even a drug-related behavior. Variations at numerous genes, particularly those involved in the neurobiological systems, are being studied as potential candidates in association studies of substance abuse. Environment also may play an important role in the risk variation, both independently and in interaction with genetic factors.

GRIEF, LOSS, AND SUBSTANCE ABUSE

Any discussion of relationships between and among grief, loss, and substance abuse must first begin with an overview of loss and the resulting grief. While grief is most commonly defined as an emotional response to loss, there are more wide-reaching consequences in one's life. Beyond emotional responses, there are

social, physical, psychological, cognitive, and spiritual dimensions to consider. Significant loss affects holistic health, including the ability to manage emotions, to function within the social environment, to make sound decisions, and to engage spiritually to uncover or find meaning in precipitating loss.

Many discussions of grief, loss, and substance abuse take place within the context of death. Although death may be the most commonly referenced event leading one to grief, most people's lives are affected by grief and loss from a multitude of sources. In addition to the loss suffered through death, there is a broad range of adverse circumstances, life events, and transitions that often result in grief. The source of loss ranges from loss of employment (either voluntary or involuntary), loss of friendships, loss of beloved pets, loss of socioeconomic state, and loss of socioeconomic status through financial hardship or social isolation or ostracism.

Individual responses to loss are varied and unpredictable, depending to a large extent on a person's support system, coping skills, and life situation. An individual's grieving process is equally complex, influenced by such factors as personality, family, culture, and spiritual and religious beliefs and practices. Each of these elements plays an important role in how someone responds to loss and the grief that frequently accompanies the loss. The relationship between job loss and individual, social, and psychological problems is well documented by counselors and researchers. The potential for loss of income, socioeconomic status, social network, and sense of purpose are numerous and potentially painful for many people. For people who lack resources and appropriate coping skills, the trauma of loss may lead to substance abuse.

In addition to personal loss, loss occurs on a larger, more public scale. Increased substance abuse sometimes results from the reaction of many people to disasters, armed conflicts, and other forms of mass violence. In a study following the September 11, 2001, attack on the World Trade Center, researchers estimated that within 5 to 8 weeks after 9/11, 265,000 people experienced increased use of alcohol and other drugs, with 226,000 consuming more alcohol and 29,000 abusing more marijuana.

Grief, Loss, and Substance Abuse

There are multifarious relationships among and between substance abuse and issues of loss and grief. One of the most common connections is grief and loss

as the stimulus to substance abuse, or causing more severe substance abuse.

Substance abuse may either begin or become more severe due to the death of a loved one, the end of a relationship, or other traumatic life transitions and experiences. An older person who loses a life partner through either death or separation may begin to abuse alcohol in response to the loneliness and grief. Unresolved grief often leads to challenges in other, seemingly unrelated areas of life. People who have experienced loss but have not yet had the opportunity to reflect and process the occurrence may seek solace in other ways, with substance abuse being among the most common.

Parents who experience the death of a child often exhibit symptoms of trauma, including post-traumatic stress disorder and intense grief reactions that place them at high risk for complicated grief and mourning. This grief response, coupled with a lack of support, can increase the risk that a parent may cope with the loss through increased substance use or abuse. In addition to complicated grief responses, some parents may have other risk factors for substance abuse, such as family history of substance abuse, depression, anxiety, current use patterns, previous addiction history, or extreme isolation and lack of support. Any of these risk factors, coupled with the recent death of a child, may signal the need for additional support and possible treatment.

Another commonly referenced relationship between loss, grief, and substance abuse is substance abuse leading to loss and grief. Substance abuse causes grief, loss, or both, for addicts' loved ones or those with whom the addict has significant relationships. For example, many addicts witness the end of important relationships in their lives as a result of their behavior or loved ones' response to their behavior.

A slightly less common but valid causal relationship is the grief or loss as a result of recovery from substance abuse. People who are recovering from addiction must often terminate relationships with people, places, and behavior that have enabled their abuse; this situation can result in perceived isolation. A shared culture and substantive supportive systems may no longer be available, leading to grief and bereavement.

Treatment

Counselors and therapists encounter clients at all stages of grief and witness a vast range of responses to loss, either prior to, during, immediately following,

or many years following the loss. In the period prior to loss and immediately following, the individual experiencing the loss is frequently given significant attention and support. As time passes, however, there is often a decline in the amount of formal and informal support available to the person who has experienced the loss. In American culture particularly, people are expected to carry on their routine lives and to recover quickly from the loss. On the contrary, many people who experience loss report their need for support increasing in the years following the loss, just as the support is receding.

Counselors, therapists, and other helping professionals who begin working with people who are grieving should acknowledge the loss and work with the client to discover the best possible sources of support. Grief counseling for the loss, even years following the experience, offers inestimable value to the client.

Clients may present to counselors and therapists with seemingly unrelated issues, including substance abuse, illustrating the need for a comprehensive loss history. Topics discussed in sessions may include the impact of the loss on the client's life and his or her relationships with others, as well as any unresolved issues associated with the loss. Such discussions may include a review of the client's relationship with a loved one who has died or terminated a relationship, an exploration of the circumstances surrounding the loss, and support for the associated issues or losses that have occurred as a result of the initial loss. Regardless of the client's presenting issue, the counselor should refer the client to treatment if the client is using or abusing substances.

Several approaches have been used successfully with clients experiencing substance abuse related in some way to loss and grief, including addiction counseling, cognitive behavioral therapy, motivational interviewing, and supportive psychotherapy. Addiction counseling, which concentrates on the symptoms of substance abuse and impaired functioning, emphasizes the building and strengthening of appropriate coping strategies and tools for recovery. The primary goals of addiction counseling are to help the client cease and abstain from the addictive behavior and to recover from the problems caused by the substance abuse. The client has an active role in his or her counseling, taking responsibility for his or her recovery.

Cognitive behavioral therapy is a short-term approach that has been extensively evaluated in

clinical trials and has empirical support as an effective treatment. Cognitive behavioral therapy has also demonstrated enduring qualities as well as efficacy in cases of severe substance abuse. The approach is structured and goal oriented, but it is also flexible enough to be used with a diverse client population in various settings.

Motivational interviewing is a more recent approach that has proven effective in addressing grief among substance abusers. Motivational interviewing is a set of formalized, theory-based therapist responses to help clients identify and acknowledge substance abuse behaviors and work toward cessation of the behavior. The strength of motivational interviewing is that the counselor or therapist has an active role in contributing to the degree of clients' motivation to change. Through the use of eight interaction technique strategies, counselors and therapists are able to facilitate and support a client's efforts to change.

Finally, social support and connectedness are essential for people who are struggling with substance abuse related to loss and grief. Bereavement groups are often an effective means through which people can relate with others who have experienced loss, many of whom may also be struggling with substance abuse as a result or cause of the loss.

GROUP THERAPY AND COUNSELING

Groups play a central role in the treatment of substance abuse. The Association for Specialists in Group Work has categorized the various kinds of groups into four categories. Psychoeducational groups provide information and limited practice in using new knowledge. They are short term and might include such groups as "driving under the influence" (DUI) classes or educational groups for addicts beginning treatment. Counseling groups address common problems and focus less on education than on members' interactions and mutual problem solving. These are generally short term and might include such groups as support groups for children of alcoholics. Psychotherapy groups aim to change people on a deeper level than do the other kinds of groups. They are typically longer lasting and ongoing. Recovering substance abusers are usually seen as candidates for psychotherapy groups. Finally, task or work groups are not considered therapeutic in that they are focused on getting specific tasks accomplished (e.g., committees and project teams). This entry focuses on counseling and psychotherapy groups.

Therapeutic Components of Groups

Although individual counseling is certainly useful in many ways, there are several therapeutic factors operating in well-conducted therapeutic groups that affirm their vital importance.

Research has shown that, in general, group and individual therapies have essentially equivalent efficacy. However, it is clear that different processes occur in group and individual treatments. That is, each type of treatment contains specific therapeutic components or factors. One widely accepted list of such components is that by Irvin D. Yalom. Yalom defined therapeutic factors as the actual mechanisms of effecting change in the patient. The 11 factors that he identified are instillation of hope, universality, imparting information, altruism, corrective recapitulation of the primary family group, development of socializing techniques, imitative behaviors, interpersonal learning, group cohesiveness, catharsis, and existential factors.

Dennis M. Kivlighan and his colleagues found overlap among many of these factors. Indeed, they found four components underlying this (and similar) lists. These components are (1) emotional awareness

or insight (including strong affective experiences associated with gaining awareness or insight); (2) relationship climate (including formation and maintenance of relationships between either client and therapist or client and other group members); (3) other-versus self-focus (including clients' focus outside of themselves, especially the factor of altruism); and (4) problem definition and change (the problem-solving aspect of therapy experiences, including cognitive identification and understanding of a problem and behavioral changes that may follow).

The two components of relationship climate and other-versus self-focus tend to operate prominently in group psychotherapies, while emotional awareness or insight and problem definition and change are more prominent processes in individual therapies. The primacy of the first two components in groups is consistent with Yalom's theory that other group members are the main source of change in group therapy. In other words, group therapy is effective, in large measure, specifically because of the impact of interpersonal and relational factors (e. g., altruism, group cohesiveness).

Of course, not all factors are equally operative in all groups. Group cohesiveness, for example, seems to be a strong factor in homogeneous groups, such as those conducted in substance abuse treatment settings. Group members in homogeneous groups also tend to report greater satisfaction with their therapy experiences. In general, there is a consensus that the factors perceived by clients as being most helpful are group cohesiveness, catharsis, and interpersonal learning.

Finally, effectiveness of group counseling and therapy is related to certain dimensions of group leadership. Morton Lieberman and Mitch Golant have identified five empirically based leader functions. These are (1) evoking/stimulating emotions (the leader uses a tactic to engage members and elicit emotional responses), (2) supporting/caring (offers support, friendship, and affection), (3) facilitating meaning attributions (providing a meaning structure in the face of members' anxieties; i.e., labeling experiences as these occur, teaching how to change by utilizing in-group exercises, introducing schemes of making sense of a member's confusing "problem" experiences), (4) exerting an executive/management function (this includes setting rules and norms for the group, setting goals with the group, and blocking "toxic" interactions), and (5) using one's self (including disclosing the therapist's feelings in the here-and-now of the group).

Although all of these functions are important, the two most significant, in terms of client outcomes, seem to be meaning attribution and management. Thus, the more that a leader provides members with schemas to understand their problems and frameworks for change and explains, compares, summarizes, and invites members to seek feedback, the more a client is likely to benefit from the group experience. Likewise, managing time effectively, setting rules and norms, and blocking toxic interactions all have beneficial effects for clients.

Basic Processes

While much has been written about group process, it is important to recognize that group counseling and therapy are essentially an experiential form of therapy. As such, they attempt to expand individuals' awareness of themselves, their feelings, their interactions with others, and others' perceptions of them. This emphasis on a group member's coming to know oneself (i.e., one's impact on others as well as others' perceptions of oneself and their feedback) is central to a therapeutic group.

The process of how a person comes to know him- or herself has historically been dealt with as a matter of introspection. It has often been assumed that thinking about what kind of person one is will lead to insight and to self-definition. One significant exception to this perspective has been the "self-perception theory" of Daryl Bem. According to self-perception theory, everyone comes to know oneself in just the same way that we come to know others. We observe our own behaviors in a various situations, and then we make attributions about our behaviors.

This is especially true in group therapy. To the extent that a group is experiential, it allows a member to experience oneself in various interpersonal situations and to observe oneself.

Self-concepts do change. People change their self-beliefs, for instance, based on the self-presentations they make to others, and such changes affect their behaviors and their self-concepts. Anita Kelly proposed that self-presentation and impression management strategies by psychotherapy clients are crucial to successful psychotherapy. She proposed a four-step model of change in psychotherapy based on a self-presentation that involves (1) clients performing various favorable self-presentations (e.g., altruistic acts in a group), (2) therapists (and group members) giving

feedback based on the client's self-presentations, (3) such feedback leading to clients' shifts in self-beliefs (e.g., "I *am* an altruistic, helpful person"), and (4) changes in self-beliefs leading to changes in clients' self-concepts.

This perspective is significant because it puts self-description and self-definition at the center of group therapy. There appear to be six steps in the self-definition process in group counseling and psychotherapy. In a therapeutic group experience, people learn about themselves by observing their own behaviors:

1. They pay attention to (i.e., observe) the things they say to others about themselves.
2. The group therapist and other members encourage new behaviors, including new recognitions of feelings, new experiences, and new cognitions.
3. Members then try out new behaviors in (and outside of) the group.
4. With the counselor's help, they reflect on these tried-out behaviors: What do these behaviors say about the kind of persons they are or can become?
5. They then redefine their selves according to their new behaviors and the feedback that other members give them.
6. Feedback from other members and from the therapist allows them to check on their changes.

When this sequence happens, therapists often notice that the therapy is "working." It is therefore part of the group therapist's role to facilitate each step of this process.

One crucial element in this process is feedback from group members. However, feedback is not always easy for members to give. A carefully done study by D. Keith Moran and colleagues pointed out that group members are happy to give positive feedback to other members but are very reluctant to provide corrective feedback. This appears to happen because most do not want to risk the loss of acceptance by the group. There seem to be at least three tactics that the group therapist should employ in order to overcome this hesitancy. First, as Yalom has suggested, it is important to remind the group that therapy is not like ordinary social intercourse. Members should be more honest as well as sensitive with the others in the group. Second, the therapist should

model giving corrective feedback in such a way that is helpful and not damaging. Third, feedback should be labeled, by the therapist, as an altruistic act whenever it is given appropriately and sensitively.

Twelve-Step Groups

The role of groups such as Alcoholics Anonymous and Narcotics Anonymous in the treatment of substance-abusing individuals cannot be ignored. Although Twelve-Step meetings clearly do not fall in the Association for Specialists in Group Work classification of therapy groups, they do seem to occupy a space somewhere between psychoeducational and counseling groups. It has been found that mental health professionals tend to view support groups significantly less positively than professionally led groups. Nevertheless, approximately 18% of the population of the United States have participated in support groups at some time in their lives, and almost 7% have done so in the past year. Furthermore, 50% of Twelve-Step group participants also obtain professional services for their substance abuse problems.

What do Twelve-Step groups have to offer? To the recovering person, they can be a lifeline to overcoming addiction and maintaining recovery. These groups utilize at least eight of the therapeutic factors outlined earlier. Instillation of hope occurs when members realize that others have overcome their problems and so they can as well. Universality occurs when members recognize that they are not alone in feelings of isolation and hopelessness. Imparting information occurs regularly in such groups. Altruism is a part of every Twelve-Step group, and it is the heart of the twelfth step itself (i.e., helping other alcoholics or addicts). Imitative behaviors often occur when members see how others have dealt with similar issues. Some groups achieve group cohesiveness to the extent that individual members “carry the group around in their heads” and thus internalize and feel close to it. Catharsis occurs often as members become emotional in meetings. Finally, existential factors abound in Twelve-Step groups. Indeed, many meetings are not about the alcohol or substance of abuse but rather focus on the meaning of one’s life. For example, it is not possible to go through the painful experiences of recovery without at least implicitly asking oneself the question: “Why am I struggling to overcome this?” The answer always has to do with the reasons for going on with life.

Conclusion

Counseling and psychotherapy groups play a major role in the treatment of substance abuse. Among the most significant therapeutic factors operating in such groups are emotional awareness, the relationships and climate of the group, other- versus self-focus, and problem definition and accompanying change. Leadership of groups has been found to be very important, especially the functions of providing members a meaning structure in the face of their addiction experiences and providing a safe and non-toxic environment for personal growth. The process of self-definition is basic to all successful therapeutic experiences in both professionally led and support groups.

H

HALLUCINOGENS

Hallucinogens are drugs that cause hallucinations or distortions in a person's perception of reality. Hallucinations are described as seeing images or hearing sounds that are not actually present and can result from medications, disease, mental illness, and even insomnia. This entry is concerned with the history, effects, and classification of hallucinogens that are discussed and/or used most frequently: lysergic acid diethylamide (LSD), phencyclidine (PCP), ketamine (known on the street as *Special K*), psilocybin (street name, *magic mushrooms*), mescaline (peyote), methylenedioxymethamphetamine (MDMA or *ecstasy*) and dimethyltryptamine (DMT). However, drugs that are not labeled hallucinogens, such as marijuana and cocaine, may cause hallucinations when taken in high doses or combined with other drugs.

Hallucinogens challenge what one knows and believes about human behavior and how the brain works. They have raised an abundant amount of controversy, and there are many different opinions regarding whether the effects of hallucinogens are positive or negative. Several researchers have labeled hallucinogens among the safest illicit drugs since they are not physically addictive. However, the heavy use of hallucinogens can result in a psychological dependence, and hallucinogen use disorders are included as diagnostic categories in the *Diagnostic and Statistical Manual of Mental Disorders*. There are no known physical withdrawal symptoms associated with hallucinogens, and overdosing is rare.

The federal government categorizes most hallucinogens as Schedule I drugs, the classification used for the most dangerous drugs in the United States. Schedule I drugs have high potential for abuse and have no known recognized medical use. With the exception of ketamine (used as an animal tranquilizer), hallucinogens have no recognized medical use in the United States and are illegal to possess.

History

Several different cultures have utilized hallucinogens for centuries. Hallucinogens have been used for social purposes, rituals, and ceremonies. Indigenous peoples discovered hallucinogens in plant form and integrated them into their religious belief patterns. Traditionally, it was believed that hallucinogens created an enlightened sense of spirituality, opened users to the gods, and provided them with greater spiritual insight. These beliefs still hold true in some North and South American countries, as well as some Asian countries such as Malaysia and Borneo.

Hallucinogens have been used in medicine and research. In the 1950s, PCP was developed for use as an anesthetic in medical procedures. The use of PCP was short-lived because the effects were extreme and dangerous. Instead, ketamine was designed as a safer replacement. Additionally, researchers wanted to identify how hallucinogens work in the brain, and this desire led to the widespread use of LSD and ecstasy by psychiatrists and researchers in the 1950s. LSD specifically was used for therapy in an attempt to aid individuals in exploring thoughts and in expressing feelings.

Hallucinogens are notorious for their seemingly mind-expanding effects. As a result, there have been documented increases in the use of hallucinogens for recreational purposes during certain periods of time. For example, LSD was discovered in 1938 by Dr. Albert Hofmann, but it was not until the 1960s' freedom movement that hallucinogens became popular for recreational use. During this time, hallucinogens were considered mind-enhancing psychedelics, and LSD became a widespread drug of choice for many people.

In the late 1990s, ketamine, magic mushrooms, and ecstasy became popular club drugs used by teenagers and college-age adults. Since then, there has been a decrease in the use of hallucinogens by young adults. In the 2007 Monitoring the Future's annual survey of drug use by young people, the use of hallucinogens in the last 30 days by 12th graders, college students, and young adults was less than half than the rate in 1995. In 2006, less than 2% of these age groups reported hallucinogen use in the previous month.

Physiological and Psychological Effects

With the exception of PCP, hallucinogens have similar physiologic effects, although differences exist between onset, duration, and intensity. Hallucinogens affect the body in numerous ways. Generally, hallucinogens can cause an increased heart rate and blood pressure, high body temperature, dilated pupils, dizziness, nausea, loss of appetite, dry mouth, sweating, numbness, and tremors. Taken in high doses, hallucinogens may result in sedation or a loss of consciousness.

The hallucinogenic effects of these drugs are sensory, emotional, and psychological. Hallucinogens affect emotional well-being and alter a person's thought processes and mood. They also affect how the brain interprets reality. Typically, hallucinogens cause an individual to experience a distorted perception of reality, affecting one's sense of time, space, and surrounding environment, as well as the way one hears, thinks, and sees.

An individual inebriated by a hallucinogenic drug might hear sounds and voices that do not exist. Individuals may see faces in clouds or visualize things that are not actually present. Another side effect, synaesthesia, can occur when the senses become crossed or mixed-up. This crossing of senses leads the individual to believe that he or she is feeling color, hearing sights, or seeing sounds.

The outcome and side effects of a hallucinogenic experience is unique to each individual. The experience is greatly influenced by several factors: the type and dose of drug, the user's state of mind before and during use, the environment in which the drug is taken, and the user's previous experience with drugs.

The use of hallucinogens is often described as a very intense experience. Some individuals become insightful or develop a sense of euphoria and increased enlightenment. They may be giddy and experience stimulating visuals with vivid, deep colors. Others might hear or see things that are frightening. They may become anxious or uneasy. This emotion can result in a panic reaction, which can lead to mood swings, paranoia, or depression. Therefore, hallucinogens have been known to result in either a good trip (enlightened experience) or a bad trip (aversive reaction). Although hallucinogens do not mimic mental illness or psychosis, in some cases they can trigger a psychotic experience.

Long-Term Effects

Hallucinogen persisting perception disorder, commonly known as flashback, is a possible long-term effect of using hallucinogens. Flashbacks are defined as experiencing spontaneous hallucinations or hallucinogenic effects after an individual is no longer taking the drug. Other common chronic effects of hallucinogens include but are not limited to persistent psychosis, anxiety, paranoia, depression, and a lack of motivation.

Classification of Hallucinogens

Hallucinogens are organic compounds. Many occur naturally in plant form or are derived from plants, while several others are synthetic. The incredible variation of hallucinogens leads to the diversity of their uses, thus making it nearly impossible to understand their complexity without looking at their chemical structure and individual characteristics. This section explains how the chemical structure of hallucinogens affects how they work in the brain and provides a brief introduction to common drugs in each group.

Serotonin-Like Group

Serotonin is a neurotransmitter important in regulating anger, body temperature, mood, sleep, nausea, and appetite. Chemically and structurally, there are

several hallucinogens that mimic the neurotransmitter serotonin and use it as their chemical messenger. These drugs are LSD, psilocybin, peyote, and DMT. All of these drugs work the same way and produce similar effects. They prohibit the breakdown of serotonin by binding to serotonin receptors. The drugs compete for the receptors, ultimately blocking the serotonin from binding. This disruption in the normal functioning prevents the uptake of serotonin and allows hallucinogens to work in the brain.

LSD is a semisynthetic drug manufactured from lysergic acid, the ergot fungus that grows on rye and other grains. According to the National Institute on Drug Abuse, LSD is the best known and most widely used hallucinogenic drug. It is also one of the most potent and mind-altering drugs. LSD is usually clear or white and is taken orally in the form of paper, sugar cubes, or liquid drops. The effects can last from 6 to 12 hours.

Magic mushrooms are another frequently used hallucinogen in the United States. Psilocybin is an alkaloid that provides the hallucinogenic effect of mushrooms. Alkaloids are nitrogen containing compounds produced by plants or fungi; some are poisonous, while others are used as analgesics. Mushrooms are usually eaten or made into tea and drank. The effects can last from 4 to 6 hours.

In the United States, peyote is a rare drug. Mescaline is an alkaloid of the peyote cactus that causes a hallucinogenic effect. There are several species of the peyote cactus that produce mescaline. Mescaline has occurred randomly in nature for thousands of years and is typically found and used by native tribes in Mexico and the southwestern United States. The effects of a typical dose (half a gram) can last up to 12 hours and may initially cause nausea.

DMT is a chemical derived from plants, but it can also be synthesized in a laboratory. The DMT experience is typical of other hallucinogens. However, the effects have a very short duration, usually lasting about 45 minutes. As a result, DMT is commonly known as the *businessman's special*. DMT is usually snorted or smoked.

Substituted Phenethylamines

Substituted phenethylamines act as a substitute for the neurotransmitter norepinephrine. Norepinephrine, also known as adrenaline, is a stress hormone that affects parts of the brain responsible for attention,

focus, and depression. The hallucinogenic drug ecstasy has a similar chemical makeup to that of norepinephrine. This similarity triggers the different sensations throughout the body, allowing the hallucinogens to work in the brain.

Ecstasy was used for hunger suppression in World War I. It is known for producing euphoric sensations. The effects of ecstasy closely resemble amphetamines, and ecstasy does not produce common hallucinogenic effects. Ecstasy is taken orally. The effects vary according to the dose, usually ranging from 4 to 6 hours.

Dissociative Anesthetics

Dissociative drugs alter the dispersal of glutamate, a nonessential amino acid throughout the brain. These drugs obstruct the functioning of neurotransmitters by preventing their binding to its receptors. Glutamate is associated with an individual's perception of pain, memory, and reactions to the environment. The obstruction of glutamate alone is enough to produce the majority of the effects of dissociative drugs.

PCP is a dissociative drug that distorts perceptions and causes dissociation from self and the environment. The effects of PCP are similar to those of alcohol, amphetamines, and hallucinogens combined. PCP in high doses can cause seizures, coma, or a psychosis-like state, often leading to medical emergencies or arrest by law enforcement officials. PCP is usually injected or taken orally; however, it can also be smoked. The effects associated with PCP use typically last several hours.

Ketamine is currently used for animal anesthesia and has recently become a regulated drug due to an outbreak in its recreational use. Ketamine was developed in 1963 as a replacement for PCP. The effects of ketamine are similar to those of PCP; however, it has a shorter duration and is much less potent. Ketamine is typically injected or evaporated and then snorted. Similar to the aversive effects of other hallucinogens, users of ketamine have described a near death experience with feelings of extreme sensory detachment known as a *K-hole*.

Conclusion

Hallucinogens are complicated drugs that generate a copious amount of controversy. Hallucinogens affect the brain and body, ultimately causing a distorted

perception of reality. Their use is diverse, and the effects are unique to each individual. Throughout history, hallucinogens have been used for both religious and medicinal purposes. There are several types of hallucinogens, and their diverse chemical structures affect the brain in different ways.

HARM REDUCTION, PUBLIC HEALTH

Harm reduction refers to strategies designed to minimize the negative consequences of drug use. There is an acknowledgement that both legal and illicit drug use is a reality and cannot be totally eliminated. Furthermore, harm reduction proponents believe that

there are differences in the level of safety among the various methods of using drugs, and they believe that drug users should be assisted to use drugs in the safest manner possible.

Rationale

Promoters of harm reduction strategies begin with the assumption that drug use can never be eliminated from any society. Consequently, it makes little sense to use the legal system to punish drug users because these sanctions do not produce the desired results and they cause harm in the process. Although many people would like to achieve a drug free society, this is not a realistic goal and should not guide public policy. If the premise is accepted that drug free is impossible to achieve, the issue becomes how the harm associated with drug use can be reduced and minimized. As a result, harm reduction advocates have proposed and in many cases, implemented a wide variety of strategies to minimize the problems associated with illicit drug use. Most harm reduction efforts are focused on illegal substances because there are already harm reduction methods in place for those using legal drugs. For example, the use of designated drivers is a harm reduction approach to reduce the possible damage caused by intoxicated drivers. The individual who chooses to drink is not discouraged from drinking to the point of intoxication, only from driving in that condition. It should be noted that people using legal drugs are typically left alone and not subjected to harassment, arrest, and serious punishment, even though they may be damaging their health and causing problems for friends, family members, and employers.

U.S. Public Policy

The position of the federal government toward harm reduction, as reflected in the National Drug Control Strategy formulated by the Office on National Drug Control Policy, is clearly negative. From both Democratic and Republican administrations, this position has been consistently maintained. This position is reflected in the following statement from the 1999 National Drug Control Strategy:

Many harm reduction partisans consider drug use a part of the human condition that will always be with us. While we agree that crime can never be eliminated

entirely, no one is arguing that we legalize other harmful activities. At best, harm reduction is a half-way measure, a half-hearted approach that would accept defeat. Increasing help is better than decreasing harm. Pretending that harmful activity will be reduced if we condone it under the law is foolhardy and irresponsible. (pp. 52–53)

Strategies

Ironically, some harm reduction strategies are widely used in the United States and actively promoted in the National Drug Control Strategy. For example, heroin substitution therapy (e.g. methadone maintenance) has been used in the treatment of heroin addicts since the mid-1960s. Methadone is a synthetic opioid that eliminates the unpleasant withdrawal from heroin but does not produce heroin's euphoria, allowing the patient to maintain a relatively normal life. Although methadone has traditionally been administered in a limited number of specialized clinics, a revision of federal guidelines now allows qualified providers to be certified to administer methadone. The purpose of this change was to make methadone more accessible for heroin addicts, since in most cases, a daily dose of methadone is necessary. Since methadone is an addictive substance, the purpose of methadone maintenance therapy is to reduce the harm caused by injecting heroin. More recently, a new opioid, buprenorphine, has been approved as a treatment for heroin addiction. Buprenorphine is administered in pill form (methadone is a liquid) by qualified physicians. A daily dose does not seem to be necessary, and the withdrawal symptoms are relatively mild. Although methadone can be diverted and abused, the pill form of buprenorphine contains another drug that blocks the euphoric properties if the drug is injected. Federal agencies such as the Center for Substance Abuse Treatment and the National Institute on Drug Abuse have actively promoted buprenorphine. This is a harm reduction strategy to replace a harmful, addictive substance (heroin) with a less harmful, addictive substance (buprenorphine).

Drug courts, another harm reduction strategy in wide use in the United States, are specialized criminal courts that handle cases involving substance-abusing offenders. Supervision, drug testing, treatment services, sanctions, and incentives are used to divert these offenders from incarceration. In 1996, there were about 100 drug courts and nearly 1,800 by 2004. The need to reduce prison populations has been a strong

motivator to increase the number of drug courts, and federal funding has regularly been increased to support these programs. With an emphasis on treatment rather than punishment (although punishment is implemented if offenders do not comply with treatment), drug courts are clearly among the harm reduction strategies. The goal is to reduce the harm that addicts cause society and themselves.

A harm reduction strategy that has been implemented in the United States and in many other countries but is opposed by the government is needle exchange programs. In these programs, intravenous drug users can exchange clean syringes for used ones. The purpose is to minimize the spread of HIV and hepatitis through infected needles. As of 1998, in the United States, there were 113 needle exchange programs in 80 cities in 38 states. In addition, these programs are common in many other countries. Many needle exchange programs include referrals for treatment and other support services as well as instruction for intravenous drug users on the proper procedures to clean their needles with bleach before use. The position of the opposition is that needle exchange programs imply that intravenous drug use is acceptable. Therefore, the federal government continues to ban federal funding for needle exchange programs in spite of evidence for their effectiveness in decreasing the transmission of HIV and lack of any evidence that these programs lead to increased drug use.

Heroin distribution programs, another harm reduction strategy, have been successfully operating in Switzerland. As the name implies, these programs involve providing heroin to addicts in controlled doses and in secure settings. In 1994 in Zurich, an experimental program was begun in which one group of addicts received heroin, one group got morphine, and a third group was administered methadone. The participants all had been using heroin for some time and had failed in earlier treatment. They were allowed to choose a dose level that would preclude drug seeking outside the clinic, where they were allowed to inject up to three times a day. They could not take drugs outside of the clinic and were offered support activities regarding employment, health, and family relationships. At the end of 3 years, the heroin group had improved health, employment, and social situations and had committed less crimes than before. Based on this evaluation, similar programs were opened in other parts of the country.

Drug consumption rooms are a controversial harm reduction strategy. These programs involve professionally supervised health care facilities where drug users can use illegal drugs in a safe, hygienic environment. The drug consumption room is part of a network of services for drug users and is separate from existing services for drug users or for the homeless. The goals of drug consumption rooms include making contact with drug users for the purpose of providing access to social, health, and treatment services; providing a safe, hygienic environment for drug use, particularly for intravenous drug use; reducing the harm of illegal drug use from overdose, the transmission of HIV and hepatitis, and bacterial infections; and minimizing public drug use and its associated problems. As of 2003, there were 72 drug consumption rooms in 39 cities in four European countries (Switzerland, the Netherlands, Germany, Spain). To participate, the clients must be dependent on heroin or cocaine. There is a registration process, personalized access cards, and limitations on numbers served. Consumption rooms do not advertise their services, and staff cannot help clients inject. However, staff can advise clients on safe injecting techniques. Obviously, drug dealing is not allowed. The staff ensures that hygienic and safety procedures are followed. Sterile equipment is provided, and the staff observes the administration of drugs.

In 2004, the European Monitoring Centre for Drugs and Drug Addiction reviewed the results of 15 research studies since 2000 on drug consumption rooms. In addition to the possible benefits of reduced high-risk drug use, increased access to treatment and support services, decreases in morbidity and mortality, and reductions in public drug use, the report also focused on the perceived risk of consumption rooms. These risks included increased drug use, initiation of new drug users, delaying treatment due to the perceived acceptance and comfort of drug use, and increases in public disorder by attracting drug users and drug dealers. The results of this review of studies found that consumption rooms do attract street users and older, long-term addicts who have never been in treatment. There was no evidence that consumption rooms recruit new users. Less risky drug use behavior was noted, with no increase in drug use. No conclusion about decreases in communicable diseases could be reached, but consumption rooms with adequate access did contribute to a reduction of drug-related deaths. The majority of clients accessed health care, social, and

treatment services, and there was no evidence that clients were more likely to delay treatment. The extent to which consumption rooms reduced public use and community problems was related to their accessibility, operating hours, and capacity. Consumption rooms located near illicit drug markets did not reduce this activity. The report concluded that consumption rooms were most effective when there was community acceptance of this program as part of a comprehensive strategy regarding drug-use problems.

With the rise in ecstasy use in the late 1990s, drug checking became a popular harm reduction strategy, particularly in Europe. As the name implies, drug checking involves testing a substance to determine its contents, with the intent to identify drugs with dangerous adulterants and to prevent the use of these substances. Drug checking has been used to test heroin but came into wider use as a harm reduction strategy when risky imitations of ecstasy came on the market and caused adverse reactions and even death among users. In European countries, warnings about dangerous ecstasy identified by drug checking have been communicated on the Internet. With on-site testing techniques, ecstasy tablets can be tested at raves or other party events with large numbers of young people, and the results immediately communicated to the participants. The drug checking service is combined with providing information and education about the risks of drug use and referrals for treatment or other services.

As with many harm reduction strategies, critics argue that drug checking encourages drug use and creates an environment that is accepting of drug use. Studies in Germany and in the Netherlands have not shown that drug checking encourages or increases drug use. These studies have found that unsafe pills were not taken, and users became cautious and critical of black market drugs.

Regulating the supply of a substance or access to it is another type of harm reduction strategy. Regulating is not the same as the supply reduction activities in the National Drug Control Strategy that involve interdiction of illegal drugs or destroying marijuana plants. For example, limitations on the location and density of retail alcohol outlets have been shown to be related to reductions in alcohol consumption, traffic accidents, and alcohol-related problems. With regard to marijuana, the Dutch try to control access by only allowing sales to adults and by limiting the number of licensed coffee houses. Supply is controlled by specifying the maximum amount of marijuana that can be

sold to any customer and the amount of marijuana that can be kept on the premises. Some countries have made an attempt to control marijuana supplies by specifying the number of plants an individual can cultivate without a significant consequence. There are obvious problems with these supply control strategies because the supply of a drug is dependent upon the production and distribution of the substance. In other words, if a country wanted to control the supply of marijuana, it would have to control marijuana growing and/or importation as well as whatever distribution network exists.

Organizations

There are organizations in the United States devoted to harm reduction. For example, the Harm Reduction Coalition is a nonprofit organization committed to improving the health and well-being of drug users and communities affected by drug-related harm. The organization promotes effective harm reduction services and policies at the national, regional, and local levels through education and training, community organizing, policy advocacy, and publications.

Another organization involved in harm reduction, as well as legalization and decriminalization initiatives, is the Drug Policy Alliance. This organization is a merger of the Lindesmith Center and the Drug Policy Foundation. The goals of the Drug Policy Alliance are as follows:

- making marijuana legally available for medical purposes;
- curtailing drug testing not related to detecting impairment;
- ending asset forfeiture abuses and restoring constitutional protections against unreasonable searches and seizures;
- redirecting most government drug-control resources from criminal justice and interdiction to public health and education;
- supporting public health measures, notably syringe exchange and other harm-reduction programs, to reduce HIV/AIDS, hepatitis, and other infectious diseases;
- supporting effective, science-based drug education and ending support for ineffective programs;
- making methadone maintenance and other effective drug treatment more accessible and available;

- removing obstacles to proper use of opioid and other medications for treatment of pain and terminal disease;
- repealing mandatory minimum sentences for nonviolent drug offenses and ending incarceration for simple drug possession;
- ending criminal penalties for marijuana, except those involving distribution of drugs to children;
- ending invidious discrimination against people with past drug abuse problems or offenses; and
- ending racially discriminatory drug policies and enforcement measures.

The Drug Policy Alliance is involved in a variety of local, state, and national legislative and policy initiatives. For example, the organization has spearheaded a ballot measure in Oakland, California, to decriminalize marijuana, has funded legal actions involving medical marijuana patients, and has helped cities adopt needle exchange programs.

Conclusion

The premise behind harm reduction strategies is that illicit drug use can never be eliminated from society; therefore, it makes sense to do whatever is reasonable to reduce the harm caused by illicit drug use. Although the position of the U.S. government is opposed to harm reduction, the reality is that policymakers are only opposed to controversial, politically volatile strategies. Although the government will not fund needle exchange programs, it advocates heroin substitution therapies. Given the tremendous economic and human costs resulting from illicit drug use and the lack of progress in reducing these costs through the strategies that have been used for years, it would make sense to carefully examine harm reduction strategies that have been successfully implemented in other countries.

HARM REDUCTION PSYCHOTHERAPY

Harm reduction is a movement that began in Europe in the 1970s as a public alternative to the moral and criminal models of addressing problematic substance use. The essence of this philosophy is to reduce the harmful consequences of substance use to both the individual and to society without requiring abstinence as a goal or precondition of treatment—a requirement that exists in many traditional mainstream treatment approaches to this day. Harm reduction has now spread throughout most of the world and is part of the national drug policy of most developed countries, except the United States.

Harm reduction psychotherapy (HRP) is a relatively recent and almost uniquely U.S. invention that reflects the encounter of psychotherapists who were working with psychodynamic and/or cognitive behavioral approaches to addiction treatment with the insights of the harm reduction movement. The aim of this entry is to present a distillation of the essence of HRP that draws on the work of such major innovators as Edith Springer, Alan Marlatt, Andrew Tatarsky, Patt Denning, Jeannie Little, and Frederick Rotgers.

Background

In the late 1980s, with the advent of the HIV/AIDS epidemic, harm reduction gained a foothold throughout the world. Once it became apparent that substance users, particularly intravenous injecting heroin-using individuals, were not only likely to get the disease, but also were at risk for transmitting it to others, the stage was set to shift the focus from drug-use cessation to stopping the spread of HIV. Needle exchanges and low-threshold, easily-accessible methadone programs became frontline actions in efforts to stop the spread of the disease. The focus was on strategies to help patients change their behavior in a positive direction to reduce the harmful

consequences of their substance use. In short, as Earnest Drucker and colleagues have pointed out, AIDS took precedence over addiction.

Harm Reduction Philosophy

Out of the incorporation of this public health perspective, a new clinical philosophy emerged that Marlatt has called *compassionate pragmatism*. Tatarsky, in his book, has outlined six core ideas that characterize the harm reduction model:

1. *Meeting the client as an individual*: This idea reflects a belief that patients come with different internal worlds, strengths, needs, vulnerabilities, biologies, social backgrounds, and use histories; consequently, their patterns of use and the meanings that they hold will be unique for each user. For treatment to be successful, it must be tailored, as best as possible, to the patients' specific needs.
2. *Starting where the patient is*: This idea means accepting the patients with whatever goals and level of motivation for change that they come in with.
3. *Assuming the client has strengths that can be supported*: Patients are more than their problems. In many respects, to have survived in a world of active users and drug dealers speaks to deeper inner resources. The goal here would be to use these to help the patient move forward in a positive way.
4. *Accepting small incremental changes as steps in the right direction*: For most people, change will involve small steps, steps that may take time to integrate before the person can move on.
5. *Not holding abstinence (or any other preconceived notions) as a necessary precondition of the therapy before really getting to know the individual*: The belief is that the goals of the treatment will emerge out of the therapist–patient relationship and dialogue. This practice enables patients to begin where they are motivated to begin and have a therapy that is shaped to their needs.
6. *Developing a collaborative, empowering relationship with the client*: In line with psychotherapeutic traditions, there is an emphasis on egalitarianism, on a teamwork approach to clarifying issues, choosing goals, developing strategies, and implementing actions.

Understanding Drug Use

From an HRP perspective, people use substances to meet a variety of psychological, social, or biological needs. The psychological reasons incorporate the view that substance use can be adaptive, a view embodied in Edward Khantzian's self-medication hypothesis. For example, substances may be used to quell the pain of anxiety or depression, help block intrusive traumatic memories, overcome a sense of inner deadness, increase the ability of those with attention deficit hyperactivity disorder to focus, and reduce the symptoms of psychosis. Leon Wurmser, in turn, has looked at the role of the inner critic, or the harsh, punitive superego, in the use of substances. For many, alcohol or drugs serve as a kind of revolt against or escape from this experience of internal tyranny.

Tatarsky emphasizes that many of these adaptive uses of drugs also carry meaning that is related to difficult interpersonal histories. Given these histories, current relationships or internal relational schemas cause individuals pain and difficulty, and as a way of coping, substance users have found that the drug takes away the pain, at least temporarily. A drug may also be seen as a comforting and controllable stand-in for untrustworthy and unpredictable people.

A useful metaphor for integrating these ideas is to view people as being in relationships with the substances they use. These relationships fall along a continuum from healthy to unhealthy—just like relationships with people. Denning suggested that the terms *abuse* and *dependence* are ways of envisioning types of relationships to substances.

The social motivations for drug use are threefold. The first, as Denning and Springer have argued, is that many people suffer from their position or role in society due to poverty, unemployment, minority group membership, sexual orientation, or living in a high-crime environment and have, or believe they have, few possibilities for changing these difficult circumstances. Drug use becomes a method for coping with the pain associated with these difficult social realities.

The second, which overlaps with the first, is that substance use is a way to make social connections and to forge an identity. Tammy Anderson has made the case that for those who are having difficulty making successful claims to mainstream identities, the drug culture provides a rebel or outsider identity

that is often fairly easy to gain access to. Scott Kellogg has noted that this social view incorporates a more complex view of substances as providers of reinforcement and meaning. For many individuals, not only does abstinence mean giving up a chemical, but also it means giving up a world and an identity in that world.

The third motivating force, which is interwoven with the other two, is the role of biology in reinforcing the use of substances. In the best of situations, people differ genetically in their responsiveness to different substances, and these differences render people more or less susceptible to finding drug use pleasurable. The scientific evidence is mounting that exposure to trauma—whether acute and dramatic or continuous—can lead to changes in brain chemistry and can leave the individual in chronic states of discomfort and/or make him or her more vulnerable to the effects of stress. It is also likely that the effects of poverty and other social ills can have a similar effect on the brain. These kinds of brain alterations can set the stage for the ability of a substance to, temporarily, bring the brain into an optimal state. This neurobiological model provides an organic understanding for the self-medication hypothesis and the trauma-oriented observations of those working in the psychological realm.

The end result is a situation in which drug use, abuse, and addiction can be understood as a complex biopsychosocial phenomena. Treatment conceptualizations and plans will need to be geared toward an understanding of the interplay of these forces.

Therapeutic Process

Therapeutic Alliance

Harm reduction therapists give the relationship with the patient, or the therapeutic alliance, central importance in their efforts. Without an alliance, there can be no work and no recovery. Making requirements about abstinence at the start of treatment for patients who are not prepared or willing to stop does not foster a good connection and is thus seen as being profoundly antitherapeutic and something to be avoided. Since many of these patients also have histories of problematic attachments, it is to be hoped that the therapy relationship will provide them with one that is attuned and affirming.

Assessment

Therapy begins with a period of assessment, and this assessment is done within a multiple-meaning framework. Not only are therapists interested in the amount, duration, and frequency of use, but also they want to know about how drug use is connected to different personal and social experiences in terms of their meaning and function.

The assessment process also serves as a vehicle for building the therapeutic alliance. As Denning put it, the goal will be the creation of an investigative team. Beyond that, assessment is viewed as an ongoing primary focus of therapy that is geared toward an ever-deepening clarification of the nature of problematic substance use and its relation to the larger context of the person.

Psychotherapeutic Goals

A treatment plan will be developed collaboratively based both on the therapist's assessment and what the patient wants from therapy. This plan will most likely include substance and non-substance-related situations. Goals for each of these problems will be chosen, and strategies for reaching each of them will be formulated. Marlatt and Rotgers each found that when patients were offered the option of pursuing either moderation or abstinence goals regarding their drinking that retention and positive outcomes significantly increased—regardless of the goal chosen.

In terms of substance use, the information from the assessment, combined with the motivational state of the patient, can be used to decide whether the goal will be to (a) continue with the current pattern but monitor it for problems, (b) make changes to reduce harm, (c) move toward a state of moderation, or (d) embrace abstinence as a goal.

Marlatt has suggested that substance use is best viewed as varying along a continuum of harmful consequences with chaotic use on one end and moderate, nonproblematic use and abstinence on the other. From this perspective, the goal of harm reduction interventions is to support the patient in making changes in substance use that move along the continuum in the direction of reduced harm. Thus, any step that reduces harm is defined as a success. Kellogg, taking a somewhat broader perspective on the role of goals in harm reduction interventions, has emphasized the importance of seeing abstinence or moderation as the ultimate,

if not the immediate, goal of the harm reduction enterprise. By keeping this endpoint in mind, the therapeutic encounter will, hopefully, contain a positive tension between the immediate or short-term goals of the patient and the long-term goals of abstinence or true moderation. This gradualist perspective on the interrelationship between goals and action can help increase the psychotherapeutic momentum.

For patients who are not seeking to achieve abstinence, Tatarsky has suggested that the ideal substance use plan be developed. This plan is worked out with the patient and is geared to maximize the positive benefits of drug use while minimizing the dangers to self and others. Developing this plan is an exercise designed to support the patient in assessing what is problematic about substance use and what are realistic goals for the him or her.

Difficulties in following through with the plan are examined in detail. Exploration of these failures can be a source of rich information about the patient's inner world. Actual techniques could include a retelling of the story with particular attention to the emotional valence of the situation, asking the patient to associate to the various details of the event, or as Jeffery Young does in his work, having the patient bring up images or memories from the past that connect to what has transpired.

Motivational Interventions

Harm reductionists have embraced the stages of change model that was developed by James Prochaska and Carlo DiClemente. In the precontemplation stage, the individual is not acknowledging that they have a problem with substances. The goal in this stage is to develop a positive therapeutic alliance that will promote the self-reflection and self-assessment that may lead patients to discover or identify the problematic consequences of their use.

In the second phase, contemplation, the patient is ambivalent about his or her drug use. Two interventions are commonly used here. Marlatt has emphasized the utility of using a decisional balance, a cognitive behavioral technique in which patients list the positives and negatives of both their current situation and of making a change. Motivational interviewing is a reflective psychotherapeutic approach developed by William Miller. In this approach, the therapist seeks to draw out and accentuate the inner conflict that the patient has about his or her drug use.

As the conflicting forces within become clearer and the cognitive dissonance more pronounced, the patient may be willing to consider resolving the conflict by changing his or her pattern of consumption.

The preparation stage follows. In this stage, the patient is moving from the abstract to the concrete. Long-term goals are selected, short-term strategies and objectives are devised to help reach those goals, barriers are acknowledged and plans to overcome them are made, and systems of support that could help in the process are identified.

The action stage has been the primary focus of mainstream treatment programs. In this stage, patients implement the planned actions—using clean needles more frequently, changing the method of taking their favored substances, eliminating specific drugs from their lives, or joining a methadone program.

The maintenance stage follows. As awareness has grown of the high rate of relapse following treatment, increasing attention has been paid to the importance of maintaining the gains the individual has achieved. Marlatt's classic work on this issue, *Relapse Prevention*, has outlined an approach for helping patients in this phase. This approach involves identifying the internal and external risk factors that could increase the likelihood that the patients would revert back to the earlier behavior. The plan is to teach patients new attitudes and new coping skills to help them successfully navigate these situations in ways that support their new choices.

Treatment Techniques

Given the comprehensive nature of HRP, psychotherapists will, ideally, be skilled in the psychodynamic, cognitive behavioral, and experiential techniques that are commonly used in integrative psychotherapies. A good place to begin is to help the patient become more aware of their drug-use process. This can be done by increasing their awareness through self-observation, which involves the cultivation of a stance of nonjudgmental, compassionate observation of the self. The benefit of this observing ego is that the person is no longer completely consumed by the addictive practice; instead, he or she is creating some inner space that provides him or her with the possibility of internal dialogue and change.

Denning and colleagues have been inspired by Norman Zinberg's work on drug, set, and setting. This view is based on the idea that the totality of the

substance-induced experience develops out of the nexus of the neurotransmitter changes induced by the chemical (drug), the personality and cognitive attitude of the user (set), and the particular setting (i.e., with friends or alone, in a familiar or unfamiliar setting). Because these combinations will be different for each user, the resulting drug experiences will again be unique, and since each of these contribute to the outcome (although not necessarily in equal amounts), effective changes can be made through targeting one or more of these factors.

Pioneering work was done on changing drug-use patterns in this arena by Dan Bigg of the Chicago Recovery Alliance. Known as substance use management, the interventions focus on making alterations in the amount, type, and frequency of drug use and/or in the route of administration. Intervening with a person's set involves understanding that people may use the same substance in different ways or use different substances at different times depending on their emotional state. In terms of setting, the most straightforward is the question of whether people are using alone or with others. For those who go to bars and then repeatedly drive when they are too intoxicated to do so safely, it might be wise for them to drink at home. For those who tend to isolate and are using dangerously high levels of drugs, it might be best for them to try to use with others so that their use does not become fatal.

Drug Use During Treatment

As a core principle, it is to be expected that people will be using substances while in treatment. HRP aims to understand the specific meanings this use has to the patient and to respond accordingly. In terms of in-session intoxication, patients may be trying to express their ambivalence about changing their pattern of use. It may also be an attempt by the patients to share their experiences of being intoxicated directly with the therapist so that he or she will better understand them. Finally, patients also drink or get high to give them the courage to speak about things that are frightening or painful. Continued substance use outside of the session may reveal an issue about their level of motivation. Again, it may also reflect the possibility that the meanings that underlie their use have not been sufficiently addressed.

HRP is, at its core, about the reduction of harm and about bringing a better quality of life to the patient. At times, substance use is clearly self-destructive, life

threatening, and potentially harmful to others; it may also reflect suicidal, self-harming, or homicidal wishes. In situations in which patients are putting themselves in immediate danger, the therapist will be required to take action. Harm reduction in these circumstances means not colluding with self- or other-destructiveness; it involves taking a position in favor of life and positive change, and it may look very much like a traditional limit-setting intervention. These responses can range from suggesting that evidence is mounting, that moderation or controlled use is clearly not working, that the patients may need to consider abstinence as a goal, and/or that they may need to enter more intensive, structured treatment.

Countertransference

Working with patients of any kind engenders feelings, and sometimes strong feelings, in the therapist. Substance users may be a particularly evocative group of patients in this regard. There are several reasons for response.

Given the ubiquitous nature of addictive behaviors, it is quite likely that psychotherapists have had unpleasant or even traumatic encounters with people who use alcohol and drugs in their personal lives. This personal experience, consciously or unconsciously, often contributes to therapists' motivation to work with substance users. In these cases, it is likely that personal countertransference reactions based on this history will be evoked by experiences with the patient.

In mainstream addiction treatment settings, the clinical institution may be putting overt or covert pressure on the therapist to "get" their patients sober. This pressure may also be rooted in obligations to funding sources. This means that counselor's success may be based on patient abstinence. Understanding therapeutic success in this manner is likely to lead to feelings of frustration and dislike as the practitioner is trapped between the patient and the administration.

A related kind of countertransference can take place with practitioners who have successfully overcome their own addictions. Knowing that it can be done, it seems particularly frustrating to work with patients who appear to refuse to take the steps that would lead to their healing.

With addictions and drug use, countertransference also has societal roots. Kellogg and Elisa Triffleman have argued that addiction is unusual among the psychiatric disorders in that our society is torn between

whether it envisions problematic drug and alcohol use as a disease to be healed or as a crime to be punished. This ambivalence permeates the treatment system as a whole, including the psyches of the treatment staff and the patients. Although harm reduction, at its best, represents the triumph of the medical over the criminal model, it does not mean that, even with the best of intentions, therapists do not carry punitive and stigmatizing voices within them. The solution is that therapists will need to engage in some form of self-examination and monitor their experience during and after their sessions to identify what has been triggered within them.

Horizontal and Vertical Interventions

Finally, it may be helpful to envision the challenge of HRP as the ability to work on two dimensions simultaneously. Traditional or mainstream treatment approaches have often focused on what might be called *horizontal* interventions or on therapeutic activities that are primarily focused on changing drug-using behavior. Earlier psychodynamic models tended to focus on what might be called *vertical* interventions; that is, they sought to understand the traumas, conflicts, and pain that were often at the root of the continued use. It now seems likely that each of these alone is an incomplete way to treat individuals who use substances in problematic ways and that harm reduction psychotherapists will need to be able to work skillfully in both dimensions.

Conclusion

Harm reduction psychotherapy is a new and exciting addition to the addiction treatment armamentarium that has great potential to make treatment more attractive to drug-using patients, to increase patient retention, and to improve successful outcomes. It is based on an expanded view of who can be treated and a corresponding emphasis of the need for treatment to be highly flexible and individualized to fit to the unique complexity of the individual. HRP aims to engage patients wherever they are interested in beginning treatment and support them in a process of positive change with abstinence as one possible goal among many. Thus, HRP builds upon abstinence-based treatment in its more ambitious goal of expanding the reach of traditional treatment.

HEALTH CARE SYSTEM AND SUBSTANCE ABUSE

The relationship between substance use disorders and health is well documented according to the World Health Organization (WHO). Alcohol and drug abuse problems can be seen in schools, the workplace, primary care practices, mental health agencies, and within the criminal justice system. It is apparent that there are significant barriers to treatment including access to services, greater health care costs, rising insurance premiums, the increasing number of people who are uninsured, and the weak infrastructures of many treatment programs. This entry describes substance abuse prevalence rates, disease burden of alcohol and drug abuse, and barriers to effective substance abuse treatment. A recommendation to link primary health care and substance abuse treatment is also discussed.

Alcohol and Drug Prevalence Rates and Disease Burden

According to a 2005 to 2006 U.S. survey of states from the Substance Abuse and Mental Health

Services Administration, the rate of alcohol use during a 1-month period ranged from a low of 32.4% in Utah to a high of 63.1% in Wisconsin. These statistics were further broken down into rates of dependence or abuse, binge drinking, perception of risk of binge drinking, and underage drinking. The national rate of alcohol dependence or abuse for individuals 12 years and older was 9.2%. In the area of binge drinking, the rate for 12- to 17-year-olds was 10.1%, slightly lower than the 10.5% recorded the year before. The highest rates of binge drinking occurred in the 18- to 25-year-old age group with figures of 56.5% in North Dakota, about twice the rate for individuals ages 26 or older (Wisconsin at 27.4%) and almost 4 times the highest rate among youths ages 12 to 17 (Montana at 15.3%).

Alcohol consumption has health as well as social consequences due to intoxication, dependence, and other biochemical effects. Although evidence suggests that intoxication contributes to car crashes and domestic violence, it has also been shown to cause chronic health and social problems. According to the WHO, there are causal relationships between average amount of alcohol consumption and over 60 types of disease and injury. Most of these relationships are detrimental, although there are some beneficial relationships in terms of coronary heart disease, stroke, and diabetes mellitus if consumption is low to moderate and is combined with nonbinge patterns of drinking.

Alcohol use has major implications for disease burden and mortality rates. Worldwide, alcohol causes 3.2% of deaths (1.8 million) with 16% of the global burden occurring in the Americas, according to WHO. The proportion is much higher in males (5.6% of deaths) than females (0.6% of deaths). In addition, the proportion of disease burden within subregions of the world attributable to alcohol is greatest in the Americas and in Europe, where it ranges from 8% to 18% for males and 2% to 4% for females. Besides the direct effects of intoxication and addiction, alcohol is estimated to cause about 20% to 30% of each of the following worldwide: esophageal cancer, liver cancer, cirrhosis of the liver, homicide, epilepsy, and motor vehicle accidents.

The WHO believes that illicit drug use is on the rise worldwide, causing significant disease burden, even though there is a paucity of research quantifying

the risks. Available prevalence rates for opioid use in the past year among people over the age of 15 vary from 0.02% to 0.04% in the Western Pacific region to 0.4% to 0.6% in the Eastern Mediterranean region. Cocaine use also varies in a similar way. The prevalence rate of amphetamine use is estimated to be 0.1% to 0.3% in most regions. Available data for stimulants and opioids, including cocaine and heroin, indicate that 0.4% of deaths (0.2 million) worldwide are caused by illicit drug use. There is higher risk among men than among women with the most at-risk patterns found among dependent users who frequently inject drugs and have done so over periods of years. Illicit drugs account for the highest percentage of disease burden among low mortality, industrialized countries in the Americas, Eastern Mediterranean, and European regions. Studies of treated injecting opioid users show this pattern is associated with increased overall mortality, including deaths caused by HIV/AIDS, overdose, suicide, and trauma. Several other adverse health and social effects that are more difficult to measure are important to note including other blood borne diseases such as hepatitis B and hepatitis C and criminal activity associated with drug abuse and addiction.

Barriers to Effective Substance Abuse Treatment

There are several major barriers to treating substance abuse. First is access to appropriate services. Treatment programs for substance use disorders are often lacking services that include primary medical care. This care is especially important since research indicates that those patients who receive primary care have reduced alcohol and drug severity. Treatment programs are faced with making referrals to other agencies for needed primary medical care or mental health services. Making referrals assumes that clients will actually follow through and access medical services.

Second, based on statistics from the National Coalition for Health Care and the Bureau of Labor Education, health care costs continue to rise at an alarming rate. The United States has the most expensive health care system in the world. National health care expenditures increased by 6.9% in the United

States in 2005. The total amount spent during this time was \$2 trillion, which breaks down to about \$6,700 a person and represents 16% of the gross domestic product (GDP). By 2015, these statistics are expected to rise to \$4 trillion, translating to 20% of the GDP.

Third, complicating treatment even more is the fact that health insurance premiums in the United States have increased 7.7%, twice the rate of inflation. This increase averages to an annual health care premium of \$11,500 for a family of four and \$4,200 for individual coverage.

Another barrier impacting access to services is lack of health insurance. In the United States, there are over 47 million people without health insurance. The Kaiser Commission on Medicaid and the Uninsured Health believes that insurance is a critical component of the ability of people to access health care because those individuals with health insurance were more likely to link with a primary care provider. According to the WHO, the greatest threats to health are poverty, homelessness, lack of education, and low-level jobs.

A. Thomas McLellan and Kathleen Meyers identified several other barriers to addiction services in their evaluation of the status of the U.S. treatment system for adults through findings from a nationally representative survey of 175 specialty treatment programs. First, they found that staff working in addictions treatment programs had inadequate training. Historically, many addictions professionals have been individuals who are in recovery. In the last 8 years, there has been a paradigm shift in substance abuse education with an increased emphasis on upgrading the profession through advanced educational programs.

Problems in the structure of substance abuse programs were also identified as barriers to treatment. Many programs are dependent on local and state funding formulas that are not adequate to providing the best care available. The organizational, administrative, and personnel infrastructures of many treatment programs are fragile and unstable, making them unable to implement evidence-based care. High turnover and inadequate pay are among the contributing factors to the tenuous infrastructure found in many addictions programs. In addition, the lack of service linkages significantly impacts the provision of appropriate treatment.

Linking Primary Health Care to Addiction Treatment

There is growing evidence that linking substance abuse treatment with primary health care, including mental health services, is important and can positively impact treatment outcomes. Service linkages can occur in several ways. The first is an independent model where primary medical care is offsite. In the independent model, patients are referred to existing systems of primary medical care in the community. Several treatment models can be implemented within a primary care setting, including (a) a brief therapy model including psycho educational materials, (b) treatment from an on-site behavioral health professional, or (c) a referral-based system where patients are referred to a community-based substance abuse treatment program. The second type of service linkage is known as an integrated model where primary medical care is part of an addictions treatment program or is configured with addictions treatment as part of primary medical care services. For integrated models, primary medical care services may be provided on site at the substance abuse treatment facility or addictions treatment may be a part of primary care services. Both independent and integrated models appear to have a positive effect on addictions treatment outcomes.

Several studies reinforce the positive consequences of independent service linkages. One study by R. Saitz, N. J. Horton, and colleagues found that 63% of 400 people participating in a detoxification program linked with primary medical care when referred off-site for these services. In addition, those individuals with health insurance, support from family or friends, and other recent visits to a medical clinic or physician were much more likely to link with primary care. Another study by Saitz, M. J. Larson, and colleagues indicated that provision of primary care was associated with a lower chance of drug and alcohol severity for 391 participants. The researchers in this study purposely decided to implement a linkage model with primary care in the community since there had been little investigation in the area. Although the independent model has some support in the literature, the integrated model appears to be more effective for patients due to increased accessibility, ability to engage patients, and increased capacity to meet the needs of those with substance abuse-related medical conditions.

Other research studies show the positive impact of integrated models of primary medical care and substance abuse treatment. In one study by C. Weisner and colleagues, 592 men and women were randomly assigned to either an integrated model of treatment or an independent model. Results indicated that both groups demonstrated positive outcomes on all drug and alcohol measures including addiction severity, substance abuse-related medical conditions, medical status, health care utilization patterns, and treatment costs. Even though both groups displayed positive outcomes, patients in the integrated program had significantly higher abstinence rates, lower inpatient emergency department use, and decreased medical costs. Another study found that on-site delivery of primary care decreased emergency department visits and hospital stays for some methadone patients. Finally, a group of researchers found that a brief therapy model including psychoeducational materials within the primary care environment could significantly decrease stigma and reluctance to seek treatment. Their view was that this type of integrated model allowed for coordination between the primary care provider and substance abuse specialist.

Conclusion

People with substance use disorders have a disproportionately higher incident of medical problems compared to the general population due in part to the many barriers to primary health care. With access to care as a primary barrier, service linkages are an appropriate alternative to solving the problem. Although both independent and integrated models of service linkages have been found to be effective, it appears that an integrated model has the most potential for delivering positive outcomes over time. Improvements were seen in addiction severity, substance abuse-related medical conditions, medical status, health care utilization patterns, treatment costs, abstinence rates, inpatient emergency department use and hospital stays, and medical costs. In addition, several researchers found that a brief therapy model within the primary care environment could significantly decrease stigma and reluctance to seek treatment.

Although there is growing evidence that integrated models of service linkages are effective, more research is needed in this area. Specific areas of future

inquiry might include an evaluation of treatment models, dual diagnosis programs, and the relationship between certain medical conditions and substance use disorders.

HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT

The Health Insurance Portability and Accountability Act (HIPAA) of 1996, a federal act, included a number of provisions for simplifying the administration of health care. In an effort to maintain protection for the privacy of health care information, Congress incorporated into HIPAA the requirement to protect health care information. The Standards for Privacy of Individually Identifiable Health Information was passed in 2001 and became effective on April 14, 2003, for large organizations and in April 2004 for small organizations. These standards are commonly referred to as the Privacy Act. The Privacy Act is quite relevant to substance abuse treatment providers as it institutes a number of protections for individuals receiving health care services (regardless of what kind of health care) if the provider of the services utilizes electronic billing.

The Privacy Act standardized many common and good business practices for protecting the privacy of information. It also establishes a number of patient rights and provides patients with information about these rights by requiring distribution of the Notice of Privacy Practice. All providers are required to provide a copy of their Notice of Privacy Practice to recipients of services (although many health care recipients are called patients, some are called clients, consumers, or

other names; even if the provider uses a name other than patients, the Notice of Privacy Practice is likely applicable to these individuals).

The Privacy Act identifies the type of information that needs to be protected. This information is called protected health care information (PHI). PHI is any information that is created or obtained during the course of providing health care services. This information can be communicated orally or recorded through any form of media (e.g., on paper, videotape, electronically). The information may relate to current, past, or future health care services. Some common examples of protected health care information include the recipient's name, date of birth, social security number, address, telephone numbers (including cell phone), e-mail address, license plate number, dates of services, billing information, diagnosis, and clinical assessment information.

Protection of PHI is assured when the health care provider uses reasonable safeguards to avoid unauthorized disclosure. An unauthorized disclosure occurs when a person receives the recipient's information (either intentionally or unintentionally) without the recipient's expressed authorization to do so and without the disclosure being allowable or required by the Privacy Act. Commonplace reasonable safeguards include locking records in filing cabinets or locked rooms; restricting the access to records to only those needing to have the information for treatment, payment, or operations purposes; and ensuring that when information is disclosed, it has been authorized or allowable.

Disclosure of PHI is always allowable to the patient. According to HIPAA, it is also allowable when it is for treatment, payment, or operations purposes; when it has been authorized for disclosure; and when it is required to be disclosed. Disclosure of PHI can be required by law, including but not limited to, when required by court orders or subpoenas issued by a court or government entity. It is also required when requested by the recipient of health care services and required when the Secretary of the U.S. Department Health and Human Services requests the information for an investigation.

In addition to following HIPAA Privacy Act guidelines, substance abuse providers may also need to follow the rules of 42 CFR Part 2, Confidentiality of Alcohol and Drug Abuse Patient Records. The rule of thumb is that the more stringent rules apply. If the process set forth in this statute (42 CFR Part 2) is more

stringent, as is the case with disclosure of information, then 42 CFR Part 2 must be followed. For example, even though HIPAA allows disclosure for payment purposes, 42 CFR Part 2 requires a signed authorization prior to disclosure.

When PHI is disclosed, the health care provider must ensure that only the minimum necessary amount of information sufficient for the purpose of the disclosure is disclosed. However, this requirement does not apply to disclosures made for treatment purposes, disclosures made to the recipient of the health care services, and disclosures made based on the authorization of the recipient or disclosures that are required.

Patients have additional rights, which include the right to request an accounting of disclosure of their protected health care information, the right to correct erroneous or incorrect information contained in the patient record, and the right to limit how and where confidential communications are conducted. Organizations establish procedures to abide by these rights.

In addition, the Privacy Act requires that all of an organization's workforce (employees, contractual employees, and volunteers) are trained on the organization's policies and procedures with respect to the Privacy Act and their responsibility for following the act. Organizations are also expected to assign a staff person as the privacy officer who acts as a contact point for patient complaints.

Compliance with the Privacy Act is legally bound, and there are financial and legal consequences for failure to follow the rule. Any individual with concerns about an organization's actions with regard to protecting the privacy of a patient is able to set forth a formal complaint to the organization's privacy officer or to the Department of Health and Human Services' Office of Civil Rights.

In conclusion, all individuals working in a substance abuse provider's agency should be well aware of the rules with regards to protecting the confidentiality of patient information through the Privacy Act and 42 CFR Part 2. Organizations should have in place solid policies and procedures that follow these statutes, provide for the rights of patients, and reduce the incidents of unauthorized disclosure of information.

HEPATITIS C

Worldwide, 170 million people are infected with the hepatitis C virus (HCV). HCV is the most prevalent bloodborne infection in the United States with an estimated 3.2 million to 3.5 million people chronically infected, and it is the most common cause of chronic liver disease, cirrhosis, and liver cancer in the United States. Although the natural history of chronic HCV infection varies greatly, it is estimated that 60% to 80% of people infected with HCV will develop chronic hepatitis. A majority will eventually develop symptoms or signs of liver damage after an average of 13 years. One third of these people will develop cirrhosis of the liver after an average of 20 years, and 20% to 40% of those who develop cirrhosis will develop liver failure or liver cancer on average 25 to 30 years after initial infection with HCV.

Most HCV infection appears to be transmitted through exposures to infected blood, such as blood transfusions, organ transplants, and injecting drug use. The incidence of HCV infection among blood transfusion recipients has fallen dramatically since 1990, when tests became available for screening blood donors for HCV antibodies. Injecting drug use is now the risk factor most commonly reported by hepatitis C patients and accounts for most HCV transmission in the United States.

Injecting Drug Users and HCV

Prevalence of HCV infection among injecting drug users (IDUs) ranges from 50% to 95%, according to the National Institutes of Health Consensus Development Program. HCV infection usually occurs relatively soon after initiation of injecting drug use with over 50% of IDUs infected in the first year, 75% within 2 years, and over 80% 3 or more years after. Although direct sharing of syringes (i.e., multiperson use of a syringe) is the most efficient method of HCV transmission, sharing of drug preparation equipment

(e.g., spoons and cookers for mixing drugs, cotton filters, and water for dissolving drugs or rinsing syringes) may account for a sizable proportion of HCV incidence among IDUs.

Noninjecting Drug Users and HCV

Although the prevalence is much lower than among IDUs, illicit drug users that have never injected (non-IDUs) are also at increased risk for HCV infection. Estimates of HCV prevalence among non-IDUs range from 2% to 35%, according to R. Scheinmann and colleagues. Although there is debate about the mechanisms of HCV infection among non-IDUs, several mechanisms have been implicated, which include engaging in high-risk sexual practices, sharing of non-injection drug paraphernalia, and tattooing. Although HCV is not readily transmitted sexually, sexual transmission does occur. Elevated levels of HCV infection have been observed among patients seeking treatment for sexually transmitted infections (STIs), particularly those that involve genital ulcers such as syphilis, chancroid, and herpes simplex virus type 2. Stimulants such as crack cocaine, powder cocaine, and methamphetamine have been associated with increased frequency of sex, greater numbers of sexual partners, exchanges involving sex for drugs, higher rates of STIs, and extended duration during sexual encounters, all of which may increase the risk of HCV infection. HIV infection also increases the risk of contracting HCV sexually. Non-IDUs may also increase their risk for HCV infection by sharing of paraphernalia such as straws for snorting or inhaling powder cocaine and pipes for smoking crack cocaine, particularly if they contain small amounts of blood from sores inside the nose from irritations caused by the cocaine or from burns on the lips from crack pipes.

Alcohol and HCV

HCV prevalence is higher among alcoholics than among the general population, and alcohol is an aggravating factor for individuals with hepatitis C. Moderate alcohol use (e.g. one to two drinks per day) in hepatitis C patients has been associated with significantly increased serum HCV RNA levels and increased histological activity. Decreases in alcohol consumption have been associated with decreased viral load and histological activity. Consumption of

greater than four alcoholic drinks per day in women and six drinks per day in men for a period of more than 5 years have been associated with increased progression to cirrhosis within 20 years of infection. The effect of alcohol consumption on the progression of hepatitis C liver disease appears to be additive for levels of alcohol consumption below five drinks per day and multiplicative for alcohol consumption above 12 drinks per day. Alcohol consumption has also been associated with increased risk of liver cancer and a reduction in the effectiveness of treatment for hepatitis C. Both the National Institute of Diabetes and Digestive and Kidney Diseases and the U.S. Centers for Disease Control and Prevention recommend abstinence from alcohol for people who test positive for HCV.

Illicit Drug Abusers and Alcohol

Illicit drug abuse among alcoholics and alcohol abuse among illicit drug users are common. Because alcohol accelerates the progression of chronic hepatitis C, it is particularly important that individuals with HCV infection know the risks of alcohol use.

Treatment for Hepatitis C

The currently recommended treatment for HCV infection is pegylated interferon alfa in combination with ribavirin. The recommended duration of treatment is 48 weeks for patients with HCV genotype 1 and 24 weeks for patients with genotype 2 or 3. Treatment is considered successful if it produces a sustained viral response, which is defined as no detectable virus 24 weeks after the end of treatment. Sustained viral response rates range from approximately 50% in patients with genotype 1 to 80% in patients with genotypes 2 and 3. Treatment can be difficult to tolerate though, and many people experience adverse side effects including fatigue, flulike symptoms, depression, fever, and anemia. These side effects cause some patients to discontinue treatment.

Prior to 2002, injecting drug use was an exclusionary criteria for HCV treatment due to concerns about difficulties adhering to treatment, psychiatric problems, and possible re-infection following successful treatment. Recommendations in the National Institutes on Health 2002 Consensus Statement on HCV revised this criteria, and current recommendations state that

decisions to treat IDUs should be made on a case by case basis.

In conclusion, prevention of new HCV infections among IDUs who are not yet infected will require behavioral interventions that are sufficiently powerful to virtually eliminate injection-related risk behaviors. Non-IDUs are also at increased risk for HCV, but there is less certainty regarding the specific behaviors that lead to infection. Slowing the onset of serious liver disease among infected drug users, IDUs as well as non-IDUs that are already infected will require increased access to existing treatments for HCV infection and behavioral interventions to reduce factors, such as alcohol use, that increase the rate and probability of HCV progression.

HEROIN

Heroin, chemical formula $C_{21}H_{23}NO_5$, is a drug that is created from extracts of the opium poppy plant. An imitator of endorphins, heroin is known to create a sense of euphoria and well-being a short time after being introduced into the bloodstream. Heroin has an extremely high potential for addiction, and tolerance

can occur quickly. Although illegal in the United States, heroin is a legal prescription in other countries under the name diamorphine. In its natural form, heroin usually exists as a brown or white powder. Popular street names for heroin include *H*, *brown sugar*, *horse*, *black tar*, *Harry*, *Bobby*, *smack*, *junk*, *dope*, *moop*, *sweet lady*, *Halloween*, *B*, *Ghetto D*, *honk*, *diesel*, *gear*, *skag*, *Jenny*, *brown*, *ice cube*, *jim nix*, *big time*, and *calipop*.

History

As long ago as 3400 BC, opium poppies were growing in Mesopotamia. The poppy plant is native to Asia and to the Middle East, is able to grow to 3 or 4 feet tall, and blooms with white, red, or purple flowers. When the poppies are blooming, the petals fall off, leaving behind a seedpod the size of an egg. When the seedpod is cut open, a milky white sap leaks out. Upon drying, the sap turns to a thick brown resin known as opium. A chemical analysis of opium reveals that two elements account for a majority of its action: codeine and morphine. C. R. Alder Wright, an English chemist, is credited with first creating heroin. In 1874 at St. Mary's Hospital Medical School in London, England, he had originally been researching the combination of morphine and a combination of acids. Boiling anhydrous morphine alkaloid and acetic anhydride for numerous hours created diacetylmorphine—a much more powerful form of morphine. Heroin did not become popular until 23 years after Wright's experiments when Felix Hoffman reproduced diacetylmorphine, instead of the codeine as he had intended. Bayer pharmaceuticals renamed the diacetylmorphine Hoffman created as heroin; this new product was actually close to twice the potency of morphine. Today's heroin is stronger than when first developed and can be 3 to 10 times the potency of morphine. Heroin has a greater potency than morphine because it is more lipid soluble than morphine. In addition, heroin travels to the brain faster and in higher amounts than morphine. The popularity of heroin spread rapidly and from 1898 to 1910. It was used as an ingredient in children's cough medicine, and ironically, as a cure for morphine addiction. Later, when Bayer Pharmaceuticals realized heroin actually converts to morphine after crossing the blood-brain barrier, its abuse potential was discovered, and its use in medicines was discontinued. Originally, when

heroin was prescribed and sold for medical reasons, casual users could legally obtain heroin. In 1914, the Harrison Narcotic Act was passed as the first federal effort to regulate production, sales, and purchase of addictive substances. In 1924, the U.S. Congress passed additional laws that banned any contact with heroin, including the sale, import, or creation of the drug. The Controlled Substances Act of 1970 divided drugs into five schedules. They range from Schedule I with the highest abuse potential to Schedule V with a low potential for abuse. Heroin is classified as a Schedule I substance and has no current medical use. The only legal use for a Schedule I substance in the United States is for experimental or research purposes. The Drug Enforcement Agency is responsible for enforcement of these schedules and penalties. According to the Substance Abuse and Mental Health Services Administration, there were 338,000 current heroin users in 2006.

Usage and Effects

Heroin use is associated with intense and immediate euphoria. Next, the user feels a sense of gradual anesthetizing, drowsiness, lethargy, and sleepiness. Heroin can be administered several different ways: injection, smoking, or snorting. Heroin is ineffective if ingested. In terms of administration, intravenous injection is the quickest way to achieve a high (7–8 seconds). When heroin is injected, the initial rush of euphoria lasts less than a minute before relaxation and drowsiness takes over. An intramuscular injection produces a slower onset of euphoria (5–8 minutes), while snorting or smoking heroin delays effects even longer (10–15 minutes). Warm skin, dry mouth, and heavy extremities are effects often reported following the initial rush of euphoria.

Speedballing is another variation of heroin administration. Users combine cocaine and heroin before injecting the mixture intravenously. It may also be dissolved in water and snorted or smoked. The rush the user feels from speedballing is much more severe than with one of the drugs alone, but it is also more dangerous. The risk of death from overdosing is much higher because of the combination of a short-acting stimulant, cocaine, with a longer acting depressant, heroin. Smoking heroin requires users to heat heroin in its powder form and inhale the vapors, often referred to as *chasing the dragon*. Gravely serious health consequences

are associated with heroin use. Depending on the route of administration, severe conditions can arise just from the method of taking the drug. The most significant examples concern injection heroin users. Poor decision making while under the influence can lead to the contraction of numerous diseases. Whether it is unprotected sexual intercourse or the decision to use dirty syringes, HIV/AIDS, hepatitis, and other bloodborne diseases are very real consequences of heroin use. Collapsed veins and bloodstream infections are other possible consequences of injection use. In general, fatal overdose, spontaneous abortion, and decreased mental functioning can occur after use. Long-term effects appear after a user repeatedly takes the drug over an extended period. Heart lining and vein infections, liver disease, abscesses, and numerous pulmonary complications may arise. During pregnancy, heroin abuse is associated with low birth weight, irritability, shorter gestation, and general withdrawal symptoms once the infant is born. Large doses of heroin are often fatal. Heroin has been responsible for many suicides and murders. In addition, heroin that is cut with other powerful drugs makes overdoses more likely. Although heroin can be extremely addictive, not everyone who uses it automatically becomes addicted. A portion of heroin users, called *chippers*, take heroin only infrequently or on the weekends. Chippers use in a controlled manner and do not fit the mold of a opioid addict. Among other characteristics, they can have the drug around without having to use it; they rarely binge and do not use the drug as an escape from life's daily hassles.

Withdrawal

Symptoms of withdrawal from heroin occur 6 to 8 hours after the last dose. Withdrawal time frames may vary depending on how often and how much heroin is used and on the level of tolerance of the user. Symptoms of withdrawal include sweating, drug craving, muscle and bone pain, insomnia, cold sweats, nausea and vomiting, diarrhea, cramps, fever, cold flashes and goose bumps, restless leg syndrome, and abnormal genital sensitivity. In addition, users may experience uncontrollable kicking movements, which are referred to as *kicking the habit*. *Itchy blood* is a term users often apply to a painful condition during withdrawal. It refers to a compulsive and out-of-control scratching that can cause bleeding and scabs on the skin as well as bruises.

Occasionally, users will employ a cold turkey approach to heroin withdrawal. They will stop using without any assistance from symptom-aiding drugs, and their negative effects of withdrawal are severe.

Treatment of Addiction

The National Institutes of Health concluded in 1997 that drug addiction to opioids is a brain disease, and when treated as a medical disorder, it can be dealt with efficiently. There are two general approaches to aid in heroin withdrawal. The first involves using a long-acting or short-acting opioid in place of heroin and then weaning the user of all drugs. In the second approach, benzodiazepines are used to aid anxiety during withdrawal from heroin. Some long-acting or short-acting opioids that may be used in place of heroin include methadone, buprenorphine, naloxone, naltrexone, and nalmefene. Methadone is used most often as a substitute for heroin in treatment for addiction. Methadone is actually a synthetic opioid, and its duration of action is around 24 hours. It is considered a less harmful substitute for heroin because although it has a high potential for addiction itself, it avoids the rapid cycles of high and withdrawal due to the 24-hour action period. The danger with methadone is that users may become addicted to methadone itself, with a longer and more intense withdrawal period than the initial heroin withdrawal. It is possible that withdrawal symptoms from methadone can continue for over a month, which is why use is gradually tapered off. Methadone maintenance clinics have been established in some cities because methadone is not carried by regular pharmacies or easily prescribed by regular physicians. These clinics are a more accessible way to treat addiction for many users.

Buprenorphine is considered less risky than methadone in terms of addiction potential and is also more easily accessed. It is also associated with a lower level of physical dependence than other medications. Naloxone, nalmefene, and naltrexone are known for blocking the effects of all opioids, including heroin. Specifically, naltrexone has effects that last from 1 to 3 days, depending on the history of the user and the dose. Naltrexone works by preventing the user from feeling the pleasurable results of heroin use and is also useful in prevention of relapse. Naloxone is often used in cases where an overdose of heroin is suspected. It works by countering the effects of an overdose,

specifically the dangerous and severe depression of the central nervous system and respiratory system. Naloxone is fast-acting when injected and begins working approximately 2 minutes after an injection. Naloxone has actually been added as a component of emergency kits for heroin users in an attempt to decrease the amount of deadly overdoses.

The second approach for heroin treatment involves benzodiazepines to aid with the severe anxiety of withdrawal. The most popular benzodiazepine used is oxazepam (Serax). Just like the long and short-acting opioids, benzodiazepines must be used with caution because they also have an abuse potential. Opioid users may also frequently use other central nervous system depressants, which can unsafely react with benzodiazepines. Other less critical symptoms of withdrawal can be treated with pharmaceuticals. For example, clonidine (Catapres) is used to treat general aches and pains. The muscle relaxant baclofen can aid with the restless leg syndrome, and loperamide can assist in curbing diarrhea. The majority of professionals believe in a combination therapy approach to heroin treatment that includes both pharmacologic tools and behavioral therapies. Residential and outpatient therapies are used most often, but contingency management therapy and cognitive behavioral interventions are new treatments that show success. Contingency management therapy utilizes a system where patients receive points for every negative drug test they complete and then subsequently redeem those points for things that will assist them in their recovery. Cognitive behavioral interventions work with patients to adjust their stress reactions so that they are better able to cope with everyday life.

Harm Reduction

Harm reduction strategies play a major role in heroin addiction treatment. Believers in harm reduction aim to minimize harms that may develop as a result of heroin use. For instance, any other method of administration of the drug other than injection is considered safer because of the high potential for infections and overdose linked to injection drug use. Methadone treatments may be considered by some people to be a harm reduction strategy. Needle exchange programs (NEPs) are another strategy favored by harm reduction proponents. NEPs involve exchanging used, dirty needles for clean ones. Some NEPs also offer education on safer

injecting techniques and safe disposal of used syringes as well as information on drug treatment resources.

Conclusion

Heroin is a dangerous drug that remains popular among different segments of the population. Because use is a serious problem in the United States, health professionals must be informed on heroin addiction and its consequences. If public officials, policymakers, and the public are made aware of the issues, it is possible to develop programs, create policies, and take action to ensure that feasible prevention and treatment options are available on the local and national level.

HIGH-RISK BEHAVIORS

High-risk behaviors are those acts that place individuals at a greater disadvantage to abuse or depend on substances. These behaviors are often health compromising acts that are preexisting or comorbid with substance use. High-risk behaviors are risk factors that, according to the National Institute on Drug Abuse (NIDA), can be both additive and potent. As an additive effect, the more risk behaviors a person has, the more the chance for substance abuse. In terms of potency, the presence of some high-risk behaviors leads to a greater chance of substance abuse than does the presence of other high-risk behaviors. Identification of these behaviors is important to substance abuse prevention, treatment, and recovery because if not targeted for prevention or addressed in treatment, these behaviors can hinder efforts to address problematic substance use and interrupt the recovery process. The effectiveness of prevention and treatment models depends greatly on proper identification of high-risk behaviors, the proper development of treatment models, and the proper application of model components to address these behaviors.

Prevention of substance abuse begins with the identification of the behaviors that increase the likelihood that individuals will initiate the substance use process. Several high-risk behaviors become consequent to substance use and must be addressed in treatment, and individuals must understand the extent of their high-risk behaviors as they go through the process of recovery. As such, research efforts attempt to identify these behaviors within specified populations to provide evidence-based prevention, intervention, and treatment models to intercept and divert these behaviors when targeting substance abuse. High-risk behaviors can exist at the individual, family, peer, and community levels and tend to vary across youth and adult populations. It should be noted that individual level risk behaviors can be influenced by family, peer, and community high-risk behaviors and vice versa.

Individual-Level Behaviors

Individual-level high-risk behaviors include substance use–related behaviors and problem behaviors. Both types are often the focus of prevention and treatment programs, particularly when targeting youth. Prevention and treatment efforts seek to either reduce the identified behaviors or enhance protective factors to combat the risk. According to the Substance Abuse and Mental Health Services Administration (SAMHSA), conceptual models that focus on both risk and protective factors have been major developments in prevention theory and programming, and nearly all prevention programs begin with an understanding of factors that place individuals at risk for problem behaviors.

Substance Use–Related Behaviors

High-risk behaviors that are substance related include the early onset of substance use, underage and binge drinking, cigarette smoking, inhalant use, and the misuse of prescription drugs such as pain relievers, sedatives, and stimulants.

Early onset of substance use and underage drinking pose the greatest risks for later abuse or dependence on substances. Numerous studies indicate that many adults who abuse substances tended to begin their substance use prior to adulthood. According to the National Survey on Drug Use and Health (NSDUH), nearly 1 in 25 teens as young as ages 12 to 13 report past-month use of an illicit drug, and as the age increases, the rate is as high as one in five. Due to this rapid increase, many prevention programs are targeted to elementary- and middle school–age children.

The NSDUH provides estimates that there are 11 million current underage drinkers, and those who start drinking before the age of 15 are 5 times more likely to have alcohol-related problems in adulthood. Binge drinking is another dangerous high-risk behavior that is highly prevalent among youth as well as among adults. Binge drinking occurs in two out of five 18- to 25-year-olds. The prevalence and concern for underage drinking and binge drinking is so high that in 2006 the 109th Congress passed the Stop Underage Drinking Act, H.R. 864. The act authorizes the use of federal funds to identify the scope of the problem and to conduct research into the effects of underage drinking and binge drinking on brain development among students.

Cigarette smoking is considered a high-risk behavior in terms of substance abuse. According to SAMHSA, research studies indicate that substance use is more frequent in smokers than in nonsmokers. Because of this higher prevalence, cigarette smoking is often targeted in prevention models.

More recently, prescription drug misuse has become the focus of research studies on substance use. Not only is prescription misuse highly prevalent in the elderly, but it is a high-risk behavior among youth as well. The NSDUH survey also reveals that youth are almost half of the individuals who use prescription drugs for nonmedical reasons.

Inhalant use is high-risk behavior that is more prevalent in youth than in adults. The NSDUH reveals that the rate of inhalant use rises each year as youth tend to use inhalants because of the relative ease of access. Because of this ease of access, younger children are often experimenting with various inhalants. In fact, statistics indicate that roughly 3% of children within the United States have experimented with inhalants by the time they are in the fourth grade, and between the years of 2002 to 2003, approximately 8.6% of youth ages 12 to 13 had used inhalants in their lifetime. Of these 12- to 13-year-olds, 35% also had illicit drug use that is a fourfold increase over the percentage of illicit drug use in those who did not use inhalants. This finding is particularly salient for treatment and recovery processes as the use of inhalants to the point of abuse can become chronic and persist into adulthood.

Problem Behaviors

Problem behaviors such as fighting, aggression, gang involvement, and impulsive and sensation seeking behaviors are high-risk behaviors for substance abuse. Problem behavior theory posits that, particularly for youth, a series of behaviors often coexist or come into existence among individuals who display one behavior. Evidence from the NSDUH indicates that youth at the greatest risk are involved in a series of problem behaviors including poly substance use. Other high-risk individual behaviors include poor academic achievement and inappropriate social behavior. For adults, criminal behaviors are high-risk behaviors that are associated with substance abuse. According to results of the 2005 NSDUH, 26% of recent parolees were current illicit drug users, and 29% of those on probation were current drug users. These rates are substantially higher than rates within the general population.

Family-Level Behaviors

Family-level behaviors such as substance use by immediate family members increases the likelihood of use by individuals due to a modeling of substance use behaviors. For youth, this modeling of high-risk behaviors attributes to perceptions that substance use is an acceptable behavior. Familial substance use is a high-risk behavior that is salient to youth and adults. Parental substance use in particular has this distinction. The National Institute on Alcohol Abuse and Alcoholism cautions adults of alcoholic parents to maintain moderate drinking patterns if they choose to drink due to the heightened increase of vulnerability to alcoholism.

Abuse and maltreatment within the home are both behaviors at the family level that are high-risk for substance use because they lead members of the family to seek out alternatives ways to cope with the situation. NIDA reports that two thirds of patients in drug treatment report being the victim of child abuse. Whether for youth or adults, research indicates that behaviors of other family members can have a significant impact on whether or not others within the home will engage in the use of substances. There is some indication that these family-level high-risk behaviors, including familial substance use, create situations of high stress. To address the stress within the family, members may engage in substance use as a coping mechanism. The behaviors of the family are key targets in prevention research.

Peer-Level Behaviors

Peer-level high-risk behaviors include peer substance use, peer pressure, the desire for peer conformity, and the association with deviant peers. The theory of differential association explains how networks of peers influence behavior. It posits that the values of reference groups reinforce behaviors. Thus, if a person's reference group places a high value on substance use, the individual will be more likely to engage in such an act. Peer behaviors appear more relevant for youth populations than for adult populations. In the case of youth, attempts to separate from parents and to gain the acceptance of peers will heavily influence whether or not the youth will engage in the behaviors that are modeled by the peers. Substance use by youth is not performed because it is expected by peers, but because it becomes a natural part of the youth's

functioning if the peer group happens to place a high value on substance use.

Community-Level Behaviors

Community high-risk behaviors are more difficult to conceptualize, but they include tendencies within groups that demonstrate an acceptance and promotion of substance use among residents. These community factors place a significant amount of stress on residents within the community to conform. These practices include advertising practices that target low-income areas and behaviors associated with community disorganization including residential mobility. Communities with high levels of disorganization create environments of high tolerance for individual-risk behaviors. For instance, community disorganization can facilitate the availability of drugs. National surveys indicate that many youth in urban areas report relative ease in acquiring illicit drugs. Drug selling in neighborhoods makes it less likely that individuals will have to go outside of their community for their drug supply. In communities with high concentrations of poverty, community resources are sparse to combat the negative influx of the drug culture. High levels of residential mobility is another high-risk community-level behavior that can contribute to substance abuse as it contributes to community disorganization and family instability.

