of the innocence of the law; it results from the mode of its execution and administration. When persons were only relieved in their own parishes, and when relief was only to be had by application to an overseer, and often, of course, distributed in a capricious and insulting manner, few would seek it who could possibly subsist otherwise, and a becoming spirit of independence diminished the number of claimants. But above all, it was ordered by the law that the idle should be set to work, and the paupers maintained in *workhouses*.

Accordingly, workhouses existed in all large towns; in most considerable villages, and in some districts, where the parishes were small, a common workhouse was established by the union of several neighbouring parishes. Nothing could render these receptacles a comfortable abode, except the wisest management and most vigilant inspection. But few persons capable of adequately discharging such an office would undertake so unpromising an employment. All ages, and all characters,—the orphan or the illegitimate child; the prostitute female, the idiots of the parish, the idle vagabond, whom no master would take the trouble to reclaim; the aged widow and the decrepit labourer; the most pitiable members of society, and those who had the least claim to compassion, were crowded into one comfortless home, and joined their quarrels, their com-

Administration of the Law up to 1795.

Poor-Laws. Poor-Laws.  
 complaints, and their sorrows together. Those who had any sense of comfort or decency, would submit to the severest privations rather than obey the threatened alternative, and go to the workhouse.

So that, twenty-five or thirty years ago, the expenses arising from the poor-laws were, in a great measure, confined to the maintenance of workhouses; and the workhouses were a resource for the aged, destitute, and impotent; a place of restraint for the idle and disorderly, and an object of terror to the able and industrious. The out-door relief was not extended beyond occasional assistance during temporary illness, or the woman's confinement; or beyond the payment of a part of the rent of the cottage in cases of large families; or a small weekly allowance to a few infirm persons of good character, who made up the rest of their support, by such trifling works of industry as they were able to perform. Some encroachments, no doubt, took place from time to time, and in peculiar situations, on these general principles of public relief; but no man in health and in work ever thought of applying for parochial pay: and as artificial encouragement had not yet disturbed, in any material degree, the general adaptation of the supply to the demand for labour, want of work was not a common case. Thinking people, it is true, even then foresaw that the principle of the poor-laws was fundamentally wrong, and had a tendency to create the distress which it professed to remove; and particularly, they argued, that the idea of providing employ at the public expense was contrary to every sound rule of justice and policy. But, in fact, this part of the act of Elizabeth had not then been called into extensive operation, and went little further than the wholesome purpose of keeping those employed who were collected in workhouses; while the discipline, the disgrace, and the misery of the workhouse itself, acted the useful part of stimulating industry, and encouraging independence, as long as the alternative of entering it, or of providing independent support, was left by the Legislature, enforced by the parish, and required by the magistrate.

Notwithstanding these checks, however, to the natural consequences of the system, the assessment to the poor is found to have progressively increased at every period for which returns have been preserved. The average sum applied to the relief of the poor for the years 1748, 1749, 1750, was L. 690,000 *per annum*. In 1776 it amounted to L. 1,531,000, an increase far beyond what the rise in the prices of corn would justify; \* in 1783-4-5, to L. 2,000,000, though the average price of corn had fallen during the nine intermediate years: † so that such gradual increase, in spite of all obstacles, and without any sufficient ex-

ternal cause, can only be attributed to the known tendency of regular and indiscriminate charity to create its own objects.

But in the year 1795 a change took place in the administration of the poor-laws, which has completely altered the state of the country. This was a winter of unusual scarcity. The price of corn *per quarter*, which for the three preceding years had stood at L. 2, 14s., averaged more than L. 4 during the whole of 1795 and 1796. As the returns of labour could not be expected to keep pace with such a sudden rise in the necessaries of life, distress was universal; and there appeared as claimants for parochial relief not only the infirm and aged, but the able-bodied and industrious, who had few of them ever before resorted to the parish, and that only during temporary illness and disability. It was at this season of acknowledged difficulty that the county magistrates, first in Berkshire, and afterwards in other parts of the middle and south of England, agreed to relieve the poor according to a fixed and uniform scale, regulated by the price of bread; and issued a table, which professed to show, at one view, what *should be* the weekly income of the labouring poor, which it fixed in a certain ratio, according to the price of bread, and the size of the family. ‡ Whatever the man's labour produced less than the provisions of this table required was made up by the parish, whose compliance was subsequently enforced by the Legislature; and the justices were empowered, under certain conditions, to order relief out of the workhouse, and to those who possessed property of their own. 36th Geo. III. c. 23.

The practical operation of this system is as follows: Practical Every labourer is presumed to require a gallon loaf of standard wheaten bread, weekly, for every member of his family, and one over: *i. e.* four loaves for three persons; seven for six.—A. B. has a wife and four children; he claims seven gallon loaves, costing, we will suppose, 12s. But his wages are only 9s.: therefore the parish supplies him with 3s. weekly. C. D. has a wife and six children; he requires nine gallon loaves, or 14s. 8d. He earns 10s.; the parish makes up the rest. E. F. is so idle and disorderly, that no one will employ him; but he has a wife and five children, and requires eight gallon loaves for their support. His allowance, then, is 9s. in lieu of the wages which he ought to earn, and 5s. or 6s. to make up the deficiency of these wages.

Many, we doubt not, of the readers of this article will imagine that this is a remarkable or insulated case. So far from it, this sort of machinery has been going on, not only in a single parish, or a single district, but throughout half the country during

\* Between 1750 and 1776, the price of wheat had risen from 35s. to 48s. The advance of price would thus account for an increase of about one-third, making the charge for expenditure upon the poor L. 920,000; and the population being increased about eighteen *per cent.*, brings an addition of L. 165,600; making L. 1,085,000 as the *natural* increase, instead of the *actual* increase, L. 1,531,000. See *Second Letter to Mr Peel on the Increase of Pauperism*, p. 84.

† Average price of corn for ten years preceding 1775, L. 2, 11s. 3½d.; average from 1775 to 1785 L. 2, 7s. 8½d. The increase of population during that period did not exceed six *per cent.*

‡ For the first introduction of this system, see Sir F. Eden *on the Poor*, Vol. I. p. 579, &c.

**Poor-Laws.** the last twenty-five years. It is, in short, universal in the agricultural counties, with such trifling variations as the discretion of some magistrates, or the indiscretion of others, may have locally introduced.

The magistrates with whom this fatal scale originated were actuated, no doubt, by feelings of humanity. The evil against which they had to contend was pressing; the price of provisions was rapidly rising, and the wages of labour bore no proportion to that increase; so that a man's weekly pay was clearly insufficient to support his family. The crisis, too, was formidable; discontent and insubordination existed very widely; and it was naturally thought, that, if real were added to imaginary evils, and hunger sharpened the exacerbation of previous ill temper, the peace of the community might be seriously endangered. The people had been often taught that revolution would make their condition better; and if it became clear that nothing could make it worse, no slight additional force would be given to the arguments of the evil-disposed and discontented. In these difficult circumstances, two modes of administering relief lay before them: one was a compulsory augmentation of the wages of labour to meet the existing case, which they were then empowered to order by a statute 5th Eliz. c. 4, since wisely repealed; the other was the enlargement of parochial aid, in the way we have described. Of two plans, both radically bad, it would be hazardous to decide which might have been followed with less permanent evil to society. Upon the consequences of interfering with the wages of labour, we can only speculate; but the consequences of legalizing this mode of public relief are too plainly written to be concealed. From its publication and general adoption, the industry of the lower classes has deteriorated; their independent feeling has been annihilated; the public burdens have been enormously increased; and the proportion of supply and demand in all the numerous departments of labour has been deranged.

Every new experiment in legislation is interesting to the philosophical inquirer, and valuable to the practical statesman. A system like that which we have been describing, in particular, has placed the inhabitants of a great country in so new and untried a predicament, that it becomes a matter of singular importance to trace its effects, political and moral. The poor, it must be acknowledged, in all crowded and highly civilized states, present a problem of great embarrassment. Where so much wealth and so much penury are seen in opposition; where there is on the one side so much superfluity, on the other so much deficiency; a plan which promises a nearer equalization of the comforts of life brings a strong recommendation, at first sight, to the best feelings of the legislator and the moralist. On this account, our English system of poor-laws has been the subject of frequent eulogy;—has been glanced at with a view to its adoption both with reference to France and Ireland; though the rulers of these countries have hitherto been wisely contented rather to take our warning than to follow our example. Scotland is still in a more hesitating state.

We shall therefore think it necessary, in this place,

to point out the consequences of this artificial system, both as they affect the community which affords the relief, and the individuals who receive it. And it will be seen that the general principle which condemns such interference has been strongly confirmed by the practical evils resulting from its infraction.

1. The first, and perhaps the greatest of the political mischiefs occasioned by the poor-laws is this; that they disturb the due proportion between the supply of labourers and the demand for labour. They encourage population, without reference to the funds by which that population is to be supported. They persuade the lower classes to marry as soon as inclination prompts, as if it were needless to reflect whether they can maintain the probable issue of that marriage.

**Poor-Laws.**  
Political  
Mischiefs  
of the Poor-  
Laws.  
1. Disturb  
the Natural  
Course of  
Population.

In the natural and healthy course of things, the case of a society increasing too fast can hardly occur in a state of civilization. Some part of the community, indeed, will be pushed to distress and indigence in all countries; but this is not to be set to the account of over-population; it results from the misfortunes to which mankind are subject, and the vicious conduct in which they indulge; and may exist to a considerable extent, where it could not be argued that the country was over-peopled. The natural arrangement is, that a man and his family should depend upon himself; should be supported by his own personal exertions: and knowing this, he considers before he marries whether the ordinary wages of labour in his peculiar vocation will support the probable expenses of the family which he has a right to expect: and if otherwise, he forbears to marry till he can either get better employment, or has laid by some provision to go in aid of his weekly earnings. When labour is so plentiful in the market, that he can only procure employ for half or two-thirds of the year; and when it is so scantily repaid, that though he may earn sufficient to support himself, he can do no more—then he has a clear intimation that he cannot marry without the risk of entailing severe want upon himself and his family. Therefore the labourers, and the demand for labour, keep pace together, by a gentle and equable arrangement, which acts wherever mankind are so far civilized as to know the use of reason, and so prudently governed, as to be allowed to exercise it.

But the law which compels the public to furnish employment to as many as come to claim it, and regulates the wages given in return, not according to the market price of labour, but according to the wants of the labourer, removes at once the natural spring which adjusts the proportion between the demand and the supply of labourers, and exposes the country to all the evils of a redundant population. For as matters are now disposed in England, the question is not whether the parent can support his probable family, but whether the parish will; and the parish pledges itself, by allowed custom, to discharge the parental duty, when it allots a regular addition to the wages of labour in proportion to the number of children. A large family of children is a treasure in America, because such is the demand for labour, that they can in very early life do more than maintain themselves: and they are a treasure in a country

Poor-Laws. most unlike America, namely, in the agricultural districts of England, because, according to the *lex Julia* which prevails, they place more of the public money at the disposal of the father.

Strange to say, an elaborate defence of the poor-laws has been attempted on this very ground, that they are calculated to accelerate the progress of population at the cheapest rate to the community. Men are not inclined, it is said, to burthen themselves with a family, unless they can promise themselves a reasonable share of comfort. That comfort can only be secured by high wages. But high wages cannot be limited to those who deserve them by their services to the state, in rearing a numerous family: They must be given to single as well as to married men—to those with small families as well as those with large. This would be unpardonably extravagant. Let us therefore sink the price of labour, but secure a support to those meritorious members of society, who furnish the manufactories and the armies with their superfluous children. Let “the law say, “provide the state with children, if you are inclined to marriage; and, should the produce of your industry not be sufficient to rear them in health and vigour, here is a fund that will supply deficiencies; or, if the expense of rearing them prevents your making a provision for old age, here is a fund out of which you shall be supported with decency, whenever your infirmities prevent your power of supplying yourselves. Such a provision must soon counteract any natural impediment to a full supply of people; and if the application of the fund be guarded by wise provisions, securing a man’s best exertions while capable, and those provisions are not perverted, the population raised thereby will be of the best sort; it will be robust, healthy, and industrious.”\*

Danger of such Interference with Population.

An argument so rash and so contradictory to experience as this requires little confutation. A statesman ought to have far more than human sagacity, who takes upon himself to give direct encouragement to population, which he is allowed to do, by the advocates of the poor-laws, “when it shall appear that an increase of people is necessary to the further progress of a nation in wealth and prosperity.”† This, surely, is an inquiry too profound and complex to be safely entrusted to any statesman: especially when we remember that encouragements to marriage, like those held out by our laws, cannot be appointed *pro tempore*: the engine, once set in motion, cannot be checked or suspended at pleasure; it is itself artificial, but the provisions for its safe operation must, after all, be those alone which nature has established, whose primary laws were violated in the original speculation. Nature has established an index, in the rate of wages, by which the wants of the society as to population may be clearly ascertained. To set aside this index, and substitute the temporary and short-sighted views of a statesman, as to “the wants, resources, and political re-

lations of a country,” is as pernicious in practice as Poor-Laws. it is unphilosophical in theory. Nature, besides, has provided by an universal principle, that the case supposed to justify this rash and impolitic legislation shall never really exist. It is a point proved beyond the possibility of gainsaying, that population will not only increase up to the limit of available subsistence, but beyond it;—will always reach a certain point of distress. Therefore, this instinctive principle, when left to itself, is always ready to fill up every channel of industry by which a family can be maintained. If, then, the politician ventures to interfere, and accelerate the natural force of this principle, he ought first to ensure the continuance of those circumstances which seem to him to require or justify such acceleration. If this is confessedly beyond his power, he has no right to interfere at all.

These obvious objections against disturbing the natural order of things have met with a most striking confirmation since the peace of 1815. The unnatural acceleration which had taken place during the war became at its conclusion the cause of such severe distress, as almost to render peace a doubtful blessing. Extraordinary circumstances continuing certainly for an unprecedented length of time, had given encouragement to extraordinary exertions; the common observer saw nothing unsound or unhealthy in the state, as long as things remained the same; but the first change of circumstances produced a dangerous revulsion, and proved the evil of empiricism in legislation.

This leads us on to the second mischief arising out of the present state of the poor-laws, which is closely connected with the preceding. They tend to overburthen the land, upon which the funds for their support are charged; and thus to introduce a system of universal pauperism. Political Evils of the Poor-Laws. 2. Tendency of Legal Provision to increase Pauperism.

Whatever be the nature of the funds destined to support population, the tendency of population is to increase beyond them. This is matter of experience in every department of labour, from the highest to the lowest. In all the branches of national industry, there are always more claimants for employ than can attain it; and, though the excess, for obvious reasons, is at different periods very different in degree, the redundancy is always on the side of the labourer;—there are always more workmen than can find employment in manufactures;—always more journeymen mechanics than can be supplied with work;—always more agricultural labourers, than, taking the year throughout, can be employed in useful husbandry. Not even the unhealthy, or degrading, or precarious nature of the employ prevents this effect of the expansive principle of population. Chimney-sweeping, street-sweeping, coal-heaving, mining, thieving, and begging, are all pursued beyond the possibility of maintenance; are all followed by claimants for support beyond the amount of support which they are capable of furnishing.

\* *Inquiry into the Policy, Humanity, and past Effects of the Poor-Laws*, page 41. The same argument is supported by the late Mr Rose, in his *Observations on the Poor-Laws*.

† *Weyland on Population and Production*, p. 83.

Poor-Laws. But this tendency to increase, while it stimulates industry and foresight, occasions little practical disturbance as long as the funds by which such claimants are to be maintained arise from *productive* labour, and are dependent on it. Because the pressure of population, while it requires fresh funds as means of support, contributes to increase those funds by the return which it makes in productive labour.

The case is widely different with respect to eleemosynary funds. Those who claim them are continually becoming more numerous; but the funds themselves, the parish funds, or whatever funds the state can employ, though not exactly defined, are necessarily limited by the ability of the payers. The population, therefore, which is dependent upon these funds, being freed from the restraints which, under usual circumstances, prevent its redundancy, must ultimately surpass any funds that are not equally unlimited, and do not admit of progressive increase in proportion to the progressive demand.