Conclusion

Identification of high-risk behaviors is a pivotal part of successful prevention, treatment, and recovery efforts. High-risk behaviors have to be targeted for prevention, but also they must be targeted in treatment efforts. Individuals must learn skills that help them cope with problem situations that enhance the likelihood of engaging in high-risk behaviors. The importance of understanding and identification of high-risk behaviors is further highlighted by the dedicated research centers that specifically focus on high-risk behaviors. One example is the Health and Human Development Program's development of the Center for Research on High Risk Behaviors that recognizes substance use as a risky behavior and seeks to identify why individuals become involved in the behavior and ways to reduce the behavior.

To facilitate efforts to address high-risk behaviors and prevent the initiation of substance use, NIDA

published guidelines for prevention programs for youth that include specific principles for addressing high-risk behaviors. These principles include addressing all forms of drug use, including inhalants and prescription drugs, and targeting modifiable risk factors from an individual perspective. From a family perspective, principles for prevention include targeting parenting behaviors that lead to risk for drug abuse. These guidelines, though specific for youth, can also be applied to prevention programs with adults. As a general principle, NIDA suggests that prevention programs should attempt to target risks as they apply to specific populations.

HIGH-RISK SITUATIONS

High-risk situations refer to any condition that may increase the chance for engagement in any undesirable behavior. In the context of drug and alcohol treatment, a high-risk situation is any cognition, emotion, location, event, or experience that could escalate the potential to use or overuse a substance. This entry reviews both the original linear model and the later dynamic model of relapse as they relate to high-risk situations and reviews cognitive behavioral treatment options of identifying and preparing for high-risk situations.

Models of Relapse

Two primary models of relapse will be explained and examined below. The initial linear model of relapse views high-risk situations as an antecedent, resulting either in successful coping or relapse. The more recent dynamic model incorporates that theory with a dynamic perspective of interrelationships among different situations.

Linear Model

The linear model of relapse posits that following exposure to a high-risk situation, outcomes will progress in one of two linear frames. In the first instance, an effective coping response is elicited following a high-risk situation. As the response is effective, the individual will experience increased self-efficacy and therefore, a decreased probability of relapse. In the second occurrence, the high-risk situation fails to elicit an effective coping response, leading to decreased self-efficacy combined with positive outcome expectancies (or the belief that using will be reinforcing). This combination may lead to a lapse, or initial use of the substance, resulting in experiencing the effects of the substance. Depending on the individual's cognitions related to the lapse, two additional outcomes are possible. If the individual views the lapse as an unfortunate occurrence or as a learning opportunity, he or she

may resume the prelapse goal of abstinence or moderation. Conversely, relapse or increased usage may follow if the individual experiences an abstinence violation effect (AVE). Common components of AVE include a feeling of loss of control over the ability to abstain from use and internal, stable, global attributions of the lapse.

A taxonomy of high-risk situations was developed to identify the precipitating events in relapse and is subdivided into eight categories: coping with negative emotional states, coping with negative physical-psychological states, enhancement of positive emotional states, testing personal control, giving in to temptations and urges, coping with interpersonal conflict, social pressure, and enhancement of positive emotional states. Each of the categories is briefly discussed.

Intrapersonal High-Risk Situations

Research studies indicate that negative emotional states are positively correlated with and predictive of relapse; however, many individual factors contribute to this risk. For example, different negative emotions (sadness, anger, grief) have different risks to different individuals. Similarly, negative physical and psychological states (such as chronic pain) may also pose a risk for relapse. As suggested by the categories, the risk may lie more in the individual's ability to cope with the emotions or sensations rather than the intensity or duration of the experience. A further emotional trigger may come from enhancing positive emotional states, rewards, or celebrations, but the research is mixed. Although some studies support this increased risk, others have determined that positive emotions may be more associated with less frequent and severe relapse.

Testing personal control may also increase the risk for lapse. In this instance, an individual may intentionally place himself or herself in a high-risk situation (returning to a bar where he or she habitually drank) as a test of willpower. In these circumstances, the risk may outweigh the preparation and coping strategies employed by the individual, leading to an increased risk of lapse. Finally, urges and temptations indicate an increased probability of relapse in specific circumstances and individuals, particularly when they do not subside and when they are present first thing in the morning. Again, the individual's

ability to cope with urges and temptations appears to be more predictive than just the experience of them.

Interpersonal High-Risk Situations

Interpersonal situations include coping with conflict, social pressure, and again enhancement of positive emotional states. The positive emotional states in this category refer more specifically to group celebrations and special occasions (going out after work on the weekend, a wedding) rather than based on internal mood and emotion. Social pressure can be present in many indirect forms (invitation to a barbeque) as well as overt encouragement or teasing and jeering. Finally, coping with conflict again illustrates the importance of positive coping strategies.

The linear model and hierarchy explains relapse by a series of if-then responses following exposure to a myriad of high-risk situations. In contrast, the dynamic model incorporates many of these situations with other potential contributors to clarify the interaction of these and other factors.

Dynamic Model

The dynamic model of relapse identifies two primary types of high-risk situations: static and dynamic. Static situations are rare and essentially are situations that are always (or by default, never) risky to the individual. More often than not, a combination of situations will produce different outcomes, even if one of the situations is identical. In the dynamic model, passing by the alleyway at night while feeling depressed may lead to a lapse, but passing by the alleyway in the morning while feeling happy may not increase risk.

The dynamic model posits two primary distinctions, though there is great overlap between them: tonic processes, or chronic vulnerabilities, and phasic responses, or transient states. Both of these processes occur within the general context of high-risk situations. Seven categories comprise tonic and phasic processes, with one category solely considered tonic, two categories solely considered phasic, and the remaining four categories having features of both.

Tonic Processes

Only distal risks, which include predispositions such as family history, social support, and dependence

on the substance, are included solely in the tonic category. These risks are not actually included in high-risk situations, but rather interact with the other factors such as emotions and cognitions. These vulnerabilities are unique to the individual, and while history is not destiny, they may interact with other processes to increase risk of lapse.

Tonic and Phasic Processes

Four categories have features identified with both tonic and phasic processes: physical withdrawal, cognitive processes, affective state, and coping behaviors. Physical withdrawal will have a baseline or tonic level for the individual, though peaks could be associated with phasic responses.

Cognitive processes include categories such as self-efficacy, outcome expectancies, motivation, and craving. Self-efficacy is a predictor of lapse and relapse, both at baseline (tonic) and during fluctuations (phasic). Initial belief in the ability to manage one's substance use can be increased both through interventions and dynamically through successes, though day-to-day variations can occur. Outcome expectancies are related to relapse, with negative expectancies decreasing the risk and positive expectancies increasing the risk. Positive expectancies indicate the individual assumes use or overuse of a substance will be reinforcing, whether through positive reinforcement of achieving some desired effect or negative reinforcement whereby an unpleasant state (pain, anxiety) is removed. Negative expectancies refer to the belief that something unpleasant could occur, or simply that using will not achieve the desired effect. Expectancies can be both explicit and implicit, increasing the difficulty of identifying and if necessary challenging these positive expectancies.

Baseline motivation refers to individuals' internal and/or external drives to meet their goals concerning substance use. Under the phasic process, motivation may oscillate as it interacts with other processes such as self-efficacy within high-risk situations. Motivation to not drink at work, for example, may be much stronger than motivation to not drink while on vacation. Finally, baseline craving as a cognitive process is strongly related to outcome expectancies, while fluctuations in cravings may be a result of interaction with other high-risk situations such as affective state or physical withdrawal.

Affective state risk factors include both baseline levels of positive and negative emotions (anger,

sadness, happiness) as described previously, as well as fluctuations that interact with other situations. For example, someone struggling with depression might be at a greater of risk of lapsing following an unusually bad day or an unusually good day, depending on the interaction with other factors such as expectancies and coping skills. Spikes in specific cognitive processes may also interact directly with emotions, whereby a decrease in self-efficacy may interact with negative emotions and increase the risk of lapse.

Finally, coping behaviors constitute the last category of tonic and phasic processes. Baseline coping mechanisms such as self-regulation play an important role in reducing risk, though phasic identification and implementation of specific strategies also predict positive outcomes. The dynamic nature of coping behaviors lies in their interaction with other processes. For example, a negative affective state such as anger may reduce the likelihood of using a coping strategy that may increase the likelihood of lapse, thereby reducing self-efficacy that may lead to further dismissal of strategies. Conversely, successful implementation of a coping strategy may help dissipate a phasic negative emotion, thereby creating a new positive expectancy related to self-control.

Phasic Responses

Two final categories comprise phasic responses: substance use behavior and perceived effects. The preceding paragraphs have incorporated both topics into the discussion and examples. Substance use behavior includes lapses if abstinence is a goal and includes quantity and frequency for moderation. Use is related to the perceived effects, through either positive or negative reinforcement or the abstinence violation effect. In the case of a goal of abstinence, a combination of low baseline motivation with high phasic negative emotion might result in use of the identified substance. If the negative emotion dissipates, the perceived effect may be that the drug was negatively reinforcing, increasing the risk of further use. Even if the drug is not reinforcing, the abstinence violation effect or belief that a lapse indicates failure and hopelessness may also increase risk. Conversely, if appropriate coping skills are used and the substance is not used, there may be an increase in self-efficacy that could also be positively reinforcing for emotions. There are an infinite number of interactions within the dynamic model.

Treatment Options

Given that high-risk situations potentially include baseline and variations in physical withdrawal, self-efficacy, outcome expectancies, motivation, craving, affective states, coping behaviors, self-regulation, substance use or misuse, and perceived effects, identification of a single situation and solution is impractical if not impossible. Standard relapse prevention treatment incorporates a number of these factors by first identifying high-risk situations that might be more salient for the client and then by developing clear alternatives to employ in risky situations. Great attention is paid to generalization due to the unlimited number of interactions the client may experience. Restructuring is often useful in treatment as well, as it directly interacts with cognitive processes that may increase risk of use. In addition, both mindfulness and acceptance approaches have been employed to counter effects of craving and urges, including the techniques of observation and urge surfing.

Conclusion

The definition of high-risk situations has evolved from a perception of greater risk at specific times of day and locations to include a dynamic model of interactions between myriad factors at both stationary and fluctuating levels. Distal risks, physical withdrawal, cognitive processes, affective state, coping behaviors, substance use behavior, and perceived effects all interact with each other, producing a unique situation for the individual. Cognitive behavioral treatments such as relapse prevention, acceptance, and mindfulness all play individual roles as well as interact to reduce the probability of lapse or relapse in high-risk situations.

HIV/AIDS

Since the first cases of human immunodeficiency virus (HIV) were reported in 1981, HIV has become a worldwide pandemic. HIV is a retrovirus that attacks and kills the body's critical immune cells known as helper-T and CD4 cells causing a gradual deterioration of the immune system. Once a person has been infected with HIV, or becomes HIV-positive, the virus replicates for years without symptoms. The point at which immune cells reach critically low levels and symptoms occur is denoted acquired immunodeficiency syndrome (AIDS). There is no cure for AIDS, and millions of people worldwide die from the disease every year.

Transmission

HIV is transmitted through the exchange of bodily fluids. Fluids such as blood, saliva, semen, vaginal and anal secretions, and breast milk may all contain the virus and are the most common vehicles for transmission. The transmission of HIV from one individual to another can occur in a number of ways. The most common form of transmission occurs through unprotected sexual activity, with anal sex representing the highest risk, followed by vaginal sex, and then oral sex. Although oral sex is a lower risk activity, the rates of transmission are potentially higher than originally thought. Blood-to-blood transmission is common through the sharing of needles and other surgical instruments. Intravenous drug use is implicated in transmission through needle sharing, but the sharing of knives or scalpels in performing surgeries is a common practice in underdeveloped countries, and this transmission method has only recently been addressed. Transmission through breastfeeding can also occur, and this is the most common method of passage from an HIV-positive mother to an HIV-negative newborn. HIV can also be transmitted through blood transfusions, although blood screenings for HIV that have occurred after 1985 in the United States have virtually eliminated this method of transmission.

Interestingly, because HIV cannot survive in open air for more than a few minutes, transmission through household objects such as toothbrushes or razors is exceedingly rare. There are two or three case reports of HIV transmission through the sharing of a toothbrush or a razor, and in these cases the toothbrush or razor was used immediately after an infected person and probably contained some blood residue. Although HIV is present in saliva, the amounts of the virus in saliva are so low that a person would have to be exposed to relatively large amounts of infected saliva in order for transmission to occur, and there are no proven cases of HIV being transmitted solely from kissing. Also, HIV cannot be transmitted through a mosquito bite. Unlike malaria, HIV is not present in the anticoagulant saliva that a mosquito injects into its victim when it bites, so no HIV-infected blood can be passed from the mosquito to the person.

Replication

Once people are exposed to HIV-infected fluids and the virus enters their bloodstream, the virus is quickly attacked by antibodies known as CD4 cells or helper-T

cells. The antibody binds to the protein coat of the virus, and then a conformational change in the binding protein allows the virus to fuse with the plasma membrane and enter the CD4 cell's cytoplasm, at which point the CD4 cell has become infected. The virus then excretes the genetic material from its core (i.e., RNA for retroviruses) into the cytoplasm of the CD4 cell, along with proteins such as reverse transcriptase, which allow transcription of a DNA strand from the viral RNA transcript. The viral DNA is then spliced into the genome of the CD4 cell with the help of a viral enzyme. This process effectively "hijacks" the cellular machinery so that instead of functioning normally, the CD4 cell begins to make viral RNA and viral proteins that congregate in the cytoplasm and are subsequently assembled into immature viruses. After assembly, the HIV particle separates from the host cell to form a plasma membrane coat, and the internal proteins and RNA are further spliced, creating a mature and infectious HIV particle.

HIV spreads rapidly throughout the body after initial infection, mostly congregating in the lymph tissue. Within the first 2 months, many people will develop the physical symptoms of a typical viral infection, such as fever. The body reacts as it would to the presence of any pathogen, with an immune response that will reduce but not eliminate the HIV levels in the body. After this initial reaction, an HIV-infected person will appear asymptomatic, usually for 2 to 10 years while the virus replicates and gradually degrades and destroys the body's immune cells, along with their ability to communicate and fight infections. This process is the transition from HIV to AIDS. Several years later, during the next stage in the cycle, the person develops general inflammation of the lymph areas. This symptom is the first physical manifestation of AIDS. Full-blown AIDS is the next stage, at which point antibody levels are so low that the person cannot fight what healthy people consider normal pathogenic infections. The individual may develop deterioration of neurological function, possibly developing AIDS dementia, and they will most likely succumb to an opportunistic infection such as pneumonia or tuberculosis.

Risk Factors

Throughout the world, 25 million people have died from HIV, with more than 500,000 deaths in the United States alone. In the 1980s, the majority of new

cases in the United States were exposed through homosexual contact, which fed rumors that HIV was simply a “gay plague.” However, the majority of cases worldwide result from heterosexual contact. This discrepancy begs the question: What factors put a person at risk for exposure to and thus contraction of, HIV? There are three recognized behaviors that have been associated with increased exposure to HIV, but there are also other high-risk groups to whom prevention efforts must be tailored. These behaviors are intravenous drug use or IDU, homosexual contact or men-having-sex-with-men, and unprotected heterosexual contact, often associated with substance abuse.

Critically, there are disproportionately high levels of infection among the Hispanic and African American populations, some of whom fall into the categories listed above. In fact, in 2003, an estimated 47% of the 1.2 million individuals infected with HIV living in the United States were non-Hispanic Blacks. Of the 40,000 new cases of HIV infection every year, 50% are African American, despite their accounting for only 13% of the general population. Similarly, 18% of new HIV-infection cases occur in Hispanic individuals, even though they make up only 13% of the general population. HIV is the number one cause of death for African American men ages 25 to 44 years old and for African American women ages 25 to 34. African Americans make up the highest percentage of new HIV cases in every age category. These statistics indicate that the spread of HIV infection among these groups must be specifically addressed in order to gain a better understanding of why the incidence of HIV among these groups is so high and to continue to develop prevention programs that target risk factors unique to these groups.

To date, many HIV-prevention interventions have targeted minority and inner-city women and adolescents. The goal of these programs is prevention through a focus on education and intervention-based treatments to reduce high-risk behaviors such as drug use and unprotected sex. Some programs have targeted adolescents for peer-education or for group education, while others target drug-abusing individuals through behavioral interventions. Results have shown that some behavioral intervention treatments have been successful in reducing high-risk behaviors among their target populations. However, many of these programs are client-specific, and more effort must be made to provide services to specific high-risk populations, such as substance abusing and dependent individuals.

Intravenous drug use has been a consistent method of HIV transmission. Among drug users, HIV can be transmitted through sharing needles and through the sharing of other drug paraphernalia such as cotton swabs, rinse water, and cookers. Professionals have sought to reduce HIV transmission by reducing the high-risk behaviors many IDUs engage in through intervention, often centering the programs in drug treatment centers. However, these programs may represent only those patients looking to reduce their drug use. Data collection has shown that HIV infection rates may be twice as high in community drug users as in those who initiated drug treatment. The intervention methods that have proven useful focus on education as well as on using behavioral intervention techniques to lower high-risk sexual behaviors and high-risk drug behaviors such as sharing needles, or association with “shooting galleries,” where drug users congregate to share drugs and needles. As high-risk drug use and sexual behaviors are decreased, HIV seroincidence levels are, of course, likely to decrease. Needle exchange programs are designed to lower exposure to HIV by allowing IDUs the opportunity to exchange their used, and possibly infectious, needles for sterile ones, which are offered at private and public clinics. The practice remains controversial, with opponents arguing that the programs encourage drug use, and current laws prohibit the use of federal funding for needle exchange programs.

Substance Abuse

Substance abuse has a strong link to HIV in the United States. In addition to the risk of direct exposure to HIV by injecting drugs and needle sharing, research conducted by the National Institute on Drug Abuse and the National Institute on Alcohol Abuse and Alcoholism indicates that drug and alcohol consumption lead to an increase in other behaviors that put people at risk for HIV exposure. For example, drug and alcohol use can lead to such behaviors such as unprotected sex when intoxicated, exchanging sex for drugs, and overall poor decision-making ability and impulsiveness. All of these are considered high-risk behaviors or have been shown to lead to an increased risk of HIV exposure. As these and other risk behaviors are targeted by interventions, the incidence of HIV transmission is expected to decrease.

Unprotected sex while intoxicated is a common problem for adolescents as well as young adults and college students. Possibly seen as a harmless vice or

less of a health risk than drug use, these individuals do not usually see themselves as engaging in high-risk behaviors. Individuals who engage in unprotected sex with multiple partners may justify their behaviors by downplaying the high-risk aspect of their encounters, or they may be more sensitized to their risk than those who engage with single partners. Oftentimes, individuals who are most at risk to be HIV-positive are least motivated to terminate high-risk behaviors that may increase the spread of HIV. Many of these individuals will avoid having an HIV test simply because they fear the results, which might cause them to appreciate that they are probably spreading the virus. Drug users have been found to avoid HIV testing due to inconvenience, distrust of clinical staff, and fears of blood-draws.

Prevention Measures

As mentioned previously, several intervention-based programs have been tailored toward drug treatment as an HIV prevention measure. Program staff in these facilities integrate behavioral interventions, education, and logistical procedures to help motivate drug users to lower their high-risk behaviors. Among IDUs in treatment, the chain of events seems to be simple: Individuals who enter drug treatment centers decrease their overall drug use, which leads to lower high-risk behaviors, leading to lower transmission risk for HIV, which leads to lower numbers of HIV-infected individuals in the community. A variety of prevention-based outcome studies specifically tailored to lower-income, high-risk groups or IDUs have been shown to be effective. Follow-up evaluations of programs targeting these groups have indicated lower high-risk sexual behaviors and increased condom use, while lowering drug use. Also, needle exchange programs are being implemented in major cities in the United States and have shown promising results in decreasing needle sharing. Similar prevention measures have recently been implemented targeting prevention of high-risk behaviors for HIV-positive individuals. Motivating seropositive individuals to lower drug use and other high-risk behaviors is important because they can maintain a low viral count and a high CD4 cell count through a combination of medical and lifestyle variables.

Antiretroviral Treatment

Several drugs have been designed to combat HIV infection. This combination has become known as

antiretroviral treatment (ART) or highly active antiretroviral treatment. There are several different physiological pathways that these drugs target, but one underlying factor is that adherence to these drugs makes it possible to turn HIV and AIDS from a fatal disease to a syndrome that can be managed over the course of a lifetime.

Antiretroviral drugs are designed to affect the virus' ability to replicate once inside the cell. This effect is accomplished through the targeting of several biochemical pathways. One of these is a class of drugs called *protease inhibitors*, which target the splicing of the protein and viral RNA in the immature virus, thereby inhibiting its ability to become a mature and infectious virus. A second type of drug is known as nucleotide-nucleoside reverse transcriptase inhibitors, which target the function of the enzyme reverse transcriptase and its ability to produce a viable DNA strand from its viral RNA transcript. This drug provides the cell with faulty building blocks from which the enzyme will construct the viral DNA. If a faulty viral DNA is constructed, than proper viral proteins and RNA cannot be made from it, and the virus cannot be replicated. Another type is nonnucleotide-nucleoside reverse transcriptase inhibitors, which physically target the reverse transcriptase enzyme. The drug physically binds to the enzyme and prevents it from transcribing a viral DNA molecule from the RNA, thus prohibiting the first step in viral replication.

One of the newer mechanisms to be targeted by antiretroviral drugs is called an entry inhibitor, which targets the antibody's ability to bind the virus. If the antibody is unable to bind HIV, it cannot enter the cell, and thus, the person cannot become infected. This new classification of drugs is in its infancy, but the ability of HIV to become absorbed by the cells and the ability of CD4 cells to become infected looks to be at the forefront of new HIV-related research.

However, adherence to the antiretroviral medications is of the utmost importance. HIV replication enzymes do not have the proofreading mechanisms of prokaryotes and eukaryotes and therefore, cannot produce DNA and RNA with the same fidelity. As a result, the virus mutates at a surprising rate. Inconsistent adherence to the HIV medications has been shown to lead to the formation of resistant strains of the virus. This resistance is due to the virus' ability to evolve methods of replication in the presence of the drug at lower-than-optimal levels required to completely debilitate the virus' replication enzymes. Medication-resistant

strains of HIV have been isolated from individuals, and these strains have a distinct advantage over medication-sensitive strains for replication and survival.

ART usually consists of a cocktail of medications that are administered on a daily basis. Patients have said that strict adherence may produce uncomfortable side effects, and many HIV-positive individuals are drug abusers who do not have the motivation to maintain the regimen over time. Inconsistencies in the adherence to the medication regimen are associated with lower levels of CD4 cells in the body, which correspond with higher levels of viral RNA, or viral load. These factors will lower the body's ability to fight the HIV infection and will increase the onset of AIDS. It also can produce a higher probability of medication-resistant strains of the virus, which may be transmitted to other individuals. For this reason, it is important to design antiretroviral regimens that stress strict adherence and underscore the reasons for this.

Further studies to examine the dynamics of ART adherence are urgently needed. Programs such as the KHARMA project have been tailored to increase medication adherence while also lowering high-risk behaviors for HIV-positive women. This ambitious project uses education about the importance of the ART adherence, as well as a motivational group intervention to reduce drug use and sexual activity. This encompasses several of the most important aspects of HIV prevention, such as educating a group of high-risk individuals, lowering high-risk drug and sexual behaviors, and adherence to ART. These issues must be confronted as higher rates of alcohol and substance use have been correlated with lower rates of adherence to ART. As substance use rates increase, adherence to ART decreases, which is coupled with higher rates of HIV viral load and with lower rates of CD4 cells. In short, if high-risk behaviors such as substance abuse interfere with ART adherence, these behaviors must be decreased if optimal treatment is to be followed.

Conclusion

Although major strides have been made in prevention measures for HIV and its links to substance abuse, much work remains to be done. Clearly this is a disease that must be brought to the forefront of worldwide research efforts. Intervention and prevention programs must be specifically tailored to high-risk groups to find what measures are successful and to determine how to bridge the gaps between research

findings and the clinical applications of those findings. Successful prevention techniques can be used in conjunction with biomolecular discoveries to allow clinicians and researchers a way to look at programs that can isolate the links between HIV and substance abuse, allowing for practical clinical execution.

HOMELESS, SUBSTANCE ABUSE AND TREATMENT

According to the Stewart B. McKinney Homeless Assistance Act of 1987, homelessness is defined as the lack of a regular and adequate nighttime residence including a nighttime residence that is either a supervised shelter, an institution that provides temporary assistance, or a public or private place not ordinarily used as sleeping accommodations for humans.

Homelessness in the United States is a significant social issue with as many as 3.5 million people estimated

to be homeless during the course of a year and 700,000 to 800,000 people homeless on any given night. The U.S. idea of who is homeless has changed over the years. In the 1950s, the stereotype was an older, White, male alcoholic who lived on the streets in an urban slum; by the 1980s, the new generation of homeless also included minorities, drug users, women, families with children, senior adults, people who are mentally ill, and those who are unemployed. Compared to the 1960s and 1970s, more people now live on the streets or in shelters than ever before. For example, in the 2006 U.S. Mayors Conference survey assessing hunger and homelessness in the United States, requests for emergency food assistance increased by 7% on average, and requests for emergency shelter increased in 74% of the 23 cities surveyed. Members of families made up 48% of the people requesting emergency food assistance. Although it is true that many homeless people suffer situational hardships causing their homelessness, others experience substance use disorders, mental illness, physical disabilities, or mental incapacities. Today, considering the events of Hurricanes Katrina and Rita, these numbers have increased even more.

People who are homeless struggle for food, safety, shelter, and services. Some people actually choose to live on the street rather than in homeless shelters out of fear for their safety. Shelters are often dangerous and overcrowded with unmet nutritional needs, poor service delivery, severe emotional problems within families, and substandard living conditions.

Substance Abuse

It is often difficult to make precise estimates of prevalence of different problems within the homeless population. With this in mind, Robert Huebner and colleagues estimated that 45% of people who are homeless are alcohol abusive or dependent and an additional 30% are drug abusive. Often these individuals are polydrug users, using more than one drug at a time.

In addition, the National Coalition for the Homeless estimated that as many as 22% to 50% of the population of people who are homeless in the United States are mentally ill. Many individuals who are homeless are dually diagnosed; that is, they have been diagnosed as having a substance abuse disorder and a psychiatric disorder. Even more alarming are the high rates of people who are homeless and drug

abusers with HIV infection. Those people who are dually diagnosed and homeless face many obstacles to recovery, including increased risk for victimization and violence; frequent cycling between the streets, jails, emergency rooms, and hospitals; and rarely showing improvement in their symptoms or functioning. Also, many of the agencies working with substance abusers who are homeless will not take those with psychiatric problems, and many who work with individuals who are homeless and mentally ill will not accept those who are substance abusing.

Contributing Causal Factors

There are many theories of the etiology of homelessness. One of the primary causes of homelessness is poverty, and contributing to poverty is unemployment. This causal relationship has become especially evident after the events of September 11, 2001, and more recently, Hurricanes Katrina and Rita. Many companies have experienced severe cutbacks and layoffs. Many people are homeless or on the verge of homelessness as a result of these events. Low-paying jobs also contribute to poverty and homelessness. A report from the U.S. Council of Mayors suggested that having a job is no longer a guarantee against homelessness and in fact, approximately 27% of people who are homeless have jobs. In addition, many shelters cannot accommodate entire families due to lack of bed space and must turn people away and back onto the streets. In general, there is a lack of support for people who are homeless, leaving many to fend for themselves on the streets with issues in substance abuse and medical and mental health.

Prior to the events of September 11, 2001, and the more recent hurricanes, the United States was experiencing a booming economy that increased the cost of houses far beyond what minimum wage workers could afford. The same holds true now, with a weakened economy and the cost for houses high. This lack of affordable housing seems to be a major contributing factor for homelessness with the federal housing budget decreasing 30% while requests for subsidized housing significantly increased. It is no surprise then that people have found themselves without homes and are unable to locate affordable housing alternatives.

Substance use disorders and mental illness are other identified causes of homelessness. Research by

Nancy Jainchill and colleagues indicated that two thirds of the entire homeless population abuse alcohol, and 50% use drugs. It appears that the substance-abusing man is no longer the stereotypical homeless person. Women have surfaced as substance abusers in the homeless population research and on the streets. In women, substance use not only creates general life problems, but it also complicates issues surrounding homelessness. Substance use not only contributes to homelessness, but it also keeps women from being self-supportive. When combined with women experiencing mental illness, substance using and abusing women have little hope for a self-sufficient life. To exacerbate the problem, homeless pregnant mothers who drink while pregnant place their unborn fetus at risk for fetal alcohol effects. Treatment programs to deal with this issue have not been effective.

According to the National Homeless Coalition and other researchers, the incidence of psychiatric disorders, including substance use disorders, among people who are homeless ranges from 22% to 50%. Additional statistics over the years have varied, for example, the Governor's Advisory Board Report in Baltimore established that 70% of the homeless population experienced mental illness. In a New York City study, 61% of the homeless population interviewed was diagnosed as schizophrenic, 28% presented with schizoaffective disorder, 25% abused alcohol, and 17% abused illicit drugs. Of 246 patients in the study, 90% were labeled with a primary psychotic diagnosis. It is not unusual for people who experience homelessness and mental illness to have co-occurring substance abuse and mental health diagnoses.

Domestic violence, lack of affordable health care, and a disorder of academic functioning, specifically learning disabilities, have also been identified as causes of homelessness. In the 2006 Conference of Mayors, 46% of cities surveyed identified domestic violence as a primary cause of homelessness. The area of academic functioning is a relatively new area being explored as a cause of homelessness. There does appear to be a relationship between homelessness and learning disability because members of both groups face a number of similar life challenges including education, daily routines and life skills, self-esteem, and social interactions. It also appears that the majority of individuals in both groups is either unemployed or underemployed, and view getting a job that pays a living wage as their top priority.

Treatment Programs

Many problems confront those who work with clients who are homeless and have substance use disorders. Most people who are homeless do not have a support network such as family, relatives, or friends. They are usually surrounded by other homeless who are using drugs and/or alcohol, and life for these clients is usually more about survival than about personal growth, development, or changing life styles. It is not uncommon for someone who is homeless and a substance abuser to have other problems parallel with the dependency, such as mental disorders and physical disorders. Many of the available treatment programs have attempted to address some or all of these problems. There are several different theoretical models currently being used to treat substance abusers who are homeless. Most of these models were developed through a demonstration program of the United States National Institute on Alcohol Abuse and Alcoholism (NIAAA).

Treatment Models

Oxford Houses

Oxford Houses began as a grassroots, nonprofit corporation by a group of men living in Silver Springs, Maryland, in 1975. By 1988, the program had expanded to 13 Oxford Houses in the Washington, D.C., area and in Pennsylvania. At about the same time, the U.S. Anti-Drug Act of 1988 was enacted and created new revolving funds within each state to be used for self-run and self-supported recovery houses. The model required by this law was based on the experiences and replications of Oxford Houses. As of 1997, there were over 870 houses being operated under the nonprofit Oxford Houses umbrella.

There are four fundamental characteristics to both the Oxford Houses model and the requirements of the act of 1988: (1) no paid staff, (2) operate democratically, (3) expel residents who relapse into using alcohol or drugs, and (4) be financially self-supporting. There is a fifth tenet required by Oxford Houses, which is officers are to be elected by majority vote of the residents and are changed every 6 months.

Alcohol-Free Living Center

The Alcohol-Free Living Center (AFLC) was a relatively new concept similar to the Oxford Houses, but with some differences. Each AFLC unit essentially ran itself and tried to be self-supporting where the units were usually satellites of a parent treatment agency offering a comprehensive range of services. Each individual AFLC had a residential manager who is usually a recovering addict and a program manager who was employed by the parent agency. AFLCs varied in size from just a few people (six) living in a house to a large number (174) living in a renovated hotel. Like Oxford Houses, the goal of the AFLC was to combat the revolving door syndrome.

NIAAA Community Demonstration Projects

The first major comprehensive legislative response to the plight of the homeless was the 1987 passage of the Stewart B. McKinney Homeless Assistance Act. Section 613 of the McKinney Act provided funds for NIAAA to support a demonstration program for homeless individuals with alcohol and other drug abuse problems that would be innovative. Numerous problems were encountered in setting up these programs including the randomization of clients to different study groups. Counselors, caseworkers, and others wanted to assign clients according to a needs-based assessment. This technique made sense; however, for research purposes, the clients had to be randomly assigned to a treatment design. Examples of community demonstration programs include the Amity Settlement Services for Education and Transition in Tucson, Arizona, a therapeutic community model, rooted in Alcoholic's Anonymous (AA) Twelve Step model; the First Things First project that addressed the problems of residential instability and long-term substance treatment in Chicago for people who were homeless and substance abusers; and the New Orleans Homeless Substance Abusers Program, which supports permanent sobriety, residential stability, economic independence, and reduction in family estrangement.

Special Homeless Populations

Several specialized treatment program models for people who are homeless have emerged over the years. They included the Grant Street Partnership (GSP), a community demonstration project in New Haven,

Connecticut, that was unique compared to other NIAAA programs because it targeted people who were homeless and cocaine abusers. The goal of GSP was to provide short-term shelter and day treatment programs, one of the first of this type in the United States. In Seattle, Washington, the Systems Alliance and Support program targeted chronic public inebriates, and in Washington, D.C., the Dual Diagnosis Project was developed for people who were dually diagnosed and homeless.

Conclusion

Most of the programs operate on the philosophy that housing is the first problem that needed to be addressed. Before drug problems can be addressed, basic needs must be met. The AFLC model and the Oxford Houses are two types of treatment programs founded on these principles, as well as the therapeutic community approach.

All of the research based community demonstration projects used some form of case management in their designs. People who are homeless and substance abusers do not have "one-stop shopping" convenience available to them when trying to access services they may need within the community.

The AFLCs and the Oxford Houses would appear to be the most successful approaches to the problem and by far the most cost-effective. However, these approaches seem to be effective because the participants have already reached a point in their lives where they are ready to begin recovery from addiction. Most of the research projects were involved in a variety of attempts to create the process that brings or assists the client to the threshold of recovery. This process provided counseling, support, encouragement, education, goals, structure, and many other things necessary to achieving the threshold of recovery. It appears that those programs that incorporated a multidimensional approach were the most successful.

More research is needed in this area. Many of the demonstration projects described in this article are lacking outcome data. Some have preliminary data indicating positive results, although none of the studies include any longitudinal or generalization data. In addition, research results from most of the studies are at least 10 years old.

ILLICIT AND ILLEGAL DRUGS

Substance abuse is among the major public health concerns of the 20th century. However defined, excessive use of illegal drugs and prescribed medications is an all-too-common societal problem, not only in the United States, but across the globe. The negative effects of excessive substance use influence not only the individuals who use these substances but also their immediate and extended families and society in general. Moreover, illicit substance use is connected to many of the most pressing of our societal ills, including illness, crime, violence, and homelessness.

Scope of the Problem

For illicit psychoactive substances, the lifetime prevalence of drug abuse or dependence is roughly 6% in the United States, with lifetime cannabis abuse (i.e., 4.6%) being the most common. The World Health Organization estimates that 28 million people worldwide incur significant health risks by using psychoactive substances other than alcohol. Annually, heroin and cocaine use claims 10,000 lives. Moreover, the results of the 2006 National Survey on Drug Use and Health revealed the following staggering statistics:

(a) An estimated 20.4 million Americans, 12 or older, are current users of illegal drugs; (b) marijuana is the most commonly used drug, used by nearly 73% of current drug users; (c) of the 9.6 million current users of illegal drugs other than marijuana, 7 million are current users of psychotherapeutic drugs (e.g., tranquilizers, sedatives, and stimulants), and most of these users (5.2 million) use prescription pain medication for nonmedical purposes; (d) approximately 12.3 million Americans 12 or older have tried ecstasy at least once in their lifetime; (e) 338,000 Americans reported current heroin use; (f) 1 million Americans 12 or older are current users of hallucinogens; (g) 2.4 million Americans 12 or older are current users of cocaine and 702,000 use crack cocaine; and (h) 731,000 Americans reported current use of methamphetamine.

Estimates of the yearly economic social costs arising from illicit drug use are enormous. According to the Office of National Drug Control Policy, in the year 2000, Americans spent an estimated \$36 billion on cocaine, \$11 billion on marijuana, \$10 billion on heroin, \$5.4 billion on methamphetamine, and \$2.4 billion on other illegal drugs. An estimated 260 tons of cocaine and 13.3 tons of heroin were used by Americans in 2000. Relatedly, individuals who abuse drugs consume a disproportionately large share of social resources (drug abuse treatment, treatment of secondary health effects, social welfare programs, and criminal justice system). In fact, estimates from the Office of National Drug Control Policy of the societal cost of drug abuse was over \$180 billion for the year 2002, with an average annual rise in costs of 5.3% per year since 1992.

Common Drugs of Abuse

Most drugs are typically developed for medicinal purposes with the intention to be used to treat specific disorders (e.g., psychological, mental, physical) or to minimize pain (i.e., morphine). However, when these drugs are not taken as prescribed (e.g., taking more pills than necessary), there is a potential for abuse or dependence.

This section provides a general description of common drugs of abuse. The effects and symptoms listed for each drug have been adapted and modified from information collected from the National Institute on Drug Abuse (NIDA).

Hallucinogens

Hallucinogens are drugs that produce altered states of feeling and perception and sometimes cause flashbacks. Lysergic acid diethylamide (LSD) and phencyclidine (PCP) are the two most commonly abused hallucinogens. In fact, 1% of Americans 12 years and older report use.

PCP is a white powder that dissolves in liquid (e.g., water or alcohol). On the street, PCP is typically sold as a tablet, capsule, or colored powder. There are three primary ways of ingestion: (1) snorted, (2) smoked, or (3) swallowed. The primary effects associated with PCP use are a distortion of the senses, which produces feelings of detachment from the environment and self (i.e., “dissociation”).

PCP abuse may result in memory loss, speech troubles, difficulty thinking, depression, and weight loss. Low or moderate doses of PCP may cause the user to experience an increase in breathing rate as well as a rise in blood pressure and pulse rate. When taken in high doses, PCP may cause a decrease in pulse rate and respiration. More specifically, the substance abuser may experience nausea, vomiting, blurred vision, drooling, loss of balance, and, in extreme cases, coma or death.

LSD creates distortions in the way a person perceives reality by disrupting the interaction of nerve cells and serotonin, which is involved in the control of behavioral, perceptual, and regulatory systems, and results in the person experiencing sounds and sensations that do not exist. The effects of LSD vary and depend on the characteristics of the user (e.g., mood, expectations, surroundings). Typically, the user will begin to feel the effects of the drug within 30 to 90

minutes after ingestion. Physical symptoms of LSD use include dilated pupils, increased body temperature, increased heart rate and blood pressure, and sweating. In addition, the changes in sensation and feeling are usually much more intense and may be characterized by a rapid cycling of emotions, which in severe cases, may cause panic, contribute to accidents, and possibly result in death.

Marijuana

Marijuana is the most widely used illegal drug in the United States. It is estimated that more than 40% of Americans 12 years and older have used marijuana in their lifetime. Derived from the plant *Cannabis sativa*, it is a mix of dry shredded flowers, stems, and seeds. Typically, marijuana is either smoked as a cigarette (i.e., “joint”) or in a pipe (i.e., “bong”). In addition, marijuana may also take the form of hashish (which is a more concentrated, resinous form of marijuana) or a hashish oil, which is a black, sticky liquid. Common street names for marijuana include *pot*, *herb*, *weed*, *grass*, *ganja*, and *hash*. The primary chemical in marijuana is THC (delta-9-tetrahydrocannabinol), which binds to certain protein receptors in the brain and produces a sense of relaxation for the user.

Short-term effects of marijuana use can include memory and learning problems, distorted perceptions, thought difficulties, loss of coordination, paranoid thinking, increased high-risk behaviors, and heart rate. Long-term effects of chronic use may include changes in activity of the stress-response system and changes in the activity of dopamine nerve cells, which can help regulate motivation and reward impulses and result in panic attacks. Smoking marijuana can also cause burning and stinging sensations in the mouth and throat and is often accompanied by a heavy cough, which may contribute to respiratory infections.

Club Drugs

Club drugs are recreational drugs typically consumed at dance clubs, parties, or concerts (e.g., techno or punk rock). Methylenedioxymethamphetamine (MDMA), also known as ecstasy, is a synthetic, psychoactive drug. Besides *ecstasy*, common street names for MDMA include *Adam*, *hug*, *beans*, and *love drug*. MDMA has the qualities of both a stimulant and

psychedelic and has an energizing effect, produces distortions in time, and causes hallucinations. From a biological perspective, MDMA primarily affects neurons in the brain that use serotonin, which produce changes in mood, aggression, sleeping patterns, and pain threshold.

Extensive use of MDMA can cause memory problems and may result in loss of consciousness. In addition, overuse of MDMA may also create problems with regulating body temperature, which may produce liver, kidney, and cardiovascular problems. Lastly, MDMA users may also experience psychological difficulties in the form of depression, drug craving, and anxiety.

Historically used at exclusive “rave” events, club drugs are now being found in more common places, such as bars and parties. Other examples of club drugs include ketamine, Rohypnol (i.e., *roofies*), gamma-hydroxybutyrate (GHB), and gamma-butyrolactone (GBL).

Stimulants

NIDA defines stimulants as drugs that elevate mood, increase feelings of well-being, increase alertness, and stimulate energy. Common stimulants include methamphetamine and cocaine.

Methamphetamine

Because of its highly addictive nature, methamphetamine is classified as a Schedule II drug. On the street, methamphetamine is commonly referred to as *speed*, *crank*, *meth*, and *chalk*. Methamphetamine can be ingested in a variety of ways: swallowed, snorted, injected, or smoked. A derivative of methamphetamine, methamphetamine hydrochloride, is composed of clear, chunky crystals and is often called *ice*, *crystal*, or *glass* because of its physical appearance.

Methamphetamine use may cause significant changes in brain activity, resulting in reduced motor speed and impaired learning ability. More recently, researchers have found that methamphetamine use has damaged areas in the brain typically associated with emotion and memory. Other difficulties associated with methamphetamine use include decreased appetite, rapid heart rate, respiratory problems, irregular heart beat, increased blood pressure, and hypothermia.

Cocaine

Cocaine is typically ingested by snorting, although some users prefer to inject the drug in order to get a more concentrated and intense high. Common street names for cocaine include *coke*, *flake*, *snow*, and *blow*. Cocaine causes the body to feel as if there is an immediate danger, which causes the release of neurotransmitters. More specifically, while the body feels the chemistry of fright, tension, and anxiety, the brain is indicating things are fine. In essence, cocaine use heightens the body’s sensitivity to stress, except the user does not realize this is occurring.

When cocaine is cooked with baking soda (i.e., sodium bicarbonate) and water, it hardens when heat dried; this form of cocaine is commonly referred to as *crack*. When smoked, the sodium bicarbonate produces a crackling sound; thus, the name crack. Crack is cut into bars or chips (i.e., “rocks”) and smoked in a glass pipe. Crack became popular during the 1980s, in part because it was a cheap alternative to cocaine.

Opioids

Heroin

Processed from morphine, heroin is derived from the opium poppy plant, *Papaver somniferum*. Whereas pure heroin is in powder form, the street varieties may take many different forms (e.g., chunky, solid, coarse) but is usually sold in powder form. Heroin is a rapidly acting drug and is commonly referred to as *smack*, *H*, *skag*, or *junk*; it may be ingested by injecting, sniffing, or smoking it.

Heroin abuse is associated with myriad serious health problems, including overdose (lethal and nonlethal), spontaneous abortion, collapsed veins, HIV/AIDS, and hepatitis. The latter two problems result from contaminated needles. Heroin users typically report feeling a “rush” (i.e., sense of euphoria) and warm flushing of the skin, dry mouth, and a sense of heaviness in both the arms and legs. Subsequent to the initial feeling of euphoria, the user experiences alternating states of wakefulness and drowsiness (i.e., the “nod”).

Conclusion

Illegal substance use is among the most pressing and intransigent health problems facing society today. Illicit

drugs directly cause many medical problems. Substance abusers are at an increased risk for health problems such as cancer, cardiovascular disease, overdose (fatal and nonfatal), hepatitis, and HIV infection and AIDS. NIDA research has shown that almost every drug of abuse harms some tissue or organ. In addition, illegal substance use also tends to have important social implications and has been found to negatively impact employment, school achievement, socioeconomic status, and family functioning. Moreover, illegal substance use contributes to an increased possibility of arrest, conviction, and incarceration.

IMPAIRED PROFESSIONALS

Impairment of therapists, counselors, medical staff, and academicians plagues the helping professions.

Although these professionals may be considered experts in assessing and treating the clinical distress and impairment of the general population, there is reluctance in identifying their own impairments. This creates the potential for them to cause harm to themselves and to those that they serve. The credibility of the profession and its purposes may be questioned when helping professionals are unable to manage their own distress or impairment.

It is important to recognize that the interpretation of professional impairment is multifaceted. The variances in conceptualizations have resulted in a number of causal factors and types of impairment. The current research surrounding professional impairment has focused primarily on areas of substance abuse, sexual misconduct, and emotional and mental health issues. The majority of work, however, has focused on substance use and abuse among helping professionals, and this topic is therefore the focus of this entry.

Substance Use Disorders Among Helping Professionals

Collectively, substance use disorders (SUDs) are the most prevalent behavioral health problem in the United States. It is estimated that approximately 810,000 individuals are dependent on opioids, 2.5 million individuals are addicted to cocaine, and approximately 3 million people are thought to be addicted to marijuana. Alcohol, however, is the substance involved in the preponderance of the drug abuse and addiction problems in this country. Of the estimated 119 million Americans who use alcohol, 16.27 million are thought to be physically dependent on it. Consequently, it is estimated that alcoholism alone accounts for 85% of the drug addiction in the United States.

Contrary to stereotypical notions of addicts, such as drunks on skid row and drug users in jail, the majority of addicts are employed. It is estimated that fully 76% of illicit drug abusers in the United States are employed, as are 81% of the binge drinkers and 81% of the heavy drinkers. In light of these numbers, it therefore should come as little surprise that some of whom Robert Coombs calls “pedestal professionals”—physicians and other health care professionals, airline pilots, and attorneys—are also members of the addicted population.

Despite high levels of education and specialized training, professionals are not exempt from developing alcohol and other drug dependencies. In fact,

research suggests that these widely admired professionals, especially health care professionals, are particularly vulnerable to drug abuse. Douglas Talbott, founder of the Talbott-Marsh Recovery Center in Atlanta, Georgia, has suggested that drug addiction can be a common occupational hazard of health care professionals.

Research has recently focused on examining potential SUD issues among health care professionals. In a survey of nearly 4,500 nursing professionals, 32% reported that they used alcohol, cocaine, prescription drugs, or marijuana on a regular basis. Among those surveyed, emergency room nurses were 3.5 times more likely to use cocaine or marijuana, and oncology nurses were more than twice as likely to binge drink. Interestingly, nicotine use was nearly 3 times more prevalent among psychiatric nurses. Among physicians, it has been estimated that 8% to 12% will develop a SUD and that emergency room physicians and anesthesiologists are most at risk. Counselors and psychologists—those generally on the frontline of SUD treatment—also have an elevated prevalence of SUDs. It has been estimated that around 10% of psychologists report current drinking problems. Another study of counseling psychologists indicated that approximately 6% used marijuana, 7% used tranquilizers, 1% used stimulants, and 3% used opioids at least occasionally. The most influential risk factor for developing SUDs among all of the professionals just described was job-related stress.

Education and Training and SUDs

Efficient, hard-working, and respected by both their colleagues and their communities, many addicted professionals tend to graduate in the top third of their classes. Ironically, however, the academic environment that provides them with the education and the opportunities to develop their professional skills may also be, for some, the same environment that enables the development of a future SUD. Many students attend colleges where recreational drug use, and in particular alcohol, is the social norm.

Even though the legal age to purchase alcohol is 21 in most states, more than 90% of college students view drinking as a central part of their social lives. Additionally, as a group, college students drink more heavily than their noncollege peers. Although binge drinking becomes less common for most individuals after the age of 23, approximately 5% to 19% of

those students surveyed continue to drink abusively over extended periods of time. Consequently, behavioral patterns of alcohol consumption acquired in college can, for some, continue into adult life and professional practice.

Professional training itself can also impede emotional development and consequently lead to an increased risk of developing SUDs. Although institutions providing professional training generally ensure that their graduates are intellectually and technically competent, many have a poor record of encouraging their up-and-coming professionals to develop emotionally. Emotional expressions generally incur a risk of appearing unprofessional. Therefore, in order to appear competent and strong, some individuals learn to rely on drugs to either suppress or alter their emotions. Additionally, the chronic overwork, fatigue, and sleep deprivation that accompany the rigors of specialized training can push trainees beyond their own stamina, which may result in intensified emotional problems and place them at further risk for burnout, depression, and substance abuse. Clearly these issues are most prevalent among nurses and physicians, who may not have learned appropriate ways to relieve stress and anxiety and hence turn to substance use to alleviate their burden. Most counseling and psychological professionals are taught ways to self-monitor throughout their training, but the risk for compassion fatigue and professional burnout remain elevated.

Owing to professional training and education, many helping professionals have the irrational belief that they can, solely through the use of their intellectual resources, solve all of their own personal problems. Furthermore, many professionals are committed to the belief that both high academic and professional achievement and competency will prevent the development of an SUD. The data, unfortunately, tell a much different story.

Denial and Underreporting of SUDs

Denial is a universal and profound defense mechanism. Denial has a healthy aspect in aiding the ability of patients to live with their illness(es) and in helping individuals deal with threatening situations. Individuals in the helping professions often learn the value of denying illness in themselves and also at times deny that they, too, can become ill or succumb to a SUD problem.

Professionals historically have been reluctant to report impaired colleagues because of a number of factors, including fear of retaliation or litigation from the accused practitioner. Instead, associates often help conceal the secret by ignoring, making excuses for, or otherwise covering up a colleague's addiction. However, enabling strategies that shield the addict from the legal, social, and work-related consequences of continued use further exacerbate the problem. Most professional associations have implemented ethical guidelines for their members that require them to report impaired colleagues. Unfortunately, however, research suggests that most professionals do not report incidences of SUDs among their colleagues.

Further compounding the problem is the impaired professional's own reluctance to admit to having an SUD. Many professionals view their professional status as an essential part of their identity. Anything that threatens their status and identity may leave them feel frightened, disgraced, and worthless. These unpleasant feelings may exacerbate the addictive behavior. Additionally, many helping professionals find it particularly difficult to move into the role of the patient. They verbalize fears of losing dignity; they experience injury to their sense of self, pride, and power; they believe themselves to be foolish; and they are disturbed by their loss of self-esteem. Their actions may be accompanied and complicated further by feelings of guilt or a sense of shame.

Signs of Impairment

Signs of impairment among professionals who suffer from SUDs manifest in several ways. The physical, mental, and behavioral symptoms mirror those that are stereotypically associated with addicts in the general population. Common symptoms include headaches, fatigue, inability to make important decisions, inability to focus, slurred or altered speech, and changes in normative behaviors. Obviously, professionals with these symptoms will find it difficult to appropriately handle the requirements of their jobs.

As is true for all addicts, difficulties and problems in family and social relationships as well as monetary and legal difficulties become manifest before difficulties in the work site are noticed. The most prominent sign of addictive illness is often a personality change. This change occurs sooner in the use of opioids and cocaine

than with alcohol use and dependence, which most often develops slowly over many years.

Healthy and Unhealthy Motivations

The choice to become a helping professional often centers around the need for achievement, desire for admiration, personal growth, intellectual stimulation, and the desire to help those in need. Although these are admirable motivations to have as a helping professional, the pressure to fulfill these needs and motivations can sometimes lead to the overwhelming stress that leads to the development of SUDs.

Ultimately, it is up to the professional to differentiate between healthy and unhealthy motives. Entering the profession with healthy motives requires consciousness and thoughtfulness. Unhealthy motives usually involve an excessive need to satisfy unresolved childhood or adult difficulties or conflicts, potential earnings, advice giving, being in recovery from a prior addiction, or creating an identity for oneself. Those that enter the profession with unhealthy motives may have an increased risk of developing inappropriate coping mechanisms, such as drug or alcohol use.

Colleague Assistance Programs

In the 1980s, the field of psychology began to research the issue of impaired professionals and what effect it could have on both the profession and the public. The result was that much was learned about the prevalence of impaired professionals. Indeed, the work done by psychologists during this time provided the groundwork necessary to define what impairment among professionals meant, how to study impairment among professionals, and how to help colleagues find assistance when necessary.

The American Psychological Association (APA) spearheaded the early work on professional impairment. They formed the Advisory Committee on the Impaired Psychologist (ACIP), which produced an information manual widely circulated among the state associations. In 1986 the APA published the book *Professional in Distress: Issues, Syndromes, and Solutions in Psychology*. The APA Council of Representatives issued a resolution in 1988 outlining its intention to provide information and assistance to the states, and state psychological associations were encouraged to create and implement programs for impaired professionals. The subsequent growth of

state association programs indicates efforts on behalf of the profession to deal with the effects of impairment on professional and ethical standards of practice.

Conclusion

Much work has been done examining the impact of trauma and stress on those in the helping professions. Physicians, nurse, counselors, and psychologists must always remain vigilant to self-monitor and to find appropriate means to deal with the inherent stressors of their jobs—stressors that can lead to an increased use of substances or to the development of SUDs. Of equal importance, too, is that professionals need to monitor one another as a service to their profession and to the people that they treat.

Alaskan Natives (AI/AN). The AI/AN comprise 560 federally recognized tribes; tribal nations range from fewer than 100 enrolled members to more than 100,000. The majority of AI/AN live in metropolitan areas, with more than half living in six states: Oklahoma, California, Arizona, New Mexico, Alaska, and Washington. The IHS currently provides health services to approximately 1.8 million of the 3.3 million AI/AN, with an annual appropriation of \$3 billion.

The first regular appropriations of funds for the relief of distress and conservation of health among AI/AN was due to the Snyder Act of 1921. In 1954, the U.S. government transferred the responsibility for provision of health care from the Bureau of Indian Affairs to the Department of Health, Education, and Welfare under the Transfer Act of 1954. As a result, the IHS was established to undertake wide-ranging responsibility for Indian health, including medical, dental, public health, and environmental health services. Health and medical care for AI/AN is currently available through IHS in the 35 states that contain Indian reservations or Alaska Native corporations. The IHS delivery system is divided into 12 administrative jurisdictions, called area offices, based on geographical boundaries. These 12 area offices are further subdivided into 127 service units, each of which may include several smaller satellite facilities and field health stations.

In the mid-1970s, two pieces of legislation were passed which had a great impact on the Native American population. The Indian Self-Determination and Education Assistance Act of 1975 provided the legal framework for individual tribes to create and operate their medical delivery systems to meet their self-defined needs. Federally recognized tribes were allowed to contract with the federal government to assume management of their health care programs. In 1976, the Indian Health Care Improvement Act specified a number of areas in which Indian people may manage contracts: training programs, specific health services, health facilities, waste disposal programs, and urban Indian clinics. Title V of that act provided support for urban health centers. Currently, there are 34 urban Indian programs receiving federal funding. Although 55% of the AI/AN population lives in urban areas, less than 1% of the IHS budget is dedicated to urban Indian health programs.

The mission of IHS is to raise the physical, mental, social, and spiritual health to the highest level among AI/AN. The IHS goal is to ensure that comprehensive,

INDIAN HEALTH SERVICES

The Indian Health Service (IHS), an agency within the U.S. Department of Health and Human Services, provides federal health services to American Indians and

culturally acceptable personal and public health services are accessible and available to all AI/AN people. Federally recognized tribes enjoy a government-to-government relationship with the United States. To carry out its mission, the IHS assists tribes in developing health programs through technical assistance and management training; assists tribes in coordinating health planning and obtaining and using federal, state, and local resources; and provides comprehensive health care, including prevention programs and hospitalization.

American Indians suffer high mortality and morbidity rates. IHS has identified alcohol and other drug abuse as the most pressing health problem in American Indian communities. According to the National Center for Health Statistics, the overall mortality rate was 35% higher for American Indians than for all other ethnic groups in the United States, combined, and deaths from alcoholism were 7 times greater than deaths among other groups. Alcoholism deaths occur more commonly among Native men than women, with the highest rates occurring in the age group 45 to 54 years. It is estimated that 80% of suicides and 93% of homicides are associated with alcohol; 65% resulting from motor vehicle crashes and 25% from other unintentional injuries. The IHS is currently funding more than 200 substance abuse programs serving Indian reservations and urban communities. However, there is a shortage of funding—the current IHS budget allows health care funding for AI/AN at approximately 40% of the rate for the rest of the American population.

The IHS has several divisions to assist with health promotion and disease prevention. The Division of Behavioral Health (DBH) supports initiatives that strive to eliminate behavioral health diseases and conditions. Within this division, there are 16 primary prevention focus areas including diabetes, mental health, and substance abuse. Within the DBH primary prevention focus area of substance abuse is the Alcoholism and Substance Abuse Program (ASAP), which serves to reduce the prevalence and incidence of alcoholism and other drug dependencies. It provides support and resources for AI/AN communities to achieve excellence in holistic alcohol and other drug treatments, rehabilitation, and prevention services. Additionally, ASAP activities include development and management of a coordinated information management system measuring alcohol problems and substance abuse

among AI/AN, programmatic evaluation and research, national leadership focusing on at-risk youth, and developmentally disabled service provision (e.g., fetal alcohol syndrome, fetal alcohol effects). Currently, 97% of the ASAP budget is earmarked for contracted or compacted services, including approximately 300 AI/AN ASAPs that provide treatment and prevention services to both rural and urban communities.

INFORMATION DISSEMINATION

Prevention is a process of influencing people to change their behavior by adopting positive behaviors or avoiding negative ones. The work of prevention is accomplished through a variety of strategies that differ in their form, intensity, and expected outcome. Information dissemination is one of six specific strategies identified by the U.S. national Center for Substance Abuse Prevention as essential to a comprehensive community approach to preventing substance abuse. Other prevention strategies include education, alternatives, problem identification and referral, community-based process, and environmental strategies.

Information dissemination is characterized by one-way communication from the source to the audience, with limited contact between the two. This strategy can involve a single message or multiple messages designed to be delivered on a repeated or sequential basis. Examples of information dissemination activities include the following:

- Clearinghouse or information resource center(s)
- Resource directories
- Media campaigns
- Brochures
- Radio and TV public service announcements
- Speaking engagements
- Health fairs and health promotion
- Telephone or electronic information lines

Whereas some of these activities involve the use of mass media, others, such as health fairs or information lines, may be single-contact situations between a sender and a receiver of the prevention messages.

Process of Development

Regardless of the particular form in which information is disseminated, the following description provides a capsule view of the process. First, the developer of the strategy analyzes the target audience to determine needs, cultural characteristics, and the most appropriate methodology for dissemination. Next, the program provides information about a particular problem, why it is important, and how the audience can act to prevent or mitigate it. The audience hears the message, gains knowledge, and changes its attitude about the problem and is motivated to act. The audience changes its behavior and adopts more effective or healthful practices and avoids negative behaviors. Finally, the changed behavior leads to improved social, health, or environmental outcomes for the audience members individually and, in the aggregate, for the population or system.

Target Populations

Information dissemination activities may be targeted at broad, general audiences or at very specific target populations. The target audience for information dissemination activities can be defined by using the

classification system developed by the Institute of Medicine in 1994. This system categorizes audiences as universal, selective, or indicated. Universal prevention audiences are large populations such as the general community or all students within a school. These audiences are identified and targeted without regard to their comparative level of risk for substance abuse. The mission of prevention with universal audiences is to delay the onset of substance use or deter the occurrence of substance abuse by providing all individuals with the information and attitudes necessary to prevent the problem. Universal prevention approaches are based on the assumption that all members of the population share the same general risk for substance abuse, although the risk may vary greatly among individuals within that population. Information is disseminated to universal prevention audiences without any prior screening for substance abuse risk. The National Media Campaign, conducted by the Office of National Drug Control Policy, is probably the best-known information dissemination program targeted at a universal audience.

Selective prevention audiences are subgroups of the general population that are determined to be at risk for substance abuse based on their common biological, psychological, social, or environmental risk factors. Targeted subgroups may be defined by age, gender, family history, place of residence, victimization by physical or sexual abuse, or other risk factors. It is important to recognize that the focus on selective prevention audiences targets the entire subgroup regardless of the degree of risk for any individual within the group. The selective audience receives the prevention message because the subgroup, as a whole, is at higher risk for substance abuse than is the general population.

Indicated prevention audiences are individuals who may or may not already be using alcohol, tobacco, or other drugs but exhibit risk factors that increase their chances of developing a drug abuse problem. Strategies targeted at indicated audiences are designed to prevent the onset or progression of substance abuse in these individuals. For indicated prevention audiences, prevention activities address risk factors associated with the individual, such as conduct disorders and alienation from parents, school, and positive peer groups. Often, less emphasis is placed on assessing or addressing environmental influences, such as community values, when targeting indicated audiences.

Activities and Methods

Information dissemination activities utilize a combination of informative and persuasive communication techniques and a variety of methods to deliver prevention messages intended to instill knowledge, change attitudes, and increase awareness about alcohol and other drug use, abuse, and addiction. Messages may also focus on the effects of substances and substance abuse on individuals, families, and communities or inform the audience about available prevention and treatment programs and services. Even though knowledge alone is not necessarily sufficient to precipitate or sustain behavioral change, it is an essential first component in the process of such change.

Many factors contribute to effective information dissemination. Four major factors are (1) the message source, (2) believability of the message, (3) environmental factors, and (4) comprehension and retention of the message. For a persuasive message to have its intended impact, the message source must be seen as credible. Credibility involves recognized expertise, a desire to do what is right, and a perception that the sender of the message respects the individuals receiving the message. The perceived credibility of a prevention message is often proportional to the strength of the science on which it is based.

The believability of the message is very much related to the credibility of the message source. For a prevention message to be believable, it must be congruent with the audience's existing knowledge and belief systems. Environmental factors are the conditions under which the prevention information is received. This can include interruptions and distractions that can affect whether a message is heard and understood. In an environment that is not conducive to presenting a prevention message, the likelihood of message comprehension and retention decreases. Obviously, for a persuasive message to be effective it must be understood and recalled. Another key factor that affects comprehension of the message is the language level of the message. The prevention message must be conveyed in language that is understood by the receiver of the message.

Information dissemination may be the prevention strategy of choice when creating an initial exposure to prevention concepts. Messages that increase awareness and knowledge may be required to develop a readiness to adopt positive behaviors or avoid negative behaviors in the intended audience. Increased awareness

and knowledge are often prerequisites to behavioral change.

Strengths and Limitations

One strength of information dissemination is the ability for messages to reach large numbers of people, often at a relatively low cost. Although mass media such as television advertisements can be fairly expensive, when the number of contacts is considered, the cost per individual is minimal. Some methods of information dissemination can be performed by persons without specialized training or experience, though others require specific skills or training. Using this strategy, information can be presented in stepped levels of complexity and variable dosages (levels of intensity or numbers of repetitions). Another strength of information dissemination is that it can be utilized with universal, selected, or indicated audiences. In addition, changes in awareness and knowledge can be relatively easy to measure in selected or indicated populations.

Limitations of information dissemination programs include the fact that awareness and knowledge alone may be insufficient to stimulate behavioral change or maintain long-term behavioral change. The dose or level of exposure in information dissemination strategies can be relatively low and may be insufficient to achieve the desired effect. Information dissemination that is targeted at universal audiences may not be particularly cost-effective, as it targets individuals who may not be at significant risk for substance abuse. The benefits of awareness and knowledge programs are highly dependent on the readiness of the audience to learn and on individual learning styles.

Research Results

The Center for Substance Abuse Prevention has summarized the available research in the area of information dissemination. Their most significant finding is that information dissemination campaigns should be viewed as complementary to more intensive and interactive prevention approaches. Effective use of the media is enhanced when the intervention is combined with other prevention strategies (e.g., education, enforcement of existing laws). While the dissemination of information regarding alcohol, tobacco, and other drugs can increase knowledge regarding the hazards of substance use and aid in the development

of negative attitudes toward alcohol, tobacco, and other drug use, programs that involve booster sessions or multiple exposures over time can help move participants from awareness to action in changing their behavior as well as to help individuals maintain their changed behavior over longer periods.

Effective use of the mass media to change substance-related knowledge, behavior, and attitudes relies on creating messages that appeal to the audience's existing belief systems and address motives for using substances or perceptions of substance use. For example, when information dissemination results in a higher perception of the risk associated with a particular substance, individuals are more likely to avoid that substance. A key to success in the use of television and radio for information dissemination is selection of choice air times, that is, when the intended audience is more likely to be viewing or listening. Free public service announcements can enhance any media campaign but, by themselves, are unlikely to have an impact if they air at times when few members of the target population are likely to hear them. Information campaigns should allow for the specific media preferences of their target audience, utilizing broadcast, print, and electronic media appropriately. The images and sounds utilized in such campaigns should resonate with the target audience. Youth-oriented mass media campaigns have been found to be more effective if they avoid the use of authority figures and exhortations. Focus group research indicates that overbearing messages are likely to lose the target audience.

Information dissemination programs are not difficult to evaluate if the focus is primarily on process or formative evaluation. The number of contacts made or brochures distributed can be easily obtained. The number and frequency of media placements is also easy to track. When evaluation turns to outcome or summative evaluation, however, the process becomes more difficult, especially with universal prevention audiences. The process is slightly easier with selected audiences and more manageable with indicated prevention audiences, when specific individuals are targeted for receiving the information. Short-term outcomes for information dissemination are increases in knowledge and awareness and adoption or intensification of attitudes that deter individuals from using or abusing alcohol, tobacco, and other drugs. Intermediate outcomes include changes in behavior—either adoption of positive behaviors or avoidance of negative behaviors.

Long-term outcomes include maintenance of behavior change for individuals and population-level changes in substance use and abuse indicators. These effects are easiest to measure in indicated prevention audiences, where specific individuals have been identified for participation in the program. Even in the best evaluations of information dissemination projects, the data seldom go beyond short-term outcomes. The assumption seems to be that the short-term outcomes will lead to the intermediate outcomes, which in turn will lead to desirable long-term effects. However, there is no certainty that such links will actually occur; in fact, it is highly unlikely unless the information dissemination strategy is part of a long-term comprehensive prevention approach that utilizes multiple strategies in addition to information dissemination.

INFORMED CONSENT

Informed consent is a foundation in the ethical practice of counseling. Not only does informed consent provide the groundwork for matters that affect the

entire course and direction of the counseling relationship, it guides the practice of client autonomy. Informed consent refers to the freedom of choice a client has regarding whether or not to enter into a counseling relationship, the right to understand the nature of the counseling process, and relevant information concerning the counselor.

Due to the significant amount of information contained in the informed consent, both verbal communication and written communication are necessary. Any discussions of informed consent are to be documented by the counselor and, when appropriate, signed by the client. The informed consent process is used as a means to continuously monitor the goals and strategies of counseling. Rather than a onetime event at the onset of the counseling relationship, informed consent is an ongoing, collaborative process between the client and the counselor for the duration of the counseling process.

Underlying issues related to informed consent include the roles, rights, and responsibilities of the client and the counselor, as well as all parties involved. Topics that, at minimum, are included in the informed consent document are referenced in the Code of Ethics provided by the American Counseling Association (ACA), NAADAC (the Association for Addiction Professionals), as well as individual state certification or licensure boards. The following subject matter is typically included in this process, although this is not an all-inclusive list.

In clinical practice, the informed consent document includes a description of the client's right to confidentiality, program procedures that safeguard them, and exceptions imposed by federal, state, or agency regulations. An explanation of the counselor's background—that is, expertise, training, credentials, and theoretical orientation—is provided. Clients have a right to know which treatment modalities are to be employed and the expected benefits and potential risks of the services. Typical approaches to addiction counseling include individual, group, and couples and family therapy, in addition to medication management, support group attendance, and drug testing. Alternative approaches that might be available to the client should also be presented. Information about the anticipated duration of treatment and any situation potentially resulting in premature termination of treatment or circumstances in which a referral may be necessary are discussed. An explanation of client's rights in

regard to an organization's policy and procedures and means to resolve disputes are included. Financial responsibility, payment options, and any other monetary obligations of the counseling relationship need to be clearly explained.

Informed consent is also utilized in research initiatives. The investigator is responsible to ensure participants are informed of any associated risks and provide them with relevant information necessary to make decisions about participation in the research project. An institutional review board oversees the research process to ensure all necessary information is provided in an comprehensible manner to participants.

Ethical considerations for the informed consent process are particularly relevant to substance abuse counseling. Individuals enter treatment with varying levels of cognitive abilities, particularly if they have recently been under the influence of drugs, alcohol, or both. In the case of detoxification, clients may actually be under the influence of substances when they agree to engage in the process. Additional factors to consider are the client's motivation for entering treatment, medical and emotional condition, and legal constraints. Such factors can significantly impair the client's autonomy and ability to provide informed consent. Once clients have initially entered treatment and are stabilized, particularly if they have gone through detoxification, information pertaining to the counseling process outlined in the informed consent is again reviewed. Under all circumstances, counselors need to respect the client's autonomy and right to consent or withdraw, of their own accord, from treatment.

When a client's ability to provide a meaningful informed consent is questionable, a third party with appropriate qualifications may intervene. If an individual is unable to provide informed consent, a representative of the client may do so. However, agreement from the individual is still necessary. Working with adolescents poses an additional consideration in that consent is required from the parent or guardian, as well as the individual receiving services.

Clients seeking substance abuse treatment may be mandated through court order, probation or parole, or child protective services. In some cases, an intervention may have precipitated the person's entering into treatment. Employers may require an employee to seek treatment as a condition of continued employment. Individuals holding a specialized professional license may be required to undergo treatment as a

condition of maintaining licensure. In all cases where treatment is coerced or mandated, conditions and circumstances under which information is reported back to referral sources should be clearly articulated in the informed consent document.

Unique to substance abuse counseling are additional legal considerations for treatment programs receiving federal funds either directly or indirectly. Under federal mandate, regulation 42 CFR Part 2, individuals seeking or receiving substance abuse treatment receive stringent confidentiality protection. Information about any client applying for or receiving services or referral for other treatment are protected under confidentiality laws and may be disseminated only with client consent. Details regarding a client's consent to release information and specific circumstances that permit disclosure should be explicit in the informed consent document.

Drug testing, such as urinalysis, is often used for the purpose of ongoing substance abuse treatment and is within the ethical standard practice of health care. Routine, random drug testing requires informed consent similar to that for other medical conditions. However, there are circumstances when explicit consent is not possible, such as in trauma or overdose. In these situations, informed consent is not required for clinical drug testing.

INHALANTS

The National Institute on Drug Abuse defines inhalants as volatile substances that produce chemical vapors that can be inhaled to induce a psychoactive (i.e., mind-altering) effect. While a multitude of other substances may be ingested, inhalants, as the name implies, are taken primarily through inhalation (i.e., either the nose or mouth). More specifically, inhalants can be abused by (a) sniffing or snorting sufficient concentrations of fumes from containers, (b) spraying aerosols into the nose or mouth, (c) sniffing fumes from substances sprayed or poured onto a rag and then placed into a bag (i.e., “bagging”), (d) heavily breathing into an inhalant soaked rag stuffed in the mouth (i.e., “huffing”), and (e) inhaling from nitrous oxide-filled balloons. Given their accessibility, inhalants are commonly the first drugs abused by young people.

A variety of common products contain substances that can be inhaled. Typically, inhalants are classified into four categories: (1) volatile solvents, (2) aerosols, (3) gases, and (4) nitrates. The information contained in this entry has been adapted and modified from the National Institute on Drug Abuse.

Volatile Solvents

Volatile solvents are liquids that vaporize at room temperatures, which are found in a variety of inexpensive, easily accessible, household products. Examples of volatile solvents include paint thinner and remover, dry-cleaning fluid, degreasers, gasoline, glue, nail polish remover, and felt tip markers.

Toluene (i.e., methyl benzene) is a common ingredient among most solvents. In an effort to prevent inhalant abuse, a number of industries have added mustard oil to products containing toluene because, upon inhalation, it causes nasal irritation. Hydrocarbon solvents, petroleum, and natural gas are the most commonly abused inhalants, with the exception of amyl nitrate and nitrous oxide.

Aerosols

Aerosols are sprays that contain propellants and solvents. Examples of aerosols include spray paints, deodorant, hair spray, and cooking oil sprays.

Gases

This category includes medical anesthetics (e.g., ether, chloroform, nitrous oxide [i.e., “laughing gas”]) as well as gases used in household products (e.g., butane lighters, propane tanks, whipped cream dispensers).

Nitrates

Although other inhalants are used to alter mood, nitrates are used primarily as a sexual enhancer. Whereas the use of other inhalants act directly on the central nervous system, nitrates serve as a muscle relaxant and act to dilate blood vessels. Examples of nitrates include cyclohexyl nitrate, isoamyl nitrite, and isobutyl nitrate, which are commonly referred to as “poppers” or “snappers.” Although the Consumer Product Safety Commission has prohibited the use of nitrates, they can still be found in items such as video head cleaner, room deodorizer, or liquid aroma.

Trends in Inhalant Use

Because of their accessibility, inhalants are typically the first drugs used by young people. In particular, adolescents and preadolescents tend to be the group most associated with inhalant abuse, with the majority of inhalant abusers being under the age of 25. More specifically, according to the National Survey on Drug Use and Health and the Monitoring the Future (MTF) study, inhalant abuse is widespread among young people in the United States. In fact, approximately 3% of children have tried inhalants by the time they enter fourth grade. Along these lines, data from national surveys suggest that inhalant abuse reaches its peak between the seventh and ninth grades, with eight graders typically reporting the highest rates of abuse. In addition, according to the 2006 MTF data, 10.5% of eighth-grade females reported using inhalants in the previous year, compared to 7.8% of eighth-grade males. Moreover, among 12th-grade students, 3.9% of females and 5.1% of males reported using inhalants. While inhalant abuse is not location specific—in other words, people in rural, suburban, and urban areas abuse inhalants—other factors that have been associated with inhalant abuse include adverse socioeconomic conditions, a history of childhood abuse, poor grades, and dropping out of school.

Consequences of Inhalant Abuse

Since most inhalants produce a rapid high, similar to being drunk, the use of inhalants offers a more accessible and cheaper way for children and adolescents to achieve an alcohol-like high. As a result, many young people abuse inhalants hoping for a quick high, without being fully aware of the serious negative consequences associated with this behavior. Although most inhalants differ in their chemical compositions, they all produce effects similar to anesthetics and act to slow down the body’s functions. Regular abuse of inhalants can cause serious physical complications (e.g., damage to the brain, heart, lungs, or kidneys). Even a single session of repeated inhalations can lead to heart failure by altering normal heart rhythms or preventing enough oxygen from reaching the lungs; in some cases, this can result in death (i.e., sudden sniffing death). The consequences of long-term inhalant abuse may include short-term memory loss, heart failure, hearing loss, numbness, central nervous system damage, blood oxygen depletion, and death. The abuse of inhalants may also result in both permanent and temporary physical problems. For example, permanent effects associated with inhalant abuse include hearing loss, peripheral neuropathies, brain damage, and bone marrow damage. Temporary effects of abuse may include liver and kidney damage and blood oxygen depletion. As noted by Susan Gray and Marilyn Zide, warning signs of inhalant abuse may include difficulties in school or work, a chemical odor to the breath, red eyes, confused appearance, and irritability.

Conclusion

Because of their relatively low cost and accessibility, inhalants are the drug of choice for many young people. Although some abusers may become dependent on inhalants, the probability of developing tolerance is small. In addition, it is also unlikely that the user will experience withdrawal when he or she stops using. However, inhalant abuse over a long period may result in physical and social problems.

INJECTION DRUG USE

In surveys such as the National Survey on Drug Use and Health, injection drug use is defined as the use of a needle to inject a drug that is not prescribed for the user or only for the feeling or experience that the drug causes. Injection drug use in a survey is assessed by asking the respondents whether they had injected heroin, cocaine, methamphetamines, or other stimulants during a specified time. Investigators, such as Vlahov and colleagues, have performed physical examinations to ascertain the presence of track marks and other physical evidence of injection drug use. Injection drug users are at high risk for human immunodeficiency virus (HIV), hepatitis C, and other bloodborne infections.

Prevalence

The National Survey on Drug Use and Health is an annual survey sponsored by the Substance Abuse and Mental Health Services Administration (SAMHSA). The survey collects data by administering questionnaires to a representative sample of the population age 12 or older through face-to-face interviews at their place of residence. According to the reports prepared by SAMHSA in 2003 and 2005, approximately 0.2% of Americans age 12 or older had injected heroin,

cocaine, methamphetamines, or other stimulants during the past year. The prevalence of past-year injection drug use is higher among young adults ages 18 to 25 (0.3%) than among adolescents ages 12 to 17 (0.1%) and older adults age 50 or older (0.02%). There also are regional variations in injection drug use with a high prevalence among individuals residing in the western region of the United States (0.3%).

In 2007, Armstrong reported that an estimated 1.5% of noninstitutionalized Americans have ever injected drugs for nonmedical reasons. According to Wu and Howard, 0.3% of American adolescents ages 12 to 17 reported having ever injected drugs and nonstudents were more likely than students to report lifetime injection drug use (1.7 vs. 0.3%).

Needles

The National Survey on Drug Use and Health asked injection drug users how they obtained their needles the last time they injected drugs. According to the 2003 reports prepared by SAMHSA, close to one half (47%) of past-year injection drug users bought needles from a pharmacy, 9% bought them on the street, and 4% obtained them from needle exchange. Other less-common needle sources include drug dealers, a shooting gallery, and stealing from others. The 2005 report indicated that 17% of past-year injection drug users obtained their needles from needle exchange. Needle exchange is one of several interventions aimed at preventing the spread of HIV infection among injection drug users and their sexual partners.

Reasons for Use

In 2003, Calzavara and colleagues examined reasons for drug use among injection drug users. They found that, among those who injected drugs in the year prior to incarceration, reasons commonly given for drug use were “makes me feel good” (76%); “because I’m addicted” (69%); “a way to escape reality” (59%); “helps me deal with feelings of sadness” (51%); “helps me forget how much I miss those I care about (family, friends, etc.)” (50%); and “helps me deal with feelings of frustration” (50%).

Bloodborne Infections

Risky injection behaviors among recent injection drug users are not uncommon. The National Survey on

Drug Use and Health found that approximately 64% of past-year injection drug users did not clean their needle with bleach before the last time they had used one to inject a drug, and 51% reused a needle that they had used before. Approximately 13% used a needle that they knew or suspected someone else had used before them, and 18% used a needle that someone else used after them.

HIV infection is closely linked with injection drug use. In 2000, Chitwood and colleagues studied a sample of injection drug users recruited from the streets of Miami-Dade County, Florida. They found that new injectors had a lower HIV seroprevalence than long-term injectors (13.3 vs. 24.7%) and that both new and long-term drug injectors exhibited a high level of current HIV-related risk behaviors.

It appears that many young or recently initiated injection drug users have engaged in unsafe injection and/or sexual practices that place them at high risk for HIV and hepatitis viral infections. For example, Kral and colleagues found that young injectors (under 30 years) were more likely than old injectors (30 years or older) to share syringes in the past month, to report drug overdose in the past 15 months, and to report engaging in unprotected sex in the past 6 months.

According to U.S. investigators, rates of HIV and hepatitis virus infections rise within the first two years following initiation of injection drug use. For instance, Garfein and colleagues found high seroprevalence rates of hepatitis C virus (64.7%), hepatitis B virus (49.8%), and HIV (13.9%) among those who had injected for 1 year or less. Two sets of behaviors that increase injection drug users' risk of becoming HIV-infected are unsafe injection practices and high-risk sexual behaviors.

Populations at Risk

Research suggests that street youths, drug users, and those involved with the criminal justice system are at risk for initiating injection drug use. In a study of street-recruited youth ages 14 to 25 years in Montreal, Canada, Roy and colleagues found that more than one third of street youth reported having ever injected drugs: 14% and 26% were former and recent injectors, respectively. During a mean 6.9-month observation period, 7% of noninjectors initiated injection drug use (injecting cocaine or heroin), and 58% of new injectors reported borrowing used needles.

In 2003, Calzavara and colleagues reported that 68% of inmates used illicit drugs in the year prior to incarceration and 32% reported a history of injection drug use. More than one half (53%) of injection drug users injected a drug in the year prior to their current incarceration, and daily injection was common among those recent injectors (45%). Drugs most commonly injected were cocaine (67%), heroin (49%), other opioids (39%), and crack cocaine (26%).

In 2004, Wu and colleagues examined the prevalence of injection drug use in a representative sample of lifetime stimulant users age 12 or older. They found that approximately one in seven (15%) lifetime stimulant users had ever injected a drug for nonmedical reasons. About one tenth of stimulant users reported having ever injected a stimulant (11%) or cocaine (11%). Less than one tenth (8%) of stimulant users had ever injected heroin.

According to a 2001 report by U.S. Centers for Disease Control and Prevention, there is a high prevalence of injection drug use among drug users admitted to addiction treatment programs. Clients who were admitted to New Jersey addiction program centers were categorized into three groups: users of heroin and cocaine, users of heroin who did not use cocaine, and users of cocaine who did not use heroin. The 1999 data indicate that 45% of users of heroin and cocaine were injection drug users compared with 37% of users of heroin who did not use cocaine and 2% of users of cocaine who did not use heroin.

Risk Factors

Studies have identified several characteristics that are associated with injection drug use, such as childhood misbehaviors, inhalant use, marijuana use, dropping out of school, running away from home, early sex-trading, childhood sexual abuse, recent experience of violence victimization, and involvement with the criminal justice system.

Longitudinal Studies

Longitudinal patterns of injection drug use were examined among a cohort of 1,339 injection drug users recruited into the AIDS Link to Injection Experience (ALIVE) Study in Baltimore, Maryland, through community outreach efforts. This study was initiated in 1988, and follow-up continued through 2000. According to Galai and colleagues, over a

12-year study period, four patterns were noted: 29% of participants remained persistent drug injectors, 20% ceased injection, 14% relapsed once, and 37% had multiple transitions (i.e., multiple cessations and multiple relapses). The observed long-term injection patterns indicate that drug addiction is a chronic disease.

The long-term trend in HIV incidence and associated risk behaviors between 1988 and 1998 also were determined among the cohort of HIV-seronegative injection drug users in Baltimore, Maryland. According to Nelson and colleagues, 277 persons were found to be HIV-positive during 8,826.45 person-years of follow-up, an incidence of 3.14 per 100 person-years. HIV infections were associated with injection of cocaine, more frequent injection, needle sharing, and injection in a shooting gallery. Sexual behavior variables associated with HIV infections included a sexually transmitted infection, male homosexual behavior, and sex with another injector.

Public Health Implications

According to the 2006 reports by U.S. Centers for Disease Control and Prevention, since the HIV/AIDS epidemic began, injection drug use has directly and indirectly accounted for more than one third (36%) of AIDS cases in the United States. Of the 42,156 new cases of AIDS reported in 2000, 11,635 (28%) were related to injection drug use. Injection drug use contributes to the spread of HIV through sharing syringes and other equipment for drug injection, as well as through sexual transmission (e.g., having sex with an injector who is HIV-positive). Children born to mothers who contracted HIV through sharing needles or having sex with an injector also may become infected. The rate of mother-to-child transmission has decreased in the United States since treatment protocols for HIV-positive pregnant women became widely available in the mid- to late 1990s.

Conclusion

There is a continued need for innovative prevention programs that target subgroups at risk for injection drug use, such as young drug users, homeless people, and people who are involved with the criminal justice system. Additional efforts also are needed to engage drug users in drug treatment and HIV prevention in

order to sustain cessation of drug use and to prevent adverse health and social outcomes among injectors.

INSTITUTE OF MEDICINE CLASSIFICATION SYSTEM

Classification systems are tools to help researchers, practitioners, and others think about large-scale problems. To avoid misuse of these tools, and to get the maximum benefit, a classification system's nature, strengths, and weaknesses must be understood. The Institute of Medicine's (IOM) classification of preventive interventions is important to the practice of substance abuse prevention.

Prior to 1994, substance abuse prevention used a public health classification system that designated

“primary prevention” as stopping a problem before it starts, “secondary prevention” as stopping a problem early in its course, and “tertiary prevention” as minimizing further injury, disease, or disability among those with a problem. This system was originally designed to apply to physical illness. This system was helpful in some ways, but not easy to apply, especially to substance abuse prevention. For example, “tertiary prevention” fits into treatment systems but is not congruent with abstinence-based substance abuse prevention.

In 1994, the IOM issued a report called “Reducing Risks for Mental Disorders: Frontiers for Preventive Intervention Research.” As part of its analysis, IOM proposed the use of a newer classification system, based on the work of R. Gordon. This new system divided mental disorder prevention into three categories: universal, selective, and indicated. The categories were based partly on the nature of the services provided rather than just the status of the service recipients.

Universal preventive interventions were defined as those for the general public or a population group (i.e., community, school, or neighborhood) with no screening to assess the risk for substance abuse of the participants. An example for substance abuse prevention would be a parenting program designed to be offered to all parents of teens in a community, irrespective of whether alcohol or other drug use by their teen had been an issue. The IOM made a cost–benefit argument for universal prevention because these interventions generally have a low cost per individual. If the interventions are perceived as effective and acceptable to the population and there is a low risk of undesirable unintended effects from the interventions, then universal prevention is worthwhile.

Selective preventive interventions are designed for groups with risk factors that indicate increased chance of developing a mental disorder. An example for substance abuse prevention would be a parenting program targeted toward parents of children experiencing academic failure. Because academic failure is a known risk factor for substance abuse (and vice versa), a prevention program that focused on this group might be appropriate, even if the cost per individual was higher than it would be for a universal population.

The IOM's report was created very specifically for the purpose of reviewing research about prevention of mental disorders, rather than substance abuse prevention. The IOM's definition of indicated preventive

interventions was especially focused toward this purpose. The definition targeted people with signs of a mental disorder whose symptoms were not yet severe enough to allow the application of a diagnosis. As applied to substance abuse prevention, this has often been taken to mean youth who have “experimented” with some substance use but have not experienced sufficient problems to be diagnosed with a substance use disorder. A wide range of interpretations have been applied to the meaning of *indicated*, including use of the term whenever individual case management services are involved.

Substance abuse prevention professionals should be aware of three shortcomings in the use of the IOM system for substance abuse prevention. One is that the notion of “universal prevention interventions” heavily implies use of a “host” (i.e., person) strategy (in the public health host-agent-environment trilogy), and so may not fit well with the current trend toward more environmentally focused efforts. A working group in Illinois in 1998 proposed that “universal” be divided into “universal inoculation” and “social change.” The former aims to reach and directly affect large numbers of persons (i.e., host strategies), while the latter aims to achieve widespread change by working with organizational entities (such as government, parent groups, or community-based organizations) that can profoundly affect communitywide risk and protective conditions (i.e., environmental strategies).

A second consideration in applying the IOM system to substance abuse prevention is that the IOM explicitly excluded health promotion from the classification system. This was done not out of doubt about the value of health promotion but simply to correspond to the mission of the group, which focused on the prevention of specific mental disorders. “Asset-based” prevention work that does not fall within the realm of the three IOM classifications may be considered to be in an additional category of “health promotion,” if that is appropriate to the particular situation.

A third weakness of the IOM classification system is one that plagues all attempts to reduce complex reality to a typology: The definitions are heavily influenced by the context in which they are applied. As was acknowledged in the original IOM report, treatment of one problem could be considered prevention of another, so one must be very clear about the problem(s) one is preventing. For example, some prevention programs may talk about prevention of youth *use*

of substances, another may talk about prevention of substance *abuse*, and another may talk about prevention of *addiction*. Each goal may be appropriate, but preventing addiction among youth who are already regularly using alcohol or other drugs is a very different problem than prevention of any substance use among the general population of youth.

The IOM report made a point of placing the three-part classification within a larger typology that included two aspects of treatment (case identification and standard treatment) and two aspects of “maintenance” following initial treatment (compliance with treatment and after-care). This serves as a reminder that substance abuse services can be considered along an analogous continuum that includes prevention, treatment, and a growing variety of posttreatment programs for relapse prevention and ongoing recovery. In most cases, “substance abuse prevention” and relapse prevention are very different, but there can be some overlap. For example, when a prevention initiative raises community awareness of the role played by alcohol promotion in initiation of youth drinking and proposes local, state, or national policy changes to restrict such promotion, it may also be helping recovering individuals by decreasing cues toward their resumption of drinking. Preventionists who understand the IOM classification system can make use of it while not being restricted to the limits of the 1994 report.

INSURANCE PARITY

Insurance parity refers to equality in health insurance benefit coverage for treatment of substance use disorders as compared to benefits for treating other medical problems. Over the past 2 decades, policies to mandate equal benefit coverage for mental health and—to a lesser extent—substance use disorders in employer-sponsored health plans have been a topic of policy debate. Over time, this debate has increasingly been informed by research evaluating the impact of parity mandates that have already been adopted.

Parity in insurance coverage for mental and substance use disorders (often called “behavioral health” benefits) arose as a policy issue because health insurance plans offered by employers have historically covered other medical conditions more generously than they do mental health and substance abuse problems. By the mid-1990s, most employers offered insurance that provided a benefit for mental and substance use disorders, and therefore the vast majority of people with private insurance have some coverage. But these benefits are often more limited; they have lower annual or lifetime dollar limits; cover fewer outpatient visits, fewer hospital-days, or both; and require higher co-payments, higher deductibles, or both.

Parity Laws

In the past decade, the federal government and a growing number of states have enacted legislation mandating that employers offer parity in their health insurance coverage for behavioral health benefits. These laws vary with respect to the types of employers, behavioral health problems, and benefit limits that are encompassed in the parity mandates.

At the federal level, the Mental Health Parity Act (MHPA) was passed by Congress in 1996 and became effective in January 1998. Opponents of parity warned that it would greatly increase costs of insurance, and in light of these concerns, the MHPA was very limited in scope. The act requires that employers who offer health insurance with mental health benefits provide lifetime and annual dollar limits that are equal to those for other medical benefits. The parity provisions do not extend to substance use disorders. Even for mental disorders, there are no requirements for parity in limits on number of inpatient days, number of outpatient visits, or in dollar

amounts required for deductibles or co-payments. Furthermore, it applies only to employers with more than 50 employees. Although the MHPA represented an important legislative victory for mental health advocates, its limited scope resulted in limited impact. In 2007, Congress debated a bill to extend parity to substance use disorders and provide for equal benefits beyond dollar limits; at this writing the bill is still under consideration. Under President Clinton’s directive, the health plans that provide benefits to all federal employees under the Federal Employee Health Benefits (FEHB) program were mandated to implement parity in benefits for mental and substance use disorders as of January 2001. The mandate called for equity across all benefit limits including dollar limits, limits on visits and inpatient days, and deductibles and co-payments. This was a far-reaching parity mandate, affecting about 8.5 million health plan enrollees.

Many states have also enacted parity legislation. Prior to the federal MHPA in 1996 only five states had adopted parity mandates, but the pace of state parity mandates quickly increased following the MHPA. Early legislation, however, was largely focused on equating particular benefits for specific mental health conditions; substance use disorders were generally excluded. Legislation including substance use disorders was slow to develop because of the absence of a well-organized advocacy community and lower public support for treatment of problems that are seen as self-incurred. In 2007, only 14 of the 36 states recognized by the National Alliance for Mental Illness as having enacted and implemented parity legislation include substance use disorders as a covered illness. Two of these states cover substance abuse services only for those with a diagnosed mental illness. Thus, benefit parity for substance abuse disorders still clearly lags behind that for mental health.

For a number of reasons, the state parity legislation that encompasses substance use disorders is likely to have little impact on insurance benefits. First, self-insured employers (including many large employers) are exempt from state insurance mandates by federal law. Second, many state laws have small firm exemptions, so that employers with 50 or fewer employees are not required to meet the parity requirements. Third, additional cost containment caps are included in many state provisions (e.g., Arkansas and Indiana), so that if offering these

benefits could lead to an anticipated increase in health care costs above 4%, the firm or insurer is exempt. Fourth, some policies do not apply to all plans in the state. For example, North Carolina's policy applies only to state employees, and Minnesota's policy applies only to HMOs. Finally, these laws apply to specific types of benefits. For example, Massachusetts's legislation applies only to annual dollar limits and visit restrictions and not to cost-sharing requirements.

Arguments for Limited Benefits

The primary arguments for limiting coverage for these services are based on two economic considerations referred to as *moral hazard* and *adverse selection*. Moral hazard refers to the problem that individuals with insurance are inclined to use more medical services than they would if they had to pay the full cost of those services. Evidence supporting the moral hazard problem with mental health services comes from the RAND Health Insurance Experiment (conducted in the 1970s); however, this study did not examine substance abuse services. A strong response to the out-of-pocket price of treatment like that found in the Health Insurance Experiment for mental health services suggests that consumers are not valuing this kind of treatment as highly as other medical care. Benefit limits provide a mechanism for balancing the incentive to use services that are not highly valued.

Adverse selection refers to the problem that plans with more generous insurance coverage for mental health and addiction services could attract individuals who anticipate greater use of these types of medical services, generating higher costs for the insurer with more generous coverage. Health plans and employers can guard against this risk by limiting benefits.

Opponents to parity legislation argue that these laws increase the cost of insurance because of the presence of moral hazard and adverse selection in the health care market. Increased costs are ultimately transferred from insurance plans to employers and, in turn, increase the cost of doing business, increase costs of insurance for employees, or put people at greater risk of not having insurance coverage at all. Moreover, there is public skepticism about the effectiveness of treatment, fueling concerns that added costs are not justified by their health benefits.

Arguments for Parity

Advocates for broader parity mandates argue that social costs of substance abuse are extremely high and that treatment of individuals with these problems will result in social cost savings that more than offset the costs of treatment. The treatment research literature documents effectiveness of a variety of treatment practices in reducing substance use and associated social problems and thus supports this view. However, it is not known the extent to which usual services received for substance abuse problems by those with private health insurance are consistent with evidence-based practices.

Available research examining the impact of implementing parity also generally supports arguments for parity mandates by showing that fears of rising costs are largely unfounded. Contrary to predictions based on moral hazard and adverse selection, benefit parity does not appear to increase use of services, or if so, to result in small increases. Most research to date has focused on the impact of implementing parity in mental health benefits, but a few studies have addressed substance abuse treatment benefits. An evaluation of the comprehensive parity ruling implemented in the FEHB program found no significant increase in use of services attributable to parity for five of seven large plans studied, a decrease in use for one plan, and an increase in use in the remaining plan studied. These results can be explained by the fact that in recent years, utilization and costs of behavioral health services are, within most private insurance plans, contained by managed care organizations. In fact, the single FEHB plan that showed an increase in use attributable to parity was the only one that did not manage its behavioral health benefits through a contract with a managed behavioral health care organization. Other studies of substance abuse parity mandates (e.g., in Virginia and for state government employees in Ohio) also suggest minimal impact on utilization of services in the context of managed care.

Conclusion

Recent data reported by Jon Gabel and colleagues show little change in substance abuse treatment benefits since the mid-1990s. About 9 of 10 workers has some coverage for substance abuse treatment services, but most have more limited benefits and higher cost-sharing requirements for their substance abuse treatment

benefits than for other medical benefits. Adjusted for inflation, total private insurance spending on substance abuse treatment has remained relatively steady over this time.

Given experience to date with implementation of parity policies, particularly the comprehensive parity mandate of the FEHB program, it is easy to wonder why benefit parity remains such a contentious policy issue and broader federal parity legislation has yet to be passed. Weak public advocacy and relatively limited research on substance abuse benefit parity undoubtedly play a role. And even though few commercial plan enrollees ever use substance abuse treatment services, high prevalence of substance use disorders in the population is well documented. It is perhaps not surprising that some remain politically opposed to parity legislation because they fear burdening employers and workers with escalating costs of insurance should the floodgates of all this pent-up need for services unexpectedly be opened.

In the debate surrounding parity, the full implications of having entered into an era of managed health care, particularly in behavioral health care, have been underappreciated. Projections of costs of parity have often assumed a world of health care like that of the 1970s Health Insurance Experiment, before managed care, when benefit limits were the only mechanism available for employers to control costs. Today, however, the great majority of privately insured people have behavioral health benefits under some form of managed care, where supply restrictions can be used in lieu of benefit design to influence utilization of services. Design of benefits with various limitations and cost-sharing is one way of controlling costs of health care; managed care is another. Benefit design controls costs through incentives that influence consumer “demand” for services, but it is a crude tool that eliminates not only low-value “discretionary” care but also appropriate care for those with severe disorders and highest need for services. Managed care controls costs by influencing “supply” of services, for example, through negotiated reductions in fees with a network of preferred providers and review of appropriateness of services to eliminate unnecessary use. Managed care is a more finely tuned and potentially appealing cost-containment strategy than benefit design, because it can offer a more flexible benefit with health services tailored to need by clinicians and case managers.

Under managed care, arguments against insurance benefit parity are greatly weakened. Even with benefit parity, concerns arise that managed care can

discourage access to care and encourage skimping on the quality of care. These issues are likely to rise to the fore of substance abuse treatment advocacy when comprehensive parity is achieved.

INTERNATIONAL COALITION FOR ADDICTION STUDIES EDUCATION

Although addiction studies is a venerable field dating from the mid-20th century, there were a small number of curricula at colleges and universities until the late 1970s. At that time, state and national systems for credentialing of addiction counselors were established, and academic programs were put in place to offer the

educational requirements for addiction counselor certification. In 1990, it became apparent that the complexion of addiction counseling was changing. This was manifested in an aging workforce, in advancements toward credentialing and licensure of addictions professionals, and in an increasingly complex body of addictions research that challenged current practitioners in the field. A group of addiction studies educators from around the United States formed a germinal organization to address this urgent workforce development need. Thus was born the International Coalition for Addiction Studies Education (INCASE).

As a relative newcomer to the many and varied addictions organizations around the country and around the world, INCASE initially struggled to find its niche and the audience with which to share its vision, mission, and goals. Addictions educators are found in many different academic departments and divisions: INCASE presidents have included a criminologist, a nurse educator, an anthropologist, human service educators and psychologists. With the publication of *Addiction Counseling Competencies: The Knowledge, Skills and Attitudes of Professional Practice* in 1997 (published by the Center for Substance Abuse Treatment [CSAT] in the Substance Abuse and Mental Health Services Administration), INCASE found both a purpose and a well-articulated role with direction. INCASE members served as field reviewers, consultants, and as members of the National Steering Committee on Addiction Counselor Competencies that voted to adopt the document as a statement from and for the field.

Initially, the multiple purposes of the organization included to disseminate professional knowledge and share ideas regarding addiction studies curricula; to conduct international seminars, workshops, and conferences in order to provide members with educational opportunities; to encourage and promote ongoing research and scholarship in the field of addictions studies; to develop standards for, and implementation of, an accreditation process for competent and comprehensive addiction studies education providers; to explore related funding sources and opportunities; to initiate discussions of reciprocity within and between nations, states, and provinces; and to develop liaisons with other organizations providing related educational services or who have related interests. Although originally broad in scope, these purposes evolved over time and are now a much more functional set of goals and objectives within the capabilities of a small but disciplined volunteer organization of educators.

Today, INCASE shares the characteristics of a traditional organization with both mission and vision statements. As a mission, INCASE has a succinct purpose: promoting new knowledge and advancing teaching and curriculum development as seminal to improving addiction professionals' education. As a vision, INCASE sees itself as important and contributory in workforce development; the education and clinical training of competent, well-informed practitioners; the production and dissemination of new knowledge; the development of products to advance the professional discipline; partnering with like-minded groups; and engaging in dialogue with allied or affiliated groups on issues of certification, licensure, supervision, and continuing education.

To meet these goals, INCASE has organized itself to be responsive to the rapidly changing environment of the addiction studies arena. As an organization, INCASE is interested in developing an identity as educators and as participants in the growth of this profession. To that end, INCASE members engage in conversations with other groups such as the Addiction Technology Transfer Centers, NAADAC (the Association for Addiction Professionals), the International Certification and Reciprocity Consortium, the Annapolis Coalition, the Association for Medical Education and Research in Substance Abuse, and many others. National conferences, held since 1994, have been cosponsored with state counselor bodies and Addiction Technology Transfer Centers, and have received support from the Center for Substance Abuse Treatment and the National Institute on Drug Abuse. As might be expected of academics who are traditionally employed and retained based on teaching, research, and service activities, INCASE characteristically focuses its efforts in three principal areas: curriculum development; program review and approval; and development, research, and planning.

Curriculum Development

The *Addiction Counseling Competencies* laid the platform for the construction of curricular experiences that would meet or exceed those minimum competencies of effective addictions practitioners. Included in this academic and educational format were the knowledge, skills, and attitudes one could expect of an individual in professional clinical practice. INCASE found itself at the heart of the matter at varied levels, from workshop presentations for continuing education to providing substantive academic programs for

degree-seeking individuals at the associate, baccalaureate, master's, and doctoral levels. Today, emphasis in clinical preparation is not only founded on knowledge but also on the application of learning to achieve effective clinical outcomes; on an understanding of the history regarding what has worked but also on an appreciation for a projected future of improved practice; and on immersion into the research to improve both preparation and practice in place of running in fear from the science of addiction.

Program Review and Approval

In organizing a program approval process for higher education addictions curricula, INCASE hopes to further the goals of quality assurance and promulgation of program standards. It is of equal importance to educators to promote the development of articulation networks and transferability and portability of degrees; to provide a resource for the creation, expansion, and upgrading of addictions curricula; and to ensure that the classroom is a bridge from science to practice in the preparation of the addictions workforce. Self-governance within the addictions higher education field, helping addictions educators advocate for their existence and needs within their institutional environment, and aiding students in moving up educational and career ladders by providing legitimacy to the curricula and academic programs they have completed are core to the mission and vision of INCASE.

Development, Research, and Planning

INCASE produces its own journal, *The Journal of Teaching in the Addictions*, a forum for the presentation of manuscripts addressing new knowledge, strategies, teaching techniques, and enhancement of workforce development. It is engaged in the future, insistent on preparing practitioners for tomorrow's workplace. It provides a supportive environment for colleagues to share via a listserve, conferences, and a platform to discuss and review curriculum and teaching strategies. INCASE is pursuing grants to further its mission and vision of continued enhancement of the workforce in academic, personal, and professional dispositions. INCASE prides itself on staying at least abreast, if not ahead, of this ever-changing discipline.

The International Coalition of Addiction Studies Education, though relatively young, is emerging as a leader in the overall preparation of the next generation of addictions practitioners.

INTERNET ADDICTION

It is estimated that more than 210 million Americans access the Internet on a regular basis, making the United States by far the top World Wide Web user in the world. Specialists estimate that between 6% and 14% of Internet users in the United States have a destructive dependency on the Web and that the vast majority of these people do not realize they have a problem.

Internet addiction has been formally recognized as a disorder by the American Psychological Association, although it is not listed in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*. The term *Internet addiction disorder (IAD)* first made headlines in 1995 when psychiatrist Ivan K. Goldberg posted a parody online spoofing the *DSM-IV* by using the criteria for pathological gambling and calling it "Internet Addiction Disorder." At the time, spending excessive time online was not considered a disorder, disease, or addiction, but soon Goldberg realized his joke was a lot more serious than originally planned, as he started receiving hundreds of requests for consultations.

Goldberg took his spoof even further, creating an Internet addiction support group online, something critics jokingly compared to holding an Alcoholics

Anonymous meeting at a cocktail party. Ironically, Goldberg is still one of those skeptics who refuse to recognize Internet addiction as a real addiction, calling it simply a symptom of other, existing disorders.

Many researchers agree with Goldberg. Sara Keisler, of Carnegie Mellon University, calls Internet addiction a “fad illness.” Others argue that Internet addiction has as much medical merit as “telephone addiction” or “television addiction.”

However, supporters of the diagnosis say that Internet addiction can have much more serious consequences than other destructive habits, because the Internet can lead obsessive users to other addictions like gambling or pornography. Just like pathological gambling, Internet addiction is considered a “pure” addiction or an impulse control disorder because it does not involve the use of intoxicating drugs.

Internet addiction typically starts with casual use of e-mail or other simple online applications, many times for work or school purposes. In a relatively short time, it progresses into an activity that results in major disruptions in life. Some mental health professionals compare Internet addiction to alcoholism or drug addiction, at least in the way it can destroy different aspects of a person’s life.

As people begin to make the Internet an important part of their daily routine, they get channeled into different areas of the World Wide Web. Some of the most popular destinations for would be addicts include chat rooms, shopping sites, pornography, day trading, gambling, social networking sites like MySpace and Facebook, dating sites, downloading music and other digital files, instant messaging, blogging, or even reading news and sports.

Preliminary research shows that most Internet addicts are usually struggling with other issues such as depression and anxiety. For them, the Internet offers an escape from reality, and the fact that it is easily accessible, affordable, and anonymous makes them more susceptible to becoming addicted.

Kimberly S. Young, founder of the Center for Internet Addiction Recovery, developed one of the most efficient instruments for diagnosing Internet addiction, the Internet Addiction Test. This test is a 20-item questionnaire that measures mild, moderate, and severe levels of Internet addiction by quizzing the participants on things like the amount of time they spend online, the feelings and mood swings that people experience when they are on- or off-line, how

personal and professional relationships have been affected by the person’s Internet usage, and the importance that the Internet has on a person’s life overall.

According to Young, some of the symptoms associated with Internet addiction are preoccupation with the Internet, use of the Internet in increasing amounts of time in order to achieve satisfaction, unsuccessful efforts to cut back usage, a change in mood or feelings of depression when off-line, lying about the extent of the problem, using the Internet to escape other problems, and jeopardizing real-life relationships, career, or educational opportunities because of excessive use of the Internet.

The biggest problem with Internet addiction continues to be, and perhaps will always be, the effects that the addiction has on a person’s off-line world. A married person may meet someone else through a chat room and cheat on his or her spouse. A high school or college student might drop in his or her grades, or even drop out of school altogether because of an Internet addiction. Personal finances can be greatly affected with shopping or even gambling sites. Using the Internet for non-work-related purposes has also been cited as being one of the top corporate time-wasting activities, costing corporations millions of dollars every year.

Even though Internet addiction is considered a relatively new illness, many mental health professionals are treating their patients with some of the same approaches used to treat chemical dependency, including Twelve-Step programs. As with some other behavioral addictions, treating Internet addiction usually does not require total abstinence, as the goal is to reduce the time a person spends online and getting them to take control of the areas of their life that have become unmanageable due to excessive Internet usage.

Some formal treatment programs for Internet addiction have been developed. For example, the Illinois Institute for Addiction Recovery has an inpatient program designed for computer addicts, located at Proctor Hospital campuses in Peoria, Bloomington, and Springfield. Doctors there say that they have seen some of the same withdrawal symptoms in excessive computer users as they see in alcoholics and drug addicts. Sierra Tucson Drug Treatment Center in Arizona also has a program to combat Internet addiction. Patients here are encouraged to attend Alcoholics Anonymous or Narcotics Anonymous meetings as part of their recovery.

Published studies on Internet addiction are still scarce compared to studies on addictions that have been around for decades, and some mental health professionals are still skeptical to call excessive use of the Internet an actual addiction because it lacks some of the characteristics and consequences of conventionally recognized addictions. However, few can deny that excessive Internet use is a growing problem among the general population, and it needs to be further researched as more people get access to, and spend more time on, computers and other devices connected to the Internet.

INVENTORY OF DRINKING SITUATIONS

The Inventory of Drinking Situations (IDS) was developed by Helen Annis and colleagues at the Addiction Research Foundation in Toronto, Canada. The IDS draws its theoretical basis from Alan Marlatt's eight categories of high-risk drinking situations and is intended to provide an individualized profile of a problem drinker's particular high-risk situations that can then be used to structure and guide treatment.

The IDS is available in two forms. The original IDS consisted of 100 items representing particular situations in which people consume alcohol (e.g., "when I'm alone at home" or "when I've had a hard day at work"). Subsequent refinement of the instrument, including its revision to include drugs other than alcohol, has resulted in a final instrument that captures frequency of drinking in up to 50 different situations commonly reported by heavy drinkers as being ones in which they are most likely to drink. Factor analytic studies of the IDS have further grouped these eight situations into three factors: Negative Affective States, Positive Affective States, and Testing Personal Control. A short (42 items) form of the IDS was described by Carl Isenhardt in 1993. The short form has been shown to have adequate reliability and validity compared to the long form, but it does not cover the full range of high-risk situations described by Marlatt, focusing on only five of the eight types of situations in Marlatt's typology.

In Marlatt's model, the key to understanding and preventing relapse is to understand the specific situations in which the individual was at high risk to use alcohol or other drugs. These high-risk situations are divided into eight categories of which include unpleasant emotions, physical discomfort, pleasant emotions, testing personal control, urges and temptations, social problems at work, social tension, and positive social situations. The respondent is asked to indicate on a Likert scale how often they consumed alcohol in the situations presented during the previous year. A summary "profile" of specific types of high-risk situations for the individual respondent is then generated and can be used to guide the teaching of relapse prevention strategies that target the situations in which the respondent was most likely to drink and therefore are considered most likely to trigger relapse.

For example, if a client reported her most frequent drinking in situations involving unpleasant emotions, the clinician might focus on teaching the client affect management strategies, such as cognitive restructuring or thought disputation, as coping strategies that could be implemented instead of drinking alcohol. The clinician and client can then use the IDS as a guide to efficiently structuring treatment for less frequently encountered high-risk situations, thus making the treatment process both more efficient and more effective.

The IDS has also led to the development of another questionnaire, the Situational Confidence Questionnaire (SCQ) by Annis and colleagues. The SCQ uses the same situations as the IDS but asks the respondent to rate his or her confidence that he or she could encounter the situation without drinking. Taken together, the IDS and SCQ comprise a useful tandem of instruments for both treatment planning and treatment outcome assessment. Thus, following an initial assessment of high-risk situations with the IDS, and the teaching and implementation of coping strategies that do not involve drinking, the clinician can assess the extent to which the client is confident in his or her ability to encounter the high-risk situations identified by the IDS and cope without using alcohol. This assessment of confidence or self-efficacy is a critical one in helping to gauge both the likelihood of relapse and the ability to identify situations in which coping skills may fail. This then permits further anticipatory planning and coping skills training for the client.

In using the IDS to plan treatment interventions, the clinician may either complete the IDS with the client or have the client do so independently. Using the profile of high-risk situations generated, the clinician and client jointly identify those high-risk situations that are most likely to occur in the client's life and can then develop specific coping strategies the client can use in order to cope effectively without drinking.

Should the client subsequently relapse, the IDS can assist the clinician and the client in understanding that relapse and in planning subsequent relapse prevention treatment by indicating other situations that initially seemed less important but that may have played a role in the client's current relapse.

Later work by Annis and colleagues has extended the basic theory behind the IDS to the development of an Inventory of Drug-Taking Situations. Subsequent work has resulted in an instrument that combines assessment of high-risk situations for both alcohol and other drugs.

The IDS has been translated into a number of languages, including French, Spanish, German and Swedish, and has demonstrated adequate reliability and validity in all versions. The main disadvantage of the IDS comes with clients whose literacy level is below the eighth-grade level at which the items are written. However, the IDS can still be a useful tool with those clients if the items are read to the client by the clinician.

J

JELLINEK, E. M. (1890–1963)

Following repeal of the National Prohibition Act, the United States began the shift from a moral to a scientific approach to alcohol problems, emphasizing a disease concept of alcoholism and treatment for alcoholics. E. M. Jellinek was at the forefront of this change, helping to shape the policies and programs of the new alcoholism movement during the 1940s and 1950s. Through his work with the Research Council on Problems of Alcohol, the Yale Section of Alcohol Studies, and the World Health Organization (WHO), he influenced and helped disseminate the work of alcohol researchers and treatment professionals around the world.

Born in New York City, Jellinek was raised in Hungary and educated at the Universities of Berlin, Leipzig, and Grenoble. His studies ranged from philosophy and theology to language and linguistics, but his claims to various degrees from European and Latin American universities have been impossible to verify. Leaving Hungary in the 1920s, he spent several years in Sierra Leone before taking a job with the United Fruit Company in Honduras. In 1931, he returned to the United States to become Director of the Biometric Laboratory at the Memorial Foundation for Neuroendocrine Research in Worcester, Massachusetts, where he studied the neuroendocrine effects of schizophrenia.

Jellinek was nearly 50 years old when he accepted an offer in 1938 from the Research Council on Problems of Alcohol—an association of concerned researchers and physicians. He directed a major review of the existing research literature on the effects

of alcohol on the individual. When the funding ended in 1941, Howard Haggard, Director of the Laboratory of Applied Physiology at Yale University, brought Jellinek and the project to Yale and made him Managing Editor of the *Quarterly Journal of Studies on Alcohol*, which Haggard had founded in 1940. Jellinek subsequently coauthored several review articles as well as two monographs, stemming from the literature review project.

At Yale, Jellinek quickly rose to a leadership position in the Laboratory of Applied Physiology. In 1943, with Haggard, he founded and directed the Yale School of Alcohol Studies, the first program to train alcoholism professionals. He also established the Yale Plan Clinics, the first outpatient alcoholism treatment programs. In 1944, with Marty Mann, the first woman to recover in Alcoholics Anonymous, he sponsored the creation of the National Committee for Education on Alcoholism. This program became a major tool for raising public awareness about the disease of alcoholism. When Haggard established a formal section of alcohol studies within the Yale laboratory in 1943, he named Jellinek as director.

During his career at Yale, Jellinek developed his own research interests, mainly in the area of epidemiology. He made various attempts to quantify the numbers of alcoholics, primarily based on liver cirrhosis deaths, which ultimately led to the Jellinek Estimation Formula, published by the WHO in 1951. He also assisted in a survey conducted by Alcoholics Anonymous to determine the course of alcoholism. His analysis, supplemented with subsequent survey data, led to his classic publication in 1952 describing the phases of alcohol addiction.

Jellinek left Yale in 1948 to set up a similar research institute at Texas Christian University. Without sufficient financial support, the venture failed in 1951. By that time, he had moved on to Geneva as consultant to the new Alcoholism Subcommittee of the WHO's Expert Committee on Mental Health. There he renewed his epidemiological work, using his estimation formula to help calculate alcoholism problems in various European and Latin American countries. He also convinced the WHO to disseminate abstracts from Yale's alcohol literature review project to research centers around the world.

Jellinek left the WHO in 1955 and spent 2 years with the short-lived International Institute for Research on Problems of Alcohol. In 1957, he accepted a grant from philanthropist R. Brinkley Smithers to return to the United States to prepare a national report on alcoholism. The final report, published in 1960 as *The Disease Concept of Alcoholism*, identified five distinct types of alcoholics: alpha (psychological dependence without loss of control), beta (physiological complications, such as cirrhosis, but no physical or psychological dependence), gamma (increased tolerance, withdrawal signs, loss of control), delta (increased tolerance and inability to abstain), and epsilon (heavy binge drinking).

While completing *The Disease Concept of Alcoholism*, Jellinek also served as a consultant to the Addiction Research Foundation of Toronto and the Alcoholism Foundation of Alberta in Canada. Then in 1961, he joined the staff of the Cooperative Commission on the Study of Alcohol Problems. The commission was a U.S.–Canadian effort to make policy recommendations on alcohol problems. While at the commission, Jellinek secured funding from the National Institute of Mental Health (NIMH) to compile an *Encyclopedia of Problems of Alcohol* to bring together the research knowledge on the subject. He died suddenly of a heart attack in 1963, leaving the work unfinished. The NIMH terminated the project, feeling that no one else was qualified to undertake it.

In just over 20 years, Jellinek helped establish a modern alcoholism field based on research, professional education, and public awareness. His own efforts to estimate the numbers of alcoholics, to delineate stages in the addiction process, and to identify different types of alcoholics provided important tools to build on this scientific approach to alcohol problems.

JOHNSON MODEL INTERVENTION

Vernon Johnson, the founder of the Johnson Institute associated with the Minnesota model of treatment, described the process of intervention that has been widely used in motivating alcoholics-addicts to seek treatment in his books *I'll Quit Tomorrow* and *Intervention: How to Help Someone Who Doesn't Want Help*. The Johnson intervention is based on the disease model of addiction. There is a need to forcefully motivate the alcoholic to enter treatment because the alternatives are dire. The Johnson intervention is seen as a dynamic, emotionally charged, confrontation by significant persons in the alcoholic's-addict's life.

The major reason for the need for forcefulness in the Johnson intervention model is the impenetrable denial systems developed by alcoholics-addicts. These denial systems are often used to explain the difficulty of motivating alcoholics-addicts to seek treatment. Therefore, this type of intervention is designed to counteract denial through dramatic means.

The rationale of the Johnson model of intervention is to break through the denial system of the alcoholic-addict by confronting the person with the crises that he or she caused. The confrontation is done by significant persons in the alcoholic's-addict's life. Through this confrontation, it is hoped that the intervention process will *raise the bottom*. The bottom may be extremely

serious (e.g., injury, health problems, loss of family, death), and those who care about the alcoholic-addict would be anxious to avoid the bottom. The confrontational intervention would serve to precipitate a crisis in the life of the alcoholic-addict that is not life-threatening or otherwise damaging, but that would result in treatment. This is the concept of raising the bottom.

To raise the bottom, Johnson believed that the alcoholic-addict needed a clear view of reality as presented by the significant people in their life. Meeting this need means clearly stating specific facts about the person's behavior and the consequences of these behaviors in an objective, unequivocal, and caring manner.

In his books, Johnson outlined the specific procedures for conducting an intervention. Although Johnson wrote a book designed to enable a layperson to organize and implement an intervention, it is highly recommended that an intervention be facilitated by a trained mental health professional. These events can be volatile and emotionally charged.

First of all, there must be two or more people involved in the intervention who are close to the alcoholic-addict and who have witnessed his or her behavior while intoxicated. Having two or more people involved offers support for those confronting the alcoholic-addict, emphasizes the seriousness of the situation to the person, and helps to dispute attempts by the alcoholic-addict to dismiss or discount the events of any one person. Clearly, someone must determine the composition of the intervention team—usually, this is done by the person or people who have instigated the intervention. Participants may include spouses or lovers, children, parents, employers, teachers, or friends. Individuals who are seen as being influential in the life of the alcoholic-addicts would be valuable participants. It is sometimes the case that those people who are the most intimately involved with the alcoholic-addict are not helpful in the intervention because of their emotional closeness to the alcoholic-addict and consequent inability to refrain from nonproductive interactions during the intervention. In addition, Johnson suggested that each person on the intervention team be educated about the disease concept.

Each participant in the intervention develops a list of specific incidents of alcohol or other drug-related behavior and describes the effect that each incident had on the participant. Specificity is important to avoid generalized statements that can be disputed. Although it is important for participants to relate the effect of the alcohol and/or drug-related behavior on them, the tone

should be nonjudgmental. Because the intervention may become quite emotional, it is suggested that the participants write down the specific events so that they can remember them during the intervention.

Each participant must also decide what action he or she will be willing to take if the alcoholic-addict refuses treatment. The actions must be serious enough to have an impact, and the participant must be willing to follow through. Thus, spouses and lovers may decide to leave the relationship, employers to terminate, or friends to disengage. Obviously, if the intervention does not result in the person's seeking treatment and if participants do not follow through on their actions, it will be extremely difficult to intervene in the future.

Someone on the intervention team must do some homework and determine the treatment options available, the cost of treatment, availability of insurance, and other hurdles such as job and family responsibilities. All of these details must be cleared up before the intervention so that all the alcoholic-addict has to say is "yes" (i.e., agree to go to treatment).

Clearly, preparation for the intervention is essential. The intervention team must meet on several occasions to rehearse the intervention and to role-play possible scenarios. The order in which people will speak should be predetermined. Someone must be assigned the responsibility of getting the alcoholic-addict to the intervention and of getting the person there sober. Often, deception is used, since the alcoholic-addict would refuse to attend if the true purpose of the intervention were known. Participants need to be prepared for the emotional reaction of the alcoholic-addict. He or she may become angry when the purpose of the intervention is revealed. He or she may simply leave.

When the alcoholic-addict arrives at the intervention, the facilitator (who should be a mental health professional) tells the alcoholic-addict that the people in the room are there because they care and are concerned. The facilitator tells the alcoholic-addict that the people want to describe what they have been seeing. The alcoholic-addict is asked to listen to each person and will then be given an opportunity to talk. Each participant (in the predetermined order) expresses love, caring, and/or concern and describes the specific incidents he or she has prepared. The final participant, who should be the most influential, begins the discussion of what is being asked of the alcoholic-addict (i.e., treatment). The facilitator will usually need to contribute to the discussion of available treatment options, should intervene when the alcoholic-addict interrupts with arguments or rationalizations, and

may need to remind the alcoholic-addict just to listen until everyone has finished. The facilitator should also intervene when nonproductive interactions occur between a participant and the alcoholic-addict.

Johnson model interventions were very popular 10 to 20 years ago. The development of motivational interviewing as an alternative has dramatically reduced the frequency of Johnson model interventions. Still, very traditional treatment programs that adhere to the Minnesota model of treatment may still conduct Johnson model interventions prior to treatment admission.

JOIN TOGETHER

Illicit drugs and inappropriate alcohol use are national public health problems that are expressed differently in every community. Therefore, solutions to more effective prevention and treatment must occur through community-based strategies and action. In the late 1980s and early 1990s, the Robert Wood Johnson Foundation was looking for a way to attack drug and alcohol problems in communities. There were hundreds of community organizations eager to address the issue, but they were often run by volunteers who had few strategic planning skills, no access to current research, and very limited funds. They were often operating in isolation from similar groups and working in a policy environment that was hostile to effective prevention and treatment. Furthermore, the idea that alcohol and drug dependence was a disease with biologic, psychological, and behavioral components was not well established or accepted.

Join Together was launched at the Boston University School of Public Health in 1991 through an

initial grant of \$5 million from the Robert Wood Johnson Foundation with a mission to help leaders in communities address the leadership, strategy, funding, and policy challenges they faced. The group continues to operate as part of the Boston University School of Public Health with funding from Robert Wood Johnson and other foundations, corporations, and government agencies. Today, the program is one of the nation's largest providers of research information, planning assistance, and advocacy support for people who are working to improve strategies that prevent and treat alcohol and drug problems.

Join Together was the first group of its kind to make strategic use of Web technology, and currently, more than a million people consult its main Web site (www.jointogether.org) annually. More than 35,000 prevention and treatment professionals subscribe to one or more of its electronic newsletters. Join Together members include community leaders, public officials, doctors, nurses, and other treatment professionals, as well as parole officers, clergy, people from labor unions and employee assistance programs, and parents and families—anyone trying to help someone tackle a problem with addiction.

Although the Internet was only embryonic in the early 1990s, Join Together believed electronic communication could become a vehicle to connect people with others who were working on the same issue, disseminate accurate and timely information, and rally action on alcohol and drug policy issues. Its first program relied on a commercial time sharing system, but plans were developed that enabled the first version of Join Together Online to go live on the Internet within a month of the release of the first public browser in 1995.

One of Join Together's initial challenges was to identify, document, and gain access to the thousands of groups that existed throughout the country. Through lists collected from state agencies and other sources, mail surveys were conducted to gather information about what the groups were doing and what they needed. The answers formed the basis for technical assistance, leadership programs, and Web content development. Join Together continues to set its information and support agenda in response to regular surveys of community-level prevention and treatment leaders, but they are now done online.

Join Together's news and information services have evolved as technology caught up with its ambitions. Every week Join Together creates online summaries of approximately 100 new research reports, press stories, and program updates from all over the

country. These are freely available on the main site, syndicated through an RSS feed to hundreds of other alcohol, drug, and tobacco Web sites, and repackaged into daily and weekly focused electronic newsletters distributed free to more than 35,000 subscribers.

Web technology also enables Join Together to initiate action campaigns on alcohol or drug issues at the national, individual state, or community level. For example, in 2006, Join Together led a national effort to get major chain stores to remove alcohol drinking games from their shelves and Web sites. It also used its Web technology to help a local group of activists launch a campaign against alcohol advertising on the regional public transit busses and subways.

From 1992 to 1999, Join Together ran a national leadership recognition program called the Join Together Fellows Program. Each competitively selected group represented all parts of the country and a mix of activists and professionals including coalition leaders, mayors, judges, police chiefs, business and union leaders, clergy, treatment and prevention counselors, and doctors and nurses. Many directors of state drug and alcohol programs were Join Together Fellows early in their careers. The mayor of San Francisco and a former head of the federal Department of Health and Human Services' Center for Substance Abuse Prevention as well as several judges have all been fellows.

Join Together is committed to using scientific evidence and demonstrated best practices as the basis for its information and technical assistance programs. The group believes it has demonstrated that strategies based on valid local data and relying on evidence-based solutions are more likely to be effective than efforts that rely on impressions and ideology. For example, communities that participated in the Fighting Back program, administered by Join Together, significantly reduced alcohol-related automobile deaths after they increased access to treatment and stepped up enforcement.

Creating sound and sane public policy on alcohol and drugs is another Join Together goal. From time to time, national policy panels are created to examine a particular issue and formulate recommendations for action. Members of panels include former and present elected officials, subject experts, and community activists. They gather information through background research and public hearings. Their findings and recommendations are published in print and online and are widely distributed to the targeted audiences throughout the country. A recent

panel chaired by the former Mayor of Baltimore and current Dean of the Howard University Law School Kurt Schmoke addressed issues of legal and social discrimination faced by people with alcohol and drug problems. The panel found that legally sanctioned discrimination often continues long after a person enters successful recovery and creates a lifetime of punishment. The panel recommended changes in federal and state laws and regulations to end these practices. In 2006, a panel chaired by former Governor of Massachusetts Michael Dukakis and Kansas State Representative Pat George focused on ways to improve state government organization of alcohol and drug services and strategies. The report called for new leadership from governors, legislatures, and courts and recommended organizational changes at the state level.

Although Join Together's primary mission has been to assist community leaders and strategies, its early internet capacity enabled it to pioneer applications aimed at helping individuals who smoke, drink too much, or use illicit drugs. In 1995, Nathan Cobb, then a Join Together staff member, created QuitNet as a free online program and community to help individuals quit smoking. Join Together sponsored the service, and it grew very rapidly. In 2000, in cooperation with Boston University, it was transformed to a private company and began providing services to state and private smoking cessation programs. QuitNet now operates as part of Healthways, Inc. and was used by more than one million people in 2007 in the United States and other countries.

Join Together also created and sponsors Web-based free screening programs to help individuals learn about the health related risks of their own drinking and/or drug taking. The Web site www.alcoholscreening.org was launched in 2002. In 2007, more than 15,000 individuals a month completed self-screens. The Web site www.drugscreening.org was launched in 2007 due to the rapid growth in use.

L

LEGAL ACTION CENTER

The Legal Action Center is a nonprofit law and policy organization whose stated mission is to combat discrimination against individuals with a history of addiction, HIV/AIDS, or criminal records. The Legal Action Center helps individuals reclaim their lives, and it also advocates for reasonable public policies on issues related to addiction, AIDS, and/or criminal histories.

In 1973, the Vera Institute of Justice in New York City established the Legal Action Center to fight issues arising from the overlap of addiction and crime, particularly by assisting those most directly impacted. During the middle of the 1980s, AIDS was added to the mission of the Legal Action Center as it became evident that persons with alcohol and other drug problems and/or those with criminal records were at an increased risk for HIV/AIDS. The Legal Action Center is dedicated to fighting the prejudice and stigma that frequently keeps people with personal histories of addiction, crime, and/or HIV/AIDS from fully participating in mainstream society. Beginning with several class action suits and other cases in the 1970s and 1980s, the Legal Action Center has successfully challenged discrimination in granting government benefits, employment, and other areas with precedent setting litigation. For example, the Legal Action Center was instrumental in ensuring that the Americans with Disabilities Act (ADA) and the Fair Housing Act specifically forbid discrimination against those in recovery from alcohol and other drug use. One high profile case that the Legal Action Center litigated was *Traynor v. Turnage*, which they

took successfully all the way to the U.S. Supreme Court and eventually got Congress to overturn the Veterans Administration ruling that classified alcoholism as willful misconduct instead of as a disease.

The Legal Action Center provides legal services to help fight discrimination, to protect privacy, and to assist with a wide range of legal issues. This legal assistance is provided nationally to help individuals in treatment, or otherwise in recovery, to deal with discriminations or privacy violations. Legal services are also available to individuals and agencies that assist individuals with criminal records or with HIV/AIDS. Assistance is intended to help eliminate legal barriers that could prevent people from gaining employment, housing, zoning, and other basic necessities. In addition to legal assistance, the Legal Action Center conducts many other programs and services.

The Legal Action Center engages in policy advocacy for the expansion of alcohol, drug, and HIV/AIDS treatment, prevention, and research. It also advocates for social welfare reform policies that will promote sobriety, increase employment, and reduce discrimination. The Legal Action Center conducts public policy research through the Arthur Liman Policy Research Institute in areas related to addiction, AIDS, and criminal justice.

The Legal Action Center is committed to helping bring about a fairer and more effective criminal justice system and strives to uphold the rights of those individuals with criminal justice records who seek to reenter society and to live crime free lives, as well as for those already rehabilitated. The Legal Action Center advocates for reform of sentencing laws and campaigns for greater funding of alternatives to

incarceration and for community corrections. Attention is also paid to removing the potentially debilitating legal barriers that make it so difficult for individuals with criminal justice records to be successful in many important areas of life, not the least of which is employment and housing.

The Legal Action Center provides education, training, and technical assistance to individuals, service providers, and governmental agencies on issues such as confidentiality, discrimination, and managed care. The Legal Action Center also helps government agencies, community-based organizations, public advocates, and other interested individuals understand how and when varied mechanisms and systems of reimbursement interact with substance abuse treatment agencies. In addition, the Legal Action Center fights against discrimination and privacy violations for people with HIV/AIDS, providing training and technical assistance on issues such as HIV testing, partner notification, living will and health care proxies, syringe deregulation, permanency planning, and HIV/AIDS reporting.

The Legal Action Center produces a series of assorted publications and videos on topics such as the Federal Alcohol and Drug Confidentiality Regulations (42 CFR Part 2), drug testing, syringe exchange, the ADA, drug law reform, and criminal records expungement. Online confidentiality courses are also available from the Legal Action Center, such as the Introduction to Confidentiality and Advanced Confidentiality. Sample forms and other materials are available for use by substance abuse treatment agencies, such as how to comply with the Federal Alcohol and Drug Confidentiality Regulations (42 CFR Part 2) and with the Health Insurance Portability and Accountability Act requirements. Other initiatives include the National H.I.R.E. (helping individuals with criminal records reenter through employment) Network and the Women's Initiative to Stop HIV. The National H.I.R.E. Network has over 5,000 members and is dedicated to increasing the number and quantity of work opportunities available to individuals with criminal justice records.

The Legal Action Center maintains a useful Web site and provides news alerts and a newsletter, the *Washington Weekly Roundup*, free of charge. Many additional publications are available for purchase from the Legal Action Center (<http://www.lac.org>).

LEGALIZATION OF DRUGS

Public opinion about drug use and drug abuse is difficult to ascertain. It would be completely impossible to live in an entirely drug-free society in that drugs help alleviate pain and misery, correct organic and social dysfunction, and treat disease. And yet, drug use and abuse can serve to create some of the very conditions that drug therapy seeks to control. Drugs create disease, damage organs and tissue, engender social and psychological problems, and create physical and interpersonal pain. Furthermore, drug use and abuse creates, at the social level, crime and criminal activities that the non-drug-abusing members of society deem unacceptable. The use of many drugs represents a crime, irrespective of the individual or social harms done by the drug or by the person under the influence of the drug. So why then is there such considerable and constant interest in the idea of drug legalization?

Historically, the topic of drug criminalization and drug legalization has emerged several times. Usually, the discussion about criminalization occurs when there is something else happening in the society that is related to drug use and the public believes (perhaps wrongfully) that criminalization will solve the

problem. Sometimes the criminalization helps, sometimes there is no noticeable or immediate effect, and sometimes the criminalization creates more problems; discussion then ensues regarding undoing the criminalization. Usually, this discussion centers either on a cost-benefit analysis of the laws or on the morality of drug use and the idea that it should remain illegal, regardless of the costs.

History

In 1914, the United States sought to control what was perceived as a growing threat to society by limiting access to cocaine, allowing it to only be obtained through a prescription offered by a health professional. In 1919, this act, known as the Harrison Act, was amended to make all distribution of cocaine illegal. In the same period, alcohol was outlawed through the Volstead Act, a prohibition that lasted until 1933.

Supporters of drug legalization cite multiple examples of miscarriages of justice and ask pointed questions in an attempt to show the illogical nature of drug laws and drug law enforcement. For instance, why was alcohol banned and not other addictive substances like tobacco? Why do similar substances, for example, powdered and crack cocaine, carry different punishments? These advocates of drug legalization are quick to point out that crime rates dropped dramatically after the approval of the 21st Amendment, which repealed the Volstead Act in 1933.

Current Issues

Even the most ardent supporters of drug legalization do not support the total and complete removal of all controls on drug use and possession. Juveniles and others who lack mature reasoning skills must be protected, but limited drug legalization could yield social and economic benefits far beyond the risks and costs to society. There is a great deal of drug use in society, and the majority of these users are adults who use these drugs for purely recreational purposes. This use does not generate thefts or robberies, it does not result in children being abused or neglected, and it rarely serves the interest of the justice system. In the 1970s, recreational drug use was treated with benign neglect by the justice system, and the majority of society had no problem with this unofficial policy.

Today, however, the mere use of drugs creates the threat of adjudication and incarceration even when there is no other harm associated with the behavior because drug use is illegal. If drug use was legal, the use would cease to be a social or legal problem.

Not all drug use is inconsequential. It would be unreasonable to assume that drug use does not generate crime beyond the simple purchase, possession, and use of the drug. Drug use does lead to crime in many cases. So how can the supporters of drug legalization advocate making them legal when the use of the drug is often either the cause or the result of crime? These advocates point out that drugs are a simple commodity, governed by the same market forces as legal commodities. It stands to reason, therefore, that the cost of the drug is a function of the availability, the demand, and the cost of production, which includes the growing or synthesizing of the substance, the processing and packaging of the drug into manageable and marketable units, and the distribution to the end user. All of these stages, due to the illegal nature of the substance, carry risk of detection and apprehension. This risk (and the associated losses caused by detection and apprehension) must be calculated into the cost of production, thereby increasing the cost of the product to the end consumer. As the risks of detection and apprehension increase, production and sales must increase to offset losses caused by confiscation, as will the legal costs associated with defense. In short, increases in enforcement lead to more production and to increased costs to end users. Since a certain proportion of the end users support their drug use through illegal activities, increases in enforcement that result in corresponding increases in both risk and price lead directly to increases in the numbers of crimes that are used to generate the money necessary to purchase the drugs. At the same time, these increases in enforcement add persons to the justice system who have been apprehended for the production, possession, use, and sales of the drug.

Arguments in Favor of Legalization

Legalization advocates argue that the legalization and control of select drugs would simultaneously drop the cost of the drugs to the end user while improving the quality and safety of the product. Add to this the reduced number of persons processed through the justice system and the diminished dollar value of drug-related crimes and you have an equation with

few negatives and multiple advantages. The costs associated with policing, apprehending, adjudicating, and incarcerating drug and drug-related crime would greatly decrease, allowing increased spending in areas neglected since the onset of the War on Drugs.

Positions such as this argument are usually considered the domain of libertarians and those who oppose laws in many forms, not just those associated with drugs. It is, however, important to note that the position that supports limiting the laws that criminalize drug use and possession has proponents on both sides of the political spectrum. In 1999, then-governor of New Mexico, Gary Johnson (a Republican), argued that the War on Drugs had been a multibillion dollar failure and that he supported drug legalization for many reasons. In response to Johnson's statements, Barry McCaffrey, the director of the Office of National Drug Control Policy, called Governor Johnson's statements and his position on drug legalization irresponsible.

Arguments in favor of drug legalization have almost always focused on the potential financial savings to society, as well as on the increased funding available for other worthy programs if less money was being spent on a War on Drugs that cannot be won. Although some opponents of legalization acknowledge that there may be financial savings associated with legalization, the risk of increased social costs and the associated social disintegration make the option of legalization less socially and economically viable.

Arguments Against Legalization

In May 2003, the Drug Enforcement Administration (DEA) released a report titled *Speaking Out Against Drug Legalization*, which focused on the dangers of legalization. Rather than disputing the points made by the legalization advocates, the DEA argued that the legalization debate has become more intense due to drug legalization trends in Europe. The DEA contends, however, that the social situation in Europe is distinctly different from that of the United States, and policies that work there would likely be disastrous in the United States.

The DEA report contends that the War on Drugs is working. Drug use is decreasing and approximately 95% of all Americans do not use illegal drugs of any type. Treatment efforts and prevention are also working, and the progress made in the treatment and prevention areas would be undone by legalization. The justice

system is often the primary conduit that gets users into treatment programs. And, although not all treatment is successful the first time it is attempted, eventually many of these users stop using drugs due to aging and the cumulative effects of treatment programming. The leverage provided by a court order or referral would disappear if drugs were legalized, and a critical element of deterrence would also vanish, making increased use of now-illegal drugs a virtual certainty.

Those who support legalization cite how the cost of drug law enforcement would diminish substantially if the drug laws were repealed, but those who support the retention of these laws cite reports that indicate the small overall impact this would have on the national budget. The DEA report notes that the entire budget for drug control (\$12.9 billion in 2008) only constitutes a minor portion of the U.S. budget, and the social and financial costs of drug use and addiction far outweigh the meager savings associated with the repeal of these laws. To support the idea that the legalization of drugs would lead to more addiction and increases in related social costs, the DEA provides the experience of Alaska as an example. In the 1970s, Alaska experimented with the legalization of marijuana, and within a short period of time, the youth in Alaska were using marijuana at twice the rate of youth in the lower 48 states. Alaskans decided in 1990 that the experiment had failed, and they subsequently voted to recriminalize marijuana in 1990. In the Netherlands, a similar situation occurred when heroin use and addiction tripled within a couple years of the legalization of marijuana. Although marijuana legalization may have kept some persons out of the justice system, the accessibility and lack of deterrence may have created more marijuana users and subsequently, more heroin users and addicts. By increasing access to a low-level drug, critics believe it may have sent a message to the citizens that drug use in general, regardless of the level, was acceptable.

Finally, those who support legalization often cite the medical uses of drugs such as marijuana. The criminalization of these drugs makes it much harder for persons with chronic health problems to get relief. Legal medications may not be as effective, and they may cost the consumer much more than illegal drugs would. According to the DEA, there are options for these persons, and these options are both safer than street-grade drugs and are legal. Marinol, which contains the active ingredient in marijuana (THC), is claimed to have the same effect as smoking marijuana,

is legal, and does not cause the damage to the lungs that inhaling marijuana smoke can cause.

Conclusion

As stated earlier, discussing drug legalization places at odds the areas of morality and economic logic. The discussion is not a true debate because the sides rarely even consider the same issues to be central to the argument. Those in favor of legalization discuss the savings to the justice system and the economic costs of locking up relatively nondangerous offenders while opponents of legalization discuss the risk to society caused by relaxing drug laws and the possible negative consequences of the removal of legal constraints on drug use. The one area that the two sides can debate is on the War on Drugs. Each side, however, argues that the War on Drugs is the best reason to support their side. Those who support retaining the current drug laws believe that the War on Drugs is going well (as evidenced by the diminishing numbers of users), and without drug laws, many former drug users would have never received the help necessary to stop using. Opponents of drug laws maintain that the War on Drugs has been a monumental waste of time and money and repealing the laws would allow spending in areas that would yield much greater benefits to all of society. Even though the two sides are discussing the same basic issue, they each define success on the War on Drugs differently, and consequently, they disagree on the success of the war and the value of the laws that make the War on Drugs necessary. In short, there is no clear answer to the drug legalization question, but strong evidence exists in support of each side of the discussion.

LEVO-ALPHA ACETYL METHADOL

There are currently three Food and Drug Administration (FDA)-approved opioid agonist treatments for opioid addiction, which include methadone hydrochloride, buprenorphine hydrochloride, and levo-alpha acetyl methadol (LAAM). All three of these drugs are long-acting opioids, which bind to opioid receptors and thus block opioids from binding to these receptors. LAAM, as well as the other opioid agonist treatments, are long-acting drugs that have minimal psychoactive effects. Use of LAAM thus permits opioid-addicted individuals to engage normally in daily routines while decreasing craving or drug-seeking behaviors.

LAAM may also be labeled as *levomethadyl acetate hydrochloride* or *levacetylmethadol*. LAAM was developed in the 1960s and was under investigation as a medication in the treatment of opioid dependence until the 1990s. In 1993, LAAM was approved by the FDA as a medication for opioid dependence. LAAM offers improvements over drugs like methadone because it has a significantly longer duration of action. However, despite the initial excitement over the introduction of LAAM for the treatment of opioid dependence, use of LAAM was found to be associated with adverse side effects, in particular, cardiac symptomatology. Such findings have since decreased the enthusiasm and thus have limited the demand for this drug.

Similar to methadone, LAAM is an oral medication. It is a synthetic opioid whose properties ameliorate symptoms for patients experiencing withdrawal from opioids. The mechanism of action for LAAM is to bind to pain receptors in the brain, and this binding

action results in a decrease in patient cravings for heroin or other opioids and a decrease in withdrawal symptoms. More specifically, LAAM acts as a mu (μ) opioid receptor agonist. It has effects that are qualitatively similar to both morphine and methadone, but has the unique characteristic of a longer duration of action. LAAM provides opioid effects for 48 to 72 hours or longer depending on the dose. In contrast, methadone provides opioid effects for approximately 24 hours. This increase in the duration of action presents a significant improvement for patients being treated for opioid dependence. Although some studies indicate that LAAM is less potent than methadone, at least one study has demonstrated that under acute dosing conditions, LAAM may be significantly more potent relative to methadone. Despite its long duration of action, it should be noted that withdrawal from LAAM can be difficult.

Recommendations for Use

Because LAAM is less familiar to patients (e.g., relative to methadone) as an option for treatment of opioid addiction, patients may have reservations about using LAAM. Thus, for patients being prescribed LAAM, further counseling, support, and psychoeducation may be necessary. Those who may be more likely to benefit from LAAM, relative to other medications, are those who would prefer or require reduced frequency of clinic visits. For example, individuals whose employment would be interrupted by daily visits to receive methadone or who have difficulty obtaining daily transportation to a methadone clinic may be good candidates for use of LAAM. In addition, LAAM may be appropriate for individuals who worry about the stigma of methadone.

The FDA recently issued a warning about the use of LAAM following a small number of reports of a ventricular arrhythmia condition that were filed following the use of LAAM; this cardiac condition is called *torsade de pointes*. As a consequence of reports of *torsade de pointes* following use of LAAM, the FDA currently requires a warning to be included with packaging that LAAM should not be used as a first-line treatment of opioid addiction. Due to reports of cardiac problems associated with LAAM, use of LAAM has declined, and availability may eventually be discontinued. The manufacturer recommends that all patients who are prescribed LAAM receive an electrocardiogram before use of LAAM is initiated. In

addition, follow-up electrocardiograms after steady-state dosage has been achieved are also recommended to provide continued monitoring of cardiac health.

Patients can be transferred to LAAM not only from opioid use, but also from methadone use. Thus, if methadone was ineffective, LAAM can be presented as another drug to try. Of note, LAAM is available in approximately 10% of opioid agonist treatment centers. This relatively low availability is due in part to higher costs associated with monitoring via electrocardiograms and because the manufacturer began to limit production due to related concerns about cardiac health.

Properties of LAAM

Use of LAAM in place of opioids prevents withdrawal symptoms. In blocking withdrawal, LAAM does not produce a subjective high, but rather acts to block the effects of other opioids. Research has demonstrated that LAAM and methadone have similar efficacy levels, as well as similar outcome levels of heroin use. In addition, despite the small number of reported cases of *torsade de pointes*, studies also suggest similar safety levels for use of LAAM and methadone.

With respect to mechanisms of action, the primary difference between methadone and LAAM is that LAAM is the alpha-acetyl congener of methadone. LAAM is metabolized by the liver into four metabolites, including nor-levomethadyl and dinor-levomethadyl. Similar to methadone, LAAM is metabolized by the hepatic P450 isozyme CYP3A4. Methadone and LAAM have the same protein binding sites in plasma and thus, if taken together, have additive effects.

LAAM is commercially available in a liquid suspension form, and is taken orally. It is absorbed by the gastrointestinal tract, but has a slower onset of effect compared to methadone (90 minutes vs. 30 minutes) and is longer acting (48–72 hours vs. 24–36 hours). After the effect of LAAM has subsided, withdrawal symptoms are likely to be intense.

Conclusion

LAAM is a long-acting synthetic opioid used for the treatment of opioid dependence and has demonstrated similar efficacy rates for opioid dependence as compared to methadone treatment. Because LAAM is longer acting than methadone, it has benefits for individuals who are unable to schedule daily visits to a methadone clinic. However, due to cardiac problems

that are associated with the use of LAAM, treatment requires consistent monitoring of cardiac health. Despite these limitations, LAAM may be a viable alternative to use of methadone in the treatment of opioid dependence.

M

MARIJUANA

Marijuana is the common way to refer to a class of drugs called *cannabinols*. The cannabinols include marijuana (*grass, pot, weed, joint, reefer, dube*), hashish, Charas, Bhang, ganja, and sinsemilla. The active ingredient is delta-9-tetrahydrocannabinol (THC). Hashish and Charas have a THC content of 7% to 14%; ganja and sinsemilla, 4% to 7%; and bhang and marijuana, 2% to 5%. However, modern growing techniques have increased the THC content of marijuana sold illicitly. For simplicity, the various forms of cannabinols will be referred to as *marijuana*.

The earliest references to the drug date back to 2700 BC. In the 1700s, the hemp plant (*cannabis sativa*) was grown in the colonies for its fiber, which was used in rope. Beginning in 1926, states began to outlaw the use of marijuana since it was claimed to cause criminal behavior and violence. Marijuana use became popular with mainstream young people in the 1960s. Some states have basically decriminalized possession of small amounts of marijuana, although according to the federal government, it remains a Schedule I drug, meaning that marijuana has no approved medical uses and has a high abuse potential.

Prevalence

Marijuana is the most widely used illegal drug. The result of the 2006 National Survey on Drug Use and Health showed that nearly 97.8 million Americans reported using marijuana sometime in their life, 25 million had used marijuana in the past year, and more

than 14.8 million had used this drug in the past month. The number of past-month users is nearly 7 times the number of past-month users of cocaine, the next most widely used illegal drug and more than double the number of past-month nonmedical users of prescription drugs. Among young people, ages 12 to 17, 6.7% reported using marijuana in the past month, and 16% of young adults ages 18 to 25 used marijuana in the past month. Over 2 million people used marijuana for the first time in 2006.

Major Effects

Acute Physical and Psychological Effects

Marijuana is usually smoked in cigarette form or in pipes. It can also be ingested, normally by baking it in brownies or cookies. Marijuana users experience euphoria; enhancement of taste, touch, and smell; relaxation; increased appetite; altered time sense; and impaired immediate recall. An enhanced perception of the humor of situations or events may occur. The physiological effects of marijuana include increase in pulse rate and blood pressure, dilation of blood vessels in the cornea (which produces bloodshot eyes), and dry mouth. Motor skills and reaction time are slowed.

Marijuana intoxication has an adverse effect on attention span, short-term memory, and psychomotor performance. Anxiety and panic attacks can occur, primarily in new users who are not familiar with marijuana's effects. At very high doses, some people experience delusions and hallucinations. There are no cases of fatal marijuana poisoning, and humans are unlikely to be able to ingest a fatal dose. The effect of marijuana intoxication impairs motor and cognitive

abilities necessary to safely drive a car or operate machinery. The extent to which marijuana is involved in auto accidents is unclear. Many motorists intoxicated with marijuana drive more slowly and carefully and take fewer risks. However, there is an increased risk of accidents after using marijuana, but marijuana alone does not appear to contribute a great deal to accidents. Marijuana in combination with alcohol does.

Physical Effects of Chronic Use

Marijuana smoke contains carcinogens. However, because of nondefinitive or conflicting results, additional research on the association between smoking marijuana and certain cancers should be conducted. There is no evidence that the rate of infectious diseases is increased among heavy marijuana users. However, with very high doses of marijuana, animal studies have shown immune system impairment, reduced resistance to infection, and compromises in the immune defense system in the lungs. Studies of HIV patients who use marijuana have not produced evidence of an accelerated progression to AIDS. The use of marijuana during pregnancy is associated with small birthweight but not with an increased risk of birth defects. Similar but smaller, behavioral, and developmental effects resulting from maternal tobacco use have been seen in studies of infants prenatally exposed to marijuana. Animal studies have demonstrated disruption in the reproduction system from chronic administration of THC. However, no definitive research has been conducted on the impact of heavy marijuana use on the reproductive systems of humans. The changes in heart rate and blood pressure from marijuana use are not likely to have an adverse impact on healthy adults but could be harmful to those with hypertension, at high risk for strokes, or with clogged heart arteries. Because marijuana smoke contains many of the same carcinogens found in tobacco smoke, it is likely that marijuana smoking increases the risk of respiratory cancers, especially if used in combination with tobacco. The regular use of smoked marijuana impairs the functioning of the airways and can cause chronic bronchitis. There is no evidence of any adverse effect of marijuana on the liver or gastrointestinal system.

Psychological Effects of Chronic Use

In the late 1960s, an amotivational syndrome was described in which young marijuana users were seen

as apathetic, withdrawn, lethargic and unmotivated. However, there is no evidence of a unique syndrome with these symptoms that is attributable to marijuana use. These symptoms are more likely the result of marijuana dependence. Clearly, heavy marijuana use can lead to dependence on the drug characterized by a combination of social, legal, financial, family, educational, and occupational problems; withdrawal symptoms when drug use is discontinued; and difficulty in controlling the use of marijuana in spite of the intention to do so. The rate of abuse and dependence problems from marijuana is lower than that of alcohol, and more people with marijuana problems are able to discontinue their use without treatment than is found with other addicting substances. Daily long-term use of marijuana may adversely impact memory, attention, and the integration of complex information in subtle ways. However, there does not seem to be any severe impairment of cognitive functioning. There is still some uncertainty regarding whether all the impairments are reversible after a long period of abstinence.

Although there is a relationship between heavy marijuana use and mental health problems, the nature of this relationship is open to interpretation. Young people who use marijuana are at high risk for mental health problems. Some of this is explained by the fact that these young people were at high risk for mental health problems before they began to use marijuana. In addition, young people who begin using marijuana at a young age are more likely to affiliate with delinquent and/or drug-using peers, which increases their risk for a variety of problems. Finally, it should be noted that the early first use of tobacco and alcohol is also associated with later mental health problems. Therefore, the likely mediating variables that explain the association between marijuana and mental health problems involve the predisposing characteristics of the users and the lifestyle associated with illegal drug use.

There is evidence that marijuana can precipitate psychosis in people who are vulnerable to developing psychotic disorders. In other words, some people will develop schizophrenia or another psychotic disorder if the proper environmental conditions are present (e.g., trauma). The heavy use of marijuana may be one of those environmental factors. In spite of the implication that marijuana can cause schizophrenia, this does not seem likely. When marijuana use has increased among adults, the incidence of schizophrenia has been stable or decreased.

Similarly, there is an association between adolescent marijuana use and noncompletion of high school, involvement in drug-related crime, early pregnancy, and divorce. Again, the characteristics of the adolescent marijuana user seem to be the factors that explain these associations. However, there is little doubt that the early use of marijuana is among the risk factors that are associated with a variety of adolescent problems.

Medical Uses of Marijuana

In 1999, the Institute of Medicine (IOM) prepared a report at the request of the federal government on the scientific evidence regarding medical uses for marijuana. The conclusion was that there was scientific evidence for the potential therapeutic value of THC for pain relief, nausea and vomiting control, and appetite stimulation. However, the IOM report also indicated that smoking marijuana was an imprecise method to deliver THC and produced harmful substances through smoking. The report also discussed the psychological effects of marijuana, such as anxiety reduction, sedation, and euphoria. It was determined that these psychological effects can influence the therapeutic effects in potentially beneficial or harmful ways. For example, some older patients reported that the psychological effects were disturbing. For patients with AIDS wasting syndrome, the combination of appetite stimulation with the psychological effects of anxiety reduction, sedation, and euphoria could be beneficial.

The IOM report also examined the risks associated with the medical use of marijuana. With the exception of the harms associated with smoking, the detrimental effects of marijuana were seen as being within the range that is tolerated for other medications. The acute effects included diminished psychomotor performance, which could impact driving or the operation of dangerous equipment. A small number of marijuana users experienced unpleasant feelings from the drug. The acute effects on the immune system could not be firmly established but if such effects exist, were not severe enough to rule out the use of marijuana for medicinal purposes. With regard to chronic effects, the conclusion was that marijuana smoke is associated with increased risk of cancer, lung damage, and poor pregnancy outcomes. There was no convincing evidence that marijuana smoke does or does not cause respiratory cancer.

There are claims that marijuana is also beneficial in the control of muscle spasticity and in reducing intraocular pressure from glaucoma. The IOM

report did not find compelling evidence to support or refute this claim with regard to muscle spasticity and concluded that marijuana was not effective treatment for glaucoma.

Treatment Admissions and Emergency Room Visits

According to information from the federal government, admissions to treatment in which the patient reported marijuana was the primary substance of abuse more than doubled from 1993 to 2003. In 1993, 7% of all admissions mentioned marijuana as the primary drug of choice, while 16% reported this in 2003. However, most of this increase was driven by referrals from the criminal justice system. In 1993, 48% of the marijuana treatment admissions were referred from the criminal justice system and 57% in 2003. Therefore, it is not possible to tell if the increase in treatment admissions is due to law enforcement changes (i.e., drug courts) or actual increases in marijuana dependence.

According to the Drug Abuse Warning Network, there were 627,923 emergency room visits related to drugs in the last half of 2003, and 12.7% of these visits included marijuana as a drug that either induced or related to the emergency room visit. In 4.5% of these cases, the emergency room visit involved a suicide attempt, 10.9% involved a desire for detoxification, and nearly all of the rest (84%) were categorized as *other*. In comparison, cocaine accounted for 20.1% of the drug-related emergency room visits, heroin was involved in 7.6%, and methamphetamine was mentioned in 4% of the cases. Therefore, marijuana was mentioned more often than any other illegal drug except cocaine.

Gateway Theory

Does marijuana use lead to other drug use? This idea is frequently referred to as the gateway theory. That is, the use of marijuana is a gateway to the use of other drugs. There is no evidence that there is something inherent in marijuana that causes a person to use other drugs. Although there is no disputing the fact that marijuana users are more likely than nonmarijuana users to use other drugs and that the earlier the age of first use of marijuana, the more likely the individual is to use other drugs, the relationship between these facts and the gateway theory is controversial. There is no evidence that

marijuana has some pharmacological property that would cause a user to crave other drugs. The most likely explanations for the relationships between marijuana and other drug use involve the characteristics of marijuana users and peer and environmental influences. Those individuals who use marijuana at an early age and/or use marijuana heavily may have genetic, personality, and attitudinal characteristics that predispose them to use mind-altering substances. Since marijuana is the most widely available illegal drug and is perceived as the least harmful illegal drug, it makes sense that this drug would be used first. The fact that tobacco and alcohol use almost always precedes marijuana use is further evidence that the most widely available substance will be used first. Furthermore, those young people who use marijuana are affiliating with peers who also use marijuana, who are accepting of illegal drug use, who generally support the experimentation of other drugs, and who have some knowledge of how to secure illegal drugs. These generalizations do not always fit, since there are certainly peer groups who use marijuana but who disapprove of the use of other drugs and not all marijuana users progress to the use of other drugs. In fact, most do not. However, it is not difficult to conceptualize a 13-year-old who begins to use marijuana as associating with a peer group that is accepting of drug use in general, while an 18-year-old who first uses marijuana may be involved in a peer group whose illegal drug use is limited to marijuana. The 13-year-old initiate is much more likely to be rebellious, risk-taking, and unconventional than the 18-year-old initiate. This difference would explain the relationship between age of first use of marijuana and the use of other drugs.

Conclusion

Marijuana is the most widely used illegal drug. Although it is classified as a Schedule I drug by the federal government, marijuana is clearly not as dangerous acutely or chronically as drugs that have lower classifications. However, marijuana, like all mind-altering substances, is a drug that has damaging effects acutely and chronically and can result in dependence among heavy users. The available scientific evidence is that there is some likelihood that marijuana has medical uses, particularly in the alleviation of nausea, pain relief, and in appetite stimulation in people with serious, life-threatening medical conditions.

MATERNAL DRUG USE

Maternal substance abuse, as the term is used here, refers to any maternal substance use disorder ranging from substance abuse, in which the use of a substance continues despite negative consequences, to dependence, the salient feature of which is loss of control over the amount of or frequency with which the substance is consumed. Maternal substance abuse covers all of the illicit substances of abuse, as well as alcohol and tobacco. This section covers the stigma associated with and the complexity of the problem of maternal substance abuse and the effects of maternal substance abuse on embryos and fetuses, as well as on children and adolescents. Also discussed are effective treatment options and support for long-term recovery.

Stigma

The stigma of addiction is particularly severe for women who are mothers. Even within the substance abuse treatment field, pregnant women seeking treatment can be judged by those with an incomplete understanding of addiction, and in society at large, the criticism can range from harsh moral judgment to criminal sanctions for prenatal drug use. In the eyes of the public, the notion that addiction is a disease and not a crime often does not extend to mothers, and the illegal behavior that often provides a woman with her substances adds to the level of criticism and judgment she experiences.

A frequent criticism leveled at mothers with addictions is that if they really loved their children, they would not use substances. This common judgment connects two myths in one sentence: love for their children and motivation and ability to stop using substances. A mother's love is considered to be stronger than any other form of love—if it cannot force a woman to relinquish her hold on substances, then there must be something wrong with the mother, and she must not really love her children. Substance dependence and love for children are not connected, and addiction is not a disease that can be cured by intense desire alone.

American society has become accustomed to alleviating woes through use of substances. Even products completely unrelated to one's happiness are associated with good feelings through the advertising industry. It is no wonder that women succumb to the use of substances ostensibly to cure them of uncomfortable conditions (pregnancy is many things, but comfortable is not one of them!). If the relationship with the substance is of longer standing than the pregnancy (and it generally is), it is highly unlikely that the pregnant woman who has relied upon the substance to alleviate discomfort, loneliness, depression, despair, or anxiety will be able to simply stop using because she has found out she is pregnant.

Prenatal Substance Abuse

Knowledge of the risks of substance use during pregnancy is relatively new. Even now, marijuana is sometimes recommended to alleviate nausea and lack of appetite associated with early pregnancy. Women have used tobacco during pregnancy for as long as the use of tobacco by women has been considered socially acceptable (and before that, in secret), and use of tranquilizers, opioids, and plant-based stimulants to control or alter feelings or behavior by women has continued into pregnancy for those women already using substances. Among pregnant women and mothers who are active in their addictions, the use of stimulants such as cocaine or methamphetamine to trigger labor is well known and is used to relieve the discomfort of late pregnancy by inducing labor.

The teratogenic effects of alcohol on the fetus are quite well documented now, however. That portion of the fetus's body (and brain) that is being formed during the time of heavy prenatal alcohol exposure is

damaged by the alcohol to which it is exposed. Being a teratogen, the alcohol causes the cells in this part of the body to divide in a different order than they should, and this sometimes leads to deformities in some facial features, as well as in those parts of the body being formed at the time the alcohol is used, and in the brain of the fetus. Even today, some well-meaning physicians tell their pregnant patients that it is okay to have a drink now and then in order to remain relaxed, thinking that the stress of attempting to remain abstinent from alcohol may be more damaging to the fetus than the alcohol would be. No safe level of alcohol use during pregnancy has been established, however, and mothers can discover through specialized evaluation later in their children's lives that the difficulties that they experience may be attributed to their alcohol use during pregnancy.

Newborns who have been prenatally exposed to substances are sometimes referred to in the media as *addicted infants* or as *the littlest addicts*. This terminology is misleading in that substance-exposed newborns may be physically dependent upon a substance (and may experience mild to severe withdrawal symptoms based on the nature of the drug, the level of exposure in utero, and the knowledge base of the neonatologist working with the mother–infant dyad), but they could not be properly labeled *addicted* or *dependent upon substances* because they do not display other symptoms of chemical dependency, such as lack of control over the use of the substance or time spent in seeking the substance.

Services are available for children who were exposed prenatally to drugs, tobacco, and alcohol, although nothing can cure prenatal substance exposure. Typically, the earlier in the child's life the exposure is identified, the better the long-term prognosis for the child's ability to function normally. Mothers tell of their guilt and shame at not having been able to stop using despite knowledge of the damage being done to their unborn children. Asking for professional help with their children's developmental and behavioral problems is particularly difficult when that request must be followed by a candid disclosure of the substance use and other behaviors in which the mother engaged during her pregnancy. Despite this difficulty, the ability to alter the child's environment in order to maximize chances of success and play to the child's strengths can make the difference between the perception of failure and hopefulness for the future for both parent and child.

Trauma

A basic understanding of trauma and the role it plays in the lives of many addicted women explains much to those seeking to provide help to mothers with substance use disorders. Estimates of the prevalence of trauma in the lives of women in treatment for substance use disorders average approximately 70% or more. Sometimes women turn to substance use to numb the painful feelings or symptoms caused by the trauma, and other times, the trauma is a result of events or circumstances connected with the addiction itself. Pregnancy and childbirth, as well as motherhood (all of which are associated with increased hormonal levels and significant levels of stress), can trigger symptoms associated with past trauma. The resulting pain, anxiety, guilt, and other negative feelings lead to a sometimes overwhelming desire to use, to increase use, or to give up on sobriety. For women with histories of sexual trauma, the experience of pregnancy and childbirth can be extremely triggering due to the loss of control she experiences over her own body during this time. As the mother of a growing child, a woman may find herself experiencing flashbacks to traumatic events that took place in her own childhood as her child enters the same stage of development at which these events took place for her. If her own past victimization has not been worked through (i.e., she has not acknowledged her experiences and feelings and has not gained an understanding of the effects of her abuse upon her current view of the world and of herself), she may leave her own child vulnerable to victimization. If her inability to protect her child results in the removal of that child from her care, her guilt and feelings of powerlessness increase, as well as her sense of failure as a mother.

For a mother whose infant tests positive for substances at birth and whose resources do not allow her to retain custody of that infant, the resulting loss can be devastating as the hormones released during birth become combined with the chemicals in her brain and body driving her addiction. If the same woman has had previous experiences with children being removed from her custody at birth, each subsequent loss and repeat of this experience compounds the trauma of the previous experiences. This cycle can lead to desires to replace the “lost” children with another child, resulting in numerous substance exposed births, unless this cycle is interrupted by treatment and recovery.

For many addicted mothers, their own childhood experiences leave them without a clear sense of the role of motherhood and how this can be carried out in a healthy, structured, and nurturing manner. Many grew up in homes in which one or both of their parents had substance use disorders that were active during the time their children were growing up. The unpredictability of the environments in which many of these women grew up led to incomplete lessons in problem solving—the lack of logical association between action and punishment leads to a lack of understanding of cause and effect. Substance use is often role modeled as the most common coping or problem-solving skill to the detriment of other more effective and well thought out methods. Mothers born into families in where there is parental substance abuse also are not protected as effectively by their parents as they might otherwise be. Because of this lack, they sometimes lack skills to provide effective protection to their own children, leaving them vulnerable to neglect by the mother and/or physical or sexual harm at the hands of their parents and others.

Relationships

Women’s identities are formed to a large degree by the relationships in their lives, both during childhood and as adults. For a woman with a substance use disorder, these relationships are perceived through the lens presented by the substance, which can cause significant distortions in the interactions between people. One primitive example of this distortion is the new mother who has smoked marijuana throughout her pregnancy and who continues to use during the first year of her child’s life. Major neural connections are made within the infant’s brain during this first year, based primarily upon interactions with the environment and the people within it. If these interactions are primarily with the mother who uses marijuana regularly, then the mother’s perceptions of the child may be such that she misses important opportunities to help the child’s brain develop. For example, 1-month-old infants begin to focus their eyes upon faces for the first time, and very often this focus may be on the face of the mother. If the infant gives off a facial cue or message that he or she is seeing the mother’s face and the mother misses the cue, the infant will present the cue for response only a limited number of times before that cue is extinguished and the baby seeks relational

interaction elsewhere, or not at all. Although this miss may not be defined as abuse or neglect under current legal definitions, the problems it presents are clear.

Relationships with partners or significant others may be affected severely by substance use disorders by the woman and/or her partner. Women with substance use disorders may be impacted by their partners' expectations of their behavior. These expectations may be very punitive toward their substance use, they may reinforce the women's continued use if substance use is something the partners engage in together, or they may involve the women's substance use disorder in divorce and child custody proceedings. Each of these different scenarios plays out in a different way, but in each case, in order to support the woman's efforts at treatment, the relationship would need to be addressed.

Treatment

In response to the advent of public fear regarding the effects of children prenatally exposed to crack cocaine on society, treatment programs have been developed specifically for women and their children together. In these programs, treatment for the mother's substance use disorder takes place along side of the delivery of services to promote health and well-being in their children. Services offered in these facilities for women include psychoeducational groups covering topics such as substances of abuse, the effects of trauma on the lives of women and children, and parenting groups. They also include more traditional addiction treatment topics, such as relapse prevention and the development of nonusing support networks in their lives. Children receive primary health care, developmental assessments and services to address any needs defined through these assessments, and socialization and play opportunities with other children. In addition, child care is frequently provided on site if the women need to leave the facility for medical appointments, to take advantage of vocational services, or to complete other portions of their treatment off site.

As the threat of involvement with the child protection system is one of the biggest fears women have about entering treatment for substance use disorders, programs such as these can help alleviate that fear and promote participation in treatment. In a controlled environment, with many professionals monitoring the safety of and care for the children there, women find it easier to work on their addictions and parenting skills together. They are more likely to retain custody of their

children in these settings than they would be if they were participating in traditional outpatient or other residential treatment that did not make provisions for the participation of children and other family members. Conversely, as the desire to parent their children well is also one of the biggest motivators for women seeking treatment, these programs can offer the services to meet that need. This paradox, embodied in every effort to engage and retain mothers in addiction treatment, is rarely resolved completely. Treatment programs for mothers with their children together are now being expanded to include the entire family as a whole, recognizing the interwoven impact of maternal substance abuse upon all members of the family.

Support Groups

The relational nature of women's growth and development throughout the life span makes women's support groups a natural component of their recovery. Either during participation in formal treatment or following its completion, women can benefit greatly from participation in recovery support groups. Traditional Twelve-Step groups are widely available, and some gender-specific meetings offer childcare for parents who need it in order to attend. One criticism that has been leveled at Alcoholics Anonymous and its offspring models such as Cocaine Anonymous and Narcotics Anonymous is that the wording of the first step is inappropriate and may be harmful for women who have histories of trauma and oppression. An alternative and women-positive model is Women for Sobriety, founded by Jean Kirkpatrick. Information regarding times and locations of upcoming meetings is kept confidential but can be obtained through contacts available on its Web site, www.womenforsobriety.org.

Conclusion

Although maternal drug use and addiction creates and is created by many social conditions including oppression, discrimination, unequal access to resources, and weak societal structure, the good news is that the relational nature of women's development lends itself well to treatment and recovery when treatment is tailored to meet their needs. Increasing attention to the unique dynamics of maternal addiction in recent years has the potential to affect the safety and well-being of many generations to come.

MATRIX MODEL

The Matrix Model is an intensive outpatient substance abuse treatment approach designed for treating individuals who abuse or who are dependent on stimulant drugs, such as cocaine or methamphetamine. This treatment model, developed in 1986 by the Matrix Institute of Los Angeles, California, came about out of a growing need for evidence-based practices in the treatment of stimulant disorders. The Matrix Institute is a nonprofit organization established in 1984. Its purpose is to disseminate empirically based information to treatment professionals in order to improve the quality of treatment for substance use disorders. Staff from the Matrix Institute developed the Matrix Model through the assimilation of numerous empirically tested treatment approaches. The Matrix Model includes elements of cognitive behavioral therapy, relapse prevention, psychoeducation, family therapy, and Twelve-Step group support. The goal of the Matrix Model is to provide stimulant users with the skills necessary to stop using, remain in treatment, and avoid relapse. Moreover, treatment clients not only receive direction and support for themselves from a counselor, their family members are included as an integral part of the client's continued recovery.

The Matrix Model is a form of long-term outpatient therapy lasting approximately 1 year. In this approach, treatment is divided into two parts: intensive treatment and continuing care. The intensive phase of

treatment includes a combination of various group sessions, family education, and individual counseling. Upon successful completion of 16 weeks of intensive treatment, the clients enter the continuing care phase. During the continuing care phase, clients continue attending social support group sessions. During these sessions, clients learn how to socialize with other clients who are further along in the program. This is a mentoring approach that allows the clients who have been in recovery longer to act as role models for newer clients. The continuing care phase lasts for 36 weeks.

Sessions

During the first 16 weeks of treatment, the clients attend several outpatient sessions per week. These sessions include individual-conjoint family sessions, which include the client, the primary counselor, and possibly the client's family. In addition to individual sessions, clients are scheduled to attend several other group sessions including early recovery skills group sessions, relapse prevention group sessions, family education group sessions, and social support group sessions. Furthermore, clients are strongly encouraged to attend Twelve-Step or mutual-help groups such as Cocaine Anonymous.

Individual-Conjoint Sessions

A primary counselor is assigned to each client. The relationship between the counselor and the client is considered essential to the therapy. The primary counselor meets with each client individually or preferably conjointly with the client and his or her family for a total of three 50-minute sessions during the first 16 weeks of treatment. The first and the last of these sessions are intended to begin and end treatment in such a way that fosters treatment engagement and transition into continuing recovery. The middle session is used to provide an assessment of client progress and to coordinate services with other referral sources if needed.

The goals of individual-conjoint sessions include (a) to give clients and their families a chance to establish rapport with the counselor and the opportunity to learn about treatment, (b) to provide a safe environment where clients can discuss issues and work out solutions with family members under counselor supervision, (c) to set aside time for clients to openly

discuss their addiction with a counselor, and (d) to allow clients opportunities to receive reinforcement and encouragement for positive change.

The Matrix Model supports the inclusion of family members or other significant others in the individual-conjoint sessions whenever possible. Clients most likely do not live secluded lives. Failure to include those with whom the client has primary relationships may impede treatment success and continued recovery. Counselors using the Matrix Model are encouraged to be conscious of how client recovery interacts with and is influenced by the family system.

Early Recovery Skills Group

Early Recovery Skills (ERS) groups typically involve up to 10 clients per session and are attended by clients twice per week during the first 4 weeks of treatment. ERS sessions are facilitated by the counselor and co-led by a client. Client co-leaders in ERS groups must have a minimum of 8 weeks of abstinence from drugs and alcohol, regular attendance in relapse prevention groups and individual-conjoint sessions, and must be willing to serve as a co-leaders for at least 3 months.

Clients in ERS are relatively new to treatment and may be feeling overwhelmed and out of control; therefore, it is necessary for these sessions to remain structured. This sense of structure can help ease any out-of-control feelings the client may be experiencing and also fosters a sense of confidence in the treatment process. The purpose of ERS sessions is twofold: first, to send a message to clients that behavior change is within their control and that ERS sessions can provide strategies for change and opportunities to practice new behaviors and, second, to communicate to clients that while professional treatment may aid in providing support and information, for optimal success a client should seek out additional mutual-help or Twelve-Step groups.

The goals of ERS sessions are (a) to introduce clients to basic recovery skills in structured groups, (b) to introduce clients to mutual-help or Twelve-Step programs, (c) to aid in client adjustment to participation in group sessions, (d) to provide an opportunity for the co-leader to model early recovery behavior, and (e) to provide the co-leader a chance to increase his or her own self-esteem and reinforcement of growth.

Relapse Prevention Group

Perhaps the most fundamental of the Matrix Model groups is the relapse prevention (RP) group. Clients attend RP a total of 32 times, two times per week during the first 16 weeks of treatment. Each of these sessions lasts approximately 90 minutes and concentrates on a specific topic. Examples of the sessions covered in RP group include (a) guilt and shame, (b) work and recovery, (c) truthfulness, (d) boredom, (e) motivation for recovery, (f) sex and recovery, (g) emotional triggers, and (h) acceptance. Client co-leaders in RP must have at least 1 year of abstinence from alcohol and drugs, have completed the entire Matrix Model treatment program, be actively participating in Twelve-Step or mutual-help groups, and be willing to be a co-leader for at least 6 months.

The principals behind the RP groups are that relapse is not a random event, and it follows a predictable pattern; furthermore, signs of impending relapse are identifiable by both client and counselor. Clients showing signs of heading toward relapse can be redirected with counselor support. Additionally, clients remaining steady in recovery are provided with encouragement to stay the course.

The goals of the RP group are as follows: (a) to encourage clients to interact with others in recovery, (b) to make clients aware of the difficulties of recovery and triggers of relapse, (c) to provide clients with strategies to use in maintaining their recovery, (d) to allow clients to benefit from the recovery experiences of the co-leader, (e) to give the counselor the chance to observe the interactions of clients, and (f) to give clients the opportunity to participate in a long-term group experience.

Family Education Group

Clients attend twelve 90-minute family education groups throughout the first 16 weeks of treatment. The primary counselor is responsible for inviting their clients' family members to these groups and educates and encourages participation by both the clients and their family members. The purpose of this group is to provide a safe environment for clients and their family to learn about and become comfortable with the recovery process. Information on stimulant dependence, other substance use, treatment, and recovery is presented during these sessions. Moreover, family members are taught ways in which they can support and aid their loved one's recovery.

Social Support Group

The last and longest phase of treatment includes 36 weeks of social support group or continuing care. Clients begin social support during their last month of primary treatment and continue attending these groups one time per week for the remainder of their treatment. The purpose of the social support sessions is to enable clients to learn socialization skills that will aid in their long-term recovery. These groups are typically facilitated by the counselor, but may be led by the co-leader. Social support groups provide an excellent opportunity for the co-leader to help other clients achieve continued recovery, while also strengthening their own recovery by becoming role models. Examples of topics discussed in social support sessions include anger, commitment, cravings, depression, friendship, honesty, and spirituality.

The goals of the social support group are to (a) allow clients a safe place to practice new social skills, (b) allow coleaders to serve as role models to other clients, (c) give clients an opportunity to increase their supportive social network, and (d) provide less structured meetings for clients in order to ease them into feeling comfortable in support groups without counselor assistance.

Role of Counselor

The Matrix Model should be implemented by counselors who have several years of experience. Although the materials provided by the Matrix Institute are well ordered and comprehensible, a counselor should have well-developed counseling skills and experience with both cognitive behavioral and motivational approaches in order to use this approach. The role of the primary counselor is to be familiar with materials from each group their client may be attending and to integrate all aspects of the Matrix Model with support groups and other services the client may be receiving. In addition to facilitating substance abuse treatment, primary counselors need to be able to coordinate and remain aware of other services that clients may be receiving, including mental health, psychiatric, and vocational services. Finally, it is imperative that counselors using the Matrix Model be culturally competent and sensitive to cultural differences within their client caseload.

Materials

In an effort to protect the integrity of the Matrix Model and to allow for extensive dissemination of the approach to treatment providers, the Matrix Institute has compiled a detailed manual of the approach. The manual includes instructions for use; a counselor's treatment manual and family education manual, including a CD-ROM with PowerPoint slides; and a client's handbook and treatment companion, including worksheets that accompany therapy sessions. The counselor's treatment manual includes all materials needed for a counselor to facilitate each group session and individual-conjoint session. The materials include a description of the topics to be discussed, goals for each session, a list of client handouts, homework assignments, and additional notes for the counselor to be aware of during the sessions. All of the Matrix Model materials are available through the U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration (SAMHSA), Center for Substance Abuse Treatment. Electronic copies can be obtained through SAMHSA's National Clearinghouse for Alcohol and Drug Information at www.ncadi.samhsa.gov.

MEDIA CAMPAIGNS

See NATIONAL MEDIA CAMPAIGN

MEDICAL CONSEQUENCES

The National Survey on Drug Use and Health estimated that in 2006, 20.4 million Americans ages 12 years or older used an illicit drug in the month prior to the survey. About 7 million could be classified with a substance abuse or dependence disorder in the past year. Substance abuse can be defined as a harmful pattern of drug use that results in repeated adverse consequences, such as the failure to meet social obligations or encountering legal problems. The consequences of substance abuse can and often do lead to serious medical problems for not only the individual who uses drugs but also for the society at large. Some of the negative effects can occur after using a huge quantity of drugs or after using for an extended period; while in other cases, a negative effect may occur immediately after just one use. Nevertheless, research has shown that abusing drugs can cause damage to the brain and to all other organ systems as a result of changes brought about by the direct and indirect effects of drug use.

Neurological Effects

All drugs manipulate the brain in way that results in the excessive release of chemicals, such as dopamine and serotonin, which can produce a euphoric effect within the user. But as mentioned before, most of the effects of drug use are not positive. Over time, long-term substance abuse can change the brain structure in way that eventually leads to dependence or addiction. In most instances of substance dependence, the user needs to continue using a particular substance in order to avoid experiencing withdrawal symptoms. The symptoms of withdrawal depend on the substance but can include tachycardia (increased heart rate), hypertension (high blood pressure), nausea, sweating, tremors, seizures, and visual hallucinations. In rare instances involving certain types of substances, withdrawal can lead to death. Addiction is a brain disease characterized by uncontrollable, compulsive drug craving, seeking, and use, even in the face of negative health and social

consequences. So individuals addicted to drugs are not only physically dependent but also psychologically dependent as well. Once addiction sets in, the likelihood of developing some kind of medical ailment is increased. In addition to the effects listed above, changes in the brain chemistry can lead to problems with memory, attention, and more serious psychological problems such as paranoia, depression, aggression, and hallucinations. The abuse of drugs can also cause widespread brain damage, seizures, and strokes.

Cardiovascular Effects

The abuse of drugs can have a damaging effect on the cardiovascular system. Some drugs, such as cocaine, cause an increase in blood pressure and heart rate, which increases the risk of cardiac arrest and heart failure. The use of drugs can also lead to disturbances in heart rhythm. The use of inhalants has been shown to induce irregular and rapid heart rhythms, which can lead to heart failure and death within minutes of sniffing. The chronic act of injecting heroin has been known to cause bacterial infections of the blood vessels and heart valves and can lead to scarred and/or collapsed veins.

Respiratory Effects

The lungs transport oxygen from the atmosphere into the bloodstream and carbon dioxide from the bloodstream into the atmosphere. The abuse of drugs can disrupt this process in many ways. Some drugs can cause an increase in breathing that makes the lungs work harder, while others can cause breathing to slow down or can reduce the capability of the lungs to absorb oxygen. Long-term use of some drugs can also have a corrosive effect on the lung tissue, which can lead to a variety of respiratory problems such as asthma, bronchitis, and emphysema.

Gastrointestinal Effects

Using drugs can have an adverse effect on the gastrointestinal system. Some of the short-term effects of drug use on the gastrointestinal system include nausea, vomiting, severe stomach cramps, and pains. Chronic abuse of certain drugs can lead to stomach ulcers and even cancers of the gastrointestinal system.

Kidney Damage

The kidneys are responsible for cleansing the blood by filtering it of waste and toxins. Drug abuse can often lead to high levels of toxins and waste being introduced into the bloodstream. This waste can cause the kidneys to become overworked and poisoned as these organs try to rid the bloodstream of these extreme amounts of toxins and waste. This along with increases in body temperature and muscle breakdown can cause kidney damage or even failure.