The experiment of supporting all who may require eleemosynary maintenance has been too often made to render this conclusion doubtful. Catholic countries, in which the nature of benevolence is every way misunderstood, afford, as might be expected, the most striking proofs that wherever gratuitous supplies are furnished, the demands soon rise above the means of meeting them, or, if the means are unlimited, increase in proportion. Rome, Naples, Cadiz, and indeed all the principal cities of Spain, are described by all travellers as being equally remarkable for indiscriminate bounties, and universal mendicity. The town of Oviedo, for instance, at the time when the late Mr Townsend visited it, afforded a most instructive example. There was an hospicio, or general workhouse, the revenues of which were L. 4000 Sterling; equal probably in Spain to thrice that sum in England; this also served as a foundling hospital; besides which refuge for the poor, and their children, the bishop ordered seventy reals to be distributed at his gates every morning to all comers, and weekly pensions both to widows and orphans. In addition to all this, the canons scattered alms plentifully as they walked through the streets; six convents administered bread and broth at noon, and a commodious hospital was ready to receive the sick and infirm. All these resources were too little, even among so small a population as 7500 souls. "Notwithstanding all that has been done," says that intelligent traveller " (and what more in the way of charity can be devised?) beggars, clothed in rags, and swarming with vermin, abound in every street."

In reading this description, we are struck at once with the folly of such undistinguishing charity. Yet what do we see in the account of Oviedo, but that stated on a small scale, which the poor-laws are calculated to render universal in England?—Workhouses in every parish, supported at the public charge, and serving as foundling hospitals, and offer-

ing a refuge to the poor and their children. Besides a regular donation to those who may not like the confinement of the workhouse, but can prefer the claim of a burthensome family. And all this independent of the private charity, which we have no wish to see curtailed, but which ought to stand alone; the "bread and broth at noon," judiciously administered, and the public "hospital ready to receive the sick and infirm." The difference in the circumstances and character of the two countries has rendered the consequences hitherto less calamitous in England than in Spain; but the tendency is similar, and the effect equally disproportionate to the means; legal provision has been seen to be no preventive to individual want, or national distress.

And why is this, but because the claimants are daily multiplying in number, and press closer and closer upon the funds destined to satisfy them? The increased and increasing burthen of the rates in England is a sufficient proof of the truth which we desire to establish. Notwithstanding the degradation of dependence,—the liability to vexatious, and often painful removals,—the restraint of workhouses,—and the murmurs of the reluctant dispensers of compulsory alms, to all which an English pauper must submit; experience has made it very evident that, as long as any public support can be relied on, the claimants for it will increase in number and importunity; and that, if any limit is to be set to the demand, it must be sought for somewhere else than in the forbearance of the people, or the decrease of indigence.

Already has the claim, in very many instances, exceeded the available resources. In numerous and extensive districts, during the years 1816, 1817, and 1818, it proved impossible for the contributor to furnish the quota which the necessities of those without labour, and, therefore, without support, demanded. Admission into the work and alms-houses, once dreaded as the last resort of hopeless penury, has been courted as a boon, and accepted as a favour. Whilst in London, and other great towns, many almost starving families were deterred from applying to the parish by the crowded, unhealthy, and horrible state of the workhouses into which they would be received, if indeed they could be received at all; many parishes were absolutely unable to raise the assessments, the increase of which, according to the existing laws, has tended only to bring more and more persons upon the parish, and to make what was collected less and less effectual; and yet there was an almost universal cry from one end of the kingdom to the other for voluntary charity to come in aid of the parochial assessments.\*

In the mean time, the amount of the rates themselves, which was, in 1785, L. 2,000,000, in 1803, had reached L. 4,267,000, in 1813, L. 6,294,000. † This increase, great in itself, becomes still more important as a proof of the effect of the system, when

Poor-Laws.

Universal Effect of Public Charities.

Actual Increase of Pauperism.

\* Malthus on Population, 5th edition, Vol. II. p. 352.

† Report of Select Committee, 1817-1821. The "Letter to Mr Peel" estimates the increase in the price of wheat at 9 per cent. in 1803, and the increased population at 17. According to which, the amount ought to have been L. 2,438,670, instead of L. 4,267,965.

Poor-Laws. we remember that the intervening years had been years of unexampled demand for men and every kind of labour: and also, that, owing to the sudden growth of the burden during the scarcities of 1800 and 1801, a remarkable improvement had taken place in the collection and disbursement of the parochial funds, to so great a degree, that any material diminution cannot generally be expected from more prudent management, whilst the system itself remains. Under these circumstances, if the disorder had not been radical, the annual expenditure ought to have become less and less, instead of increasing, from 1803 to 1813, by a third of the whole, or about a sixth of the proportional amount, after allowing for the increase in population and the price of corn.

It is especially necessary that the price of corn should always be taken into the account. The public is very liable to be misled by an apparent decrease—a decrease in the actual sum, whilst the increase is really proceeding, and the burthen heavier than ever. It is plain, that L. 100, with wheat at 40s. *per* quarter, is equal to L. 200, with wheat at 80s., and is paid with far more difficulty by the agriculturist, who furnishes the great proportion of the rates. If corn continues at the prices of 1822, the rates will not be *effectually* lower, till the L. 7,500,000 of 1819 are reduced to L. 4,000,000; an event which we no more expect to witness than the reduction of three millions of the population.

The alarming distress which followed the spring of 1815, the consequent increase of the rates, and the difficulty of meeting this demand, led to a long and diligent inquiry into the whole subject before a Committee of the House of Commons, in the session of 1817. From the returns which were then made from the manufacturing towns of Birmingham, Manchester, Coventry, &c.\* and also from many districts solely agricultural, it clearly appeared that the excess of demand above the funds prepared to answer it, was no theoretical or even distant danger, but one which some districts had already experienced, and to which all districts were more or less rapidly approaching. Distraint for rates became very general; and every distraint is an encroachment upon the national resources, and a conversion of capital into income. We soon become alive to the probable result where an individual does this; and if a nation is but an aggregate of individuals, national extravagance and individual extravagance must pay the same penalty, and end in the same fate.

It is impossible to predict, with any certainty, how long or how short a time the present system might go on, before such a crisis arrived. Whenever the charge upon the land for the support of those who do not add enough to the annual produce of the country to support themselves, is so great that the land can be no longer cultivated with a profit, then, of course, it will be thrown up. This charge is gradually increasing every year, if not actually, yet re-

lative to the price of corn; and the natural effect has already followed in some districts where the pressure is particularly severe. It is evident that, in proportion as this takes place, the rates become still heavier on those who continue to pay. So that the tendency is to contract the contributors annually into a narrower and narrower circle, each step bringing some upon the rates for support who had before assisted to pay them, till the whole cement of society gives way, and the natural gradation of ranks and fortunes, on which its prosperity depends, is sunk and lost in national pauperism.

Such a crisis was clearly apprehended by the Committee of the House of Commons; and with a short extract from their deliberate and valuable *Report*, we shall confirm, as well as conclude, our own reasonings:—

“Whether the assessment be confined to land and houses, as at present, or other denominations of property be made practically liable to the same charge, the Committee feel it their imperious duty to state their opinion, that, unless some efficacious check be interposed, there is every reason to think that the amount of the assessment will continue, as it has done, to increase, till at a period, more or less remote, according to the progress the evil has already made in different places, it shall have absorbed the profits of the property on which the rates may have been assessed: producing thereby the neglect and ruin of the land, and the waste or removal of other property, to the utter subversion of that happy order of society so long upheld in these kingdoms.

“The gradual increase which has taken place both in the number of paupers and in the assessment for their support, can hardly fail to have arisen from causes inherent in the system itself; as it does not appear to have depended entirely upon any temporary or local circumstances. Scarcity of provisions, and a diminished demand for particular manufactures, have occasioned, from time to time, an increased pressure in particular parishes. But by comparing the assessments in the two counties in this kingdom in which the largest portion of the population is employed in agriculture, namely, Bedfordshire and Herefordshire, it will be seen that there has been the same progressive augmentation in the amount of the assessments, as may be observed to have taken place in the manufacturing counties.”

	Money Expended on Paupers, in the Year ending Easter 1776, (omitting fractions.)	Average Expenditure on Paupers, 1783, 1784, 1785.	Expenditure, 1803.	Expenditure, 1815.
County of Hereford, } Bedford, }	L.10,593	16,727	48,067	59,255
	16,662	20,977	38,070	50,370

\* In Manchester, the relief given to the *out-door* poor increased within ten years from 1805 to L. 14,000, instead of L. 8000 *per annum*; and the whole expenditure, from L. 16,000 to L. 27,000, in the most moderate years—in dear seasons, one-third more. In Birmingham, the increase in ten years was one-third, being L. 20,000 in 1806, L. 30,000 in 1816.—*Commons' Report*.

**Poor-Laws.** The evidence afforded by this table is not to be resisted. The charge on the rates, in 1815, not in two or three counties only, but taking England throughout, was double its amount in 1795; though, in 1815, the price of corn had sunk to a moderate average. What then, except a change in the existing laws and management, is to hinder their doubling again in twenty more years—at least virtually doubling, with respect to the ability of the payers? But it certainly cannot be supposed that land which now, in many cases, pays a rate equal, or more than equal, to the rent, can afford to double that charge, and be cultivated with a profit. In fact, many petitions were laid before Parliament, complaining that the annual value of the property assessed to the poor-rates, was not sufficient to maintain the numerous and increasing claimants, even if it were to be set free of rent; so that the parishes were threatened with a total abandonment of the occupiers of their land. And though these are, indisputably, extreme cases, there is quite enough in the general appearance of the country to warrant the conclusion expressed in the *Report*, and to justify the worst apprehensions respecting the eventual consequence of the system.

This is sufficiently proved by the experience of the five years succeeding 1815, as digested in the following table: \*

Years.	Expended for the Relief of the Poor. †	Average Price of Corn per Quarter.
		s. d.
1815	L.5,418,845	70 6
1816	5,724,506	61 10
1817	6,918,217	87 4
1818	7,890,118	90 7
1819	7,531,650	82 9
1820	7,329,594	69 5

Now, upon the first glance at this table, it will appear, that as the price of corn in 1815 and in 1820 was the same, the amount of the rates ought likewise to have been the same, with the addition of ten per cent. for increase of population. It ought, therefore, to have been six millions in 1820, according to the scale of 1815. But it is seven millions, giving a million, or one-sixth of the whole, as the actual growth of five years. This surely must satisfy every doubt concerning the ruinous tendency of the system, and shows that the only remaining question must be, not whether the evil is in its own nature progressive, but how the progressive evil may be most wisely and effectually restrained.

Such are the political consequences of the system of poor-laws, as now administered in England. Its moral effects are no less pernicious.

1. The first of these which we shall mention is that total improvidence which exists in so remarkable a degree both among the manufacturing and agricultural labourers. In the former class, this is peculiarly inexcusable. The demand for all labour is fluctuating, and liable to occasional and sudden variations. But in manufacturing labour such differences are of most frequent occurrence. A change of fashion at home, or a municipal regulation abroad, the discovery or failure of a mine, the wealth or poverty of a customer, all bear directly upon it, independently of the more important fluctuations arising from the hostile or peaceful relation of neighbouring countries. Therefore labour of this sort, though far more productive in its flourishing seasons, is far more precarious in its eventual success than any other.

The remedy against the inconveniences arising from these causes is to be found in that moral foresight which belongs to intelligent beings, and distinguishes, or ought to distinguish, the civilized and social man from the thoughtless savage. If it is the nature of manufacturing labour to be barren at one season, and productive at another, the superabundance of the harvest must provide against the time of scarcity. But notwithstanding all that must be clearly known, and bitterly experienced on this account, there is among the manufacturing bodies in our large towns a most profligate disregard of any moment beyond the present. The system of the savage is seen in the midst of a crowded population. For a time, on the sudden acquisition of plenty, there is the same waste, the same idleness, the same debauchery, which is quickly succeeded by a similar want, a similar necessity for extraordinary exertion. When the wages of the manufacturer experience a sudden rise, his weekly expenses rise in the same proportion. Perhaps he works but half the week, and spends the rest in low and profligate excess. Perhaps he squanders his superfluous wages in a manner the most absurd, and the most unsuitable to his station in life. But at all events, when the year ends, he is in no sense better than he was at the beginning; his advantages have been altogether thrown away; he is not richer, and in a moral sense he is poorer, because his dissolute habits are more confirmed. It appeared in evidence before the House of Commons, that the ribbon weavers at Coventry, who were at that moment requiring parish relief, had six months before been in the receipt of two or three guineas a week, which they had expended in the most sumptuous manner upon poultry and other luxuries; in selecting which they were so fastidious, that the usual market of the place was not good enough for them, and supplies were regularly sent down from London.

The agricultural labourer has fewer golden opportunities than the manufacturer; still most of them, with frugal habits, might save L. 5 per annum, whilst

\* *Report on the Poor-Rate Returns*, ordered to be printed 10th July 1821.

† The particular sums expended in law and removals are not specified in the returns after 1815, and therefore cannot be subtracted from the total amount. They amounted in 1813, 1814, 1815, to about L. 330,000 per annum.

Poor-Laws. they are unmarried; whereas not one in fifty, perhaps, is master of that sum at any period of his life. Whenever their wages go beyond their actual necessities, the overplus is carried to the alehouse. If an accident, or an illness, or a failure in the demand for labour, keeps the man from work a fortnight, the parish is called upon to supply the deficiency. That he should have even a week's provision beforehand is entirely out of the question. It would be thought a most unreasonable expectation. Though perhaps he is a single man, and has no family demands; or a man in the flower of his age, who may have earned large wages at task-work for years; or an elderly man whose children are all off his hands. In short, whatever may have been his situation or opportunities, he has always lived, to use a common, but expressive phrase, from hand to mouth.

Now it is impossible to believe that the known and regular provision of the poor-laws is not at the bottom of this unprincipled extravagance, which has now become inveterate throughout the country. We cannot but suppose that in a land where so much intelligence, so strong a moral sense, so active a spirit of industry exists, men who knew that they were liable to accidents and reverses, if they also knew that they had only themselves to depend upon, would employ some part of their present earnings to provide against future contingencies. It may be said that to men who work hard, and are necessarily much collected together, the temptation to low dissipation and extravagance is irresistible. But these temptations are not stronger to one part of the community than the other; and in servants, petty tradesmen, and small farmers, considered as a body, there is much of that forethought and frugality which is the best foundation of individual and national welfare. Many of these, during the unparalleled vicissitudes of the last 25 years, have had more to struggle with than the labourers; yet they have not, in the same regular manner, fallen upon the parish funds, because to these classes such a resource is still considered a reproachful degradation. We argue, that similar frugality would have characterised our labourers also, if their natural disposition to sensuality had not been favoured, rather than restrained, by the assurance of a systematic provision, when vice and imprudence should bring on their necessary results, and terminate in penury.

2. Discontented Spirit arising from Errors as to the Causes of Poverty.

2. Another injurious effect of the poor-laws is the bad and discontented temper which is generated by ignorance of the real causes of poverty. Almost every thing which has hitherto been done for the poor has tended, as if with care and intention, to throw a veil of obscurity over this subject, and to hide from them the real origin of their difficulties. In all cases, the last man whom any one, labouring under misfortune, is inclined to accuse, is himself. But the poor-system tends to maintain the opinion, that he is the last person who ought to be accused. The workman who can find no employment; the labourer who feels his large and increasing family a burthen which he can ill support; the aged and decrepit, whose pittance barely furnishes them with the necessaries of life; each lay the fault of their particular distress upon the parish, or upon the over-

seer, or upon the magistrate: but never blame their own imprudence in neglecting a provision, or their extravagance in throwing one away. And when relieved, to the full extent that legal charity can relieve them, they never acknowledge any sense of obligation, unless they should be brought to a better mind by feelings which the poor-laws are rather calculated to extinguish than to awaken.

We can hardly be wrong in setting these errors to the account of the system itself. "On these occasions," as Mr Malthus justly observes, "the only way I have of judging, is to put myself in imagination in the place of the poor man, and consider how I should feel in his situation. If I were told that the rich, by the laws of nature and the laws of the land, were bound to support me, I could not, in the first place, feel much obligation for such support; and, in the next place, if I were given any food of an inferior kind, and could not see the absolute necessity of the change, which would probably be the case, I should think that I had good reason to complain. I should feel that the laws had been violated to my injury, and that I had been unjustly deprived of my right. Under these circumstances, though I might be deterred by the fear of an armed force from committing any overt acts of resistance, yet I should consider myself as perfectly justified in so doing if this fear were removed: and the injury which I believed that I had suffered, might produce the most unfavourable effects on my general dispositions towards the higher classes of society. I cannot, indeed, conceive any thing more irritating to the human feelings, than to experience that degree of distress which, in spite of all our poor-laws and benevolence, is not unfrequently felt in this country; and yet to believe that these sufferings were not brought upon me, either by my own fault, or by the operation of those general laws which, like the tempest, the blight, or the pestilence, are continually falling hard upon particular individuals, while others entirely escape; but were occasioned solely by the avarice and injustice of the higher classes of society.