Liver Damage

The liver plays a huge role in just about every process that takes place in the body and is essential in keeping the body running properly. It removes or neutralizes poisons, germs, and bacteria from the blood. It also produces bile to help the body to absorb nutrients digested by the stomach. Chronic use of some drugs, such as inhalants and steroids, can cause severe damage to the liver, which can lead to the breakdown of normal bodily functions and complete liver failure.

Musculoskeletal Effects

The use of some drugs such as steroids can signal the body to stop growing or developing earlier than they would have. This can lead to stunted growth or permanent sexual immaturity. Other drugs can cause violent muscle spasms or muscle weakness. PCP is known to cause muscle contractions, which, when severe, can result in kidney damage or failure as a consequence of muscle cells breaking down.

Hormonal Effects

Drugs such as steroids are known to have a damaging effect on normal hormone levels, causing both reversible and irreversible changes. In men, these changes can include breast formation, testicular atrophy, infertility, and male-patterned baldness. In women the abuse of steroids causes masculinization. So, females may experience a deepening of the voice, facial hair growth, a decrease in breast size and body fat, enlargement of the clitoris, and male-pattern baldness.

Indirect Effects

As shown in the previous sections, drugs of abuse can directly cause many medical problems. They can also

indirectly impact the health of the user as result of the circumstances and behaviors associated with drug abuse. Different routes of administration can produce different adverse effects on the body. For instance, snorting cocaine can lead to nosebleeds, problems with swallowing, hoarseness, and an overall irritation of the nasal septum, which can lead to a chronically inflamed, runny nose.

Injecting drugs can cause blood clots, scarred and/or collapsed veins, and severe skin infections. In addition to these effects, the sharing of injection equipment or fluids increases the risk of the user acquiring some kind of infectious disease such as hepatitis (HCV) and HIV. In fact, research has shown that injection drug users (IDU) represent the highest risk group for acquiring HCV infection. It is estimated that almost 80% of new HCV infections occurring in the United States are among IDUs.

The abuse of some drugs can repress inhibitions and lead people to take risks while under the influence, such as engaging in impulsive sexual activity. This activity of course, increases the risk of contracting HIV or some other sexually transmitted disease. Drugs can also lead people to engage in other unsafe behaviors such as driving under influence or getting into a fight, which can result in injuries that require medical care.

Drug abuse can complicate the treatment of other illnesses or injuries. Research has shown that a large proportion of chronic drug abusers do not comply with their medication regimens and many do not seek proper medical care. Also, some illicit drugs are known to negatively interact with medications used for treating diseases. So, if a user continues to use an illicit drug while taking medication for a medical condition, this can cause the medication to become less effective as well as cause other adverse effects.

Societal Effects

Many of the consequences of drug abuse can have a negative impact on the health of the non-drug-abusing public. Not only are drug abusers more likely to contract HIV and other sexually transmitted diseases due to engaging in high-risk behaviors such as having unprotected sex, they also risk passing these diseases onto their sexual partners. In addition to this, many drug abusers are at greater risk for contracting other diseases such as tuberculosis (TB) if their immune system has been compromised due to various factors such as long-term drug use, inadequate nutrition, or HIV/AIDS. Furthermore,

even if they do seek medical attention, many are not compliant with their treatment regimes and continue to compromise their health by using alcohol and other drugs. This has led to the development of a multidrug resistant strain (MDR) of TB that does not respond to the usual medication. Since TB is an airborne disease, the spread of TB and MDR can be rapid in crowded situations and public institutions such as hospitals or prisons, which potentially places millions of nonaddicted individuals at risk for a serious and possibly deadly disease.

Prenatal Effects

According to the National Institute on Drug Abuse, more than 5% of the 4 million women who gave birth in the United States in 1992 used illegal drugs while they were pregnant. Abusing drugs while pregnant not only harms the body of the user but also the developing fetus. The full extent of prenatal exposure to drugs is unknown because there are many factors (such as the amount and number of drugs abused, extent of prenatal care, socioeconomic conditions, maternal nutrition, and other health conditions) that can make it difficult to determine the direct impact of a particular drug on fetal and child outcomes. But it is known that abusing drugs increases the risk of miscarriage and other developmental abnormalities. Premature birth can also occur. Studies on babies born to mothers who use cocaine have shown that they are often delivered prematurely and have low birthweights. Using drugs while pregnant can also increase the chances of the infant becoming dependent on the substance that is being abused, which can result in the infant experiencing withdrawal symptoms after birth.

Conclusion

Substance abuse is a major problem in society today. Studies have shown that drug users have a greater risk of developing health problems than nonusers as a result of the negative effects that various drugs have on the body and other factors associated with the drug-using lifestyle. In addition, substance abuse can lead to the premature death of the user due to overdoses and drug-related accidents, homicides, and diseases. Based on estimates from a study conducted by The Lewin Group, drug abuse is one of the most costly health problems in the United States due to direct costs (health care costs associated with treating drug-related illnesses)

and indirect costs (loss of potential productivity from crime-related costs, illness, disability, or death). In 2002 alone, the overall economic cost came to about \$180.9 billion, with \$15.8 billion of that amount attributed to health care costs and \$128.6 billion to productivity costs. Given that substance abuse is a complex and pervasive health issue, education, prevention, and treatment efforts must encompass a public-health approach in order to effectively combat this costly disease.

MEDICAL USE OF MARIJUANA

Medical marijuana (*cannabis sativa*) refers to the medically controlled use of marijuana or tetrahydrocannabinol (THC, the main psychoactive ingredient in marijuana) by patients seeking a means to address medical problems including nausea, vomiting, weight

loss, multiple sclerosis, asthma, inflammation, glaucoma, poor appetite, spasticity, chronic pain, and acute pain. There is a consensus that marijuana's medical use developed first in China, spreading to India, Rome, and Greece by the 1st century and eventually reaching Europe and Africa. The use of marijuana as medicine finally spread to the European colonies in North America sometime in the 18th century.

Thus, the use of medically controlled marijuana in the United States predates the 1937 Marihuana Tax Act, which rendered cannabis illegal even with a physician's prescription. Moral crusades condemning the use of marijuana for any purpose prior to the 1937 Marihuana Tax Act and widespread illegal use of marijuana since the passage of that law contributes to the contemporary controversy over developing clinical studies to assess the efficacy of medical treatments using marijuana. Although a few states did enact legislation (primarily in the 1970s and 1980s) that allows physicians to prescribe marijuana, federal law prohibiting this practice prevents physicians from prescribing marijuana as medication. Currently, the federal government of the United States does not recognize marijuana as serving any legitimate medical function. However, some synthetic cannabinoids, for example, dronabinol, fall into the Schedule III drug category. These synthetic cannabinoids mimic some of marijuana's medical effects while costing considerably more. However, because they have a standardized dosage, regulators consider these to have a low potential for abuse.

The contemporary debate over medical marijuana consists of two opposing arguments. One side of the debate suggests that medical marijuana is unnecessary because existing drugs address all conditions that medical marijuana may ameliorate. Opponents suggest that medical marijuana is more effective and less expensive than existing legal drugs. Although in the United States medical marijuana legislation is limited to compassionate use laws in approximately 13 states, global legislation (and attitudes) toward both marijuana and medical marijuana vary greatly, and there is a social movement industry centered around marijuana use, particularly decriminalizing-legalizing the medical use of marijuana.

Contemporary Debate

Many studies conducted in the 1970s, some of which resulted in follow-up studies in the 1980s and 1990s, confirm that cannabinoid drugs are effective in treating appetite loss, glaucoma, nausea and vomiting,

pain, spasticity, and weight loss. Opponents of decriminalizing-legalizing marijuana for medical use contend that legal drugs, such as dronabinol, alleviate medical conditions as efficiently as marijuana. To this argument, supporters of medical marijuana reply that the presence of an existing treatment does not preclude developing and approving alternative treatments. For example, there is more than one drug therapy approved for the treatment of depression and more than one kind of pain medication. In addition, the legal cannabinoid drug dronabinol, which mimics the effect of marijuana, has more side effects than inhaled marijuana, costs more, takes longer for a patient to experience the beneficial effects, and presents ingestion difficulty for both vomiting patients and patients whose symptoms include throat swelling. It is also far easier for patients to control their dosage of inhaled marijuana because they can monitor their body's reactions and cease inhaling when undesirable side effects present themselves, an advantage that cannot be obtained with a dosage-standardized pill.

Almost 40 years ago, tests demonstrated that inhaled marijuana was effective in treating glaucoma by lowering pressure within the eye, thus protecting the patient from damage to the optic nerve. However, alternative treatments developed in the late 1990s are equally efficacious in safeguarding the optic nerve. Additionally, The American Academy of Ophthalmology does not promote marijuana as a safe or effective treatment for glaucoma because while marijuana may reduce intraocular pressure, at the high dosage required to treat glaucoma (8–10 per day) undesirable side effects appear.

Further research on using medical marijuana to treat glaucoma is unlikely. Though studies show that it is an effective means of reducing intraocular pressure, existing treatments protect the optic nerve as effectively without the numerous side effects of a therapeutic dosage of marijuana. However, professional organizations such as The American Academy of Ophthalmology and The National Eye Institute, while not currently endorsing medical marijuana as a glaucoma treatment, state their willingness to reconsider this position following further research.

Although case studies testing the effectiveness of inhaled marijuana on both specific and general pain, including pain induced by surgical intervention, headache, and chronic illness do exist, it is difficult to separate the actual effect of inhaled or ingested marijuana on physical pain from the expectation that inhaled marijuana produces a pain-relieving effect (the placebo effect).

Conclusions drawn from large-scale studies assessing the effectiveness of marijuana on acute pain are mixed. In one 1977 study, most respondents preferred a presurgical intervention of diazepam (antianxiety medication) or a placebo to intravenous THC prior to tooth extraction. However, at least one controlled experiment conducted in 1974 using more reliable measures of pain tolerance indicate that higher doses of THC may reduce acute pain.

One 1975 study regarding the efficacy of marijuana for treating chronic pain resulting from cancer demonstrated that chronic pain caused by cancer responds to high doses of oral THC (20 mg) and high doses of codeine (120 mg) comparably. However, researchers also concluded that the negative side effects of high-dosage oral THC were more negative than that of high-dosage codeine, including anxiety, paranoia, dizziness, and depression. However, this study utilized oral, rather than inhaled doses, which affects several factors related to the efficacy of treatment, including strength and absorption of the drug. Although it is true that the use of marijuana induces side effects, not all patients experience these effects, and indeed, some patients may prefer the side effects of marijuana use to the pain cancer causes.

In addition to treating chronic pain resulting from cancer, numerous studies demonstrate that both orally ingested and inhaled marijuana is effective in treating nausea and vomiting related to cancer treatments. Studies also demonstrated that the synthetic cannabinoids nabilone and levonantradol reduced nausea and vomiting when taken prior to treatment. The differing anti-emetic effects of inhaled marijuana, ingested marijuana, and synthetic cannabinoids warrants further research because inhaled marijuana is more cost-effective, offers patients more control over dosage, and serves as an additional drug with which to rotate patients developing tolerance to existing anti-emetics. Additionally, because medicines vary in their impact on the individual, some patients may find inhaled marijuana more effective than standard anti-nausea drugs. Although it is true that medically controlled marijuana does present side effects, patients may prefer these side effects to chemotherapy-induced nausea.

U.S. Legislation

The 1970 Comprehensive Drug Abuse Prevention and Control Act divided substances into categories based on their medical use and potential for addiction.

Marijuana, along with heroin, mescaline, and lysergic acid diethylamide (LSD), is a Schedule I drug, meaning that the Drug Enforcement Administration legally classifies marijuana and cannabis as (a) carrying a high potential for abuse, (b) without currently accepted medical use in the United States, and/or (c) lacking accepted safe use even with medical supervision. Even with this classification, for a brief period, the federal government allowed citizens to apply for relief from this law as part of a compassionate use program. A compassionate use exception would allow collection of data regarding the efficacy of medical marijuana; however, the federal government discontinued compassionate use exceptions in 1992 despite the increasing number of people who applied for it every year.

Since marijuana is a Schedule I drug, physicians cannot legally prescribe it, and possession of the drug can lead to large fines and/or jail time. However, the use of medical marijuana outside the United States, state legislation related to medical marijuana developed over the past 10 years, and contemporary efforts to reschedule marijuana to allow medical use provides evidence for the conflicting attitudes that characterize the current climate toward medical marijuana.

California's 1996 Compassionate Use Act (Proposition 215) states that a seriously ill Californian may use marijuana with a physician's recommendation that the patient might benefit from its use. Since 2000, legislators in Hawaii, Vermont, and Rhode Island have passed bills protecting seriously ill patients from prosecution for using marijuana as medicine. In 2007, New Mexico's legislators passed a law giving the state Department of Health a mandate to develop rules for the use and distribution of medical marijuana to patients authorized by the state. These are only some of the examples of state laws regarding medical marijuana.

A ruling in *Conant v. Walters* in 2002 found that federal authorities could not legally sanction physicians for frankly discussing medical marijuana with patients. Although the holding did not affect physicians' inability to prescribe medical marijuana, it did affirm that physicians could legally endorse or recommend the use of marijuana to patients.

Social Movements, Global Attitudes

National and international social movement organizations supporting the decriminalization or legalization

of marijuana, particularly medical marijuana, continue to thrive. These social movement organizations include the Drug Policy Foundation and the Drug Policy Alliance operating in the United States, The National Organization for the Reform of Marijuana Laws operating in the United Kingdom and the United States, the European Movement for the Normalization of Drug Policy, and the International Anti-Prohibition League.

Drug laws in Western Europe vary widely from country to country. Today, in some European countries, it is a criminal offense to use medical marijuana; in some, it is a civil matter; and in a few, marijuana is completely decriminalized. Most recent legislation demonstrates a trend of moving away from harsh penalties for marijuana use and toward a harm reduction model that would allow more patients to access marijuana for medical use. In 2003, the Netherlands, continuing its trend of liberal drug policy and legislation, became the first country to enact federal regulations that allowed pharmacies to distribute medical cannabis.

In recent years, the United Kingdom moved toward harm reduction policies in its drug laws. Marijuana is decriminalized and simple possession does not result in arrest. However, in the United Kingdom, medical marijuana is not legal. This policy means that even patients using marijuana to address medical conditions are subject to verbal warnings and the confiscation of the drug. In Canada, patients may use medical marijuana if (a) they suffer from serious illness, (b) existing treatments do not provide relief for either the illness or symptoms related to treatment of the illness, and (c) the benefits offered to the patients outweigh the risks posed by use of marijuana. Mexico's drug laws are similar to the United States, and Mexico does not currently have any laws decriminalizing or legalizing medical marijuana.

Conclusion

Proponents of medical marijuana focus on the benefit of inhaling smoke rather than on ingesting pills when treating patients with nausea, as well as on the importance of developing medical alternatives for patients who fail to respond to conventional drug therapy. Current federal legislation in the United States creates difficulty for large-scale assessment of medical marijuana's effectiveness as a treatment, though older studies (primarily from the 1970s) confirm the efficacy of cannabinoids for treating a variety of maladies. Contemporaneously, following California's 1996

Proposition 215, several states enacted compassionate use laws that allow patients to use marijuana with a physician's recommendation without legal penalty. Opponents of legalizing and/or decriminalizing marijuana for medical purposes aver that existing drugs offer sufficient treatment for all medical conditions that may respond to marijuana, as well as argue that marijuana causes harmful physiological effects. Both the potential medical benefits and negative side effects created by medically controlled marijuana warrant further research.

MENTORING

In the larger context of health and social service provision, formal treatment for substance abuse is a relative newcomer to the field, emerging only in the last several decades. Substance abuse treatment originated primarily from grassroots effort, first through churches and the temperance movement and later from the Twelve-Step movement whose genesis began with Alcoholics Anonymous in 1939. Although the first federal monies for substance abuse treatment also emerged in the 1930s in the form of funding for a program in Lexington, Kentucky, in 1935, and for a smaller program in Fort Worth, Texas, in 1938, it was not until the passage of the Narcotic Addict and Rehabilitation Act of 1966 and the Comprehensive Alcoholism Prevention and Treatment Act (Hughes Act) of 1970 that a national infrastructure began to develop to systematically

address both the prevention of, and treatment for, substance dependence and alcoholism. As is often the case with grassroots origins, early leaders in substance abuse treatment were often those who had successfully overcome their own addictions. Following Twelve-Step principles of giving back to the community, treatment program graduates were often subsequently employed as substance abuse counselors and continued their career development paths upward toward senior management positions. Thus, a legacy of peer leadership and mentorship in substance abuse was born.

Changes in the Field

However, as the field of substance abuse has developed into a mainstream public health concern with regular budget allocations from the federal, state, and county governments, concomitant requirements for treatment service elements have increasingly begun to shape, monitor, and circumscribe the demands of substance abuse treatment provision. In addition, the rise of substance abuse research and clinical outcome trials in the quest for evidence-based treatment practices has also intensified the regulations placed on treatment providers in order to obtain funding from governmental block grants.

As a result of these new external demands, the specificity and nature of skills needed for successful leadership in substance abuse treatment in the 21st century is radically different from what was necessary a few short decades earlier. Not only must newly emerging substance abuse leaders be well versed in the diagnosis and treatment of addiction, but also stakeholders need to understand the interaction effects of addiction as it relates to trauma, mental illness, criminal justice, and child welfare domains. In addition, as substance abuse treatment has increasingly become corporate big business, leaders increasingly need to develop specific management skills, including but not limited to contract management; development of financial revenue from multiple and divergent funding streams; data collection, outcome monitoring, and participation in research; large property acquisition and buildings management; public policy development; and political advocacy efforts with various governmental agencies. As the culture of substance abuse codevelops from the avenues of recovery as well as from research, clinical service, and corporate business expertise, the development of new leaders via specific mentoring opportunities is crucial.

This need for mentorship is necessary not only to develop effective leaders for single-agency substance abuse prevention and treatment providers but also to mentor and grow key public health, public policy, and state and national leadership positions. Furthermore, it is essential that current field leaders, particularly those in national stakeholder positions, recognize that emergent trailblazers will be developing new models for prevention and treatment and will need to provide and allow opportunities for these new leaders to succeed.

Workforce Concerns

The need for mentoring and cultivating new leaders in substance abuse has reached a critical juncture in the last decade. Demographic data for the substance abuse workforce indicates two significant trends: first, that the average age of an employee in this field is higher than for other professions, with the mean age hovering between 45 and 50 years, and, second, that there is an excessive rate of workforce turnover, with up to 33% of employees vacating substance abuse positions annually, a rate three times higher than the national average workforce turnover of 11% across all employment fields. This workforce turnover negatively impact frontline staff positions but also key leadership roles. It has been estimated that for the 50 state directors who are responsible for all substance abuse treatment and prevention efforts for the constituents within their geographic boundaries, there is 30% turnover in these key positions every 2 years. Further complicating workforce development concerns, demographic data indicates that the ethnic distribution of substance abuse staff is not diversely represented, with a range of 70% to 90% of employees being non-Hispanic Caucasians. Another significant workforce concern is the paucity of remuneration in substance abuse, whereby compensation for work is consistently less than equivalent jobs in other social services provision, both for frontline service and senior administrative positions.

Mentorship Initiatives

Recognizing that single-agency leaders were struggling to consistently generate and cultivate the resources and structure for successful workforce development on their own, in 1993, the Addiction Technology Transfer Center (ATTC) network was created to aid in these efforts. Under the auspices of the Substance Abuse and Mental Health Services

Administration (SAMHSA), 14 regional ATTCs across the nation were developed to provide linkage to local and national resources, to facilitate collaboration between agencies, and to conduct technical assistance trainings and subsequently promote the dissemination of substance abuse prevention and treatment best practices.

Although the ATTCs demonstrated continued success in increasing the skill set of substance abuse practitioners, it became evident that in order to nurture and grow the nation's next generation of leaders would require more than informal mentoring. To achieve more effective succession planning, in October 2003, the Southern Coast ATTC implemented a pilot Leadership Institute program, which was designed to provide a more structured approach to the mentoring process.

In collaboration with the Graduate School of the U.S. Department of Agriculture, the Leadership Institute inducts mentorship protégés in a 6-month program comprising four core elements: (1) evaluation of leadership gaps and potential candidates' management interests and abilities; (2) a thorough 360-degree evaluation of strengths and weaknesses by the protégés supervisors, peers, and supervisees, resulting in developmental suggestions and an action plan; (3) participation in an intensive 5-day immersion course with a subsequent pair-matching of protégé and mentor; and (4) 6 months of ongoing experiential mentoring between protégé-mentor pairs, for a recommended minimum of 1 to 4 hours per week, culminating in the completion of a specific project designed to fulfill one of the protégé's leadership development goals.

Based on the success of this pilot project, SAMHSA's Center for Substance Abuse Treatment created the Partners for Recovery (PFR) initiative with the other ATTCs, and utilizing this model has subsequently implemented regional Leadership Institutes across the country. As of mid-2007, 354 protégés have graduated from the PFR Leadership Institutes.

Conclusion

In addition to the benefits of structured mentorship models, it is equally important to recognize and incorporate the values and successes of the field's self-help and recovery origins. Substance abuse treatment has a long history of nonhierarchical, democratic leadership from within its own. Communication in substance

abuse is omnidirectional, with feedback provided not only leader to leader and leader to client but also client to client and client to leader. Despite the increasing skill set required for effective leadership, it is important to embed the strengths of historical peer leadership and recovery values within newly emergent business demands and continually developing governmental oversight. Toward that end, a culture of mentorship both within and without organizations may provide the optimal path for balancing the historical values of substance abuse treatment with the contiguous need for more business, research, and co-occurring clinical service skills.

METHADONE

With hundreds of thousands of people abusing heroin and other opioids such as oxycodone and hydrocodone, methadone treatment clinics are found worldwide. These clinics are intended to assist injection drug users and prescription opioid abusers from the numerous physical and mental health problems that go hand in hand with substance abuse and dependence. Although methadone has been found to be beneficial in treating heroin dependence, methadone itself has a potentially problematic addiction potential of its own. Other alternatives such as buprenorphine (Suboxone) have been developed in order to prevent such abuse from developing.

Methadone is used medicinally with management of cancer pain and other chronic pain. Indeed, physicians outside of addiction treatment facilities have very limited prescription privileges for methadone, and are generally limited to prescribing it for pain management. It is a synthetic opioid (derived from morphine) and has analgesic effects that help reduce pain. Methadone-related deaths have seen a drastic increase throughout the world since it was first developed. It is of particular note that of those who die from methadone related overdoses, the majority are prescribed methadone for pain.

Methadone is most often used in treating those with opioid addiction through licensed methadone maintenance programs. It is generally given only to a patient in a clinical setting, but on rare occasions, it will be sent home with a patient. Not only does methadone help substance abusers avoid cravings for opioids, but it also blocks the euphoric effects commonly associated with abuse and the many unwanted withdrawal symptoms associated with opioids. Although it is a highly regulated drug, it is still found sold on the streets illegally, which is one of the reasons that it is usually dispensed at a clinic and not sent home with a patient. Once sold, substance abusers will mix methadone with other drugs such as Xanax in order to get the same effect as heroin.

Methadone's effects are not as intense as that of heroin, yet they can be just as addicting. Methadone maintenance has been used for heroin addicts for years; however, the abuse of this drug has led to increases in addiction, abuse, overdose, and death. In this instance, methadone may simply be providing substitute addiction among drug users. It is for this

reason that alternative medications have been developed in order to prevent such addiction. The abuse of methadone is most likely due to concomitant increases in heroin and prescription opioid use. Also, substance abusers are turning to methadone when they cannot obtain other drugs such as heroin.

Studies indicate that the average patient in methadone maintenance can be described as a Caucasian female in her mid-30s who lives in a county with a population of over a million. Although heroin abuse is commonly found in people who enroll in methadone maintenance programs, it is also common to see prescription opioid abuse reported in these enrollees. Not only is the abuse potential high in those treated with methadone, but since it is usually given under supervision, the cost of this treatment is relatively high. This cost may deter substance abusers from entering and remaining in treatment; however, government subsidies to some facilities do allow treatment for individuals who are underinsured, uninsured, or otherwise unable to afford treatment.

Prescription drugs can sometimes be viewed as legal and more socially acceptable. Access to drugs such as methadone is relatively easy, and it is not uncommon to see it sold in much safer locations than illicit drugs such as heroin or cocaine. Prescription opioids such as methadone are sold at higher costs than heroin, and their abuse potential is most commonly found in suburban areas where access to money is not as limited as it may be in inner cities or rural areas.

Methadone Alternatives

Buprenorphine

Since the abuse potential and death rates of prescription opioid analgesics have seen an unwanted increase over the years, alternatives such as buprenorphine have been prescribed in place of methadone.

Buprenorphine was approved by the Food and Drug Administration (FDA) after numerous years of testing. The mu opioid receptors that mediate analgesia (relief from pain) are partially displaced by buprenorphine, and it has its own characteristics that are unique and set it apart from heroin and methadone. Like methadone, buprenorphine is used as an alternative in detoxification of opioid substance abusers. Although more expensive than methadone, buprenorphine has a lower rate of illicit use and has also been found to be a safer

medication. Unlike heroin and methadone, once buprenorphine is discontinued, withdrawal symptoms are relatively mild and overdose risk is lower. One of buprenorphine's beneficial characteristics involves the fact that it has a high affinity for the mu receptor and helps in preventing other opioids (e.g., heroin) from binding to the receptors. Thus, if it is given to an individual who has already taken an opioid such as heroin, buprenorphine will take the place of heroin and help with symptoms of withdrawal.

Suboxone

Although buprenorphine has been found to be an effective drug in treatment for opioid addiction, there is still abuse potential, especially when buprenorphine is crushed and injected intravenously. Thus, an alternative mixture of buprenorphine and naloxone (Suboxone) has been developed in order to deter intravenous use. This buprenorphine-naloxone mixture is usually found in a 4:1 ratio and is suitable for unsupervised administration unlike methadone and buprenorphine. Overdose due to respiratory depression is less likely with Suboxone, and withdrawal symptoms are also much lower than with methadone use.

Conclusion

Although methadone is a common and widely used prescription drug in the treatment of opioid addiction, there are also many unwanted and deleterious effects associated with its use. Thus, drugs such as buprenorphine have been developed in order to help avoid the potential risks involved with opioid maintenance. Careful consideration must be taken when determining what drug is administered in opioid treatment in order to help reduce abuse and death rates due to prescription opioid addiction.

METHADONE MAINTENANCE TREATMENT

Methadone maintenance treatment (MMT) has been the primary form of treatment for heroin addiction for many years and has been recognized as the most effective treatment for this condition by the Institute of Medicine and the National Institutes of Health. As a treatment for opioid dependence, MMT involves the daily administration of the oral opioid agonist methadone, a long-acting, orally administered drug, to replace the shorter acting heroin that is usually injected. As a maintenance medication, methadone has distinct advantages. When administered in adequate oral doses, a single dose lasts between 24 and 36 hours. Methadone is dispensed orally in different forms, which include tablets (also called diskettes), powder, and liquid. Most importantly, methadone relieves the persistent narcotic craving or hunger that is believed to be the major reason for relapse to heroin. MMT involves providing drug abusers with methadone in a clinical setting, a methadone maintenance treatment program (MMTP). In the United States alone, there are more than 1,200 MMTPs, with an estimated staff of 20,000 serving more than 220,000 patients annually. MMT is intended to do three things for patients who participate: (1) keep the patient from going into withdrawal, (2) keep the patient comfortable and free from craving street opioids, and (3) block the effects of street opioids.

The operations of a MMTP are regulated by federal and state regulations. MMTPs are staffed by physicians, physician assistants, nurses, social workers, addiction counselors, case managers, vocational counselors, HIV counselors, and administrative supervisors. The methadone dose is determined by the physician, who adjusts it according to the patient's

need, withdrawal, and craving symptoms. Daily dispensing and observation of methadone, supervised urine drug screens, and other medical treatments (i.e., HIV/AIDS and hepatitis screening) are provided by nurses and physicians assistants. Clinical staff members provide individual and group counseling, case management, cognitive and behavioral treatments, and psychotherapy. The ability to provide all of these treatments in one location has made MMT the most effective treatment for opiate dependence to date.

Effectiveness

For over 30 years, methadone maintenance has been the most extensively researched form of maintenance treatment for opioid dependence in the United States. Methadone has been demonstrated repeatedly to be a safe and effective treatment with minimal side effects when used with appropriate safeguards and psychosocial services. Randomized trials have shown that methadone treatment, even with minimal counseling, is far superior to no treatment. Studies have shown that heroin users in MMT show marked reductions in illicit drug use and criminal activity and improvements in employment rates and psychological status.

Research has shown that program characteristics are critical factors in successful outcomes. The major factors in treatment retention are methadone dosage and length of time in treatment. Patients maintained on a daily dose of 60 milligrams (mg) or more had longer retention in treatment, less use of heroin and other drugs (including cocaine), and a lower incidence of HIV infection and AIDS. Other studies demonstrate the effectiveness of methadone was even greater for patients on a 70-mg dose and more pronounced for patients on 80 mg a day or more (further-reduced intravenous heroin). Studies also show that doses in excess of 100 mg a day are safe and necessary to eliminate opioid abuse and, in some cases, reduce abuse of alcohol and other drugs.

Many studies have documented a substantial reduction in criminal behavior from pretreatment behavior. Like most other factors, reduction in criminal behavior increases with length of time in treatment. This trend has been consistent throughout the almost 4 decades of methadone treatment in a variety of settings. Drug-offense arrests decline because MMT patients reduce or stop buying and using illegal drugs. Arrests decline because MMT patients no

longer need to finance a costly heroin addiction and because treatment allows many patients to stabilize their lives and obtain legitimate employment. Other factors that influence retention in treatment are well-trained staff, trusting and confidential relationships between patients and program staff, clear policies and procedures, low staff turnover, high patient morale, and flexible policies for take-home methadone.

MMT is also an important point of contact with service providers and supplies an opportunity to teach drug users harm reduction techniques such as how to prevent HIV/AIDS, hepatitis, and other health problems that endanger drug users. Studies have confirmed that methadone maintenance treatment plays a crucial role in the prevention of transmission of HIV infection among injectors of heroin, reducing the risk four- to sixfold. MMT reduces the frequency of injecting and of needle sharing.

The success of methadone in reducing crime, death, disease, and drug use is well documented. Compared to the other major drug treatment modalities—inpatient detoxification, drug-free residential and outpatient treatment, and therapeutic communities—methadone is the most rigorously studied and has yielded the best results.

Special Issues of Women

Women's health care needs necessitate a better integration of medical care and addiction treatment. Most methadone clinics are unable to adequately coordinate specialty care for pregnancy, sexually transmitted diseases, and menopause, and few have reproductive health care available to women on site. As a result, most women will seek care from a prenatal care provider with limited experience caring for women on methadone, and the patient may be reluctant to disclose that she is on methadone due to negative attitudes and stigma. Nonetheless, many women view methadone treatment as the only means to obtain medical care and as a defense against losing their children to child welfare authorities. In addition, due to the aging of this population, menopause affects many women in methadone treatment. Menopausal symptoms mimic some of the effects of narcotic withdrawal and are easily confused (by both patients and practitioners) with symptoms related to improper methadone dosage. Yet little attention is currently paid to menopausal care with methadone treatment.

Additional Approaches

The system of methadone treatment in the United States has changed very little since its inception more than 30 years ago. Methadone treatment in this country remains almost exclusively based in specialized methadone treatment clinics—the only model permitted under a set of federal and state regulations in place for over 30 years. But this single model of care varies greatly in its quality and generally employs large clinics (averaging 300 patients) that, due to their large size and visibility, are often unpopular with the communities they serve. Because of the limitations of this single model and the strong local resistance to opening any new methadone clinics, fewer than 15% of opioid addicts are in MMT in the United States. Despite the increased urgency of AIDS and years of serious efforts to address opioid addiction through expanded methadone treatment, the number of enrollment slots (about 220,000 nationally) has increased very little since the 1970s.

These considerations led to renewed efforts on the part of medical and public health authorities to reform and expand methadone treatment in the United States. In 1996, the Institute of Medicine issued a series of studies and a report calling for the expansion and modification of methadone treatment, and in 1997, a National Institute of Health Consensus Conference reasserted the conceptualization of opioid addiction as a medical disorder. It called for “effective medical treatment of opiate addiction” through the reduction of misperceptions and stigma, improved medical training, assurance of greater access to methadone, and the reduction of unnecessary regulations which restrict the availability and quality of methadone treatment. The Center for Substance Abuse Treatment and the American Society of Addiction Medicine, working with the American Methadone Treatment Association, convened a task force to revise the regulations and support innovation in practice to increase treatment availability.

Medical Maintenance

The only alternative model of care that has been used in the United States is medical maintenance (MM), available to about 5,000 very-long-term patients since the 1960s. MM provides services to a highly select group, that is, private patients who are employed with

several years of abstinence from illicit drugs—criteria currently met by approximately 5% to 10% of all current patients in MMTPs. In this model, physicians provide take-home methadone directly from their offices.

There have been several small demonstration projects limited to a few programs in New York, Chicago, and Baltimore in the 1980s. These produced positive results for their patients. The strict criteria for acceptance includes 5 or more years in continuous treatment, stable and verifiable employment, financial self sufficiency (all pay private fees for their treatment), and no criminal involvement or use of illegal drugs or alcohol abuse within 3 or more years. These patients are considered to be socially rehabilitated and are dispensed their medication at monthly visits to the doctor who also supplies them with 30 days of medication. Results of this approach have been excellent for these patients—with over 85% retention, little or no evidence of concurrent illicit drug use, continued employment, and good social adjustment. These outcomes are comparable or superior to those seen in usual care in methadone clinics.

In Connecticut, six community practitioners prescribed methadone to 46 patients using a MM model with monthly visits and weekly pickup from the practitioners' offices. There were a low percentage of patients who became clinically unstable during the 6-month period of the program. Patient satisfaction with the medical maintenance was very high, and the majority expressed that, if given the option, they would prefer to receive methadone maintenance in their physicians' offices.

Another model in Washington transferred 31 stable methadone patients to a unit of the outpatient medical clinic that provides their primary medical care. In this medical model, methadone is distributed through a pharmacy unit with weekly and biweekly pickup, which keeps separate records for methadone patients. Patients had the option of continuing with psychosocial services at MMTPs. The goal of the program was to implement MM outside of the experimental context that prevented previous medical maintenance programs from being replicated widely. Overall, the patients felt that they were leading a more productive life outside of treatment with some requesting decreases in their levels of methadone, but most patients requested increases (>100 mg) in order to reduce the frequency of their office visits. Clinicians learned about treating this population with a noticeable

decrease in stigma. However, even with a 1-year criterion of stability, only 10% of potential patients qualified for MM with pharmacy dispensing.

Office-Based Opioid Treatment

Office-based opioid treatment (OBOT) provides medically supervised maintenance treatment for opioid dependent individuals through primary care physician practices in conjunction with community pharmacies dispensing. This model is a well-established clinical practice throughout the world with hundreds of thousands of patients in care in dozens of countries, but not in the United States. Office-based care in conjunction with community pharmacy dispensing can clearly increase access as current methadone maintenance delivery in specially licensed, centralized programs reaches only an estimated 15% of patients with opioid dependence because of limited treatment slots and geographical constraints. Greater access is needed to cope with the upsurge in heroin use and in the increasing proportion of HIV transmission resulting from injecting-drug use. This model holds appeal because it would expand methadone treatment options to rural and underserved communities, embed treatment in an environment that is less stigmatized, and integrate treatment with other health management in the United States.

A 1-year pilot demonstration study was implemented with the aim of assessing the safety, feasibility, and efficacy of a primary care; community pharmacy; and social work model for methadone maintenance treatment in an urban New Mexican community. Five medical practitioners provided continuous and comprehensive care for 12 stable (minimum 6 months of no illicit drug use) female patients. Patients met monthly with the prescribing physician for clinical review and urine toxicology. Five community pharmacists supervised the self-administration and dispensing of take-home methadone. As in MMTP, doses administered at the pharmacy were observed, but unlike most MMTPs, dosing took place in a private consultation area. A master's-level social worker coordinated all patient care and provided all psychosocial treatment and documentation according to federal and state regulations. The results suggested that properly selected, trained, and supervised medical providers and pharmacists can safely and effectively manage and dispense methadone for maintenance. This pilot supports the practice and implementation of

physicians, pharmacists, and social workers to provide community-based treatment to expand the options available for MMT in the United States.

In another pilot study, a primary care physician prescribed and a community pharmacist observed and dispensed take-home methadone to 10 stable MMTP patients in Lancaster, Pennsylvania, which, at the time of the pilot, had hundreds of heroin users but no methadone clinic. Patients met monthly with the prescribing physician (a general internist) in the office for clinical review, urine toxicology, and individual counseling. Methadone dispensing with an observed dose at each visit occurred at a family-owned, community pharmacy. Patients were followed for 24 months. This model of OBOT (one doctor, one pharmacy, and a small group of patients) allowed stable MMTP patients to be in methadone treatment in a community setting and produced clinical results equal or superior to the MMTP, at lower cost and with greater patient satisfaction.

The introduction of buprenorphine (another opioid maintenance medication similar in its action to methadone) and its FDA approval in the United States may allow this drug to be routinely employed in an OBOT model (i.e., with medications prescribed by a general or primary care physician and dispensed by community pharmacists).

Conclusion

MMT has been recognized as the most effective treatment for opioid addiction for many years. Although the benefits of MMT in reducing illicit drug use, criminal behavior, and the transmission of HIV and other communicable diseases is unquestioned, access to MMT has been limited due to stringent federal and state regulations on the dispensing of methadone. Stigma toward opioid addicts and misconceptions about MMT has contributed to the problems in changing regulations. The result has been that many communities, particularly in rural areas, have limited access to MMT, and inconvenience may prevent some opioid addicts from accessing this treatment. Recently, models of dispensing methadone through primary care settings and community-based pharmacies have yielded promising results, and a widespread application of these models would solve many of the problems of the current system of MMT.

METHAMPHETAMINE

Methamphetamine production, use, and abuse are becoming widespread, affecting many Americans. Most methamphetamine production is occurring

within the U.S. borders. This drug not only ruins the user's life but also has negative consequences on families, friends, communities, the environment, the government, and law enforcement agencies. Millions of tax dollars and countless man-hours must be spent each year to address control, prevention, and intervention of this devastating drug.

Methamphetamine (chemical formula $C_{10}H_{15}N$) is a synthetic central nervous system stimulant and an incredibly potent and dangerous drug. Methamphetamine is noted for its extreme toxicity and severely addictive properties. Central nervous system stimulants work by speeding up mental and physical processes within the body. Many stimulants closely resemble the chemical structure of hormones that direct the brain into an artificial fight-or-flight state. By introducing methamphetamine into the body, the user can experience a high commonly referred to as euphoria. In a methamphetamine-induced euphoric state, the user will experience elevated alertness and attention, an increase in energy, raised blood pressure, elevated heart rate, and increased respiration. Other effects may include restlessness, an irregular heart rhythm, psychotic episodes, tremors, headaches, increased impulsiveness, and aggression. When a user takes methamphetamine, it quickly enters the brain causing a rush of the neurotransmitters norepinephrine, dopamine and serotonin. Norepinephrine affects alertness and arousal. Serotonin in the brain helps control aggression and anger, sleep, appetite, and sexuality. Dopamine levels control behavior, movement, the ability to experience pleasure and pain, and the brain's motivation and reward center. The elevated level of these neurotransmitters is followed by a cascading effect as the amount released slowly diminishes.

Methamphetamine generally comes in three forms: powder, a larger crystal form, or a pill, usually by prescription. Common street names for methamphetamine include *meth*, *speed*, *crystal meth*, *crank*, *glass*, *shard*, *tweak*, *chalk*, and *ice*.

Methamphetamine was first synthesized in 1919 by A. Ogata, a Japanese chemist. During World War II, methamphetamine was distributed in bulk as a performance enhancer for soldiers. The overuse of methamphetamine during the war led to widespread addiction issues throughout Japan post-World War II. In the 1940s, methamphetamine was sold under the trade

name Methadrine as an antidepressant and also an appetite suppressant for obesity.

Manufacturing

Some methamphetamine is produced legally according to the rules and regulations of the federal government and distributed through a prescription for certain medical conditions such as narcolepsy (frequent and uncontrollable episodes of sleep). Illegal methamphetamine, however, is produced in clandestine or *tabletop* laboratories. These labs are referred to as tabletop due to their easy portability. Lab portability is a major factor for the producers of methamphetamine, as they tend to travel frequently to avoid law enforcement and to supply their product to a large number of dealers and users.

Large-scale illegal methamphetamine labs, or super-labs, outside of the United States produce a large portion of the methamphetamine that enters the United States. Although a significant proportion of the drug is imported, the ease in obtaining the necessary components to manufacture methamphetamine is the principal reason why small-scale methamphetamine production has increased exponentially over the last several years. Methamphetamine can be produced using pseudoephedrine from cold and allergy medications as well as from other ingredients from household products such as white gasoline, muriatic acid, acetone, denatured alcohol, drain cleaner, and battery acid. Individually, each of the ingredients is legal and has a specific purpose, but when all are combined, the results are dangerous and sometimes deadly to the manufacturer, the user, and often the innocent bystander.

Although production of methamphetamine is relatively simple, the use of highly volatile and flammable chemicals makes the production of methamphetamine extremely dangerous with serious and sometimes deadly consequences. The mixture of such volatile chemicals often results in explosions of the labs and causes chemical burns to the manufacturers and those in close proximity. It is estimated that for every pound of methamphetamine produced, there may be up to 5 pounds of toxic waste that needs to be disposed. These toxic by-products of methamphetamine production are frequently dumped into freshwater ecosystems, as well as in fields, forests, and sewage systems. This influx of

toxic waste has a tremendous negative effect on wildlife and water quality in the area surrounding the dump site. The toxic gases that result from methamphetamine production adhere to many surfaces inside of the lab area including carpets and walls. These tainted facilities are extremely expensive to correctly clean. Until these facilities have been cleaned, they are uninhabitable.

Routes of Administration

Methamphetamine can be introduced into the body in many ways. The principal route of administration for medical use of methamphetamine is oral intake, by swallowing a prescribed pill. In recreational methamphetamine use, however, the drug is usually smoked, snorted, injected intravenously (after being dissolved in water), or inserted into the anal cavity or urethra to be absorbed by the mucous membranes.

When smoking the drug, the methamphetamine is vaporized, or heated until the fumes are able to be inhaled. Generally speaking, inhalation is the fastest mechanism for introducing a drug to the brain, even more so than intravenous use. As with all modes of administration, injecting the methamphetamine is inherently dangerous. Injection can carry serious consequences due to the risk of disease transmission through the use and reuse of syringes. Injection is also dangerous due to the difficulty in gauging a proper dose for beginning users (see Overdosing section). What may be the proper dose for one user to achieve a desired high may not be the proper dose for another user. Dissolving the methamphetamine in water or alcohol and inserting it into the anus or urethra is said to intensify sexual pleasure, but little research has been done to investigate the validity of this method.

Short-Term Effects

There are many signs and symptoms of methamphetamine use that will be present in users. Although these effects are common, not all users will exhibit the same signs and symptoms. Methamphetamine users may experience euphoria followed by depression, paranoia, and nervousness; decreased appetite; rapid eye movement; dilated pupils; fever; excessive sweating; hallucinations; aggression; impaired speech; increased heart rate; and convulsions.

Long-Term Effects

Many of the short-term effects of methamphetamine use will continue to be present in long-term users, but chronic users tend to have more severe effects including kidney and lung disorders, brain damage, liver damage, extreme weight loss, nose bleeds, constant scratching or picking of the skin, damaged blood vessels, discolored teeth or tooth loss, paranoia, chronic hallucinations, insomnia, malnutrition, increased susceptibility to illness, stroke, and repetitive motor activity, referred to as behavioral stereotypy. Long-term use can also cause cardiovascular problems such as elevated blood pressure, rapid heart rate, and circulatory complications leading to stroke(s). Although these are some of the most common signs of long-term methamphetamine use, signs and symptoms are certainly not limited to the aforementioned.

With long-term use of methamphetamine, dependence will develop. Most addicts will develop a tolerance for the drug as well. This tolerance forces the user to increase the dosage or to change the route of administration of the drug in order to achieve the desired effects. In many cases with long-term use, the drug user will pass up food and sleep in what is known as a *binge* in order to maximize the use and effects of methamphetamine. Some users may binge for several days and go without sleep during that time.

Overdosing

Because illegal methamphetamine is produced in home-made labs and can be manufactured using different components and amounts of ingredients, the potency of methamphetamine can vary greatly from one batch to another. This inconsistency in the potency of illegal methamphetamine makes it nearly impossible to predict what will be an appropriate dose for a methamphetamine user. If users introduce more methamphetamine into their bodies than can be processed, the result is what is known as an overdose. The symptoms of a methamphetamine overdose can include sudden spike in blood pressure, abrupt rise in body temperature (externally visible through excessive sweating), convulsions, dilated pupils, rapid respiration, and collapse.

As the methamphetamine takes effect on the user's body, norepinephrine is released in the brain. Norepinephrine stimulates the heart, causing acceleration in heart rate. As the heart beats faster, the body temperature rises. The body compensates for the

increase in temperature by sweating since the evaporation of sweat on the skin cools the body. After an extended period of sweating, the body lacks the fluids to produce any more sweat and becomes dehydrated. As the heart rate continues to increase, blood vessels constrict, causing limited flow of oxygenated blood throughout the body. Without proper oxygen, kidney tissue starts to deteriorate and can no longer filter the methamphetamine toxins out of the body. With the sharp increase in body temperature (hyperthermia) and a lack of circulating oxygen, muscle tissue starts to breakdown. As the muscles break down they produce proteins that are normally absorbed by the kidneys. When there is a large influx of these proteins, the kidneys cannot compensate and begin to shut down as the overdosed user goes into renal (kidney) failure.

Use During Pregnancy

The medical community believes that the use of methamphetamine by a pregnant mother places the unborn fetus at serious risk for abnormalities and developmental issues. Although it is not conclusive, research suggests that methamphetamine use during pregnancy is linked to issues in the child such as heart and circulatory problems, central nervous system abnormalities, urinary and reproductive system complications, and deformed extremities. Many studies suggest that babies exposed to methamphetamine in utero have a tendency to be asocial and have problems with motor skill development, have short attention spans, and are extremely irritable, causing them to cry more frequently and for longer periods. Methamphetamine use during pregnancy puts the mother at a higher risk for spontaneous abortions or miscarriage. Research has shown that children born to parents who use methamphetamine are at an increased risk for neglect and child abuse, in addition to an increased risk of burns and deaths from accidents and explosions in methamphetamine labs in the homes.

Legislation in the United States

Recent increases in methamphetamine production, sale, use, and arrests have led to the creation and enforcement of many new laws. Under the U.S. Controlled Substances Act, methamphetamine is listed as a Schedule II drug due to its high potential for abuse, which may lead to severe psychological or physical

dependence. However, it does have some medical uses, which are limited to narcolepsy and short-term weight reduction programs. As a Schedule II drug, methamphetamine manufactured for medical use is subject to production quotas set by the U.S. Drug Enforcement Agency.

The Federal Combat Methamphetamine Epidemic Act, signed into law in March 2006, placed restrictions on the sale of over-the-counter medications containing primary ingredients used to manufacture methamphetamine such as pseudoephedrine, ephedrine, and phenylpropranolamine products. Purchasers of such products must sign in and are restricted to the purchase of no more than 9 grams of these products in any given 30-day period. In addition, under this act penalties were increased for people manufacturing methamphetamine in residences where children live.

Conclusion

With more information about the use of methamphetamine, federal government, health agencies, and community-based prevention efforts including law enforcement, social services, and educational institutions must plan effective prevention, intervention, and treatment programs to curtail this devastating problem and save lives.

METHODS OF DRUG ADMINISTRATION

Drugs can enter the body in numerous ways. Whether a particular substance is taken for strictly medicinal purposes or for recreational purposes, no effect(s) will occur in the body unless absorption of the substance takes place. In the case of drugs of abuse (i.e., psychoactive drugs), the central nervous system will be activated in some way in order to cause the desired, and often times undesired, effect(s).

Absorption of substances can occur through either an enteral route or a parenteral route. Enteral routes include those methods that require absorption through the gastrointestinal tract (e.g., oral ingestion or rectal absorption). Enteral routes are generally safer in that the active substance may get diluted or broken down prior to reaching the bloodstream; this safety is also a disadvantage in that metabolism of the drug may result in irregular absorption, gastrointestinal discomfort, and/or dangerous metabolic breakdown products. Parenteral routes include all other forms of absorption (e.g., injection, pulmonary, or topical absorption). Parenteral routes are more rapid and eliminate gastrointestinal breakdown; unfortunately, however, the potential for overdose and infection is greatly increased.

In more general terms, there are five common ways in which chemical substances (including illicit substances) enter the body. These include inhalation of volatilized vapors, injection into the skin or bloodstream, absorption by contact with a mucous membrane, ingestion through the alimentary tract, and absorption through the dermis.

Inhalation

The most rapid and arguably the most common method of absorption of psychoactive drugs occurs via inhalation. This method can be used with any substance that can be volatilized and inhaled. Most often a substance is heated or burned until vapors are released, and then these vapors are taken into the lungs. However, vapors need not come from heated substances. Liquids can also be inhaled into the lungs using nebulizers, and any substance that can be turned into tiny droplets can be

inhaled in this way. Owing to the large surface area of the alveoli of the lungs and the millions of tiny capillaries that line these alveoli, drugs that are inhaled can reach the brain in less than 10 seconds.

Medically, inhalation of drugs saves lives because the effect is so fast (e.g., *inhalers* or *puffers* used to counteract acute asthma symptoms). Alternatively, substance abusers find reprieve from withdrawal symptoms quite quickly and reach a rapid and desired high by volatilizing common substances (e.g., methamphetamine and cocaine) that have been buffered into altered compounds (e.g., *crystal meth* or *ice* and *crack cocaine*). The most commonly inhaled psychoactive substance is nicotine. An obvious negative effect of this method of use is irritation of the epithelial lining of the trachea and lungs and the potential development of cancerous lesions.

Because the effects of substances can be felt so quickly using this method, substance users often claim that they can self-regulate their intake until a desired effect is achieved. This ability is easily illustrated by a marijuana smoker who inhales one-to-two puffs or by a cigarette smoker who smokes only part of a cigarette. It should be noted, however, that self-regulation is not an exact science, and substance abusers can easily overdose via inhalation. Indeed, self-regulation via inhalation would require that the user know precisely the concentration of the active substance in the drug of choice, and it is widely known that street-grade drugs vary quite drastically in their concentration.

Injection

This parenteral route of administration is also quite rapid. For illicit drugs, a substance is injected directly into the body in one of three ways, as described below. Note, however, that in addition to those discussed, medically there are four additional injection routes generally not used by illicit drug users:

1. intrathecal—into a cavity or space,
2. intraperitoneal—into the peritoneum or visceral lining,
3. intracerebral—into the brain, and
4. intra-arterial—direct injection into the arteries.

For illicit drug users, the most rapid and most dangerous method of injection is intravenous injection (referred to as *IV* or *slamming*), wherein a user directly injects a substance into the bloodstream and feels the effect(s) in

less than 30 seconds. Because a large amount of a substance enters the body at one time, a rapid and intense rush results. If a user inadvertently injects too much or obtains a substance that is of a higher quality (i.e., concentration) than normal, overdose is often a result. In fact, many substance abusers have been found deceased with a syringe still in their arm. Another route of injection is intramuscular injection (referred to as *IM* or *muscling*), wherein a user injects a substance into the muscle tissue (e.g., steroids). Since the substance must first be absorbed into muscle tissue and then into the bloodstream, effects generally are not felt for 3 to 5 minutes after injection; the large range of time here is because absorption via the muscle depends on the amount of blood flow to the region. The last route of injection is intradermal or subcutaneous injection (referred to as *ID* or *sub-Q* or *skin popping*), wherein a substance is injected just under the surface of the skin (i.e., intradermally) or just under the skin layers (i.e., subcutaneously). As with intramuscular injection, substances taken in this way must first be absorbed through tissue before entering into the bloodstream making the effects less intense and delaying the response by 3 to 5 minutes. Also, this is the leading cause of tissue necrosis in injection drug users, causing ulceration and sloughing of tissue around the injection site. Any of these routes of injection are particularly dangerous since users must use needles, greatly increasing the risk of exposure to a number of bloodborne infections (e.g., HIV, hepatitis) and dangerous adulterants and impurities.

Mucous Membranes

Absorption through the mucosal membranes is another method of drug administration. For certain substances of abuse, insufflation (referred to as *snorting*) provides a common route of exposure that results in the desired effect in 3 to 5 minutes. Insufflation allows drugs to make contact with the lining of the nasal passages, which are heavily lined by blood vessels. Consistent and persistent insufflation can permanently damage tissue and lessen the rate of absorption of psychoactive substances. In addition, the high acidic content of some substances (e.g., cocaine hydrochloride) can permanently damage and/or alter tissues.

Mucosal absorption can also be accomplished by placing a substance under the tongue (referred to as *sublingual* absorption), between the cheek and gum (referred to as *buccal* absorption), or by use of suppositories. Because mucous membranes are found

throughout the body, reports of unusual drug abuse are sometimes noted (e.g., vaginal absorption). Another interesting, and very dangerous, twist to mucosal absorption gained popularity in England and involved *snorting* alcohol. Alcohol absorbed in this way can be particularly dangerous in that this toxin enters the bloodstream rapidly and undiluted since it does not first enter the alimentary system and hence avoids first-pass hepatic metabolism. In addition to snorting alcohol directly, some have experimented with vaporizing alcohol and then inhaling it into the lung tissue (as described for nebulized drugs above). Although proponents claim that the amount of alcohol consumed in this way is small, scientists and physicians warn that there is an increased risk of brain damage.

Digestion

Absorption via the alimentary tract is one of the oldest and most widely used routes of drug administration. Historically and presently, many herbal remedies are taken by drinking various steeped concoctions, and the most commonly employed way to take medications is by ingesting liquids and pills. Certainly, drugs of abuse are often taken by mouth, and alcohol, the most widely used and abused of the psychoactive substances, is primarily taken by ingestion. Most substances, with the exception of limited amounts of alcohol and barbiturates, are not absorbed directly by the stomach. Rather, most absorption takes place in the small intestines. In general, weak acids generally are absorbed more readily from the stomach and weak bases from the intestines.

Ingestion of foods and liquids can reduce and/or slow absorption in the alimentary tract. Further, the liver metabolizes ingested substances prior to their distribution to the body, and this reduces the overall effect of many substances. However, it should be noted that some substances, for example, some benzodiazepines, are metabolized into highly active metabolites by the liver. Owing to liver metabolism and relatively slow rate of digestion, absorption by the alimentary tract is upwards of 20 to 30 minutes.

Contact Absorption

The final route of absorption of psychoactive substances is by contact absorption. Many ophthalmologic drugs are administered by using eye drops because of the relatively large number of ocular capillaries. Interestingly, LSD and other illicit substances have

also been taken in this way. Another common way to absorb drugs is by direct contact with the skin (referred to as *transdermal* absorption). Commonly, medication patches (e.g., fentanyl) and nicotine patches are used to administer low-levels of substances over a long time. Because the low number of capillaries under the skin and the difficulty of getting substances through the dermis, absorption of drugs using this route can take several hours to several days. Absorption can be aided and quickened by the use of certain solvents that are readily absorbed by the skin (e.g., dimethyl sulfoxide).

Research and Summary

The National Institute on Drug Abuse provides educational materials on all drugs of abuse. As can be seen in the adapted illustration (Table 1), many drugs enter the body through multiple routes.

Other than anecdotal reporting of administrative routes of exposure that are commonly part of surveys conducted by researchers and clinicians, few studies are designed with the specific intent of providing drug use methods as reported by the substance-using population. One such study, however, does provide an interesting account of drug use. A study conducted by Carl Latkin, Amy Knowlton, and Susan Sherman consisted of interviews of nearly 1,800 individual drug users in the Baltimore area; about half of the participants were chosen to participate in the study because they reported using opioids and/or cocaine. Of the participants, 63 different patterns of use of heroin and/or cocaine were identified (e.g., heroin insufflation only, smoking crack and heroin). Indeed, simply assessing methods of drug administration can be a complex task, particularly since those who abuse or are dependent on drugs are generally associated with using multiple substances.

Conclusion

Drugs can enter the body in any number of ways. Administration of medically necessary drugs has been extensively studied over the last several centuries to find the most appropriate way to treat particular ailments. In addition, modern chemistry has resulted in more complex administration possibilities (e.g., enteric coating to reduce gastrointestinal breakdown or buffering to reduce stomach upset). Unfortunately, modern street chemistry has also kept pace with medical developments, and hence illicit

Table 1 Drugs of Abuse and Common Administrative Routes

drugs are often designed to be taken in alternative ways to increase the active dose of the drug or to decrease the absorption time into the bloodstream (e.g., smoking crack cocaine as opposed to insufflation of powder cocaine). Other unfortunate side effects of using medical routes of administration for illicit drugs include the potential of developing dangerous infections, accidental overdose because of exposure to high drug concentrations, and the spread of communicable diseases.

MICHIGAN ALCOHOL SCREENING TEST

The Michigan Alcohol Screening Test (MAST) is a patient self-report alcoholism screening measure. The items ask individuals about a range of alcohol-related problems (e.g., Item 10: Have you gotten into fights when drinking?), the extent to which they have had diminished control over drinking (e.g., Item 4: Can you stop drinking without a struggle after one or two drinks?), and symptoms of alcohol tolerance and withdrawal (e.g., Item 19: Have you ever had delirium tremens [DTs], severe shaking, heard voices, or seen things that weren't there after heavy drinking?). Consistently, the MAST has been shown to perform well in identifying individuals who have abused alcohol or been dependent on it.

The MAST contains 25 yes or no questions that are differentially weighted. Individuals complete the MAST individually as a questionnaire or in an interview format. The measure yields an overall score ranging from 0 to 53 by summing individual items as follows: no answers get a score of 0, and yes answers get a score of 1, 2, or 5 depending on the inherent severity of the symptom covered in the item. The recommended interpretation of the total score is for 0 to 4 to indicate absence of alcoholism, 5 to 6 to suggest

possible alcoholism, and 7 or more to indicate probable alcoholism. Symptoms included in the MAST are not explicitly linked to any standard diagnostic criteria for alcohol use disorders.

It takes approximately 5 minutes to administer the MAST and 2 minutes to score it. It can be scored by the administrator or by computer. No special training is required for administration. Several briefer versions of the MAST also are available. These tests include the 13-item Short MAST (SMAST), the 10-item Brief MAST, and a geriatric version called the MAST-G. All of these instruments are in the public domain and do not require permission for use.

The MAST scores have been shown to be consistent when re-administered to the same individuals over brief periods (1-day to 1-week intervals) and several months, demonstrating that the scale is reliable. The MAST also has been shown to accurately detect alcohol use disorders when checked against clinician-interview diagnoses. Different cutoff scores have been examined to yield the best combination of correctly distinguishing individuals with true alcohol use disorders from those persons who do not have drinking problems. Cutoff scores between 5 and 15 have been recommended. The MAST scores also have been shown to correspond with other measures of alcohol use severity. Notably, the originator of the MAST, Melvin Selzer, found that the 13-item SMAST was as effective as the MAST in screening for alcoholism. SMAST scores of 0 to 1 suggest no problems with alcoholism. SMAST scores of 2 point to possible alcohol use problems. SMAST scores of 3 or higher are likely to meet criteria for alcohol abuse or dependence. Selzer concluded that when time is limited, the SMAST may be substituted for the MAST.

The strengths of the MAST include that it can be administered reliably in a variety of clinical and non-clinical settings, including when used in psychiatric settings. It also provides a gross, general measure of lifetime problem severity that can be used for choosing treatment intensity and guiding further inquiry into alcohol-related problems. Because the items do not specify a time frame, however, the scale does not distinguish between current and past alcohol problems and, therefore, is not useful as a change measure. It also does not assess drinking frequency and quantity. Furthermore, because the focus is typically on late-stage symptoms of alcoholism, it may miss less severe use or patterns of use that occur earlier in the course of the illness and thus not perform as well as a screening

measure in populations where drinking patterns may vary more widely (e.g., college students). Finally, because the intent of the MAST questions is straightforward, individuals may easily disguise actual problems related to their lifetime history of drinking.

MINNESOTA MODEL

The Minnesota model refers to a structured treatment model for alcoholism that began in the late 1940s and early 1950s in the state of Minnesota. Today, it is the leading model for addiction treatment for many alcohol and other drug treatment centers in the United States and worldwide.

The development of the Minnesota model of treatment for alcoholism and other drug addiction arose from the confluence of a series of historical events.

This history is recounted in 1993 by Jerry Spicer, who was at the time president of the Hazelden Foundation. Three important events took place involving a small number of recovering individuals and health professionals strongly influenced by Alcoholics Anonymous (AA). These three events reflect an evolution from informal and basic Twelve-Step programs to a more formal, multidisciplinary treatment program.

The first event was the development of what would become known as Pioneer House in Minneapolis, Minnesota. Originating as a treatment center based on the Twelve-Step model and receiving its first support from the city Relief Department in 1948, this recovery program came about through the efforts of Patrick Cronin, the first documented person to recover through AA in Minnesota. He and several other persons in recovery first began an AA club that allowed people to stay over night and that subsequently developed into a treatment center. This first AA-based treatment center was eventually housed in an old stone building that had been a potato warehouse. The program was christened Pioneer House and is now owned by Hazelden and has been renamed the Hazelden Center for Youth and Families, which offers services for addicted adolescents.

Another event important to the establishment of the Minnesota model was the development of Hazelden, a private treatment program for alcoholics first funded in 1949 by a group of Minnesota businessmen on land made available by Richard Lilly who was a local entrepreneur and philanthropist. Lilly was inspired to stop drinking and to help other alcoholics when he fortuitously landed unhurt on a barge full of sand in the Mississippi River after he drove off the side of a bridge while returning home drunk. The Hazelden program in the early 1950s was organized using the principles of the AA program of recovery within a therapeutic community located in a peaceful rural setting.

The third and most important historical event was the establishment of the original philosophy and initial treatment program that would become known as the Minnesota model by two professionals at the Wilmar State Hospital. Wilmar was the only state hospital in Minnesota that was required to accept alcoholics and addicts. Nelson Bradley met Daniel Anderson at a state hospital in Hastings, Minnesota, where Bradley was staff physician and Anderson was an attendant. Later, in 1950, when Dr. Bradley was named superintendent of Wilmar State Hospital, he

hired Anderson as a key staff person. At that time, the hospital housed about 1,800 mentally ill patients, including approximately 100 *inebriates* (a term that was used at the time to refer to persons whose use of alcohol or other drugs caused serious harm). These inebriates were mostly legally committed chronic, desocialized, and homeless alcoholics. Bradley and Anderson recognized that alcoholics and addicts needed a specialized program at the hospital, separate from the mentally ill patients. The first major step was hiring alcoholics as counselors who were in recovery through the Twelve-Step program for the chemically dependent clients at the hospital. This resulted in a 28-day inpatient treatment program with participation in AA and family involvement. A multidisciplinary team was put in place that included physicians, psychologists, social workers, and clergy. Anderson was later hired as director of Hazelden in 1961 and brought with him the key components of the model.

The Minnesota model, developed at Wilmar in the early 1950s, provides the perspective that alcoholism is an illness in its own right, that it is a chronic and primary disease and is in no way due to choice or volition of the afflicted individual. Analysis of the data on early program effectiveness resulted in an important assumption of the model that initial motivation for treatment is not related to outcome. Recovery rates were similar for individuals who voluntarily came for treatment and for those who entered the program as a result of court action or family pressure.

The core of the program has remained stable since its initial development. However, programs, both nationally and internationally, that adopt the Minnesota model as their central organizing structure supplement the basic model with a broad range of other compatible techniques, procedures, and services derived from contemporary clinical practice and empirically based research. Currently, numerous clinically and empirically supported approaches, such as cognitive behavioral therapy, motivational interviewing, and mindfulness meditation, are used to enhance ongoing recovery. Cognitive behavioral therapy is included to address issues such as anger, anxiety, self-pity, and other emotions that put the recovering person at risk of relapse. For example, a series of booklets for both counselors and clients, published by the Hazelden Foundation, focuses on rational-emotive behavior therapy techniques aimed at changing irrational thoughts and behaviors that are associated with

increased relapse potential. Motivational interviewing and mindfulness meditation are used as means to develop meaning and significance for living beyond self-centered interests.

Programs may also provide the opportunity to use cutting-edge medications to reduce cravings or act as antagonists to the physiological effects of various chemicals. Services for coexisting psychiatric disturbances are an important recent component of many programs and are often available through coordination with mental health agencies.

The orientation remains a caring versus curing mode with emphasis on managing the illness rather than on ameliorating it. The Twelve-Step program of recovery provides the essential elements of the treatment process and allows for continuity of support following treatment through AA meetings. The major therapeutic modality of the model is group participation. Groups include a variety of educational lectures and discussions related to the disease of addiction as well as effective strategies for maintaining sobriety. Peer groups are also an important part of the program where individuals in recovery help themselves by helping others. Psychoeducational groups provide knowledge and skills applicable to addiction-related issues, such as anger, blame, resentment, anxiety, grandiosity, self-pity, or procrastination. Finally, groups for family members are important as a means to both educate significant others related to characteristics of addiction, to develop effective roles of family members to foster the recovery process, and to directly help family members whose lives have been negatively impacted by the addicted person.

Evaluation of the effectiveness of Minnesota model of treatment has been an ongoing effort since the late 1950s. In a review of research studies from 1957 through mid 1980s, Christopher Cook concluded that the model has an established research base supporting its effectiveness with the majority of clients who are treated with this model. More recent research completed by Randy Stichfield and Patricia Owens at Hazelden found that 53% of adult clients treated with this model reported abstinence at a 1-year follow-up with an additional 35% reporting reduced alcohol and other drug use. Similar findings have been published regarding the use of the model with adolescents, with 53% of teens who completed treatment reporting abstinence with minor slips over a 12-month period compared to 15% to 28% abstinence of teens who

failed to complete the program or who were on a waiting list control group. In a recent study comparing the Minnesota day clinic treatment program with traditional public psychosocial treatment, researchers in Denmark found that through a 12-month follow-up period, 35% of Minnesota day clinic patients abstained while only 20% of patients treated in the public outpatient clinic did.

Today, the Minnesota model is also known as the Hazelden model due to the Hazelden treatment center continuing the legacy of the original model through ongoing evaluation of research and the enhancement of the model with newer and more effective techniques. Scientific studies of addiction treatment conducted by The Butler Center for Research at Hazelden are made available to addiction professionals and researchers worldwide through educational programs and publications.

MODERATION APPROACHES TO ALCOHOL PROBLEMS

Moderation training and the concept of moderation of drinking at safe levels as a resolution of problem drinking have a long history. Although still somewhat controversial in the United States, moderation training and moderation as a goal of treatment for problem drinkers have wide acceptance in most Western European countries, as well as in Canada and Australia. Historian of addictions treatment William White has identified self-help groups whose aim was promoting moderate drinking rather than abstinence as long ago as the 1880s in the United States. These groups, however, were overwhelmed by the political power of the American Temperance Movement, which focused on abstinence as the only acceptable goal for problem drinkers, and the notion of moderation as a resolution of drinking problems did not surface systematically again in the United States and in Europe until the second half of the 20th century. In 1962, D. L. Davies reported on a series of alcohol dependent individuals who seemed to have achieved moderate drinking after years of problem drinking.

Since Davies's first report, and with the advent of behavioral and cognitive behavioral approaches to treating problem drinking, moderation training has gradually become a mainstream approach outside the United States, although still controversial among U.S. clinicians who espouse Twelve-Step approaches. Nonetheless, because research has supported their effectiveness, moderation approaches have garnered significantly more research attention and significantly more research support than virtually any other treatment approach for alcohol problems. In a 2000 paper in the *Journal of Studies on Alcohol*, Nick Heather and colleagues described behavioral self-control training (BSCT), one form of moderation-focused treatment, as perhaps the most researched single treatment modality in the alcohol problems field and as supported by the second largest number of positive studies of any treatment modality in the literature. Despite having been developed and extensively studied by William Miller and colleagues at the University of New Mexico in the United States, BSCT has been largely ignored by mainstream alcohol treatment providers. Researcher Harold Rosenberg, who has reviewed both predictive factors associated with successful moderation and the acceptance of moderation

approaches by clinicians, has documented that outside the United States, moderation-focused treatments are much more widely accepted and used.

Philosophy

Moderation training approaches fall within a category of interventions that focus on harm reduction rather than on eliminating the use of the substance altogether. Harm reduction approaches, while sometimes incorporating abstinence as a goal of intervention, typically focus on other factors associated with substance use, specifically the negative consequences associated with use. In drinkers whose use of alcohol has created problems, harm reduction approaches, exemplified by moderation training, focus on helping individuals restructure their use of alcohol in ways that will minimize negative consequences associated with drinking rather than on eliminating drinking altogether. Thus, although some individuals who undergo moderation training eventually may elect to abstain from alcohol either permanently or temporarily, most enter moderation training with the goal of reducing their drinking to levels of alcohol consumption that are pleasant and create minimal negative consequences for the individual.

Approaches

Although a number of moderation training approaches have been developed over the years, only a few have been adequately tested for effectiveness. With the exception of the Behavioral Alcohol Screening and Intervention for College Students (B.A.S.I.C.S.) developed by Alan Marlatt and colleagues at the Alcohol Skills Training Program in the late 1980s, all of the most studied and validated moderation approaches were developed in the late 1970s and early 1980s. Three approaches represent the most efficacious approaches to moderation: *Drinkwise* developed at the Addiction Research Foundation in Toronto, Canada, by Martha Sanchez-Craig and colleagues; BSCT, developed by Miller and colleagues at the University of New Mexico; and Guided-Self Change developed by Linda Sobell and Mark Sobell at the Addiction Research Foundation and Nova Southeastern University. At least two other moderation focused treatments have been reported in the literature: a cue exposure program developed and studied by Heather in the United Kingdom, and the

use of naltrexone as a moderation tool reported by Henry Kranzler and colleagues in the United States. Moderation-focused general treatments (which essentially are standard treatments in which the client is allowed to choose moderation instead of abstinence as their treatment goal) have been reported and studied in Sweden, Norway, Australia, New Zealand, Spain, and Canada.

Defining Moderation

One of the critical aspects of moderation training is the definition of moderation that is used in determining when and whether a client has achieved moderate drinking. There are a number of different definitions of moderation that have appeared over the decades since moderation approaches were first developed. Each approach to moderation varies slightly from the others, but all tend to focus around three characteristics: (1) a specific limit to the number of standard drinks per day that a person may consume, (2) a specific limit to the number of standard drinks a person may consume over the course of a typical week, and (3) a specific limit to the number of days in a typical week that the person may consume alcohol. Guidelines also specify different limits for men and women based on research showing distinct differences between men and women with respect to how alcohol is metabolized.

One typical definition of moderate drinking that has been adopted by the support group Moderation Management (MM) is one derived from empirical studies of the relationship between drinking and negative consequences associated with drinking by researchers at the Addiction Research Foundation in Canada and at the National Institute on Alcohol Abuse and Alcoholism. This set of guidelines specifies that for the average man, moderate drinking consists of consuming no more than four standard drinks per drinking day with no more than 4 drinking days per week and a total of no more than 16 standard drinks per week. For women, the guidelines specify no more than three drinks per drinking day with no more than 3 drinking days for a total of no more than nine drinks per week.

Another approach to defining moderate drinking is to use peak blood alcohol concentration (BAC) as the guide. Unlike the specific number of drinks limits described above, peak BAC definitions are fixed. To use the example of MM again, MM specifies a peak

BAC level of .05% as a maximum BAC that the individual may achieve and still be considered to be drinking moderately. Practically, peak BAC guidelines permit much more flexibility than do number of drinks guidelines in that the peak BAC that a specific person will achieve with a specific number of drinks varies by sex, weight, and the duration of the drinking episode. For example, for a 100-pound woman, the number of drinks she may consume and not exceed a peak BAC of .05% in a drinking episode of 4 hours is dramatically less than the number of drinks a 200-pound man may consume in the same 4 hours and not exceed a peak BAC level of .05%. The 100-pound woman may only be able to consume one or two drinks in 4 hours and remain below .05%, while the 200-pound man may be able to consume five or six drinks in the same time period and not exceed .05%.

When comparing number of drinks guidelines with peak BAC guidelines, it is clear that there is great variability in the extent to which the two sets of guidelines coordinate with each other. For a particularly heavy woman, for example, three drinks (the number of drinks considered moderate by MM for women over one drinking episode) will result in dramatically different peak BACs depending on the length of the drinking episode than the same number of drinks will for a petite woman. For this reason, most moderation training programs suggest that clients choose a metric to guide drinking and to develop a personalized set of limits that keeps both number of drinks and peak BAC within safe limits.

Clients

A recurrent question among clinicians has been to ask for which clients a moderation approach is appropriate. Concerned with both ethical and safe practice and in the context of the idea that some clients simply cannot moderate their drinking consistently over time, clinicians are frequently concerned about doing moderation training with their clients.

Research on this question has been somewhat mixed, but generally studies of the efficacy of moderation training approaches have suggested that those clients with lower levels of alcohol dependence are more likely to be able to successfully moderate their drinking over time. Nonetheless, there have been both anecdotal reports and research reports over the past decade that suggest that for more seriously dependent clients who are highly committed to moderating their

drinking, moderation training may be effective. In one study by Heather, in fact, more severely dependent drinkers actually showed greater improvements on a variety of measures of drinking than did drinkers who were less alcohol dependent.

A large body of research on client choice of drinking goals in treatment (moderation or abstinence or a combination) has suggested that when clients are permitted to choose the goal of treatment, they do better regardless of whether the chosen goal is moderation or abstinence. This same body of research has also suggested that working with clients who choose moderation may in fact facilitate a shift in client goal to abstinence among clients who do not, after assessment, appear likely to become successful moderators.

At present, what can be said in response to this question is that clinicians should explain the risks of moderation approaches as well as the potential benefits but then rely upon client preference in guiding treatment in the early stages. Given that many of the skills necessary to successfully moderate one's drinking are also applicable to the maintenance of abstinence, it is likely that actively working toward moderation with virtually all clients who choose that goal will produce positive benefits (either in terms of success at moderating or the provision of strong experiential data supporting goal shift to abstinence) regardless of whether the client achieves successful moderation.

Basics of Moderation Training

The same basic principles are used throughout the various moderation training approaches. The approaches differ from each other along only two dimensions: (1) the extent to which training is coupled with ancillary social skills over and above those detailed below and (2) the extent to which training is therapist delivered versus delivered through bibliotherapy and/or a computer program.

Principles and Variations

Five basic principles are used in all moderation training approaches. These approaches are strongly client centered in the sense that client autonomy and ability to make personal decisions about drinking is recognized and reinforced. The decisions about whether or not to follow particular aspects of the training explicitly rest with the client, as does the choice of

drinking goal. Clients are assumed to be capable of making effective decisions about drinking, and the desire to moderate is not viewed as a symptom of denial or other failure of problem recognition.

Moderation approaches emphasize goal setting and commitment on the part of the client. This emphasis is consistent with research indicating that when clients are strongly committed to specific behavioral goals, they are much more likely to achieve those goals. The key conditions for eliciting commitment revolve around the clinician's respect for and reinforcement of client autonomy and decision-making capacity noted above.

Moderation approaches focus on helping clients understand and adhere to specific guidelines for how many drinks to consume on a given occasion and for how many drinking occasions are safe during a given week. Although the guidelines are specific, as discussed previously, they may be tailored to specific client goals and preferences, all with the aim of helping the client establish a safe relationship with alcohol.

Self-monitoring of either drinking behavior or urges to drink (if the client has decided to abstain in preparation for an attempt at moderation, see below) is a central component of all moderation training approaches with the exception of cue exposure and medication. Clients are taught techniques to assist them in keeping track of drinks within and across drinking episodes. It is usually suggested that clients track number of drinks per drinking day during and after the period of training and to use instances in which moderate limits were exceeded as learning situations to refine their skills at accomplishing moderation.

Even clients who are highly committed to moderation may have days that their drinking exceeds moderate limits (whether general or self-imposed). Contingency planning and tailored skills training is used to help clients cope with these instances and to use them to develop new skills. For example, a client may find that at a birthday party for an old school friend she or he drank more than the drink limit she or he had set. After examining what happened in the situation, the client concludes that she or he was more ready to accede to the urgings of the host to have another one than she or he really wanted to be. In this circumstance, training in saying no thanks gracefully and assertively might be called for to assist this client in coping with similar high-risk situations in the future. Skills training is tailored to specific client self-analyses of drinking episodes in which moderate guidelines are exceeded.

Role of Abstinence in Moderation

Some moderation training approaches suggest that a useful way for clients to begin the process of learning to moderate is to initiate a short period of abstinence, typically 30 days. During that time, several things are accomplished. First, heavy drinking clients essentially detox from alcohol and begin to experience enhanced physical well-being as a result (frequently increased energy, sounder sleep, and a general feeling of better health). Second, the client who begins self-monitoring during this abstinent period will begin to understand more clearly the conditions under which he or she used alcohol to cope rather than as a pleasurable accompaniment to meals or social gatherings. Finally, an abstinence period of 30 days reduces the individual's tolerance to alcohol. For clients who drink largely for the psychoactive effect of alcohol (the "buzz"), this may result in a greater psychoactive effect with less alcohol, thus facilitating the client's efforts to keep within moderate limits.

Personalized and Normative Feedback About Drinking

All moderation approaches make use of some form of personalized normative feedback about how the individual's drinking compares to some general standard (e.g., drinking limits or population consumption levels). One approach, Marlatt's B.A.S.I.C.S., makes use of annual brief sessions with a counselor in which the student is provided with both normative information about how much people in his or her age group actually drink (as opposed to what the individual might perceive based on observations of heavy drinking peers alone) and brief feedback about the individual's own self-reported drinking over time. Combined with minimal social skills training, this approach has been highly effective in randomized controlled trials at reducing alcohol-related harm among college student heavy episodic drinkers.

Variations in Delivery of Moderation Training

As noted above, moderation training has been delivered through several mechanisms. Which of these mechanisms is used depends largely on client preference. Many clients want to have regular face to face contact with a therapist, and moderation training may be delivered in that way. However,

moderation training has also been shown to be effective with less direct therapist involvement. For example, Sobell and Sobell's guided self-change program is essentially a self-help bibliotherapy process in which written assignments are given to clients who then carry them out and check in only periodically with a therapist. Reid Hester has designed a computer administered version of behavioral self-control training, Behavioral Self-Control Training for Windows, that has been shown in a randomized controlled trial to be as effective as a therapist-delivered version of behavioral self-control training. Hester has also designed and tested an Internet-delivered version of Miller's Drinkers Checkup that has also been shown in a randomized controlled trial to be as effective as a therapist delivered version.

Conclusion

Despite their somewhat controversial nature among traditional abstinence-focused treatment providers, moderation approaches are among the demonstrably most effective approaches to helping drinkers reduce drinking-related harm that are currently available. As such, they deserve wider incorporation into treatment programs in the United States than they now enjoy. Outside the United States, where the abstinence-only, temperance-driven ideology that dominates much of alcohol treatment in the United States is less hegemonic, moderation approaches have wide acceptance among treatment providers. Moderation approaches rely on established cognitive behavioral and motivational interventions and form a group of interventions that would likely be much more acceptable to problem drinkers with milder levels of dependence than are current abstinence-focused approaches.

MODERATION IN USE

Moderation in the use of intoxicating substances generally refers to a level of use that is not accompanied by detrimental health or lifestyle outcomes. Although moderate substance use has long held a privileged position in Western society, in the past century, emphasis on moderation has decreased in favor of abstinence. Indeed, proposals that moderate use represents an appropriate, generally harmless, lifestyle choice remain controversial, especially in the United States. However, in the last 3 decades, the scientific community has come to increasingly recognize moderation as a legitimate treatment goal for some individuals with substance use related problems, particularly for those whose difficulties involve the excessive use of alcohol.

Moderation as a Lifestyle Choice

The principle of moderation in the use of intoxicating substances has been recognized since the dawn of Western civilization. The ancient Greeks listed temperance among the four central virtues, and the Old

Testament counseled against drunkenness but also described alcohol as emanating from divine providence. Indeed, an emphasis on moderation characterized Christian doctrine for several centuries, and this orientation remained largely unchallenged until the middle of the 19th century. Early critics of moderation argued that abstinence was a more exemplary stance toward alcohol use, as it presented a more robust defense against moral turpitude than did moderation. Antimoderation sentiment gained popularity throughout the latter half of the 19th and early part of the 20th century in the United States and reached its pinnacle in the ill-fated prohibition movement of the 1920s. Since the repeal of prohibition in the United States in 1933, the moderate use of alcohol has regained widespread acceptance. Indeed, the majority of adults in the United States and other Western nations enjoy alcohol in moderation.

Although moderation is a generally accepted principle in alcohol use, attitudes toward the use of other intoxicating substances continue to emphasize abstinence. The use of cannabis, which is the most widely used intoxicant after alcohol, is prohibited in most Western nations. According to the National Survey on Drug Use and Health, more than 10% or over 25 million adults in the United States report having used cannabis in the past year. These rates of use are comparable to those reported for other Western nations, and in consideration of this widespread cannabis use, several nations have reduced legal sanctions and enforcement of laws related to cannabis. The reduction of these sanctions might allow for a reevaluation of the consequences of moderate cannabis use, and for a more comprehensive determination of the feasibility of moderation with regard to this widely used intoxicant. In contrast to the increasing social leniency toward cannabis, the use of other substances such as cocaine and opioids is associated with severe sanctions in virtually all Western societies. Currently, highly punitive sociolegal attitudes toward these substances prohibit an investigation of whether these drugs may be used in moderation, since their use is inherently criminal and associated with negative consequences.

Moderation as a Treatment Goal

A proportion of individuals who use intoxicating substances experience significant deleterious outcomes and seek professional assistance in resolving their

substance use problems. Trends in the treatment of substance use such as Alcoholics Anonymous and related Twelve-Step recovery programs have emphasized abstinence as a preferred goal of treatment. However, in the past several decades increasing attention has been devoted to treatments including behavioral self-control training and Moderation Management that recognize goals other than abstinence, such as controlled use and harm reduction. Importantly, these programs do not conceptualize moderation as necessarily preferable to abstinence but instead recognize that the adoption of less harmful patterns of use is a viable alternative for many individuals who seek to reduce the negative consequences associated with substance use.

There is substantial empirical support for the efficacy of moderation-based treatments for alcohol use among individuals who have not been severely dependent on alcohol. However, the extent to which moderate use is endorsed as an acceptable treatment goal varies considerably across Western nations. Surveys of Western European nations suggest that moderate drinking outcomes are endorsed by approximately 75% of treatment facilities. In contrast, moderate use goals are endorsed by slightly more than 50% of treatment providers in Canada and by fewer than 30% of providers in the United States. These differences are largely reflective of differences in the treatment cultures of the respective nations. Specifically, the prevalence of the disease model of alcoholism in North America and its reliance on former treatment recipients as treatment providers have resulted in a distrust of alternatives to abstinence. Indeed, powerlessness against alcohol is a central tenet of the disease model and provides an emotionally compelling premise for rejecting moderate use as a valid treatment aim.

Given resistance to the recognition of moderation as a valid aim of alcohol treatment in the United States, it is not surprising that treatments aimed at moderation in the use of other substances has received little support. Nonetheless, the emergence of less punitive attitudes toward substance use in Canada and Europe may be conducive to the development of moderation-based treatments for substances other than alcohol. Such treatments may provide valuable assistance to individuals who struggle with problems related to the excessive use of these substances, but the viability of moderation of use of these substances is an empirical question.

MODERATION MANAGEMENT

Moderation Management (MM) is a harm reduction–focused self-help support group for problem drinkers who want to reduce or stop drinking. MM was founded in 1994 by Audrey Kishline, a housewife from Ann Arbor, Michigan, and incorporated in 1995. Relying on a strong basis in research supporting the effectiveness of moderation training approaches with problem drinkers, MM provides support in several different forms for people attempting to change their drinking habits. MM sponsors face to face meetings around the United States and maintains a number of e-mail list-serves and a variety of international online chat rooms devoted to providing support for MM members in their efforts to reduce drinking to healthy, nonharmful levels. MM also sponsors an online drinking self-monitoring program called Abstar (Abstar and other information about MM can be found on the MM Web site at www.moderation.org). MM has members in the United States, South America, and Europe.

The basic program of MM is based on cognitive behavioral moderation training approaches including William Miller and Ricardo Munoz's behavioral self-control training, and Martha Sanchez-Craig's *DrinkWise*. Drawing on these two well-researched treatments, MM holds a number of assumptions about problem drinkers and behavior change that are

consistent with research in these areas. These assumptions, as listed on the MM Web site, are as follows:

- Problem drinkers should be offered a choice of behavioral change goals.
- Harmful drinking habits should be addressed at a very early stage, before problems become severe.
- Problem drinkers can make informed choices about moderation or abstinence goals based upon educational information and the experiences shared at self-help groups.
- Harm reduction is a worthwhile goal, especially when the total elimination of harm or risk is not a realistic option.
- People should not be forced to change in ways they do not choose willingly.
- Moderation is a natural part of the process from harmful drinking, whether moderation or abstinence becomes the final goal. Most individuals who are able to maintain total abstinence first attempted to reduce their drinking, unsuccessfully. Moderation programs shorten the process of discovering if moderation is a workable solution by providing concrete guidelines about the limits of moderate alcohol consumption.

MM's assumptions are further guided in their implementation by a clearly stated set of values with respect to helping people resolve problems associated with drinking. These values are also stated on the MM Web site:

- Members take personal responsibility for their own recovery from a drinking problem.
- People helping people is the strength of the organization.
- People who help others to recover also help themselves.
- Self-esteem and self-management are essential to recovery.
- Members treat each other with respect and dignity.

Two important components of the MM program are the use of empirically derived drinking limits that assist members in determining what level of drinking is likely to be safe for them, and a recommendation that members begin the process of moderating their drinking by abstaining from alcohol for up to 30 days.

MM's drinking limits are an amalgam of empirically derived drinking guidelines that have been generated

over the years by researchers in both the United States and other countries. The limits, which are considered to be the maximum safe amount an individual may drink during one drinking episode, are no more than four drinks per day for males, with no more than 14 drinks in a given week, and 3 drinks per day for females, with no more than 9 drinks in given week. Members are also provided with blood alcohol concentration (BAC) charts to assist them in calculating their own level of intoxication and helping ensure that even if limits are exceeded on a given day, the member will not exceed a BAC that is safe (generally .05%).

At the beginning of moderation efforts, MM members are encouraged to abstain from all alcohol use for a period of 30 days, although shorter or longer periods are also considered helpful. There are three reasons for this recommendation, which is not a binding one or a prescription but rather a suggestion to members: (1) 30 days of abstinence help lower tolerance so when the member resumes drinking, he or she will experience greater subjective effects with fewer drinks; (2) having a period of 30 days without drinking frequently has significant benefits to the individual's health and sense of well-being with improved sleep and more energy often noted by MM members during periods of abstinence; and (3) eliminating alcohol from the member's life for a short period highlights both situations in which the member is strongly tempted to drink and helps to bring out and clarify ways in which alcohol served as a coping tool for that individual.

MM is the only self-help support group for people who want to resolve problems with alcohol that accepts any healthy change (not solely abstinence) in drinking as a positive outcome. Relying on its values and assumptions, MM promotes members' self-examination and self-regulation in ways that the member chooses and is willing to commit to pursuing. MM is a program of personal empowerment and self-efficacy that rejects the idea that alcohol problems are universally manifestations of a biologically based disease. Although MM specifically supports member efforts of moderation, studies of MM members have shown that as many as 30% pursue abstinence as their primary goal.

Research on MM conducted by Keith Humphreys and colleagues of Stanford University and Ana Kosok of Columbia University has also shown that MM attracts a disproportionately large (compared to other alcohol support groups) proportion of women, that members tend to have less severe drinking problems than people who opt for support from Alcoholics Anonymous (AA),

and that MM members tend to be better educated and more affluent than the average AA member. MM members frequently state that they would never have pursued an abstinence-only program, but nonetheless, many MM members ultimately choose abstinence from alcohol as their goal. These data suggest that MM is the first large-scale personal harm reduction program to reach predominantly middle-class problem drinkers, most of whom are not alcohol dependent and for whom abstinence-only support and change programs are not only unlikely to be acceptable but avoided as well. As such, MM fills a major gap in services for problem drinkers that has been largely unaddressed in the United States.

Controversy and MM

Despite its strong empirical basis and scientific support, MM has not met with a ready reception among treatment providers in the United States. Few programs or practitioners, if any, include MM among the support groups to which their clients are referred. This reflects a continued belief in the United States that abstinence is the only acceptable resolution for alcohol-related problems and that persons seeking help for such problems must be actively induced to pursue abstinence as their goal.

This skepticism with regard to moderate drinking goals and outcomes has persisted and has been a focus of controversy surrounding MM when the group's founder, Kishline, was involved in a drunk-driving accident that resulted in two deaths in the late 1990s. Opponents of moderation approaches generally and MM in particular pointed to the program of MM as being responsible for Kishline's difficulties, despite the fact that Kishline had recognized that she was unable to moderate her drinking successfully and was attending AA meetings for several months prior to the accident. This suggestion that the attempt at moderation was responsible for Kishline's difficulties is an example of the passionate opposition to MM and moderation approaches by many within the abstinence-only community. Despite such opposition, MM has continued to grow, particularly in its Internet-based formats, and is increasingly attracting members from among people who would not seek other abstinence-only support to overcome problem drinking.

MONITORING THE FUTURE

Monitoring the Future (MTF), started in 1975, is a large-scale, long-term study of American youths, college students, and adults through age 45. The study grew out of an increasing concern regarding the health risks of both legal and illegal substance use during adolescence. Illegal drugs emerged from specific youth subcultures to the general adolescent population in the 1960s and have remained a national concern ever since. In order to adequately understand and respond to adolescent substance use, it became obvious that reliable and valid data were needed. For more than 30 years now, the MTF has gathered data that assesses the prevalence and trends of adolescent substance use and has impacted many policy and intervention efforts to curb adolescent substance use.

Since the study's inception, significant changes have occurred regarding the use of and attitudes toward most of the licit and illicit substances investigated in the survey. Among those changes, for example, is the almost incessant emergence of new drugs and alterations of known substances. Thanks to the continuous collection and reporting of self-report data, the MTF has successfully mapped the changing landscape of substance use and its contributing factors among American adolescents and young adults.

The study is conducted by the University of Michigan's Institute for Social Research and has been funded

continuously by a number of investigator-initiated research grants from the National Institute on Drug Abuse. Principal Investigators are Lloyd D. Johnston, Jerald G. Bachman (both are Research Professors and Distinguished Research Scientists at the University of Michigan's Institute for Social Research), Patrick M. O'Malley (Research Professor at the University of Michigan's Institute for Social Research), John E. Schulenberg (Research Professor at the University of Michigan's Institute for Social Research and Center for Human Growth and Development and Professor of Developmental Psychology in the Department of Psychology), and John M. Wallace, Jr. (Associate Professor at the University of Pittsburgh's School of Social Work, Visiting Associate Professor at the University of Michigan's School of Social Work, and a Faculty Associate at the Institute for Social Research).

Study Design and Methods

Goals and Purposes

The underlying rationale for undertaking the MTF study was the belief that the hidden behavior at issue was in need of systematic research and reporting. During the 1960s, adolescent substance use had become more widespread with no indication that use would disappear in the future. The original survey included only self-reports from high school seniors. The age range was subsequently increased to include younger students to account for the fact that the onset of substance use typically takes place during early adolescence. In addition, the researchers argued it was important to survey those adolescents who drop out of school before graduation.

The MTF has 11 key objectives. At the top of the list is the assessment of prevalence and trends in substance use as well as the determination of causal factors contributing to adolescents' use of licit and illicit substances. Furthermore, among other goals, the study seeks to (a) determine risk factors for various patterns of drug use, (b) gain insight into the lifestyles and values inherent in different substance use patterns, (c) examine differences and similarities between different subgroups of adolescent users and nonusers, (d) analyze which social environmental factors contribute to or protect adolescents from substance use, (e) assess the impact of major life transitions (e.g., college, employment, marriage,

pregnancy) on substance use patterns, (f) determine and evaluate age and cohort effects, (g) examine potential consequences of substance use, and (h) investigate trends in multiple substance use.

Sampling and Field Procedures

To achieve the study's objectives, a team of researchers collect extensive data from nationally representative samples of 8th, 10th, and 12th graders. In addition, yearly follow-up surveys are carried out with representative samples of high school seniors until they reach age 30. After that, additional data from those young adults is collected every 5 years. The 2007 wave was the 33rd survey of high school seniors, the 28th of college students, and the 17th survey of 8th and 10th graders in the series.

To date, the study includes between 44,000 and 50,000 secondary school students. About 420 public and private high schools and middle schools participate in the project. For each of the targeted grade levels, data are collected for about 15,000 to 17,000 students. The follow-up surveys include about 8,000 college students and young adults between 19 and 30 years of age.

Data collection takes place during the springtime. A multistage random sampling design is used where geographic areas are selected first, followed by the determination of schools in each selected area, and finally, individual classes in each of the schools. Any resulting unequal probabilities of selection are corrected with sampling weights procedures during the analysis stage.

Parental consent is mandatory for participation in the study. Prior to data collection, parents receive information about the study along with a consent form. However, even with parental consent, participation in the study is voluntary. The survey instrument is administered during a regular class in the students' classroom. Self-report are anonymous for the two lower grade levels, and confidential for high school seniors. Respondents are randomly assigned to fill out one of six questionnaires. Each version of the questionnaire contains a set of core questions about the respondent's background and substance use, as well as different subsets of various categories of questions. In total, there are approximately 1,400 to 1,500 variables across the various survey instruments. Surveys for 8th and 10th graders contain fewer questions.

Key Measures

The core questions of the study relate to substance use. The following drugs are included in the questionnaire: alcohol, tobacco, marijuana-hashish, inhalants, nitrites, hallucinogens (LSD separately), PCP, MDMA (i.e., *ecstasy*), cocaine, crack, heroin, OxyContin, Vicodin, amphetamines, Ritalin (methylphenidate), methamphetamine, crystal methamphetamine (i.e., *ice*), sedatives (barbiturates), Quaaludes (methaqualone), tranquilizers, Rohypnol, GHB (gamma hydroxybutyrate), ketamine, and steroids.

With the exception of tobacco, a set of questions about the frequency of use is asked to determine past-month, past-year, and lifetime usage levels for the various drugs. For cigarettes, questions cover only past-month use. In addition to the regular alcohol use measure, students are asked about the frequency of getting drunk and about drinking five or more drinks in a row (binge drinking). Information on substance use is augmented by questions about age of onset, likelihood of future use, perceived availability of drugs, exposure to drugs, experience of feeling high, perception of the harmfulness of drugs, disapproval of drug use, and attitudes about legalization of drugs. Besides reporting their personal attitudes, students are asked how they think their parents and peers feel about drug use.

A second set of key measures includes questions about respondents' background and demographics (e.g., respondents' sex, race-ethnicity, college plans, residential information, and parental education). Information about the respondents' family situation is collected as well. The survey further covers questions about a series of deviant and delinquent behaviors (e.g., theft, vandalism, drunk driving, and carrying weapons to school), incidents of victimization, deviance proneness (e.g., self-esteem, self-control, and risk-taking tendency), and attitudes toward various issues (e.g., religion, sex roles, ecology, and major social institutions).

Long-Term Trends and Recent Findings

According to reports from the MTF study, the 1990s marked some important changes in the drug-using behavior of adolescents. As risk perceptions and disapproval decreased, the use of illicit substances increased significantly for all three grade levels in the first half of the decade.

In 1997 through 1998, use began to decline for the first time in 6 years. Although numbers dropped significantly for 8th graders during the following years, use among 10th and 12th graders seemed to just level off. In 2002 and 2003, overall use of illicit substances finally dropped significantly among the older age cohorts. Unfortunately, the most recent waves of data indicate that the long-term decline may be coming to an end.

Marijuana

Marijuana, the most commonly used illicit drug among adolescents and young adults, experienced a surge in the early 1990s until 1997 for middle and high school students. More specifically, annual prevalence rates for 8th graders jumped from 6% to 18%, while those for 10th graders more than doubled (from 15% to 35%). Use among high school seniors also rose significantly (from 22% to 39%), albeit not as extremely as in the younger cohorts. Interestingly, rates for college students and young adults were fairly stable during that period. Because of this discrepancy, researchers argue that the changes in consumption behavior witnessed during the 1990s reflect cohort effects rather than broad secular trends. Beginning in 1997, annual prevalence began to slowly decline for 8th graders and modest declines for 10th and 12th grades started 1 year later. The downward trend is still ongoing, though not statistically significant.

A reliable indicator for changes in use has been the measure of perceived risk. Parallel to increases in use, perceived risk of marijuana fell during the late 1970s and again in the 1990s. Disapproval of marijuana use dropped significantly in the 1990s, but has increased some in recent years.

Tobacco

Similar to the overall rate of illicit substance use mentioned above, rates of current cigarette smoking among 8th- and 10th-grade students increased by approximately 50% during the early 1990s. The upward trend halted in 1996 and declined in the following years, but recently the rate held steady, indicating a halt to the long-term decline in current smoking among these adolescents. Long-term trends for current smoking among high school seniors nearly parallel those of the younger cohorts, albeit with a 1-year time lag. Data from college students and young adults

did not evidence declines in the smoking rate until after 1999 and 2004, respectively. Data indicate a clear cohort effect for cigarette use.

According to most recent data, 3% of 8th graders, 7% of 10th graders, 12% of high school seniors, 9% of college students, and 19% of young adults qualify as current smokers. Adolescents most commonly pick up smoking between sixth and ninth grade.

Risk perceptions of smoking decreased between 1993 and 1995, followed by a significant increase until 2000. Since then, data shows a leveling off in perceived risk associated with a pack-a-day smoking. Disapproval of smoking declined in the first half of the 1990s until 1996, when it began to steadily increase.

Alcohol

The majority of survey respondents report experience with alcohol. Approximately 39% of eighth-grade students reported having tried alcohol, compared with 62% of 10th graders. By the time students graduate from high school, 72% have used alcohol. Finally, 85% of college students had had at least one drink in their lifetime. Long-term trends in alcohol use indicate slight declines in drinking among all three grade levels between 1991 and 1995, followed by an upward shift until 1996 to 1997 that corresponds to the trend of increased use of illicit substances during that same period. Since then, more downward drifts materialized, with a significant decrease in drinking after 2002.

More concerning than simply trying alcohol, however, are figures on occasional heavy drinking episodes (five or more drinks in a row at least once in the prior 2 weeks). After gradual increases for all grades in the early 1990s, rates began to decline in the second half of the decade. In 2007, 10% of 8th graders, 22% of 10th graders, and 26% of 12th graders reported heavy drinking. Heavy drinking typically peaks in the early 20s, as evidenced by the 40% of college students who reported engaging in such drinking behavior. Self-reports of having been drunk in the past month have followed a very comparable pattern for all three grades.

Long-term data from the MTF thus evidences that trends and patterns of alcohol use show more similarities with illicit drug use than differences.

Gender Differences

Overall, males are more likely to use both licit and illicit substances than females. Gender differences are

rare and fairly insignificant among the youngest age cohorts. Younger females show slightly higher rates of use only for inhalants and amphetamines. Although males of all ages drink more and drink more often, the gender gap has been decreasing, as is the case for gender differences in use of other substances.

MORAL MODEL

For several hundred years, conceptions of tobacco, alcohol, and drug dependence have been based on incongruent beliefs involving moral judgments and

medical considerations. To this day, neither set of beliefs has supplanted the other. As a result, in the general population there is much disagreement and confusion about the nature of addiction and how to best address problems involving substance abuse. These conflicting views are at the center of the ongoing debate about public policies on tobacco, alcohol, and other drug abuse prevention and treatment. The moral model can be considered the philosophical foundation of much of the U.S. federal drug control policy and the so-called War on Drugs.

Features of the Model

In the moral model, addiction represents a refusal to abide by some ethical or moral code of conduct. Excessive drinking or drug use is considered freely chosen behavior that is at best irresponsible and at worst evil. This conception of addiction does not require one to equate addiction with the sinfulness of committing rape, larceny, or murder. Nevertheless, in this view addiction is seen as misbehavior because substance use is thought to be freely chosen conduct. Persons who are dependent upon a substance are not considered to have experienced a loss of control. Instead, they are seen as selfish and hedonistic and personally responsible for creating suffering for themselves and others. Therefore, they are blameworthy and the justified targets of punishment and are thought to deserve the health and medical problems, employment problems, and legal sanctions that they encounter. Furthermore, punishment is perceived to be a viable and credible means of deterring further involvement in substance use and abuse. Relapse is generally considered evidence of lingering evil that needs to be suppressed with the threat of further sanctions.

In American culture, the moral model of addiction has long been the guiding conceptual framework of politically conservative groups, law enforcement organizations, and some zealous religious communities. Also, U.S. politicians have been known to appeal to this sentiment by proposing tougher legal penalties for possession and distribution of illicit drugs, underage drinking, and for alcohol-impaired driving. Unfortunately, U.S. history is marked by failed government efforts to eliminate addiction via criminal legislation and law enforcement actions. The crack-down on Chinese opium smokers in the 1800s and the enactment of Prohibition in the early 20th century stand as two noteworthy examples.

Disease Models

To fully understand the conceptual underpinnings of the moral model, it is necessary to contrast them with those of the disease models of addiction. In the latter view, substance use and abuse is seen through a different lens—it is considered to be a disease process. Persons who are dependent upon a drug are thought to be suffering from an underlying disease process that causes compulsive use. In other words, the high rate and volume of use are merely the manifest symptoms of a latent or less apparent illness. The exact nature of the illness is not fully understood at this point, but many proponents of the disease models believe that it has genetic origins. For these reasons, it is hypothesized that individuals cannot smoke, drink, or drug themselves into addiction. If the disease (possibly arising from a genetic vulnerability) is not present, then a dependency will not usually develop.

The addiction-as-a-disease conception maintains that the alcoholic and addict are victims of an illness. The afflicted individual is not evil or irresponsible, just sick. Thus, it is believed that substance abuse is not freely chosen; rather, the excessive smoking, drinking, or drugging is seen to be beyond the control of the sufferer. In fact, a common feature of the disease conceptions is believed to be the loss of control over substance use. It is hypothesized that once an addict has consumed a small amount of a drug, intense cravings are triggered via physiological mechanisms, and these cravings lead to compulsive overuse. This mechanism is beyond the personal control of the addict.

Since drug-dependent persons are seen as suffering from an illness, the logical conclusion is that they deserve compassionate care, help, and treatment. Because the condition is considered a disease, medically supervised treatment is thought to be legitimate. Clearly, the acceptance and rise of the disease model of addiction over the past 50 years or so has been responsible for the allocation of resources to help individuals with substance abuse problems. Without the advent of the disease models, it is likely that there would be little, if any, assistance available to substance abusers in the United States today.

There are also a number of disadvantages to the disease models. Several of the key concepts of these models have not held up under scientific scrutiny. For example, the loss-of-control hypothesis, the supposedly progressive course of alcoholism, and the belief that a return to controlled drinking is impossible are all

propositions that have been seriously challenged by scientific investigations.

Supreme Court Decision of 1988

In 1988, the U.S. Supreme Court weighed in on the controversy surrounding the two competing definitions of alcoholism. In a 4-to-3 ruling on a narrow issue, the court concluded that the Veterans Administration had the authority to define some types of alcoholism as a willful misconduct rather than as a disease in determining eligibility for specific veteran benefits. Writing for the majority, Justice Byron R. White indicated that the court was not deciding whether alcoholism was a disease, but instead was upholding the authority of the Veteran's Administration to make decisions about the treatment of a disorder that, according to medical research, is not fully understood. The majority opinion stated that under these circumstances, it was reasonable for the Veteran's Administration to identify alcoholism as willful misconduct.

Behavioral Science Theories

In addition to the moral model and the disease models, there are number of other conceptual frameworks that arise out the social and behavioral sciences that provide a distinct perspective on the nature of addiction and how to address these problems. The position of some in the social and behavioral sciences is that addiction is a learned pattern of behavior shaped by the same laws that shape all human behavior. Essentially, then, addiction is learned. It is neither sinful (as the moral model purports) nor out of control (as the disease models purport). Instead, it is seen as a problem behavior that is clearly under the control of environmental, family, social, and/or even cognitive contingencies. As in the disease models, the person with an addiction problem is seen as a victim—not a victim of a disease, but a victim of destructive learning conditions. For the most part, addictive behavior is not freely chosen, although some behavioral science theories (e.g., social learning theory) do assert that addicts retain some degree of control over their drinking or drug use.

It is important to understand the value placed upon objectivity in the behavioral sciences. When alcoholism (or addiction) is described as a maladaptive behavior, this description is very different from

describing the condition as misbehavior (the moral model). Behavioral scientists avoid passing judgment on the rightness or wrongness of substance abuse. By maladaptive, the behavioral scientist means that the behavior pattern has destructive consequences for addicts and/or their families (and possibly society). It does not imply that the addicts are bad or irresponsible.

In this behavioral science view, the most appropriate interventions are based on learning principles and definitely not on punishment as advocated by the moral model. Typically, clients are taught skills to prevent relapse. The medical aspects of treatment are attended to when necessary, but they are generally deemphasized. Interventions based on behavioral science theory are labor intensive and evaluation focused. Though these characteristics are consistent with today's emphases on efficiency and accountability, many prevention and treatment programs are slow to adopt this kind of empirical approach because of inadequate resources and training opportunities.

Conclusion

The moral model will not fade in importance because it has several advantages over those perspectives that embrace disease conceptions or other theories. One advantage of the moral model is that it is straightforward and clear. There is little ambiguity or murkiness associated with this viewpoint. Furthermore, it is absolute; there is no need for theorizing or philosophizing about the nature of addiction. Addiction is thought to simply be wrong behavior that needs to be confronted and addressed with punishment. Scientific investigation of the problem is believed to be unnecessary because that which must be done to correct it (i.e., provision of punishment) is already well understood. In this view, our society's inability to adequately address substance abuse problems reflects a widespread moral decay and the decline of conservative, family-based values.

Nevertheless, the moral model also has several weaknesses. First, science suggests that tobacco, alcohol, and other drug dependencies are anything but a simple phenomena. They appear to be multifactorial in origin, stemming from pharmacological, biological, psychological, and social factors. The apparent complexity of addiction is underscored by the variety of diverse theories seeking to explain it. Moreover, as

science has begun to shed light on various aspects of compulsive substance use and abuse, it has become clearer that much still remains to be learned. The genetic vulnerability hypothesis, alcohol expectancy theory, and the purported stabilizing effects of alcoholism on family structure are all cases in point.

Another disadvantage with the moral point of view is that it is not at all clear that these dependencies are freely chosen. The various disease models of addiction maintain that exactly the opposite is the case. That is, excessive drinking or drugging represents a loss of control that is considered a chief symptom of an underlying disease process. A further point of departure is offered by the behavioral sciences, where, at least in several theoretical perspectives, a high rate of drug self-administration is understood to be under the control of social or environmental contingencies. These contingencies are usually external to alcoholics or addicts and are not under their personal control. Thus, both the disease models and the behavioral sciences challenge the notion that addiction is willful misconduct.

A third disadvantage with the addiction-as-sin position is that history suggests that punishment is an ineffective means of reducing the prevalence of addictive problems in the population. Aside from the possibility of inhumane sanctions, a reasonably strong case can be made, based upon historical precedents, that striking back at substance abusers via governmental authority simply does not work over an extended period of time. Law enforcement crackdowns often have the unintended effects of being an impetus for strengthening organized crime networks, creating underground markets, bolstering disrespect for the law, clogging court dockets, and overloading prison systems with inmates convicted of drug crimes.

MORPHINE

Morphine is an opioid that acts directly on the central nervous system to relieve pain. Morphine, in effect, mimics our endogenous opioids. Morphine also produces sleepiness, mood alteration (euphoria or dysphoria), reduced gastrointestinal motility, diminished respiration, peripheral vasodilatation, and pupil contraction. Morphine can be administered through injection, orally, by inhalation, through rectal suppositories, and is available in capsules and in extended-release tablets. Some chronic pain patients have an implanted morphine pump. Morphine is also used for epidural injections. Morphine is the only opioid that has been approved by the Food and Drug Administration for intrathecal administration. Morphine crosses the placenta and has been found in breast milk. Morphine is contraindicated for use in patients with acute alcoholism, delirium tremens, convulsive disorders, acute pancreatitis, renal failure, bronchial asthma, and head injury.

Morphine is a derivative of the juice of the opium poppy, *Papaver somniferum*. By weight, morphine constitutes about 10% of opium, the coagulated juice of the poppy plant. Since pure morphine is not very water soluble, morphine is generally produced as a morphine sulfate, an odorless white crystalline powder that darkens with exposure to light.

In about 1805, Friedrich Wilhelm Serturmer, a German pharmacist, was the first to isolate and identify the organic alkaloid compound, morphine, from the gum resin excreted from the opium poppy. Serturmer used hot water to extract the opium and then used ammonia to precipitate out the bitter crystalline morphine. This research set the stage for the identification of other alkaloids, such as strychnine in 1818, caffeine in 1821, and nicotine in 1828. Serturmer named his new substance morphium after the Greek god of dreams, Morpheus. By the 1820s, morphine was available from pharmaceutical companies and other sources across Western Europe. By the 1850s, the development of hypodermic syringes with hollow pointed needles by Francis Rynd and Charles Pravaz permitted the widespread administration of morphine. Morphine was initially used as a cure for opium addiction, as well as for its analgesic and antitussive effects. Like many other drugs, morphine became hailed as a panacea soon after its introduction. The regular use of morphine by soldiers during and after the U.S. Civil War, as well as the subsequent Franco-Prussian War in Europe, led to morphine addiction being known as the *soldier's disease*. During the 19th century, morphine was commonly used in remedies for assorted conditions, including headaches, diarrhea, menstrual pains, and colic. Morphine was thought to be a useful cure for alcoholism, even though it was known to be addictive. Physicians and others considered alcoholism to be worse than morphine addiction. It was regularly included in an array of patent medicines and could also be ordered by mail. Growing public concern with this accessibility led to the passage of the Pure Food and Drug Act in 1906 and then to the Harrison Narcotic Act in 1914. An unintended effect of the Harrison Narcotic Act was the closure of the few drug treatment programs then available. Ironically, heroin was introduced to treat morphine addiction. Heroin is metabolized into morphine by the removal of the acetyl groups.

Morphine is a highly effective painkiller. It is commonly prescribed for the relief of severe pain, such as that associated with surgery or cancer. Side effects of morphine include nausea, vomiting, constipation, blurred vision, lethargy, and respiratory suppression. The effects of morphine are generally potentiated by alkaline substance and antagonized by acidic substances. The analgesic effects are potentiated by melatonin, methocarbamol, and chlorpromazine.

Morphine is a highly addictive substance, with tolerance and dependence developing rapidly. The direct analgesic effect of morphine appears to become attenuated over the history of use. Successive administration of the drug appears to elicit a compensatory learned hyperalgesic response leading to tolerance. This process seems to be a combination of the conditioned association to the rituals accompanying use as well as to the systemic effects of the substance. Overdose is possible, resulting in depressed respiration, constriction of the pupils, cold and clammy skin, stupor or coma, sometimes accompanied by drop in a blood pressure and slowed heart rate. The effects of morphine can be countered by the use of opioid antagonists, such as naltrexone or naloxone. Methadone and buprenorphine have been used to treat morphine addiction. Clonidine (Catapres) can be used for relief of withdrawal symptoms. Rapid detoxification has been attempted through joint administration of clonidine and naloxone. Levo-alpha acetyl mehadol (i.e., LAAM) and naltrexone, a longer acting opioid antagonist, can be given to prevent relapse. The half-life of morphine is between 1.5 and 4.5 hours. Morphine is eliminated primarily through renal excretion.

Physical dependence to morphine results in moderate to severe withdrawal symptoms in those who suddenly stop using the drug. Signs of withdrawal can include restlessness, drippy nose, teary eyes, sweating, yawning, gooseflesh, and sleep disturbance during the first 24 hours, with other symptoms becoming more severe over the next 72 hours including extreme irritability; anxiety; nausea; spasms and twitching of muscles; abdominal, leg, and back pains; hot and cold flashes; diarrhea; vomiting; and insomnia. Although extremely uncomfortable, the symptoms of withdrawal are not physically dangerous in otherwise healthy individuals. However, it is important to maintain appropriate fluid and electrolyte balance during the abstinence syndrome. Withdrawal treatment is primarily supportive and concerned with symptom relief.

Morphine sulfate is marketed under names such as MS-Contin, Infumorph, Roxanol, Duramorph, Oramorph, and MSIR. In the United States, morphine is classified legally under the Controlled Substances Act (21 U.S.C. 801–886) of the Comprehensive Drug Abuse and Prevention Act 1970 as a Schedule II drug by the Drug Enforcement Agency (DEA Number 9300). Schedule II drugs have a high

potential for severe dependence but can be medically useful, such is clearly the case with morphine. Internationally, morphine is listed as a Schedule I drug under the Single Convention on Narcotic Drugs.

MOTIVATIONAL ENHANCEMENT THERAPY

Motivational Enhancement Therapy (MET) is a counseling approach that combines motivational interviewing (MI) and personalized feedback of assessment results. This intervention can be applied to a wide variety of behavioral domains but originated in the area of addictions and has been most widely applied to individuals with alcoholism and substance use disorders. MET was developed and tested empirically in a format that involved an assessment of factors related to the early effects of alcohol and a 1-hour review of results in a MI consistent style. Although the term *Motivational Enhancement Therapy* was first used to describe the treatment approach used in Project MATCH (described further in this entry), it has broadened to signify the combination of MI and feedback within any clinical or research context. In fact, the first application of MET occurred before its implementation in Project MATCH, and many trials since Project MATCH have used the approach. Since its inception, MET has been tested in a variety of clinical trials and among populations with varying substance abuse issues. The intervention is generally effective, although there is high variability in its effect.

Motivational Interviewing

MI is therapeutic approach that aids individuals in exploring and resolving ambivalence about change. The approach is consistent with client-centered treatment approaches, as it relies heavily on the expression of empathy through reflective listening. However, MI is also directive in its use of techniques to facilitate the exploration of ambivalence and draw out client arguments for change.

MI operates under the assumption that motivation to change should be elicited from the client, instead of imposed from without. In MI, the interventionist resists taking on the expert role and instead seeks to join patients as a nonjudgmental companion in their exploration of ambivalence. MI is intended to facilitate change by aiding patients in identifying and mobilizing their own intrinsic values, helping them to develop discrepancies between these values and their current behavior, and encouraging and supporting commitment to change. The developers point out that, while specific learnable skills are an important part of the intervention, if it is seen simply as a collection of techniques, its spirit and likely effectiveness will be lost.

MI was first described by William Miller as an extension of his intuitive clinical perspectives on the nature of change. The intervention was further described and elaborated by Miller and Stephen Rollnick in the book *Motivational Interviewing: Preparing People for Change*, which is now in its second edition. The first empirical tests of MI were actually tests of MET, as they combined the intervention with reporting of personalized assessment results.

Early Applications

The first empirical tests of MET were conducted by Miller, the codeveloper of MI, in the late 1980s. In multiple clinical trials, MET was tested as part of an intervention labeled the Drinkers Check-up, in which individuals were given a 2-hour battery of assessment instruments that are sensitive to the early effects of alcohol. Assessment instruments included behavioral measures, such as quantity and frequency of alcohol use, neuropsychological measures, such as executive functioning and attention tasks, and biomedical indexes, such as serum samples to be assayed for liver function. Following assessment, Drinker's Check-up participants received personalized

objective feedback in which their assessment scores were compared to normative samples or other objective criteria. Participants were given a written personalized feedback report, which was reviewed by a clinician who helped the participant to understand and interpret the feedback relative to normative samples. Consistent with MI, feedback was given in a client-centered, empathic style, and labeling and confrontation were avoided.

Early applications of the Drinker's Check-up found that self-referred problem drinkers who received the intervention experienced significant reductions in drinking. A follow-up study compared feedback styles, randomizing participants to an MI-consistent or confrontational style. No significant differences in outcome were found between the two groups, but variability in therapist style led the researchers to conduct post hoc analyses in which they determined that confrontational therapist behavior was highly correlated with poor drinking outcome.

Several other early investigations tested the efficacy of the intervention as a prelude to treatment entry. In the first randomized study on the topic, outpatient substance abuse patients either received MI-consistent feedback of assessment results or an attention-placebo intervention at intake to treatment. Results demonstrated that MI patients had improved outcomes and were more likely to attend their first outpatient treatment session. Follow-up investigations replicated the findings with different populations and settings. MET was found to enhance treatment engagement when added to the intake session of residential alcohol treatment participants. In addition, MET was found to be an effective prelude to treatment for polysubstance-using outpatient adolescents.

Large Multisite Trials

Following the promising early findings of MET, the intervention has been tested more extensively in large, multisite clinical trials. Three of those trials, including Project MATCH, the Cannabis Youth Treatment project, and the Clinical Trials Network community-based studies, are discussed.

Project MATCH

The Drinker's Check-up was expanded to a four-session intervention, and a manual was created for Project MATCH. Project MATCH was a large, multisite

clinical research trial, designed to test whether specific patient characteristics interacted with treatment modality to predict outcome. Alcohol outpatients and aftercare patients were given an extensive assessment battery and randomized to one of three treatment conditions, including 12 sessions of cognitive behavioral therapy, 12 sessions of Twelve-Step Facilitation therapy, or 4 sessions of MET. Few specific patient-treatment matching results were found in the trial, and few differences in outcome were noted between treatment condition. However, all interventions resulted in significant improvements among participants, including the shorter duration MET intervention.

The MET intervention tested within Project MATCH was composed of four treatment sessions spread out across 12 weeks. The first two treatment sessions focused on feedback of assessment results, exploration of motivation to change, and discussion of future plans. The last two sessions took place at 6 weeks and 12 weeks and were designed to further explore change and reinforce progress. The Project MATCH intervention manual describes the basic principles of MI, including expressing empathy, developing a discrepancy, avoiding argumentation, rolling with resistance, and supporting self-efficacy. The intervention is described in two phases. In phase one, the therapist builds motivation for change by presenting feedback and eliciting self-motivating statements through the use of reflective listening and other important strategies. In phase two, the therapist is encouraged to recognize readiness for change and strengthen commitment through information, advice, and the development of a change plan. The intervention also allowed for the inclusion of a significant other.

Cannabis Youth Treatment Project (CYT)

As part of the CYT project randomized, multisite clinical trial, MET was combined with cognitive behavioral therapy (CBT) to form a five session intervention for outpatient youth with cannabis use disorders. The intervention combined two sessions of individual MET with three group session of CBT. CYT was designed to test the efficacy of this intervention compared to other interventions, including 12 sessions of adolescent Community Reinforcement Approach, 12 sessions of multidimensional family therapy, and two interventions that added additional sessions to the MET-CBT combination. In the trial, all interventions were found to improve participant substance use

across time, and no differences between interventions were found. However, the MET-CBT combination was more cost-effective.

The MET-CBT intervention has a corresponding manual, which describes the intervention protocol for the two sessions of MET. During the first session, therapists are encouraged to build rapport and increase motivation for change by helping youth explore and resolve ambivalence about change. In addition, the feedback report is reviewed. During the second session, goals are identified and participants are prepared for CBT group sessions. CBT sessions focused on developing skills for living a drug-free life, but therapists were encouraged to rely on their MI skills throughout the intervention.

Clinical Trials Network Studies

Two multisite investigations of MET have been conducted within community-based treatment programs that are part of the National Institute on Drug Abuse's Clinical Trials Network. In the first study, investigators compared outcomes for outpatient substance users who received a standard intake-evaluation with those who received an intake-evaluation with components of MET. Consistent with the goals of the Clinical Trials Network, the study was done using community-based treatment programs and therapists. MET participants were found to have increased treatment retention; however, differences in substance use were not observed. The MET intervention is described in a manual that is based on adaptations of other manuals, including Project MATCH. The intervention involved providing feedback in an empathic style and eliciting change talk using directive MI techniques.

In another Clinical Trials Network multisite trial, outpatient substance users were randomly assigned to three sessions of MET or three session of standard treatment. The intervention embodied the spirit of MI, using client-centered and directive strategies to elicit change talk and motivation to change. No differences in treatment retention or short-term substance use outcomes were observed between the two groups. However, long-term substance use outcomes were superior for MET participants. Follow-up analyses revealed a variety of factors that interacted with treatment condition, including differential effects across sites. An intervention manual was created and that was based largely on the Project MATCH manual.

Other Outcome Studies

Given the early promising findings MET, the intervention has been widely studied in a variety of alcohol and substance use settings. In fact, the majority of clinical trials that have been conducted on the efficacy of MI in addictions use a MET intervention format. Clinical trials have expanded in breadth from early alcohol studies to include investigations targeting opioid, cocaine, marijuana, and dually diagnosed patients. Recent meta-analytic findings suggest that MET generally has a positive impact on patients, with moderate effect sizes observed when comparing it to other treatment approaches. However, results vary widely across studies, with some investigations finding highly positive findings when comparing MET to other evidence-based interventions and other investigations failing to find positive effects when comparing MET to standard care. This variability in findings can also be found within multisite clinical trials, where the effects of MET have been found to vary significantly by site. Several factors have been hypothesized to influence this variability in outcomes. For example, MET may show diminished effectiveness when applied to substance users with multiple psychosocial risk factors. In addition, MET interventions which are limited to one treatment session may be less promising. Finally, differences in therapist training vary widely across and within studies, likely contributing to variability in outcome.

Conclusion

MET is a widely utilized treatment approach that combines MI and the reporting of personalized feedback results. MET was first tested empirically with patients with alcohol problems as part of the Drinker's Check-up. Further studies tested MET as a prelude to treatment or as a part of the treatment intake process. The promising early findings of MET led to several randomized, multisite clinical trials and other investigations that have had generally favorable, but variable results.

MOTIVATIONAL INTERVIEWING

Motivational interviewing (MI) is a client-centered, directive therapy for helping individuals to explore and resolve ambivalence about change. Although MI has been applied to a wide variety of behavioral domains, it arose as a treatment for substance abuse and has been most widely tested and applied in this area.

Overview

MI is a therapeutic approach designed to help individuals explore and resolve ambivalence about change. The approach is both client-centered and directive in its use of techniques to facilitate the exploration of ambivalence and draw out client utterances regarding change. MI can be implemented in a variety of formats and by a range of interventionists. However, it is typically applied as a brief intervention of one to two

sessions. Thus, its duration is often much shorter than most other evidence-based substance abuse treatments. MI can be administered as a stand-alone treatment, as a prelude to other treatment approaches, or in combination with other interventions. It is also commonly combined with objective feedback. Treatment agents also vary greatly, ranging from physicians to community layperson volunteers. The flexibility of MI makes it applicable to a wide variety of settings, but this diversity in applications can present some challenges to researchers who wish to draw generalized conclusions regarding its effect.

Brief History

MI was originally conceptualized by William Miller, who was influenced by clinical experience, previous psychotherapy traditions, and empirical findings in cognitive psychology. Miller credits the formal conceptualization of MI with a sabbatical experience in Norway during which he was encouraged by trainees to explain and verbalize decision rules for his clinical approach. This process motivated him to describe the rationale for his approach in writing. After publishing his first description of MI in 1983, Miller joined with Stephen Rollnick to further develop the intervention and to create the first edition of the book *Motivational Interviewing* in 1991. The book is now in its second edition.

MI has its roots in client-centered, Rogerian therapy, which holds that all individuals house within them the potential to change and that unconditional positive regard by therapists can help germinate positive change. Both techniques rely on the use of reflective listening to communicate empathy and facilitate exploration of change. However, although traditional client-centered therapy is nondirective in its use of reflective listening, MI uses reflective techniques strategically to encourage the exploration of ambivalence and elicit change talk.

Several cognitive psychology principles also influenced the development of MI. Cognitive dissonance theory argues that perceived discrepancies between beliefs and behavior are uncomfortable for individuals and can motivate them to reduce dissonance by changing their behavior. MI relies on this principle in its attempts to help clients identify important goals or values and then develop a discrepancy between these goals and values and their

current behavior. In addition, Daryl Bem's self-perception theory holds that individuals' beliefs can be influenced in part by their own verbal behavior. Consequently, MI aims to facilitate change talk and commitment language on the part of the client.

Spirit

The developers of MI point out that, while specific learnable skills are an important part of the intervention, if it is seen simply as a collection of techniques, its spirit and likely effectiveness will be lost. MI is intended to facilitate change by aiding clients in identifying and mobilizing their own intrinsic values, helping them to develop discrepancies between these values and their current behavior, and encouraging and supporting commitment to change. To achieve these goals, the therapist operates within the spirit of MI, relying on certain assumptions regarding the nature of human change. Three important constructs help describe the spirit of MI: collaboration, evocation, and autonomy.

Collaboration

The relationship between client and therapist is seen as an important aspect of MI. Instead of the expert–recipient dynamic that dominates many psychotherapeutic interventions, the client and therapist are seen more as partners or companions. The role of the therapist is to join with the client and be supportive through the exploration of ambivalence. In this role, the therapist is encouraged to be aware of his or her own aspirations and avoid direct persuasion, as this is seen as an ineffective means of promoting behavior change. As the developers point out, because of this, the intervention can often be perceived as quiet and eliciting when compared to more directive or skills-based approaches.

Evocation

Within MI, motivation to change is not imposed from without, but elicited from the client. Interventionists often see themselves as being uniquely situated to see the potential dangers of clients' behaviors and hold a great deal of information regarding corrective courses of action. This position can lead to temptation to use direct persuasion as a means to change

behavior, despite evidence that suggests that this approach is not effective. In MI, instead of the therapist generating reasons and contingencies to stimulate behavior change, interventionists are encouraged to identify and mobilize the client's own intrinsic motivation. MI operates under the assumption that clients have important goals and values that, if drawn out, can promote healthy behavior change.

Autonomy

Within MI, responsibility for change lies with client, and it is the therapist's job to communicate and respects the client's freedom of choice. Here, it is the client's responsibility to articulate and resolve his or her own ambivalence. The therapist can support this process by affirming that the client has the ability and right to make decisions about change that are in line with his or her goals and values.

The Four Principles

Several basic principles are key to the successful implementation of MI, including expressing empathy, developing a discrepancy, supporting self-efficacy, and rolling with resistance.

Expressing Empathy

Within MI, empathy is largely operationalized as the skillful application of reflective listening, or accurate empathy. This therapist behavior is thought to communicate to the client that he or she is accepted and understood, as it provides a safe atmosphere for the client to explore ambivalence and decisions about change. MI operates under the seemingly paradoxical principle that respectfully accepting clients' ambivalence toward change, including positive feelings about maladaptive behaviors, is the most effective means of motivating positive behavior change.

Developing a Discrepancy

In addition to communicating an acceptance and understanding of the client, MI techniques can be used in a strategic manner to help clients resolve ambivalence in the direction of positive behavior change. One such technique involves helping clients to consider important goals and values in the context

of their current behavior. When a discrepancy exists between these constructs, the client may then be motivated to reduce dissonance. In seeking to develop a discrepancy, although the MI therapist may encourage the client to identify and articulate what is important to him or her, consider values in the context of current behavior, or imagine the future having and not having made changes, it is the client who must ultimately determine whether a discrepancy exists and whether that discrepancy is sufficient reason to change.

Support Self-Efficacy

In MI, it is acknowledged that a desire to change may not be sufficient to motivate change, if the individual does not believe that he or she is capable. Clients' beliefs about their chances of success can often influence behavior in a way that makes them self-fulfilling. Consequently, another goal of MI is to increase the client's confidence regarding his or her chances of success. To accomplish this, MI utilizes techniques that affirm strengths and past successes and emphasize personal responsibility for change.

Roll with Resistance

MI views resistance as a byproduct of the interaction between client and therapist. Consequently, a strong emphasis is placed on the importance of therapist behavior in response to such resistance. Therapists are encouraged to respond to resistance with acceptance and empathy, versus confrontation, counter-arguments, or therapist generated reasons to change. MI also normalizes resistance, by seeing it as normal aspect of ambivalence and representative of the clients underlying struggle to find resolution.

The Core Skills: OARS

Four basic skills can be used to help accomplish the goals of MI.

Open-Ended Questions

Open-ended questions are inquiries that cannot be answered with a simple yes or no response and instead encourage the client to speak in more depth about a particular issue. This technique is often used to provoke client talk (e.g., "What brings you in today?") or steer the conversation in specific directions

(e.g., "What have your friends and family said about your substance use?"). Open-ended questions can also be used to help clients explore their ambivalence (e.g., "What are some things you like and don't like about your substance use?") or can be strategically placed to encourage clients to think about their behavior in different ways (e.g., "If you continued using substances in this way, what do you think your life might be like 5 years from now?"). Open-ended questions can be used in a directive fashion to accomplish the goals of MI; however, interactions that take the form of question-answer-question-answer may reduce collaborative spirit and restrict exploration on the part of the client.

Affirmations

Affirmations are statements that reinforce client strengths, efforts, progress, or accomplishments. Affirmations can take many forms, including compliments (e.g., "You have accomplished a lot since our last meeting.") and expressions appreciation (e.g., "I appreciate you taking the time think about these difficult issues with me."). Affirmations serve to reinforce positive client behaviors, increase rapport between client and therapist, and build confidence or self-efficacy.

Reflections

Reflections are the most commonly utilized skill within MI. Therapists implementing MI actively listen to clients using reflective listening techniques, with the intention of helping clients to feel heard, valued, and understood. Within MI, reflections are conceptualized as hypotheses or guesses about the meaning of what a client has said. Reflections can vary in depth, ranging from simple repetitions of what the client has said, to paraphrases that have increased depth or add meaning. Reflections can also vary in focus, being strategically used to highlight the emotional content or ambivalence in client utterances. Structurally, reflections are formed as statements that inflect down at the end. Using reflective listening helps ensure that the therapist is accurately understanding the meaning of what the client has said and communicates to the client that the therapist is interested and invested in understanding. Reflective listening allows the client to openly explore ambivalence in an environment that is nonjudgmental and free from unsolicited advice.

Summaries

Summaries are a special form of reflection in which the therapist reflects back a larger sample of a client's thoughts or feelings. Summaries are commonly used to highlight ambivalence, reflecting two or more ways that a client feels about a situation. In addition, they can be used to highlight discrepancies in a client's behavior, by reflecting what is important to the client and his or her current high-risk behaviors. Finally, reflections can be used to transition for one topic to another or at the end of a session to integrate the information that has been shared by the client.

Empirical Evidence

Many clinical trials of MI have been conducted in the area of substance abuse. One early clinical trial of MI that helped to establish it as a valid treatment approach was Project MATCH, a randomized, multi-site clinical trial comparing Twelve-Step Facilitation therapy, cognitive behavioral therapy, and an adaptation of MI, Motivational Enhancement Therapy. All three interventions in the clinical trial were found to perform equally well in the treatment of alcohol-dependent clients. Despite this finding, other studies have generally found positive findings with small to moderate between-group effect sizes in the areas of alcoholism, substance abuse, and treatment engagement. Results to date appear less promising in the area of smoking cessation, with MI not appearing to consistently add any benefit to other commonly utilized treatment approaches. MI has also been shown to improve client behavior in areas related to substance abuse, such as high-risk sexual behavior and medication compliance.

Drawing generalized conclusions regarding the efficacy of MI has been challenging to researchers since it has been applied and tested in a variety of formats. In addition, clinical trials vary in their comparative method, with some studies comparing control groups or comparison interventions with pure MI and others combining or adding MI to another form of treatment. Early evidence seems to suggest that MI often performs equally as well or superior to other established treatments and that any superior effects of MI tend to be prolonged when MI is added as a prelude or adjunct to another treatment. In addition, preliminary research seems to suggest that MI may work better with Latino and African American populations.

In addition to outcome research, some process research has been conducted on MI. The role of language has been identified as a particularly salient factor. MI consistent therapist techniques have been found to increase client change talk, or expression of the desire, ability, reasons, need, and commitment to change. In turn, the presence and strength of this language within sessions has been found to predict client outcome, leading to an increased emphasis on encouraging therapist behaviors that lead to an increase in client change talk.

Another challenge involved in empirically studying MI is the inconsistency observed in the training of MI therapists. Teaching MI varies widely in both clinical and research settings, ranging from short didactic sessions to multiple day interactive trainings. This issue has been addressed in part by the Motivational Interviewing Network of Trainers, which provides standardized training for MI trainers themselves and has provided guidelines for different types and functions of training. Several treatment fidelity measures have also been developed to measure adherence to the treatment model. Early application of these instruments suggests that ongoing support through feedback, coaching, and supervision is necessary to maintain skillfulness in MI following training.

Conclusion

MI is a clinical approach to the treatment of substance abuse that is unique in its efforts to increase motivation by collaborating with clients and helping them to identify their own personal reasons for change. The spirit of MI is complimented by specific principles and clinical skills that communicate acceptance and confidence in helping clients to explore and identify reasons for change. MI has been tested empirically with generally positive findings, particularly when added as a prelude to another treatment approach or used with minority samples. Finally, early work suggests that clinicians wishing to utilize MI trainings should receive ongoing support following training.

MULTICULTURALISM

Longevity, mobility, and other issues make our population demographics increasingly dynamic. Multiculturalism represents acknowledgement that assumptions, experiences, and meanings are not universal; that the worldviews they give rise to are not identical between or among individuals or groups; and that these numerous perspectives are all valid (even if seemingly undesirable or unjust). In health, mental health, and substance abuse treatment, cultural competency (the ability to work effectively with varied cultures and with that of the current client in particular) is positively correlated with clients' treatment entry, engagement, and favorable outcomes. In the last decade, cultural competency and culturally relevant interventions have been of increasing concern and interest among clinicians; researchers in psychology, social work, and public health; and policymakers as health disparities between non-Hispanic Whites and ethnic minorities persist—at least in part due to lack

of cultural competency. The body of this entry defines and discusses relevant terms, articulates elements of culturally competent practice including skills required of practitioners for cultural competence, discusses current substance use epidemiological data for specific minority groups, and makes suggestions for development and evaluation of substance use intervention programs in light of multiculturalism.

Terms and Concepts

Several concepts and terms are central to the discussion of multiculturalism. *Culture* encompasses the socially constructed patterns, practices, and norms of behavior that guide our daily lives. Explanatory systems, meanings, values, expectations, and boundaries of acceptable or unacceptable behavior are all part of culture. Culture is distinct from one's physical appearance and demographic census category. Culture is socialized and transmitted through interactions with influences around us including interpersonal (e.g., family members, friends, acquaintances), communal (e.g., schools, religious organizations, worksites), and national (e.g., economic systems, mass media, Internet). Daily, people are socialized by others while simultaneously being a socializing agent for others. Each person may simultaneously be part of several cultures: in one's home, work or school, peer group, and community lives. The culture(s) people most identify with become their personal reference framework and have the greatest influence on their beliefs and behaviors.

Further, this framework stems from their personal history and also from the norms, roles, behaviors, expectations, and experiences currently and historically experienced by the cultural groups to which they belong. As culture becomes internalized, each person carries ideas about what is right and acceptable or wrong and unacceptable for others and for themselves. A *worldview* is based on these personal and collective experiences and the collective and individual meanings attached to them. Race and ethnicity are complex constructs that, while often considered to have universal definitions, are in fact the topic of much debate and inconsistent interpretation in the field. *Race* generally encompasses biologically heritable traits that may or may not influence aspects of groups' experiences. Historical and structural factors also play a large part in the conceptualization of race. *Ethnicity* connotes a shared identity among a group of

people, which may stem from cultural (e.g., religious, linguistic), racial, or geographic (regional or national) attributes represented in the group. With both race and ethnicity, it is important to acknowledge that racial identity and ethnic identity are separate constructs and often the more useful constructs to consider when discussing multiculturalism. An important consideration for substance use assessment and intervention planning is that some racial and ethnic groups have histories of horrific injustices and chronic discrimination, sanctioned and maintained by government institutions and the majority population. Consequently, group members may be justifiably dubious of programs and aid offered by government, institutions, or those seemingly different from themselves.

Disability status may be another factor in cultural identification for some individuals. Further, as some believe alcoholism and substance abuse are diseases, clients may link illness and disability status with acknowledgement of their use. Consideration of this and general physical, mental, and emotional disabilities are important aspects of multiculturally competent care. Social class is not yet universally addressed within current literature discussing multiculturalism, cultural competency, and substance use treatment, but social classes have different cultures (e.g., consider role expectations, priorities, alternatives, explanatory styles, and other values) and should be considered in light of appropriate multicultural care.

It is important to recognize that while all culture-based worldviews are valid, they are not all treated equally. We may be exposed to varied influences and cultures, but there exists a dominant culture that is a common barometer for standards and normality. In the United States and in many Western countries, this dominant culture represents a non-Hispanic White, middle-class, Christian, male worldview—complete with values, expectations, rules of behavior, roles, priorities, and morals. Even if this is not one's own worldview, it is known to us because it is represented as normal in the media and codified in our social institutions (such as medicine and substance use interventions) and practices (such as medication researched on men being transferred for use with women without evaluation for sex differences in reaction or dosing). The more one identifies with the dominant culture, the harder it will be to see implicit assumptions, or how common knowledge or imperatives are only common to those within one's culture. Cultural competence in the rapidly changing and multicultural environment

requires a rigorous and critical evaluation of the worldview and culture that people, as interventionists, hold. Unexamined, their internalized cultural ideas are blindly applied in their dealings with others (termed *ethnocentrism*).

Culturally Competent Interventions

As interventionists, unchecked cultural biases lead to ethnocentricity in the assumptions, framing, planning, and delivery of interventions to the frequent detriment of those with different worldviews. Cultural competency requires that one's interventions be acceptable, accessible, meaningful, and helpful to one's client or target populations. Several things are required to address those requirements: (a) the interventionist's awareness of his or her own culturally driven assumptions; (b) general epidemiological-type knowledge of cultural specifics of ethnic groups with which the client might identify; (c) collaboration with the client to understand his or her particular worldview and culture, which may or may not be what we expect or what is representative for people with his or her perceived characteristics; (d) flexibility to adjust elements of the intervention to bring it in line with the client so that it is acceptable, accessible, meaningful, and helpful to him or her; and (e) willingness and commitment to a process that, by design and nature, may challenge the status quo and the interventionist's personally held beliefs.

A tension between evidence-based substance use intervention and required fluidity in intervention planning for culturally competent care does exist. One of the difficulties with both epidemiological data and large, positivistic scientific methodological research studies is that the nuances of particular individual(s) get lost. That is to say, a particular assessment tool or intervention program may work with the "average" person, but it may systematically fail with specific individuals or populations because of cultural characteristics. Finding and addressing these instances is the thrust of culturally competent care. Qualitative research methods and population-specific randomized trials are ways of evaluating the specific needs and efficacy of programs within a given cultural population. However, the blending and changing nature of the multicultural population and the importance of the clients' most salient, particular cultural identity mean individualized assessment and intervention tailoring are the cornerstone of truly multiculturally competent care.

Multicultural substance use assessment and treatment starts from a multicultural framework with critical awareness of one's own cultural worldview and should generally include exploration of the following:

- The client's thoughts about problematic substance use—what are the boundaries, occasions, levels, and consequences of substance use in his or her cultural group? Do certain substances have different significance or meaning to the client? How would one know when substance use is a problem?
- What causes substance use problems? What would it mean to the client and his or her family if the client has a problem with substances? What are the consequences of having a substance use problem (social sanctions)? How would one behave if they have a problem?
- What assistance would be useful for a person with a substance use problem (sanctions, prayer, will power, is help possible)? Who controls this help and where could the client get help? Will the client be expected to discuss his or her substance use treatment with elders, extended family, or community members, and how might they help the client?
- What is an acceptable substance use treatment goal (abstinence, moderation with use at specific occasions, abstinence save for certain substances with cultural meaning)?
- What language does the client speak at home? Is the client conversant in English (as spoken, as written)? If the client has immigrated, what circumstances prompted the immigration? How long has the client been here? What is the client's legal status? How much has the client adapted to American life (*enculturation*)? What family or supports do they have here and who was left behind?
- Is the client religious or spiritual? Even if not now, what faiths or practices currently or previously surround the client?
- What concerns does the client have about working with a therapist or exploring substance use treatment in general? What personal or cultural knowledge does the client hold about programs such as this treatment and about health and health care in general? Are there specific fears or requirements that need to be considered in treatment planning? Physical requirements might include location, language, time, day care, wait room for escorts, or ability to pay co-pays or treatment fees. Philosophical requirements might include same sex interventionist or group members,

no mention of God or faith as part of treatment, or adequate privacy protections.

- Broadly consider general epidemiological information known about the client and consider or directly explore with the client what is acceptable, accessible, meaningful, and helpful to him or her (or target population) based on age, sex, sexual identity, racial identity, ethnic identity, religious identity, disability status, social class, language, living situation, and degree of national acculturation.
- Finally, consider how what is learned about the client's culture and worldview may aid the client in realizing mutual goals regarding the client's improved health and quality of life.

Epidemiological Data for Minority Groups

National studies conducted by government organizations such as the Substance Abuse and Mental Health Services Administration (SAMHSA), the National Institute on Alcohol Abuse and Alcoholism (NIAAA), and the Centers for Disease Control and Prevention (CDC) have identified many unique trends in alcohol and drug use among different populations. Unfortunately, these organizations typically do not use the same categorization systems, making comparisons and generalization problematic. In addition, by grouping together many different ethnicities into one race, many within-group differences are lost. The purpose of the following review is to introduce the reader to current epidemiological data, highlight the need for treatment options, and emphasize the inherent difficulties in a one-size-fits-all conceptualization of alcohol and drug use.

In reviewing SAMHSA studies on alcohol use, results show similar past-year use among Native Americans (63.7%), Mexican Americans (63.7%), and non-Hispanic Whites (58.7%). However, when considering only heavy drinking statistics, Mexican Americans have a disproportionate representation (6.9%, compared to 5.3% of non-Hispanic Whites and 4.6% of Native Americans). When comparing alcohol dependence trends reported by SAMHSA and NIAAA, Native Americans have the largest representation among individuals identified as alcohol dependent (ranging from 5.6% to 6.4%, compared with 4.0% of Hispanics and 5.6% of Mexican Americans, and 3.4%–3.8% of non-Hispanic Whites).

Substance use related health concerns are also variable and not necessarily proportional to drinking prevalence. For example, although African Americans reported less alcohol use in the past year (55.4%), less heavy alcohol use (4.7%), and a lower alcohol dependence rate (3.4%–3.6%), the percent of males with alcohol-related liver disease identified by NIAAA is almost double that for non-Hispanic Whites (8.3% compared to 5.3%). Hispanic males exceeded both groups with 12.7% diagnosed with alcohol-related liver disease. SAMHSA also identified substantial differences in need for drug treatment, ranging from 2.5% of non-Hispanic Whites to 3.6% of Mexican Americans to 3.9% of African Americans to 7.8% of Native Americans.

Prevalence of and patterns of alcohol use vary as well. The CDC found that alcohol use varied from 55.2% of non-Hispanic Whites to 52.4% of Hispanics to 48.8% of Native Americans to 46.6% of African Americans. In these findings, more non-Hispanic Whites reportedly consumed alcohol and were more likely to identify as a current drinker (63.6%, compared to 49.6% of Hispanics, 48.8% of Native Americans, and 46.6% of African Americans). In spite of these differences, heavy drinking rates, defined as consuming five or more drinks in one occasion, were very similar among Native Americans (33.2%), Hispanics (31.8%), and non-Hispanic Whites (32.5%). These findings indicate that although non-Hispanic Whites were more likely to use alcohol and identify as current drinkers, the risk of heavy drinking and associated consequences was disproportionately greater for Hispanics and Native Americans.

Many studies indicate alcohol and drug use rates among Asian Americans are lower than population norms, including the CDC's findings of 3.1% drug use, 37.4% alcohol use, and 12.4% binge alcohol use. However, this CDC study excluded Pacific Islanders due to a small sample size and did not distinguish between Asian American subgroups. Other studies suggest Pacific Islanders and Filipino Americans report much higher alcohol and drug use than Japanese and Chinese Americans subgroups, for instance. In addition, Asian American college student drinking is similar to and sometimes greater than the general population, indicating that the national surveys may be failing to detect some of the variance inherent in this population.

Again, the use of different categorical groupings among studies means both variance and similarity

found among populations may be attributable to the consolidation of disparate groups that masks true differences. Further, apparent differences may also be attributable to treatment accessibility, problematic programming, or in the diagnostic system itself. Some ethnic groups have been thus far neglected in the literature, such as Arab Americans. Another significant limitation of recent studies is the limited categorization of biracial or multiracial individuals. In much of the current literature, study participants are limited to identifying as one race or on rare occasion, as two or more races, which equally loses the specific and complex nuance of multiracial, multiethnic individuals. With these limitations in mind, it is apparent that there is substantial variability in alcohol and substance use and impact among different cultural groups which is important to consider and incorporate into one's multicultural framework.

Development and Evaluation of Intervention Programs

When considering multiculturalism in the development and evaluation of substance use intervention programs, one must consider both content and processes. Focusing on principles known to be broadly efficacious across cultures in designing and evaluating interventions provides a concrete foundation to a complicated and multifaceted issue. Three such principles emerging from recent literature are discussed below.

One principle of multiculturally appropriate substance use intervention programs is that the environment and process of the delivery of treatment should be culturally sensitive and culturally relevant to clients. This principle often requires organizational, programmatic, and staff self-assessment of current (or planned) formal, informal, and physical infrastructures. Changes may be necessary to ensure cultural sensitivity and cultural relevance, including multicultural congruency between the physical environment, staff, and treatment delivery. This self-assessment should include considerations of process variables such as the following:

1. Are the cultural and linguistic competencies of individuals implementing the interventions appropriate for the clients being served? Will clients likely assess practitioners to be culturally competent to work with them?

2. Are assessment and intervention frameworks based on theory and tools that are sensitive to issues of oppression, discrimination, and racism?
3. Will clients be comfortable with the objects, symbols, and seating, and so on within waiting and meeting rooms and in written material?
4. Are the interventionists committed to a common goal of improving health and are willing and able to adapt to the cultural context of the clients served?
5. Are values and principles promoting diversity and commitment to effective treatment for all clients broadly and constantly reflected in the organization's formal and informal policies and procedures (including client outreach, assessment, treatment planning, billing, scheduling, and all personnel policies)?

A second principle shown to be effective with diverse cultural groups is meeting the client where he or she is. This principle is widely found in the substance use literature as a whole, but examining it with a focus on multiculturalism emphasizes some specific approaches and captures the content and parameters for multicultural substance use treatment.

Outreach is critical. This includes not only basic approaches such as physically entering the community, but also intentionally building rapport by gaining community buy-in, trust, and respect (e.g., conduct focus groups, consult with community leaders); work with the community to reach an understanding of what, when, and how substance use is normal or problematic to individual community members and the community as a whole; communicate and collaborate directly with the target community (e.g., build partnerships with existing community organizations, community leaders, and current programs within the community that may serve as referrals, treatment collaborators, or cultural consultants in the efforts); and clearly outline the incentives to participation in treatment (e.g., vouchers, input in treatment development).

In addition to the use of culturally sensitive and relevant outreach to inform the content aspect of appropriate multicultural care, it is imperative that each client be approached via a culturally integrated assessment. This assessment should culminate in a culturally sensitive diagnosis and lead to development of a culturally relevant treatment plan. There are real and valid differences in how an individual's cultural group

conceptualizes substance use and when it is a problem. The majority of assessment measures have not been adequately normed on diverse cultural groups and thus may generate under or overestimations of use, distress, consequences, and dependence. Suggested elements of culturally integrated assessment and culturally relevant treatment planning were bulleted for reference above.

Recognition of not only stressors related to minority status (racism, prejudice, discrimination) but also of group strengths (social support, values, traditions) should not be overlooked. Incorporating these and other cultural protective factors into substance use assessment and treatment or health behavior promotion planning is critical. This is a third principle of multicultural practice, the strengths perspective. Look for and therapeutically utilize sources of strength, support, tradition, expectations, meaning, and values with all clients, but particularly when working with clients with cultures and worldviews different from the therapist's, as their strengths may be found in unexpected places or easily overlooked.

An important part of competent multicultural case conceptualization is recognition of the injustices that can be and have been perpetuated by the mental health system both historically and presently (e.g., minority individuals are more likely to receive restrictive services than nonminority individuals despite the same diagnosis). This is important to recognize both to validate the client's concerns and to avoid perpetuating further injustices. It is easy to lose sight of the fact that personal interactions occur in larger contexts. Current context occurs amid racial and culturally based health disparities. Lack of attention to culturally specific factors, and their importance, as well as misinformation about group dynamics, statistics, and conditions can contribute to clients' problem behaviors and be inadvertently included in interventions intended to help the client.

Conclusion

In a pluralist society, multiculturalism accepts that varied personal and group histories give rise to numerous worldviews. Culturally competent care (known to relate to treatment entry, engagement, and better outcomes) must accommodate these worldviews and stems from adaptability of the interventionist and the intervention to provide substance use assessment and treatment that is acceptable, accessible, meaningful,

and helpful to the client. Teasing out the boundaries of what is typical and expected within a different culture from what is atypical and problematic is a necessary component of culturally competent care.

This entry has been written in consideration of primary, direct intervention care efforts; public health level efforts have similar premises, but may also include identification of culturally sanctioned behavior that is problematic (both within dominant American society and also within the specific cultural community) that can be targeted for public education and group attitude and behavior change efforts (i.e., current trends in smoking behavior or binge drinking). This level of interventive agenda is beyond the scope of this entry, but should necessarily be approached in collaboration and partnership with targeted community group leaders to assure the community's interests are represented and honored and to avoid further oppression of marginalized or minority groups.

In general, both content and process are of concern for competent multicultural care and three principles of development and evaluation of intervention programs can guide direct-level program planning: (1) the environment and process of the delivery of treatment should be culturally sensitive and culturally relevant to clients, (2) meet the client where the client is, and (3) draw upon cultural strengths. Collaborating with cultural leaders of targeted service populations can help illuminate places where interventions or interventive organizations may need to adjust their assumptions or interventive or organizational protocols. Commitment, personal insight, and willingness are among five elements identified as required of interventionists to provide competent multicultural care. Programs in which the organization, the intervention, and the interventionist are all aligned in support of multiculturalism are preferable as each of these levels contributes to the context, content, and delivery of care to clients. Ultimately, culturally competent assessments and culturally relevant treatment plans stem from understanding the individual client within his or her own group context. Several bulleted suggestions that facilitate doing this have been offered.

Evidence-based programs normed on the general population offer tools shown to be efficacious. However, while being generally helpful, they may be systematically unhelpful to specific individuals or populations. The hope is that the discussion in this article will help the reader discern when standardized protocols may need to be adapted or created afresh to suit the

needs and worldviews of specific target populations. The goal, after all, is helping people. Services offered need to be acceptable, accessible, meaningful, and helpful to the client. If clients fail to present or adhere to treatment, then the therapists have failed as well.

MULTIDIMENSIONAL FAMILY THERAPY

Multidimensional family therapy (MDFT), created by Howard A. Liddle, is a family-based treatment that was developed for adolescents with drug and behavior problems and for substance abuse prevention with early adolescents. MDFT as a community and home therapy works in a variety of environmental domains such as the self, family, school, peers, and neighborhood in an effort to eliminate or significantly reduce drug use, as well as providing alternatives to a drug-using lifestyle. It is a multiple systems-oriented and developmentally focused therapy that can be utilized to target the known areas of risk associated with adolescent drug abuse and delinquency. MDFT also focuses on enhancing those protective factors and processes that are understood to promote successful teen and family development.

Theoretical Basis

MDFT was developed in part from the social ecology theory, which suggests that children develop within several interconnected subsystems, such as schools, peer groups, neighborhoods, and families. By understanding and working with the influence of the subsystems that surround the troubled adolescents, lasting behavior changes are thought to be possible.

Research in adolescent developmental psychology and psychopathology has shown that the family is the main context of healthy identity formation, that peer influence operates in relation to the buffering effect of the family against a possibly deviant peer subculture, and that adolescents require the

development of an interdependent (as opposed to emotionally separated) relationship with their parents. MDFT was created to allow for symptom reduction and the enhancement of prosocial and normative developmental functions by targeting the family as the basis for the intervention while at the same time allowing for curative processes to develop in several domains of functioning and across multiple systemic levels.

Structure

MDFT is recognized internationally as among the most effective treatments for adolescent substance misuse and has been developed and tested in different forms, increasing the flexibility of the program. This flexibility allows the format and components of MDFT to be modified to specifically meet the needs of different clinical populations. Sessions may occur multiple times during the week and can be tailored to take place in a variety of contexts such as in the home, in the MDFT clinic, in community settings, or by phone. The program is designed to produce behavioral changes in 3 to 6 months using 12 to 25 therapy sessions.

Session content may vary according to the stage of treatment; however, four assessment and intervention modules structure the approach within three stages. Stage one includes a comprehensive assessment covering the problems areas as well as areas of strength that the adolescent may possess and that may not be currently utilized. Assessment in MDFT is important in directing therapists as to where intervention is needed among the myriad of domains within an adolescent's life.

Stage two is the working phase of the treatment during which the therapist attempts to help the patient make significant changes within and across individual, family, peer, school, and other subsystems. The focus during this stage of treatment is on the facilitation of developmentally appropriate competence across a multitude of areas of the patient's life while teaching individualized communication and problem-solving skills. During this stage, parents are helped to examine their relationship with their child, as well as the strategies they use to influence their child. The therapists work to change negative family interaction patterns in order to change the family's everyday environment and to coach parents on innovative ways of reaching out to their children.

The third stage of treatment helps the family to cement the changes that have been made while preparing the adolescent and the family for their next stage of development. In this stage, progress and changes that have been made are acknowledged and any remaining issues that may need to be addressed are refined by the therapist. The main focuses during this stage are on having the family work to maintain the progress that has been made, to encourage the family to work on its own, and to help the family understand the ability to generalize and expand upon its new ideas and behaviors in current and future situations. These new skills, ideas, and behaviors are applied in treatment to new real-world situations to illustrate appropriate usage.

The four assessment and intervention modules within these stages are the adolescent module, the parent module, the family module, and the extrafamilial module. The adolescent module helps address developmental issues including peer relations, identity formation, prosocial involvement, and drug use and its consequences. The parent module helps the parents enhance parenting skills in areas such as monitoring and limit-setting, teaches them how to participate in their child's life outside of the family, and helps them learn how to rebuild emotional bonds with their adolescent. The family module works with the entire family to help them develop the motivation and skills to interact in more adaptive ways and rejuvenate their familial attachments. Finally, the extrafamilial module attempts to establish collaborative relationships among the various social systems with which the adolescent interacts. The core focus of each of the therapy sessions within these modules may cover a variety of subjects, such as the adolescent's developmental tasks and concerns, peer relations, involvement in legal and juvenile justice systems, and drug use as a way of coping with circumstances or psychological status.

MDFT is implemented by a clinical team that is comprised of one clinical supervisor for two to four therapists and may also include one to two case manager therapist assistants. The treatment length can vary, with one example of an intensive outpatient version of MDFT ranging between 16 and 25 sessions over 4 to 6 months, and another example of a less intensive version with twelve sessions over 3 months. MDFT has been implemented in over 16 sites throughout the United States, with clinical groups that have been comprised of ethnically and linguistically diverse adolescents at risk for abuse and/or abusing substances and their families, with ethnicities represented from White, African

American, and Hispanic backgrounds. The parents of the adolescents who have been targeted in MDFT randomized controlled studies have had a range of economic and educational levels; however, the majority of families treated have been from disadvantaged inner-city communities. Adolescents treated in MDFT trials have ranged from high-risk early adolescents to multi-problem, juvenile justice-involved, dually diagnosed female and male adolescent substance abusers.

There are 10 clinical operating principles that create a framework for multidimensional family therapists to work from. These principles help guide the therapist as to what is prescribed and proscribed during the treatment process:

Principle 1: Adolescent drug abuse is a multidimensional phenomenon. This allows for MDFT clinical work to be guided by ecological and developmental research and perspectives.

Principle 2: Problem situations provide information and opportunity. Symptoms and problem situations provide assessment information and intervention opportunities to the therapists working on the case.

Principle 3: Change is multidetermined and multifaceted. Change comes from the effects of interaction among different systems, people, time periods, domains of functioning, and intra- and interpersonal processes, allowing a clinician to access multiple methods and paths to produce change.

Principle 4: Motivation is malleable. Not all of those who enter treatment are motivated to change and resistance to change may need to be understood as part of the therapy process.

Principle 5: Working relationships are critical. This points to the importance of making treatment possible through supportive and outcome-focused working relationships with familial and extrafamilial support systems while also working through relationship and life themes through therapeutic interactions.

Principle 6: Interventions are individualized. It is important for interventions to be customized according to each family seeking treatment in the program.

Principle 7: Planning and flexibility are two sides of the same therapeutic coin. This indicates the need for continuing evaluation on the part of the therapist as the intervention progresses to allow for changes to be made to the intervention plan if and when necessary.

Principle 8: Treatment and its multiple components are phasic. This explains the reason that the overall therapy process is organized and executed in stages, with progress in each area setting up the therapy for the next stage while still allowing for flexibility within the program.

Principle 9: Participation and motivation of those involved in therapy is a responsibility that belongs in large part to the therapist. It is the therapist's responsibility to provide, evaluate, and change the treatment as needed to prompt behavior change.

Principle 10: Therapist attitude and behavior are fundamental to success. Therapists should advocate for both the adolescent and the parent while understanding and using the therapists' own abilities to remain positive, creative, energetic, and committed despite whatever challenges may arise during therapy.

Through the process of understanding these 10 principles, therapists are able to be guided through the training and practice of MDFT.

Efficacy

MDFT has been tested in federally funded research projects since 1985, and this research has been able to provide evidence for the efficacy and effectiveness of MDFT for working with adolescent substance abuse. The studies have been conducted at several sites across the United States among adolescents ranging in ages from 11 to 18 across urban, suburban, and rural settings. MDFT studies include adolescent research participants who meet diagnostic criteria for substance use disorders, which are often comorbid with other problems such as delinquency and depression. MDFT has demonstrated superior outcomes relative to several other interventions such as cognitive behavioral therapy, family group therapy, peer group treatment, and comprehensive residential treatment when tested in six randomized controlled trials.

Five of the controlled clinical trials showed that substance use was reduced in MDFT to a significantly greater extent than all comparison treatments, with substance use decreasing 41% to 82% from intake to discharge. Also, both during the treatment and 12-month follow-up, youth taking part in MDFT showed higher rates of abstinence from substance use than those taking part in comparable treatments, with 56% showing abstinence from all substances and

64% showing either complete abstinence or substance use only once per month. At the 12-month follow-up, youth receiving MDFT showed a 58% reduction in marijuana use.

In addition to significantly reducing substance use, substance-related problems such as antisocial, delinquent, and externalizing behaviors were also significantly reduced. Among those treated with MDFT, school functioning was also seen to improve at higher rates than among those treated with other therapies. MDFT clients returned to school and earned passing grades 43% of the time as opposed to 17% of those treated with family therapy and 7% of those treated with peer group therapy. Family functioning and interaction has also been shown to improve at higher rates in MDFT when compared to family group or peer group therapy, and this improvement was maintained at 12-month follow-up.

MDFT has also been shown to work effectively as a community-based drug prevention program. In addition to the previously mentioned improvements, MDFT has demonstrated high effectiveness when used to treat youths with comorbid diagnoses and multiple impairments. MDFT is associated with decreased delinquent behavior and involvement with delinquent peers and reduced the likelihood of being arrested or placed on probation.

The average weekly cost of treatment with MDFT is significantly less than both community-based outpatient treatments and residential treatments. Training and treatment in MDFT is available in various locations throughout the United States, with research projects also currently taking place in Europe.

N

NAADAC, THE ASSOCIATION FOR ADDICTION PROFESSIONALS

Founded in 1972 as the National Association of Alcohol and Drug Abuse Counselors, NAADAC was created as a professional association to represent the interests and concerns of substance abuse counselors. Since then, NAADAC has evolved as an organization addressing the needs of professionals who are active in prevention, intervention, treatment, and education. The professionals filling these roles have expanded to include the increasing number of tobacco, gambling, and other addiction professionals.

The mission of NAADAC is to lead, unify, and empower addiction-focused professionals to achieve excellence through education, advocacy, knowledge, standards of practice, ethics, professional development, and research. With this mission and a new name, NAADAC—the Association for Addiction Professionals has become the largest membership organization serving addiction counselors, educators, and other health care professionals. There are nearly 11,000 members, 46 state affiliates, and an expanding international presence. Therefore, NAADAC is the premier global organization of addiction-focused professionals attempting to enhance the health and recovery of individuals, families, and communities.

The association promotes excellence in care by supporting the highest-quality, science-based services to clients, their families, and their communities. NAADAC strives to achieve this goal by providing education, clinical training, and professional certification. Among the organization's national certification

programs are the National Certified Addiction Counselor, Tobacco Addiction Credential, and Master Addiction Counselor designations. Since 2007, NAADAC has credentialed more than 15,000 counselors, playing an important role in sustaining quality health care services and protecting the well-being of those seeking and participating in services.

According to the NAADAC's Web site, at the national level, the NAADAC Certification Commission operates as an independent body managing the association's credentials and education. The NAADAC Certification Commission deals with test administration, fees, ethics, and rules of procedure. Established in 1990, the NAADAC Certification Commission instituted three levels of credentials specifically for alcoholism and drug abuse counselors: National Certified Addiction Counselor, Level I (NCAC-I); National Certified Addiction Counselor, Level II (NCAC-II); and Master Addiction Counselor (MAC). Additionally, NAADAC offers certifications, including the Tobacco Addiction Specialist Credential and Certificate in Spiritual Care-giving to Help Addicted Persons and Families. Finally, NAADAC offers the Substance Abuse Professional qualification (*not* a certification); individuals with that credential are qualified to evaluate workers who have violated a Department of Transportation drug and alcohol program regulation and make recommendations concerning education, treatment, follow-up testing, and aftercare.

The NCAC-I certification can be the first step to professional recognition with a nationally recognized credential. By holding this credential, the individual demonstrates to employers and clients the commitment to quality care by verifying, through certification,

the skills the individual has developed through years of work experience. The credential reflects an endorsement of the highest ethical standards for addiction professionals. Eligibility is demonstrated by verifying the following: current state certification or licensure as an alcoholism and/or drug abuse counselor; 3 years or 6,000 hours of supervised experience as an alcoholism and/or drug abuse counselor; 270 contact hours of education and training in alcoholism and drug abuse or related counseling subjects (must include 6 hours of ethics training and HIV/AIDS training); and a passing score on the national examination for NCAC-I.

The NCAC-II distinguishes the professional from practitioners who lack specialized addiction treatment training. This level of credential increases the educational criteria by requiring a bachelor's degree from an accredited institution of higher learning. Other variances from the Level I certification include 10,000 hours of supervised experience as an alcoholism and/or drug abuse counselor and 450 contact hours of education and training in alcoholism and drug abuse or related counseling subjects (including 6 hours of ethics and HIV/AIDS training). The counselor also must attain a passing score on the national examination for Level II certification. This credential further demonstrates the counselor's commitment to developing excellence in addiction treatment practice.

The MAC credential positions the professional for career advancement and increased salary potential while enhancing opportunities for independent practice. This credential is the only master-level certification available to addiction counselors. Requirements for this credential include an official transcript of a master's degree from a regionally accredited institution of higher learning (the official transcript must be sent by the institution). Additionally, the counselor must provide documentation of current state certification or licensure as an alcoholism and/or drug abuse counselor and 6,000 hours of supervised experience as an alcoholism and/or drug abuse counselor and/or in the healing arts. Two years or 4,000 hours of professional addiction counseling experience must be acquired after completion of the master's degree.

Further requirements for the MAC credential include written verification of competency in all skill groups, verified by a supervisor or other health care professionals who have personally observed the candidate's alcohol and/or drug abuse counseling work and documentation of 500 contact hours of specific alcoholism and drug abuse counseling training (within

a degree area or elsewhere), including 6 contact hours of ethics training and 6 contact hours of HIV/AIDS training. Finally, the candidate must receive a passing score on the MAC written examination within four years of the application.

NAADAC's members provide treatment in a variety of settings, including private and public treatment centers, hospitals, private practice, and community-based behavioral health agencies. Research has demonstrated that addiction is a brain disease responding well to treatment and is providing a better understanding of how drugs, alcohol, tobacco, and other chemical substances affect the brain. NAADAC supports continued research and is a powerful advocate for policies improving the understanding of, and financial support for, prevention and treatment of addiction.

NAADAC offers membership in both individual and organizational categories. Individual membership is open to anyone engaged in the field of counseling or related human services. Organizational membership is open, rather than being limited to treatment centers, prevention programs, private practitioners, educational institutions, state and local agencies, and hospitals.

Membership benefits include financial incentives, such as discounts on training, national certification, educational products, liability insurance, and access to health insurance. NAADAC also works in partnership with its 46 state affiliates to shape the public's perception of addiction. By joining the 11,000 NAADAC members, an addiction professional can gain access to current information on clinical and professional issues, establish networking connections with professional colleagues, mentor people new to the profession, increase opportunities to enhance leadership skills, and join the only national political action committee dedicated to promoting the support of addiction issues.

NALOXONE

Naloxone is a prescription medication used to reverse the effects of opioids. Unlike other medications used in treating chronic opioid dependence, it lacks the potential for abuse. Currently, the mainstays of naloxone use are to treat acute opioid overdose and to provide maintenance therapy in individuals who are opioid dependent. Naloxone is a synthetic opioid receptor antagonist that works by binding to opioid receptors in the central nervous system. Primarily, naloxone targets the μ -receptor in the central nervous system, although it also blocks other opioid receptors, such as kappa and delta, to a lesser degree. By binding and therefore blocking these opioid receptors, naloxone can reverse the effects of opioids, including but not limited to heroin, oxycodone, hydrocodone, and morphine.

Of note, naloxone is not to be confused with naltrexone, which has a different chemical structure and different opioid receptor-binding affinities. Naltrexone has qualitatively different effects and is used primarily in the treatment of opioid addiction.

Naloxone's patent has long since expired as it was first synthesized in the 1960s. It is currently marketed as a solution or as a pill when combined with other medications. Naloxone hydrochloride solution uses several trade names, including Narcan, Nalone, and Narcanti. It is a stabilized sterile solution available for intravenous, intramuscular, intranasal, endotracheal, or subcutaneous use.

When naloxone hydrochloride is combined with buprenorphine hydrochloride, it is marketed as Suboxone. Suboxone is a sublingual pill designed for self-administration due to its limited abuse potential.

As an alternative to daily methadone maintenance, Suboxone has been administered in combination with weekly outpatient counseling sessions. This approach is gaining popularity because it attempts to address the psychosocial issues involved in drug addiction, and it has the added advantage over methadone because it can be prescribed for self-administration rather than requiring daily attendance at a methadone clinic.

In addition to being used in outpatient opioid treatment centers, naloxone has been used for rapid detoxification and as a self-administered lifesaving tool in opioid overdose. In the emergency medical service setting or in the emergency department, naloxone is routinely given via intravenous or intranasal routes to reverse problems associated with an actual or suspected opioid overdose, including hypotension, respiratory depression, and central nervous system depression. When administered intravenously, naloxone's onset of action occurs within 2 minutes and reaches its serum half-life in adults in approximately 30 to 80 minutes. One important consideration is that the duration of action of some opioids can exceed that of naloxone, so the overdose patient will usually need to be monitored for at least 1 to 2 hours after successful use of naloxone to make sure that he or she does not lapse back into an overdosed state as the naloxone wears off.

When a patient is unconscious and intubated, endotracheal administration is also commonly used. All these routes effectively provide for a safe and rapid way to revive the otherwise comatose patient with a life-threatening opioid overdose. The intramuscular and subcutaneous routes are also feasible; however, they have a longer delay until onset of action, which limits their use in the emergency setting. The naloxone dose needed to reverse an opioid overdose can be as little as 0.2 milligrams (mg) up to the full reversal dose of 2 mg. If the desired effect is not reached after administration of 10 mg of naloxone, then the diagnosis of suspected opioid overdose should be questioned.

Traditional treatment programs for opioid addiction involve substituting the opioid with methadone and then gradually weaning the individual off the methadone, or using methadone as long-term maintenance therapy. Alternatives to this approach include rapid detoxification and ultrarapid detoxification treatments, where the goal is to rapidly detoxify the user. This occurs by using naloxone to rapidly precipitate opioid withdrawal while the patient is deeply sedated or under general anesthesia. Afterward, maintenance therapy is typically provided by using

a combination of naltrexone and counseling. Proponents of rapid detoxification and ultrarapid detoxification argue that it is quicker and more cost-effective to go through the withdrawal process in the hospital setting than over the typical 10-day withdrawal that occurs when the drug of abuse is stopped. Opponents argue that safety is a concern when rapid detoxification or ultrarapid detoxification is not performed in the hospital setting. Most experts agree that the patient will still have to address the psychosocial aspects of opioid dependence if he or she is to be successful in the long term.

It is well documented that accidental overdose is a significant cause of mortality in the opioid injection drug population. Studies have shown that fatal overdose is largely preventable if injection drug users are provided with education and access to naloxone. Consequently, naloxone kits have been developed as part of a harm reduction approach to treatment of opioid overdose. These kits are designed for self-administration by the injection drug user (or a peer who discovers the overdose) in an attempt to prevent fatal accidental overdose. Various drug treatment centers and needle exchange programs in Europe and North America distribute emergency naloxone kits to injection drug users and provide the education on how to prepare naloxone for injection.

In individuals with opioid dependence, any abrupt reduction or cessation in use of opioids can produce withdrawal symptoms. This is a common occurrence when the opioid-dependent user tries to quit or runs out of the opioid. Symptoms of opioid withdrawal can include nausea, vomiting, abdominal pain, diarrhea, dilated pupils, sweating, runny nose, and piloerection (“goose bumps”). Clinically, these symptoms may be mistaken for a flulike illness. Likewise, the administration of naloxone will produce rapid reversal of opioid effects, essentially bringing about an accelerated withdrawal state. Symptoms of severe opioid withdrawal can include pulmonary edema, seizures, tachycardia, hypertension, and even hypotension. Thus, monitoring by a health care professional as soon as possible after administration of naloxone is important for safety and health reasons.

NALTREXONE

Naltrexone is a medication that has been found to be efficacious in the treatment of opioid (e.g., heroin, morphine) and alcohol dependence. In 50-milligram (mg) pill form (the dose approved by the U.S. Food and Drug Administration [FDA]), naltrexone goes by the trade name ReVia. In its long-acting injectable form, naltrexone goes by the trade name Vivitrol. Oral naltrexone was approved by the FDA for the treatment of opioid dependence in 1984. In 1994, oral naltrexone was approved by the FDA for the treatment of alcohol dependence, and the injectable form was approved in 2006.

Naltrexone acts as an opioid antagonist, meaning that it binds to opioid receptor sites in the brain and blocks the activity of endogenous opioids such as beta-endorphin, which has a euphoric effect and is known to be stimulated by alcohol and opioid use. Unchecked, release of endogenous opioids can lead directly or indirectly to increased dopamine activity in areas of the brain such as the nucleus accumbens. The process of beta-endorphin release leading to enhanced dopamine activity is believed to underlie many of the reinforcing and pleasurable or euphoric effects of alcohol and opioids.

In the treatment of opioid dependence, naltrexone has particularly strong pharmacological properties.

Naltrexone essentially eliminates all opioid effects for 24 to 72 hours depending upon the dose of the medication. The majority of clinical trial findings support the efficacy of naltrexone in the treatment of opioid dependence following detoxification. In a 2006 review of the literature, Minozzi and colleagues affirmed the advantages of oral naltrexone in comparison with placebo, particularly when paired with psychosocial therapy. Despite naltrexone's beneficial effects, it is, at present, used infrequently for the treatment of opioid dependence, due in large part to poor adherence and lack of retention in treatment. Opioid users are accustomed to taking a drug with rapid and strong effects. In sharp contrast, naltrexone has no reinforcing properties. Further difficulty stems from the fact that naltrexone effectively blocks the pleasurable effects of opioids but does not tend to decrease craving for the drug. For these reasons, methadone maintenance is typically preferred by patients. As a result, naltrexone is prescribed infrequently. However, for patients who are highly motivated to cease opioid use, such as health professionals, naltrexone has been found to be particularly effective.

Due to concerns about adherence, microcapsules have been developed, which can be either implanted or injected under the skin. Microcapsules can deliver steady levels of naltrexone into the bloodstream over the course of a month or longer. Evidence has tended to support the efficacy of these forms of naltrexone for the treatment of opioid dependence, although none is currently FDA-approved.

Naltrexone has also been used as a component of opioid detoxification either as an alternative to methadone maintenance or, in some cases, following a period of methadone treatment. The main purpose of using naltrexone and other opioid antagonists such as naloxone for detoxification is to speed up the process. Opioid antagonists induce rapid withdrawal by moving opioids off of their receptor sites in the brain. This process can be uncomfortable and sometimes painful. For this reason, a medication such as clonidine, which is both sedating and effective in reducing withdrawal symptoms, is typically given in conjunction with naltrexone in the detoxification process. Opioid antagonist-facilitated detoxification has also been tried under heavier sedation and anesthesia. Recently, literature reviews were conducted of antagonist-facilitated detoxification using both minimal and heavier sedation and found that the procedure appears

to be feasible under minimal sedation although it is questionable whether opioid antagonists offer additional efficacy above and beyond clonidine and similar medications by themselves. The adverse effects of the procedure under heavy sedation or anesthesia were found to be too serious and not worth the added risk.

Although the pharmacological effects of naltrexone are probably not as strong in its use in the treatment of alcohol dependence, naltrexone has shown greater efficacy with alcohol than with opioid dependence. Patients responding to naltrexone have reported a number of changes in their experience of drinking. These changes include diminishing pleasurable effects of alcohol and a decrease in alcohol's reinforcing properties. These effects likely contribute to a phenomenon whereby individuals attempting to abstain who have a drink are less likely to enter into full-blown relapse when taking naltrexone. It has also been observed that cues associated with alcohol (e.g., the smell of alcohol, the sight of a favorite local bar) lead to less craving among drinkers taking naltrexone. The craving-reducing effect of naltrexone with alcohol differs from its effect with opioids. Another key difference between alcohol and opioid treatment with naltrexone is that detoxification is not required for alcohol treatment, whereas it is required for opioid treatment.

FDA approval for naltrexone in the treatment of alcohol dependence was spurred by positive findings in two 1992 clinical trials, one conducted at the University of Pennsylvania and the other conducted at Yale University. Since then, the majority of clinical trial findings have supported the efficacy of naltrexone. A meta-analysis including 27 randomized controlled trials of naltrexone by Srisurapanont and Jarusuraisin that was last updated in 2004 showed that naltrexone treatment decreased the likelihood of relapse in the short term but that more research was needed to assess the efficacy of naltrexone over the long term.

Although the majority of research findings have supported the benefits of using naltrexone for the treatment of alcohol dependence, there have been a number of clinical trials that have yielded negative findings, perhaps most notably the VA Cooperative Study, a multicenter, double-blind trial. However, a recent reanalysis of the data from this study indicated that there were subgroups of participants in this study for whom naltrexone was beneficial.

Two large, multisite trials published after the VA Cooperative Study provided evidence supporting the efficacy of naltrexone. One study, led by Garbutt, provided evidence for the efficacy of a long-acting injectable form of naltrexone. Compliance has been a long-standing concern in the use of naltrexone for alcohol dependence as well as for opioid dependence. The number of prescriptions written for naltrexone for alcohol dependence has been consistently low, and in focus groups, physicians have cited concerns about compliance as a deterrent to the use of naltrexone. The use of the long-acting injectable form of naltrexone addresses these concerns in that only one injection is required per month. In 2006, Anton and colleagues reported findings from the COMBINE study, a large, multisite trial evaluating the efficacy of 16 weeks of oral naltrexone, acamprosate—another FDA-approved medication for alcohol dependence—and an intensive psychosocial intervention. Naltrexone but not acamprosate showed a significant effect in reducing the number of heavy drinking days although this effect diminished somewhat at 1-year follow-up.

In addition to medication compliance, another factor influencing the efficacy of naltrexone for alcohol dependence is a family history of alcohol problems. Clinical trials and a recent human laboratory study have demonstrated that having a positive family history of alcohol problems has been found to increase the likelihood that a patient will respond to naltrexone. One possible explanation for this pattern is enhanced sensitivity to the effects of endogenous opioids among those with a positive family history.

In addition to its use for opioid and alcohol dependence, naltrexone has also been tested as a component of treatment for nicotine dependence. According to a 2006 review, evidence for the efficacy of naltrexone for smoking cessation is limited. However, a group headed by O'Malley recently reported that smokers taking naltrexone gained less weight during their quit attempt than smokers taking placebo. This finding, if replicated, could have an impact on smoking cessation treatment given the high number of smokers concerned about gaining weight after quitting.

Naltrexone is nonaddictive and has been found to be well tolerated in its use in treatment for opioid and alcohol dependence. The most frequent side effects of naltrexone are gastrointestinal and can typically be alleviated through the use of over-the-counter medications such as antacids and, in the case of oral naltrexone, by ensuring proper use of the medication

(i.e., with a lot of water and with food). There have been reports of liver toxicity, but these tend to be only at high doses (i.e., 300 mg or higher). Nonetheless, naltrexone carries a “black box” warning from the FDA due to these findings of its effects on the liver. There have been concerns about the use of microcapsules and other long-acting forms of naltrexone for opioid dependence due to reports of overdoses resulting from patients taking large amounts of opioids in an attempt to override naltrexone's effects. Naltrexone has been found to be safe for use with patients interested in reducing but not stopping alcohol use. However, when used for treatment of opioid dependence, naltrexone must be preceded by detoxification; otherwise, naltrexone will trigger immediate withdrawal. Accordingly, naltrexone's use in detoxification carries greater risk of side effects such as strong gastrointestinal discomfort and delirium and should take place only under close medical supervision using minimal sedation. Use of naltrexone and other opioid antagonists in detoxification under heavy sedation or anesthesia carries a risk of severe adverse effects and is not recommended.

NARCOTICS ANONYMOUS

Narcotics Anonymous (NA) was founded in 1953 in the Los Angeles, California, area by Jimmy Kinnon and other individuals who had previously found recovery from addiction through the Alcoholics Anonymous (AA) program. The founders of NA developed a program that is based on the Twelve Steps of AA but takes a broader view toward recovery from substance use disorders than does the AA program. AA granted the early members of NA the permission to adapt the Twelve Steps of AA to deal with all forms of chemical dependency as opposed to simply alcoholism. However, the NA founders were not granted the permission to use the Alcoholics Anonymous name, and subsequently, the group's name was changed to Narcotics Anonymous. The program began as a small U.S. movement, but currently, NA is the second largest Twelve-Step recovery program of its kind.

The NA program inextricably links together a recovery process and support network, and a key component of NA's approach to recovery is the therapeutic value of one addict helping another. The program is a nonprofit, independent organization of recovering addicts. Narcotics Anonymous is not linked to political, religious, law enforcement, or other organizations—including other Twelve-Step programs, treatment, or correction facilities—and the program completely self-supporting. That is, although NA members are not required to pay any fees, most members contribute small sums of money to their NA group to help cover the expenses of meetings, and the NA groups operate solely on members' funds, not accepting donations from outside sources.