"On the contrary, if I firmly believed that, by the laws of nature, which are the laws of God, I had no claim of right to support, I should, in the first place, feel myself more strongly bound to a life of industry and frugality; but if want, notwithstanding, came upon me, I should consider it in the light of a sickness; as an evil incidental to my present state of being, and which, if I could not avoid, it was my duty to bear with fortitude and resignation. What I received would have the best effect on my feelings towards the higher classes. Even if it were much inferior to what I had been accustomed to, it would still, instead of an injury, be an obligation; and conscious that I had no claim of right, nothing but the dread of absolute famine, which might overcome all other considerations, could palliate the guilt of resistance.

"I cannot help believing, that, if the poor in this country were convinced that they had no claim of right to support, and yet in scarcities, and all cases of urgent distress, were liberally relieved, which I think they would be, the bonds which unite the rich with the poor would be drawn much closer than at

**Poor-Laws.** present; and the lower classes of society, as they would have less real reason for irritation and discontent, would be much less subject to such uneasy sensations."

**Poor-Laws.** privilege of murmuring at its amount. Indeed, the injustice of the system, as it sometimes falls upon payers of this nature, is so glaring, that nothing but the uselessness of remonstrance could prevent its being loudly heard. Those who are constantly supported on parish pay are better off than a large number of those who contribute; they are certain of receiving, as long as there is any capital stock on which a distress can be levied; but the power of paying in the others depends upon their customers, and upon many contingent circumstances. The pauper also is secure in the possession of his effects, those of the contributor are daily liable to be seized.\* The pauper, too, can afford to live better, and to spend more on his family or himself throughout the year, than the petty tradesman, or annuitant, or renter of a little land, or many others in that humble but useful class just above the common labourer. These are the persons on whom a scarcity falls heavy; these are the persons who must diminish their consumption; these are the persons who feel the revulsions of trade, and the pressure of taxes; their families must commute bread for potatoes, while their pauper neighbours are living in comparative plenty. Under such circumstances, it is scarcely possible for man not to complain; or to acknowledge the truth of the Christian maxim, "It is more blessed to give than to receive."

3. Extinction of the Genuine Spirit of Charity.

3. To this habitual discontent is to be added the selfishness and mercenary spirit arising from the habit of looking to parochial assistance in every emergency. Instead of that sympathy and active charity which would be shown, we fully believe, in this country at least as much as any other, if the poor were not brought up to expect that relief must be awarded to all in whatever shape it is required, a certain price, an adequate repayment, is demanded, for every trifling service. If an aged parent is lodged under the roof of a child, the parish must give a remuneration. If an orphan is to be provided for, the first question of the relation is, what will the parish allow? If age or occasional illness require some domestic attendance, a demand is regularly made for trouble and loss of time. Dr Chalmers speaks the result of experience both south and north of the Tweed, when he laments it as "a heavy encumbrance on the work of a clergyman, that, in addition to the primary and essential evils of the human constitution, he has to struggle, in his holy warfare, against a system so replete, as pauperism is, with all that can minister to the worst, or that can wither up the best, affections of our species." (*Christian and Civic Economy*, No. 10.)

The effect upon the giver is certainly no better than that upon the receiver of these legal alms; and thus the most valuable part of real charity is thrown away. The immense sums distributed to the poor in this country by the parochial laws are improperly called charity. They want its most distinguishing attribute; and as might be expected from an attempt to force that which loses its essence the moment it ceases to be voluntary, their effects upon those from whom they are collected are as prejudicial as on those to whom they are distributed. On the side of the receivers of this miscalled charity, instead of real relief, we find accumulated distress and more extended poverty; on the side of the givers, instead of pleasurable emotions, unceasing discontent and irritation. How can it be otherwise? The rich, who are little affected by the amount of the rate, pay it as a tax, and either view it in no other light, or apply it as a quietus to their conscience, as if having furnished their legal assessment, they had fulfilled their duty in the way of charity. The middling classes, upon whom the burthen presses most severely,—as the little annuitants, small tradesmen, and inferior farmers,—not only pay it as a tax, but feel it as a tax, and consider that they have the usual

4. There are other immoral consequences of the poor-laws which are too obvious to need particular illustration. Husbands are encouraged to desert their wives, and fly from the burthen of their families, knowing that they will not be unprovided for. Women are encouraged to admit illicit intercourse, from a confidence that if it should prove fruitful, a marriage will be probably forced from the ordinary operation of the laws; a calculation which begins in vice, and can only end in premature and ill-sorted marriages. Indeed, their general effect on character admits of indisputable proof, independently of all argument or theory. It is notorious that the most steady, industrious, and moral workmen, on whom the employer can place his surest reliance, are those who do not *legally belong* to the parish in which they are living. It would be impossible to desire a more convincing evidence of the pernicious tendency of the present laws. We shall therefore conclude this branch of the subject, by noticing a collateral evil of the system, also tending to demoralize the people. It collects an undue proportion of the population into towns. The population of cities and towns, instead of comprising, as had been calculated during a considerable part of the last, and the whole of the preceding century, about one-third of the na-

4. Encouragement to Immorality.

\* "You do not compel the poor man to sell his furniture before you relieve him?—No—certainly not. But if a man has to contribute to the relief of the poor, and from loss of trade, or from the pressure of children, he is not able to pay his rates, you sell his furniture and effects!—I have been compelled to sign a warrant of distress. Then, is not the pauper that is relieved in a much better condition than the pauper who contributes?—He is so far in a better condition, that what he possesses is more secure to him."

*Lords' Report*, p. 25.

By a statute (54th Geo. III. c. 170, s. 11), such persons may now be, by magistrates, legally exonerated from charges.

Poor-Laws. tion, now approaches to nearly one-half. From 1801 to 1811, the increase of houses in the towns of Great Britain average 12 *per cent.*, and the inhabitants 15 *per cent.* In the country, the increase of houses somewhat exceeds 11 *per cent.*, and the inhabitants 13 *per cent.* Mr Colquhoun observes, that to whatever cause it may be attributed, there has been a considerable tendency to diminish the rural population, and to increase that of the towns in general.\* But the cause is very evident to any one who has watched the operation of the poor-laws. Cottages entail upon the land so heavy a burthen, that no proprietor will suffer one to be erected upon his estate which is not absolutely necessary. He can obtain no rent which can indemnify him for the probable charges of an additional family, which will possess a perpetual claim for support upon his land. But in towns, where the property in land is much subdivided, the immediate advantage of letting small houses at a considerable profit, far overbalances the distant evil arising to the individual from the increase of the rates, to which all the inhabitants of the town will be forced to contribute their share. The consequence is, that there only are houses built, and thither the overflow of the country parishes resort, and going out into the neighbourhood for daily employ, spend their leisure hours in the town, and lose the simple habits as well as the simple recreations of the village.

Plan proposed for Amendment of the System.

Having now explained the poor-system, as it exists at present in England, and shown its injurious effects, both upon the moral and political health of the community, it only remains to advert to the several plans which have been hitherto proposed for its melioration or abolition. And of these, leaving the compulsory contribution to friendly or other provident societies; the assessment of all other property to the rates, as well as that upon which they have been heretofore raised; and the allotment of cottages, with a small quantity of land to the labourers who might have the most numerous families;—as either inadequate, inexpedient, or impracticable remedies—we shall confine ourselves to the two which best deserve the attention of the Legislature, and have obtained the most of it. These are, first, the establishment of a maximum, beyond which the annual amount of the rates in each parish shall not be increased; and next, the gradual abrogation of the law of Elizabeth, on which the whole system has been erected.

I. Plan of establishing a Maximum of the Amount to be raised.

The plan of fixing a maximum has been often recommended, under the alarm arising from the progressive increase of the annual rates. It is proposed to take the average of a certain number of years past, and fix that as the sum which no future assessment should exceed; so that, if the rates of any given parish had amounted, on an average of the largest and smallest sums during the last ten years, to L. 500, L. 500 should be considered as the utmost limit of charitable relief to which the claimants on that parish were legally entitled. A plan

of this nature was brought forward in Parliament in <sup>Poor-Laws.</sup> the year 1821; but clogged with so many objectionable alterations in the law of settlement, that it met with less attention than the respectability of the mover would otherwise have secured it. There are, however, radical objections to the plan itself. "Under such a law, if the distresses of the poor were to be aggravated tenfold, either by the increase of numbers or the recurrence of a scarcity, the same sum would invariably be appropriated to their relief. If, in the meantime, the statute which gives the poor a right to support, were to remain unexpunged, we shall add to the cruelty of starving them, the injustice of still professing to relieve them. If this statute were expunged or altered, we should virtually deny the right of the poor to support, and only retain the absurdity of saying that they had a right to a certain sum." (Malthus, III. p. 353.)

In order to obviate this evident objection to the measure, a provision was introduced into the bill allowing additions to be made to the fixed maximum, by an extraordinary assembly of the inhabitants and neighbouring magistrates, in very peculiar cases of local pressure or general scarcity. It is plain, however, that this is a virtual abandonment of the principle of the measure; and by necessary consequence, of the measure itself. The right of the people to certain support being recognized, no legislative fiat can limit the extent of that right. No inhabitant could resist the demands of the people; no magistrate could be expected to maintain the maximum, in any season of difficulty, when alone it would be of much practical value. If a dam, which is raised to keep out the encroachments of the water, is to be opened whenever the water presses forcibly against it, the surrounding country has little reason to trust to its effect, when threatened with an inundation.

This objection equally applies to an amend. Plan of a gradually decreasing Maximum ment which has been since proposed, to render the maximum a gradually decreasing maximum, by subtracting from its amount 10s. or 20s. *per cent.* annually, till the whole was extinct. But to any one acquainted with the manner in which the affairs of a parish are and must be conducted, taking the country at large, such impossibilities must occur in the execution of a law of this nature, as render it quite undeserving attention as a national measure. The business of overseer, for the first half of the year, would go on smoothly enough. By that time, three-fourths of the legal assessment would probably be spent. Then all, whatever might be their wants, must be put on short allowance, and future claimants excluded. But each of such claimants would justly consider that he had as good a right to be supported in his hour of need, as those who happened to be visited with misfortune a few months before; and those whose mischance it was to be in distress when the fixed sum was collected and expended, would be particularly ill used on being refused assistance, while so many others around them had enjoyed this advantage. If such a measure were pass-

\* Colquhoun on the Population and Resources of the British Empire, p. 27.

Poor-Laws. ed, it would be virtually repealed in half the parishes of the kingdom before the expiration of five years.

Besides, there is nothing in any measure of this kind, which tends to stem the progress of pauperism; nothing to prevent the numbers from annually increasing, which require public assistance. All the channels by which the main stream is supplied, as described in the beginning of this article, remain the same; why, then, should we expect that the stream itself should grow narrower, or cease to overflow its bounds? If, then, the sum collected were to be divided among all who might be in want, however their number might increase, great misery must ensue; and all the blame of it would be laid, not without much apparent justice, to the charge of the society, which undertook the support of the poor, yet supplied them so sparingly, that they must necessarily die of hunger and disease.

2. Plan for the gradual Abolition of the Poor-Laws.

2. The only measure which can be considered as either politically wise, or practically efficient, is one which shall gradually annihilate the system by attacking directly its vital principle, and striking at the root of the disease. To this end Mr Malthus proposes that a regulation should be made, declaring that no child born from any marriage taking place after the expiration of a year from the date of the law, and no illegitimate child born two years from the same date, shall ever be entitled to parish assistance. And, to give a more general knowledge of this law, and to enforce it more strongly on the minds of the lower classes of people, the clergyman of each parish should, after the publication of banns, read a short address, stating the strong obligation on every man to support his own children; the impropriety, and even immorality, of marrying without a prospect of being able to do this; the evils which had resulted to the poor themselves from the attempt which had been made to assist by public institutions in a duty which ought to be exclusively appropriated to parents, and the absolute necessity which had at length appeared of abandoning all such institutions, on account of their producing effects totally opposite to those which were intended. "This would operate as a fair, distinct, and precise notice, which no man could well mistake; and, without pressing hard upon any particular individuals, would at once throw off the rising generation from that miserable and helpless dependence upon the government and the rich, the moral as well as physical consequences of which are almost incalculable."

Some measure of this kind is not only expedient, but indispensable, if the Committee of the House of Commons are justified in solemnly stating it as their opinion, That unless some efficacious check be interposed, there is every reason to think that the amount of the assessment will continue as it has done to increase, till, at a period more or less remote, it shall have absorbed the profits of the property on which the rate has been assessed, producing thereby the neglect and ruin of the land.

Answer to the usual Objection to this Plan.

The chief practical objection which has been urged against such an enactment is, that it would create two distinct classes, which would exist together in the country for a considerable period of time,—the one class having, and the other not having, a claim

to public support; and that this would occasion Poor-Laws. confusion, discontent, and ultimately turbulence, by which the nation would be kept in continual disorder.

We are of a different mind: and that not only on general grounds, but for reasons of experience. No new measure, in truth, can reduce the lower classes to a more unequal state than the existing system. Every parish has its own rule, founded partly on the ability of the payers, and partly on the character of the overseers. Every district has its own scheme of administration, dependent on the discretion or indiscretion, foresight or carelessness, of the local magistrates. A few parishes, a few bright spots appear, which careful management has preserved from the infection of the surrounding plague; and those parishes are in all respects the best satisfied, because the most comfortable. An account of one of these appears in the evidence before the House, in which the custom of employing labourers by task-work has enabled them to support their families without application to the magistrate; and yet it comes out incidentally that this parish is so great a favourite, that false oaths and other fraudulent means are frequently taken to get into it.

Already, too, there exist in every parish those who have, and those who have not, a claim to support, according as it may happen that they do or do not legally belong to it. What keeps the residents who are non-parishioners from turbulence, or even from complaint? The known law. We argue, that the known law would have the same effect upon those who are born without claim upon any parish. Indeed, the whole country abounds with inequalities of condition among those whose claims are similar; of whom some are, and some are not, effectually relieved by the law on which their claims are founded. Nothing, for instance, can be more different than the degree of assistance awarded to the manufacturing and the rural labourer. In country parishes, the poor do really receive some compensation for their low wages; their children, beyond a certain number, are really supported by the parish; and though it must be a most grating reflection to a labouring man, that he can hardly marry without becoming the father of paupers; yet if he can reconcile himself to this prospect, the compensation, such as it is, is no doubt made to him. But in London, and all the great towns of the kingdom, the evil is suffered without the compensation. The population raised by bounties in the country, naturally and necessarily flows into the town, and as naturally and necessarily tends to lower wages in them; while, in point of fact, those who marry in towns, and have large families, receive no assistance from their parishes, unless they are actually starving: and altogether the assistance which the manufacturing classes obtain for the support of their families, in return for their lowered wages, is perfectly inconsiderable. Whereas the nominal rate of wages is of no more consequence to the labourer who is married and has a family throughout the South of England, than its rate in Hindostan. (See Malthus, II. p. 369.)

It is plain, therefore, that the poor of this country have been used to unequal and very different treatment, and that with much greater appearance of in-

Poor-Laws. justice than any difference which was founded upon an established law. To say nothing of the advantage which the impudent and daring have long possessed over the humble and unobtrusive character; which imposture has had over honesty, and shameless beggary over honest independence; the circumstance that men who were born in the same class, and labour in the same vocation, and are burthened with the same family, are liable to suffer, and do actually suffer, the widest variations according to the district in which they may happen to reside;—according as the magistrates of that district agree to act; according to the scale of relief they may have adopted; according to the strictness of the inquiry which they are in the habit of making, before they issue an order for relief; in short, according to the views they may take of their own duty and of public expediency. So that we should have no fear of discontent, in any material degree, from the operation of an enactment like that proposed. More especially, as the majority of those whom it concerned finding themselves, according to the natural order of things, so much the more prosperous in consequence of their depending on their own exertions, would be free from the principal temptation to murmur and complain.

It ought to be remembered, farther, that the system now in operation is by no means exempt from the danger of discontented turbulence. Every one is brought up with the belief that the state is bound to provide him with employment and support. When, therefore, the employment assigned him is such as he does not approve, and the recompense awarded him falls below his expectations (and when the employment is a loss to the public, the recompense must often be below even reasonable expectations), he becomes an irritated and uneasy subject; and unless he is restrained by the fear of detection, or by the better influence of moral principles, he vents his spleen by any mischief that is in his power; and the burning of stack-yards, or the destruction of machinery, results from an unsatisfactory interview with the overseer, or an ineffectual appeal to the bench of magistrates. Proofs of this have been already too visible; and vestry meetings, in some counties, have assumed a very seditious appearance: quite enough to prove the evil of accustoming the mass of the population to depend upon any thing except the natural demand for their labour.

The Statute for furnishing Employment may be first repealed.

Should it, however, be considered that more caution and preparation is necessary to pave the way for a total alteration in a system of laws which are unhappily interwoven with the habits of the people; it would be an important step, to begin by repealing that part of the statute of Elizabeth, which empowers the overseers to set the poor to work; that

is, in effect, which empowers the labourer to demand Poor-Laws. work, or money as its substitute. This would confine relief to the impotent and aged, and would take away that part of the law which is most confessedly adverse to all sound principles of policy, and is least capable of any rational defence. There is a satisfaction, no doubt, attendant upon the knowledge, that every individual in the country, if reduced to helpless indigence, has a "local habitation" and a home; that the aged, and the infirm, and the orphan, have a sure provision.\* And though man may, no doubt, become improvident, and parents may sometimes be induced to abandon their children, from a conviction, that they will not be allowed to starve, yet if relief had never been extended beyond these objects, the evil would not have become practically burthensome as it is now experienced to be.

If then it should be determined, for the present at least, to retain this part of the system, let a wiser course be commenced, by laying aside the attempt to "set the poor on work;" and let it be declared that from such a time, no able-bodied man shall have any claim to employment or relief from the parish for himself or his family. Such a measure has the advantage of being strongly recommended by the *Report* of the Committee, to which we have so often alluded. Indeed, a decided opinion is there given, that, even as the law now stands, "an order for relief is invalid, which does not adjudge the party to be 'impotent,' as well as 'poor.'" And a mode is suggested in which this alteration of the prevailing system might be effected humanely and gradually. It is submitted to the consideration of the House, whether, when the demand for labour may have revived, it may not be safely provided, that from and after a certain time, no relief shall be extended to any child whose father, being living, is under years of age; a principle which, by altering the age from time to time, might, if it should be thought desirable, be carried still further into operation. It may also be provided, with a similar view, that from and after a specific time, no relief shall be provided for any child whose father, being living, has not above children, under years of age. The *Report* proceeds to suggest that it may be hereafter enacted, that no person should be provided with work by the parish other than those who are already so provided, and who might be permitted to continue till they could provide for themselves; but if the change made by this provision might be thought too rapid, limitations might still be introduced, the effect of which would render it more gradual: as, by enacting that none shall be provided with employment who are between the ages of 18 and 30, and then, after a certain

No Able-bodied Labourer to be relieved.

\* This feeling has induced the author of the Letter to Mr Peel, who well deserves attention, to make the following reflection:—"Let me thus dismiss the present branch of the argument, with the hope that indigence, arising either from infirmity, age, infancy, great number of children, and even accidental failure of employment, may possibly be relieved by law—not fully and adequately to our feelings—yet permanently and systematically, without necessarily extending the evil."

Such a concession, from one so well aware of the moral evils of the poor-laws, shows the embarrassments with which the subject is involved.

lapse of time, that none between 16 and 35, 40, and so on, till the object shall be gradually effected.

We entertain no sort of doubt that a law of this kind would, in a very short time, benefit the labourers themselves. What, indeed, can be more depressing or injurious to them, than the system which is common in some districts, according to which labourers, under the denomination of *roundsmen*, are sent from farm to farm, and paid at the lowest possible rate, and that rate not depending upon their skill or industry, but upon the largeness of their families? and not by the person for whom they labour, but, in a great part, out of the parish funds? Both the Committees reprobate this practice in pointed terms, but the Lords do not seem to have observed that it grows naturally out of the system of our poor-laws; and if that "system is essentially maintained," every labourer in the kingdom must in the end be treated as a roundsman. The poor-laws encourage the increase of the number of workmen beyond the demand for their labour: the poor-laws then oblige the parish to employ these supernumeraries at its own expense. But none of the employers of labour are in want of these hands, otherwise they would not be left to seek for work: still they must be supported: what alternative is there, except either to maintain them in idleness, or to parcel them out in the district which contributes to the rate? Certainly it is a plan which reduces the free labourer to the condition of a slave; but let the blame fall where it is due, upon the law itself; or let it be shown how some such scheme can be avoided, unless the men are to be unemployed altogether.

In conjunction with some enactment denying the claim of the able-bodied labourer to legal relief in any shape, and so tending to undermine the whole system—a limitation of the assessment to be annually raised might be useful, because it would be a sort of acknowledgment of the indisputable truth, that the Legislature had hitherto taken more upon itself than it was able to accomplish, and that the funds for the relief of the distressed, as well as for the employment of labour, really are limited, though the practice of the country supposes them inexhaustible; and that, in point of fact, they have already reached the bounds beyond which it is either not possible or not safe to proceed. This would gradually open the eyes of the poor to a truth which cannot be long concealed, and induce them to depend upon themselves. It would also furnish an argument to those who attempt to restore, or rather to create, in the poor a feeling of reliance on their own industry. As matters stand at present, all recommendations of Saving Banks, all enforcements of the necessity of foresight, are cut short by reference to the parish. You may be out of work; the parish must find it for me. You may be overburdened with a young family; the parish must allow accordingly. You may grow infirm or old; I can but come to the parish. But if a positive limit were set to the parochial assessment, what is theoretically absurd, might be practically useful; because there would be opportunity of rejoinder to these conclusive reasonings, from the inadequacy of the parish allowances; and a whole meal from former savings might

appear better than the half loaf which public charity would procure. But, in the mean time, the encouragement of frugal habits is proved to be a visionary hope among the lower classes of the community; and the declaration of the Lords' Committee, however undeniable, will remain a dead letter as to practical effect: "Parochial relief, under the best and most considerate administration of it, can never be so satisfactory to the person who is the object of it, or so consistent with those honourable feelings of pride and independence which are implanted in the heart of man, as that resource which is the result of his own industry and the produce of his own exertions." This is unintelligible language, to those at least who have been born in the south of England within the last forty years. Parish relief, instead of being dreaded as a disgrace, or looked to as a last resource, is, in truth, the first consideration. To become domiciliated in a *good parish* is the grand object, and leads to numberless cheats and perjuries; the next concern is to obtain as much as possible from it; which the single men effect by threatening to bring a wife and family upon the parish funds, if they are not relieved to their satisfaction; and the married men by actually doing so. A system which encourages these feelings and habits has been called a humane, a wise, an economical system; and justly, if it is humanity to support profligacy at the expense of the industrious; if it is wise to diffuse habits of improvidence, vice, and dishonesty throughout the land; if it is economical to sink capital in order to furnish income to the extravagant.

The most plausible objection to this plan of commencing an improvement in the principle of the poor-laws, by confining relief to the *impotent* poor, arises from the variations in the price of corn; a recurrence of which it seems right to anticipate in the present state of our agriculture and population. There have been many years since 1795 in which the market rate of wages would not generally support a family: neither is it in the nature of things that the wages of labour should rise with the price of corn, when that increase of price is occasioned by a deficiency in the supply. To raise them arbitrarily, as some persons have ventured to recommend, would only be to relieve one evil in the body politic by the introduction of another; and, though no remedy could easily be worse than the present disease, it is wiser, at all events, to "bear the ills we have, than fly to others which we know not of."

In reply, however, to this objection, it may be remarked, that the natural price of labour will be more nearly approached by the market price, in proportion as parochial payments are done away; and the employer will still be a gainer, because his assessment will be diminished in the same proportion: while population and production, keeping more even pace together, when relieved from the disturbing influences which prevail at present, the prices of corn will be subject to less variation. In the case, however, of any unusual disparity between the price of labour and the price of provisions, such as occurred in the years 1795 and 1800, or of any temporary or local pressure, from a difficulty in procuring employment, such as must always be expected

Poor-Laws.

Answer to the Objection, from Variations in the Price of Corn.

With such a Provision, the Plan of a Maximum might be advantageously united.

*Poor-Laws.* in some districts of a great manufacturing county, and which was almost universal in the years immediately succeeding the peace;—the principal inhabitants ought to agree together on the most practicable mode of assisting the largest families, and enabling their poorer neighbours to weather the exigencies of the season.\* The political objections which exist against indiscriminate relief do not affect extraordinary cases. That which would be most pernicious as daily diet, when applied as medicine, restores health to the constitution. Neither are we so forgetful of the duties enjoined upon us as Christians as to exclude charity from our domestic economy: our object is not to annihilate charity, but to render it profitable both to the giver and receiver. This is truly the case when our assistance, of whatever sort, is bestowed upon a known object, and for a definite purpose, instead of being thrown into a common fund, for which all scramble, and from which those who scramble most shamelessly get the largest share. The known claim to parochial aid, and the actual pressure of the funds which it demands, are an impediment, in the present state of the law, to private benevolence; together with a general conviction, that what is called, though falsely called, *the charity of the country*, has increased the distress which it professes to relieve.

And to say the truth, when we consider the degree of labour, and attention, and intelligence employed upon the concerns of the poor in late years, we may justly affirm, that, if it had been possible for things to go on well upon a wrong system, and to succeed on an erroneous principle, they must have succeeded, and the condition of the poor in England must have been most prosperous; and that it has not been so, with all these advantages, is in itself a sufficient evidence that the principle is radically unsound.

*Scotch Poor-Laws.*

It will be observed, that our remarks in the preceding article apply principally to England, as the native country of the poor-laws, and to those few districts of Scotland where the practice has been assimilated to that of England. An abstract of the laws which relate to the assistance and management of the poor in Scotland will be found in the *Encyclopædia*. We must add, however, that, since that publication, a very important case has been determined by the Court of Session, which turned upon this question; viz. Whether, under the Scotch poor-laws, those persons are entitled to relief who, without any personal infirmity, are rendered unable, by the high price of provisions, to maintain themselves in time of

dearth? And whether an assessment for the relief of such persons was legal? The Court decreed, on the 17th of January 1804, that such relief and assessments were legal under the statutes; and the arguments used to obtain a contrary decree were, *not that the statutes were not in force*, but that they did not strictly include this particular case. It came from the parish of Dunse in Berwickshire.

The Court of Session has also repeatedly decided that "a pauper has a title to the charity of any parish in which he has resided three years, supporting himself during that period by his own industry."

In consequence, many parishes have had recourse to legal assessments. "In small country parishes, or in parishes where there are no considerable towns or villages, the assessments are levied according to the valued rent of the lands, the one-half being paid by the heritors, and the other half by the tenants. But in large parishes, the assessments are made according to the real annual rents of lands and houses, a fourth part being deducted to the proprietors of houses for reparations; the half of the assessment is paid by the proprietors or landlords, and the other half by the tenants or possessors. The assessments are made annually by a joint meeting of the heritors and kirk-session of the parish, held, by act of Parliament, on first Tuesday of August or first Tuesday of July, who appoint a collector, who makes a new rental each year of lands and houses. †

The parishes in which such assessments have been enforced present a striking contrast to those which are managed upon the more primitive and economical system. The demands upon the legal funds have increased at least tenfold, and thus furnish a remarkable confirmation of the arguments by which the English poor-laws are impugned; against the further admission of which into this comparatively prudent and well regulated country, all its wisest and most benevolent members are lifting up their voice of warning and exhortation. ‡

Dr Chalmers, in particular, in addition to all his other important obligations, has recently conferred a new benefit upon the public, by practically showing that even the unpromising population of Glasgow may be satisfactorily provided for through the old channel of voluntary contributions, without recourse to compulsory funds. We would gladly refer any readers of the foregoing article who may entertain a prejudice against its tendency, to the Speech delivered by that gentleman before the General Assembly of the Church of Scotland in May 1822, and especially to the practical details related in the Appendix to it.

(N. N. N.)

\* In this way of occasional contribution, great local distress in Ireland has been effectually relieved during the summer of 1822. But what miserable politicians would those prove, who, on account of a temporary evil in a country so every way anomalous as Ireland, would venture to introduce, and apply to the Irish character, a permanent system of parochial legislation?

‡ *Report of the Committee of the General Assembly*, 1817, appended to the *Report of the House of Commons*.

## POPULATION.

Population.  
Object of  
the Article.

THE population of the principal states, of which an account has been given in the course of this work, will be found under their proper heads. The object of this article is to explain the general laws which regulate the increase or decrease of population, and the manner in which they affect the state and condition of human society.

Natural and  
Necessary  
Tendency of  
all Plants  
and Animals  
to Increase  
in a Geome-  
trical Pro-  
gression.

In taking a view of animated nature, we cannot fail to be struck with a prodigious power of increase in plants and animals. Their capacity in this respect is, indeed, almost infinitely various, according with the endless variety of the works of nature, and the different purposes which they seem appointed to fulfil. But whether they increase slowly or rapidly, if they increase by seed or generation, their natural tendency must be to increase in a geometrical ratio, that is, by multiplication; and at whatever rate they are increasing during any one period, if no further obstacles be opposed to them, they must proceed in a geometrical progression.

In the growth of wheat, a vast quantity of seed is unavoidably lost. When it is dibbled instead of being sown in the common way, two pecks of seed wheat will yield as large a crop as two bushels, and thus quadruple the proportion of the return to the quantity of seed put into the ground. In the *Philosophical Transactions* for 1768, an account is given of an experiment in which, by separating the roots obtained from a single grain of wheat, and transplanting them in a favourable soil, a return was obtained of above 500,000 grains. But, without referring to peculiar instances, or peculiar modes of cultivation, it is known that calculations have often been made, founded on positive experience of the produce of wheat in different soils and countries, cultivated in an ordinary way, and making allowance for all ordinary destruction of seed.

Humboldt has collected some estimates of this kind, from which it appears that France, the north of Germany, Poland, and Sweden, taken generally, produce from five to six grains for one; some fertile lands in France produce fifteen for one; and the good lands in Picardy and the Isle of France from eight to ten grains for one. Hungary, Croatia, and Sclavonia, yield from eight to ten grains for one. In the Regno de la Plata, twelve grains for one are produced: near the city of Buenos Ayres, sixteen for one: in the northern part of Mexico seventeen; and in the equinoctial regions of Mexico twenty-four for one. (*Nouvelle Espagne*, L. IV. C. ix. p. 98.)

Now, supposing that in any one country during a certain period, and under the ordinary cultivation, the return of wheat was six grains for one, it would be strictly correct to say, that wheat had the capa-

city of increasing in a geometrical ratio, of such a nature as to sextuple itself every year. And it might safely be calculated hypothetically, that if, setting out from the produce of one acre, land of the same quality could be prepared with sufficient rapidity, and no wheat were consumed, the rate of increase would be such as completely to cover the whole earthy surface of our globe in fourteen years.

In the same manner, if it be found by experience that on land of a certain quality, and making allowance for the ordinary mortality and accidents, sheep will increase on an average, so as to double their numbers every two years, it would be strictly correct to say, that sheep have the natural capacity of increasing in a geometrical progression, of which the common multiple is two, and the term two years; and it might safely be said, that if land of the same quality could be provided with sufficient rapidity, and no sheep were consumed, the rate of increase would be such, that if we were to begin with the full number which could be supported on an acre of land, the whole earthy part of the globe might be completely covered with sheep in less than 76 years.

If out of this prodigious increase of food, the full support of mankind were deducted, supposing them to increase as fast as they have ever yet increased in any country, the deduction would be comparatively inconsiderable; and the rate of increase would still be enormous, till it was checked, either by the natural want of will on the part of mankind to make efforts for the increase of food, beyond what they could possibly consume, or after a certain period, by their absolute want of power to prepare land of the same quality, so as to allow of the same rate of progress.