The NA program is open to any person who feels that he or she has a problem with any substance (whether legal or illegal, including alcohol) and wants

to stop using. NA is not concerned with what substance or combination of substances one has used. To be a member, no one is required to pay dues or fees, sign pledges, make promises, or follow any regulations. Members are not required to sign attendance sheets and are under no surveillance at any time. Anyone is allowed to join NA regardless of his or her age, race, sexual identity, creed, political persuasion, religion, or lack of religion. The only requirement for membership is a desire to stop using a substance or substances, including alcohol.

The basic unit of NA's recovery program is the NA group meeting. NA groups usually hold meetings at the same time and in the same place each week, and usually groups rent space in buildings run by public, religious, or civic organizations. Group members share the responsibilities of chairing, opening, running, sharing at, and closing group meetings as well as caring for the space that the group rents for meetings. NA meetings follow an informal format, which varies from group to group, but all meetings are based on principles shared by the entire NA organization (found in NA literature). Although meetings may follow many formats (participation, speaker, question and answer, topic discussion, literature study, or any combination thereof), there are two basic forms of meetings: open meetings, which are open to the general public (anyone interested in the program and its form of recovery); and closed, which are closed to the general public (open only to addicts). The primary function of all NA group meetings is to provide a safe and consistent environment for personal recovery.

The local group is the only level of organization in areas of the world where NA is a reasonably novel phenomenon, but in areas where NA groups have had the chance to mature and stabilize, a number of groups may choose to form a local service committee (also known as an area committee), consisting of delegates from each group in the area, which can offer a number of services for the local area (e.g., phone services or literature distribution for one or more counties). In countries where NA is well established, local or area committees have organized into regional committees, which handle services within the larger geographical region (i.e., services that deal with the concerns of a state or section of two or more states). The World Service Conference, an international delegate assembly, provides direction and assistance with issues affecting the entire NA organization.

The core of the program is the Twelve Steps (as adapted from AA). The steps are guidelines that outline certain spiritual principles, providing a practical approach to recovery that does not mandate any particular belief system. Some of the spiritual principles covered in the steps are honesty, open-mindedness, willingness, humility, and anonymity. NA's view of recovery is one of process. That is, members believe that through working the steps and sharing with other recovering addicts, they make an individual decision to recover at their own pace. Recovery is ongoing and personal.

Anonymity is the key spiritual principle of NA, which allows NA groups to maintain an atmosphere of equality within their meetings while also allowing individual addicts to attend meetings without anxiety or fear of others outside the program discovering their identity as addicts. Anonymity is especially important for first-time meeting attendees. However, because of the principle of anonymity, NA as a whole does not keep a written record of its members, and each local group remains autonomous from the higher organization of NA (a group is not required to join an area or regional committee or register with the Narcotics Anonymous World Service Conference). Although this lack of record keeping protects NA members, it makes the gathering of information about the NA program difficult. NA cannot provide outside parties with comprehensive information about the demographics of its membership and the continued recovery rate among members. However, some data, such as the rate of membership growth, can be tracked by other means. The increasing number of registered NA meetings is a sure indicator of the program's rapid growth. In 1978, NA consisted of fewer than 200 registered groups in 3 countries with no basic text (NA's equivalent to AA's Big Book). Currently there are more than 25,065 registered groups, with 43,900 weekly meetings in 116 countries on 7 continents, and literature is available in 34 languages.

NATIONAL CLEARINGHOUSE FOR ALCOHOL AND DRUG INFORMATION

The National Clearinghouse for Alcohol and Drug Information (NCADI) is funded by the Substance Abuse and Mental Health Services Administration to distribute information about substance abuse prevention and addiction treatment free of charge or for a low-cost recovery fee. Located in Rockville, Maryland, NCADI is one of the largest federal clearinghouses, distributing hundreds of titles of materials produced by various federal agencies, including the U.S. Department of Education, the U.S. Department of Labor, the Centers for Disease Control and Prevention, the Center for Substance Abuse Prevention, the Center for Substance Abuse Treatment, the National Institute on Alcohol Abuse and Alcoholism, and the National Institute on Drug Abuse.

NCADI was established to be consistent with the Public Health Service Act, as amended by the Anti-Drug Abuse Act of 1986, the Omnibus Anti-Drug Abuse Act of 1988, and the Alcohol, Drug Abuse and Mental Health Administration (ADAMHA) Reorganization Act of 1992. The ADAMHA Reorganization Act of 1992 abolished ADAMHA and created the Substance Abuse and Mental Health Services Administration (SAMHSA), with three centers: the Center for Substance Abuse Treatment, the Center for Substance Abuse Prevention (CSAP), and the Center for Mental Health Services. NCADI, whose predecessor was the National Institute on Alcohol and Alcoholism's National Clearinghouse for Alcohol Information, was created to support and promote demand reduction and represents the effort of the federal government to provide a single point of entry, or one-stop shop, for comprehensive effective prevention, intervention, and treatment resources and links to scientific research on substance abuse and mental health issues, policies, programs, and practices.

SAMHSA's NCADI is funded through a \$57 million contract, which was awarded to IQ Solutions in 2004. IQ Solutions, an information, education, and communications company, is headed by president and chief executive officer Ileana Quintas, who was an information specialist at the National Clearinghouse for Alcohol Information, the predecessor to NCADI. Under the new contract, IQ Solutions will establish a new SAMHSA Health Information Network, under

which it will manage both NCADI and the National Mental Health Information Center. Under the new contract, federal support for the NCADI distribution system—the Regional Alcohol and Drug Awareness Resource (RADAR) network—was defunded, resulting in the elimination of some NCADI services and positions, including the NCADI reference library and the positions of librarian, RADAR network director, and inventory manager.

NCADI services include, or have included, an information services staff, with English, Spanish, and telecommunications device for the deaf (TDD) capacity; distribution of such substance abuse–related materials as fact sheets, brochures, pamphlets, monographs, posters, and videotapes; culturally diverse prevention, intervention, and treatment resources for audiences such as parents, teachers, youth, communities, and professionals in substance abuse and related fields; annotated bibliographies from alcohol and drug databases; access to a prevention materials database and a treatment resources database; and access to federal grant announcements for alcohol-, tobacco-, and other drug–related funding opportunities.

Requests to the NCADI Information Services Department may be placed by telephone, e-mail, voice mail, postal mail, TDD, or fax. Information specialists are specially trained to answer questions about alcohol and substance abuse prevention, intervention, and treatment; are available 24 hours a day, 7 days a week; and have the capability to refer inquirers to other alcohol and substance abuse organizations. NCADI information specialists are also trained to handle crisis telephone calls.

NCADI's RADAR network, which still remains the largest substance abuse prevention and treatment distribution network of its kind, consists of four types of RADAR network centers:

State centers: Each state has one RADAR network state center that serves as a centralized information and distribution service. State centers are located in all 50 states as well as American Samoa, Guam, the Commonwealth of Puerto Rico, the Virgin Islands, the Federated States of Micronesia, Palau, and the Commonwealth of the Northern Mariana Islands.

Specialty centers: RADAR network specialty centers have a national or international focus and provide specific areas of expertise in substance abuse prevention, such as ethnic populations, persons with disabilities,

rural populations, substance abuse libraries, substance abuse research, workplace issues, and schools. Specialty centers can designate specialty associate centers to provide connections between the national organizations and the communities they serve.

Associate centers are affiliated with either a state center or a specialty center and may include community-based coalitions and task forces, prevention programs, and other groups. Associate members affiliated with state centers represent the state centers' connections to their local communities. CSAP and the state centers work together in designating RADAR network state associate members.

Specialty center associates represent other organizations that work closely with the specialty centers and share their expertise. Specialty associate members enhance the specialty centers' ability to distribute information and represent expertise at the local level.

In addition to the four types of regular RADAR network centers, RADAR network international documentation centers serve high-risk populations in their own countries. These centers provide for maintenance of collections of substance abuse prevention resources, assist other organizations within their own countries, and provide international substance abuse prevention information to CSAP that can be shared with the rest of the network. There have been up to 700 active centers worldwide throughout the history of the RADAR network, which was established to be the eyes and ears of CSAP at the community level. The RADAR network historically provided a feedback loop, informing CSAP of needs, as well as developments and innovations, in the substance abuse prevention field through its mission to strengthen communication, prevention, and treatment activities among a broad range of organizations.

NCADI also maintains an electronic network to provide online access to materials and information about alcohol, tobacco, and other drug abuse prevention. PREVline includes access to research data, scientific studies, full-text online resources, and information on topics related to substance abuse, such as violence, substance abuse among women, or binge drinking, and information on special populations, such as college students, veterans, or the elderly.

NATIONAL COUNCIL ON ALCOHOLISM AND DRUG DEPENDENCE

Since 1944, the National Council on Alcoholism and Drug Dependence, Inc. (NCADD) has been a leader in the effort to raise public awareness of the disease of alcoholism and drug dependence, and support for prevention, as well for effective and accessible treatment. As the oldest advocacy organization in the country dedicated to addressing alcoholism and drug dependence, NCADD works at the national level on public awareness and policy issues related to barriers in education, prevention, and treatment for individuals and families affected by alcoholism and drug dependence. NCADD's national network of affiliates work on the state and local levels to provide community-based information and referral, education, prevention, training, intervention, treatment, recovery support services, and policy and advocacy services.

NCADD and its national network of affiliates serves a wide variety of individuals, groups, and organizations, including individuals and families affected by alcoholism and drug dependence, government policymakers, the media, educators, the medical community, schools and universities, public health professionals, and other health organizations. From the

beginning, affiliates have been a source of innovation and leadership within the alcoholism and addiction community.

Throughout NCADD's history, individuals and families in recovery from alcoholism and drug dependence have played a critical role in all of NCADD's activities as volunteers, board members, advocates, donors, and staff.

NCADD History

Historians have characterized the period from 1939 to 1944 as the start of the modern alcoholism movement. During this period a series of organizations began; these include Alcoholics Anonymous in 1935, the Research Council on Problems of Alcohol in 1937, the Yale Center of Alcohol Studies in 1943, and the National Committee for Education on Alcoholism in 1944. Over time, the National Committee for Education on Alcoholism evolved into the National Council on Alcoholism and Drug Dependence, Inc. (NCADD).

NCADD was founded on April 1, 1944, as the National Committee for Education on Alcoholism, by Marty Mann, the first woman to achieve sustained recovery in Alcoholics Anonymous (AA). Early on in her recovery, Marty was working as a researcher and scriptwriter and found herself inspired by Helen Marshall's biography of the famed mental health reformer Dorothea Dix. As she read the biography, Marty wondered if she might be able to do for alcoholism what Dix had done for mental illness. In February 1944, Marty Mann sketched out and presented a strategy to create a national organization with local affiliates, modeled after national organizations that were reducing the stigma associated with tuberculosis, cancer, polio, and heart disease.

The other founders of the National Committee for Education on Alcoholism included E. M. Jellinek of the Yale Center of Alcohol Studies, Bill W. and Dr. Bob, cofounders of AA (both recipients of NCADD's Gold Key Award), Ruth Bangs of the *New York Herald Tribune*, Austin McCormick of the Osborne Association, Dwight Anderson of the New York State Medical Society, and Ruth Fox, a psychiatrist who specialized in the treatment of alcoholism.

Over the years, although NCADD's mission has always remained focused on Marty's vision, the organization has evolved to keep up with the changing environment. In 1957, the name changed to the National Council on Alcoholism; in 1987 it added

drug dependence to its mission, and in 1990, it became the National Council on Alcoholism and Drug Dependence, Inc. (NCADD).

NCADD Affiliate Network

At the heart of Marty's vision for NCADD was the establishment of a nationwide network of affiliates that would operate at the local and state levels. The NCADD affiliates are community-based, voluntary, nonprofit organizations that have evolved to provide (a) information services; (b) intervention, treatment, and recovery support services; and (c) advocacy. Last year alone, NCADD and the national network of affiliates handled more than 675,000 information and referral calls and reached more than 38 million people.

Public Awareness

NCADD's mission was to fundamentally redefine how the public perceived and responded to alcoholism and other addictions. Marty's goal was focused on generating public understanding and support for five "kinetic" ideas that were taken from an article written by one of NCADD's founders, Dwight Anderson of the New York State Medical Society:

1. Alcoholism is a disease.
2. The alcoholic, therefore, is a sick person.
3. The alcoholic can be helped.
4. The alcoholic is worth helping.
5. Alcoholism is our No. 4 public health problem, and our public responsibility.

To convey NCADD's "kinetic" ideas, Marty embarked on a national speaking tour and addressed an estimated 34,000 people within the first 24 months of the founding of NCADD.

As part of NCADD's effort to educate Americans about alcoholism and addiction, NCADD produced its first radio and TV ad campaigns. In 1976, NCADD sponsored Operation Understanding, which brought together more than 50 well-known and widely respected figures, including actor Dick Van Dyke, astronaut Buzz Aldrin, U.S. Senator Harold Hughes, Congressman Wilbur Mills, philanthropist R. Brinkley Smithers, actress Mercedes McCambridge, and baseball players Don Newcombe and Ryne Duren, as well

as others, to publicly announce their recovery from alcoholism. *Newsweek* magazine later called it one of the most important news stories of the 1970s.

NCADD's efforts with the national and local press aroused public interest in alcoholism and drug dependence, pioneering public education campaigns based on scientific information. In 1945, NCADD was featured in a March of Time film, *Problem Drinkers*, which reached millions of viewers across the United States. NCADD initiated National Alcohol Information Week, which, in 1987, became Alcohol Awareness Month, held each April. In 1981, advocacy efforts with the U.S. Postal Service resulted in the issuance of an alcoholism postage stamp to raise public awareness of the disease. NCADD developed a highly effective prevention program to help parents talk to their children about alcohol use and created the video *What Should I Tell My Children About Drinking?* narrated by actress Meryl Streep.

Impact on the Medical Community

In 1950, Marty Mann wrote her first widely acclaimed book, *Marty Mann's Primer on Alcoholism*. Throughout the 1950s, NCADD concentrated its primary activities on the destigmatization and medicalization of alcoholism with a focus on shifting the public view of alcoholism as a moral problem to alcoholism as a medical problem.

At the center of NCADD's focus was educating the American public that alcoholism was a disease. In 1943, the year before NCADD was born, only 6% of the public felt that alcoholism was a disease; by 1957 it was 58%, and in 1993 it had risen to 87%. In addition, NCADD focused on engaging key health care organizations to address alcoholism. In 1958, Ruth Fox became NCADD's medical director and led NCADD's efforts to (a) establish an alcoholism treatment specialty within medicine, (b) create an alcoholism policy voice within the medical community, and (c) encourage the major medical associations to take a policy stand on alcoholism.

The first two of these goals were accomplished through the 1954 founding of the New York City Medical Society on Alcoholism (precursor to the American Society of Addiction Medicine) and the National Nurses Society on Alcoholism. These two organizations, as well as the Research Society on Alcoholism, began within the NCADD offices and later became incorporated and independent organizations in 1982.

The third goal was reflected in NCADD's efforts to get the American Medical Association and the American Hospital Association to develop policies that would support alcoholics being admitted to local hospitals for detoxification and rehabilitation. With NCADD playing a key role, the American Medical Association defined alcoholism in 1952 and, in 1956, passed a landmark resolution declaring that chronic alcoholism should not bar admission to a hospital and that the alcoholic should be viewed as a sick person. This resolution paved the way for a more unequivocal statement, issued 11 years later, that alcoholism was a disease. The American Hospital Association passed resolutions in 1951 and 1957, declaring that the best placement for alcoholism treatment services was in the local community general hospital. These early achievements laid the foundation for the subsequent decriminalization of public intoxication, the extension of insurance coverage for alcoholism treatment, and the public funding of alcoholism treatment and prevention efforts. In 1944, as NCADD began, fewer than 100 general hospitals accepted acute cases of alcoholism. By 1953, more than 3,000 hospitals offered such care. NCADD developed the *Medical Criteria for Diagnosis of Alcoholism*, which was jointly published by the *American Journal of Psychiatry* and the *Annals of Internal Medicine*, setting professional standards for the diagnosis and treatment of alcoholism for the first time. In 1992, NCADD, with the American Society of Addiction Medicine, published a comprehensive definition of alcoholism in the *Journal of the American Medical Association (JAMA)*.

Advocacy for Government Support

In the late 1940s and 1950s, NCADD worked diligently to expand city, state, and national government support in response to the problem of alcoholism. Oregon, Utah, Connecticut, Alabama, and New Jersey were among the first states to legislate funds to respond to alcoholism and to create state-level alcoholism commissions. By 1954, 23 states were providing some funds for alcoholism treatment services, in great part as a result of the unrelenting travel and speeches of Marty Mann and the work of NCADD affiliates across the country. In 1948, 473 alcoholics were treated in state-sponsored treatment programs; in 1960, that number had risen to 26,000. Even where state efforts were inconsistent and underfunded, they laid a foundation upon which more substantial efforts could later be built. At the same time, NCADD was

instrumental in getting the National Institute on Mental Health to establish a Division on Alcoholism, and NCADD provided consultation to the U.S. military on development of the first alcoholism education programs in the military.

NCADD and Alcohol and Drugs in the Workplace

NCADD was the lead organization in developing interest in addressing alcoholism within the workplace. In 1948, NCADD hosted the first national conference on the problem of alcoholism in industry. Later, NCADD staff member Ralph "Lefty" Henderson wrote "The Half Man," an article describing how alcoholic employees invisibly drained a billion dollars per year from business and industry. Henderson's article has been described as the launching of the midcentury industrial alcoholism movement, a precursor to modern employee assistance programs (EAPs). In addition to publishing the first EAP standards and EAP manual, NCADD played a key role in the development of the Association of Labor Management Administrators and Consultants on Alcoholism, which later became the Employee Assistance Professionals Association. In 1974, NCADD established a Joint Labor-Management Committee chaired by George Meany, president of the AFL-CIO, and James Roche, director of General Motors Corporation, which resulted in starting more than 600 occupational alcoholism programs across the country. These programs have evolved into EAPs, which provide a broader range of services.

NCADD and the Religious Community

In the 1950s, NCADD's activities within American churches were developed in its collaboration with two organizations, the National Clergy Council on Alcoholism and Related Drug Problems and the North Conway Institute. As a result of these collaborations, the National Council of Churches issued a proclamation in 1958 that called for ministries to those afflicted and affected by alcoholism and for alcohol education programs in the church and the larger community.

NCADD and Women

In 1976, NCADD established an Office on Women with the slogan, "Alcoholism Is a Woman's Issue." At the time, very few women were involved in treatment, and there were virtually no women-specific treatment

programs. Through its Office on Women, NCADD established a public and professional education campaign and led the development of Task Forces on Women at the state level and hosted a series of national conferences. As a result, there was a dramatic increase in awareness and understanding of alcoholism among women, as well as support for expanded program opportunities for women.

NCADD and Policy and Advocacy

NCADD has always placed a high priority on policy and advocacy as nothing more than “targeted education,” aimed at changing the public response to alcoholism and drug dependence. NCADD’s advocacy has played a pivotal role in campaigning for government recognition of, and support for, alcoholism and drug dependence as a treatable disease, culminating in the passage of the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act in 1970, which paved the way for the creation of the National Institute on Alcohol Abuse and Alcoholism. In addition, NCADD’s advocacy has resulted in many significant changes that have increased prevention and education efforts and expanded access to treatment. Some of NCADD’s most significant advocacy accomplishments include the decriminalization of public intoxication, placement of warning labels on all alcoholic beverage containers, the establishment of 21 as the minimum legal drinking age, and increased federal funding for prevention and treatment services.

NCADD is proud of the role it has played and the great progress that has been made. NCADD remains committed to fighting for policy changes that will eliminate the discrimination that individuals who suffer from alcoholism and drug dependence are subjected to in health care, in access to services, in the workplace, and in the community.

NATIONAL COUNCIL ON PROBLEM GAMBLING

The National Council on Problem Gambling (NCPG) is the national advocate for programs and services to assist problem gamblers and their families. The NCPG was founded in New York City in 1972 by Joseph Dunne, Irving Sacher, and Robert Custer. It was originally known as the Council on Compulsive Gambling (1972–1976), then the National Council on Compulsive Gambling (1976–1989), before the change to the current name in 1989. The NCPG’s mission is to increase public awareness of pathological gambling, ensure the widespread availability of treatment for problem gamblers and their families, and encourage research and programs for prevention and education.

As an advocate for problem gamblers, NCPG does not take a position for or against legalized gambling but rather concentrates on the goal of helping those with gambling problems. The National Council is a 501(c)(3) tax-exempt charity and accepts donations from individuals and corporations in the United States. NCPG does not accept any restrictions on the use of contributions except as provided under federal and state nonprofit guidelines.

Membership and Organization

The NCPG membership consists of affiliate, individual, and organization members. Members do not receive goods or services. Affiliate members, also commonly known as councils or state councils, are state-based nonprofit groups that apply to become affiliate members of NCPG. Only one affiliate member is permitted per state. Affiliate councils are required to maintain a neutral stance on legalized gambling. Each affiliate appoints a representative to the NCPG board of directors, and the chair of the affiliate committee, which is voted on by the affiliates, serves on the executive committee.

Individual members are drawn from those who have been affected by problem gambling or those who work with problem gamblers. The majority of individual

members are recovering problem gamblers, loved ones or family members of problem gamblers, or counselors who treat this addiction.

Organization membership is restricted to corporations and government agencies in the United States. Sometimes referred to as a corporate membership, organizations from the gaming industry, state substance abuse and mental health agencies, counseling centers, treatment facilities, and general corporations all fall in this category.

NCPG is governed by a volunteer board of directors that is drawn from two sources. Each affiliate member receives one seat on the board, and this representative can be reappointed indefinitely. The board also seeks nominations for at-large board members, who currently have 20 seats. At present there are 35 affiliate members, resulting in a board of 55 individuals. The NCPG bylaws require that at least 51% of seats be held by affiliate members.

The National Council leadership is composed of five officers (president, executive vice president, vice president, treasurer, secretary) elected to 1-year terms, with a term limit of 3 years. The affiliate and at-large board members annually elect a representative to serve with the officers on the executive committee, which oversees all operations when the board is not in session. The executive director serves as an ex-officio member of the executive committee.

The NCPG maintains a number of standing and ad-hoc committees. Standing committees include bylaws, executive, finance, and personnel. The remaining committees, such as Conference, Helpline, National Problem Gambling Awareness Week, and Youth, are all ad-hoc. Committee chairs must be members of NCPG, although committee members can be drawn from anywhere.

The NCPG office is located in Washington, D.C., and houses three full-time staff: executive director, program manager, and administrative assistant.

Programs

Major NCPG programs include the National Problem Gambling Helpline Number and Network (800-522-4700), a single national point of access for problem-gambling information. The number is active in all 50 states, and calls are routed to one of 27 state and regional call centers based on their originating area code. Calls have risen from 145,470 in 2003 to 236,460 in 2006. The system is designed to ensure

that callers, regardless of location, will have to make only one call to get immediate assistance.

National Problem Gambling Awareness Week is an annual national effort to educate health care providers about problem gambling and provide “hope and help” to problem gamblers and their families. Thousands of comprehensive toolkits are provided free of charge to state advocacy and health care organizations, addictions clinics, senior centers, and schools. TV, radio, and print public service announcements are distributed in all 50 states and last year reached an estimated audience of 125 million.

The annual Conference on Prevention, Research and Treatment of Problem Gambling is the oldest and largest problem gambling-specific event in the world. Attendees receive more than 2 days of training on the latest clinical, research, and policy developments in the field.

Another important NCPG activity is to increase public awareness of problem gambling. Among the public awareness initiatives is the NCPG Web site, which receives more than 500,000 hits and 50,000 visits per month. NCPG has distributed, free of charge, more than 100,000 self-help workbooks to help family members of problem gamblers deal with the financial consequences of this addiction. Staff and board members are frequently quoted in local, state, national, and international media. NCPG is also active in educating Congress on problem gambling issues that arise in various bills.

NCPG has been involved in most of the other significant events in the problem gambling field. In 1985, Henry Lesieur established the *Journal of Gambling Behavior*, now known as the *Journal of Gambling Studies*. Also in 1985, the first National Conference on Problem Gambling was held in New York. Board members Custer, Lesieur, and Richard Rosenthal contributed directly to criteria for pathological gambling in the third and fourth editions of the *Diagnostic and Statistical Manual of Mental Disorders*. In 1998, Rachel Volberg received the first National Institute of Mental Health grant to study problem gambling in the community. In 1999, the NCPG provided crucial input regarding the recommendations of the National Gambling Impact Study Commission on problem gambling. Also that year, NCPG conducted the inaugural National Survey of Problem Gambling Programs, which found that approximately \$20 million in public and private funds is spent on problem gambling programs, including prevention, employee

training and education, and research and treatment. Nineteen ninety-nine was also the year that NCPG received its first federal contract from the U.S. Center for Mental Health Services.

Significant Trends and Future Directions

In 2004, NCPG officers and staff identified three significant trends in problem gambling that needed to be addressed. First, programs to serve problem gamblers were deemed inadequate to the needs of the current and projected problem gambling population. Second, there was and continues to be a growing need for greater support of and increase in the personnel who serve problem gamblers. Finally, the NCPG's years of successful growth resulted in a large and unwieldy governance structure that hinders its effective management and future growth.

At current rates and as the U.S. population increases, by 2014 the number of problem gamblers is expected to reach 12 to 18 million. This increase will place even greater demands on scarce national resources, as major shortfalls occur in the problem gambling workforce. On the federal level, attention and funding for problem gambling services are limited. The majority of states do not currently provide funding for problem gambling services, severely hampering the development of comprehensive programs. Additionally, current delivery standards, guidelines and best practices for gambling-specific prevention, education, training, regulation, legislation, certification, and treatment are rudimentary or nonexistent. As a result, the need for both collaboration and shared expertise in problem gambling services is expected to increase.

The strategic plan adopted in June 2007 outlined 14 interrelated and interdependent goals that include a continued focus on the NCPG's four core programs (helpline, annual conference, Problem Gambling Awareness Week, public awareness) with a reconstituted governance structure that will effectively promote both active participation of the NCPG members through a smaller, more responsive board of directors and an increase in membership participation through direct involvement in nominations and elections and on the board's standing and ad hoc committees. The plan seeks to increase NCPG membership in each of the categories with a goal of 50 affiliates, 500 organizational members, and 25,000 individual members by 2014. The National Council will create a development

office and build reserve and endowment funds, as well as a state-of-the-art management information system. A priority will be placed on a continuation of NCPG's national advocacy for federally funded services for problem gamblers and their families, continued encouragement of certification of 4,000 gambling counselors, and renewed collaboration with universities and other organizations to fill gaps in problem gambling research and policy.

NATIONAL DRUG CONTROL STRATEGY

In an effort to combat drug use, the Anti-Drug Abuse Act of 1998 established the White House Office of National Drug Control Policy (ONDCP) to oversee the country's domestic and international drug control policies. The ONDCP issues an annual National Drug Control Strategy (NDCS) report, which details efforts designed to prevent and reduce the production, distribution, use, and impact of illegal drugs. The NDCS has two main goals: (1) to decrease the availability of drugs in the United States, which is referred to as "supply reduction," and (2) to prevent and treat the use of illicit drugs to reduce the number of users, which together comprise "demand reduction." The objectives and procedures discussed in each yearly NDCS report describe the responsibilities and coordinate the activities of local, state, and federal agencies involved in the reduction of drug-related activities. The NDCS also outlines the annual budget, which funds the initiatives for all federal agencies with activities in supply reduction or demand reduction. Although there are methodological flaws in the research examining the effectiveness of the NDCS, it is fairly clear that the NDCS has not met its goals to reduce the supply and demand of illicit drugs in the United States.

NDCS Agencies and Activities

The NDCS coordinates the activities of federal agencies involved in antidrug-related programs, with funding in each yearly budget allocated specifically to the areas of supply reduction and demand reduction. Although the goals of the NDCS change on a yearly basis, several overarching activities and agencies continue to receive support.

Supply Reduction Agencies and Activities

The Department of Defense and the State Department work to combat drug producers and traffickers, as well as to reduce drug crops in countries involved in drug production. The Department of Homeland Security is involved in protecting the borders of the United States from drug trafficking through the activities of agencies such as Customs and Border Protection, the U.S. Coast Guard, and Immigration and Customs Enforcement. The Justice Department is provided funding under the NDCS to maintain agencies—for example, the Drug Enforcement Administration, the Office of Justice Programs, and the Interagency Crime and Drug Enforcement—that disrupt drug distribution and production. These agencies, among others, aim to interfere with drug production, distribution, and money laundering within the United States and other countries.

The NDCS has other focal points in continuing the process toward disrupting the supply to the drug market within the United States. By eradicating illicit crops, interdicting illegal drugs, and attacking drug organizations, the NDCS hopes to further reduce drug availability, which in turn would cause drug traffickers' costs to increase and reduce the overall profits associated with drug trafficking. By increasing the risk of arrest to drug traffickers, the NDCS attempts to deter traffickers from entering the market while also encouraging others to leave. The hope is that disrupting the drug market will result in less availability of drugs, a decline in purity, and an increase in the price of drugs within the United States. Proponents of these programs believe that interfering with the drug supply will reduce initiation of drug use and make it harder for users to sustain their drug dependencies.

Demand Reduction Agencies and Activities

The Department of Health and Human Services receives funding to focus on programs in the area of

demand reduction, with research on drug abuse, drug prevention and treatment, and pharmacology taking a large portion of the NDCS demand reduction budget in recent years. One third of monies dedicated to demand reduction in 2005 were directed to these activities. The Substance Abuse and Mental Health Services Administration (SAMHSA) and other programs under the Department of Health and Human Services provide money to states for alcohol and drug treatment programs. Previous studies have shown that 25% of the drug-using population is responsible for 75% of illicit drug consumption. Thus, changing the behavior of chronic drug users (typically addicted, frequent, high-volume drug users) may result in significant societal benefits.

A variety of prevention-specific agencies and activities fall within the previously mentioned departments and attempt to reduce demand by targeting youth. The Department of Education supports the Safe and Drug-Free Schools and Communities program, which allocates money to, and designs programs for, school districts to fund programs earmarked for drug and violence prevention. The Drug Free Communities Support Program combats substance abuse among youth by enabling and enhancing community and intergovernmental collaboration and cooperation, supporting more than 700 drug-free community coalitions, which help communities to identify and respond to local substance use problems. The Gang Resistance, Education, and Training (G.R.E.A.T.) program provides classroom instruction with law enforcement personnel who address issues relating to violent crime and street gangs in an effort to decrease gang and youth violence. The Youth Substance Abuse Prevention Initiative educates and enables youth to reject illegal drugs and underage use of alcohol and tobacco.

Demand reduction among adolescents has been seen as especially important in the overall reduction of demand, as studies have demonstrated adolescence as a critical time period in determining a person's risk for later drug dependency. Studies have suggested that those who initiate drug use during their early teen years are at a much greater risk for later drug dependency than those who initiate drug use in later life. Studies have also shown that if drug use is not initiated by age 18 to 20, it is unlikely that the individual will ever develop a drug dependency problem. This protective effect has been seen to last for life and points to why reducing drug use in youth is a key priority under the NDCS, as the goal is to reduce overall drug use in the United States over the long term.

The proponents of these programs believe that real advances are feasible with effective policy that comprises enforcement, treatment, and prevention, in addition to the support of state and local officials and the efforts of multiple faith-based and community organizations.

Budget

The budget for the NDCS focuses on the two broad areas of supply reduction and demand reduction. From 1996 to 2008 supply reduction received nearly \$119 billion in overall funding while demand reduction received nearly \$65 billion. Supply reduction consistently received around two times more funding than demand reduction from the years 1996 to 2001, although that gap lessened from 2002 to 2005. From 2002 through the currently requested budget for 2009, supply reduction budgets have increased by 57% while demand reduction budgets have increased by only 2.7%. This budget trend has continually moved toward increasing funding for supply reduction, which seems contrary to research that has shown that treatment and prevention, rather than supply reduction, are the best ways to reduce overall drug use. Research has shown that attempts to reduce drug problems in the United States by attacking drugs at their source and focusing on eradication and interdiction are not as effective as treatment and prevention programs, which reduce drug demand, save lives, and reduce crime and negative health consequences.

NDCS Effectiveness

More than \$180 billion has been devoted to supply and demand reduction from 1996 to 2008. Given the tremendous budget, it is reasonable to expect that funded initiatives be able to demonstrate effectiveness. Over the past decade, 21 specific performance goals have been set through a combination of the ONDCP Reauthorization Act of 1998, the Clinton administration, and the George W. Bush administration. Determining exactly how successful the NDCS has been in reducing the availability of drugs and decreasing drug-related crime, illness, and injury is difficult, as appropriate performance data have not been collected and some of the measures used to conduct assessments have changed over time. Therefore, although available data limit the ability to draw conclusions as to whether some individual goals have been met, they do provide a more general sense of overall change.

The Reauthorization Act and 1999 and 2002 NDCS reports included goals for decreasing prevalence rates of illegal drug use among adolescents and adults. Three national surveys have been used to evaluate how successful the NDCS has been in meeting these objectives. The National Survey on Drug Use and Health is a federally sponsored survey that measures cigarette, alcohol, and illicit drug use among American adults and adolescents; the Monitoring the Future Survey and Youth Risk Behavior Surveillance System assess similar behaviors among youth. The target included in the 1999 NDCS report was to reduce the prevalence of illegal drug use by 25% by 2002 and 50% by 2007, with 1996 as the baseline. The 2002 report set the goal for an overall reduction in illegal drug use as 10% by 2004 and 25% by 2007, with 2000 as the baseline.

According to the National Survey on Drug Use and Health, the prevalence of drug use from 1996 to 1998 was stable, increased from 1999 to 2001, and remained the same from 2002 to 2006. Although firm conclusions cannot be drawn about prevalence trends due to changes in survey procedures, it nonetheless remains clear that none of the proposed goals has been achieved. Data from the Monitoring the Future Survey are more encouraging. Younger adolescents (8th and 10th graders) reported greater reductions in illicit drug use than older adolescents and adults from 1996 to 2007, with 8th and 10th graders achieving the 2002 goal of a 25% reduction in prevalence set by the 1999 NDCS. In contrast, older adolescents and young adults reported smaller decreases or increased rates of use over the same years, so that the overall prevalence of drug use among adolescents continues to exceed target levels. Taken together, it appears that the NDCS has not been successful in reducing the prevalence of drug use behaviors, although certain age groups did show progress.

The Reauthorization Act and the 1999 NDCS report each included goals for reducing the supply of illegal drugs from domestic production and international drug trafficking, and for decreasing the purity of available drugs. Unfortunately, these goals are more difficult to assess because of the lack of a benchmark comparison coupled with insufficient means for evaluating available supply, given that drugs are an illegal commodity. However, taking into consideration the principles of supply and demand, the fact that the price of cocaine, crack, and heroin have dramatically decreased over the past decade, without a concomitant reduction in quality, would suggest that the supply of those drugs in the United States has not been greatly

impacted. Moreover, methamphetamine has experienced a price reduction even though the purity has increased. Similarly, the price of marijuana increased about 12% from 1996 to 2003, but the THC (active ingredient) content in marijuana rose nearly 5 times as much during the same time period. This information—combined with numerous federal reports, including the National Drug Threat Assessment, which testifies to the ongoing struggle against cocaine, heroin, and marijuana trafficking, production, and supply—suggests that efforts to dramatically reduce the availability of drugs in the United States have been generally unsuccessful.

The Reauthorization Act and the 1999 NCDS report also included targets for decreasing the social and economic costs of illegal drug use, including crime, illness, and accidental injury. Again, it is difficult to gauge the success of these initiatives as there are few direct measures for assessment. Regarding drug-related crime, it is impossible to estimate how many arrests were drug related because drug involvement is often not recognized. However, from 1996 to 2002, the number of drug abuse arrests increased by approximately 2%. Moreover, the ONDCP commissioned a study to determine the economic costs of drug abuse. It was reported that the crime-related costs of drug abuse were \$107.8 billion in 2002 compared with \$78.4 billion in 1996. Another report issued by the ONDCP noted that the overall economic cost of drug abuse was \$129.6 billion in 1996 as opposed to \$180.8 billion in 2002, which certainly implies that the drug-related economic burden in the United States has risen rather than declined. Regarding health consequences of drug use, the prevalence of drug-related deaths increased substantially from 1996 to 2002, from 14,843 to 21,683. During this same time, the number of drug-related emergency room visits among 18- to 25-year-olds and the number of drug users living with AIDS also showed steep increases. On the other hand, the number of drug-related emergency room visits among 12- to 17-year-olds decreased. Overall, it appears that progress on goals related to reducing drug-related economic and social costs has also failed to meet proposed levels.

Conclusion

Although the proponents of the NDCS believe that advances are possible in the fight to prevent and reduce the production, distribution, use, and impact of illegal drugs, very few goals have been achieved.

Clearly the NDCS aims to address a critical public health problem in the United States; however, the future goals and direction of funding may be more effectively tailored on the basis of comprehensive, ongoing program evaluation. Although the NDCS was created with good intentions, it is heavily influenced by political pressures. With few exceptions, it is clear that the NDCS has not been effective. Billions of dollars are spent each year to implement its strategies without much examination of how the policies could be revised or improved. Discussions about alternative approaches to the NDCS, such as harm reduction, decriminalization, and legalization, have typically been discouraged among researchers, clinicians, and policymakers who are involved with the NDCS.

NATIONAL EPIDEMIOLOGIC SURVEY ON ALCOHOL AND RELATED CONDITIONS

The National Epidemiologic Survey on Alcohol and Related Conditions is a longitudinal study that was conducted by the U.S. Census Bureau for the National Institute on Alcohol Abuse and Alcoholism. The survey collected information about present and past alcohol use, alcohol use disorders, co-occurring mental health disorders, and the use of treatment services for alcohol abuse, as well as basic demographic information and information related to tobacco and illicit drug

use. The complete data set provides a detailed and comprehensive source of information on alcohol and comorbid disorders. To date, it is the largest longitudinal study ever conducted in the United States on alcoholism and related conditions. This study is also the first study to use the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* definitions of independent mood and anxiety disorders to examine the co-occurrence of mental health disorders.

One of the major goals of the survey was to determine the prevalence of alcohol use disorders and their associated disabilities in the general population and to increase the understanding of the natural history of alcohol use disorders. Other goals of the survey included obtaining a measure of how many people are or are not receiving treatment for alcohol use disorders, getting a picture of the demographic characteristics of those people receiving treatment, and uncovering any barriers to treatment, especially among low-income groups, women, young adults, and minorities. The survey also sought to determine the associations between alcohol use disorders and major physical and mental disabilities.

The survey was conducted in two waves. The first wave was conducted from 2001 to 2002 and the second wave from 2004 to 2005. The waves differed from each other in that the first wave focused on the respondent's entire lifetime, whereas the second wave focused on things that happened since the last interview. Wave 2 also added questions on sexual orientation; adverse events; physical, sexual, and psychological abuse; social integration; acculturation; perceived experiences of discrimination; and questions for classifying mental disorders that were not included in the first wave.

Using laptop computer-assisted software, approximately 1,800 interviewers from the U.S. Census Bureau administered the survey. Before going into the field, the interviewers completed a 5-day home study and a 5-day in-class training. The training supervisors from each regional office also completed a home study and in-class training by National Institute on Alcohol Abuse and Alcoholism sponsors and Census Field and Demographics Survey Division Headquarters staff.

During Wave 1, face-to-face interviews were conducted with 43,093 respondents. The respondents recruited to participate in the survey were the civilian, noninstitutionalized adult (18 and older) population of the United States, which included residents

residing in the District of Columbia. To get data from people not usually captured by household surveys, the researchers chose to survey not only individuals living in traditional households but also those living in different types of living situations. Therefore, the researchers included military personnel living off base and people living in a variety of group accommodations, such as boarding houses, rooming houses, nontransient hotels and motels, shelters, facilities for housing workers, college quarters, and group homes. Because one of the aims of the survey was to look at racial and ethnic disparities in comorbidity and access to health care, the researchers oversampled Blacks and Hispanics to make sure that they were well represented in the sample. Young adults (ages 18–24) were also oversampled in order to get a better understanding of the nature of alcohol use among this age group.

The sampling frame for the housing unit was the Census 2000/2001 Supplementary Survey (C2SS). This is a national survey conducted by the U.S. Census Bureau of about 78,300 households per month. The C2SS collects information about person and housing units in all 50 states and the District of Columbia. The group quarters sampling frame came from the Census 2000 Group Quarters Inventory.

One adult from each household was randomly selected to take part in the survey. Individuals living in group accommodations were randomly selected from a systematic sample of group quarters. All survey respondents were informed in writing about the nature and purpose of the study and that their participation was completely voluntary. Those who consented to participate took part in a face-to-face interview at their home.

The overall response rate for Wave 1 was 81%, with an 89% household response rate (a nonresponse for this was counted when an interview was not obtained from the household and a sample person was never selected), a 93% person response rate (a person nonresponse occurred when the sample person selected was never interviewed), and a 99% sampling frame response rate (this included nonresponders from the C2SS who were eligible to be interviewed for this survey but were not). Interviewers successfully completed a follow-up interview with about 87% of the sample during Wave 2.

Analyses using these data have so far shown that about 9% of the population meets the clinical criteria for a substance use disorder, which includes either an alcohol or drug use disorder or both. Also, the findings

show that the occurrence of comorbid psychiatric disorders with alcohol use disorders happen in a quarter to almost half of clients in treatment. The previously mentioned examples are just a few of the many findings that have come out of this data set. Overall, the data from this survey provide a wealth of information that can help researchers and policymakers gain a greater understanding of alcohol use disorders, which can lead to the development of more effective prevention and treatment programs for those with alcohol and other substance abuse problems.

NATIONAL GAMBLING IMPACT STUDY COMMISSION

The U.S. Congress created the National Gambling Impact Study Commission (NGISC) to investigate the social and economic impacts of legalized gambling on

the U.S. population. Established in 1997, the NGISC was formed in response to the dramatic expansion of legalized gambling over the previous 25 years. Between 1973 and 1997, the number of states offering lotteries increased from 7 to 37, and cumulative annual sales rose by \$32 billion. Prior to 1990, Nevada and New Jersey were the only two states offering legalized casinos; by 1999, 28 states had legalized casinos. Despite the widespread expansion, very little was known about the societal impact of legalized gambling. The NGISC's mandate was to provide an accurate assessment of the social and economic benefits and costs of legalized gambling at both individual and community levels.

The NGISC Report

The NGISC report provides an overview of the current research (including research commissioned specifically for the report) on gambling behavior, along with recommendations for government action and future research. The NGISC commissioned two independent research bodies to supplement their investigation: the National Opinion Research Center (NORC) and the National Research Council (NRC) of the National Academy of Sciences. The NRC was mandated to review the existing literature on problem and pathological gambling, whereas NORC conducted a survey of gambling behaviors in the U.S. population. These two efforts provide a foundation for the NGISC report's findings and recommendations and offer unique and wide-ranging data that continue to be used by researchers a decade later.

The Role of Government

Reviewing the influence of government on the expansion of legalized gambling, the NGISC report argues that governments—be they local, state, tribal, or federal—have not created a unitary policy on the expansion of legalized gambling. Instead, what exists across each level of government is a series of apparently discrete laws, established independently of one another and without consideration for the overarching repercussions of the policy as a whole. One reason for this lack of a unitary policy is the presence of multiple decision makers. The heterogeneous blend of local, state, tribal, and federal gambling laws has generated a similarly heterogeneous policy. The gambling industry is also heterogeneous, comprising multiple

distinct segments, including state lotteries, pari-mutual wagering venues, and casinos, among others. This heterogeneity has also contributed to differences in governmental policies. The NGISC noted that governments often favor policies that maximize immediate public profit, without fully considering the long-term public costs. Considering the heterogeneous state of gambling regulation, in conjunction with legalized gambling's rapid increase and multiple existing knowledge gaps regarding the impact of gambling, the NGISC recommended a pause in gambling expansion.

Individual and Societal Impacts of Gambling

The economic benefits of gambling, such as job creation and increases in tourism, have long been recognized. The subsidizing of state governments through lotteries has become commonplace, with 37 states offering lotteries. However, the individual economic and personal costs of gambling are more difficult to assess. For example, although it is possible in some cases to assign monetary costs to gambling-associated consequences, such as divorce, the overall human cost (e.g., emotional damage, children living in a single-parent household) is difficult to quantify.

Problem Gambling and Pathological Gambling

Along with the expansion of legalized gambling, data suggest a concurrent rise in the prevalence estimates of problem gambling and pathological gambling, and the NGISC recommended that more attention be devoted to these phenomena. Pathological gambling was first included in the *Diagnostic and Statistical Manual of Mental Disorders (DSM)* in 1980, classified as an impulse control disorder. Based on the data gathered by the NRC and NORC (discussed in greater detail in the next section), the NGISC estimated the overall prevalence of lifetime pathological gambling as between 1.2% and 1.5% of the adult population. It also estimated that an additional 1.5% to 3.9% of the adult population met criteria as lifetime problem gamblers.

The NRC Report

The NRC report, aimed at assessing both the prevalence and repercussions of pathological gambling in the American population, examined 4,000

gambling-related references, of which 1,600 specifically addressed pathological/problem gambling. The committee found little systematic research into estimates of gambling prevalence. Among existing studies seeking to estimate the prevalence of pathological gambling, various methodological limitations, including the underrepresentation of both female and non-White gamblers, were identified. The NRC recommended that more research involving larger, more heterogeneous populations be performed to generate improved prevalence estimates.

Estimating the Prevalence of Pathological Gambling

Over the past several decades, the diagnostic criteria for pathological gambling have undergone several revisions, and multiple instruments have been used to assess pathological gambling. The South Oaks Gambling Screen (SOGS) has been the most widely used measure employed to assess pathological gambling. However, the SOGS is based on earlier diagnostic criteria for pathological gambling. Furthermore, as the SOGS was designed as a screening instrument for use in clinical populations, it is prone to overidentify individuals as engaging in pathological gambling. Consequently, instruments using current *DSM-IV-TR* (4th ed., text rev.) criteria have been preferentially used in more recent surveys. The NRC further notes that an additional complication is in the frequent misapplication of the term *prevalence* in studies of pathological gambling. The most common misapplication of prevalence occurs when the population and geographical location are correctly defined but there is a failure to define the specific time frame studied.

Prior to the NORC study (discussed in the following section), only two studies had attempted to assess national gambling prevalence. A 1975 study conducted by the University of Michigan Survey Research Center concluded that roughly 0.77% of the population were "probable compulsive gamblers" and that 2.33% were "potential problem gamblers." The researchers cautioned that their estimates failed to control for the presence of other disorders that could account for inclusion as a "compulsive gambler." A 1997 meta-analysis of 120 studies of gambling prevalence conducted by Howard Shaffer and colleagues estimated that 5.4% of the general population of both the United States and Canada met criteria for lifetime problem or pathological gambling and that 2.9% met

criteria for past-year problem or pathological gambling. More recent studies using instruments based on *DSM* criteria have generated lower estimates; for example, the National Epidemiologic Survey of Alcoholism and Related Conditions found past-year and lifetime prevalence estimates of pathological gambling of 0.2% and 0.4%, respectively.

Etiology

Although the etiologies of problem and pathological gambling are incompletely understood, research has identified multiple risk factors, including early age at gambling onset, male gender, and a family member with a gambling problem. Studies of twins indicate a high degree of heritability for pathological gambling, and biological investigations have implicated serotonergic, dopaminergic, noradrenergic, and opioidergic neurotransmitter systems. Co-occurring disorders provide insight into the etiology of gambling problems. Studies indicate that a broad range of Axis I and Axis II disorders commonly co-occur with pathological gambling, and recently emerging data suggest that co-occurring disorders can help select appropriate treatments for individuals with pathological gambling.

Treatment

At the time of the NRC report, there had been limited research into the treatment of pathological gambling. Treatment options having received empirical support and performed predominantly since the time of the NRC study include motivational enhancement, cognitive, and cognitive behavioral therapies; pharmacological agents, including serotonin reuptake inhibitors, opioid antagonists, and mood stabilizers; and support group (i.e., Gamblers Anonymous) approaches.

Costs and Consequences

The literature yielded few conclusive data on the economic and social costs of problem and pathological gambling both to the individual and to society as a whole. For societal costs, only a few studies were found to have analyzed the overall economic impact of legalized gambling, and those that did so examined primarily casino gambling. Studies aimed at assessing the individual costs of pathological gambling tended to examine the repercussions experienced by the individual, as well as by those impacted by the pathological

gambler (i.e., employers, family members). Not surprisingly, there is a positive association between bankruptcy and pathological gambling. Problem and pathological gamblers also appear at high risk for suicide, alcohol or drug use or abuse, and criminal activity. The family members of problem and pathological gamblers are at risk for emotional problems, physical and verbal abuse, and substance abuse. However, as with the research into the etiology of problem and pathological gambling, existing studies were often limited by their use of treatment populations.

The NORC Gambling Impact and Behavior Study

Analysis of Gambling Prevalence

Employing a random-digit-dialing paradigm, NORC conducted a nationally representative survey of the gambling attitudes and behaviors of 2,417 adults. As a supplement to this sample, they administered an abbreviated face-to-face version of the telephone questionnaire to 530 adult patrons intercepted in 21 gambling facilities. In a separate phone survey, NORC administered the full questionnaire to 534 adolescents between the ages of 16 and 17. To study the community effects of casino proximity, NORC analyzed previously gathered social and economic data from 100 communities.

To estimate the prevalence of pathological gambling, NORC created the DSM-IV Screen for Gambling Problems (NODS), an instrument based on the inclusionary criteria for pathological gambling. Initial work was dedicated to preliminary examination of the psychometric properties of the NODS. Thereafter, the NODS was employed in the surveys and used to categorize individuals into one of four groups: low-risk gambler (has lost at least \$100 in a single day or year but meets no *DSM-IV-TR* criteria or has not lost \$100 or more in a single day or year), at-risk gambler (one or two *DSM-IV-TR* criteria), problem gambler (three or four *DSM-IV-TR* criteria), and pathological gambler (five or more *DSM-IV-TR* criteria). Lifetime and past-year gambling severity measures were assessed.

Analysis of the combined data obtained from the adult phone survey and the patron survey yielded prevalence estimates as follows: 0.7% of the population were classified as past-year problem gamblers, 1.5% were classified as lifetime problem gamblers, 0.6%

were classified as past-year pathological gamblers, and 1.2% were classified as lifetime pathological gamblers. Men were more likely than women to be classified as at-risk or problem gamblers for both past-year and lifetime prevalence rates and were also more than twice as likely to be classified as both past-year and lifetime pathological gamblers. Based on participants' self-categorization as either Black, White, Hispanic, or other, it was found that Black adults were more likely to endorse problem and pathological gambling and that Hispanic adults were more likely to endorse at-risk gambling than were any of the other three racial groups.

Social, Economic, and Health-Related Correlates of Gambling Behavior

Analyses of the Gambling Impact and Behavior Study (GIBS) data revealed that lifetime pathological gamblers were twice as likely as low-risk gamblers to report fair or poor subjective general health over the previous year. Similarly, both problem and pathological gamblers were twice as likely as low-risk and nongamblers to have sought treatment for mental or emotional problems within the past year, and were more likely than low-risk gamblers and nongamblers to have lost a job in the past year and to have previously declared bankruptcy. Lifetime and past-year at-risk, problem, and pathological gamblers were all more likely than low-risk gamblers or nongamblers to have used illicit drugs in the past year and were also more likely to have previously been dependent on alcohol or drugs.

NORC analyzed the costs associated with negative life events (e.g., divorce, bankruptcy, incarceration, health problems) for problem and pathological gamblers in comparison to nonproblem and nonpathological gamblers. Based on their analysis, NORC concluded that problem and pathological gamblers suffer greater personal costs associated with negative life events than do low-risk gamblers and nongamblers, often fail to attribute their problems to gambling, and cost society \$5 billion each year.

Adolescent Gambling

Using an augmented random-digit-dialing paradigm, NORC additionally surveyed 534 adolescents between the ages of 16 and 17. They found that adolescents not only gamble less frequently than adults but also display different gambling patterns, such as a tendency to gamble on small, unlicensed games

(e.g., card games). Although adolescents typically gamble less frequently than do adults, adolescent gambling behavior is a highly important area of gambling research, particularly as an early age of gambling onset has been associated with pathological gambling and other mental health problems in adults.

Conclusion

In response to the expansion of legalized gambling, the congressionally mandated National Gambling Impact Study Commission was asked to assess the wide-ranging social and economic costs and benefits of legalized gambling in the United States. The resultant Final Report includes the data gathered by the NRC and the NORC. Together, these documents provide an unprecedented analysis of legalized gambling, and the unique and diverse data obtained under the commission's mandate are still used by researchers today.

NATIONAL INSTITUTE OF MENTAL HEALTH

The National Institute of Mental Health (NIMH) is the U.S. federal government's principal agency for conducting and funding research on mental illnesses and behavioral disorders. The NIMH was established on July 3, 1946, when President Harry S. Truman signed

the National Mental Health Act (Public Law 79-487). The NIMH is one of 27 components of the National Institutes of Health (NIH). The NIH is the lead federal agency for behavioral and biomedical research. The NIH, as well as the NIMH, is part of the U.S. Department of Health and Human Services.

The mission of the NIMH is to decrease the impacts of mental illness and behavioral disorders by researching behavior, the brain, and the mind. It is currently felt that this public health mandate can best be met by using science to help elucidate mental illnesses and behavioral disorders, including how to treat, as well as how to prevent, these conditions.

To fulfill the NIMH's mission, its scientists conduct research on mental and behavioral disorders and on the underlying science of the brain and behavior, and the agency also funds basic and clinical research conducted by other researchers across the country. The NIMH collects, analyzes, and disseminates information on the causes, incidence, treatment, and prevention of mental illnesses and behavioral disorders.

The strategic plans and priorities of the NIMH are to support basic scientific investigations on the pathophysiology of mental illnesses and behavioral disorders and to translate those findings into new interventions to alleviate the suffering of those with such conditions. This includes ensuring that appropriate approaches are implemented in diverse settings to serve diverse populations suffering with mental illnesses and behavioral disorders. Genetics and neuroscience are areas being examined for future advances in predicting, identifying, and treating mental illnesses and behavioral disorders. Cutting-edge research is conducted by NIMH scientists and those they sponsor in many areas relating to mental disorders, such as studies of the mechanisms of brain functioning. Clinical trials are also conducted by the NIMH to determine the effectiveness of treatments. Clinical studies conducted by the NIMH have, for example, already indicated the efficacy of antidepressant medications for treating adolescents, as well as the effectiveness of generic antipsychotic medicines for treating adults with chronic schizophrenia. The NIMH strives to combine rigorous scientific studies with a multidisciplinary perspective to move forward in addressing the underlying causes of mental and behavioral disorders.

The NIMH has been a leading governmental agency in federal initiatives addressing substance abuse prevention, treatment, and recovery. In 1965,

the National Center for Prevention and Control of Alcoholism was established as part of the NIMH, and in the same year a research program on drug abuse was created: the Center for Studies of Narcotic and Drug Abuse. In 1970, the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act (Public Law 91-616) established the National Institute on Alcohol Abuse and Alcoholism (NIAAA) within the NIMH. In 1972, the Drug Abuse Office and Treatment Act (Public Law 92-255) established the National Institute on Drug Abuse (NIDA) within the NIMH. In 1973, the secretary of the U.S. Department of Health, Education and Welfare administratively established the Alcohol, Drug Abuse, and Mental Health Administration, which consisted of NIMH, NIAAA, and NIDA. This was authorized in 1974 by Public Law 93-282. In 1992, Congress abolished the Alcohol, Drug Abuse, and Mental Health Administration with Public Law 102-321, which placed the research components of NIMH, NIAAA, and NIDA in the National Institutes of Health and the service components of these agencies in the newly created Substance Abuse and Mental Health Services Administration.

The NIMH is currently organized into seven major divisions: Division of Neuroscience and Basic Behavioral Science, Division of Adult Translational Research and Treatment Development, Division of Pediatric Translational Research and Treatment Development, Division of AIDS and Health and Behavior Research, Division of Services and Intervention Research, Division of Extramural Activities, and Division of Intramural Research Programs. The National Advisory Mental Health Council serves as an advisory board to the director of the NIMH, the director of the NIH, and the secretary of Health and Human Services.

The NIMH publishes materials providing information on an array of mental illnesses and behavioral disorders, treatment approaches, and research findings. These publications include fact sheets and booklets, some of which are available in Spanish. Online sources of information are available as well. The NIMH research initiatives include the Human Genetics Initiative, Neuroinformatics: Human Brain Project, and the Prevention Research Initiative. The NIMH hosts public forums and dialogues across the country to inform the public—including consumers and their families, advocates, health care providers, and policymakers—about research-based findings on

mental illnesses and behavioral disorders. The NIMH also hosts scientific meetings, such as the Human Brain Project annual conference, and is committed to the training of new researchers.

NATIONAL INSTITUTE ON ALCOHOL ABUSE AND ALCOHOLISM

The National Institute on Alcohol Abuse and Alcoholism (NIAAA) is the National Institutes of Health entity responsible for research on the prevention and treatment of alcohol use and abuse. This entry summarizes the development and mission of NIAAA and describes the Comprehensive Alcoholism Prevention, Treatment, and Rehabilitation Act of 1970.

According to its mission statement, NIAAA supports research related to the prevention and treatment of alcohol disorders, coordinates with other federal agencies, collaborates internationally, and disseminates research findings. NIAAA's federal fiscal year (FY) 2006 appropriation of approximately \$440 million supported 953 research grants and 257 training grants; resources were also provided for contracts, clinical trials, and an intramural research program. Budgets for the National Institutes of Health are projected to be stable or slightly negative for the foreseeable future.

NIAAA was formally authorized in the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act of 1970 (Public Law [P.L.] 91-616). This landmark legislation shaped the nation's system for the prevention and treatment

of alcohol and drug disorders and created a research infrastructure to assess the causes and consequences of alcohol use and abuse. In addition to authorizing NIAAA within the National Institute of Mental Health (NIMH) to administer alcoholism prevention and treatment services and coordinate federal activities, the act established federal formula grants for states, specified identification of a Single State Authority to coordinate state applications and activities, and required the development of comprehensive state plans for the treatment and prevention of alcoholism and alcohol abuse. NIAAA administered those funds and reviewed state plans. The act also created the National Advisory Council on Alcohol Abuse and Alcoholism to assist in the development of national policy, mandated development of treatment and prevention services for federal civilian employees, encouraged hospitals to admit alcoholics, protected the confidentiality of patient records, and funded research. Some refer to the legislation as the Alcoholic's Bill of Rights because it created a national program to support the development and funding of alcoholism treatment and prevention services and encouraged programs of research on alcoholism and its treatment. Most often, however, P.L. 91-616 is known simply as the Hughes Act, in honor of its chief sponsor, Senator Harold Hughes.

The National Center for the Prevention and Control of Alcoholism was already established within NIMH and became the foundation for NIAAA. The reauthorizations of the Hughes Act in 1974 (P.L. 93-282) and 1976 (P.L. 94-371) increased NIAAA's visibility. Congress established the National Institute on Drug Abuse (NIDA) in 1973 and moved NIAAA, NIDA, and NIMH out of the National Institutes on Health and into a newly created entity called the Alcohol, Drug Abuse, and Mental Health Administration, which funded alcohol, drug, and mental health services and administered research grants. Many of the nation's alcohol and drug treatment centers began or expanded during this period with demonstration grants from the federal institutes.

Funding for alcoholism and drug abuse treatment services was dramatically altered in 1981 when the Omnibus Budget Reconciliation Act (P.L. 97-35) combined funds from direct project grants and state formula grants and created the Alcohol, Drug Abuse, and Mental Health Services block grant. The Reagan administration and Congress argued that the expansion of project grants had produced multiple programs

servicing the same individuals and increased burdensome reporting requirements. The Omnibus Budget Reconciliation Act consolidated categorical grants into nine block grants. The goals included administrative savings, decentralization of decision making, improvements in local coordination, and more flexibility and innovation with a general expectation of reduced reporting requirements. Total federal appropriations for the services included in the block grants declined about \$1 billion, or 12% of the 1980 appropriations; the Alcohol, Drug Abuse, and Mental Health Services block grant incurred a disproportionate 26% reduction. The Alcohol, Drug Abuse and Mental Health Administration administered the block grant. There were relatively few restrictions on how states could spend block grant funding.

Federal control of alcohol and drug abuse prevention and treatment services was firmly restored and enhanced in 1992 when Congress separated the administration of treatment and prevention services from research activity. Legislation amended the Public Health Service Act and (a) eliminated the Alcohol, Drug Abuse and Mental Health Services Administration; (b) created, in its place, the Substance Abuse and Mental Health Services Administration, composed of the Center for Substance Abuse Treatment (previously the Office for Treatment Improvement), the Center for Substance Abuse Prevention (previously the Office for Substance Abuse Prevention), and the newly created Center for Mental Health Services; (c) restricted the activities of NIAAA, NIDA, and NIMH to research; and (d) returned the three research institutes to the National Institutes of Health (P.L. 102-321).

NIAAA's *Five Year Strategic Plan* for federal fiscal years 2007 to 2011 uses a life span perspective to articulate research priorities that promote insight into alcohol use and the development of alcohol use disorders. A life span perspective recognizes that biology and behavior change as individuals mature and supports research into how changes in biology, psychology, and social environment influence the development and expression of alcohol use and alcohol use disorders. As a result, NIAAA seeks research that examines age-appropriate issues related to prevention and treatment of alcohol disorders. Priority research areas for studies of alcohol use and abuse include metabolism, interactions between genetics and environment, gene expression, neurobiology, and diagnosis of alcohol use disorders. The following life stages

are examined: embryo and fetus, early and middle childhood, youth and adolescence, young adult, midlife, and senior adult. The report examines epidemiology, biology, prevention, treatment, research opportunities, outreach efforts, and research collaborations for each age group.

Alcohol Research & Health is NIAAA's journal. Each issue is organized around a topical theme, and articles are written for the general public. It is an excellent resource on the latest research developments and is available on NIAAA's Web site.

NATIONAL INSTITUTE ON DRUG ABUSE

The National Institute on Drug Abuse (NIDA) is the federal focal point for research on drug abuse and addiction. Originally established in 1974, NIDA became part of the National Institutes of Health, within the U.S. Department of Health and Human Services, in October 1992. NIDA's mission is to lead the nation in bringing the power of science to bear on drug abuse and addiction. NIDA has two focus

points: The first is the strategic support and conducting of research across a broad range of disciplines. The second is ensuring the rapid and effective dissemination and utilization of that research to improve prevention and treatment services as it relates to drug abuse and addiction. NIDA's research agenda strives to address the essential questions about drug abuse, ranging from how drugs affect the brain and body to the development and testing of new treatment and prevention approaches.

NIDA encourages research on the developing brain and the effects that abuse of drugs have on the brain across the life span. Understanding how these brain processes, as well as other factors such as social context, play in decision-making and risk-taking behaviors will help to develop targeted interventions to prevent the initiation of drug use and its escalation to abuse and addiction. Furthermore, NIDA encourages research into the comorbidity of drug addiction and mental illness. This research plans to braid the neurobiological underpinnings of both disorders with research at a more clinical level to elucidate the risk and protective factors for the development of mental health and substance abuse problems across the life span. NIDA is also interested in research aimed at understanding the role the environment plays on neurobiological factors, such as gene expression. By supporting research that simultaneously works to uncover the genetic factors involved in the addiction process, NIDA and its partners will be able to tease out genetic, social, and cultural risk and protective factors.

Within the context of treatment, NIDA's primary goal is to bring effective new medications and behavioral treatments to practitioners. Researchers are encouraged to capture the knowledge generated from science to develop new and improved interventions. Finding treatments to help the nearly 4 million Americans who are addicted to marijuana is a top priority for the institute, as is the development of new medications to treat methamphetamine and prescription drug abuse. NIDA hopes to foster research on behavioral interventions that take advantage of new imaging tools to monitor changes linked with the interventions themselves and their subsequent effects on addiction.

NIDA also continues its efforts to develop medications to reverse changes in the brain caused by chronic drug exposure. For example, chronic drug use causes changes to occur in the brain so that further exposure to drugs or to environmental cues linked to drugs

results in a conditioned response. These conditioned responses often precipitate relapse in former drug users. NIDA is conducting research aimed at developing medications that interfere with the expression of conditioned responses. Development of these medications, along with behavioral therapies and other support services, may make it possible to more effectively treat drug addiction and help people return as functioning members of society.

Bridging the gap from scientific discovery to application in the community is a focus of NIDA. NIDA researchers play a critical role in facilitating the translation of research into useful tools, programs, and interventions. Equally important is the reality that basic research is guided by what is happening in the community. As of 2007, NIDA had programs focusing on AIDS research, international issues, special populations, and women's health and gender differences.

The AIDS Research Project provides direction and leadership for the ongoing development of an innovative and multidisciplinary HIV/AIDS research portfolio that addresses the unique dimensions of drug use and abuse as they relate to HIV/AIDS. The development and implementation of this program is guided by the role of drug use and its related behaviors in the evolving dynamics of HIV/AIDS epidemiology, natural history and pathogenesis, treatment, and prevention, in coordination with the current priorities and objectives of the National Institutes of Health.

The NIDA international program coordinates the institute's collaborative activities with scientists in other countries, with government agencies in other countries, and with international organizations. Within this NIDA program, the aim is to foster international cooperative research and the exchange of scientific information. The goals of this program include promoting international research activities, supporting research training and exchange opportunities, communicating and disseminating science-based information on drug abuse, and supporting international research collaboration.

NIDA has been a strong proponent of encouraging new and minority researchers to enter the substance abuse research field. The Special Populations Office is dedicated to ensuring that minority issues are adequately represented and appropriately included in the extramural research program. A focal point of this effort is to increase the number of underrepresented scholars, such as minorities and

women, participating in drug abuse research. To achieve this goal, NIDA sponsors several programs to encourage and foster research careers among minority researchers. Examples of these programs include the following:

The Special Populations Research Seminar Series provides drug abuse grant-development training to minority and women researchers. This training is provided in intensive one-on-one and small-group sessions.

Research Supplements for Underrepresented Minorities are research awards for two or more years made to individual minority students and investigators who propose to work with current NIDA grantees.

The Minority Recruitment and Training Program is a program run by NIDA's intramural division. Among other activities, summer research placements with NIDA intramural scientists are available for students and faculty.

Minority Access to Research Careers is a support program available to institutions providing support to significant numbers of minority students for the purpose of increasing the participation of minorities in research careers.

Historically Black Colleges and Universities (HBCU) Initiative is a special initiative intended to increase the interest and capacity of HBCUs to conduct drug abuse research and train students in drug abuse research.

Research on women's health and gender differences was initiated by NIDA as a result of prior research on drug abuse where research subjects or participants were primarily male, revealing little knowledge about women. Data from laboratory, field, and clinical research are beginning to show gender differences in biological factors, progression from drug use to abuse, antecedents and consequences of drug use and abuse, and prevention and treatment. This research is now supported in all of NIDA's programmatic branches and is grouped into four major program areas (etiology, consequences, prevention, and treatment and services).

NIDA possesses a complex set of responsibilities on the national and international levels. NIDA's strategic effort to facilitate the development of research-based knowledge and application of this knowledge into practitioner and community interventions in both prevention and treatment efforts is substantial.

Clinical and research practitioners in the world of prevention and treatment are challenged with improving the lives of individuals with drug and alcohol struggles. Their connection to NIDA may facilitate their pace of improved research and service capacity by increasing their knowledge and skills on both national and international levels.

NATIONAL INSTITUTE ON DRUG ABUSE CLINICAL TRIALS NETWORK

A large and complex drug treatment system has grown up in the United States, a system that provides residential and outpatient services to more than 1 million drug abuse patients annually at more than 13,000 treatment clinics. At the same time, an active drug abuse research initiative has also been thriving in this country. The research enterprise is based at academic research institutions and derives funding primarily from two federal grant funding agencies: the National Institute on Drug Abuse and the National Institute on

Alcohol Abuse and Alcoholism. In the past, researchers and treatment providers have generally operated independently, pursuing slightly different goals and priorities, although their common goal is to ensure that high-quality treatment of substance abuse is available in this country.

In 1998, a sobering study was published by the Institute of Medicine, pointing out the gap that existed between new drug abuse treatments developed and tested for efficacy by researchers working at academic centers and the real-world practices of drug abuse treatment providers operating in the community. Specifically, treatments shown to be efficacious in research were not finding their way into use in community programs. This gap between research and practice is not unique to the drug abuse treatment field but is common in medical practice, where providers are always trying to keep up with and employ the most recent research-based findings and practices.

Based on recommendations from the Institute of Medicine study, the National Institute on Drug Abuse established a Drug Abuse Treatment Clinical Trials Network (CTN) in 1999. The overarching purpose of the network was to foster the adoption of evidence-based practices in community treatment programs, using research as the vehicle. The three specific missions were to (1) foster communication and collaboration between researchers and providers within the network, (2) conduct effectiveness research at community treatment programs with new practices developed and shown to be efficacious in smaller-scale research studies, and (3) disseminate findings from CTN research to promote adoption of evidence-based practices. The CTN was modeled after similar networks that had been established to verify effectiveness of new treatments for cancer and other medical disorders and to help move new treatments more quickly into clinical practice.

Structure and Function of the CTN

The National Institute on Drug Abuse CTN comprises several regionally diverse centers where experienced treatment researchers, working at some of the leading academic institutions in this country, have formed a coalition with local community treatment providers. The number of such academic-practice coalitions has increased from 6 at the start of the network to 16 or 17 at its maturity. Many of the research-practice centers (or “nodes”) are located on the East and West

Coasts (e.g., Massachusetts, New York, Connecticut, Pennsylvania, Maryland, South Carolina, Florida, California, Oregon, and Washington), where many of the drug users in this country reside, but nodes have also been funded in Ohio, Texas, New Mexico, and other noncoastal regions. Communication and collaboration between researchers and treatment providers within the CTN is fostered through the steering committee, a unique governance structure in which academic researchers and community program directors are equally represented and equally involved in the decision-making processes of the network, including selection and design of research projects.

Effectiveness Research

A central mission of the CTN is to conduct effectiveness research. This means taking treatments that have been established as efficacious in smaller-scale research projects and testing them in large, multisite studies. This strategy can establish whether the treatments still work when implemented in real-world community treatment settings. Multidisciplinary teams composed of researchers and treatment providers within the CTN are formed to decide on research topics, details of the intervention to be tested, and details of experimental methods. The goal of these teams is to strike a balance between fidelity to treatments as originally tested in smaller-scale studies and feasibility for implementation and sustainability in real-world settings. Leadership for study design and implementation is provided by an investigator located at a single node, but many people are involved in carrying out a CTN study. Logistic and technical support for studies is provided by experienced study coordination and data management organizations. Overall leadership is provided by the Center for Clinical Trials Network at the National Institute on Drug Abuse, and each participating node provides a project coordinator to oversee the research and clinical staff who are implementing the study at clinical sites. Typically, between 300 and 800 patients will be enrolled in each study at 4 to 12 different treatment sites around the country. Such large sample sizes and regional diversity ensures that study findings will be applicable to a broad array of substance abusers in this country.

To date, more than 25 studies have been conducted within the CTN, examining both medications and behavior therapies. Several studies have tested

buprenorphine, a relatively new medication for treatment of opioid use disorders. The studies have asked whether the new medication improves treatment outcomes over those seen when older medications are employed in usual care detoxification treatment and have looked at the effectiveness of longer versus shorter detoxification treatments with buprenorphine. These studies have shown promising results for both adult and adolescent opioid abusers. An ongoing study is examining the ability of buprenorphine to provide effective treatment to prescription opioid addicts.

Motivational interviewing is a counseling technique designed to improve client engagement and retention. This technique has been tested and shown to be effective for improving early engagement with adults coming into outpatient psychosocial counseling treatment programs and is being investigated with special populations including pregnant drug-abusing women and Hispanics. Motivational incentives provide positive rewards for clients who stop using drugs during treatment. This intervention was tested as an add-on to usual care practices and shown to be effective for reducing stimulant drug use in methadone maintenance patients and for improving retention and longer periods of drug-free treatment participation among stimulant abusers enrolled in outpatient psychosocial counseling.

HIV infection is a serious problem among drug abusers, and several CTN studies have focused on this important problem. Several counseling interventions have been tested for their ability to reduce risks related to drug use (e.g., needle sharing) and risks related to sexual activity. Finally, a number of specialized interventions have been tested, including interventions to help drug-abusing women deal better with histories of trauma, to help treatment patients who want to find employment, to help smokers desiring to quit, and to help patients making a transition from residential to outpatient care. Results from most of the CTN studies have been published in the scientific literature. Publications from CTN research can be found at <http://ctndisseminationlibrary.org>.

Dissemination

Those interventions that prove to be effective in real-world testing are then moved into a dissemination phase. Here, the CTN partners with another network of treatment training providers, the addiction technology

transfer centers (ATTCs). Working together in blending teams, CTN and ATTC members produce training materials such as manuals and informational slide shows that can be used by clinicians who want to learn and implement the new treatment interventions. Currently, there are five such training packages available: Two focus on use of buprenorphine as a treatment for opioid abuse; one teaches clinicians how to effectively use information derived from a comprehensive intake interview, the Addiction Severity Index, for treatment planning; a fourth focuses on clinical supervision for enhancing proficiency in motivational interviewing; and the fifth provides information and training on how to use motivational incentives. Additional training packages will be developed as studies are completed and additional effective interventions are identified. These training materials can be found at www.nattc.org. This adoption phase of the CTN is important because it will ultimately fulfill the final mission of the CTN, which is to improve treatment services nationwide through fostering the adoption of evidence-based practices.

NATIONAL MEDIA CAMPAIGN

The National Youth Anti-Drug Media Campaign, often referred to as the National Media Campaign, is a large-scale communication strategy that aims to prevent drug abuse through television, radio, and newspaper advertisements; Internet programs and Web sites; and entertainment venues. Some of the most memorable advertisements include short commercials such as the "This is your brain on drugs" ad, which depicted a person frying an egg in a hot, burning skillet as being

analogous to the harmful consequences drug use has on the human brain. The messages promoted through the campaign aim to convince the viewing public that drug use is bad and should be avoided.

In 1998 Congress created the National Youth Anti-Drug Media Campaign with the goal of preventing and reducing youth drug use. Unprecedented in size and scope, the campaign was designed to be the most visible symbol of the federal government's commitment to youth drug prevention and is housed in the Office of National Drug Control Policy (ONDCP). The campaign's focus was to be a strategically integrated communication effort that included advertising with public communication outreach to deliver antidrug messages and skills to America's youth, their parents, and other influential adults. From 1998 through 2008, \$1.602 billion has been spent on the National Media Campaign.

The U.S. Government Accountability Office published a report in August 2006 to present findings on a national evaluation of the National Media Campaign. This report states that the evaluation did not find that the campaign was effective in reducing youth drug use. The National Institute on Drug Abuse awarded evaluation contracts to Westat, Inc., through June 2005 for a total of \$42.7 million.

Published Keys to Success

The National Media Campaign hosts a Web site, which highlights information about its programs. The following published bullets or "keys to success" describe the foundation for the campaign, according to ONDCP:

- Strong bipartisan congressional support and recognition of the critical importance of the issue to the American public
- A solid scientific and research base to serve as the campaign's foundation
- Pro bono advertising created in conjunction with the Partnership for a Drug-Free America
- Participation by leading media corporations as well as civic, volunteer, youth-serving, education, prevention, public health, and multicultural organizations

Components

The National Media Campaign Web site also describes seven campaign components that constitute the overall media approach. They are as follows:

1. *Advertising*: Paid and donated campaign advertising on television and radio, in print, and on the Internet delivers antidrug information to target audiences through more than 1,300 media outlets across the country.

2. *Media*: News media outreach and promotional activities (such as the marijuana initiative) enable the campaign to deliver important antidrug information while at the same time elevating the profile of the campaign.

3. *The Internet*: The campaign has been a leader in social marketing on the Internet. The campaign's family of Web sites for teens (Freevibe.com) and parents (TheAntiDrug.com), along with other sites developed to reach adult influencers, receive approximately 5 million page views and almost 2 million visitors per month. Traffic is driven to the sites through online and traditional advertising and publicity, Web links through Internet sites that support the campaign messages (e.g., news, health, or target age related), Internet search engines, and direct access. Campaign Web partners work to reach the elusive teen target through popular sites such as MTV.com and CosmoGirl.com. News-related sites, such as *The New York Times*, *ABC News*, and *US News and World Report*, and search engines, such as Google.com and Yahoo.com, assist the campaign in reaching parents and influencers.

4. *Entertainment Outreach*: The campaign provides information and resources to entertainment writers and producers to increase accurate depictions of drug abuse in entertainment programming. The campaign holds regular media roundtable events for entertainment writers on hot topics such as ecstasy, methamphetamines, steroids, and early intervention.

5. *Multicultural Outreach*: Advertising and outreach is targeted to African American, Hispanic, Asian American, and American Indian/Alaska Native audiences; materials are produced in Spanish, Mandarin, Cantonese, Korean, Vietnamese, and Cambodian.

6. *Partnerships*: Campaign partners distribute antidrug information and messages to their members and communities through a number of different channels, including events and highly visible meetings attended by young people and their parents. Campaign partners include the Boys and Girls Clubs of America, the National PTA, YMCA, the National Middle School Association, the American Academy of Pediatricians, the National Education Association,

the Congress of National Black Churches, UNITY (United National Indian Tribal Youth, Inc.), ASPIRA (the largest Hispanic youth organization), Community Anti-Drug Coalitions of America, the U.S. Hispanic Leadership Institute, and the National Asian Pacific American Families Against Substance Abuse.

7. *@Work Program*: The campaign developed the @Work program to reach parents where they spend much of their time—at work. Many human resource professionals say that they believe that employees who have children with substance abuse problems are more likely to suffer from decreased morale and productivity, and they use an increasing amount of health care dollars. The @Work Web site, www.TheAntiDrug.com/AtWork, makes it easy for employers, labor organizations, associations, community coalitions, and other groups to share youth drug prevention information with working parents. The site features newsletter articles, e-mail parenting tips, and information about ordering or downloading campaign posters and brochures. All of the electronic resources are formatted for easy adaptation and customization.

Evaluation Report

The U.S. Government Accountability Office published a report in August 2006 to a U.S. Senate appropriations subcommittee on transportation, treasury, the judiciary, housing and urban development, and related agencies. The report highlighted some disturbing findings on the overall effectiveness of the National Youth Anti-Drug Media Campaign. The report concluded that the campaign was not effective in reducing youth drug use.

NATIONAL OUTCOME MEASURES

The Substance Abuse and Mental Health Services Administration (SAMHSA) is an agency within the U.S. Department of Health and Human Services. With a vision to create “a life in the community for everyone,” the National Outcome Measures (NOMs) were developed by SAMHSA in partnership with states and jurisdictions as the data strategy for measuring the success of the agency’s block grant programs and key initiatives. In addition, NOMs were designed to meet the various reporting requirements of the federal government.

There are two primary federal activities that are concerned with the effectiveness and accountability of federal programs: the Government Performance and Results Act of 1993 and the Performance Assessment Rating Tool (PART) administered by the White House Office of Management and Budget. While each has its own distinct purpose and reporting requirements, NOMs are an attempt to create a single mechanism for meeting a variety of reporting requirements. As of September 2007, all grantees from any of SAMHSA’s centers currently report, or will be required to report, relevant NOMs data.

SAMHSA administers grants and programs through its three centers: the Center for Mental Health Services, the Center for Substance Abuse Treatment, and the Center for Substance Abuse Prevention. Each center is obligated to develop and maintain systems for collecting NOMs data in order to measure outcomes and maintain accountability for the centers’ unique missions.

Federal Performance Activities

Government Performance and Results Act

Established in 1993, the Government Performance and Results Act was designed to improve efficiency

and effectiveness among federal agencies and to hold these agencies accountable for setting and achieving outcomes. The act details requirements of federal agencies for developing strategic plans that outline goals and objectives and a plan for achieving desired outcomes. This act mandates measurable performance objectives along with regular reporting procedures and timelines.

Performance Assessment Rating Tool

The Office of Management and Budget is responsible for the administration of the PART. This tool serves as a mechanism for measuring the performance of federal agencies and is conducted separate from Government Performance and Results measures. The PART guides the budgetary and management process of the federal government and is intended to provide an assessment of the strengths and weaknesses of the various federal agencies and their respective programs. Fifty percent of the total PART score is an assessment of outcomes. In addition to outcome assessment, the PART allows the Office of Management and Budget to monitor federal programs and track action taken in identified areas of need. The PART is consistent across all programs, allowing for comparison among similar programs while providing a system for measuring progress over time. PART scores are available to the public on the Internet at expectmore.gov.

Overview of National Outcome Measures

In response to these federal performance mandates, SAMHSA developed the NOMs. The NOMs consist of a set of 10 domains that reflect SAMHSA's vision. Within each domain are respective outcomes and measures organized according to the three primary activities within SAMHSA (mental health, substance abuse treatment, and substance abuse prevention). See Table 1 for a complete matrix of these domains, outcomes, and measures. Updated versions of the matrix can be viewed on SAMHSA's Web site at www.nationaloutcomemeasures.samhsa.gov.

While SAMHSA is collecting data across all 10 domains, there are certain measures within the domains that may not be applicable to each center.

Table 1 includes these measures that are not applicable or that are still under development as of October 2007.

Data Collection

SAMHSA utilizes national data sets to collect state-level NOMs, often referred to as "prepopulation" of data. Sources of prepopulated data include SAMHSA's own National Survey on Drug Use and Health. Other data sources used for the NOMs, such as the National Highway Traffic Safety Administration or the Fatal Analysis Reporting System, can be found on SAMHSA's Web site at www.nationaloutcomemeasures.samhsa.gov/new_reserve/substance_info.asp?id=999. While SAMHSA aims to collect state-level data for the NOMs on behalf of the states, there are some measures that require states and other grantees to report their own data. For example, states may need to collect data on the "number of persons served by age, gender, race and ethnicity" and the "services provided within cost bands" measures. Additionally, states and other grantees may also be required to collect relevant NOMs data at the community, program, and individual levels according to their funding contract.

There are pros and cons associated with prepopulation of data at the state level. For states with little infrastructure and few resources, prepopulation of data reduces the burden of maintaining a valid and reliable source of data. This would allow states to apply valuable resources to those NOMs that are not prepopulated. A downfall of prepopulated data is that some states may review their data and determine that the sample size for their state is not representative of their population and produces inaccurate estimates of drug use and health measures. Other complications include jurisdictions and tribes funded by SAMHSA whose data is not represented in some of the national sources such as the National Survey on Drug Use and Health. In these cases, SAMHSA centers may work individually with grantees to develop solutions. For example, the Center for Substance Abuse Prevention has developed procedures for supplementing prepopulated data and identifying other sources of data that may provide a more accurate picture of a state, tribe, or jurisdiction. In this case, a jurisdiction without any prepopulated data, for example, may work with SAMHSA to supplement missing data by implementing the Youth Risk Behavior Survey to collect necessary NOMs.

Table 1 Substance Abuse and Mental Health Services Administration, National Outcome Measures

<i>DOMAIN</i>	<i>OUTCOME</i>	<i>MEASURES</i>		
		Mental Health	Substance Abuse	
			<i>Treatment</i>	<i>Prevention</i>
Reduced Morbidity	Abstinence from drug/alcohol use	Not applicable	Reduction in/no change in frequency of use at date of last service compared to date of first service	30-day substance use (nonuse/reduction in use) Perceived risk/harm of use Age of first use Perception of disapproval/attitude
	Decreased mental illness symptomatology	Under development	Not applicable	Not applicable
Employment/ Education	Increased/retained employment or return to/stay in school	Profile of adult clients by employment status and of children by increased school attendance	Increase in/no change in number of employed or in school at date of last service compared to first service	Perception of workplace policy; alcohol-, tobacco-, or other drug-related suspensions and expulsions; attendance and enrollment
Crime and Criminal Justice	Decreased criminal justice involvement	Profile of client involvement in criminal and juvenile justice systems	Reduction in/no change in number of arrests in past 30 days from date of first service to date of last service	Alcohol-related car crashes and injuries; alcohol- and drug-related crime
Stability in Housing	Increased stability in housing	Profile of client's change in living situation (including homeless status)	Increase in/no change in number of clients in stable housing situation from date of first service to date of last service	Not applicable
Social Connectedness	Increased social supports/social connectedness ¹	Under development	Under development	Family communication around drug use
Access/Capacity	Increased access to services (service capacity)	Number of persons served by age, gender, race and ethnicity	Unduplicated count of persons served; penetration rate, i.e., numbers served compared to those in need	Number of persons served by age, gender, race and ethnicity

(Continued)

Table 1 (Continued)

<i>DOMAIN</i>	<i>OUTCOME</i>	<i>MEASURES</i>		
		Mental Health	Substance Abuse	
			<i>Treatment</i>	<i>Prevention</i>
Retention	Increased retention in treatment— Substance Abuse	Not applicable	Length of stay from date of first service to date of last service Unduplicated count of persons served	Total number of evidence-based programs and strategies; percentage youth seeing, reading, watching, or listening to a prevention message
	Reduced utilization of psychiatric inpatient beds—Mental Health	Decreased rate of readmission to state psychiatric hospitals within 30 days and 180 days	Not applicable	Not applicable
Perception of Care	Client perception of care ²	Clients reporting positively about outcomes	Under development	Not applicable
Cost-Effectiveness	Cost-effectiveness (average cost) ²	Number of persons receiving evidence-based services/number of evidence-based practices provided by the state	Number of states providing substance abuse treatment services within approved cost per person bands by the type of treatment	Services provided within cost bands
Use of Evidence-Based Practices	Use of evidence-based practices ²	Number of persons receiving evidence-based services/number of evidence-based practices provided by the state	Under development	Total number of evidence-based programs and strategies

Source: Substance Abuse and Mental Health Services Administration. (2007). *National outcome measures*. Retrieved from http://nationaloutcomemeasures.samhsa.gov/outcome/index_2007.asp

1. For Access to Recovery, “social support recovery” is measured by client participation in voluntary recovery or self-help groups, as well as interaction with family and friends supportive of recovery.

2. Required by the 2003 White House Office of Management and Budget Performance Assessment Rating Tool review.

To assist states and other grantees in reporting NOMs data that are not already prepopulated, SAMHSA centers have developed data collection systems. The Center for Substance Abuse Treatment developed the State Outcomes Measurement and

Management System (SOMMS), and the Center for Substance Abuse Prevention developed the Center for Substance Abuse Prevention Accountability and Monitoring System (CSAMS). Each system represents a partnership between SAMHSA, states, and

jurisdictions in their work to standardize definitions of outcomes, promote state reporting of NOMs, produce reports, and assess performance benchmarks. As of October 2007, SAMHSA reported 45 states as being enrolled in the SOMMS data collection program. SAMHSA expects to achieve full participation across states in the use of SOMMS and CSAMS by the end of fiscal year 2007. The Center for Mental Health Services is working to expand and refine its data collection strategy and use of the Uniform Reporting System as of October 2007.

A complete description of NOMs data standards for substance abuse treatment and prevention is available on SAMHSA's NOMs Web site. Additionally, this Web page has mental health, treatment, and prevention data available by state for public review.

Conclusion

While a primary purpose of the NOMs is to comply with Government Performance and Results Act and PART mandates by providing SAMHSA with consistent and appropriate data, the data also has many other uses. For example, states can use the data to inform local legislators and constituents of program success and demonstrate a need to continue efforts. Data may also be used to develop and enhance strategic plans, to identify population-level trends to guide future practices, and to identify gaps in service or other implementation challenges.

The NOMs provide an opportunity for SAMHSA to collect state-level data to create a national picture of mental health and substance abuse. However, gradual implementation of the NOMs across SAMHSA centers and throughout the states has made it difficult to report accurate nationwide data. In October 2007, SAMHSA's Web site highlighted action steps for improving the quality of data collected to overcome this challenge. For example, SAMHSA aims to reduce time between data collection and data availability for performance management. Also, SAMHSA has developed benchmarking strategies that will determine acceptable levels of outcomes. As SAMHSA continues to develop its systems and procedures to fully implement nationwide collection of NOMs data, the Web site should be consistently monitored for updates.

Finally, consumers of NOMs data are reminded that the data are for the purpose of *performance*

management. This is not to be confused with *evaluation* of a program or initiative, which may provide a more complete picture of the service.

NATIONAL REGISTRY OF EVIDENCE-BASED PROGRAMS AND PRACTICES

In recent years, evidence-based practices have grown in popularity. Currently, both the Substance Abuse and Mental Health Services Administration

(SAMHSA) and the National Institute on Drug Abuse have made the distribution of and research on evidence-based practices a high priority. Evidence-based practices are prevention or treatment interventions that have been scientifically shown through controlled clinical studies to be effective. Evidence-based practices are reputed to be better than other approaches because scientific evidence, rather than tradition or anecdotal justifications, suggests they are effective.

SAMHSA has developed an online registry of evidence-based programs and practices known as the National Registry of Evidence-based Programs and Practices (NREPP). This is a searchable Web site that allows users to locate evidence-based substance abuse and mental health interventions. All of the interventions found in NREPP have been scientifically tested to demonstrate their effectiveness in treating or preventing substance use or mental health disorders. The purpose of NREPP is to provide a readily accessible online source for disseminating information on effective interventions.

Intervention Summaries

NREPP includes the following types of interventions: mental health promotion, mental health treatment, substance abuse prevention, substance abuse treatment, and interventions for co-occurring disorders. For each intervention, SAMHSA provides an intervention summary. Each of the intervention summaries includes the following: (a) a description of the intervention itself and its targeted outcomes, (b) ratings of the quality of the research and its readiness for dissemination, (c) a list of research studies and other materials that were submitted for review, and (d) contact information for the developer of each intervention.