Owing to these two causes combined, we see that, notwithstanding this prodigious power of increase in vegetables and animals, their actual increase is extremely slow; and it is obvious, that, owing to the latter cause alone, and long before a final stop was put to all further progress, their actual rate of increase must of necessity be very greatly retarded; as it would be impossible for the most enlightened human efforts to make all the soil of the earth equal in fertility to the average quality of land now in use; while the practicable approaches towards it would require so much time as to occasion, at a very early period, a constant and great check upon what their increase would be, if they could exert their natural powers.

Elevated as man is above all other animals by his intellectual faculties, it is not to be supposed that

Population. the physical laws to which he is subjected should be essentially different from those which are observed to prevail in other parts of animated nature. He may increase slower than most other animals; but food is equally necessary to his support; and if his natural capacity of increase be greater than can be permanently supplied with food from a limited territory, his increase must be constantly retarded by the difficulty of procuring the means of subsistence.

The Power which Man possesses of Producing his own Food, is strictly limited by the Quantity and Nature of the Soil which he can command.

The main peculiarity which distinguishes man from other animals, in the means of his support, is the power which he possesses of very greatly increasing these means. But this power is obviously limited by the scarcity of land, by the great natural barrenness of a very large part of the surface of the earth, and by the decreasing proportion of produce which must necessarily be obtained from the continual additions of labour and capital applied to land already in cultivation.

It is, however, specifically with this diminishing and limited power of increasing the produce of the soil, that we must compare the natural power of mankind to increase, in order to ascertain whether, in the progress to the full cultivation and peopling of the globe, the natural power of mankind to increase must not, of absolute necessity, be constantly retarded by the difficulty of procuring the means of subsistence, and if so, what are likely to be the effects of such a state of things.

Mode of determining the natural Rate of Increase which applies to Mankind.

In an endeavour to determine the natural power of mankind to increase, as well as their power of increasing the produce of the soil, we can have no other guide than past experience.

The great check to the increase of plants and animals, we know from experience, is the want of room and nourishment; and this experience would direct us to look for the greatest actual increase of them in those situations where room and nourishment were the most abundant.

On the same principle, we should expect to find the greatest actual increase of population in those situations where, from the abundance of good land, and the manner in which its produce is distributed, the largest portion of the necessaries of life is actually awarded to the mass of the society.

Of the countries with which we are acquainted, the United States of America, formerly the North American Colonies of Great Britain, answer most nearly to this description. In the United States not only is there an abundance of good land, but from the manner in which it has been distributed, and the market which has been opened for its produce, there has been a greater and more constant demand for labour, and a larger portion of necessaries has been awarded to the labourer than in any of those other countries which possess an equal or greater abundance of land and fertility of soil.

Here, then, we should expect to find that the na-

tural power of mankind to increase, whatever it may be, would be most distinctly marked; and here, in consequence, it appears that the actual rate of the increase of population has been more rapid than in any known country, although, independently of the abundance of good land, and the great demand for labour, it is distinguished by no other circumstances which appear to be peculiarly favourable to the increase of numbers.

It has been stated that all animals, according to the known laws by which they are produced, must have a capacity of increasing in a geometrical progression. And the question with regard to man is, what is the rate of this geometrical progression?

Fortunately in the country to which we should naturally turn our eyes for an exemplification of the most rapid rate of increase, there have been four enumerations of the people, each at the distance of ten years; and though the estimates of the increase of population in the North American Colonies at earlier periods were of sufficient authority, in the absence of more certain documents, to warrant most important inferences, yet as we now possess such documents, and as the period they involve is of sufficient length to establish the point in question, it is no longer necessary to refer to earlier times.

According to a regular census made by order of Congress in 1790, which there is every reason to think is essentially correct, the white population of the United States was found to be 3,164,148. By a similar census in 1800, it was found to have increased to 4,312,841. It had increased then during the ten years from 1790 to 1800, at a rate equal to 36.3 per cent., a rate which, if continued, would double the population in twenty-two years and about four months and a half.

According to a third census in 1810, the white population was found to be 5,862,092,\* which, compared with the population of 1800, gives an increase in the second ten years at the rate of nearly 36 per cent., which, if continued, would double the population in about twenty-two years and a half.

According to the fourth census in 1820, the white population was found to be 7,861,710,† which, compared with the population of 1810, gives an increase in the third ten years at a rate per cent. of 34.1, which, if continued, would double the population in twenty-three years and seven months.

If we compare the period of doubling according to the rate of increase in the most unfavourable ten years of this series, with twenty-five years, we shall find the difference such as fully to cover all the increase of population which would have taken place from emigration.

It appears from a reference to the most authentic documents which can be collected on both sides of the Atlantic, that the emigration to the United States, during the last twenty-five years, falls decidedly short

\* These numbers are taken from Dr Seybert's *Statistical Annals*, p. 23.

† This number is taken from the *American National Calendar* for 1822, and has since been compared with the original census as published for the use of the members of Congress.

Population. of an average of 10,000 a-year. Dr Seybert, the best authority on the other side of the water, states that, from 1790 to 1810, it could not have been so much as 6000 a-year. Our official accounts of the number of emigrants to the United States from England, Ireland, and Scotland, during the ten years from 1812 to 1821, inclusive, give an average of less than 7000, although the period includes the extraordinary years 1817 and 1818, in which the emigrations to the United States were much greater than they were ever known to be before or since. The official American accounts, as far as they go, which is only for two years from the 30th September 1819, tend to confirm this average,\* and allowing fully for the emigrants from other European countries, the general average will still be under the ten thousand.

A new mode has, however, lately been † suggested of estimating the amount of increase in any country derived from emigration. It has been justly stated, that when a census is taken every ten years, and the population is distinguished into those above, and those below ten years of age, all above ten years of age, exclusive of emigrants, must have existed in the census immediately preceding, and, consequently, after having made a proper allowance for the mortality during these ten years, the excess above the remaining number must be attributed to emigration. If we had the means of estimating with accuracy the loss which would be sustained in America in ten years by a population not increased by additional births, this mode of estimating the amount of emigration would be unobjectionable, and often very useful.

But, unfortunately, the means are deficient. Even the annual mortality in the United States is not known. It was supposed by Dr Price (Vol. II. p. 50, 7th edit.) to be 1 in 50; by Mr Barton, in the *Transactions of the Society at Philadelphia* (Vol. III. No. 7), 1 in 45; and it is stated by Mr Bristed, in his work on *America and her Resources* (p. 20), that the annual deaths average throughout the United States 1 in 40, in the healthiest districts 1 in 56, and in the most unhealthy 1 in 35.

If, however, we could ascertain accurately the average annual mortality, we should still be unable to ascertain the amount of the loss in question; as, under any given law of mortality, it would depend so very much upon the rate at which the population was increasing. The truth of this observation will be placed in a striking light by the following short table, with which we have been favoured by a very able calculator, Mr Milne, author of a well-known *Treatise on Annuities and Assurances*. It is constructed on the supposition that the population, in each case, is always subject to the same law

of mortality as that which prevailed in all Sweden and Finland during the five years, ended with 1805, and that the number of births in the present year living in each case is 10,000.

	The Population constantly the same.	The Population increasing and having increased in geometrical progression for more than 100 years so as to double itself every	
		50 years,	25 years,
Total population ten years since, - -	393,848	230,005	144,358
Total above 10 years of age now, - -	320,495	195,566	126,176
Died during the term of 10 years, out of those living at its commencement,	73,353	34,439	18,182
Being one of -	5.3692	6.6786	7.9396

We see from this table, that, under the same law of mortality, the difference of loss sustained in ten years, by a people not increased by fresh births, would in the three cases supposed of a stationary population, a population doubling in 50 years, and a population doubling in 25 years, be as 1 in 5.3692, 1 in 6.6786, and 1 in 7.9396; and that when the population is doubling itself in 25 years, the loss would be very little more than one-eighth.

But the censuses must be allowed to form a *prima facie* evidence, that the population of the United States has, for a considerable time, been going on doubling itself in 25 years; and assuming this evidence to be true, which we are warranted in doing till better evidence is produced on the other side, it will appear that the amount of immigration, deduced from the rule here referred to, is less than 10,000 a-year.

Thus the white population of the United States in 1800 was 4,312,841. ‡ This population, without further accession of births, would in 1810 be diminished one-eighth, or reduced to 3,773,736. In 1810 the population above ten years of age was 3,845,389; and subtracting the former number from the latter, the difference, or amount of emigration, will be 71,653, or 7165 a-year.

Again, the white population of 1810 was 5,862,092, which, diminished by one-eighth in ten years, would be 5,129,331. The population above ten years of age in 1820 was 5,235,940. § Subtracting the former from the latter, the difference, or amount of emi-

\* *American National Calendar* for 1821, p. 237, and *North American Review* for October 1822, p. 304.

† This mode was suggested by Mr Booth in Mr Godwin's *Answer to Mr Malthus*.

‡ Seybert's *Statistical Annals*, p. 23.

§ *American National Calendar* for 1822, p. 246.

Population. gration, is 106,608, or 10,660 a-year; showing, as we should expect, a greater amount of emigration from 1810 to 1820 than from 1800 to 1810, but even in the latter ten years, and including emigrations from Canada, as well as all other countries, little exceeding 10,000.

Altogether then we can hardly err in defect, if we allow 10,000 a year for the average increase from emigration during the 25 years from 1795 to 1820, and applying this number to the slowest period of increase, when the rate was such as to double the population in 23 years and 7 months; it may be easily calculated, that in the additional year and five months, a population of 5,862,000 would have increased to an amount much more than sufficient to cover an annual emigration of 10,000 persons, with the increase from them at the same rate.

Such an increase from them, however, would not take place. It appears from an account in the *National Calendar* of the United States for the year 1821, that of the 7001 persons who had arrived in America from the 30th of September 1819 to the 30th of September 1820, 1959 only were females, and the rest, 5042, were males,\*—a proportion, which, if it approaches towards representing the average, must very greatly reduce the number from which any increase ought to be calculated.

If, however, we omit these considerations; if we suppose a yearly emigration from Europe to America of 10,000 persons for the 25 years, from 1795 to 1820, the greatest part of which time Europe was involved in a most extensive scene of warfare requiring all its population; and further, if we allow for an increase of all the emigrants during the *whole period*, at the fullest rate, the remaining numbers will still be sufficient to show a doubling of the population in less than 25 years.

The white population of 1790 was 3,164,148. This population, according to the rate at which it was increasing, would have amounted to about 3,694,100 in 1795; and supposing it to have just doubled itself in the 25 years, from 1795 to 1820, the population in 1820 would have been 7,388,200. But the actual white population of 1820 appears, by the late census, to be 7,861,710, showing an excess of 473,510, whereas an emigration of 10,000 persons annually, with the increase from them at 3 per cent., a rate which would double a population in less than 24 years, would only amount to 364,592.

But the most striking confirmation of the censuses of the United States, and the most remarkable proof of the rate of increase being occasioned almost exclusively by procreation, have been furnished to us by Mr Milne. In his work on *Annuities and Assurances*, which contains much valuable and interesting information on the subject of population, he had noticed the effects of the frequent pressure of want on the labouring classes of Sweden; which, by increasing the proportion of deaths,

rendered the law of mortality so accurately observed in that country by Professors Wargentin and Nicander, inapplicable to other countries more favourably circumstanced. But the law of mortality was observed to be gradually improving from the time that Dr Price constructed his Swedish table; and the period from 1800 to the end of 1805 was so free from scarcities and epidemics, and the healthiness of the country had been further so much improved by the introduction of vaccination, that he justly thought the law of mortality, as observed during these five years, might suit countries where the condition of the people was known to be much better than it had generally been in Sweden. On these grounds he applied the Swedish law of mortality, during the term mentioned, to the hypothesis of a population which had been increasing by procreation, in geometrical progression, for more than a hundred years, so as to double every twenty-five years. Assuming this population to be one million, he distributed it, by a process well known to persons conversant with these subjects, into the different ages referred to in the American censuses, and then compared them with the same number of persons distributed according to the actual returns of the ages in the American censuses for the three periods of 1800, 1810, and 1820.

The results are as follows:

*Distribution of a Population of 1,000,000 Persons in the under mentioned intervals of Age.*

Between the Ages of	According to			
	The Hypothesis.	United States. Census of 1800.	States. Census of 1810.	Census of 1820.
0 & 10	337,592	334,556	344,024	333,995
10 & 16	145,583	154,898	156,345	154,913
16 & 26	186,222	185,046	189,227	198,114
26 & 45	213,013	205,289	190,461	191,139
45 & 100	117,590	120,211	119,943	121,839
0 & 100	1,000,000	1,000,000	1,000,000	1,000,000
Under 16	483,175	489,454	500,369	488,908
Above 16	516,825	510,546	499,631	511,092

The general resemblance in the distribution of the ages in the three different censuses to each other, and to the hypothesis, clearly proves,

1st, That the distribution of the ages in the different enumerations must be made with some care, and may, therefore, be relied on as in the main correct.

2dly, That the law of mortality assumed in the hypothesis, cannot deviate essentially from the law of mortality which prevails in the United States; and,

\* The details for the next year have not yet been printed, but it is known that the whole number of passengers arriving in the United States was 10,722, of which 2415 were from the United States, leaving 8307 foreigners. *American Review* for October 1822, p. 304.

Population. 3dly, That the actual structure of the American population differs very little from what it would be if it were increasing regularly from procreation only, in geometrical progression, so as to double itself every 25 years; and that we may, therefore, safely infer that it has been very little disturbed by immigration.

If to these proofs of the rapid increase of population which has actually taken place, we add the consideration that this rate of increase is an average applying to a most extensive territory, some parts of which are known to be unhealthy; that some of the towns of the United States are now large; that many of the inhabitants must be engaged in unwholesome occupations, and exposed to many of those checks to increase which prevail in other countries; and further, that in the western territories, where these checks do not occur, the rate of increase is beyond comparison more rapid than the general average, after making the fullest allowance for immigration, it must appear certain, that the rate at which the population of the whole of the United States has actually increased for the last 30 years, must fall very decidedly short of the actual capacity of mankind to increase under the most favourable circumstances.

The best proof that can be obtained of the capacity of mankind to increase at a certain rate, is their having really increased at that rate. At the same time, if any peculiarly rapid increase which had appeared to take place in a particular country, were quite unsupported by other evidence, we might be disposed to attribute it to error or accident, and might scarcely be justified in founding important conclusions upon it. But this is far from being the case in the present instance. The rate of increase which has at times taken place in other countries, under the operation of great and obvious checks to the progress of population, sufficiently shows what might be expected if these checks were removed.

The countries most resembling the United States of America are those territories of the New World which lately belonged to Spain. In abundance and fertility of soil they are indeed superior; but almost all the vices in the government of the mother country were introduced into her colonial possessions, and particularly that very unequal distribution of landed property which takes place under the feudal system. These evils, and the circumstance of a very large part of the population being Indians in a depressed state, and inferior in industry and energy to Europeans, necessarily prevent that rapid increase of numbers which the abundance and fertility of the land would admit of. But it appears from the instructive and interesting account of New Spain, which M. Humboldt has not long since given to the public, that for the last half of the eighteenth cen-

Population. tury; the excess of the births above the deaths, and the progress of the population, have been very great. The following are the proportions of burials to baptisms in the registers of eleven villages, the details of which were communicated to M. Humboldt by the curates:

	Burials.	Baptisms.
At Dolores,.....	100	253
Singuilucan, ...	100	234
Calymaya, .....	100	202
Guanaxuato, .....	100	201
St Anne, .....	100	195
Marsil,.....	100	194
Queretaro,.....	100	188
Axapuzco, .....	100	157
Yguala, ...	100	140
Malacatepec, .....	100	130
Panuco, .....	100	123

The mean proportion is 100 to 183.

But the proportion which M. Humboldt considers as best suited to the whole of the population is 100 to 170.

In some of the villages above mentioned, the proportion of the births to the population is extraordinarily great, and the proportion of deaths very considerable, showing, in a striking point of view, the early marriages and early deaths of a tropical climate, and the more rapid passing away of each generation.\*

At Queretaro, it appears that the baptisms were to the population as 1 to 14, and the burials as 1 to 26.

At Guanaxuato, including the neighbouring mines of St Anne and of Marsil, the baptisms were to the population as 1 to 15, and the burials as 1 to 29.

The general result from all the information which could be collected was, that the proportion of births to the population, for the whole of the kingdom of New Spain, was as 1 to 17, and of the deaths as 1 to 30. These proportions of births to deaths, if they were continued, would double the population in 27½ years.

M. Humboldt further observes, that the information which he had collected respecting the proportions of the births to the deaths, and of these to the whole population, proves, that if the order of nature were not interrupted by some extraordinary and disturbing causes, the population of New Spain ought to double itself every nineteen years.†

It is known, however, that these causes do occur in the actual state of things: consequently we cannot consider the actual rate of the increase of population in New Spain as greater than according to the former calculation. But a rate of increase such

\* The details which M. Humboldt has given of the population of New Spain are highly interesting, as they are the first of any consequence which the public has yet received of a tropical climate. The peculiarities which mark them are exactly of the kind which might have been expected, though the proportion of births is still greater than we could have ventured to suppose.

† *Essai Politique sur le Royaume de la Nouvelle Espagne*, Liv. II. Chap. iv. pp. 330, et seq. Vol. I. Oct.

Population. as to double the population in 27½, in spite of all the obstacles enumerated by M. Humboldt, is very extraordinary. It is next to the increase of the United States, and greatly superior to any that can be found in Europe.

Yet in Europe, the tendency to increase is always very strongly marked, and the actual increase for periods of some length is sometimes much greater than could be expected beforehand, considering the obstacles to be overcome.

It appears from Susmilch,\* that the population of Prussia and Lithuania, after the great plague in 1709 and 1710, doubled itself in about 44 years, from the excess of the births above the deaths enumerated in the registers.

In Russia, the whole population in 1763 was estimated, by enumeration and calculation, at twenty millions, and in 1796 at thirty-six millions.† This is a rate of increase which would occasion a doubling in less than 42 years.

In 1695, the population of Ireland was estimated at 1,034,000. According to the late returns in 1821, it had increased to the prodigious amount of 6,846,949:‡ and it is thought that when the deficiencies have been supplied by the final returns of the enumerators, it will be upwards of seven millions. This is an example of an actual increase for 125 years together, at a rate which would double the population in about 45 years; and this has taken place under the frequent pressure of great distress among the labouring classes of society, and the practice of frequent and considerable emigration.

But for the proof of the power of population to increase under great obstacles of the preventive, as well as of the positive kind, we need not go out of Great Britain. The rate of increase since our enumerations have commenced has been very remarkable for a country which was considered as well peopled before, and some of the details accompanying the returns tend strikingly to illustrate the principle of population.

Increase of the Population of Great Britain from 1800 to 1821.

The population of Great Britain, according to the late enumerations, was, in 1801, 10,942,646, and, in 1811, 12,596,803.§ This is a rate of increase, during the ten years, of rather above 15 per cent., a rate which, if continued, would double the population in between 49 and 50 years.

By the last enumeration of 1821, it appears that the population was 14,391,631,|| which, compared with the population of 1811, gives a rate of increase during the ten years of 14.25 per cent., a rate which would double the population in about 52 years.

According to these numbers, the rate of increase during the last ten years was slower than that of the first; but it appears from the excess of the number of males above females in the enumeration of 1811, so opposite to the state of the population in 1801

and 1821, when the females exceeded the males, particularly at the latter period, that of the large number added to the population for the army, navy, and registered merchant ships in 1811, a considerable proportion must have been foreigners. On this account, and on account of the further difficulty of knowing what part of this number might properly belong to Ireland, it has been proposed to estimate the rate per cent. at which the population has increased in each of the ten years by the females only; and according to this mode of computation the population increased during the first period at the rate of 14.02 per cent., and during the second at the rate of 15.82.—(*Preliminary Observations*, p. 8.) This last rate of increase would double the population in less than 48 years.

The only objection to this mode of computation is, that it does not take into consideration the greater destruction of the males during the war. In 1801, the females exceeded the half of the population by 21,031, and in 1821 by 63,890, while, at the intermediate period, owing to the causes above mentioned, the females fell short of the half of the males by 35,685.

When, however, a proper distribution has been made of the army and navy among the resident population, and taking England and Wales alone, it appears that from 1801 to 1811 the population increased at the rate of 14½ per cent., and from 1811 to 1821, at the rate of 16½ per cent.—(*Preliminary Observations*, p. 32.) At the former of these rates, the period of doubling would be rather above 50 years—at the latter, under 46 years, and taking the whole period, the time of doubling would be about 48 years. Yet in Great Britain, there is a much larger proportion of the population living in towns, and engaged in occupations considered as unhealthy, than in any other known country of the same extent. There are also the best reasons for believing that in no other country of the same extent is there to be found so great a proportion of late marriages, or so great a proportion of persons remaining unmarried, as in Great Britain. It is further known that the number of emigrants from Great Britain greatly exceed those who come into the country. And if, under these circumstances, a demand for labour and an increase of the funds for its maintenance, could for 20 years together occasion such a rate of increase, as, if continued, would double the population in 48 years, and quadruple it in 96 years, it is in the highest degree probable, that if the encouragements to marriage and the means of supporting a family were as great as in America, the period of doubling in Great Britain would not be more than 25 years, even in spite of her great towns and manufactories; and would be decidedly less if these obstacles were removed.

sumed for  
the natural  
Progress of  
Population.

Population.

Taking, therefore, into consideration the actual rate of increase, which appears from the best documents to have taken place over a very large extent of country in the United States of America, very variously circumstanced as to healthiness and rapidity of progress; considering further, the rate of increase which has taken place in New Spain, and also in many countries of Europe, where the means of supporting a family, and other circumstances favourable to increase, bear no comparison with those of the United States; and adverting particularly to the great increase of population which has taken place in this country during the last 20 years, under the formidable obstacles to its progress which must press themselves upon the attention of the most careless observer, it must appear, that the assumption of a rate of increase such as would double the population in 25 years, as representing the natural progress of population, when not checked by the difficulty of procuring the means of subsistence, or other peculiar causes of premature mortality, must be very decidedly within the truth.

It may be safely asserted, therefore, that population, when unchecked, increases in a geometrical progression of such a nature as to double itself every twenty-five years.

Different  
Character of  
the Rate of  
Increase in  
the Food of  
a Limited  
Territory.

It would be unquestionably desirable to have the means of comparing the natural rate of the increase of population when unchecked, with the possible rate of the increase of food, in a limited territory, such as that in which man is actually placed; but the latter estimate is much more difficult and uncertain than the former. If the rate of the increase of population at a particular period of some little extent can be ascertained with tolerable exactness, we have only to suppose the continuance of the same encouragements to marriage, the same facility of supporting a family, the same moral habits, with the same rate of mortality, and the increase of the population at the same rate, after it had reached a thousand millions, would be just as probable as at any intermediate and earlier period; but it is quite obvious that the increase of food in a limited space must proceed upon a principle totally different. It has been already stated, that while land of good quality is in great abundance, the rate at which food might be made to increase would far exceed what is necessary to keep pace with the most rapid increase of population which the laws of nature in relation to human kind permit. But if society were so constituted as to give the fullest scope possible to the progress of cultivation and population, all such lands, and all lands of moderate quality, would soon be occupied; and when the future increase of the supply of food came to depend upon the taking of very poor land into cultivation, and the gradual and laborious improvement of the land already cultivated, the rate of the increase of food would certainly have a greater resemblance to a decreasing geometrical ratio than an increasing one. The yearly increment of food would, at any rate, have a constant tendency to diminish, and the amount of the increase of each successive ten years would probably be less than that of the preceding.

Practically, however, great uncertainty must take

place. An unfavourable distribution of produce, by prematurely diminishing the demand for labour, might retard the increase of food at an early period, in the same manner as if cultivation and population had been further advanced; while improvements in agriculture, accompanied by a great demand for labour and produce, might for some time occasion a rapid increase of food and population at a later period, in the same manner as if cultivation and population had been in an earlier stage of their progress. These variations, however, obviously arise from causes which do not impeach the general tendency of a continued increase of produce in a limited territory to diminish the power of its increase in future.

Under this certainty with regard to the general tendency, and uncertainty in reference to particular periods, it must be allowable, if it throws light on the subject, to make a supposition respecting the increase of food in a limited territory, which, without pretending to accuracy, is clearly more favourable to the power of the soil to produce the means of subsistence for an increasing population, than any experience which we have of its qualities will warrant.

Supposition  
respecting  
the Power of  
increasing  
Food.

If, setting out from a tolerably well peopled country such as England, France, Italy, or Germany, we were to suppose that, by great attention to agriculture, its produce could be permanently increased every twenty-five years by a quantity equal to that which it at present produces, it would be allowing a rate of increase decidedly beyond any probability of realization. The most sanguine cultivators could hardly expect that, in the course of the next two hundred years, each farm in this country on an average would produce eight times as much food as it produces at present, and still less that this rate of increase could continue, so that each farm would produce twenty times as much as at present in 500 years, and forty times as much in 1000 years. Yet this would be an arithmetical progression, and would fall short, beyond all comparison, of the natural increase of population in a geometrical progression, according to which the inhabitants of any country in 500 years, instead of increasing to twenty times, would increase to above a million times their present numbers.

It will be said, perhaps, that many parts of the earth are as yet very thinly peopled, and, under proper management, would allow of a much more rapid increase of food than would be possible in the more fully inhabited states of Europe. This is unquestionably true. Some parts of the earth would no doubt be capable of producing food at such a rate as to keep pace for a few periods with an unrestricted increase of population. But, to put this capacity fully into action, is of all things the most difficult. If it is to be accomplished by the improvement of the actual inhabitants of the different parts of the earth in knowledge, in government, in industry, in arts, and in morals, it is scarcely possible to say how it ought to be commenced with the best prospect of success, or to form a conjecture as to the time in which it could be effected.

If it is to be accomplished by emigration from the more improved parts of the world, it is obvious that it must involve much war and extermination besides all the difficulties usually attendant upon new

Insufficiency  
of Emigra-  
tion.

Population. settlements in uncivilized countries; and these alone are so formidable, and for a long time so destructive, that, combined with the unwillingness which people must always naturally feel to quit their own country, much distress would be suffered at home before relief would be sought for in emigration.

But, supposing for a moment that the object could be fully accomplished, that is, supposing that the capacity of the earth to produce the necessaries of life could be put fully into action, and that they were distributed in the proportions most favourable for the growth of capital, and the effective demand for labour, the increase of population, whether arising from the increase of the inhabitants of each country, or from emigrants issuing from all those countries which were more advanced in cultivation, would be so rapid, that, in a period comparatively quite short, all the good lands would be occupied, and the rate of the possible increase of food would be reduced much below the arithmetical ratio above supposed.

If, merely during the short period which has elapsed since our Revolution of 1688, the population of the earth had increased at its natural rate when unchecked, supposing the number of people at that time to have been only 800 millions, all the land of the globe, without making allowance for deserts, forests, rocks, and lakes, would on an average be equally populous with England and Wales at present. This would be accomplished in five doublings, or 125 years; and one or two doublings more, or a period less than that which has elapsed since the beginning of the reign of James the First, would produce the same effect from the overflowings of the inhabitants of those countries, where, owing to the further progress of cultivation, the soil had not the capacity of producing food so as to keep pace with the increase of an unrestricted population.

Whatever temporary and partial relief, therefore, may be derived from emigration by particular countries in the actual state of things, it is quite obvious, that, considering the subject generally and largely, emigration may be fairly said not in any degree to touch the difficulty. And, whether we exclude or include emigration,—whether we refer to particular countries, or to the whole earth, the supposition of a future capacity in the soil to increase the necessaries of life every twenty-five years by a quantity equal to that which is at present produced, must be decidedly beyond the truth.

Effect of the two different Rates of Increase when brought together.

But, if the natural increase of population, when unchecked by the difficulty of procuring the means of subsistence, or other peculiar causes, be such as to continue doubling its numbers in twenty-five years; and the greatest increase of food, which, for a continuance, could possibly take place on a limited territory like our earth in its present state, be at the most only such as would add every twenty-five years an amount equal to its present produce; it is quite clear that a powerful check on the increase of population must be almost constantly in action.

By the laws of nature man cannot live without food. Whatever may be the rate at which population would increase if unchecked, it never can actually increase in any country beyond the food necessary to support it. But, by the laws of nature in

respect to the powers of a limited territory, the ad- Population. ditions which can be made in equal periods to the food which it produces must, after a short time, either be constantly decreasing, which is what would really take place; or, at the very most, must remain stationary, so as to increase the means of subsistence only in an arithmetical progression. Consequently, it follows necessarily that the average rate of the actual increase of population over the greatest part of the globe, obeying the same laws as the increase of food, must be totally of a different character from the rate at which it would increase if unchecked.

The great question, then, which remains to be General character of the Checks to Population. considered, is the manner in which this constant and necessary check upon population practically operates.

If the soil of any extensive well peopled country were equally divided amongst its inhabitants, the check would assume its most obvious and simple form. Perhaps each farm in the well peopled countries of Europe might allow of one, or even two doublings, without much distress, but the absolute impossibility of going on at the same rate is too glaring to escape the most careless thinker. When, by extraordinary efforts, provision had been made for four times the number of persons which the land can support at present, what possible hope could there be of doubling the provision in the next twenty-five years?

Yet there is no reason whatever to suppose that any thing besides the difficulty of procuring in adequate plenty the necessaries of life, should either indispose this greater number of persons to marry early, or disable them from rearing in health the largest families. But this difficulty would of necessity occur, and its effect would be either to discourage early marriages, which would check the rate of increase by preventing the same proportion of births; or to render the children unhealthy from bad and insufficient nourishment, which would check the rate of increase by occasioning a greater proportion of deaths; or, what is most likely to happen, the rate of increase would be checked, partly by the diminution of births, and partly by the increase of mortality.

The first of these checks may, with propriety, be called the *preventive check* to population; the second, the *positive check*; and the absolute necessity of their operation in the case supposed is as certain and obvious as that man cannot live without food.

Taking a single farm only into consideration, no man would have the hardihood to assert that its produce could be made permanently to keep pace with a population increasing at such a rate as it is observed to do for 20 or 30 years together at particular times and in particular countries. He would, indeed, be compelled to acknowledge, that if, with a view to allow for the most sanguine speculations, it has been supposed that the additions made to the necessaries produced by the soil in given times might remain constant, yet that this rate of the increase of produce could not possibly be realized; and that, if the capacity of the soil were at all times put properly into action, the additions to the pro-

Population. duce would, after a short time, and independently of new inventions, be constantly decreasing, till, in no very long period, the exertions of an additional labourer would not produce his own subsistence.

But what is true, in this respect, in reference to a single farm, must necessarily be true of the whole earth, from which the necessaries of life for the actual population are derived. And what would be true in respect to the checks to population, if the soil of the earth were equally divided among the different families which inhabit it, must be true, under the present unequal division of property, and variety of occupations. Nothing but the confusion and indistinctness arising from the largeness of the subject, and the vague and false notions which prevail respecting the efficacy of emigration, could make persons deny in the case of an extensive territory, or the whole earth, what they could not fail to acknowledge in the case of a single farm which may be said fairly to represent it.

It may be expected, indeed, that in civilized and improved countries, the accumulation of capital, the division of labour, and the invention of machinery, will extend the bounds of production; but we know from experience, that the effects of these causes, which are quite astonishing in reference to some of the *conveniences* and *luxuries* of life, are very much less efficient in producing an increase of *food*; and although the saving of labour and an improved system of husbandry may be the means of pushing cultivation upon much poorer lands than could otherwise be worked; yet the increased quantity of the necessaries of life so obtained can never be such as to supersede, for any length of time, the operation of the preventive and positive checks to population. And not only are these checks as absolutely necessary in civilized and improved countries, as they would be, if each family had a certain portion of land allotted to it, but they operate almost exactly in the same way. The distress which would obviously arise in the most simple state of society from the natural tendency of population to increase faster than the means of subsistence in a limited territory, is brought home to the higher classes of an improved and populous country in the difficulty which they find in supporting their families in the same rank of life with themselves; and to the labouring classes which form the great mass of society, in the insufficiency of the real wages of common labour to bring up a large family.

If in any country the yearly earnings of the commonest labourers determined, as they always will be, by the state of the demand and the supply of necessaries compared with labour, be not sufficient to bring up in health the largest families, one of the three things before stated must happen; either the prospect of this difficulty will prevent some and delay other marriages; or the diseases arising from bad nourishment will be introduced, and the mortality be increased; or the progress of population will be retarded, partly by one cause and partly by the other.