Using NREPP

Currently, the NREPP includes 100 interventions. Interventions can be located at www.nrepp.samhsa.gov/find.asp. This Web site allows users to search for interventions by topic, area of interest, evaluation/study design, implementation history, population, or setting. Users can choose one or more of these search options to find an intervention suitable to their needs. For example, a clinician looking for a substance abuse treatment intervention for African American males would use his or her computer

mouse to click on the box next to “substance abuse treatment,” “Black or African American,” and “male.” After choosing the selected criteria, the clinician would then click on the “search” button located on the screen. All the interventions in the registry that match the selected criteria would then be listed for the clinician to view. However, a user could also access interventions by entering key words into the search engine located on the Web page rather than selecting criteria from the listed options.

Submissions to NREPP

Researchers or developers who have scientifically tested a prevention or treatment intervention for substance use or mental health disorders can submit their intervention to NREPP for review. If a submission is found to meet NREPP’s minimum requirements, then it will be included in the NREPP. The minimum requirements are as follows: (a) The intervention has been found to have statistically significant ($p < .05$) outcomes in one or more clinical studies; (b) the clinical study has been published in a peer-reviewed publication or evaluation report; and (c) there are adequate materials made available to the public to allow for implementation of the model, including manuals, process guides, and training materials.

Review Process

During the review process, each reviewer gives the submitted intervention two types of ratings: quality of research and readiness for dissemination. The *quality of research* rating evaluates and summarizes the clinical studies on the intervention. Each reviewer carefully examines the research to determine if there is enough evidence to suggest that the outcome of the study is a result of the intervention or if it could be due to extraneous variables. The quality of research is determined based on the following criteria: reliability, validity, fidelity to the intervention, missing data and attrition, extraneous or confounding variables, and the appropriateness of the statistical analysis. High-quality research ratings suggest that the outcome likely resulted from the intervention. Some interventions may target multiple outcomes, for example, marijuana use, alcohol use, and behavioral problems. Therefore, an intervention is rated on each outcome rather than overall. An intervention targeting multiple outcomes may be rated higher on some outcomes than on others.

The *readiness for dissemination* rating applies to the general quality of the materials made available for utilizing the intervention. Reviewers determine this rating based on the availability of the materials, training and support resources, and quality assurance procedures. High-quality resources supporting the intervention are given a high rating.

Other Guidelines

NREPP suggests that professionals contact the intervention developers before using an intervention. NREPP also reminds site users that the registry is not exhaustive or exclusive, and users are advised to use NREPP to carefully consider if a specific evidence-based practice meets their needs. Moreover, a list of potential questions to ask developers is available on the NREPP Web site.

NATIONAL SURVEY ON DRUG USE AND HEALTH

The National Survey on Drug Use and Health (NSDUH), formerly known as the National Household Survey on Drug Abuse, is a nationwide survey used to determine substance abuse trends by household. Endorsed by Section 505 of the Public Health Service Act, the NSDUH is supported by the Substance Abuse and Mental Health Services Administration (SAMHSA), a federal agency under the jurisdiction of the U.S. Department of Health and Human Services. The survey is conducted annually to measure patterns of use of alcohol, tobacco, and illicit substances in addition to related health and other behaviors associated with substance use in the

United States. After a competitive bidding process, the Research Triangle Institute was awarded the contract to conduct the survey. SAMHSA's Office of Applied Studies is responsible for disseminating findings of the study and making the data available to the public.

Section 505 of the Public Health Service Act

The Public Health Service Act is overseen by the U.S. Food and Drug Administration and encompasses the Public Health and Welfare sections of the U.S. Code. Section 505 of the Public Health Service Act states that the secretary, acting through the administrator, shall collect data each year on the following:

- The national incidence and prevalence of the various forms of mental illness and substance abuse
- The incidence and prevalence of such various forms in major metropolitan areas selected by the administrator

Section 505 lists required areas for data collection on mental health and substance abuse, mandates that the survey be conducted annually, requires the use of uniform criteria for the overall collection of data through the use of the best available technology, and mandates that data be analyzed, summarized, and made available to the public. The harvesting and distribution of NSDUH data is overseen by SAMHSA's Office of Applied Studies.

Research Triangle Institute

The Research Triangle Institute (RTI) is a nonprofit, independent organization based in Research Triangle Park, North Carolina. RTI's goal is to advance the field of research while assisting government and other organizations through surveys and statistics, education and training, and health and pharmaceuticals, as well as advances in technologies that will assist in economic and social development around the world. RTI has been administering and analyzing the NSDUH since 1988 and is currently contracted through the year 2009. Their responsibilities include, but are not limited to, annual examination of study design, sample selection, data collection, data processing, analysis, and reporting of the information collected from the NSDUH.

Survey Methodology

The NSDUH is the federal government's chief source of national data on the use of alcohol, tobacco, and illicit substances for populations 12 years of age and older in the United States. The survey has undergone numerous changes since its inception in 1971. The survey consists of multiple inquiries into the respondent's health, illegal behaviors, age of initiation for use of substances, and other topics that may be associated with substance use. According to the NSDUH project description, the survey aims to monitor the course of substance use by doing the following:

- Collecting data in a timely manner
- Providing accurate data on the level and patterns of licit and illicit drug use
- Tracking the nationwide trends of use of alcohol and various types of drugs
- Ensuring that the data collected measure the magnitude and patterns of alcohol, tobacco, and illegal substance use and abuse across the United States
- Assessing the consequences of substance use and abuse
- Identifying groups of individuals (e.g., specific ethnicities, minorities) who are at an increased risk for substance abuse and use

Confidentiality

All parties involved in the creation, implementation, and dissemination of the data collected from the NSDUH place the issue of confidentiality as essential to the quality and validity of responses made by interviewees. The focus of the NSDUH responses is not on individual answers but rather on the collective whole. The names of all individuals interviewed are never recorded or associated with their responses in any way. All responses are protected under federal law by the Confidential Information Protection and Statistical Efficiency Act of 2002. Each individual who completes the NSDUH is identified by a code number, and data are electronically transmitted to RTI on the day the survey is completed. Data collected from the NSDUH are for research and analysis only. Federal law protects the data from being used for any other purpose, with such use being subject to prosecution.

Sample

According to the NSDUH report, the survey collects information from approximately 70,000 randomly selected residents, age 12 years or older, from households across the United States including noninstitutional group quarters (e.g., shelters, rooming houses, dormitories) and civilians living on military bases. Persons not included in the sample are homeless persons who do not use shelters, active-duty military personnel, and residents of institutional group quarters, such as prisons and long-term hospitals. Each selected individual is generalized to represent approximately 3,000 other U.S. residents. After households have been selected, an RTI field representative visits each of the households and discusses the process of the survey, confidentiality, and any questions that the interviewee may have regarding the process. Once participation has been secured, no other person or household may be substituted. The interviewee who has agreed to participate receives \$30 cash once the NSDUH has been completed.

The NSDUH is designed to oversample youth and young adults, so that each state's sample is spread equally among three age groups; 12 to 17 years of age, 18 to 25 years of age, and 26 years and older. The sample of the individuals interviewed employs a 50-state design with an independent, multistage area probability sample for each state and the District of Columbia. Since 1994, NSDUH has been drastically reformatted to restrict the variety of data collected. Prior to 1994, the management of the survey and the sample design were less rigorously regulated. Many of the questions allowed for conflicting results and led to less-valid information.

Survey Administration

Data are collected continuously from January 1 through December 31 for the target year. The survey takes, on average, an hour to complete dependent upon the respondent's individual characteristics such as age and duration of the respondent's attention span. The survey is typically administered in English, but it is available in Spanish for those individuals who prefer it to the English version. Quality control measures include follow-up phone calls or letters from RTI to verify that the interviewer completed the survey with the respondent.

Computer-Assisted Personal Interviewing

RTI is a leader in the development of advanced research methods utilizing technology and applies a mixed-mode approach to data collection. For the collection of NSDUH data, RTI created the computer-assisted personal interviewing (CAPI) system to enhance data collection for face-to-face interviews. Because some of the questions on the NSDUH involve sensitive subjects (e.g., the use of illicit substances), RTI developed the audio computer-assisted self-interviewing (ACASI) system, which allows respondents to listen to recorded questions through headphones and then type their responses on a computer. The RTI professional sets up the computer system and audio system for the interviewee, explains the format of the survey, and stays through the duration of the interview.

The CAPI and ACASI methods are much more effective and efficient for the collection of data compared with previous methods used for the administration of the NSDUH. Interviews are conducted in the privacy of the interviewees' own homes, and the format allows respondents to revisit questions they have already answered or to have questions repeated to them as many times as needed.

Software and Data Analysis

RTI utilizes its own software package, SUDANN, Software for Statistical Analysis of Correlated Data, to code and total NSDUH data, which are then turned into statistics for further analysis. Data collected from the NSDUH are available to the public from SAMHSA's Office of Applied Research on its Web site.

Utilization and Dissemination of NSDUH Data

NSDUH Report

Survey findings are published in the annual NSDUH report from SAMHSA's Office of Applied Studies. This report includes a summary of the NSDUH findings and information in the following content areas:

- An introduction that provides a brief explanation of the NSDUH, trend measurements, format and explanation of the report, and an explanation of tables
- Illicit drug, alcohol, and tobacco use by age group, gender, ethnicity, education level, employment,

geographic area, frequency of use, association with cigarette and alcohol use, driving under the influence of illicit drug use, and the source by which individuals obtain their prescription drugs

- Youth-specific prevention-related measures according to perceptions of risk, perceived availability, perceived parental disapproval of substance use, feelings about peer substance use, fighting and delinquent behavior, religious beliefs, participation in activities, exposure to substance use prevention messages and programs, and parental involvement
- Substance dependence, abuse, and treatment by age of first use, gender, ethnicity, employment, education level, geographic area, and treatment facility usage
- Prevalence and treatment of mental health problems by age groups, level of distress, comorbidity of substance abuse or use, and mental health treatment usage
- Final discussion of trends in substance use among youth and young adults

Utility of NSDUH Data

According to RTI, multiple government agencies, private organizations, and individual researchers, as well as members of the public, use the information collected from the annual NSDUH. For example, many state health agencies utilize the data to measure progress toward goals, prepare reports on substance use patterns and trends, determine needs, and develop relevant funding strategies.

The following are recent examples from RTI's Web site of how NSDUH data have been utilized:

- SAMHSA uses the information to identify at-risk populations and geographic areas so that federal resources can be used in those areas to create prevention and treatment programs.
- As part of the Centers for Disease Control and Prevention, the Office on Smoking and Health uses NSDUH data to monitor the patterns and trends of youth tobacco usage in order to develop and implement strategies to reduce youth tobacco use.
- Media and national organizations use data from NSDUH to develop public media campaigns to curb behaviors such as underage drinking.

Conclusion

Through the collaboration of multiple federal agencies, private research firms, and willing participants,

NSDUH continues to provide Americans with information on the ever-changing trends and patterns of substance use in the United States. Each year, data collected from this survey informs public policies and programs of service needs, gaps in service areas, and impact of current programs. The annual collection of these data provides a wealth of information necessary to monitor needs, progress, and trends over time.

NATIONAL TREATMENT IMPROVEMENT EVALUATION STUDY

The National Treatment Improvement Evaluation Study (NTIES) was a congressionally mandated 5-year evaluation of the effectiveness of substance abuse treatment services delivered in comprehensive treatment demonstration programs supported by the Center for Substance Abuse Treatment (CSAT). The demonstration programs (Target Cities, Critical Populations, and Incarcerated and Non-incarcerated Criminal Justice Programs) provided treatment services to underserved and vulnerable populations whose drug problems tend to be more severe and who have few social supports to help in their recovery. Conducted from 1993 to 1995, NTIES built upon earlier national multisite treatment evaluation studies, including the Drug Abuse Reporting Program (1969–1973), the Treatment Outcome Prospective Study (1979–1981), the Drug Services Research Study (1989–1990), and the Drug Abuse Treatment Outcome Study (1991–1993). NTIES sought to answer questions about the following: (a) the use of demonstration funds, (b) enhancements that were deployed, (c) the number of programs and clients that were affected by the demonstration programs, (d) the extent to which the comprehensive treatment model has been validated and the evidence that more comprehensive treatment yields effective results in terms of client access to services and outcomes of treatment, and (e) the lessons that can be learned for future treatment about the implementation and cost of delivering comprehensive drug abuse services.

Study Design

NTIES was conducted by the National Opinion Research Center at the University of Chicago, in conjunction with the Research Triangle Institute. They used a two-level study design with an administrative level and clinical outcomes level. The administrative level of data provided information on treatment orientation, size, budget, staffing distribution,

and specific use of CSAT funds in all service delivery units (SDUs) eligible to receive support through a CSAT demonstration grant. The clinical outcomes level collected data from clients enrolled in eligible units during three waves: shortly after their first day in treatment, when they left treatment, and then at 12 months after the end of treatment. The sample for the administrative level consisted of all of the SDUs that receive direct support as part of the CSAT demonstration programs. The clinical outcome data were collected from clients who received treatment from SDUs in a subsample of the NTIES SDUs.

The unit of analysis for the administrative component was the SDU, which could be a stand-alone treatment provider or one component of a multitiered treatment organization. The unit of analysis for the clinical outcomes portion was individual client data. Clinical outcomes of treatment were measured primarily through a before and after, or pretreatment to posttreatment, design.

Instrument Development

The forms developed for the administrative data collection were a baseline administrative report, an administrative update, an exit log, and a clinician form. The SDU administrators completed the baseline and update forms, which asked about staffing, facilities, costs and revenues, admissions procedures, client composition, services offered, and treatment philosophy. The exit log was a monthly report on client admissions and discharges. The clinician form was filled out by the clinicians on staff at NTIES SDUs. It was a brief questionnaire about demographics, training, and treatment philosophy.

The intake form, discharge form, 1-year follow-up questionnaire for clients, and records abstraction forms were the instruments developed for the clinical outcomes portion of the study. The intake and 1-year follow-up questionnaire collected data on family background, education, drug and alcohol use, living arrangements and social support, mental health, criminal activity, sources of financial support, physical health, and sexual behavior. The discharge form and records abstraction collected data on treatment experience, such as admission characteristics, services received during treatment, and the conditions of discharge from treatment.

Staffing

Data collection activities at the administrative level were performed by a team of about 15 people responsible for mailing documents, entering and editing data, telephone prompting, interviewing, and retrieving data. The data collection team at the clinical outcomes level was co-led by the associate project manager and a field project manager. They were mainly responsible for assisting in the development of data collection protocols, management of schedules and budgets, and interviewer training. There were also six field managers who were responsible for the implementation of protocols and for supporting and guiding interviewers in their day-to-day activities. They directly supervised the field interviewing staff, which averaged about 70 interviewers at any one time. The interviewers were primarily responsible for identifying, locating, recruiting, and interviewing clients; collecting urine specimens; completing records abstractions; and coordinating the completion of the clinician forms.

Data Collection

Administrative-level data collection began in July 1993. The baseline administrative report was mailed to 792 SDUs who received funds through the CSAT demonstration grants in 1990–1992. A total of 519 reports were completed, either as a self-administered questionnaire or through telephone administration. In August 1994, the interviewing staff began to administer the follow-up instrument to the SDU directors over the phone. SDU directors from about 369 facilities completed the update form. The monthly exit log was completed on a monthly basis for about 6 months from all SDUs in the original baseline report population. This started in July 1993 and ended in November 1994. The SDUs mailed in a one-page form listing discharge and admission dates for clients who had left treatment during the month. Project staff ended up receiving 6,220 exit logs. The clinician form was fielded in September 1993 and November 1994 with clinical staff. Directors of SDUs participating in the clinical outcomes study were asked to create a list of clinical staff who were presently practicing at the facility. NTIES interviewers sent the forms to the directors to pass out to their clinical staff to fill out. A total of 727 out of 808 eligible clinicians completed the form during the first administration, and 497 out of 747 eligible clinicians completed the form during the second administration.

For the clinical outcomes study, the design team selected 82 SDUs that could possibly provide clients for this portion of the study. Of the 82, clients from 78 SDUs were included in the study. However, several SDUs were dropped throughout the course of the study for various reasons. A couple of programs were dropped when they were unable to secure sufficient local funds to support their continued operation after their CSAT grant had expired. About six programs were dropped after it was determined that the intake interviews were proving to be too expensive to complete as a result of unusually low client flow and other difficulties like uncooperative staff or excessive approval procedures. Respondents who had been enrolled into the study before their SDU was dropped were retained in the client sample, but no additional respondents were enrolled from these sites. Of the SDUs sampled, 44% were Target Cities programs, 38% were Critical Populations programs, and 23% were Criminal Justice programs.

Intake interviews were administered to 6,593 respondents between July 1993 and November 1994. The 1-hour intake questionnaire was administered using computer-assisted personal interviewing technology within 3 weeks of the enrolled client's first treatment session. The discharge interviews were administered to 5,274 respondents between July 1993 and April 1995. Clients became eligible for the discharge interview at the end of their treatment episode, whether or not treatment had been successfully completed. The follow-up interviews began in August 1994 and lasted through the end of October 1995. A total of 5,388 clients were located and interviewed, yielding an 83% follow-up rate. Urine samples were also collected at the time of the follow-up interview from a random sample of half of the clients completing the follow-up questionnaire. The interviewers completed the abstraction of SDU records. Even though interviewers experienced difficulties with abstracting information from the programs, due to the variation in record-keeping practices across SDUs and in terms of the quality and format of the data, records abstractions were completed for 6,412 clients.

Key Findings

The researchers found that clients served by CSAT-funded programs significantly reduced their alcohol

and other drug use during and immediately following treatment, and these reductions were reported a full year after treatment. In fact, the results show that clients' use of their primary drug (the drug that led them into treatment) declined from 73% to 38% one year after treatment.

The clients in this study were, for the most part, generally candid in reporting drug use. When asked about drug use over the last 12 months, self-reports of cocaine/crack use (33.5%) and marijuana use (27.8%) were higher than those detected by urine tests. Self-reports of heroin use (16.5%) for this time period were about the same as what was detected by the urine tests (16.2%). However, there was some underreporting of recent (last 30 days) heroin and cocaine use. Of those interviewed, 20.4% reported cocaine/crack use and 11.3% heroin use, whereas the urine tests found that 28.7% were positive for cocaine/crack use and 16.2% positive for opioid use.

Research has shown that there is a strong link between substance abuse and crime. The results from this study add to the literature by suggesting that substance abuse treatment can play a major role in crime reduction. The clients in this study reported statistically significant decreases in multiple indicators of criminal involvement. Researchers found that there was a 64% reduction in arrests 1 year following treatment. Also, the percentage of clients who supported themselves largely through illegal activity dropped by nearly half, and the number of clients who reported selling drugs declined by 78%.

In addition to reduced criminal activity, there were gains in employment and a general move toward greater self-sufficiency following treatment. The rate of employment increased from 51% to 60%. The percentage of clients who reported receiving welfare decreased from 40% to 35%. Client reports of homelessness dropped from 19% before treatment to 11% after treatment.

The findings show that there were improvements in the mental and physical health of clients after treatment. The number of alcohol- and drug-related medical visits decreased by 53%. There was a small decline (28%) in the number of clients who received inpatient care for mental health problems. The clients in this study also reported significantly fewer suicide attempts after treatment.

Treatment proved to have a significant effect on reducing high-risk sexual behaviors that can lead to

the transmission of HIV/AIDS and other sexually transmitted diseases. In this study the percentage of persons who had sex for money or drugs dropped by 56%, and the number of people who had sex with an IV drug user was reduced by 51%. The number of clients who reported having heterosexual sex with more than one partner while not always using a condom decreased by 35%.

The researchers found that treatment proved to be cost-effective, especially when compared with incarceration, which is often the alternative. A study reported by the American Correctional Associations estimated that the annual cost of incarceration in 1994 came to about \$18,330. The results from this study show that treatment costs range from about \$1,800 per client to about \$6,800 per client.

Conclusion

NTIES was one of the largest and most rigorous studies of substance abuse treatment ever conducted. In the course of its conduct, the study examined many issues related to substance abuse treatment. As a result, the NTIES provides a rich database on substance abuse treatment at all levels of analysis. The results of the study indicate that society benefits from publicly supported substance abuse treatment provided to critical populations, such as those supported by the CSAT-demonstration grants and represented in this study through reductions in crime-related costs and health care costs and increased earnings. Further research is needed to assess the factors that result in increased client retention and better treatment outcomes.

NATURAL RECOVERY

The concept of natural recovery is not a new one in the addictions field and is synonymous with terms such as *self-change*, *spontaneous remission*, *maturing out*, and *natural remission*. Collectively, these terms refer to the resolution of addiction without formal treatment. There has been continued debate among addictions experts about the utility of promoting natural recovery as an alternative to formal treatment or support groups. Traditionally, the disease model approach dominated the field and proponents asserted that in the absence of treatment, addictions were progressive and irreversible. Advocates of natural recovery argue that many people quit addictions without seeking help. Moreover, they argue that abstinence-based philosophies deter many people from seeking treatment and promote a false belief

that moderation is not possible. In the past decade it has generally been acknowledged that natural recovery is not wholly inconsistent with the disease model approach. Empirical evidence has demonstrated that the effectiveness of a recovery program (self-initiated or treatment based) is dependent partially on the level of addiction severity, with more extreme cases benefiting more from formal support. The addictions field has started to embrace different styles of initiating and maintaining recovery. This growth and diversification in addictions treatment has led to the burgeoning of self-help books and brief intervention initiatives. Notwithstanding these facts, controversy still exists among addiction experts. Even at the most basic level, disagreement exists about what constitutes addiction, resolution, or formal treatment.

Despite the evidence that the majority of people recover from addictions without any professional help or other formal assistance, the concept of natural recovery has met with resistance. There are three phenomena that have contributed to this opposition. First, addiction counselors generally see severe cases where individuals seek help because they have been unsuccessful in combating the problem on their own. With these cases, treatment providers have historically had more success with an abstinence-based approach. Second, up until the 1990s, the preponderance of research in the addictions area focused on clinical cases. In these cases, the success of formal treatment over self-help was generally well supported. Once again, these are extreme samples that do not represent the spectrum of addiction severity. The third reason that natural recovery has been overlooked is the continued adherence to the disease model in viewing addiction as a dichotomy. The American Medical Association defines drug dependency, including alcoholism, as a disease. Polls have demonstrated that the majority of Americans also hold this belief. People all over the world have successfully quit drinking with the help of the abstinence-based principles of programs such as Alcoholics Anonymous, and many residential treatment programs, such as the world-renowned Betty Ford Clinic, similarly support a disease model approach to treatment and recovery. Although some would argue that natural recovery is in opposition to the disease model, the following points should be considered. Supporters of self-change recognize the utility of formal treatment and would agree that it increases the prospects of recovery, particularly for those with more serious problems. Moreover, the

issue is resolved semantically because advocates of abstinence-based philosophies would contend that if an individual is able to quit on his or her own, the individual was never truly addicted in the first place.

The controversy surrounding natural recovery has been primarily in the area of alcoholism, but it is known that people frequently recover on their own from many other addictions without seeking treatment. Prior to the advent of nicotine cessation aids, the majority of people quit smoking without any form of treatment. Another frequently cited example is the high number of soldiers who were addicted to heroin during the Vietnam War but were able to quit without intervention upon return to the United States. Gambling has been shown to be a transitory addiction at the individual level. For example, Wendy Slutske and her colleagues followed an untreated sample of problem gamblers for 11 years and found that natural recovery was more common than was an enduring or progressing gambling problem.

Many empirical studies have shown that people tend to “mature out” of addictions; this is evidenced by the fact that a high proportion of college students engage in hazardous drinking patterns and frequent substance use, but that number substantially declines in later years. As people take on more life responsibilities and make role transitions into marriage, jobs, and parenthood, they are less likely to continue with destructive addictive behaviors. Research evidence shows that there is a strong age-graded decline in lifetime substance use that peaks in early adulthood and declines thereafter.

Research Evidence

Research evidence for self-change is limited and controversial and primarily consists of general population prevalence surveys, cross-sectional comparisons of wait-list control group designs, and case-seeking methods through media recruitment of recovered individuals. Only one meta-analysis has been conducted in the area of natural recovery from alcohol or other drugs. In the analysis of 38 articles with 40 separate samples, Linda Sobell and her colleagues found that most individuals recovered without formal treatment or support groups. The most frequently cited reasons that individuals provided for deciding to change included health concerns, financial issues, negative personal consequences, cognitive changes, and influences from a significant other. The long-standing

belief in abstinence-based recovery as the most common and effective method of resolution was found to be incorrect. Three quarters of the individuals in the meta-analysis who had recovered from an alcohol problem reported that low-risk drinking was part of their recovery. Similar evidence was found for recovery from drug addiction, with nearly half of the combined sample reporting recoveries involving some form of continued use. Although this review provided much-needed support to the natural recovery field, the authors reported that the majority of the studies reviewed were methodologically very weak.

One of the largest surveys to examine drinking patterns in the United States was the National Longitudinal Alcohol Epidemiological Survey, which despite its name, was cross-sectional. The survey included information about the drinking behavior of both treated and untreated individuals with alcohol problems. Results indicated that the majority of drinkers with a former but not current dependence on alcohol recovered on their own. The problem with cross-sectional research is that it includes individuals who may not maintain stable recovery. Research evidence has shown that until about 5 years of sustained recovery, relapse is common. Longitudinal research over an extended period of time provides the most valid evidence for stability of natural recovery. In response to the need for more longitudinal evidence, the National Institute on Alcohol Abuse and Alcoholism is conducting the National Epidemiologic Survey on Alcohol and Related Conditions, which is a survey examining alcohol and drug use longitudinally in more than 40,000 Americans.

The longest follow-up study in the area of addiction recovery is being conducted at Harvard Medical School, where they have been following the drinking patterns of a group of males since 1940. Results indicate that many of the participants have continued to abuse alcohol for decades without progressing to more severe dependence. This is contrary to the assertion that alcoholism invariably progresses to a more acute state. They have also found that men with more severe problems are generally unable to continue drinking without progression to more hazardous levels of intake. These results buttress the commonly held belief that the best recovery option may be partially dependent on the severity of the problem. Individuals with less problematic consumption patterns may be best suited for controlled drinking, but abstinence may better facilitate recovery for more extreme cases.

Why Study Natural Recovery?

It is known that for all forms of addiction, the vast majority of people do not seek treatment. Stigma and negative labels like “alcoholic,” “drug addict,” and “problem gambler” are major barriers to treatment seeking. Individuals are often reluctant to view their behavior as an addiction or disease and often simply see it as a bad habit. Even when there is recognition of a problem, it is generally not regarded as serious enough to warrant formal treatment. Moreover, many addicts are not ready or willing to commit to complete abstinence.

Proponents of natural recovery argue that empowering people to believe that they have the ability to control their own behavior is advantageous on a number of levels. First, acknowledging that there are numerous pathways to resolution can have implications for drawing more people into treatment. Providing options for the desired level of support is beneficial for reaching a more heterogeneous group of people. Second, it is well documented that some addicts attempt moderation as an initial resolution and then decide on abstinence. Allowing for self-directed recovery gives people the option to decide what works best for them. Third, many current treatments are only minimally effective in maintaining stable change, so it is advantageous to explore alternatives. Empirical evidence supports the fact that brief interventions that promote self-change have been found to be quite successful in some populations. Financial resources are often a stated treatment obstacle in managed care; thus, efficacious cost-effective treatments are needed. Finally, moderation is more common than abstinence among individuals who are not seeking treatment. Advocating for self-change in this group could include public health campaigns that disseminate information about effective harm reduction approaches.

Traditionally, it has been the belief that recovery from addiction requires hitting rock bottom and seeking formal treatment. Interventions that successfully create change in the early stages of addiction could serve to obviate progression in severity. These kinds of changes necessitate deviating from the long-held assertion that addiction should be thought of as a yes/no dichotomy and recognizing that addictive behaviors lie on a continuum. Other countries have been active in promoting harm reduction and minimal intervention approaches. In North America people are adhering less to conventional beliefs. There are many pathways to change, and many factors that are likely to influence an individual’s decision about what route

to take. Thus, researchers need to consider more complex and diverse models of recovery that include a variety of approaches for a heterogeneous group of people in various stages of change.

Conclusion

Recovery from substance abuse problems without formal treatment is common, in particular for less-severe problems. The notion of natural recovery has met with resistance because traditionally the disease model approach has dominated the field and its proponents asserted that in the absence of treatment, addictions were progressive and irreversible. Acknowledging that there are numerous pathways to resolution can have implications for increasing the number of people who enter treatment by broadening the number of treatment options. Providing the desired level of support is beneficial for reaching a more heterogeneous group of people. The addictions field has started to embrace different styles of initiating and maintaining recovery, such as self-help books and brief intervention initiatives.

NEEDLE EXCHANGE PROGRAMS

Needle exchange programs (NEPs) consist of two components: (1) the collection and safe disposal of used syringes and (2) the provision of sterile syringes to individuals. NEPs were developed to prevent the spread of human immunodeficiency virus (HIV) and viral hepatitis (HBV and HCV) among injection drug users (IDUs), most of whom inject heroin, methamphetamine, or cocaine. NEPs prevent the spread of HIV, HBV, and HCV by removing from circulation potentially contaminated syringes and replacing them with sterile syringes. Most NEPs also provide other disease prevention supplies, such as condoms; infectious disease testing and counseling; and access to other medical and social services, including substance abuse treatment. NEPs can operate in a variety of settings, including pharmacies, street and alley sites, mobile vans, substance abuse treatment centers, and hospitals.

Drug injection is associated with a wide range of health ailments. However, with the emergence of HIV and viral hepatitis, the societal health consequences of drug injection have increased in magnitude and reach. IDUs are at risk for becoming infected with infectious diseases anytime they use syringes that have been previously used by another IDU. Transmission of HBV and HCV may occur through sharing of injection materials, including rinse water, cookers, filters, or tourniquets.

According to the World Health Organization, there are an estimated 13.2 million IDUs in the world, and approximately 3 million current and former IDUs are believed to be infected with HIV. Approximately 10% of all new AIDS cases worldwide are attributable to drug injection. HCV epidemics among IDUs have been reported in 57 countries, and 2 million people are estimated to be infected with HCV due to drug injection in the United States alone. The number of individuals impacted by injection-related HIV and HCV represents a significant global health problem.

NEPs employ harm reduction principles of easy access, practical services, and nonjudgmental and nonpunitive attitudes to attract IDUs into service settings where they can obtain prevention supplies, counseling, and other services. Because harm reduction principles do not condemn drug use and might be perceived to actually facilitate it, some governments and stakeholders (i.e., police) have sometimes opposed NEP implementation.

Short History of Needle Exchange Programs

The first NEP was implemented in 1984 in Amsterdam to combat HBV infections among IDUs. This effort was started by a drug user organization named the Junky Union. With the identification of HIV as the cause of AIDS in 1984, interest in the potential of NEPs to prevent HIV transmission among IDUs also grew. Many European countries, including the United Kingdom, Germany, Switzerland, and Italy, rapidly implemented NEPs as one key strategy in their efforts to prevent the spread of HIV among IDUs. Australia followed suit and today is widely regarded as having among the most comprehensive systems of sterile syringe access in the world. Adoption of NEPs has proceeded more slowly in other regions of the world, such as North America and Central and Eastern Europe, despite significant populations of IDUs.

In the United States in particular, NEPs have been regarded as politically controversial. The controversy stems from the U.S. War on Drugs, which regards NEPs as facilitating drug use rather than preventing HIV, HBV, and HCV infections. Similar concerns were raised about methadone treatment programs when they were developed in the 1960s and 1970s. A ban on federal funding for NEPs that resulted from this controversy has slowed NEP implementation in the United States.

Evidence of Effectiveness

Over the past 20 years, hundreds of studies have been conducted on the effectiveness of NEPs. These studies have consistently shown that IDUs who use NEPs are less likely to become infected with HIV and to engage in injection-related risk behaviors for HIV and viral hepatitis infection. In ecological studies, it has been found that locales with NEPs have lower rates of HIV incidence among IDUs (rate of HIV-negative IDUs

becoming HIV positive) and lower rates of HIV seroprevalence (percentage of IDUs who are HIV positive) as compared with those without NEPs. The consensus among governmental and scientific bodies is that NEPs are a vital component of any comprehensive approach to HIV prevention among IDUs.

In addition, NEPs have been shown to be associated with increased access to other medical and social services for IDUs. Studies have demonstrated that NEPs are excellent venues for IDUs to receive services such as tuberculosis screening and treatment, influenza, pneumococcal, and tetanus vaccination, HIV and HCV testing and counseling, HBV screening and vaccination, and wound care. More recent studies have documented that NEP clients who do not receive recommended preventive and medical services at NEP sites are unlikely to receive them elsewhere. NEPs have also been found to be a reliable route to drug treatment for IDUs; studies show high rates of referral to substance abuse treatment and comparable success in treatment once NEP clients have entered.

Finally, a number of studies have examined potential negative consequences of NEP implementation on drug use among youth, increased uptake of drug injection among other drug users, increased drug use among NEP clients, increased community crime, and unsafe disposal of syringes. Studies have found that knowledge of an NEP is no more likely to trigger drug use among youth than is an antidrug advertisement. At-risk youth in communities with NEPs were no more likely to report any substance use than similar youth in communities without NEPs. A number of longitudinal studies have examined trends in drug injection among IDUs who use and do not use NEPs and found no evidence of increased drug injection among NEP users. Likewise, IDUs who used NEPs were as likely to regard their own drug use as out of control and to be ready to enter substance abuse treatment as those IDUs who did not use NEPs.

Potential negative consequences of NEPs are a significant concern and have been a barrier to the implementation of NEPs in the United States and elsewhere. The two key concerns are crime and syringe disposal. Only one published study has examined crime trends in communities with and without NEPs. This study found that crime rates were similar in both communities, and no positive or negative trends in crime types or rates were observed over time. By contrast, a large number of studies have tackled the issue of unsafe syringe disposal. Using physical observation

techniques, these studies have consistently found that unsafe syringe disposal has tended to decrease following the implementation of NEPs. Nonetheless, in areas with high concentrations of IDUs, unsafe syringe disposal remains a concern. Researchers, community groups, and public health agencies have come up with a variety of methods to reduce community biohazardous trash including stationing biohazardous waste containers in public settings and providing 24-hour pick-up of publicly discarded syringes.

The Next Generation of NEP Research

NEP research can be seen as passing through at least three phases. The first phase focused on establishing that NEPs reduce HIV risk and infection among IDUs. The second phase examined potential negative consequences at the individual and community levels. A third phase examined the benefits of ancillary services at NEPs, including access to substance abuse treatment, use of preventive medical care, and routine screening and vaccination for infections and diseases common among IDUs. The fourth phase is attempting to codify evidence-based practices for NEPs and establish parameters of effective individual NEP use and geographic coverage.

Best-practice guidelines have been developed by NEP providers. Researchers have been slow to examine in detail how variations in NEP practice relate to outcomes among IDUs. Three key questions that must be addressed in future research are the following: (1) How many sterile syringes does an IDU need to maximize the prevention benefits of NEP use? (2) What percentage of IDUs must be reached in a geographic area to provide population-based prevention? (3) What is the effectiveness of novel syringe access strategies such as supervised injection facilities (SIF) and prison-based NEPs?

To address the first question, researchers have examined syringe dispensing policies at NEPs. “Syringe dispensing policy” refers to how many syringes might be exchanged at one time (are there limits on the number of syringes that can be exchanged?) and if the exchange provides new syringes on a one clean syringe per one used syringe basis or provides syringes to IDUs beyond the number of used syringes that are brought to the NEP. The earliest studies on syringe dispensing found a strong association between more liberal syringe

dispensing and lower odds of syringe re-use, but not syringe sharing, among IDUs. In later work, researchers measured the ratio of syringes received from an NEP to number of injections by IDUs—referred to as syringe coverage percentage—and found that IDUs who used NEPs with more liberal policies were more likely to have sufficient syringes to permit adherence to the “one shot, one syringe” guidance provided by the U.S. Centers for Disease Control and Prevention. Subsequent analyses also found that IDUs without adequate syringe coverage are significantly more likely to report syringe sharing than those with adequate numbers of syringes.

Less empirical research has been conducted on what constitutes adequate syringe access in an area to provide population-based impacts. It has been estimated that if 40% of IDUs used NEPs at least once a month, AIDS cases should stabilize. However, no studies have empirically tested this threshold level of access.

Research on innovative NEP schemes, particularly SIFs—places where illicit drugs can be injected under medical supervision—has been very promising. In addition to eliminating syringe sharing, SIFs that observe IDUs for 30 minutes following injection have been found to reduce overdose deaths significantly. Prison NEPs have been implemented in six countries. Evidence suggests that such NEPs reduce risk without increasing negative consequences. Both SIFs and prison NEPs are politically controversial, as NEPs were, and dissemination of these novel approaches are likely to be modest over the coming years.

Conclusion

Drug injection has been reported in over 130 countries, and incidence of HIV related to drug injection has been documented in at least 110 of these countries. HCV is likely to spread in these countries as well. NEPs should be considered an essential component of efforts to stem these twin epidemics internationally. Ongoing research, continued innovation by providers, increased disseminations of evidenced-based practice among NEPs, and growing political acceptance will be key to ensuring that NEPs have the maximum impact on HIV and HCV prevention in this century.

NETWORK FOR THE IMPROVEMENT OF ADDICTION TREATMENT

The Network for the Improvement of Addiction Treatment (NIATx) is a community of drug and alcohol treatment centers that apply process improvement strategies to the management and delivery of addiction treatment services. In this entry, the development of NIATx is described, basic principles of process improvement are outlined, and initial evaluation results are summarized.

NIATx began in 2003 as a public–private partnership through the Robert Wood Johnson Foundation’s

Paths to Recovery program (Paths) and the Center for Substance Abuse Treatment’s (CSAT’s) Strengthening Treatment Access and Retention (STAR) initiative. Ten Paths awards and 13 STAR awards were coordinated and integrated through the National Program Office at the University of Wisconsin (David Gustafson, director), and a second round of 15 Paths awards were added in 2005 (one additional treatment center participated without an award). The goal is to treat alcohol and drug disorders more efficiently and effectively.

Process improvement strategies were originally developed to reduce error and improve product quality in manufacturing settings and were based on statistical process control theory. Subsequently the approach has been extended and applied to organizational management and service delivery. The Institute of Medicine’s *Crossing the Quality Chasm* series, moreover, recommends the application of these strategies to health care and to treatments for alcohol, drug, and mental health disorders. The challenge for addiction treatment agencies is to gain perspective on the delivery of treatment as a process of care and identify errors in service delivery that lead to inefficiency and weaken patient outcomes. Missed appointments, for example, might be considered errors in treatment retention processes that lead to lower counselor productivity and loss of revenues. Reductions in missed appointments, conversely, enhance productivity and generate increased revenues.

NIATx members use learning sessions, coaching, interest circles, and Web pages and learn to test rapid cycle changes that reduce days to admission, enhance retention in care, increase admissions, and minimize appointment no-shows. Five simplified process improvement principles guide organizational change initiatives.

The first principle is to understand and involve the customer (the client in substance abuse treatment). Focus on the customer is a key to process improvement. To gain insight into client experiences, the organization’s change team walks through the processes that they seek to improve. Programs often begin with client intake processes. A member of the change team assumes the client role and calls for an appointment and, after waiting the typical period, arrives for the assessment and completes the intake interview. A second member of the change team acts as a family member and accompanies the “client” to help record impressions of the intake process (e.g., Was the telephone call for an appointment answered promptly and politely? Did the client speak with a real person? Were directions clear? Was the interview held in a confidential location and conducted with

sensitivity?). These insights help the change team identify processes that require improvement and help the treatment organization become more responsive to client needs and expectations.

The second guiding principle is to address important problems—the problems that vex program leadership. Typically, the problems affect the agency's revenues and expenses. Delays in admission lead to poor attendance at scheduled appointments. No-shows reduce counselor productivity and increase expenses. Change efforts should be directed at solving problems that hamper agency operations.

Third, a powerful change leader should be chosen. Change requires action and action is more likely with individuals who have status within the corporation, access to resources, and direct contact with the chief executive. Change leaders provide direction in moments of uncertainty and command respect because of their record of prior successes.

Fourth, it is useful to look at other treatment programs and other industries for insights into what to change and how to change it. Fast food franchises, for example, serve meals quickly. Can standardized menus, portion control, and queue management techniques be applied to treatment for alcohol and drug disorders? The most effective corporations seek new perspectives from many areas.

The fifth, and final, principle is to use rapid plan-do-study-act cycles to test and implement the proposed changes. The change team identifies a problem and proposes a solution (plan). A potential solution is tested on a small scale (do). The change team examines data to assess the effect of the change (study). The change is modified and tested again or moved toward institutionalization (act). The key is to start small—one patient or one week. Changes are scaled up if they prove to be effective. Thus, the change process is not overwhelming for staff, and they can study and invest in the changes as operations improve.

A review of the initial 18 months of NIATx suggested that treatment programs reduced days between first contact and the first treatment session 37%—from about 20 days to 12 days. Retention in care also improved. The percentage of clients who returned for a second treatment session increased 18%, from 72% in October 2003 to 85% in December 2004; retention through a third unit of care increased 17% (from 62% to 73%). Case studies of the participating treatment programs provide more detail on specific changes and impacts. Acadia Hospital, for example, reduced days to

admission for their intensive outpatient program from 4.1 to 1.3 days (68% improvement), enhanced the proportion of admissions completing four sessions of care from 36% to 67% (85% improvement), and increased admissions from detoxification 36% (from 55% to 75%). Acadia Hospital also extended the application of process improvement and reduced the use of restraint in their psychiatric units by 36%. For more detail on NIATx and case studies of individual treatment centers, see the project Web site at www.niatx.net.

The initial successes have led to an expansion of NIATx. Three states participated in a CSAT-supported pilot study of state involvement, and CSAT has expanded its STAR-SI (Strengthening Treatment Access and Retention—State Initiative) to 12 states. The National Institute on Drug Abuse is supporting a randomized trial of NIATx implementation (NIATx 200)—four states and 50 outpatient programs in each state will be randomly assigned to five levels of support to determine how much support is required for successful adoption of NIATx. The Robert Wood Johnson Foundation is supporting a new national program (Advancing Recovery) to facilitate the adoption of evidence-based practices in 12 partnerships between the state alcohol and drug treatment and prevention authority and treatment programs in the state. NIATx principles are used to foster adoption. Finally, NIATx is becoming a membership organization that continues to support addiction treatment centers and promote coordinated efforts to improve the quality of treatment for alcohol and drug disorders.

NEUROBIOLOGY OF ADDICTION

This entry provides a general overview of the neurobiology of addiction including (a) background information regarding the state of the field, (b) information regarding the specific neuroimaging techniques and methods used to study addiction in humans, and (c) information about the specific neuroanatomical circuitry and neurochemical changes involved in addiction. Potential risk factors for addiction, implications for addiction treatment, and directions for future work are discussed.

Background

Drug addiction is a process defined by uncontrollable, compulsive drug seeking and use, which persists despite negative health and social consequences. Although addiction is complex, there is consensus on several established principles. First, while sustained exposure to drugs of abuse is a necessary prerequisite for drug addiction, addiction is also influenced by biological and environmental factors, as well as the developmental stage of the affected individual. Second, during the initial stages of drug use, individuals often choose to use drugs to replicate an originally pleasurable experience with the substance. However, as addiction progresses, fundamental motivational shifts take place whereby the drug is no longer consumed to provide pleasure to the consumer but rather to relieve drug craving and withdrawal-associated distress. Third, there is an accumulating amount of evidence regarding the cumulative impact of chronic drug exposure on the human brain.

Although different types of drugs have different pharmacological and pharmacokinetic properties, their

habit-forming effects appear to involve a common denominator, namely, an impact on brain mechanisms involved with reward and motivation. These regions evolved to aid the organism in the search for, and motor approach of, natural rewards, such as food and sexual contact, which are essential to survival and reproduction. Evidence increasingly suggests that drug addiction is a process through which drugs of abuse “hijack” the neural circuitry of reward and motivation and produce a chronic state of drug seeking, which continues even in the face of strong negative consequences of use.

Neuroimaging Methods Used in Addiction Research

Recently the scientific community has witnessed a revolution in the field of human brain imaging. New technology, specifically positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and single photon emission computer tomography (SPECT), allow imaging of brain activity in vivo among human drug users. These advances provide a unique opportunity to understand the processes of addiction through the ability to measure changes in the function of the human brain, including the mapping of molecular kinetics and enzyme reactions over reasonably short time intervals. At the same time, spatially clear neural networks are displayed. Thus, imaging techniques can track neurochemical and neuroanatomical changes that occur due to neural plasticity and the effects of drugs.

Positron Emission Tomography (PET)

PET measures the radioactivity released by radio tracers in the body, such as natural molecules (i.e., oxygen, nitrogen, or glucose) and addictive drug compounds (i.e., amphetamine). This provides a way to measure changes in blood flow, glucose, and oxygen levels in the human brain. This method has been used to study the ways in which addiction and addictive drugs affect the brain neurotransmitters (dopamine, serotonin, opiate, and GABA) through the injection of neurotransmitter-specific tracers. For example, a dopamine-D₂ receptor tracer (i.e., C-raclopride) detects changes in intrasynaptic dopamine. This technology provides a method to track the ways in which addictive drugs bind to various parts of the brain after consumption of labeled

versions of the drug. PET can also be used to measure neurochemical changes after short- or long-term use of abused drugs, such as their effects on receptor density in specific brain regions.

Functional Magnetic Resonance Imaging (fMRI)

fMRI is an imaging method that provides information about the circulation of oxygenated and deoxygenated blood in the brain. This method relies on differences in the magnetic properties of oxygenated versus deoxygenated hemoglobin in the bloodstream at different locations in the brain, which provides a proxy for brain activity in the specific brain regions under study. fMRI can be used to study addiction because it provides information about the ways in which brain activity changes in response to specific types of stimuli (such as drug cues) and how brain responses to stimuli can be altered by drugs. One strength of the fMRI technology is its high temporal resolution, which makes it useful for disentangling the neural systems involved in, for instance, time-dependent subjective responses after drug consumption and specific brain responses to particular stimuli.

Single Photon Emission Computer Tomography (SPECT)

SPECT scanning measures blood flow using the injection of a radioactive substance. Radio-tagging offers the possibility of selecting specific neurotransmitter or binding sites to provide information about localized function and reactivity. Like PET, SPECT is being used to study the neurochemistry of addiction and drug use. Recently, SPECT has been used to trace the GABA receptor system. For example, the GABA_A-benzodiazepine (GABA-BDZ) receptor network is being imaged using the SPECT technology. This tracer elucidates the processes and implications of sedative and memory effects of GABA and benzodiazepines.

The advancement of human neuroimaging technologies, together with preclinical research on addiction, has developed a nearly inclusive biological model of addiction. The use of imaging has shown that addiction is coupled with specific changes in neuroanatomy and neurochemistry.

Structures Involved in Addiction

The brain comprises a network of interconnected structures whose evolutionary function is to ensure pursuit of the natural rewards necessary for survival (food) and for survival of the species (sex). Drugs of abuse act through the brain's circuitry for natural rewards, but they activate the system in a much stronger way, providing a "supranormal" stimulus that produces intense subjective effects and strong learning about the association between drug cues and the drug effect. Though the brain circuitry of reward is complex, a large body of imaging work on addiction has focused on the neurotransmitter *dopamine*.

Neurochemistry of Addiction: Dopamine

The dopaminergic brain network plays a fundamental role in the mechanisms of drug addiction. The dopamine system has an important role to play in generating acute drug effects and in the pairing of drug-related cues with responses. Dopamine is a neuromodulator that is involved in reward and motivation, salience attribution and attention, and motor and cognitive function. This system is activated by natural stimuli relevant to evolutionary survival, such as food and sex, as well as nonnatural stimuli that can be addictive, such as gambling. Dopamine is activated by addictive drugs, such as cocaine and alcohol. Dopamine is thought to contribute to a number of drug effects involved with addiction, including reward, craving, and alterations in motivation for the drug relative to other types of reward and the environment.

Reward/Drug "Liking"

There is a relationship between the rewarding effects of drugs and their self-administration. When a drug yields pleasurable effects in people, the chance of taking that drug again increases. This phenomenon of repeated use is guided by the principles of instrumental conditioning that associate contingencies with behavioral outcomes. Most studies investigating the role of dopamine in the experience of pleasure in humans are compatible with the view that dopamine release and high levels of extracellular dopamine in the ventral striatum (located in the forebrain, which receives input from the hippocampus) are associated with the pleasurable effects of drugs of abuse. The

amount of dopamine release required for these processes is unclear, as different substances of addiction have differing effects on the dopamine system.

Craving/Drug "Wanting"

The pleasurable effects of drugs by themselves cannot explain the total spectrum of addictive behaviors, which include use in the face of adverse consequences. Both addicted and nonaddicted persons may experience pleasurable effects of drugs. The focus in addiction research has made a shift from the rewarding aspects of drug use toward the motivational aspects of addictive behavior. The motivational properties of drugs may last for several years after the termination of drug use. Stimuli, or cues, in the environment associated with drug use are still able to trigger motivational circuits and elicit a high motivation to use these drugs, a phenomenon known as cue-elicited craving. This conditioned craving contributes to the continuation of drug use in active drug abusers and to relapse in detoxified abusers.

Based initially on work with rats and future support with human PET scans, research studies suggest that craving involves two separate neurobiological pathways. The first craving pathway (chronic craving) is the result of reduced dopamine activity (reduced dopamine receptor D_2 density in the striatum and orbitofrontal cortex). This reduction results in a chronic state of anhedonia, the inability to experience pleasure. Drugs are used to stimulate the dopamine activity in the striatum and orbitofrontal cortex in an attempt to alleviate this chronic anhedonic state. Essentially, this state can be regarded as a "need for dopamine," which is experienced as chronic craving. The second craving pathway (instant craving) results from a temporary enhanced cue-elicited dopaminergic activity in the striatum, amygdala, and cingulate cortex.

Other Pathways: GABA and Serotonin

Craving also involves other systems such as GABA, which interacts with dopamine. Some drugs, such as opioids, nicotine, and marijuana, affect dopamine indirectly through the stimulation of GABA neurons in the substantia nigra and prefrontal cortex. GABA is an inhibitory neurotransmitter that normally acts through two types of receptors: A and B. The stimulation of receptor A in the hippocampus reduces excessive craving for drugs such as alcohol, which in turn releases noradrenaline in the locus coeruleus, another key area

in the gratification pathway. Type B receptors stimulate the opening of potassium channels that determine the level of inhibition of dopamine release.

Serotonin provides important modulatory influence over neurons and neurotransmitters, such as dopamine, which are critically involved in addiction pathways and substance use disorders. A monoamine neurotransmitter, serotonin, plays a key role in the regulation of anger, aggression, and sexual behavior. Cocaine is a known drug wielding major neurochemical effects by binding to the serotonin, dopamine, and noradrenaline receptors. This blocks reuptake of these neurotransmitters from the extracellular space. Recent research suggests that serotonin and dopamine are necessary prerequisites for the development of cocaine addiction-related behaviors, such as craving. The neurotransmitter pathways involved in addiction suggest chronic adaptations in signaling and receptor responses, which impact specific anatomical circuitry and networks.

Anatomical Substrates of Addiction

Dopamine and other neurotransmitters involved in addiction impact function in a variety of neural circuits, particularly those involved in motivation, the processing of rewards, and making decisions about how to deal with rewards. In these regions, what begins (before drug use) as a normal system in homeostatic balance appears to undergo an allostatic shift (i.e., dysregulation of neurotransmitters) such that equilibrium is later maintained only by the continuing consumption of drugs. Anatomical structures involved in reward, motivated behavior, and acute and chronic drug effects include the following:

- *Orbitofrontal cortex*, which is involved in stimulus evaluation or "telling us what we want"
- *Nucleus accumbens*, located in the ventral base of the human forebrain, which is a key structure for reward, motivation, and addiction and is implicated in learning to predict rewards and to express adaptive behaviors
- *Amygdala*, which responds to the intensity of rewarding and aversive stimuli and also links motivationally relevant events with neutral stimuli and the autonomic and endocrine systems
- *Anterior cingulate*, which has a high concentration of dopaminergic receptors that are interconnected with both higher level structures (e.g., orbitofrontal cortex) and limbic structures (e.g., amygdala)

Neuroanatomical Pathway: Ventral to Dorsal Activation Patterns

At the neurophysiological level, there is a gradual change from ventral to dorsal activation in the nucleus accumbens, with an accompanying shift in activity from the ventral tegmental area to substantia nigra dopaminergic projections. There is also a reduction in orbitofrontal cortex and ventromedial prefrontal cortex activity at rest in addicts, which reflects a switch from prefrontal control, with reflective decision making, to more compulsive striatal control. This switch from drug use, with associated pleasure and liking, to drug dependence, with compulsive drug wanting, is marked by changes in synaptic plasticity and neurotransmitter function. Research suggests a final common pathway consisting of prefrontal cortex/nucleus accumbens/ventral pallidum in drug-craving and drug-seeking behavior. Changes in the strengths of synaptic connections in this pathway can account for the rapid reinstatement of drug use during a relapse from abstinence. Such reinstatement can be triggered by stress, a drug-specific cue, or a single dose of the drug. These changes in synaptic connections depend upon glutamatergic fibers from the prefrontal cortex, which converge on nucleus accumbens dendritic spines with dopaminergic afferents from the ventral tegmental area. Repeated use of drugs may lead to plastic reorganization of these synaptic connections, which then cements changes in neural activity, and so behavior. Molecular changes that affect synaptic connection strengths may occur both presynaptically and postsynaptically in the nucleus accumbens and also in the prefrontal cortex itself, as reflected by changes in activity seen there in neuroimaging studies. Dysfunction in the neural circuitry outlined here may underlie the development and maintenance of addiction in a general sense; however, individual substances disrupt this circuitry in specific ways. This means that different perturbations of the circuitry can give rise to addiction.

Adolescence: Development and Drug Use

Distinct age-related responses and developmental differences to drug use indicate that adolescence may constitute a critical period of vulnerability for addiction. Age-specific behavioral responses following repeated drug exposure include motivation and performance deficits that suggest the existence of

age-dependent differences in the vulnerability to addiction. The prefrontal cortex, the limbic system (i.e., amygdala and nucleus accumbens), anterior cingulate, and orbital-frontal cortices undergo significant and widespread refinement and maturation during adolescence, which include development of global and white matter volume, synaptic density, and oxygen uptake. Each of these structures is heavily innervated by ascending dopamine fibers, and each is involved in addiction.

Research suggests that a failure of executive functioning is coupled with addiction. Recently this connection has piqued interest, as it is linked with normally slow maturation of the prefrontal cortex in human adolescents. Thus, the integration of addiction research and neuroanatomical research might indicate adolescent risk for drug use and addiction processes. Additionally, it is possible that the impairment of higher-order cognition prolongs abuse or relapse.

Studies looking at the composition of gray matter in the human brain have found negative trends in gray-matter volume and age in drug-dependent individuals. In the temporal lobe, the drug-dependent individuals show a significant age-linked decline in gray-matter volume. Additionally, frontal lobe gray-matter volume tends to be negatively correlated with age in normal, drug-dependent subjects. The implication of gray-matter volume reductions as related to age suggests a potential biological link to addictive and risky behaviors, which statistically also decreases with age.

Treatment Implications

Treatment for addictions most often includes behavioral and pharmacological interventions. Based on clinical research, there is hope for the development of treatments that combine a variety of techniques, such as cognitive behavioral therapy and pharmacological therapy.

As noted earlier, research indicates that different neural networks and neurotransmitter systems are involved in different stages of the addiction pathway. The focus of current pharmacological treatment options looks to “reset,” or alter, the neurotransmitter systems that are affected by drug addiction processes. Toward this end, several behavioral and medication interventions are being assessed. Relevant behavioral interventions include cognitive behavioral therapy, which seeks to increase mastery and control over stressors, as well as teaching strategies for coping

with cue-induced craving. These strategies include alternative responses, aversive imagery, mastery imagery, and cognitive techniques.

There are many pharmacological interventions that seek to correct the neurotransmitter imbalances that appear due to addiction. In the treatment of cocaine, alcohol, and opioid dependence, the GABA_B agonist baclofen has shown some promise. Additionally, there are many promising treatments against nicotine dependence, such as bupropion (Wellbutrin, Zyban), which inhibit norepinephrine and dopamine reuptake and act as nicotine antagonists. These treatments work to reduce craving and withdrawal symptoms associated with nicotine abuse.

Additionally, there are treatments for a variety of drug addictions that replace, at lower levels, the drug currently in the system. For example, with nicotine addiction, the use of the nicotine patch replaces nicotine in the bloodstream at lower doses and a slower rate than one would get through smoking a cigarette. Similarly, with heroin addiction, methadone is given as a treatment. Methadone is an opioid replacement therapy that uses a substance that is slow to metabolize. Therefore, methadone has long-lasting effects on reducing craving and withdrawal symptoms.

Future Directions

The pace of identifying drug-induced molecular changes in the ventral tegmental area–nucleus accumbens and in the many other brain regions important for addiction has increased dramatically over the past 5 years with the advent of neuroimaging and genomic tools. Studies have indicated that multiple drugs of abuse produce common, chronic actions in reward regions in the brain, in addition to a given drug's specific effects. One challenge for future drug-addiction research is to better understand the ways in which molecular and cellular changes in neurons in the reward circuitry in the brain contribute to the behavioral phenomena of reward and addiction. For example, it is unknown how decreased excitability of nucleus accumbens neurons specifically contributes to an alteration in the sense of reward and how altered activity of these cells contributes to craving and relapse. Such understanding requires additional appreciation of how the nucleus accumbens and its interrelated brain-reward structures function as complex neural circuits.

An important area of future research is investigation of between-person risk factors for addiction, which will increase our understanding of the ways in which some individuals are particularly vulnerable to addiction. Available data indicate that approximately 50% of the risk of drug addiction (including addiction to opioids, cocaine, nicotine, and alcohol) appears to be genetically influenced, but the specific genes involved have not yet been identified. Identification of the specific genes involved will elucidate the ways in which genetic and nongenetic factors may interact to influence an individual's risk for an addictive disorder. Wide genomic associations for addiction will enhance the ability to identify vulnerable populations and enable individually tailored treatments of those afflicted by addiction.

In addition, a wider view of neurobehavioral chemistry and behavioral development during adolescence is needed to better characterize and understand the differential vulnerability seen at this age. This should include the scope and extent of drug-induced changes in neural systems—for instance, where changes occur, how persistent are age-related changes, and the links between these changes and short-term and long-term behavior. Second, in understanding the neurobiology of addiction, attention on nondopaminergic processes, including contributions of other neurotransmitter systems, such as glutamate, 5-HT, and opioids, may facilitate understanding of the neural bases of the full spectrum of addiction outcomes, including the compulsion to use in the face of adverse consequences. In addition, the neurobiology of many current treatments has not been fully characterized to date.

Advances in brain imaging, neurochemistry, and molecular biology are adding crucial depth to the understanding of the complex pathophysiology involved and revealing new targets for pharmaceutical, behavioral, and combined treatments. The implications of such developments are likely to be profound, given the large societal, personal, and interpersonal costs of addiction.

NEUROCOGNITIVE EFFECTS OF ALCOHOL AND OTHER DRUGS

As understanding increases regarding the effects of alcohol and other drugs on the brain, it is becoming increasingly apparent that the use of most drugs is accompanied by short- and long-term changes in cognitive abilities such as attention, learning, memory, and problem solving. The term *neurocognitive* is often used to describe these abilities in order to reflect the link between biology and behavior—in this case the link between the brain and the complex cognitive abilities (behaviors) that it supports. New discoveries have demonstrated that the manner in which individual substances affect neurocognitive function is very complex. Not only does each substance have its own influence on brain function, with some having few demonstrable long-term effects and others having devastating effects; it is also apparent that the brain can be compromised in multiple ways by chronic substance use. Compromised brain function and resulting alterations in neurocognitive function can occur as a result of the direct effects (e.g., agonist or antagonist) of substances on neurotransmitter function during

intoxication. Neurocognitive deficits can also become evident during withdrawal, where the chronic effects of substance use have caused upregulation or downregulation of various neurotransmitter systems. Alterations in neurocognition as a result of intoxication and withdrawal effects are transient in nature and typically resolve as the symptoms of intoxication and withdrawal resolve. It is also the case that some substances are neurotoxic, causing damage to the brain itself as more and more of the substance is used. Deficits in neurocognitive abilities resulting from neurotoxic effects persist after withdrawal is complete, and although they may demonstrate some improvement over the long term, some also may continue to persist for many years following cessation of substance use. The brain can also be negatively affected through the indirect influences of substances by at least two mechanisms. In these cases, the neurotoxic effects of the substances are not responsible for brain damage per se. First, some substances can damage organ systems other than the brain, which in turn compromises brain function. Liver damage, which is common in alcoholism, is an example of this type of indirect effect. A second means by which substances can indirectly affect brain function is by causing or exacerbating neurological disorders. For example, because cocaine increases blood pressure and causes blood vessels to constrict, it can cause cerebrovascular accidents or “strokes,” which significantly impact brain function and cognition. Seizures that occur during withdrawal from alcohol or barbiturates are another example of this type of influence. Finally, some psychiatric and medical disorders that occur at increased frequency in individuals with substance use disorders may have their own negative effects on neurocognitive abilities. Depression and HIV infection are two such conditions. Thus, neurocognitive deficits resulting from substance use are complex in that they may be transient or enduring in nature, result from direct or indirect effects on the brain, are associated with neurotoxic effects that are unique to each substance, and are oftentimes difficult to separate from other coexisting psychiatric or medical disorders. The following sections review the assessment of neurocognitive impairments and describe impairments that have been associated with use of specific substances that have received the most attention in the research literature, including alcohol, cannabis, cocaine, amphetamines and MDMA, opioids, and benzodiazepines.

Assessment of Neurocognitive Impairments

The assessment of neurocognitive effects of substances can be challenging, as such effects (e.g., memory impairment) can interfere with a person's ability to accurately report details of substance use. Indeed, there is some evidence to suggest that individuals with neurocognitive impairments are more likely to underreport or deny substance use in contrast to their noncognitively impaired counterparts. Additionally, because individual substances are often associated with unique neurocognitive impairments, careful consideration should be given to the selection of neuropsychological tests that are sensitive to the unique impairments associated with each substance. Prior to attributing cognitive deficits to neurotoxic effects of any particular substance, potential influence of the aforementioned factors must be considered, with special attention given to comorbid medical and psychiatric disorders. In all patients who have substance use disorders, thorough physical examination is necessary to rule out comorbid disorders that could affect neurocognitive functioning, including disorders resulting from malnutrition such as Wernicke–Korsakoff syndrome, cirrhosis of the liver leading to hepatic encephalopathy, subdural hematoma secondary to head injury, epileptic seizures, and infectious diseases associated with substance use (e.g., HIV resulting from intravenous drug use).

Treatment providers who are unfamiliar with neurocognitive tests or wish to learn more about specific tests can consult one of the standard neuropsychology texts. However, in general terms, neurocognitive effects of substance use are assessed through tests of learning and memory, attention and concentration, psychomotor speed, language abilities, and verbal and nonverbal problem solving (also referred to as “executive” functions). These tests are administered and interpreted by trained professionals, typically neuropsychologists. Test results can be compared with cutoff scores, which indicate the presence of absence of impairment, or by comparisons with the performance of large groups of unaffected or normal individuals that match the subject's age and education level. Assessment of these abilities requires multiple tests, which may take several hours to administer. When there is limited time or expertise to administer and interpret full neuropsychological test batteries, neuropsychological screening instruments can be employed. Cognitive screening instruments, such as the Cognistat and the Repeatable Battery for the

Assessment of Neuropsychological Status, require minimal training and take 30 minutes or less to administer. However, because these instruments have not been extensively validated with individuals who have substance use disorders, it is unclear whether they are sensitive to specific and sometimes subtle neurocognitive deficits that characterize this population.

In addition to neuropsychological tests, brain imaging has been utilized to determine the impact of substance use on brain structure and function. As neurocognitive deficits are impairments in cognitive ability that are closely linked to the functioning of brain areas, neural pathways, or cortical networks, a clearer understanding of brain functioning is highly relevant to investigations of neurocognitive effects. Neuroimaging studies have typically examined either (a) the physical *structure* of the brain in attempts to determine whether substance use decreases the size of some brain regions, which could indicate the death of brain cells (neurons); or (b) the actual *function* of the brain to determine if substances cause abnormal increases or decreases in the activity of specific brain regions. Common structural neuroimaging techniques include computerized tomography (CT) and magnetic resonance imaging (MRI), and functional neuroimaging techniques include positron emission tomography (PET), single photon emission computerized tomography (SPECT), and functional magnetic resonance imaging (fMRI).

Neurocognitive Effects in Specific Substance Use Disorders

Of all substances, alcohol is the most widely abused substance, and the neurocognitive effects of alcohol, as compared with other substances, have received considerably more attention in the scientific community. Because of this, much of this section focuses on alcohol-related neurocognitive deficits, but it also covers cannabis, cocaine, amphetamines and club drugs, opioids, and benzodiazepines.

Alcohol

Alcohol is a central nervous system depressant that has been shown to produce both acute neurocognitive impairment (associated with intoxication and withdrawal) and long-term deficits, some which gradually resolve in those who abstain from alcohol consumption and others that appear to persist indefinitely. In extreme cases in which there has been prolonged heavy use, dementia or amnesic disorder may also occur, which

causes severe neurocognitive deterioration. In the following sections, neurocognitive deficits without dementia and amnesic disorder are discussed first. This discussion is divided into three time periods following cessation of alcohol use and the deficits that occur during these time periods: acute deficits (first week of abstinence), short-term deficits (2–5 weeks after abstinence), and long-term deficits (13 months or more after abstinence). Alcohol-induced persisting dementia, amnesic disorder (Wernicke–Korsakoff syndrome), and hepatic encephalopathy are then discussed.

Acute Deficits

Common neurological symptoms of alcohol intoxication are slurred speech, ataxia, incoordination, and nystagmus (involuntary eye movements). Psychological symptoms such as fluctuations in mood state and impaired cognitive abilities (memory, attention, and judgment) are also present. Physiological dependence develops after heavy prolonged consumption, and withdrawal usually occurs within 4 to 12 hours of drinking cessation, and almost always within 48 hours. Withdrawal symptoms vary in severity, and most resolve within 1 week. Neurocognition is most significantly impaired immediately after cessation of alcohol use during this period of withdrawal. In younger individuals, this impairment gradually improves over 3 to 4 weeks. Older individuals exhibit slower recovery. During the first and second weeks of sobriety, performance on tasks assessing intellectual functioning, memory, and visual motor skills often shows marked improvement. This spontaneous improvement probably results not only from abstinence but also from other factors, such as improved nutrition. However, this spontaneous improvement in neurocognition is diminished or reversed if the individual resumes drinking.

Short-Term Deficits

Studies of recently detoxified individuals (2–5 weeks) indicate presence of impairment across a number of cognitive and motor domains, although there does appear to be an age effect. For younger individuals (less than 35 years old) with relatively short drinking histories (5–10 years), those who consume more alcohol over the course of their lives exhibit poorer performance on neuropsychological measures. However, when younger individuals are abstinent an average of 4 to 6 weeks, cognitive functioning appears to return to expected or

“normal” levels. Neurocognitive deficits that persist after drinking cessation may be a result of the cumulative effects of a lifetime pattern of alcohol abuse. The most prominent deficits are in the areas of abstraction ability and problem solving, perceptual-motor ability, short-term and long-term verbal and nonverbal memory (with nonverbal memory relatively more impaired), visuospatial abilities, and gait and balance.

Long-Term Deficits

Studies examining those abstinent for longer periods of time are less conclusive regarding the nature and severity of impairment. In general, it appears that verbal abilities recover more quickly than do nonverbal learning and memory. Improvement in some cognitive domains is related to age, length of abstinence, and interim drinking. Complex memory deficits found in some individuals with chronic alcoholism may be due to use of inefficient organization strategies during encoding and may actually represent a learning strategy formation deficit. Other deficits that may persist after long-term abstinence, particularly in older individuals, include problem solving, perceptual-motor abilities, visual learning and memory, and contextual memory deficits.

Amnesic Disorder (Wernicke–Korsakoff Syndrome)

Wernicke–Korsakoff syndrome is caused by a deficiency in thiamine (vitamin B₁), to which some individuals with alcoholism are particularly susceptible because of poor dietary practices. Thiamine deficiency causes hemorrhages to structure in the middle of the brain, which causes unsteady gait, nystagmus, ophthalmoplegia (partial or full paralysis of the eyes), and confusion during the acute phase of the disorder, which is referred to as Wernicke’s encephalopathy. If untreated, it will result in coma and death. With large doses of thiamine, symptoms of Wernicke’s encephalopathy typically resolve within 4 weeks. Most patients then go on to develop Korsakoff’s syndrome, which is characterized by severe memory deficit that makes them incapable of consciously learning new information. Impairment in other areas of cognitive functioning may be present, including problem-solving abilities or executive functions. General intellectual functioning and memory for events prior to the onset of the disorder are typically preserved. Some have suggested that milder forms of

Wernicke–Korsakoff syndrome may account for much of the persisting neurocognitive deficits in chronic alcoholism, although this suggestion remains controversial. Because neurocognitive deficits due to thiamine deficiency are severe and debilitating, treatment providers should always evaluate the patient's nutritional status and consider giving thiamine prophylactically.

Alcohol-Induced Persisting Dementia

Controversy exists regarding the etiology of alcohol-induced persisting dementia, which is a condition that is characterized by impairment in memory as well as in other cognitive abilities, such as object recognition and problem solving. Some reports indicate that as many as 25% of elderly patients with alcoholism and 24% of institutionalized elderly people have alcohol dementia. Alcohol-induced persisting dementia has an insidious onset. Neurocognitive deficits are permanent, persisting long after alcohol consumption has ceased, and interfere significantly with daily functioning. Time and place orientation and language abilities remain relatively well preserved in alcohol dementia, which may help clinicians distinguish it from dementia due to Alzheimer's disease, in which disorientation and prominent disturbances in language are present.

Hepatic Encephalopathy

Approximately 30% of individuals with alcohol use disorders develop cirrhosis of the liver, which can cause neurocognitive deficits. This condition is referred to as hepatic (liver) encephalopathy (pathology of the brain). Studies have found that individuals with cirrhosis resulting from alcohol use disorders perform worse on tests of short-term memory, eye tracking, and hand–eye coordination when compared with individuals with cirrhosis not induced by alcoholism. Many of these cognitive deficits improve after liver transplantation in cirrhotic patients with alcoholism, although memory capacity does not. Additionally, subclinical hepatic encephalopathy (i.e., typical alterations in mood, cognition, and consciousness are not present) can produce significant memory impairment and motor slowing, although intellectual functioning and abstraction abilities remain intact.

Brain Structure and Function

Neuroimaging findings with computed tomography (CT) and magnetic resonance imaging (MRI) indicate that in recently detoxified individuals, cerebral atrophy is present, in which reduction in the tissue on the surface of the brain (cortex or “gray” matter) and the tissue that lies underneath it (subcortex, much of which is “white” matter) occurs. This loss is most pronounced in older individuals with alcoholism. The front regions of the brain appear especially sensitive to combined effects of aging and alcohol. Prolonged abstinence over 3 to 6 months may cause white matter volume increases. Positron emission tomography (PET) studies suggest that neuropsychological impairment is associated with overall decreased metabolism of glucose in the frontal cortex and subcortical structures.

Cannabis

The most frequently abused category of illicit drugs is the cannabinoids, with the most common form of use being marijuana. Delta-9-tetrahydrocannabinol (THC) causes the psychoactive effects of cannabinoids. Although cannabis use disorders are associated with a variety of negative outcomes, long-term neurocognitive deficits appear to be minimal. With regard to acute effects caused by cannabis intoxication, significant and widespread cognitive deficits in the areas of problem solving, abstraction, attention, expressive and receptive language, and memory have been noted. Several short-term deficits have also been reported to occur during the 24 hours following cessation of cannabis use, including impairments in attention, executive functioning, mental arithmetic, immediate recall of verbal information, and complex reaction times. Subtle long-term deficits may also be present in the ability to learn and recall new information for heavy users. It is not clear whether these deficits reflect neurological damage caused by cannabis or if they are present prior to onset of cannabis use.

A number of neuroimaging studies suggest that cannabis use may be associated with abnormalities in brain function although the structure of the brain appears normal. PET imaging studies following acute administration of cannabis demonstrate increased cerebral blood flow in the cerebellum, which may be consistent with a high concentration of cannabinoid C_1 receptors in that region of the brain. Increased

blood flow has also been reported in other brain areas, such as the orbitofrontal cortex, insula, and cingulate gyrus, following acute intoxication. Functional magnetic resonance imaging (fMRI) investigations of chronic cannabis users examined after short-term and long-term abstinence demonstrate abnormal activation in some brain regions when individuals are performing tests requiring memory. Chronic users also demonstrate reduced baseline levels of cerebral blood flow, which improve with abstinence.

Cocaine

Cocaine is a stimulant drug that causes constriction of blood vessels in the brain and increased blood pressure, which may lead to seizures or cerebrovascular accidents, also called strokes. Use of cocaine can also cause failure of the respiratory or cardiac systems, which in turn decreases blood flow to the brain, thus causing brain damage. Although general intellectual ability remains intact in most cases, cocaine use is associated with several distinct neuropsychological and neurological abnormalities. These abnormalities differ in relation to time since use, whether withdrawal symptoms are present, and the extent of use. Current use is associated with impairments in verbal and visual recall, working memory, and attention. Measures have found attention, executive function, and various aspects of memory to be the most frequently impaired immediately following cessation of cocaine use. However, memory abilities improve during the first month following cessation of cocaine use with gradual improvement thereafter. The pattern of recovery for other neurocognitive abilities during the first 5 weeks of sobriety is unclear, although it appears that little recovery occurs even after 6 months of sobriety, particularly for attention, executive function, spatial processing, and delayed memory.

Neuroimaging studies indicate that those who use cocaine and also develop seizures have brain atrophy and specific decreased tissue volumes in frontal brain regions. There is a strong association between amount of cortical atrophy and length of cocaine use, suggesting that increased and lengthier use causes increased cerebral damage. During cocaine intoxication, unique patterns of increased and decreased activity are present in frontal brain regions, as well as in brain structures that regulate emotion and reward. These brain regions are also integral to normal functioning of a number of

neurocognitive abilities, including executive function, memory, and attention. Long-term cocaine use causes decreased brain activity across a wide variety of brain regions. Interestingly, women may tend to have fewer cerebral abnormalities than men and often appear normal. For individuals abstinent from cocaine for several months, decreased activity continues in frontal regions of the brain; this abnormality in brain function appears to be related to dose and length of cocaine use. Thus, neuropsychological and neuroimaging studies suggest that abnormalities in brain function are associated with pattern and length of use and that, although some improvement occurs after cessation of cocaine use, abnormalities in neurocognitive function may persist for months.

Amphetamines and Methylenedioxymethamphetamine (MDMA)

Amphetamines are stimulant drugs with properties similar to cocaine. However, their stimulant actions tend to be longer lasting and their sympathomimetic effects are generally more potent than cocaine. MDMA (3,4-methylenedioxymethamphetamine), also known as ecstasy, is a member of the amphetamine family, but it is described here independently due to its hallucinogenic properties. MDMA use is associated with significant long-term abnormalities in the neurotransmitter serotonin, which leads to changes in a variety of psychological functions, such as behavior, mood, and sleep. For chronic users, long-term damage has been reported, with the extent of damage proportional to the amount and duration of use.

Amphetamines

Few studies have been conducted on the neuropsychological effects of amphetamines, but findings are similar to those with cocaine abuse, which reveal deficits primarily in attention, executive functions, and memory. During intoxication, amphetamines produce general cognitive arousal and increased vigilance without a corresponding improvement in other complex cognitive abilities such as memory. Immediately following cessation of use, short-term deficits are present for attention, psychomotor speed, some aspects of verbal abilities, and learning and memory of verbal information, with some impairments persisting even after 1 month of abstinence. Long-term deficits in attention and motor skills also appear to persist for 1 year or

more following cessation of use in those with a history of heavy stimulant use.

Neuroimaging studies of individuals who are methamphetamine dependent have also provided evidence for the neurotoxic effects of this drug. Overall reductions in brain volumes have been identified across a number of brain regions. Additionally, increased volume in a number of brain structures has been found that is associated with increased neurocognitive impairment. There is also some evidence of nerve terminal degeneration in the central motor areas of the brain in methamphetamine users who have been abstinent for at least a month.

Methylenedioxymethamphetamine (MDMA)

For MDMA, a number of neurocognitive deficits have been identified in the weeks immediately following cessation of MDMA use, including deficits in some aspects of memory. Both occasional and chronic users exhibit impairments in some language functions as well as in immediate and delayed memory for stories. Long-term neurocognitive deficits have also been reported to persist for up to 1 year following abstinence. These deficits are most consistently reported in the domains of learning and memory, particularly memory for verbal information. Additional deficits have been found in the areas of executive function and planning, attention and vigilance, and visual scanning.

Neuroimaging findings suggest that MDMA use results in significant functional brain impairment. A single dose of MDMA causes increased cerebral blood flow in some posterior regions of the brain (occipital lobe, cerebellum, and temporal lobe), with corresponding decreases in cortical areas responsible for motor and sensory functions, frontal brain regions, and a variety of other regions (temporal lobe, cingulate cortex, insula, and thalamus). For heavy MDMA users, global decreases in serotonin transporter densities are also present in some brain regions, indicating injury to the serotonin neurons.

Opioids

Opioids include naturally occurring, semisynthetic, and synthetic substances; heroin is the most frequently abused opioid. Several medical and psychological factors are associated with heroin use, such as head trauma, poor school or occupational performance, and

hyperactivity or attention problems. However, relatively few studies have investigated the neurocognitive deficits resulting from opioid use, and the results of these studies are conflicting particularly with regard to long-term effects. As in other substance use disorders, it appears that neurocognitive deficits vary in relation to duration and quantity of use. Studies examining cognitive effects during acute opioid administration suggest that heroin use impairs long-term memory for verbal and nonverbal information, as well as attention and concentration. Some studies of current users also suggest impairment of fine motor speed, visuospatial and visuomotor abilities, attention, and memory, as well as more generalized and diffuse cognitive impairment. Deficits that persist following cessation of heroin use in chronic users may include impairment of executive functions and nonverbal reasoning. However, cognitive deficits noted in individuals with histories of chronic heroin use may reflect the influence of other drug use (e.g., cocaine and alcohol), childhood factors (e.g., attention-deficit/hyperactivity disorder, poor education), or comorbid medical and psychiatric disorders.

Structural neuroimaging studies have also produced discrepant results, which may be due to the imaging method used, the sample of individuals who were studied, or other methodological factors. Some have found no significant differences between users of heroin and controls, while others had identified cortex reductions in frontal brain regions. Functional neuroimaging studies report global decreases in cerebral activation following acute heroin administration, as well as diffuse decreases in cerebral blood flow in opioid-dependent individuals, particularly in the frontal area of the cortex. These abnormalities persist during withdrawal.

Benzodiazepines

Benzodiazepines are classified as central nervous system depressants or sedative/hypnotics and are among the most widely prescribed medications in the world. They have a high potential for abuse because of their calming and sometimes euphoric effects. Although abused by individuals of all ages, elderly individuals, who receive almost 40% of all benzodiazepine prescriptions, abuse benzodiazepines more often than other age groups. Elderly individuals who abuse benzodiazepines are at increased risk for adverse reactions, including neurocognitive deficits associated

with delirium, seizures, and confusion that can occur during withdrawal. Abrupt discontinuation of benzodiazepines with long half-lives (e.g., Valium) increases the risk for seizures within 3 days of discontinuation, although discontinuance of shorter-acting benzodiazepines may cause more intense withdrawal symptoms. Neuropsychological deficits observed with benzodiazepine use depend upon the age of the user. Studies suggest that benzodiazepines have several acute cognitive effects on elderly individuals, although these effects are negligible (at least at low doses) in younger individuals. Additionally, elderly individuals display cognitive impairment even at low doses, and these impairments increase as dose increases. However, it has been reported that deficits become less severe with chronic administration. Drug half-life may also influence the type of neuropsychological deficits observed with benzodiazepine use. Long-acting benzodiazepines are associated with multiple neurocognitive abnormalities, including impairments in immediate and delayed memory for verbal and nonverbal information, speed of information processing, and psychomotor functioning. Short-acting benzodiazepines impair attention, as well as several memory functions, including memory. These neurocognitive impairments typically subside rapidly once benzodiazepine use is discontinued. However, for long-term users, neurocognitive deficits may persist up to 6 months after discontinuation of use.

Structural neuroimaging studies provide no evidence of brain differences between benzodiazepine users and controls. However, functional neuroimaging suggests that regional decreases in brain metabolism occur that are associated with benzodiazepine administration.

Neurocognitive Deficits and Treatment

There is increased interest in the means by which neurocognitive deficits interfere with treatment response and effectiveness in those with substance use disorders. This is because treatment effectiveness may be mediated by the type of neurocognitive deficits observed and thereby differ based upon the types of substances abused. For instance, deficits in executive function may hinder the application of problem-solving strategies needed to resist impulses to use. Memory impairment may interfere with approaches that rely heavily on the learning of psychoeducational information. Nevertheless, the relationship between treatment outcome and neurocognitive deficits is

complex, and clinicians should consider type and severity of neurocognitive deficits when planning treatment for individuals with substance use disorders. When deficits are present, cognitive rehabilitation procedures may help remediate specific neurocognitive deficits and thereby increase treatment efficacy.

Conclusion

Although there is still much to learn regarding the detrimental effects of alcohol and other drugs on the brain and the neurocognitive deficits that result from these effects, it is now clear that long-term neurocognitive deficits result from the use of some but not all substances. Alcohol continues to be a significant source of concern in this regard, given its high prevalence of use and the large number of studies that have identified persisting deleterious effects resulting from heavy and prolonged use. Other substances, such as MDMA, although less studied, appear to be highly detrimental, causing substantial neuronal damage even after only a few doses. As the neurocognitive deficits resulting from the use of these drugs become more clearly understood, it may be possible to develop pharmacological and behavioral interventions that remediate them. Additionally, neurocognitive and neuroimaging studies show promise for elucidating brain mechanisms that are central to the development and maintenance of substance use disorders. Therefore, despite major advances in knowledge over the past 2 decades, continued research using neuropsychological and neuroimaging methodologies is clearly needed to lay the groundwork for the development of more effective treatments and to identify abnormalities in brain structure and function that are central to substance use disorders.

NEUROTRANSMITTERS

The adult human brain weighs about 1,400 grams and contains about 100 billion neurons (that may vary by perhaps 1,000 different types) capable of performing billions of calculations a second and has 20 to 50 times as many supportive nonneural cells called *glia*. The intraneural signals generated can travel at 400 meters per second. The signaling process by which a neuron excites (behaviorally promotes activity and wakefulness) or inhibits (behaviorally promotes calm and sleep and lessens aggression) the next neuron in the net is called neurotransmission. This event is both electrically (about a tenth of a volt) and chemically mediated primarily by neurotransmitter substances (NTs).

The way that neurons signal each other is via the release of chemicals (designed to provide a highly specific signal to alter the target neurons' firing rate). The signaling process of the nervous system is often conceptualized as falling into two categories: input and output. Inputs are the signals generated by sensory transducer cells that specialize in transforming external stimuli into neural firing patterns. These resulting signals go toward the central nervous system (CNS; brain and spinal cord) for processing. The outputs are stimuli that travel away from the CNS. Many output signals terminate at muscle tissue.

NTs do not act alone; their signals are analogous to a different instrument in an orchestra creating the grand symphony called physiology and behavior. The other "players" are *neuromodulators*, *neuromodulators*, and *neuromediators*, terms reserved to identify chemical messengers, other than NTs, that are released and serve to inhibit or facilitate the functions

of NTs and receptors (specialized proteins where NTs act). Neurohormones are secreted by specialized neurons that release substances into the bloodstream, cerebral spinal fluid, and intracellular spaces for target tissues outside of the CNS. Some neurohormones are also NTs. Each substance plays an important role in determining the type, frequency, strength, and magnitude of nervous system responses (signaling process).

Neurotransmission

A description of this signaling process can start with events that are initiated when an electrical signal travels down the axon and invades an end-swelling of a neuron called a bouton. A neuron's supply of NT is stored in protein packages called synaptic vesicles, located in the boutons. An electrical signal traveling down a neural track called an axon opens calcium ion channels in the bouton wall which, in turn, allows calcium to enter the bouton. This calcium entry then causes the vesicles to transport to the neural membrane where the vesicles fuse and NT is released into the synapse (the gap between neurons which do not physically touch). This process is called exocytosis.

On the other side of the synapse are other receiving neurons that have specialized receiving proteins called receptors, which are activated by the NT. Receptor proteins can be ion channel gated (regulating the opening and closing of charged elements such as calcium, sodium, potassium, and chlorine), guanine-coupled receptor gated, carrier protein gated, or enzyme gated. There are also intracellular hormone gates. All types are capable of contributing to change in a neuron's firing rate (able to inhibit or enhance the generation of neural electrical firing). In short, NTs attach to receptors and alter the neural membrane of the postsynaptic neuron's firing frequency (neurons in the CNS fire normally about every 4 milliseconds).

Neurotransmitter Types and Classification

Sir Henry Dale was among the first to study NT release. He proposed that a neuron made one and only one NT. Initially, in support of Dale's principle, was the evidence that the seven earliest discovered and, thus, now "classical" NTs (acetylcholine [ACH], serotonin [5HT], epinephrine [EP], norepinephrine [NE], dopamine [DA], gamma-aminobutyric acid [GABA], and histamine [HT]) were not found in combination to be synthesized, stored, or released by the same neuron.

Table 1 Neurotransmitter Profile Categories

Name(s)	Common, serotonin; chemical 5-hydroxytryptamine
Classification	Catechol, indole, peptide, amino acid, gas
Structure	Stick-and-ball molecular model
History	When discovered, by whom, which tissue assay
Chemistry	Biosynthetic pathway, degradation enzymes (MAO, COMT, AChE), rate-limiting step
Precursors	Amino acid, other NTs
Receptor types and subtypes	E.g., DA ₁ , DA ₂ , DA ₃ , DA ₄ , DA ₅
Ion system regulated; second messenger system	Calcium, sodium, potassium, chloride; G-protein
Disorders wherein levels are elevated or lowered	Schizophrenia, depression, addiction
Associated neuropathology disorder(s)	Alzheimer's disease, Parkinsonism, schizophrenia
Brain sites of synthesis pathway	Substantia nigra
Representative drugs that are agonists	E.g., For DA, amphetamine
Representative drugs that are antagonists	For DA, haloperidol
Postsynaptic effect	Inhibitory, excitatory, both
Activates second messenger system and in what amount	Low, moderate, high; picomolar, nanomolar, micromolar
Specific reuptake transporter name	Yes, no; sodium-dependent serotonin transporter
Co-stored and co-released with	E.g., prolactin, enkephalin

However, recent evidence supports the explanation that several nonclassical NTs (e.g., purine and pyrimidines, amino acids, and neuropeptides) are co-stored and co-released with classical NTs. They serve a major neuromodulatory role for the classical seven NTs and are involved in regulating the expression (quantity and quality) of signaling. The concept that NTs work cooperatively is now referred to as the coexistence principle, forwarded by the Swedish neuroanatomist and neuropharmacologist Tomas Hökfelt.

There are a variety of schemes to classify NTs. One popular classification is to divide NTs into small and large molecule categories. For example, NE is a small molecule with a diameter of about 20 Angstrom units (0.02 microns). The small NTs can be further subdivided into five categories: the amine ACH, biogenic amines (DA, NE, EP, 5HT, HT), amino acids (glutamate, GABA, aspartic acid, and glycine), neuromediating gases (oxygen, nitric oxide, carbon monoxide), and other small messengers (nucleotides [adenosine, adenosine triphosphate] and peptides [Substance P, dynorphins, enkephalins: methionine and leucine]). NTs can be more easily understood given the following categories of facts. Each category fact provided in Table 1 is for demonstration purposes; together they do not represent a complete profile for any specific NT.

Brief Descriptions

A few short elaborations of common NTs follow. The amine ACH is in a category all its own for a variety of reasons, including that it was the first NT discovered. Dale identified ACH as a potential NT, but its importance was first demonstrated in nervous tissue by Otto Loewi's experiments with frog heart tissue. Loewi discovered that ACH was released from vagus nerve terminals following electrical stimulation and slowed heart muscle contractions. Dale and Loewi shared the 1936 Nobel Prize in Physiology or Medicine for their work on ACH.

ACH is not a monoamine, and it is usually excitatory. ACH is synthesized in the brain from two simple molecules using acetyl coenzyme and from a dietary source of choline. The two families of ACH receptors are muscarinic with five subtypes and nicotinic with four subtypes of receptors. It is a consistent observation that NTs have more than one type or subtype of receptors where they attach. The names of the ACH receptor types come from muscarine, found in some mushrooms, and nicotine, found in tobacco. These "poisons" were the first chemicals identified to bind to and activate ACH receptors.

ACH receptors in the brain are involved in processing memories (when they are dysfunctional, they contribute to Alzheimer's disease), sensory pain processing (processing signals from hair cells of the cochlea), peripheral smooth skeletal muscle function (dysfunctions include myasthenia gravis and Parkinson's disorders), and addiction resulting from arecoline (a mild psychostimulant and euphoriant substance in areca nuts chewed with betel plant leaves used mainly in India and Vietnam) and nicotine (tobacco smoking). Unlike many other NTs, there is no specific cellular way to reuptake ACH intact (reuptake means to recapture the NT back into the releasing cell for reuse as a way that the cell can conserve energy). NTs are energy-expensive for the neuron to make and transport, and reuptake can be considered a form of cellular ecology. ACH neurons do, however, have an active reuptake protein for one ACH component, called choline. ACH deactivation relies on very efficient enzymes called cholinesterases (AChE and BuChE) by rapidly destroying 4×10^5 molecules per minute. It takes an estimated 150 milliseconds to break ACH into inactive components acetate and choline.