According to all past experience, and the best observations which can be made on the motives which operate upon the human mind, there can be no well founded hope of obtaining a large produce from the

soil, but under a system of private property. It seems perfectly visionary to suppose that any stimulus short of that which is excited in man by the desire of providing for himself and family, and of bettering his condition in life, should operate on the mass of society with sufficient force and constancy to overcome the natural indolence of mankind. All the attempts which have been made since the commencement of authentic history to proceed upon a principle of common property, have either been so insignificant that no inference can be drawn from them, or have been marked by the most signal failures; and the changes which have been effected in modern times by education, do not seem to advance a single step towards making such a state of things more probable in future. We may, therefore, safely conclude that while man retains the same physical and moral constitution which he is observed to possess at present, no other than a system of private property stands the least chance of providing for such a large and increasing population as that which is to be found in many countries at present.

But though there is scarcely any conclusion which seems more completely established by experience than this, yet it is unquestionably true that the laws of private property, which are the grand stimulants to production, do themselves so limit it, as always to make the actual produce of the earth fall very considerably short of the *power* of production. On a system of private property no adequate motive to the extension of cultivation can exist, unless the returns are sufficient not only to pay the wages necessary to keep up the population, which, at the least, must include the support of a wife and two or three children, but also afford a profit on the capital which has been employed. This necessarily excludes from cultivation a considerable portion of land, which might be made to bear corn. If it were possible to suppose that man might be adequately stimulated to labour under a system of common property, such land might be cultivated, and the production of food and the increase of population might go on, till the soil absolutely refused to grow a single additional quarter, and the whole of the society was exclusively engaged in procuring the necessaries of life. But it is quite obvious that such a state of things would inevitably lead to the greatest degree of distress and degradation. And, if a system of private property secures mankind from such evils, which it certainly does, in a great degree, by securing to a portion of the society the leisure necessary for the progress of the arts and sciences, it must be allowed that such a check to the increase of cultivation confers on society a most signal benefit.

But it must perhaps also be allowed, that, under a system of private property, cultivation is sometimes checked in a degree, and at a period, not required by the interest of society. And this is particularly likely to happen when the original divisions of land have been extremely unequal, and the laws have not given sufficient facility to a better distribution of them. Under a system of private property, the only effectual demand for produce must come from the owners of property; and though it be true that the effectual demand of the society, whatever it may be,

Population. is best supplied under the most perfect system of liberty, yet it is not true that the tastes and wants of the effective demanders are always, and necessarily, the most favourable to the progress of national wealth. A taste for hunting and the preservation of game among the owners of the soil will, without fail, be supplied, if things be allowed to take their natural course; but such a supply, from the manner in which it must be effected, would inevitably be most unfavourable to the increase of produce and population. In the same manner, the want of an adequate taste for the consumption of manufactured commodities among the possessors of surplus produce, if not fully compensated by a great desire for personal attendance, which it never is, would infallibly occasion a premature slackness in the demand for labour and produce, a premature fall of profits, and check to cultivation.

It makes little difference in the actual rate of the increase of population, or the necessary existence of checks to it, whether that state of demand and supply which occasions an insufficiency of wages to the whole of the labouring classes be produced prematurely by a bad structure of society, and an unfavourable distribution of wealth, or necessarily by the comparative exhaustion of the soil. The labourer feels the difficulty nearly in the same degree, and it must have nearly the same results, from whatever cause it arises; consequently, in every country with which we are acquainted, where the yearly earnings of the labouring classes are not sufficient to bring up in health the largest families, it may be safely said, that population is actually checked by the difficulty of procuring the means of subsistence. And, as we well know that ample wages, combined with full employment for all who choose to work, are extremely rare, and scarcely ever occur, except for a certain time, when the knowledge and industry of an old country is applied, under favourable circumstances, to a new one; it follows, that the pressure arising from the difficulty of procuring subsistence is not to be considered as a remote one, which will be felt only when the earth refuses to produce any more, but as one which not only actually exists at present over the greatest part of the globe, but, with few exceptions, has been almost constantly acting upon all the countries of which we have any account.

It is unquestionably true, that, in no country of the globe have the government, the distribution of property, and the habits of the people, been such as to call forth, in the most effective manner, the resources of the soil. Consequently, if the most advantageous possible change in all these respects could be supposed at once to take place, it is certain that the demand for labour, and the encouragement to production, might be such, as for a short time, in some countries, and for rather a longer in others, to lessen the operation of the checks to population which have been described. It is specifically this truth constantly obtruding itself upon our attention, which is the great source of delusion on this subject, and creates the belief that man could always produce from the soil much more than sufficient to support himself and family. In the actual state of things, this power

has perhaps always been possessed. But for it we are indebted wholly to the ignorance and bad government of our ancestors. If they had properly called forth the resources of the soil, it is quite certain that we should now have but scanty means left of further increasing our food. If merely since the time of William the Conqueror, all the nations of the earth had been well governed, and, if the distribution of property, and the habits both of the rich and the poor had been the most favourable to the demand for produce and labour, though the amount of food and population would have been prodigiously greater than at present, the means of diminishing the checks to population would unquestionably be less. That difficulty in procuring the necessaries of life which is now felt in the comparatively low wages of labour almost all over the world, and is occasioned partly by the necessary state of the soil, and partly by a premature check to the demand for produce and labour, would then be felt in a greater degree, and would less admit of any relaxation in the checks to population, because it would be occasioned wholly and necessarily by the state of the soil.

It appears, then, that what may be called the proportionate amount of the necessary checks to population depends very little upon the efforts of man in the cultivation of the soil. If these efforts had been directed from the first in the most enlightened and efficient manner, the checks necessary to keep the population on a level with the means of subsistence, so far from being lightened, would in all probability be operating with greater force; and the condition of the labouring classes, so far as it depends on the facility of procuring the means of subsistence, instead of being improved, would in all probability be deteriorated.

It is to the laws of nature, therefore, and not to the conduct and institutions of man, that we are to attribute the necessity of a strong check on the natural increase of population.

But, though the laws of nature which determine the rate at which population would increase if unchecked, and the very different rate at which the food required to support population could be made to increase in a limited territory, are undoubtedly the causes which render necessary the existence of some great and constant check to population, yet a vast mass of responsibility remains behind on man and the institutions of society.

In the first place, they are certainly responsible for the present scanty population of the earth. There are few large countries, however advanced in improvement, the population of which might not have been doubled or tripled, and there are many which might be ten, or even a hundred times as populous, and yet all the inhabitants be as well provided for as they are now, if the institutions of society, and the moral habits of the people, had been for some hundred years the most favourable to the increase of capital, and the demand for produce and labour.

Secondly, Though man has but a trifling and temporary influence in altering the proportionate amount of the checks to population, or the degree in which

Population.

The Laws of Nature responsible for the necessity of checks to Population.

Man responsible for the scanty Population of the Earth, and the prevailing character of the Checks to it.

**Population.** they press upon the actual numbers, yet he has a great and most extensive influence on their character and mode of operation.

It is not in superseding the necessity of checks to population, in the progress of mankind to the full peopling of the earth (which may with truth be said to be a physical impossibility), but in directing these checks in such a way as to be the least prejudicial to the virtue and happiness of society, that government and human institutions produce their great effect. Here we know, from constant experience, that they have great power. Yet, even here it must be allowed, that the power of Government is rather indirect than direct, as the object to be attained depends mainly upon such a conduct on the part of individuals, as can seldom be directly enforced by laws, though it may be powerfully influenced by them.

This will appear, if we consider more particularly the nature of those checks which have been classed under the generalheads of Preventive and Positive.

**The Positive and Preventive Checks** resolvable into Moral Restraint, Vice, and Misery. It will be found that they are all resolvable into *moral restraint, vice, and misery.* And if, from the laws of nature, some check to the increase of population be absolutely inevitable, and human institutions have any influence upon the extent to which each of these checks operates, a heavy responsibility will be incurred, if all that influence, whether direct or indirect, be not exerted to diminish the amount of vice and misery.

Moral restraint, in application to the present subject, may be defined to be, abstinence from marriage, either for a time or permanently, from prudential considerations, with a strictly moral conduct towards the sex in the interval. And this is the only mode of keeping population on a level with the means of subsistence, which is perfectly consistent with virtue and happiness. All other checks, whether of the preventive or the positive kind, though they may greatly vary in degree, resolve themselves into some form of vice or misery.

The remaining checks of the preventive kind, are the sort of intercourse which renders some of the women of large towns unprolific; a general corruption of morals with regard to the sex, which has a similar effect; unnatural passions and improper arts to prevent the consequences of irregular connections. These evidently come under the head of vice.

The positive checks to population include all the causes, which tend in any way prematurely to shorten the duration of human life; such as unwholesome occupations—severe labour and exposure to the seasons—bad and insufficient food and clothing arising from poverty—bad nursing of children—excesses of all kinds—great towns and manufactories—the whole train of common diseases and epidemics—wars, infanticide, plague, and famine. Of these positive checks, those which appear to arise from the laws of nature, may be called exclusively misery; and those which we bring upon ourselves, such as wars, excesses of all kinds, and many others, which it would be in our power to avoid, are of a mixed

**Population.** nature. They are brought upon us by vice, and their consequences are misery.

Some of these checks, in various combinations, and operating with various force, are constantly in action in all the countries with which we are acquainted, and form the immediate causes which keep the population on a level with the means of subsistence.

Mr Malthus, in his work on this subject, has taken a view of the checks of population in most of the countries of which we have the best accounts. His object was evidently to trace in each country those checks which appeared to be most effective in repressing population; and to endeavour to answer the question, generally, which had been applied, particularly, to New Holland by Captain Cook, namely, By what means is the population of this country kept down to the number which it can subsist?

It was hardly to be expected, however, that the general accounts of countries which are to be met with, should contain a sufficient number of details of the kind required, to enable us to ascertain what portion of the natural increase of population each individual check which could be traced, had the power to overcome. In particular, it was not to be expected, that any accounts could inform us of the degree in which moral restraint prevails, when taken in its strictest sense. It is necessary, therefore, to attend chiefly to the greater or smaller number of persons who remain unmarried or marry late; and the delay of marriage, owing to the difficulty of providing for a family, when the degree of irregularity to which it may lead cannot be ascertained, may be usefully called the prudential restraint on marriage and population. And this will be found to be the chief mode in which the preventive check practically operates.

But if the preventive check to population, that check which can alone supersede great misery and mortality, operates chiefly by a prudential restraint on marriage, it will be obvious, as was before stated, that direct legislation cannot do much. Prudence cannot be enforced by laws, without a great violation of natural liberty, and a great risk of producing more evil than good. But still, the very great influence of a just and enlightened government, and the perfect security of property in creating habits of prudence, cannot for a moment be questioned. The principal causes and effects of these habits are thus stated in Mr Malthus's last work. (*Principles of Political Economy*, c. iv. sec. 2.)

“From high wages, or the power of commanding a large portion of the necessaries of life, two very different results may follow; one, that of a rapid increase of population, in which case, the high wages are chiefly spent in the maintenance of large and frequent families; and the other, that of a decided improvement in the modes of subsistence, and the conveniences and comforts enjoyed, without a proportionate acceleration in the rate of increase.

“In looking to these different results, the causes of them will evidently appear to be the different habits existing among the people of different countries, and at different times. In an inquiry into the

Prudential Restraint on Marriage.

Causes which principally affect the Habits of the Labouring Classes of Society.

The Causes of Population Restraint in the Labouring Classes of Society.

Population. causes of these different habits, we shall generally be able to trace those which produce the first result to all the circumstances which contribute to depress the lower classes of the people, which make them unable or unwilling to reason from the past to the future, and ready to acquiesce for the sake of present gratification, in a very low standard of comfort and respectability; and those which produce the second result, to all the circumstances which tend to elevate the character of the lower classes of society, which make them approach the nearest to beings who "look before and after," and who, consequently, cannot acquiesce patiently in the thought of depriving themselves and their children of the means of being respectable, virtuous, and happy.

"Among the circumstances which contribute to the character first described, the most efficient will be found to be despotism, oppression, and ignorance; among those which contribute to the latter character, civil and political liberty, and education.

"Of all the causes which tend to encourage prudential habits among the lower classes of society, the most essential is unquestionably civil liberty. No people can be much accustomed to form plans for the future, who do not feel assured that their industrious exertions, while fair and honourable, will be allowed to have free scope; and that the property which they either possess or may acquire, will be secured to them by a known code of just laws impartially administered. But it has been found by experience, that civil liberty cannot be permanently secured without political liberty. Consequently, political liberty becomes almost equally essential: and in addition to its being necessary in this point of view, its obvious tendency to teach the lower classes of society to respect themselves, by obliging the higher classes to respect them, must contribute greatly to all the good effects of civil liberty."

"With regard to education, it might certainly be made general under a bad form of government, and might be very deficient under one in other respects good; but it must be allowed that the chances, both with regard to its quality and its prevalence, are greatly in favour of the latter. Education alone could do little against insecurity of property; but it would powerfully assist all the favourable consequences to be expected from civil and political liberty, which could not indeed be considered as complete without it."

The varying prevalence of these habits, owing to the causes above referred to, combined with the smaller or greater mortality occasioned by other customs, and the varying effects of soil and climate, must necessarily produce great differences in different countries, and at different periods, in the character of the predominant checks to population and the force of each. And this inference, which inevitably follows from theory, is fully confirmed by experience.

The Positive Checks to Population predominated in Ancient Times.

It appears, for instance, from the accounts we have received of ancient nations, and of the less civilized parts of the world, that war and violent dis-

Population. eases were the predominant checks to their population. The frequency of wars, and the dreadful devastations of mankind occasioned by them, united with the plagues, famines, and mortal epidemics of which there are records, must have caused such a consumption of the human species, that the exertion of the utmost power of increase must, in many cases, have been insufficient to supply it; and we see at once the source of those encouragements to marriage, and efforts to increase population, which, with inconsiderable exceptions, distinguished the legislation, and general policy of ancient times. Yet there were some few men of more extended views who, when they were looking to the settlement of a society in a more improved state, were fully aware, that under the most beautiful form of government which their imagination could conceive, the greatest poverty and distress might be felt from a too rapid increase of population. And the remedies which they proposed were strong and violent in proportion to the greatness of the evil which they apprehended. Even the practical legislators who encouraged marriage, seemed to think that the supplies of children might sometimes follow too rapidly for the means of supporting them; and it appears to have been with a view to provide against this difficulty, and of preventing it from discouraging marriage, that they frequently sanctioned the inhuman practice of infanticide.

Under these circumstances, it is not to be supposed that the prudential restraint on marriage should have operated to any considerable extent. Except in a few cases where a general corruption of morals prevailed which might act as a preventive check of the most vicious kind, a large portion of the procreative power was called into action, the occasional redundancy from which was checked by violent causes. These causes will be found resolvable almost wholly into vice and misery; the first of which, and a large portion of the second, it is always in the power of man to avoid.

In a review of the checks to population in the different states of modern Europe, it appears that the positive checks to population have prevailed less, and the preventive checks more, than in ancient times, and in the more uncultivated parts of the world. The destruction occasioned by war has unquestionably abated, both on account of its occurring, on the whole, less frequently, and its ravages not being so fatal, either to man or the means of his support, as they were formerly. And although, in the earlier periods of the history of modern Europe, plagues, famines, and mortal epidemics were not unfrequent; yet as civilization and improvement have advanced, both their frequency and their mortality have been greatly reduced, and in some countries they are now almost unknown. This diminution of the positive checks to population, as it has been certainly much greater in proportion than the actual increase of food and population, must necessarily have been accompanied by an increasing operation of the preventive checks; and probably it may be said with truth, that in almost all the more improved countries of modern Europe, the principal check which at pre-

Prudential Restraint the predominant Check to Population in Modern Times.

Population. sent keeps the population down to the level of the actual means of subsistence, is the prudential restraint on marriage.

Yet in comparing together the accounts and registers of the different countries of modern times, we shall still find a vast difference in the character and force of the checks which are mainly in action; and it is precisely in this point of view that these accounts afford the most important instruction. Some parts of Europe are yet in an unimproved state, and are still subject to frequent plagues and mortal epidemics. In these countries, as might be expected, few traces are to be found of the prudential restraint on marriage. But even in improved countries, the circumstances may be such as to occasion a great mortality. Large towns are known to be unfavourable to health, particularly to the health of young children; and the unwholesomeness of marshy situations may be such as in some cases to balance the principle of increase, even when nearly the whole of the procreative power is called into action, which is seldom the case, in large towns.

Thus in the registers of twenty-two Dutch villages given by Sussmihl,\* and quoted by Mr Malthus, the mortality (occasioned, as may be supposed, chiefly by the natural unhealthiness of the country) was as high as one in twenty-two or twenty-three, instead of the more common proportion of one in thirty-five or forty; and the consequence was, that the marriages, instead of being in the usual proportion of one in about 108 of the population, were in the extraordinary high proportion of one in sixty-four; † showing a most unusual frequency of marriage, while, on account of the great mortality, the number of inhabitants was nearly stationary, and the births and deaths about equal.

On the other hand, in Norway, where the climate and modes of living seem to be extremely favourable to health, and the mortality was only one in forty-eight, the prudential restraint on marriage was called more than usually into action, and the marriages were only one in 180 of the population. (Malthus, Vol. I. p. 365, 5th ed.)

These may be considered as extreme cases, but the same result in different degrees is observable in the registers of all countries; and it is particularly to be remarked, that in those countries where registers of births, deaths, and marriages have been kept for a considerable time, the progressive diminution of mortality occasioned by the introduction of habits more favourable to health, and the consequent diminution of plagues and mortal epidemics, have been accompanied invariably by a smaller proportion of marriages and births. Sussmihl has given some striking instances of the gradual diminution in the proportion of the number of marriages during a part

of the last century. (*Gottliche Ordnung*, Vol. I. pp. 134, *et seq.*)

In the town of Leipsie, in the year 1620, the annual marriages were to the population as 1 to 82; from the year 1741 to 1756, they were as 1 to 120.

In Augsburgh, in 1510, the proportion of marriages to the population was 1 in 86; in 1750 as 1 to 123.

In Dantzie, in the year 1705, the proportion was as 1 to 89; in 1745, as 1 to 118.

In the Dukedom of Magdeburgh, in 1700, the proportion was as 1 to 87; from 1752 to 1755, as 1 to 125.

In the principality of Halberstadt, in 1690, the proportion was as 1 to 88; in 1756, as 1 to 112.

In the Dukedom of Cleves, in 1705, the proportion was 1 to 83; in 1755, 1 to 100.

In the Churmark of Brandenburg, in 1700, the proportion was 1 to 76; in 1755, 1 to 108.

Instances of this kind are numerous, and they tend to show the dependence of the marriages on the deaths in all old countries. A greater mortality almost invariably produces a greater number of marriages; and it must be equally certain, that except where the means of subsistence can be adequately increased, a greater proportion of marriages must occasion a greater mortality.

The proportion of yearly births to the whole population, must evidently depend principally on the proportion of marriages; and it appears, consequently, from registers, that in countries which will not admit of any considerable increase of population, the births, as well as the marriages, are mainly influenced by the deaths. When an actual decrease of population is not taking place, the births will always supply the vacancies made by death, and exactly so much more as the increasing wealth of the country and the demand for labour will admit. Every where in the intervals of plagues, epidemics, and destructive wars, the births considerably exceed the deaths; but while from these and other causes the mortality in different countries is extremely various, it appears from registers that, with the exception above stated, the births vary in the same proportion. ‡

Thus, in 39 villages of Holland, where the deaths, at the time to which the registers refer, were about 1 in 23, the births were also 1 in 23. In 15 villages round Paris, the births bore the same, or even a greater proportion to the whole population, on account of a still greater mortality, the births being 1 in 22  $\frac{7}{10}$ , and the deaths the same. In the small towns of Brandenburg, which were in an increasing state, the mortality was 1 in 29, and the births 1 in 24  $\frac{7}{10}$ . In Sweden, where the mortality was about 1 in 34  $\frac{1}{2}$ , the births were 1 in 28. In 1056 villages of Brandenburg, in which the mortality was about 1 in 39 or 40; the births were about 1 in 30. In Norway,

† This very large proportion of marriages could not all have been supplied from the births in the country, but must have been occasioned in part by the influx of strangers.

‡ Sussmihl, *Gottliche Ordnung*, Vol. I. p. 225.—*Essay on Population*, Vol. I. p. 456, 5th ed.

Population. where the mortality was 1 in 48, the births were 1 in 34.

In all these instances the births are evidently measured by the deaths, after making a proper allowance for the excess of births which the state of each country will admit. In such a country as Russia, this allowance must be great; as although the mortality might perhaps be taken as low as 1 in 48 or 50; the births were as high as 1 in 26, owing to the increasing resources of the country which admit of a rapid increase of the population.

Dependence of the Births on the Deaths strikingly illustrated in Switzerland.

Of all the countries which Mr Malthus has reviewed, there is none which so strikingly illustrates the most important fact of the dependence of the proportions of marriages and births on the deaths, and the general principles of population, as Switzerland. It appears, that between 1760 and 1770, an alarm prevailed respecting the continued depopulation of the country; and to ascertain the point, M. Muret, minister of Vevay, made a very laborious and careful search into the registers of different parishes from the time of their first establishment. He compared the number of births which had taken place during three different periods of 70 years each, the first ending in 1620, the second in 1690, and the third in 1760. And finding by this comparison, that the number of births was less in the second period than in the first, and less in the third period than in the second, he considered the evidence of a continued depopulation of the country from the year 1055 as incontrovertible.\* But the accounts which he himself produces, clearly show that, in the earlier periods to which he refers, the mortality was very much greater than in the latter; and, that the greater number of births found in the registers formerly, was not owing to a greater population, but to the greater proportion of births which always accompanies a greater mortality.

It appears from accounts, which are entirely to be depended on, that during the last period, the mortality was extraordinarily small, and the proportion of children reared from infancy to puberty extraordinary great. At the time when M. Muret wrote his paper, in 1766, the proportion of deaths to the population in the Pays de Vaud, was 1 in 45, of births 1 in 36, and of marriages 1 in 140. These are all very small proportions of births, deaths, and marriages, compared with other countries; but the state of things must have been totally different in the sixteenth and seventeenth centuries. M. Muret gives a list of all the plagues which had prevailed in Switzerland from 1520, from which it appears that this dreadful scourge desolated the country at short intervals during the whole of the first period, and extended its occasional ravages to within 22 years of the termination of the second. We may safely conclude, that, in these times, the average mortality was very much greater than at present. But what puts the question beyond a doubt, is the great mortality which prevailed in the neighbouring town of

Geneva in the sixteenth century, and its gradual diminution in the seventeenth and eighteenth. It appears from calculations, published in the *Bibliothèque Britannique*, (Tom. IV. p. 328,) that in the sixteenth century, the probability of life, or the age to which half of the born lived, was only 4.883, or under four years and eleven months; and the mean life, or the average number of years due to each person 18.511, or about eighteen years and a half. In the seventeenth century, the probability of life in Geneva was 11.607, about eleven years and seven months; the mean life 23.358, or twenty-three years and four months. In the eighteenth century, the probability of life had increased to 27.183, twenty-seven years and two months; and the mean life to thirty-two years and two months.

There can be no doubt, from the prevalence of the plague, and its gradual extinction as noticed by M. Muret, that a diminution of mortality of the same kind, though not perhaps to the same extent, must have taken place in Switzerland; but if with a mortality, which could not have been less than 1 in 30 or 32, the proportion of births had been what it was when M. Muret wrote, it is quite evident that the country would have been rapidly depopulated. But as it is known, from the actual amount of births found in the registers, that this was not the case, it follows as a necessary consequence, that the greater mortality of former times was accompanied by a greater proportion of births. And this at once shows the error of attempting to determine the actual population, either of different countries, or of different periods in the same country, by the amount of the births; and the strong tendency of population to fill up all vacancies, and very rarely to be limited by any other cause than the difficulty of supporting a family.

Switzerland and the Pays de Vaud afford other most striking instances of the dependence of the births on the deaths; and the accounts of them are perhaps more to be depended upon, as they appear to contradict the preconceived opinions of the person who collected them.

Speaking of the want of fruitfulness in the Swiss women, M. Muret says, that Prussia, Brandenburg, Sweden, France, and indeed every country, the registers of which he had seen, give a greater proportions of baptisms to the number of inhabitants than the Pays de Vaud, where this proportion is only as 1 to 36. He adds, that from calculations lately made in the Lyonois, it appeared that in Lyons itself the proportion of baptisms was 1 in 28, in the small towns 1 in 25, and in the villages 1 in 23 or 24. What a prodigious difference, he exclaims, between the Lyonois and the Pays de Vaud, where the most favourable proportion, and that only in two small parishes of extraordinary fecundity, is not above 1 in 26, and in many parishes it is considerably less than 1 in 40. The same difference, he remarks, takes place in the mean life. In the Lyonois it is little

\* *Mémoires, &c.* par la Société Economique de Berne, 1766, pp. 15, et seq.—*Essay on Population*, Vol. I. pp. 464, et seq. 5th edit.

Population. above 25 years; while in the Pays de Vaud, the lowest mean life, and that only in a single marshy and unhealthy parish, is  $29\frac{1}{2}$  years, and in many places it is above 45 years.

"But whence comes it (he says,) that the country where children escape the best from the dangers of infancy, and where the mean life, in whatever way the calculation is made, is higher than in any other, should be precisely that in which the fecundity is the smallest? How comes it again, that of all our parishes, the one which gives the mean life the highest, should also be the one where the tendency to increase is the smallest?"\*

To resolve this question, M. Muret says, "I will hazard a conjecture, which, however, I give only as such. Is it not that, in order to maintain in all places a proper equilibrium of population, God has wisely ordered things in such a manner as that the force of life in each country should be in the inverse ratio of its fecundity? In fact, experience verifies my conjecture. Leyzin (a village in the Alps), with a population of 400 persons, produces but a little above eight children a-year. The Pays de Vaud, in general, in proportion to the same number of inhabitants, produces 11, and the Lyonois 16. But if it happen that at the age of 20 years, the 8, the 11, and the 16 are reduced to the same number, it will appear that the force of life gives in one place what fecundity does in another. And thus the most healthy countries, having less fecundity, will not over-people themselves, and the unhealthy countries, by their extraordinary fecundity, will be able to sustain their population."

These facts and observations are full of the most important instruction, and strikingly illustrate the principle of population. The three gradations in the proportion of births which are here so distinctly presented to our view, may be considered as representing that variety in the proportion of births which is known to take place in different countries, and at different periods; and the practical question is, Whether, when this variety prevails without a proportionate difference in the rate of increase, which is almost universally the case, we are to suppose, with M. Muret, that a special providence is called into action to render women less prolific in healthy countries, and where improved habits of cleanliness have banished plagues and mortal epidemics; or to suppose, as experience warrants, that the smaller mortality of healthy and improved countries is balanced by the greater prevalence of the prudential restraint on marriage and population.

The subject is seen with particular clearness in Switzerland, on account of the population of some of the districts being stationary. The number of inhabitants on the Alps was supposed to have diminished. This was probably an error; but it is not improbable that they should have remained stationary, or nearly so. There is no land so little capable of providing for an increasing population as mountainous pastures. When they have been once fully

Population. stocked with cattle, little more can be done; and if there be neither emigration to take off the super-abundant numbers, nor manufactures wherewith to purchase an additional quantity of food, the deaths must equal the births.

This was the case with the Alpine parish of Leyzin before referred to, where, for a period of 30 years, the mortality and the proportion of births almost accurately kept pace with each other; and where, in consequence, if the positive checks to population had been unusually small, the preventive checks must have been unusually great. In the parish of Leyzin, according to M. Muret, the probability of life was as high as 61 years;† but it is obvious that this extraordinary degree of healthiness could not possibly have taken place under the actual circumstances of the parish with respect to the means of subsistence, if it had not been accompanied by a proportionate action of the prudential restraint on marriage; and accordingly the subsisting marriages, being late and unprolific, yielded only one birth to every twelve; the births were only 1 in 49, and the number of persons below 16 was only  $\frac{1}{4}$  of the population.

There can be little doubt that in the present case the extreme healthiness of the people, arising from their situation and employments, had more effect in producing the prudential check to population, than the prudential check in producing the extreme healthiness; yet it is quite certain that they must constantly act and re-act upon each other, and that if, when the circumstances are such as to furnish no adequate means for the support of an increased population, and no relief in emigration, the prudential check does not prevail, no degree of natural healthiness could prevent an excessive mortality. Yet to occasion such a mortality, a much greater degree of poverty and misery must have taken place, than in districts less favourably circumstanced with regard to health; and we see at once the reason why, in countries of mountainous pasture, if there be no vent in emigration, the necessity of the prudential check should be more strongly forced on the attention of the inhabitants, and should, in consequence prevail to a greater degree.

Taking countries in general, there will necessarily be differences as to natural healthiness in all the gradations, from the most marshy habitable situations to the most pure and salubrious air. These differences will be further increased by the nature of the employments of the people, their habits of cleanliness, and their care in preventing the spread of epidemics. If in no country was there any difficulty in obtaining the means of subsistence, these different degrees of healthiness would make a great difference in the progress of population; and as there are many countries naturally more healthy than the United States of America, we should have instances of a more rapid increase than that which has there taken place. But as the actual progress of population is, with very few exceptions, determined by the

\* *Mémoires, &c. par la Société Econ. de Berne, 1766, pp. 48, et seq.*

† *Ibid.* Table V. p. 65 of the Tables.

Population. relative difficulty of procuring the means of subsistence, and not by the relative natural powers of increase, it is found by experience that, except in extreme cases, the actual progress of population is little affected by unhealthiness or healthiness; but that these circumstances show themselves most powerfully in the character of the checks which keep the population down to the level of the means of subsistence, and occasion that sort of variety in the registers of different countries which was noticed in the instances mentioned by M. Muret.

Thus the population of two or three countries may be increasing at nearly the same rate, but one may be increasing chiefly from a great proportion of births, another from a small proportion of deaths, and a third from a more common proportion of both, in which three different cases the structure of the population and the registers of births, deaths, and marriages will be essentially different.

The rate at which the population of Sweden and Norway was increasing, at the time referred to by Mr Malthus, was not far from the same; but their registers differed in almost all points. While the births in Sweden were 1 in 28 of the population, the births in Norway were only 1 in 34; while the marriages in Sweden were 1 in 112, in Norway they were only 1 in 130; and while the mortality in Sweden was 1 in 34½, in Norway it was only 1 in 48.\* These different proportions of births, deaths, and marriages must essentially alter the whole structure of the population. The proportion of persons living at different ages, would be essentially different; the generations in one country would pass away sooner than the generations in the other; and Sweden might be said to increase principally from the large proportion of its births, and Norway, from the small proportion of its deaths, or its small mortality.

A large proportion of births, when they have room to expand themselves, is the most powerful element of increase, and is absolutely necessary in order to effect the shortest period of doubling with which we are acquainted; but two countries may have nearly the same proportion of births, and yet the population of one be quite stationary, while the population of the other is increasing with the greatest known rapidity. The proportion of births in the Dutch villages first noticed, approaches towards that of the United States of America; yet in the one case the population did not increase at all, and in the other it has increased so fast, as to be taken as a specimen of the natural progress of population when interrupted by the fewest checks to which human society is subject. In this case, though the proportions of births and marriages to the whole population might not be very unlike, and possibly no very great difference might appear in the proportion of marriages to births, the other points in the registers would be in

the opposite extremes. While the mortality in the Dutch villages was as high as 1 in 22, it would probably be 1 in 41, or less, in the United States.— While the births and deaths in the Dutch villages were in the ratio of equality, in the United States they would be nearly in the proportion of 41 to 19.

In the same manner, two countries might have nearly the same mortality, and yet, in other points, be very different; and while one was increasing most rapidly, the other might be increasing very slowly. The proportion of deaths to the population in the Pays de Vaud, is not very essentially different from that of the United States, but the proportion of births, and the structure of the population present the most striking contrasts. The proportion of births for the whole of the Pays de Vaud was, according to M. Muret, 1 in 36, in many parishes it was considerably less than 1 in 40, and in one parish as low as 1 in 49; while, in the United States, it must be somewhere between 1 in 19 and 1 in 20.— The structure of the population was different accordingly. In the whole of the Pays de Vaud, the proportion of the population under 16 was one-third, in many parts and in the whole of the Canton of Berne one-fourth, while in the United States, it is as high as one-half.