The monoamine NTs consist of catecholamines (DA, NE, and EP) and noncatechol amines (melatonin and HT as well as the indole amine 5HT). The designation *catechol* stems from three characteristic chemical requirements: (1) a beta-hydroxy group, (2) a nitrogen-containing amine, and (3) a catechol nucleus. Catecholamine biosynthesis starts with the precursor amino acid tyrosine, available from dietary sources. It takes a series of enzymatic steps to produce DA. If the enzyme dopamine beta hydroxylase (DBA) is present, all the DA in a neuron is transformed into the NT NE, and if NE is acted upon by the enzyme phenylethanolamine-N-methyltransferase to attach a methyl group (CH₃) on to the terminal amine, the NT EP is produced. What sets apart DA neurons from NE neurons is that only NE-producing cells contain DBA capable of converting all DA into NE. Catechol-oxygen-methyl transferase and monoamine oxidase are two enzymes that are primarily responsible for deactivating about 10% of all released brain catecholamines. It is believed that about 90% of these NTs are recaptured by reuptake transporter proteins embedded in the bouton membranes for reuse.

DA has four major brain pathways (nigrostriatal, tuberoinfundibular, mesocortical, and mesolimbic) and plays a role in brain reward, stress, pain, sexual behavior, placebo effects, mood regulation, hormone control, attention deficit, hypertension, drug abuse, Parkinson's

disease, Tourette's syndrome, Huntington's chorea, and regulation of fine motor control. NE functions include regulating sleep, wakefulness, mood, learning, and smooth muscle relaxation. Neurodegenerative disease is caused by a decrease in the number and functioning of DA-secreting neurons located in the basal ganglia; symptoms include bradykinesia (slowness and poverty of movement), muscle rigidity, resting tremor, and impairment of postural balance leading to disturbances in walking and frequent falls.

5HT derives its name from its initial blood pressure regulating effects via the 5HT receptor on red blood cells or serum tone (serotonin). The major workhorse in the brain is 5HT, which has more than 15 receptor types and subtypes and is synthesized from a dietary source of the amino acid L-tryptophan. It is involved in brain reward, pain, regulating sleep, feeding, migraine headaches, emesis, irritable bowel syndrome, cardiac contraction, smooth muscle relaxation, and LSD-25 effects. Mental disorders involving 5HT include anxiety, depression, suicide, hyper-aggression, schizophrenia, and hallucination. Melatonin is synthesized from 5HT in the mammalian pineal gland. Melatonin is released in high levels during periodic rest cycles (at night); it regulates sleep, circadian cycles, insomnia, mood, NT release, and immune functions.

GABA is the major inhibitory amino acid in the brain active at about 80% of the brain's inhibitory synaptic signals. GABA reduces the frequency of seizure and epileptic disturbances. The major mechanism of action for most antianxiety drugs (benzodiazepines and barbiturates) is to facilitate GABA's ability to reduce the frequency of neural firing by holding a Cl⁻ ion channel open wider and longer, thus making a neuron less likely to fire (called prolonging hyper polarization).

Larger-molecule NTs include beta-endorphin, somatostatin, vasopressin, prolactin, angiotensin II, oxytocin, gastrin, cholecystokinin, thyrotropin, neuropeptide Y, glucagon, calcitonin, neurotensin, bradykinin, steroids (progesterone, estrogen, and testosterone), glucocorticoid, bombesin, corticotrophin-releasing factor, and many others.

Complexity of Neurotransmitter Diversity

NTs serve as the first chemical messengers that begin signaling between neurons. Given that brain function is required for conscious awareness, cognitive

abilities, and personality, NTs serve as one of the most direct measurable and manipulatable ways to study and alter behavior via both electrical and drug administration methods of inquiry. It is the task of neurochemists, neurophysiologists, and neuropharmacologists to study neuron diversity, and it is believed that neurons synthesize more than 100 currently identified and putative (suspected) NTs. The sheer high number of distinct NTs and the diversity of their receptors remain surprising and have no adequate explanation. Solmon H. Snyder, director of the Department of Neuroscience at the Johns Hopkins University School of Medicine, once speculated that there may be as many as 2,000 brain chemicals that act as NTs or neuromodulators. It would appear there may be many more brain-regulating gene NT products that have yet to be discovered. Thus, as impressive as all these facts may sound, the brain remains in the category of the most complex and possibly least understood products of evolution.

NICOTINE REPLACEMENT THERAPY

Nicotine replacement therapy (NRT) is a pharmacological treatment for nicotine dependence. Most frequently used by individuals attempting to quit smoking cigarettes, NRT provides nicotine in an alternative administration, generally through the skin or mouth. NRT has been shown to significantly increase quitting success rates in individuals attempting smoking cessation. This entry describes current types of NRT and their potential side effects, reviews the effectiveness of NRT, presents considerations for using NRT with specific populations, and lists alternatives to NRT.

Types

Six types of NRT are currently available to consumers: patches, lozenges, gum, spray, inhalers, and tablets. Whereas some of these are available over the counter, others are by prescription only. A discussion of each type, including side effects and contraindications, follows.

Nicotine Transdermal Patch

The nicotine transdermal patch is the most popular of all of the NRT choices and is available over the counter. The adhesive patch is attached directly to the skin in a location below the neck and above the waist. It is replaced once per day and delivers a continuous level of nicotine over the 18 to 24 hours for which it is worn. Over-the-counter doses are available in 21 milligrams per day (mg/day), 14 mg/day, and 7 mg/day, though research has been done with doses as high as 63 mg/day. Typical duration of treatment is 6 to 10 weeks, with some brands recommending a gradual tapering regimen and others combining a single dose with abrupt termination. While stopping patch use too early has been associated with a greater risk of relapse following termination in some studies, other findings indicate no benefit in continuing use beyond 8 weeks. Patches are also the safest form of NRT for individuals with stable cardiovascular disease due to the constant level of delivery of nicotine.

Side effects of the nicotine transdermal patch most frequently involve skin irritations at the site of the patch and disrupted sleep, vivid dreams or

NICOTINE

See TOBACCO

nightmares, or insomnia. The user is directed to move the location of the patch each day and to wash the area thoroughly after removing the patch to reduce the impact on the skin area. To address the sleep disturbances sometimes associated with patch use, the consumer can choose to wear the patch for only 16 hours, removing it before bed. As there is no current research indicating superiority of the 24-hour versus the 16-hour patch, removal before attempting to sleep can maintain the effectiveness while reducing this side effect.

Nicotine Lozenge

The nicotine lozenge is available over the counter in doses of 1 mg, 2 mg, and 4 mg per piece. The lozenge is placed between the gum and the cheek and dissolves, delivering the nicotine to the bloodstream. The lozenge will take about 20 to 30 minutes to dissolve, and it is recommended that consumers use at least nine per day for the first 6 weeks, tapering off by the 12th week. Common side effects include upset stomach or indigestion (especially if the lozenge is swallowed), hiccups, sore teeth and gums, throat irritation, headaches, and excessive flatulence.

Nicotine Gum

Nicotine gum delivers nicotine in a manner similar to the lozenge. The 2-mg or 4-mg over-the-counter piece is chewed a few times until the nicotine is released, and then it is placed between the gum and the cheek. The consumer repeats this process for up to a half hour, when chewing no longer releases the peppery taste associated with nicotine delivery. Typical use of the gum involves 10 to 15 pieces per day used for 1 to 3 months, and chewing too few pieces or stopping use too soon is associated with relapse.

Common side effects of nicotine gum include a bad taste, which may be offset by citrus or mint flavored nicotine gum, and a tingling on the tongue while chewing. Nausea and heartburn are typically associated with improper use, especially continuous chewing rather than setting it between the gum and cheek. Excessive chewing results in higher nicotine levels being swallowed and passing through the stomach, resulting in this discomfort. Jaw pain can also be associated with using nicotine gum, and this method is not recommended for people with disorders of the jaw.

Nicotine Spray

Nicotine spray is currently available by prescription only and tends to be more effective for consumers who have not been able to quit smoking through other methods. The delivery of the nicotine spray is faster than other methods, such as gum or lozenge. The consumer uses the spray like other nasal sprays, with 0.5 mg delivered in each nostril. Most people start at 1 to 2 doses per hour, and are advised not to exceed 5 doses per hour or 40 doses per day.

Typical side effects of the nicotine spray include a burning feeling in the nose or throat, which is uncomfortable enough for about 80% of consumers to stop use; this side effect usually diminishes after a week of use. Other side effects include sneezing, runny nose, watering eyes, and coughing. Nicotine spray is not recommended for people with breathing problems like allergies or asthma, as it affects the breathing and nasal passages.

Nicotine Inhaler

The nicotine inhaler, available only by prescription, resembles a cigarette and includes cartridges with nicotine. The nicotine is inhaled into the mouth and throat and, similar to the spray, delivers a dose of nicotine quickly. Consumers hold the inhaler like a cigarette, puffing on it for about 5 minutes per use. The cartridge is replaced after about 20 minutes of puffing, or every four uses. Typical use involves 6 to 10 cartridges (24–40 sessions) per day for the first few weeks, tapering off by the 12th week. Side effects of the nicotine inhaler include cough, throat irritation, and upset stomach. Like the nicotine spray, it is not recommended for individuals with breathing problems.

Nicotine Tablet

The nicotine tablet is not currently available in the United States, though it is approved in many European countries. The sublingual 2-mg tablet is held under the tongue until it dissolves. Standard use is 1 to 2 tablets per hour not to exceed 40 tablets per day, decreasing by the 12th week. Typical side effects include itchy or dry mouth, cough, and unpleasant taste.

Other Considerations

Nicotine overdose is a potential side effect of all forms of NRT. Typical symptoms include nausea, lightheadedness, and anxiety or nervousness. Given that most forms of NRT include variable doses or schedules, use can be varied to reduce or eliminate these symptoms. Improper disposal of used NRT modalities can result in nicotine overdose for children and pets. Overall, side effects of NRT are typically mild, do not result in stopping use, and tend to be less uncomfortable than side effects from other cessation aids like bupropion. Additionally, although dependence on NRT modalities is rare, it is possible to become psychologically or physically dependent. Dependence risk increases with faster nicotine delivery through methods such as the spray or inhaler. Whether over the counter or through prescription, NRTs should be taken according to listed doses and duration unless otherwise indicated by a physician.

Effectiveness

General Effectiveness

NRT has been shown to increase cessation rates by 1.5 to 2 times compared with placebo or no additional aid. These findings are independent of other factors typically associated with cessation success like social support, although NRT is most effective when combined with a behavioral intervention. NRT is equally effective whether it is prescribed or purchased over the counter.

NRT increases cessation rates through three primary mechanisms. First, NRT reduces unpleasant nicotine withdrawal symptoms by continuing to provide brain receptors with a dose of nicotine, either continuously at a low dose like the patch or in brief peaks like the lozenge and gum. Second, NRT replaces the positive reinforcement associated with cigarettes by simulating the increased mood and affective effects of nicotine. Finally, NRT assists in a disassociation of cigarettes with the administration of nicotine. Whereas some studies indicate that NRT has more of an impact on cravings than on withdrawal symptoms, recent studies indicate that NRT can decrease cravings and withdrawals as well as eliminating mood and concentration disruptions associated with cessation.

Research is also mixed on NRT effectiveness on moderation. While most instructions require consumers

to stop using cigarettes before starting any form of NRT, studies have indicated that NRT can assist in moderation prior to or independent of cessation, though this may be due in part to a placebo effect. Use of NRT for moderation may have another potential benefit for recruiting individuals who are otherwise not motivated to quit. Research has also indicated NRT may be less effective for smokeless tobacco cessation, producing short-term cessation but not long-term abstinence, though higher doses appear to increase the effectiveness.

Effectiveness of Specific Types of NRT

As discussed previously, effectiveness of each type of NRT is similar, though some considerations may increase or decrease the potential for individuals. The nicotine patch, while beneficial for those with a history of cardiovascular disease, may be more effective for general cravings and withdrawals but not cue-provoked cravings. Some findings indicate a combination of a slow-release patch with a quickly delivered alternative such as gum or spray can increase success at least slightly. Other studies indicate that a combination of NRT with the antidepressant bupropion may increase effectiveness, though side effects tend to be greater with the medication.

The inhaler may be more effective in reducing the cues found in social situations and breaking the physical habits involved in smoking. The lozenge has shown effectiveness in smokers who have previously failed quit attempts using other NRT and, used in combination with the patch, has been more effective for very heavy smokers (more than 40 cigarettes per day) with less relapse, though heavy smokers tend to prefer either the spray or inhaler to other modalities. The gum and lozenge increase individual tailoring though they require multiple doses per day, and effectiveness decreases when too little is used especially early in the quit attempt.

Specific Populations

Thus far, discussions of NRT have been limited to general use by the general population. This section discusses NRT effectiveness and considerations for specific populations, including women, pregnant women, adolescents, homeless and low-income individuals, and inpatient and hospitalized individuals, as well as multicultural findings.

Women

Some studies report that NRT may be less effective for women because of differential social reinforcements that contribute to initiation and maintenance of smoking. More recently, the patch and lozenge have been determined to be equally effective for women and men, though the effectiveness may be more short-term without behavioral support, which did not impact quit duration in men.

Pregnant and Nursing Women

The use of NRT by pregnant and nursing women is an area of great controversy. The U.S. Food and Drug Administration approved use of NRT for pregnant women only when the benefits outweigh the risks to the fetus. Given the vague nature of this guideline, literature can be found both supporting and condemning the use of NRT by pregnant and breastfeeding women. While both sides argue that NRT should be a last resort, only to be attempted when other cessation methods such as behavioral and social interventions have been exhausted, proponents suggest that NRT may not be good for a child, but smoking is much more dangerous and carries greater risk. Opponents contend that the impact of any nicotine on a child or adolescent represents a substantial health risk, and NRT is contraindicated in this population.

Adolescents

As indicated earlier, there is some concern with health risks to adolescents exposed to nicotine. Here the same argument applies: NRT may be bad, but smoking is worse. Although there have been no randomized control trials of NRT with adolescents, experts contend that it is probably effective for smoking cessation.

Low-Income and Homeless Populations

One barrier to using NRT is the cost of the products. Studies examining programs targeted at low-income and homeless populations that offer free NRT found increased enrollment and short-term cessation, and effectiveness was increased when given in conjunction with brief motivational interventions for smoking, general health behaviors, or both.

Inpatient

Studies have found that up to one fourth of inpatients seeking alcohol and drug treatment are interested in smoking cessation, and NRT is effective at least for short-term cessation.

Cultural Considerations

Very few studies to date have examined NRT in a multicultural setting. Those that have reviewed effectiveness indicate that cultural adaptations in addition to NRT were effective for Chinese and Korean participants, and that free patch programs were very effective for foreign-born participants of many countries of origin. More research is needed before conclusions can be drawn regarding the effectiveness of NRT in multicultural settings.

Alternatives

This section reviews alternatives to NRT, specifically the use of bupropion and comparisons with community interventions.

Bupropion is an antidepressant medication that has been effective in aiding smoking cessation. It is as effective as NRT, though the specific mechanism is unknown. Bupropion is typically begun 1 to 2 weeks before quitting and is continued for at least 7 to 12 weeks after quitting. Bupropion is contraindicated for individuals who are taking certain other medications or have seizures, an eating disorder, or an alcohol use disorder. Side effects may include dry mouth, insomnia, dizziness, concentration problems, nausea, anxiety, constipation, or rashes. Although side effects tend to be minimal, some studies indicate they may be more intense or unpleasant compared with NRT alone. A combination of bupropion and NRT may also increase cessation outcomes.

Community interventions have also shown some effectiveness at increasing smoking cessation. Programs that involve tax increases on cigarettes and smoke-free legislation tend to produce more quit attempts, though financial increases make more of an impact in low-income than high-income areas. Workplace changes, such as initiation of smoke-free workplace guidelines, also increase quit attempts and cessation and are cheaper than NRT. Each of these is individually effective, but a combination of interventions, such as tax increases, restrictive legislation, and free NRT programs, may have the greatest impact.

Conclusion

NRT is an effective method to increase smoking cessation quit rates. The myriad modalities, including the patch, lozenge, gum, spray, inhaler, and tablet, have similar effectiveness. Consumer preference coupled with consideration of the medical indications and potential side effects may result in the best choice for the individual. Additional care should be sought when considering NRT with vulnerable populations, including pregnant women and adolescents. Although NRT alone has a substantial impact on cessation rates, it does not replace behavioral interventions and is most effective in combination.

OFFICE OF NATIONAL DRUG CONTROL POLICY

The White House Office of National Drug Control Policy (ONDCP) was established as a component of the Executive Office of the President of the United States by the Anti-Drug Abuse Act of 1988. ONDCP has been charged, from its inception, with establishing national priorities, developing and implementing policy and strategies, and coordinating agencies and functions of the federal government involved in illegal drug supply and demand reduction activities. Subtitle F of the Anti-Drug Abuse Act of 1998 established a goal of “a drug-free America.” Through the act, ONDCP is charged with guiding and supporting the United States in achieving this goal.

The Anti-Drug Abuse Act of 1988 created three leadership positions, which are appointed by the President and confirmed by the U.S. Senate, the ONDCP director, commonly known as the “Drug Czar,” the deputy director for demand reduction, and the deputy director of supply reduction. The enacting legislation also established within ONDCP a Bureau of State and Local Affairs and directed that it be led by an associate director for national drug control policy, thereby establishing the basic organizational structure of ONDCP and formalizing the economic concepts of supply and demand as organizing principles for its activities and for U.S. drug control policy.

ONDCP Leadership

From its inception to the date this entry was written, ONDCP has had five directors: William J. Bennett (1989–1991), former director of the National Endowment for the Humanities and secretary of education under Ronald Reagan, was appointed by George H. W. Bush; Bob Martinez (1991–1993), also appointed by George H. W. Bush, previously served as mayor of Tampa, Florida, and as governor of Florida; Lee P. Brown (1993–1995), a former professor at Texas Christian who served as Houston, Texas, chief of police and subsequently as mayor of Houston, was appointed by William Jefferson Clinton; General Barry R. McCaffrey (1996–2001), former head of the U.S. Southern Command (SOUTHCOM), was also appointed by William Jefferson Clinton; John P. Walters, who previously served as chief of staff for ONDCP director William J. Bennett and as deputy director for supply reduction and before that served as assistant to the secretary of education, was appointed by President George W. Bush in 2001.

Expanding Scope

The authority and responsibilities of ONDCP and its director were expanded and clarified through a number of executive orders, through reauthorization bills, and through other legislation. On November 16, 1993, President Bill Clinton signed Executive Order 12880, which clarified and expanded the authority and responsibilities of ONDCP. Among the requirements of the order were that the ONDCP director provide guidance

in the development of relevant national security programs and that the director oversee all international counternarcotics policy development. The order also established an Interagency Working Group on international counternarcotics under leadership of the Department of State and directed that it report to the ONDCP director on its activities. Additionally, Executive Order 12880 required that the ONDCP director designate a drug interdiction coordinator to ensure that resources dedicated to interdiction were sufficient and were effectively coordinated and required that the ONDCP director assist the Department of Justice in disseminating statistics and studies relating to anti-drug abuse policy. The order also required ONDCP to develop and implement national drug control strategy outcome measures that include long-range goals for reducing drug use and its consequences, including reduced medical and criminal justice costs, high school drop out rates, and prenatal exposure to drugs and ensuring adequate substance abuse treatment capacity. ONDCP budgetary, planning, and coordination authority was also increased by Executive Order 12880, which called on the ONDCP director to ensure efficiency in spending and to improve interagency cooperation to enhance drug control efforts and treatment and prevention services. The order authorized the director to request studies, data, and analyses to support this function. Additionally, the order instructed the director to provide budget recommendations to department heads and agencies under the National Drug Control Program by July 1 of each year and certify the adequacy of agency budget requests to implement the provisions of the annual National Drug Control Strategy. In cases where the director determined requests inadequate to certify, he was required under the order to recommend and certify funding levels that would make budget requests adequate to meet plan goals. Finally, Executive Order 12880 charged the director with coordinating efforts to monitor and evaluate the quality, administration, effectiveness, and accountability of substance abuse treatment, prevention, and education; oversee other demand reduction activities; and ensure adequate access to those services.

Under the Violent Crime Control and Law Enforcement Act of 1994, ONDCP budgetary authority was further increased and specific reporting requirements regarding the availability of drugs, prevalence of drug use, its consequences, and treatment services were mandated. On March 15, 1996, Executive Order

12992 established the President's Council on Counter-Narcotics. In November of that year, Executive Order 13023 expanded council membership, changed its name to the President's Drug Policy Council, and officially designated the ONDCP director as the White House's lead spokesperson on drug control issues. Chaired by the President, the Drug Policy Council includes the Vice President, the secretaries of state, treasury, defense, interior, health and human services, education, and transportation; the chairman of the Joint Chiefs of Staff; the director of the Office of National Drug Control Policy; and other key officials.

Through the Drug Free Communities Act of 1997, ONDCP was charged with awarding grants to community coalitions seeking to engage private and public sector stakeholders and the general public in efforts to reduce adolescent substance use. This gave rise to the Drug Free Communities program, which currently provides grant funding to more than 700 community coalitions to support them in developing local responses to substance use. Drug Free Communities program resources are focused primarily on the development of youth substance abuse prevention activities. ONDCP activities were further expanded through the Media Campaign Act of 1998, which directed ONDCP to conduct a national media campaign for the purpose of reducing and preventing drug abuse among young people in the United States. The act gave rise to the ONDCP National Youth Anti-Drug Media Campaign.

The Office of National Drug Control Policy Reauthorization Act of 1998 further broadened the ONDCP scope of authority and activities. It required a reorganization of ONDCP, as well as the development of a long-term national drug control strategy and a 5-year national drug control budget; granted permanent authority to the High Intensity Drug Trafficking Areas program and mandated changes to its management; expanded reporting to Congress relative to drug control activities; and increased the scope of demand reduction activities of the Counterdrug Technology Assessment Center, which was established in 1990 to serve as the central counterdrug enforcement research and development organization of the federal government. The Counterdrug Technology Assessment Center focuses primarily on the development of technology relevant to support law enforcement activities relevant to the National Drug Control Strategy. The 1998 reauthorization also established the Parents Advisory Council on Drug Abuse, which was later dissolved.

In 2000, Executive Order 13165 established the White House Task Force on Drug Use in Sports, which was charged with developing recommendations regarding doping and drug use in sports. The order designated the ONDCP director, the secretary of health and human services, and the vice chairs of the Olympic Task Force as chairs and further designated the ONDCP director as the U.S. government representative to the board of the World Anti-Doping Agency (WADA).

ONDCP was again reauthorized in 2006. The Office of National Drug Control Policy 2006 Reauthorization Act elevated the ONDCP director to a cabinet-level position over the objections of the White House and included detailed requirements for the National Drug Control Strategy. It also established the National Methamphetamine Information Clearinghouse and the National Methamphetamine Advisory Council. Additionally, it eliminated the Advisory Council on Youth Drug Abuse and amended the Controlled Substances Act, increasing the number of patients to whom eligible medical practitioners in office-based practices can prescribe buprenorphine for the treatment of opioid dependence from 30 to 100 patients concurrently. The act further required ONDCP to fund demonstration programs to reduce drug use by chronic drug users and required it to submit reports to Congress on best practices for reducing illegal drug use among such individuals.

In response to a finding by the Government Accountability Office that prepackaged video news releases produced and distributed by ONDCP constituted covert propaganda because ONDCP did not identify itself to the viewing audience as the producer and distributor of the news stories on ONDCP activities, the 2006 authorization required that any advertisement or other communication funded by ONDCP disclose to the target audience that it was paid for by ONDCP. Finally, the act required that any policy regarding syringe exchange programs be based on the best medical and scientific evidence and further instructed ONDCP to consult with the National Institutes of Health and the National Academy of Sciences when developing policy regarding syringe exchanges.

A December 29, 2006, signing statement issued by the President announced an interpretation of the 2006 ONDCP reauthorization act that indicated that portions of the act may not be implemented as intended by Congress. For example, the statement indicated that requirements that the ONDCP director request

authorization from Congress for any reallocations of funding that exceeded specific threshold amounts would be interpreted as a requirement to inform Congress when such actions were taken. Similarly, it stated that provisions in the act that required that executive branch officials submit legislative recommendations to the Congress would be interpreted and implemented in a manner consistent with the administration's understanding of the constitutional authority of the President and that the President would determine what recommendations would be made to Congress by executive branch officials.

National Drug Control Strategy

The National Drug Control Strategy (NDCS) is released annually and is available online through the ONDCP Web site. The 2007 NDCS identifies a three-part approach: (1) preventing drug use before it starts, (2) intervening and healing those who already use drugs, and (3) disrupting the market for illicit substances. The report is divided into three corresponding chapters. It is 57 pages in length and includes a 1-page budget summary in table format. Since 2003, the NDCS has been structured in this manner. The 2003 NDCS consisted of an abbreviated 27-page report using the same structure as subsequent reports and appendices that included more detailed budget information, a proposed restructuring of the national drug control budget, and detailed tables on drug use trends. It was 118 pages in length. Strategies developed under prior administrations were structured differently. The 2000 NDCS, for example, was 153 pages in length and included five chapters: (1) Annual Report and the National Drug Control Strategy: An Overview, (2) America's Drug Use Profile, (3) Report on Programs and Initiatives, (4) National Drug Control Budget, and (5) Consultation. The 2000 NDCS was associated with a *Classified Annex*, which was transmitted directly to Congress and addressed the administration's interagency plans for countering international cultivation, production, and trafficking activities.

Each of the three sections in the 2007 NDCS contains relevant data on trends and administration activities and makes broad suggestions for future activities. The report also includes the fiscal year (FY) 2006 and 2007 budgets and the President's proposed federal FY 2008 budget for drug control activities. The introduction to the 2007 NDCS attributed a significant reduction in youth drug use since the

start of the presidency of George W. Bush to the administration's drug control policy. Citing administration goals to reduce rates of reported past month drug use by 10% within 2 years and by 25% within 5 years, the introduction reported that drug use among youth had declined by 11% after 2 years, and by 23.2% after 5 years, a decline that the report characterized as astonishing. It further stated that this reduction demonstrated that a robust drug control policy—consisting of coordinated efforts in the domains of enforcement, treatment, and prevention, in combination with support from state and local governments and faith-based and community organizations—could achieve measurable reductions in drug use. The 2007 NDCS did not explain how the causal link between policies intended to reduce drug use and actual declines in drug use among youth was established. Although the NDCS contains a significant amount of data and illustrative anecdotes, it provides limited specific information regarding the strategy moving forward.

NDCS Critics: Policy Debate

Critics have protested that, under the NDCS of the George W. Bush administration, funding for drug demand reduction efforts has declined and that the NDCS does not reflect a balanced approach. When the President's 2008 drug control budget is compared with that of FY 2002, interdiction programs are seen to have grown by 72%, international programs by 29%, domestic law enforcement by 27%, and total supply reduction by 42%. Conversely, demand reduction funding decreased over this period by approximately 3%, driven primarily by reductions in funding to substance abuse prevention. Overall, supply reduction funding increased from 55% to 64% of drug control funding over that period while demand reduction funding went from 45% to 36% of the overall drug control budget. A change in how ONDCP counts expenses, critics argue, actually results in an understatement of the extent of the shift of resources from demand to supply reduction.

Numerous other critics have opposed the NDCS. In 1999, for example, during the Clinton administration, a coalition of drug policy organizations released, as a counterpoint to the NDCS, the Effective National Drug Control Strategy, which recommended that two thirds of the drug control budget be directed to treatment and prevention. Written from a public health and harm reduction perspective, the alternative strategy was

developed around two primary goals: (1) reducing the harm caused by drug abuse, and (2) reducing the harm caused by existing drug control policies. The U.S. drug control policy differs from those of Canada, the majority of Western Europe, Australia, and New Zealand in its emphasis on abstinence and its explicit rejection of harm reduction approaches. In a speech delivered in Brussels, Belgium, on March 1, 2005, ONDCP director Walters stated that policies of other nations, which they characterized as harm reduction, were, in effect, ways of acquiescing to the disease of addiction and of abnegating their responsibilities to fight it. An ONDCP report stated that policy in Western Europe focused on what the report called the "social welfare" aspect of drug use and that law enforcement received less emphasis there than it did in the United States. The report noted that European countries had adopted what it characterized as alternative policies. These included harm reduction programs and, in some cases, decriminalization and legalization initiatives. The prior ONDCP director, General Barry McCaffery, characterized harm reduction approaches as a defeatist half-measure. McCaffery noted that while it is generally agreed that crime cannot be entirely eliminated, no one would argue that other harmful activities be legalized. He further argued that harm reduction would increase rather than decrease harm and that it represented tacit approval of harmful behavior.

Whereas the annual NDCS report and other ONDCP documents and official communications have consistently depicted harm reduction strategies in a negative manner, harm reduction approaches are widely prevalent in the public health arena and even in the addictions treatment field itself. These include noncontroversial policies such as designated driver programs and more controversial ones, such as syringe exchanges and condom distribution. Moreover, motivational interviewing and the stages of change theory, which are widely recommended in the addictions treatment field, including in government documents such as Treatment Improvement Protocol 35, are fully compatible with, and broadly adopted within, harm reduction frameworks.

U.S. drug control policy and practice regarding the balance between supply and demand reduction activities and the role of harm reduction approaches as a component of policy continue to be topics of contentious debate. However, since the government first began to regulate drug use under the Harrison Act of 1914, interdiction, enforcement, and abstinence have

dominated U.S. counterdrug policy. This has consistently been reflected in subsequent federal legislation and in the NDCS.

Conclusion

The ONDCP emerged as a product of a history of legislative action geared toward regulating the use, production, importation, and trafficking of drugs that began with the Harrison Act of 1914. Established through the Anti-Drug Abuse Act of 1988 and progressively expanded through successive legislation and executive orders, ONDCP is charged with developing and implementing what has been designated as drug control policy. From its inception, ONDCP has reflected an overarching policy framework that is inspired by economics and by law enforcement policies. Its activities are broadly divided into supply reduction and demand reduction, and its scope does not include policy related to alcohol or tobacco. Its framework, policy, and priorities have long been the subject of contentious debate. As a component of the Executive Office of the President, ONDCP has broad powers and reflects the policies of both the executive and legislative branches, and the national politics of drug control.

OPIATES

See OPIOIDS

OPIOIDS

Opioids, opium, and opiates are all derived or synthesized from the opium poppy, *Papaver somniferum*. Each of these drugs has different characteristics, uses, and effects on the body. Whereas raw opium comes directly from the plant (generally the pod), opiates (e.g., morphine and heroin) are refined from opium,

Table 1 Common Opioids and Opiates With Category, Trade, and Street Names

<i>Drug Name (Generic)</i>	<i>Category</i>	<i>Trade Name</i>	<i>Street Name</i>
Diacetylmorphine	Semisynthetic opioid	Heroin	Smack, tar, China white, shit
Hydrocodone	Semisynthetic opioid	Vicodin	
Hydromorphone	Semisynthetic opioid	Dilaudid	Perc
Meperidine	Fully synthetic opioid	Demerol, Mepergan	
Methadone	Fully synthetic opioid	Dolophine	Juice
Morphine	Natural opiate product	Empirin, Tylenol w/codeine	Murphy, Miss Emma, "M"
Oxycodone	Semisynthetic opioid	Percodan, Tylox	Percs, Cody, Oxy's
Propoxyphene	Fully synthetic opioid	Darvon, Darvocet-N	Pink ladies, pumpkin seeds

Sources: Adapted from Inaba and Cohen (2004), NIDA, and other sources.

and opioids (e.g., hydrocodone and methadone) are synthetic derivatives (Table 1) of morphine. Many opioids are used medically; for example, methadone and buprenorphine are used for detoxification, and oxycodone is prescribed for anxiety due to shortness of breath. However, the most common medical use for opioids is for pain management.

History

Although opium use originated for medicinal purposes, abuse of it has become a problem. In approximately 4000 BC, opium was cultivated by the Sumerians and used for purposes such as management of pain, treatment of diarrhea, and sedation. Opium use is noted in Ancient Egyptian medical texts as an antidote for mental and physical pain among Islamic cultures and was used as a general sedative among Portuguese traders around AD 1500. The commodity of opium became extremely important to the Chinese, which led to one of the world's biggest drug problems. These problems stemmed from disagreements between British and Chinese trade officials and are known historically as the Opium Wars.

Morphine was used commonly in the 19th century for soldiers who were wounded in wars such as the Crimean and the U.S. Civil War. In the 1800s, opium was used as a "cure-all" drug. It was prescribed to women for menopause and also for depression and nervousness. Not knowing that opium prescriptions could lead to addiction, physicians also prescribed hypodermic morphine for asthma and angina and even to those who were anemic. At the beginning of the 20th century, over-the-counter medications such as cough syrup and cold medications were loaded not only with opium but

also with a mixture of cocaine, morphine, and alcohol. Kits with heroin were sold in stores such as Macy's and Sears, and it was not uncommon to find a drug kit including vials of heroin along with a reusable syringe.

Opiates Versus Opioids

Coming from the Greek word *opos*, which means "juice" or "sap," opium was originally blended in liquids to drink or even chewed and eaten. Owing to the bitter taste of opium, the potential for abuse was relatively low. However, over the years experimentation with different usages, new refinements of the drug, and the synthesis of chemicals that mimic natural opiates have increased the benefits of opium as well as the abuse. Although opioids are safe when used correctly, they have the potential for addiction. When used illicitly, opioids are used to induce feelings of euphoria and pleasure.

Opioids

Opioids are biochemical synthetics and have been prescribed by physicians to help alleviate pain and suppress coughing. Opioids have morphine-like action upon entrance into the body. Clinically, opioids are also used in postoperative analgesia and have therapeutic uses for pain management in cancer and terminal illness. They act by binding to receptors in the brain (mu receptors) and limit the release of neurotransmitters involved with pain.

Opiates

Opiates have distinguishingly different characteristics than opioids. Opiates are known as narcotic

alkaloids and are derived from opium. Such derivatives include morphine, codeine, and thebaine. Although heroin does not fall into the alkaloid category, it is also chemically considered an opiate. The most prevalent opium alkaloid is morphine, which can cause many deleterious effects on the body including lung edema, coma, and death.

Opium Poppy: *Papaver Somniferum*

Opioids, also known as alkaloid analgesics, occur naturally in the opium poppy, *Papaver somniferum*. The plant grows 3 to 4 feet high, and its flowers are about 4 or 5 inches in diameter. The flowers vary in color (white, pink, red, or purple), and the pods, stems, and leaves of these flowers contain opium. Cultivation of the opium poppy has increased by over 30% in recent years, as revenue from the illicit opium trade is used to fund many regional wars and conflicts.

Early Uses of Opioids in the United States

The use of opioids originated in Europe and spread to Asia, finally making its way into the United States. Opium smoking was introduced to the western United States by Chinese railroad workers, who used it as a painkiller and for diarrhea treatment. Opioids were also used as pleasurable substances, as poisons, for dysentery, and for a diverse number of other illnesses. To treat diarrhea, opium mixtures such as opium, alcohol, and camphor were used. These tinctures of opium and alcohol were commonly sold by roadside merchants as “cure-alls.” There are naturally occurring derivatives, as well as semisynthetic and fully synthetic opiates (Table 1). Smoking opioids was common to those who first began to use them. Upon inhalation of opium, the drug can have an affect on the brain in as little as 6 seconds. When use of opium became prevalent, women were more likely to be found smoking it, whereas men were more commonly found drinking alcohol that contained it.

Morphine and Codeine

Morphine and codeine are derived from opium and are refined directly from the milky fluid of the opium poppy. Morphine is by far the most potent drug derived from opium. It is the standard treatment for

pain relief and is processed from opium into many different forms such as tablets, capsules, injectable solutions, and suppositories. Codeine, on the other hand, is only one fifth the strength of morphine and is commonly used in cough syrups.

Illicit Opioids

Heroin, a semisynthetic opioid (Table 1), was originally used as a cough remedy and for treating tuberculosis. Its abuse became prominent in the 20th century, and it has highly addictive characteristics. Heroin does not come from opium; rather it is made synthetically by adding an acetyl group to morphine. Heroin is usually a white or brownish powder, and it is common to see it burned while the fumes are inhaled through a straw (“chasing the dragon”). Other forms of heroin include China white, black tar, and Colombian heroin. Black tar can be up to 80% pure and is the most common form of heroin found in the United States today, with Mexico as the most popular supplier of heroin to the United States. Heroin is especially dangerous when mixed with other depressants such as alcohol or benzodiazepines. This mixture has a higher potential to slow down the basal areas of the brain that control breathing, which can result in death. Examinations of opioid receptors and how they are affected by heroin have found that heroin fills the brain’s opioid receptors almost completely, stimulating feelings of well-being and pain relief at a high intensity. This is why addiction to the drug is so common and the withdrawal effects are so intense. With such a high depression rate among heroin users, it is not uncommon to find abusers switching to an upper such as cocaine or methamphetamine in order to alter their mood. This transition between heroin and stimulants continues and leads to an extremely dangerous and addicting habit. Not only are stimulants found among heroin users; depressants such as alcohol and benzodiazepines are also commonly abused. Rehabilitation for heroin users can be a challenge, especially when alternatives, such as methadone, can be just as addicting. Once the abuse rate began to rise, other new drugs were developed to help people overcome heroin addiction.

Prescription Opioids

Methadone

A common treatment for heroin users is methadone, a fully synthetic opioid that has been designed as a

legal substitute for heroin. Although its effects are not as intense as those of heroin, it can be just as addicting. Unfortunately, a great number of people end up becoming addicted to methadone, and a higher prevalence of death rates related to methadone has been reported over the years. Also, concurrent ingestion of benzodiazepines with methadone enhances the effects of opioids, which poses another potential abuse problem. A couple of newer treatments for heroin substance abusers are buprenorphine and Suboxone (buprenorphine with naloxone added). Unlike heroin and methadone, buprenorphine and Suboxone have a lesser likelihood for addiction and help people overcome opioid addiction. There have been reports of lower withdrawal symptoms with these alternative medications as well as lower rates of illicit use. It is important that these drugs be used as substitutes for methadone, because the withdrawal phase of methadone can last many years and includes phases of depression and insomnia.

Buprenorphine

The Food and Drug Administration approved buprenorphine after numerous years of testing and analysis. It interacts with receptors that mediate relief from pain. A beneficial characteristic of buprenorphine is that it helps displace opioids such as methadone and heroin from binding to the receptors that mediate pain. This alternative to methadone has a lower rate of withdrawal; however, it is more expensive.

Suboxone

Another alternative for methadone is Suboxone, which is a mixture of buprenorphine and naloxone. It is commonly prescribed with counseling and psychotherapy and was developed to help prevent intravenous drug use, which is commonly found with methadone and buprenorphine.

OxyContin (Oxycodone)

Approved in 1995 by the Food and Drug Administration, OxyContin is an analgesic prescribed to individuals with moderate to severe pain. One of the fastest growing concerns for public health and non-medicinal use of prescription opioids is that of OxyContin and its generic competitor, oxycodone. Far exceeding reports for heroin misuse, the 2006 National

Survey on Drug Use and Health reported that 5.2 million Americans had used prescription pain relievers in the past month. Oxycodone is less expensive than OxyContin, making the abuse of this drug more accessible to potential substance abusers.

Millions of Americans use prescription pain relievers illicitly. Moreover, opioids such as hydrocodone and oxycodone are commonly found in emergency room visits resulting from overdose. It is also common to find opioids concomitantly used with other drugs such as alcohol or benzodiazepines. Opioids are known to be abused for the euphoric effect, which is similar to that of a narcotic.

Demographics and Opioids

The most common sources of illicit prescription drugs are those that contain opioid analgesics, stimulants, anxiolytics/sedatives, and sleeping medications. Owing to an upward trend in the illicit use of medications, it has been found that more than 2 million persons age 12 and older in the United States reported using opioid analgesics in 2006 for their first time. In the mid-1980s only about 400,000 individuals experimented with such drugs for their first time. Furthermore, between the years of 1994 and 2001, the number of emergency room visits increased 300% for oxycodone and over 100% for hydrocodone. This trend shows how opioid abuse is now becoming a drug abuse epidemic, and rates of abuse are increasing throughout the United States.

Heroin is most prevalent in the inner cities of large metropolitan areas; however, prescription opioid abuse is most common among rural, suburban, and small or medium sized urban areas. There is a growing problem among adolescent Americans with illicit use of opioid analgesics. Although marijuana is the most commonly misused drug among adolescents, millions of adolescent youth have been reported to misuse prescription opioids as well. Delinquent activities, emotional problems, and other substance abuse problems are common cofactors found in youth who misuse opioids.

Conclusion

Opioid use, whether it be prescription or illicit, can be extremely dangerous to an individual. Not only are opioid abuse rates increasing, but death rates owing to overdose are also a problem widely found throughout the United States. Providing counseling and rehabilitation to opioid abusers is important in helping decrease

the abuse rates. Also, alternative drugs such as buprenorphine and Suboxone can help prevent the possibility of addiction during recovery from opioid abuse. However, although these drugs can be used for rehabilitation, close monitoring and distribution need to be practiced in order to prevent abuse.

OTHER ADDICTIONS

Use of the term *addiction* has traditionally been limited to the habitual and destructive use of alcohol and other drugs. The more casual use of the word in recent years, however, has created a new designation for behavioral problems that spiral out of control. Compulsive gambling, shopping, spending, eating, working, and exercising, as well as excessive Internet use and sexual behaviors are now often called “other addictions.” While debate continues as to whether the repetitive occurrence of these behaviors is a true addiction, a compulsion, or just a behavior gone awry, it is clear that people suffer from the repercussions these problem behaviors bring.

The Debate

Questions about whether compulsive behaviors should be defined as addictions center on several points. One rationale against the idea comes from

the fact that many of the behaviors already have their own diagnostic label or are embedded within other diagnoses. Pathological gambling, eating disorders, and impulse control disorders, for example, are diagnoses presently in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, and are grouped separately from substance use disorders.

Another aspect of the debate on whether these repetitive behavioral problems are addictions or not is framed by one’s underlying theory. Social learning model theorists, for example, focus on the cessation of “bad behavior,” whereas neurobiologists focus specifically on changes within the brain from alcohol and other drug (AOD) use. Those who subscribe to the medical model of addictions question if the physiological symptoms of tolerance and withdrawal in behavioral compulsions are similar enough to chemical addictions to warrant the term *addiction*.

As researchers discover more variation in the tolerance and withdrawal factors of differing drugs, this argument becomes less defining. Not all drugs, for example, have both the quality of physiological cravings and withdrawal. And for some drugs, tolerance is not a factor, but the recurrent use of such substances is determined to be an addiction due to the harmful personal, social, legal, and vocational consequences. This variation and other research and practice aspects challenge the need for separation of substance and behavioral addictions.

Research into the brain’s reward system, for example, indicates more similarity than difference between AOD and compulsive behavior reactions. It appears that biochemistry and brain activity may be impacted in much the same way whether the repetitive object is a substance or a behavior. The brain experiences a positive reward from the use or behavior and, in both cases, neurological adaptation occurs. Such adaptation adds to the decreasing ability to abstain or resist the object of desire. A purist viewpoint with only medical definitions of tolerance and withdrawal becomes less useful as more is discovered about the brain’s reaction to any addictive behavior.

Other points that support the perspective that substance and behavioral problems are very similar come from the treatment rather than the diagnostic world. Because individuals with compulsive disorders often face similar emotional and cognitive concerns, efforts such as Twelve-Step recovery groups and relapse prevention activities have been adopted for behavioral

addictions. The effectiveness of these cross-over treatments has led to the development of new strategies, protocols, and best practices.

In preparation for an updated, fifth-edition *DSM* that more accurately reflects the psychological thought of the 21st century, advocates are proposing a new diagnosis that includes criteria for both problem behaviors and chemical addiction disorders. The proposed diagnosis for an addiction disorder incorporates both (a) the aspect of pleasure seeking with the goal of resisting physical and emotional pain found in chemical dependency and (b) the aspect of an inability to control the behavior even in the face of harmful or negative consequences found with impulse-control disorders. This new definition puts theoretical purity aside and confirms that all addictions, whether behavioral or substance, have many biological, environmental, and social realities in common.

Rather than fueling the debate of whether “other addictions” are separate and uniquely different from substance addictions, a focus on identifying parallel patterns appears to be more useful. Understanding the overlap within such a variety of compulsive behavior addictions allows the spotlight to shift from diagnosis to developing more effective treatment strategies that can be critical to changing the destructive path of both substance and behavioral problems.

The Parallels

As scientists discover more about the addictive process, the parallels between behavioral compulsions and substance addictions become clearer. From a neurochemistry standpoint, repetitive use of the substance or behavior triggers changes in the body. These changes initially include a variety of rewards. For example, the behavior or substance is typically chosen because it brings about a positive experience. People enjoy the fun, excitement, and self-medicating opportunities that abound with use. Many of the behaviors, similar to those induced by alcohol, are socially acceptable activities that initially enhance interpersonal interaction and often increase self-esteem.

The endorphin high from a good workout or a positive comment from one’s boss for a job well done certainly supports society’s emphasis on success. Compliments on a new purchase or the excitement received from an unexpected win when gambling can easily reinforce a desire to go back for more. And, of course, the hope of finding friendship, companionship, or even love without a great deal of risk can be

very enticing. Habitual behaviors increase in frequency because they effectively modify or mute a person’s negative affect. Engaging in an activity that provides escape, reassurance, action, or connection allows a person to be distracted from negative feelings of anger, loneliness, depression, or disappointment. Indulging a bit in the activities that bring such positive experiences and social rewards certainly appears to do little harm in the beginning.

Over a period of time, however, the feelings associated with the addictive behavior itself become primary. The tension and arousal experienced prior to involvement and the pleasure experienced while participating in the activity intensify. When behaviors become compulsive, the positive attributes of the actions diminish and are replaced by more negative consequences. Feelings of anxiety or guilt emerge in the aftermath of participating in the behavior. Clearly this roller coaster of feelings specific to the addictive behavior becomes a larger problem and creates a constant conflict between the initial desire and facing the negative results.

As a behavior moves from fun to habit, issues related to tolerance, withdrawal, and behavioral control expand along with the changes in mood alteration. Individuals describe how they can’t stop thinking about shopping, gambling, eating, surfing the net, or watching sexually provocative videos and that it takes more and more of their time to reach the same mood adjustment. The bombardment of compulsive thought and the time requirements to achieve satisfaction begin to interfere with a person’s daily activities. As life becomes more imbalanced, efforts to resist the temptation become more unsuccessful. The recurrent effort and failure to stop the behavior, even though it is becoming harmful to self or significant others, is a final characteristic of an addictive disorder.

Although the object (e.g., drugs, alcohol, gambling, sex, food, relationship, exercise, work) of the addictive behavior may be different, the outcomes sought are similar. The goal of seeking excitement, connection, power, identity, escape, or a sense of well-being provides a broader understanding of the underlying expectations found in the “other addictions,” some of which are briefly described in the following section.

Gambling

Problem gambling is a behavioral disorder that most closely resembles drug use. It frequently starts

because it is viewed as fun and exciting, but it can quickly turn into a serious and debilitating addiction. Similar to prescription drug use, gambling usually starts as a legal activity. For many, the use remains appropriate and beneficial. For others, the benefits turn quickly into an ongoing search for a “quick fix.” The stage of winning in gambling, like the relief of pain from prescribed medications, intensely rewards the individual. The chase for another win, unfortunately, is ultimately met with losing. The intermittent reinforcement found with gambling helps delude a gambler into believing that another win is just around the corner.

Cravings, tolerance, and withdrawal symptoms escalate rapidly as gambling behavior takes on a compulsive quality. The compulsion to get to the next win intensifies, leading a gambler to more frequent and higher stakes betting. As the behavior becomes more pathological in nature, withdrawal symptoms occur. The irritability and agitation when not in the game and cravings for another opportunity to “try one’s luck” move the gambler into riskier and riskier situations. Such physiological symptoms and the cognitive dissonance that occurs with losing only thrust the gambler into a downward spiral. The skewed thinking that develops from the winning and losing cycle includes an illusion of control and superstitious beliefs about how to make this time a winning time. Gamblers are resistant to giving up these unsubstantiated beliefs. Struggles with stopping amplify, and financial strife and family problems arise. As the gambler reaches the desperation stage, damage to self and significant others become all encompassing. Losing overtakes the winning so dramatically that many problem gamblers face psychological and legal difficulties. Because of the financial hole that is dug, it is not uncommon to find compulsive gamblers creating legal problems for themselves through unpaid debt or illegal activities such as embezzlement. A large number of pathological gamblers, in fact, become so emotionally distraught over their life situations that they become suicidal.

Clearly the concomitant financial and mental struggles that emerge as gambling behavior increases affect one’s entire life. Unfortunately, for many gamblers it is only when the problems become so severe that their behavior becomes visible to others. The ability to hide problem or pathological gambling makes it a behavioral addiction that is particularly dangerous to personal, family, work, and financial health.

Compulsive Activity

Hidden addictions are frequently difficult to diagnose or even envision prior to their creating severe problems in a person’s life. Similar to gambling, other addictions involving money present financial concerns along with the obsessive realities of the behaviors themselves. Compulsive shopping, like obsessive investment trading, can create an illusion of sophistication or importance. The self-image that a compulsive spender or investor develops supports the continuation of the behavior, even in the face of financial difficulties. Again, the felt sense of superiority and excitement with the activity is hard to resist. Its internal nature makes it difficult for an outsider to notice or interrupt.

Yet, some hidden addictions are positively reinforced in a success-oriented society. The encouragement found in working or exercising hard can keep a person seeking more opportunities to increase the frequency and duration of these activities. Diagnostic symptoms, however, do occur when these positive behaviors begin to develop into an addiction. People who exercise or work addictively begin to feel tense if they are not doing the behavior and never seem to be able to do enough to feel satisfied. They will tend to push other things and important people to the background and feel guilty if they do not meet their own expectations of involvement with the behavior.

The rewards inherent within these behaviors diminish as people work or exercise beyond a healthy level. The positive recognition or sense of well-being is replaced by dissatisfaction and agitation. The irritation with self transfers to irritation with others as the “workaholic” or “exercise addict” looks down upon others who are unwilling to commit to the same level of involvement. Indignation with others interferes with home and work relationships, leaving the person believing he or she is not receiving the level of accolades or support he or she deserves. As these behaviors become more addictive, the intense focus creates an inability to find pleasure in other activities and pushes the person to continue working or exercising even when ill, injured, or in need of relaxation.

Another compulsive activity that has been gaining notice recently is Internet addiction. As with most other behavioral compulsions, the initial attraction to spending time online appears to be

inconsequential. As the amount of time spent in the behavior increases and other parts of life suffer from inattention, the addictive quality of this behavior becomes more visible. Unfortunately, the availability of many new computer-assisted activities (i.e., interactive games, social networking, online gambling opportunities) makes it easy to get lost in these numerous experiences. Such access makes Internet activities one of the fastest growing behavioral addictions today.

Compulsive Attachments

The anonymity of the Internet paired with society's focus on the importance of relationships has opened up new methods for engaging with others. Chat rooms, romantic Web sites, and e-mail communication provide enough obscurity to reduce some of the fear many feel about relationships. This detachment from the love object generates extra excitement, making new love even more enticing. Romance abounds under the Internet's veil, but sadly, it also adds to the possibility of compulsive attachments developing.

As many a popular song can attest, those with an unhealthy attachment to a person, relationship, or the idea of romance are commonly thought of as "addicted to love." Whether online or in person, compulsive patterns in love can vary. For example, codependent love is viewed as an overwhelming desire to care for another, even in the face of losing one's self or destruction of the family. Narcissistic love, on the other hand, describes a possessive, demanding type of love compulsion where the other is a projection of one's own self-aggrandizement. Clingy love, another type of unhealthy attachment, is more focused on the idea of constant connectedness with another person.

As the compulsive attachment strengthens to the point of personal difficulties, three core characteristics are typically seen. Persons addicted to love seem to be "obsessed" with the other person, they often have unrealistic expectations of "positive regard" from the love object, and they frequently neglect themselves in the face of such love. Similar to gambling and shopping addictions, attachment disorders create an illusion of importance. The excitement and attention focused on the love object or the idea of love becomes primary, and the thought of losing this love creates intense anxiety. A desperate attachment forms with an increasing belief that life would be meaningless without one's partner.

Clearly, no matter the type, romantic addiction can interfere with a person's ability to manage the rest of his or her life effectively. Actual loss of the love object can bring about an emotional experience similar to substance abuse withdrawal. No wonder such compulsive attachments can be considered an addiction.

Sexual Addictions

Compulsive sexual behavior, on the other hand, is not about love of another person. For many who define themselves as a "sex addict," it is the activity itself that becomes the compulsive love object. Sexual practices begin to disrupt one's life when the constant desire (urge) and increased focus on specific and frequent repetitive behaviors takes over time and energy. If the favored practice is then paired with obsessive fantasy and begins to alter mood, it has many of the characteristics found in most other behavioral addictions.

Culture and personal preference determine variations in sexual activities. Books abound about improving a person's sex life, and many couples seek assistance from professionals if they believe they are not as satisfied as they should be with this aspect of their relationship. While culture and religion may provide direction for what is considered "normal," as long as partners are consenting adults and activities are practiced in private, most sexual behavior is legally tolerated. Pursuit of pleasure, while not the primary goal for all, clearly becomes a desired secondary gain in most sexual engagements.

It is when the pursuit of pleasure becomes the constant aim of one's actions that difficulties arise. Behaviors such as looking at sexually provocative magazines or movies or masturbating are not typically viewed as problematic in and of themselves. Yet, if they become obsessive activities, life can become disorganized. It is clear that any compulsive sexual activity that interrupts involvement with a significant other or interferes with an individual satisfying his or her daily requirements can be determined as a detrimental behavioral addiction.

Intimate relationships suffer from the secret keeping inherent in compulsive sexual behaviors, causing many individuals to experience confusion and shame. It is only in the past 25 years that sexual addiction has been defined and discussed openly. Patrick Carnes, an expert in the field, likens the sexual addiction cycle to other substance and behavioral addictions. As with substances, an individual's preoccupation with sexual self-gratification

takes on the addictive quality of experiencing the anticipatory high, chasing the original excitement, and feeling as though one's behavior is becoming "unmanageable." The similarities between this behavioral compulsion and drug and alcohol addiction are common enough that a primary method for understanding the patterns, changing the behaviors, and healing includes a variation of the Twelve-Step approach.

Food Addictions

Similar to work and romance, eating is central to a person's everyday life. The premise of "three meals a day" requires a concentration beyond any other activity and demands attention to bodily needs. In addition, eating is so ritualized into celebrations, social encounters, and daily activities that it has become an organizing principle regarding how people think, feel, and act. For example, food often determines the success of an event or the feelings associated with one's participation. Self-image regarding appearance and sense of self-control are often associated with issues of food and eating.

It is no wonder then that food management has emerged as one of the most frequently discussed behaviors. Diets abound, and concerns about whether someone is eating too much or not enough continue to gain public attention. Excessive restriction of food intake is called anorexia, and overconsumption with bouts of purging is called bulimia. When the repetitive behavior is about the consumption of more food than is necessary for survival and health, it is called compulsive eating. Because anorexia and bulimia have their own diagnoses, they will not be discussed here as addictions to food. The newer category of compulsive eating, having many characteristics similar to those of other addictive disorders, will briefly be discussed as an addictive problem.

Nearly everyone overeats periodically. For example, holiday dinners are touted as times to be cautious about overeating. For some people, a special food (typically sweets) may periodically be consumed in too large a quantity. However, when overeating is employed in an effort to numb feelings such as anxiety, loneliness, or boredom, it can damage an individual's physical and psychological health. Chronic obesity and poor body image are examples of such difficulties that develop as a product of out-of-control eating.

The secretive nature of addictive behaviors is typically found with compulsive overeating. The hiding of food consumption is similar to that found with the

hiding of excessive gambling and compulsive shopping. The effort to escape from life or to bring pleasure through a behavioral compulsion such as overeating is not unlike that found with people struggling with many other addictive behaviors.

Conclusion

Despite debate over whether any or all of the behavioral compulsions are addictions, the need for treatment is obvious. Whenever a problem spirals out of control, a comprehensive assessment is helpful. Questions addressing habits around eating, spending money, working, exercising, and relationships are essential for developing an appropriate plan of action unique to each individual. Group, individual, and family interventions would naturally be included in any treatment plan.

It is important to restate that many of the treatments tested on drug and alcohol addictions incorporate methodologies useful to any addictive behavior. Like in substance addictions, support groups have already proven to be of benefit to those suffering from chronic problems with gambling, eating, and sexual compulsions. In addition, cognitive behavioral strategies found in relapse prevention have been used successfully with shopping, working, and exercise addictions.

While new diagnostic criteria and definitions for many of the "other addictions" described in this entry are being developed, it is important to address the multiple factors affecting the difficulty. For example, describing the activities surrounding the addiction allows a treatment provider to develop specific actions effective in interrupting the recurrent behavior. Spotlighting the secret behavior so that individuals and families can receive assistance is critical to ongoing recovery. Most important, the goal of easing individual suffering and repairing health, family relations, and financial concerns remains the focus, no matter the particular addiction being addressed.

OUTPATIENT TREATMENT

Outpatient treatment for substance abuse refers to services that address a client's substance abuse or dependence while permitting the client, as much as possible, to continue daily life functioning outside of treatment. Examples of outpatient treatment include medication maintenance, standard outpatient, intensive outpatient, and day treatment. Services that may overlap with outpatient treatment include ambulatory detoxification, continuing care, and street outreach. Determination of appropriate treatment placement involves a number of factors, including medical history and status, co-occurring psychiatric conditions, environmental risk issues, and history of previous treatment.

According to the most recent data available from the National Survey of Substance Abuse Treatment Services, at least 80% of all substance abuse treatment facilities are outpatient programs, and approximately 90% of clients receiving treatment are in outpatient programs. As of March 2006, of all clients receiving treatment, 52.1% were seen in standard outpatient and another 22.5% in methadone maintenance, 11.4% received intensive outpatient treatment, 2.1% were in day treatment, and an additional 1.1% were undergoing detoxification on an outpatient basis. Outpatient treatment in its many forms is

by far the most commonly used group of treatments for substance abuse in the United States.

Levels of Outpatient Treatment

The intensity of outpatient treatment ranges from weekly brief contact to daily full-day programming. Standard outpatient treatment generally consists of one to two weekly sessions of 30 minutes to 2 hours per session. One common structure is weekly 1- to 2-hour group counseling sessions accompanied by periodic individual contacts for treatment plan review, crisis management, urine drug monitoring, individual or family counseling, or all of these components. Such a program generally takes place over 3 to 12 months. Another common structure is one to several contacts weekly to obtain opioid maintenance medication, combined with periodic individual counseling or case management sessions. This type of treatment may last from several months to several years or longer. The standard outpatient setting is also used to implement brief treatment options for individuals at risk for substance abuse or with mild substance use disorders. Such brief therapies are often administered in weekly sessions over 4 to 8 weeks.

Intensive outpatient treatment provides services for those with a substance dependence diagnosis who need higher-intensity treatment than standard outpatient provides but do not require a residential treatment setting. In most cases, clients are in the early days of abstinence when entering intensive outpatient treatment and benefit from more and longer sessions. Clients attend treatment several hours per day several days per week, and treatment generally continues for 1 to 3 months. One widely used regimen is treatment sessions on three weekday evenings and one weekend half-day for 6 to 8 weeks, with most of the treatment taking place in the group setting. Clients are typically given assignments to complete outside of treatment hours, providing them with ongoing engagement in the treatment process while offsite. Intensive outpatient treatment allows clients to continue to fulfill many daily life functions, such as attending to work and family responsibilities, while getting needed treatment.

Day treatment is often recommended when clients are experiencing moderate to severe symptoms of both substance abuse or dependence and one or more comorbid psychiatric disorders. Day treatment programs, which are typically hospital based, provide

services throughout the daytime (and often into the evening) on a daily basis. This allows programs to meet the needs of clients with complex symptomatology without the expense and life disruption of inpatient hospitalization. This treatment environment also supports medication compliance where applicable. (Note: The term *partial hospitalization* has been used to indicate both hospital-based intensive outpatient treatment and hospital-based day treatment. To avoid confusion, this term is not used in this entry.)

Types of Outpatient Treatment

In terms of purpose and design, outpatient treatment includes a wide range of services. Medication maintenance programs for opioid dependence—that is, those that prescribe and dispense methadone, levo-alpha acetyl methadol (LAAM), buprenorphine (Subutex), and buprenorphine-naloxone (Suboxone)—provide outpatient treatment that allows opioid-dependent individuals to stabilize their lives. Many outpatient medication maintenance programs utilize methadone exclusively, whereas some offer LAAM and/or buprenorphine medications as well. Medication maintenance, especially for those in the first year of treatment, generally includes counseling and case management. Participation in group counseling, individual counseling, or both, assists clients in making the transition from active addiction to maintenance, while case management helps coordinate their efforts to face challenges in multiple domains (e.g., employment, family, legal, and housing). In addition, urine drug screening helps determine whether clients have discontinued use of illicit drugs and continued use of the maintenance medication. Those who remain on medication maintenance long term typically require fewer clinical contacts. For those clients who choose to terminate treatment through long-term detoxification, however, additional counseling can help in this new transition. Subutex and Suboxone are available from some physicians through their private practices. Although physicians are not likely to offer counseling in their own practices (although some do), they are expected to ensure that their opioid-dependent clients are involved in psychosocial services and supports as well.

Standard outpatient abstinence-based treatments typically involve weekly counseling sessions. Although some clients may be seen exclusively in individual counseling, a more common structure is weekly group

sessions. Group methods may include psychoeducation, facilitator-driven feedback and support, peer-driven feedback and support, strategizing and role playing, history sharing, psychotherapy, and others. Periodic individual or family sessions, urine drug screening, and case management may then complement group counseling. Many outpatient programs have most or all of their clients entering treatment through mandatory referrals, particularly from the criminal justice system. Clients may be assessed as at risk, substance abusing, or substance dependent and are in outpatient treatment to address use and reduce legal recidivism. Substance-dependent clients often find it challenging to maintain abstinence in the relatively low intensity of outpatient treatment and so may be referred to intensive outpatient or residential programs.

Brief treatments for substance abuse are designed to facilitate immediate change in substance use and related behaviors. There are many brief therapy methodologies; however, according to the Center for Substance Abuse Treatment and others, they share a number of specific characteristics. First, brief therapies address the current situation; they focus on the problem and solution in practical terms, without psychodynamic or other exploration of causal factors. Second, brief therapies depend upon the rapid development of an empathic and supportive relationship between the client and the treatment professional. Third, the client and the professional create clear, specific, measurable, and immediate goals for behavior change (e.g., reducing alcohol use to no more than two drinks no more than 3 times weekly). Fourth, brief therapies place responsibility for change fully on the client, with the professional supporting enhancements in client self-efficacy by expressing belief in the client and emphasizing short-term successes. Fifth, treatment takes place in a set number of sessions over a relatively short period of time, and the client and professional discuss termination from the beginning. Some widely used methods include Motivational Enhancement Therapy, cognitive behavioral therapies, strategic interactional therapies, and brief treatments for specific issues. Examples of the latter, taken from the National Registry of Evidence-based Programs and Practices, include Brief Marijuana Dependence Counseling, the Trauma Recovery and Empowerment Model, and Twelve-Step Facilitation Therapy. Intensive outpatient treatment grew largely out of the need to develop effective treatment for substance dependence that did not depend on admission to inpatient or

residential programs. While much of the initial drive for this came from refusal of third-party payers to pick up the cost of residential treatment, research and clinical experience also suggested that many of those referred to residential treatment did not require such a restrictive setting in order to maintain abstinence and show positive treatment outcomes. In addition, in many cases clients benefit from remaining in their current home and work environments, providing these environments do not present significant risks for relapse.

The Center for Substance Abuse Treatment lists the following as services to be found in intensive outpatient treatment programs: group counseling, individual counseling, psychoeducational programming, pharmacotherapy and medication management, monitoring alcohol and drug use, case management, community-based support groups, 24-hour crisis coverage, medical treatment and psychiatric examinations or psychotherapy, vocational training and employment services, and enhanced treatment services (e.g., adult education, housing, childcare). Not all intensive outpatient programs include all of these services; many rely heavily on group counseling, psychoeducational programming, community-based support groups, and medical treatment, with pharmacotherapy or medication management (e.g., naltrexone for alcohol dependence), psychiatric examinations or psychotherapy, and 24-hour crisis coverage being included as needed. The extent to which case management and related services (e.g., alcohol and drug monitoring, vocational training, and enhanced treatment) are available varies widely with the overall purpose, philosophy, and location of the program. Intensive outpatient treatment programs are typically abstinence based, may or may not provide services for clients with comorbid psychiatric disorders, may be hospital based or freestanding, and may be found in urban and suburban settings.

The majority of day treatment programs are hospital based, and their purpose is to meet the specific needs of those with comorbid psychiatric and substance use disorders. While some clients with comorbid disorders (particularly those stabilized with ongoing medication, therapy, or both) may be appropriately treated in other forms of outpatient treatment, those currently experiencing active symptoms of both disorders are often better served in day treatment. This is true especially if the client is or has recently been a suicide risk, is currently using drugs in an attempt to

self-manage psychiatric symptoms, is at risk for or has a history of poor medication compliance, has a low level of global functioning, or otherwise presents a complex clinical picture. Day treatment programs offer safety and structure as well as a variety of therapeutic services; clients are engaged in services throughout the day and return home overnight. Activities often include psychoeducation about substance abuse, group counseling, individual and/or family therapy, expressive therapies, written assignments, and peer support.

Services Overlapping Outpatient Treatment

Certain other services offered on an outpatient basis overlap with, and are sometimes components of, outpatient treatment. Ambulatory detoxification is frequently used in patients with alcohol dependence (benzodiazepine-assisted), opioid dependence (methadone- or buprenorphine-assisted), and other forms of drug dependence (e.g., cocaine, methamphetamine, marijuana) where medication assistance is typically not needed. Whereas some patients are not suitable for ambulatory detoxification due to medical concerns (e.g., history of seizures with alcohol withdrawal) or environmental risk (e.g., cannot maintain abstinence in current living environment), many qualify for detoxification outside of an inpatient or residential treatment setting. As with other forms of detoxification, ambulatory detoxification alone does not constitute treatment, but is seen as a bridge from alcohol and other drug use to treatment. Ambulatory detoxification is used widely in conjunction with intensive outpatient treatment, with the client completing detoxification just prior to admission or in the first few days of treatment.

Continuing care is a follow-on to both outpatient and residential substance abuse treatments. Continuing care is intended to provide support during the post-treatment period and to aid clients in maintaining abstinence or other treatment gains. Continuing care is often provided in a group setting and typically focuses on implementing action plans, coping with emotional and environmental stressors, and preventing relapse. While provided on an outpatient basis and usually facilitated by one or more treatment professionals, continuing care is not treatment per se. Continuing care programs generally do not offer case management,

treatment planning, medication management, or other treatment-associated services other than counseling. In many cases, treatment professionals play a relatively minor role in the therapeutic process, as peer feedback and support may be sufficient to sustain positive group norms.

Street outreach efforts are often associated with outpatient treatment programs. An outpatient clinic offering counseling, case management, health education, psychoeducation, or all of these components may have an outreach component. Outreach activities may include information distribution, brief education or intervention, brief screening, infectious disease testing, needle exchange, or one or more other substance abuse-specific offerings. Although outreach efforts do not themselves constitute treatment, they may help channel substance-abusing or dependent individuals into outpatient treatments or other services.

Patient Placement Guidelines

Appropriate patient placement is key to positive outcomes in outpatient treatment. The American Society of Addiction Medicine Patient Placement Criteria (PPC-2R) are used to assess clients on several dimensions, thereby determining what level of treatment best meets clients' needs without unduly restricting clients' daily life functioning. These dimensions include severity of use, medical status (including withdrawal history and status), psychiatric status, family and social support (including environmental risk factors for ongoing use), and others. PPC-2R scores suggest optimal placement, from Level 0.5 (early intervention services) to Level IV (medically managed intensive inpatient treatment). In this schema, outpatient (standard outpatient treatment) is Level I, intensive outpatient is Level II.1, and partial hospitalization (day treatment) is Level II.5.

Conclusion

Outpatient treatment for substance abuse or dependence includes a range of treatment environments, modalities, methodologies, and structures. Outpatient treatment programs constitute about 80% of programs available for substance abuse, and service covers nearly 90% of those seeking treatment. Standard outpatient treatments, which typically do not exceed 1 to 2 hours of client contact each week, include medication

maintenance programs, abstinence-based outpatient treatments, and brief therapies for substance abuse. Intensive outpatient treatments for substance dependence include many of the elements of inpatient or residential addiction treatments but cause less disruption to clients' daily life functioning. Day treatment programs provide greater intensity and structure for clients with comorbid substance abuse and psychiatric disorders. Additional services that overlap with outpatient care include ambulatory detoxification, continuing care, and street outreach. Placement of clients in the appropriate level of care is aided by careful assessment; one tool for such assessment is the PPC-2R. Outpatient treatments are, and are likely to remain, the mainstay of substance abuse and substance dependence treatment.

OVER-THE-COUNTER DRUGS

Over-the-counter (OTC) medications are available to the public without a prescription and have the potential of being misused or abused. Common examples of these medications are analgesics, sleep aids, and cough-and-cold remedies. Corticosteroids are also popular drugs found over the counter and are used to control inflammation and pain. Although easily accessible, nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin can produce serious problems if abused. OTC medications may be obtained for a variety of ailments, such as allergies, colds, and coughs, and even as an aid to help keep someone alert when driving for long hours. Although OTC medications may seem harmless, and in fact they generally are when taken at the recommended dosages, there are many common misconceptions about these drugs. Many think they work differently than prescription drugs and that they are completely safe and do not cause any undesirable side effects. However, this is false, and individuals should be extremely cautious when taking these drugs and when giving them to children. Owing to the fact that many ingredients found in OTC medications can be addictive when misused, there are a great number of people who seek professional help for such addictions. Trained professionals can help these people who abuse such medications, and although there are relatively few people who suffer from OTC abuse, it is important that they receive the same level of treatment as anyone else who has a substance use disorder.

Many OTC medications were initially designed and marketed as prescription drugs. The Food and Drug Administration can change a prescription drug to an OTC if it has a good safety profile and is used for conditions or symptoms that can be self-diagnosed. Although OTCs are usually given in smaller dosages or are found in smaller concentrations compared with prescription medications, they work in the same way in the body and have the potential to cause the same types of side effects as prescription drugs. This is especially true if the OTC is not used as directed.

Pseudoephedrine

A common procedure for synthesizing illicit drugs is to chemically convert OTC drugs into more potent substances; the most common of the OTC drugs used in

this capacity is pseudoephedrine, a sympathomimetic amine that is used to manufacture methamphetamine. The simplicity of making methamphetamine stems from the fact that it can be made with common household items such as OTC cold medicine, drain cleaner, and iodine tablets. To help decrease the production of methamphetamine, OTC sales of pseudoephedrine have become more stringent, and many pharmaceutical companies have started making cold medications with phenylephrine instead of pseudoephedrine.

Analgesics and NSAIDs

OTC analgesics are common medications used in treating pain and discomfort. Although these medications can be extremely safe when used correctly, the risk for gastrointestinal effects and liver damage increases when they are taken for long periods of time.

An examination of the statistics of analgesic overdose indicates that they are among the top 10 drugs used to assist in suicides. Of the NSAIDs that are commonly available, acetaminophen and ibuprofen are two of the most commonly found medications and are frequently found in patients during emergency room visits.

It has been found that among high school students who were enrolled in a voluntary counseling course, nearly a fifth of them did not believe acetaminophen could be lethal, and only a quarter of them thought death could occur as a result of acetaminophen overdose. These statistics strongly suggest that high-school-age individuals are not aware of the fact that common OTC medications can be just as dangerous as illicit drugs when used inappropriately.

Other individuals who have been found using OTC analgesics consist of those age 65 and older, as well as females between the ages of 45 and 55 years of age. In both of these age groups, OTC analgesics were found to be the most commonly used drugs.

The elderly commonly use NSAIDs for treatment of pain, fever, pain associated with inflammation, and headaches. Unfortunately, side effects such as ulcers and bleeding of the gastrointestinal tract are commonly associated with these drugs. NSAIDs can furthermore lead to trips to the hospital for the elderly, and risk of ulceration is extremely high within this age group and can lead to death. Owing to the fact that the elderly make up the majority of people who are prescribed medications, the risk for drug interactions of NSAIDs and other medications also increases the risk of adverse reactions.

Older women (age 65 and over) are more likely to have adverse reactions to OTC medications, including NSAIDs, especially when taken concomitantly with other drugs. These reactions occur nearly 3 times more than in women younger than 65. Also, toxicity is more commonly found in older women with respect to gastrointestinal and kidney problems.

Among the myriad medications taken by many pregnant women, OTC medications are among the most common drugs used by pregnant women. A common NSAID, aspirin, is used for pain yet should be used cautiously. Because of the mechanisms of action in preventing the clotting of blood and platelet aggregation, NSAID use in a pregnant woman can cause deleterious effects not only to the mother but to the fetus as well. All drugs can affect the fetus during pregnancy; therefore, women should abstain from all unnecessary drug exposure while pregnant.

OTC Stimulants

Some OTC stimulants, which contain pseudoephedrine and phenylephrine, not only have a decongestant effect but also can cause stimulant and anorexic effects as well. These drugs can be found in common OTC medications that are used for allergies or colds and in many diet pills. Some common side effects include anxiety attacks and increased or erratic heartbeat in those who use these pills while drinking caffeinated beverages such as coffee or soda. Caffeine can also present dangers when taken in large doses and is easily accessible in OTC medications such as Vivarin and NoDoz.

OTC Depressants, Antihistamines, and Motion Sickness Pills

Some common OTC depressants include Sleep-Eze and Sominex. These drugs have been shown to be associated with narcolepsy if abused. Antihistamines that are commonly found over the counter include medications such as Benadryl, Actifed, and Sudafed. Because these drugs cross the blood-brain barrier, they can induce depression of the central nervous system. Both OTC depressants and antihistamines are occasionally abused for their depressant and sedating effects similar to prescription medications such as Valium and Xanax. When taken in excessive doses (6–10 pills at a time), antihistamines such as Benadryl and Sudafed can even produce psychedelic effects in an individual. Most

recently, diphenhydramine, the active ingredient in many OTC antihistamines, has been found to be mixed with low-grade heroin in a concoction known as “cheese,” which has caused deaths among teenagers. Last, dimenhydrinate, commonly known as Dramamine, is a common OTC medication used to help treat motion sickness. However, when taken in large doses, this drug has the potential to cause delirium resulting in hallucinations.

Dextromethorphan (DXM)

Numerous OTC cough-and-cold medications contain DXM, a synthetic drug that is similar to morphine. In the mid-1900s it was approved by the Food and Drug Administration as a cough suppressant and has been added to cough syrup as a replacement for codeine since the 1970s. Teenagers and young adults can obtain cough syrup containing DXM at a very low cost and, because it is not an illicit substance, do not have to worry about legal consequences of having it in their possession.

In large doses, OTC medications such as Robitussin and Vicks can cause feelings of hallucinations and out-of-body feelings of detachment from the environment. Once an individual purchases cough medications that contain DXM, the powder can be extracted from the liquid and sold illicitly over the Internet. Large doses of these medications can also cause seizures and overdose and although easily accessible over the counter, they have a very high potential for abuse. Common effects from DXM abuse include confusion, dizziness, blurred vision, impaired physical coordination, and disorientation. All of these effects are similar to the effects of phenycyclidine hydrochloride (PCP), an illegal hallucinogen originally used as an anesthetic by veterinarians. Serious damage can occur to the body, especially when it is abused with other drugs such as alcohol.

Prevention of OTC medication abuse has been seen in pharmacies where some pharmacists are keeping medications such as Robitussin and Coricidin (the now infamous C-C-C or “triple C” drug) behind the counter in order to regulate purchase. Some states have even banned the sale of cold products containing DXM to minors. Educational campaigns such as the Consumer Health Care Products Association’s “StopMedicineAbuse.org” have also been launched in order to warn parents and educators about the potential risks of having cold remedies stocked in medicine cabinets.

OTC Medications and Children

OTC drugs such as cough-and-cold preparations, analgesics, and vitamins also can be harmful to children. The fact that they are widely available in homes and stored in easily accessible cabinets and cupboards places children at a higher risk for overdose. Research suggests that the prevalence rate of OTC use among children is staggering. In fact, based on a recent survey it was estimated that 54% of all 3-year-olds in the United States had taken some type of OTC medication. NSAIDs such as Tylenol and cough-and-cold medications were the most prevalent, comprising an estimated 67% of OTCs used.

Although OTC cough suppressants are commonly given to children to help reduce cough, it has been found that when giving children placebo versus these OTC medications, there was no significant difference in the two. It is also important to note that the side effects of OTC medications can be extremely harmful, and deaths have been reported in children younger than 6 years of age who were given these drugs. Parents should be cautious when giving children cough-and-cold medications, as sometimes the wrong dose can be given when the medication label is not read closely. By having awareness of the correct dosage and potential side effects associated with OTC medications, toxic reactions can be avoided.

Conclusion

Although OTC medications may seem to be safe because they are readily available at local pharmacies, groceries, and drug stores, they can be addictive. Education in order to prevent abuse of easily accessible medication is extremely important with any drug, no matter how safe it may seem. Although it is not common to hear about OTC drug abuse, one should be aware of the potential side effects these drugs can cause not only to adults but also to teenagers who are experimenting with different substances. Keeping common OTC medications such as cold, cough, and allergy medicines away from young children and teenagers is extremely important in order to reduce the risk of OTC abuse. Furthermore, any drug can be toxic if taken in large enough doses, and serious risks such as organ damage, overdose, and even death can result from the common misconception that OTC drugs are harmless. Unfortunately, manufacturers of OTC medications do not support warnings about the potential for addiction with these

drugs. They believe that because only a tiny percentage of people suffer from OTC abuse, warning labels on common medications accessible to the general public are not warranted.

OXYCONTIN

OxyContin is a controlled-release formulation of oxycodone hydrochloride developed and marketed by Purdue Pharma LP of Stamford, Connecticut. Currently, OxyContin is available in dosage strengths of 10, 20, 40, 80, and 160 milligrams per tablet. Purdue Pharma developed OxyContin as a long-acting opioid analgesic indicated for moderate to severe pain and began marketing it in December 1995. However, the wax matrix controlled-release formulation of OxyContin can be bypassed by crushing the tablet, resulting in an immediately available, large dose of oxycodone that can be taken by routes unintended in its original formulation (e.g., intranasally or intravenously). The ease with which such a large dose of oxycodone is available resulted in reports of widespread abuse, particularly in

rural areas of the United States. Such reports have led to rising concerns about rural drug abuse. This entry reviews the pharmacology of the active ingredient in OxyContin (oxycodone), the epidemiology of OxyContin use, prevention efforts to limit OxyContin abuse and dependence, and treatment options available.

Pharmacology

The active ingredient in OxyContin, oxycodone hydrochloride, is an active ingredient in other prescription analgesic formulations (e.g., Percocet, Roxicet, Percodan) and was first formulated in the early 20th century. Oxycodone is a mu-opioid receptor agonist like morphine, hydromorphone, and hydrocodone. It produces analgesic effects, which peak 1 hour after oral administration and last for 3 to 4 hours. The positive effects of oxycodone (e.g., feelings of “high” or “euphoria”) mirror the time course of the analgesic effects. The effects of oxycodone following administration by routes associated with abuse (i.e., intranasal or intravenous) have not been well characterized, and although they are likely to be similar, they would also have a faster onset and perhaps be greater in magnitude.

Epidemiology

Nationally, the prevalence of illicit past month use of prescription pain relievers like OxyContin has remained relatively stable at about 2% of the population since 2003. This prevalence is higher than that for cocaine, methamphetamine, heroin, or prescription tranquilizers. Perhaps even more alarming is the finding that the number of first-time illicit users of prescription pain relievers was higher than such numbers associated with all other drugs surveyed in 2006 at approximately 2,150,000 individuals in the United States, according to the National Survey on Drug Use and Health. When illicit OxyContin use is examined on a national level for 2006, 1.7% of the U.S. population reported past lifetime use, 0.5% of the population reported past year use, and 0.1% reported past month use. While these overall rates of illicit OxyContin use are similar to those of other pain relievers, it is important to note that research targeting specific areas of the United States (e.g., rural areas) indicates that rates of OxyContin use vary. In fact, Theodore Cicero and colleagues identified illicit pain reliever use in about 60% of areas surveyed. In that study, OxyContin was identified as the most prevalent pain reliever.

Prevention

No published results of prevention programs have specifically targeted OxyContin abuse, yet there are efforts that may prove efficacious. For example, prevention programs can target geographic areas with demonstrated OxyContin abuse problems or where OxyContin is widely available (e.g., rural areas). In addition, limiting the availability of online pharmacies that provide OxyContin or other prescription pain relievers can reduce supply. Another way to limit supply is electronic prescription reporting programs. These electronic programs identify physicians who commonly prescribe drugs of abuse or patients who inappropriately fill prescriptions for drugs of abuse. One such program is the National All Schedules Prescription Electronic Reporting System. Formulations that limit misuse can also be developed to prevent and decrease OxyContin abuse and dependence. For example, oral OxyContin tablets could be formulated with naloxone, an opioid antagonist with limited absorption following oral administration. When taken as prescribed, naloxone would remain inactive. However, if OxyContin is used by a route other than oral (e.g., injected), the naloxone would block the OxyContin effects and could precipitate withdrawal in individuals who are physically dependent. For example, the formulation approach has been used for buprenorphine (Suboxone), a drug used in the treatment of opioid dependence, to prevent misuse.

Treatment

Specific treatments available for OxyContin abuse and dependence are similar to those for other prescription pain relievers and heroin treatment. One option is detoxification. Patients generally reside on an inpatient unit and are stabilized with methadone or buprenorphine to manage their withdrawal. Although opioid withdrawal is not fatal, it is markedly unpleasant, and individuals often relapse because withdrawal symptoms are severe. During detoxification, the maintenance dose of methadone or buprenorphine is gradually reduced until the patient is opioid free. Following detoxification, it is recommended that patients attend programs like Narcotics Anonymous, receive cognitive behavioral therapy, or participate in contingency management programs to support abstinence. Naltrexone, an opioid antagonist that can be administered orally, can also be used following detoxification to block the effects of opioids if a patient lapses or relapses.

Another option available to opioid-dependent individuals is agonist replacement therapy with methadone or buprenorphine. This option is controversial because it is perceived that patients are switching their dependence from one drug to another. However, from a harm reduction perspective, agonist replacement therapy is beneficial because it brings a dependent individual's drug taking under the control of a physician, reduces risky behavior required to obtain drugs (e.g., criminal activity, exchanging sex for drugs), and reduces the risk of HIV and hepatitis infection caused by risky drug use practices.

P

PAIN MANAGEMENT

It is estimated that 50 million to 75 million people suffer from malignant or nonmalignant chronic pain, yet only about 25% of them receive adequate treatment. Although a variety of pharmacological and nonpharmacological interventions exist, the use of opioids—that is, drugs containing naturally occurring or synthetic analgesics including morphine, methadone, oxycodone (OxyCotin, Percocet, Roxicet), and hydrocodone (Lortab, Vicodin)—for chronic pain management is a topic that continues to divide perspectives in the medical and addiction communities. Both the medical and addiction fields have valid claims in the use of opioids for chronic pain, and current research and theory provide a way to integrate the concerns and goals of both. This section will examine factors related to the initial reluctance of physicians to prescribe opioids. The current use of opioids will be explored as well as the gaps that exist in research. The relationship between pain management and addiction will be examined. Finally, principles of opioid use with substance abusers and those with the potential to abuse will be explored.

Physicians and Opioids

There are several factors that contributed to the initial reluctance of the medical community in prescribing opioids for chronic pain. Up until the 1940s, the use of opioids was not considered illegal. However, due to the growing number of street users and the increased dangers of using opioids such as morphine and heroin,

restrictions were put on the use of opioids for the general population. Opioid use was only considered legal if it was prescribed by a physician. However, the risk of losing one's medical license if opioids were misused decreased the probability that opioids would be prescribed. The additional risk was facing possible legal and criminal repercussions for inappropriate use.

Another factor contributing to physician reluctance to prescribe opioids for pain relates to the limited information that was available on the efficacy of opioids. Physician perceptions of opioid use were largely based on the experience of treating street users, where addiction and the manifestations of addiction were the norm. The belief that anyone using opioids would manifest this stereotype prevented the prescription of these substances. Unfortunately, at the time, the combination of these factors led to the undertreatment of pain.

Current Use of Opioids

Research on opioid use has significantly increased in the past 20 years. As a result, new information provides evidence that opioids can be effective in treating chronic pain. The general consensus of clinical studies indicates that opioid use in low and stable dosages can provide effective relief from chronic pain and improve overall functioning. As a result, the medical community is becoming more accepting of the use of opioids to provide relief if the dosage and effects of these substances are being monitored. Although limited research is currently available for the efficacy of long-term, high dose use of opioids, it appears that monitored and regulated increases by a physician have the best outcomes. Some studies indicate that increasing

the dosage of opioids too much, too soon can have an adverse effect on patients, including a reduction of pain relief and functioning.

For patients who have a history of substance abuse and who are currently abusing alcohol and other drugs, no substantial research exists on the use of opioids for pain relief. The general consensus, however, is to find alternative, nonaddictive substances for pain relief. Patients seeking pain relief with a history of substance use but who are not currently abusing substances need to be educated on the acceptable and unacceptable behaviors relating to opioid use and need to be regularly monitored by a physician. The pain management and addiction principles listed below can be used as guidelines to provide opioids for pain relief for patients who are not currently abusing substances.

Opioid Use and Addiction-Dependence

Research has focused on whether continuous opioid use would result in addiction. Although it is evident that opioid users will develop tolerance and physical dependence to opioids due to the nature of the substances, the primary question was whether an individual using opioids to manage pain would manifest symptoms of addiction. In one clinical study, 12,000 opioid users were followed but only four developed an addiction. Other studies suggest similar outcomes. There is no clinical evidence suggesting that patients who use opioids for pain will develop an addiction with its resulting manifestations (i.e., drug seeking behaviors).

A common occurrence that happens with undertreated chronic pain involves behaviors that are similar to behaviors of addicted individuals. For example, a chronic pain sufferer may go from doctor to doctor for medications. The individual may intentionally seek narcotics or other potentially addictive substances from various sources or demonstrate occasional non-compliance with dosages. However, once pain relief is achieved, such behaviors cease. The individual does not exhibit behaviors of loss of control of use or cravings or urges, and no further consequences occur. Therefore, chronic pain sufferers, in seeking pain relief, may demonstrate behaviors that occur in addicted individuals but that do not necessarily reflect an addiction. Rather, the behaviors reflect inadequate pain relief.

Pain Management and Addiction Principles

In an effort to avoid the onset of addiction to opioids, most physicians will avoid prescribing these medications. However, no evidence exists that opioid users become addicts. They may develop a physical dependence, as to be expected, but defining criteria of addiction are not met. There are many principles of using opioids with active and recovering alcoholics-addicts; the guidelines listed below are a combination of these as well as other principles, with the primary goal of providing adequate pain relief while monitoring addictive behaviors.

1. *Use opioids after other reasonable attempts at pain relief occur.* Most chronic pain sufferers have tried various techniques to manage pain. It is important to investigate these further. Some patients may not have received adequate training in the use of these techniques, which limits the efficacy for pain relief. In addition, there may be techniques the patient has not tried that may provide adequate pain relief prior to the use of opioids. When the use of opioids does begin, dosages begin at the minimum levels to help determine appropriate amounts for pain relief. If a patient asks for increased dosages before an appropriate interval, it is necessary to discuss the patient's motive as well as to be mindful of addictive behaviors.

2. *Involve a multidisciplinary team.* Although one physician needs to be the primary professional for the patient, it is necessary to involve other professionals who can also guide the patient in pain relief using non-pharmacological approaches. These professionals may be occupational therapists, body movement therapists, and psychologists-therapists. Psychologists and therapists who specialize in pain management can educate patients on techniques revolving around cognitions and behaviors. Although pain can be managed through pharmacological means, evidence exists that nonpharmacological interventions can be equally effective. Psychologists and therapists also can help patients look at their beliefs and expectations relating to their pain and pain interventions that may limit pain relief.

3. *Recognize drug abuse behaviors.* Patients who are prescribed opioids will manifest symptoms of loss of control, cravings, and continued use despite significant consequences if they are abusing these substances. For example, if a patient frequently reports lost prescriptions

and is obtaining medications from multiple sources, this may indicate abusive behavior. It is necessary to discuss appropriate and inappropriate behaviors with the patient when it comes to ongoing opioid use for pain relief.

4. *Ongoing pain assessment.* In order to determine that the use of opioids is effective in managing chronic pain, ongoing daily or frequent assessment by the patient needs to occur. Assessments can be done using a pain diary, professional reporting measures, or other means of gauging pain levels.

5. *Use of a treatment contract.* Patients with a history of addiction can sign a treatment contract relating to the use of opioids. This contract needs to include the basic agreement of medication used, dosage, frequency, and the like. Other elements, particularly for an active or recovering addict-alcoholic, may include the following: agreement that one or two pharmacies are the designated sources to obtain medications (these can be listed); the patient agreeing that the primary physician will be the only prescribing physician for such medications; and consequences if the physician suspects illegal activity as well as subsequent legal consequences if indicated. Another consideration to include is a section that is a release of consent that allows reciprocal permission for the physician to contact pharmacies, emergency rooms, and the like if addictive behaviors are demonstrated so that the physician can determine what action, if any, to take.

6. *Documentation.* It is vital to document all reports from the patient. Documentation requires information on medication efficacy, side effects, patient level of functioning, pain levels, and any manifested behaviors the physician observes. These documents can support any legal ramifications that may occur, but they also provide a consistent picture of how the patient is managing pain while on opioids.

Conclusion

Pain management for active alcoholics-addicts and those in recovery involves several components necessary for adequate pain management and prevention of relapse to active addiction of the primary substance of choice. Professionals need to engage their patients in ongoing pain assessment and to look for manifestations of addictive behaviors. Taking opioids for pain relief does not necessarily lead to the development of an addiction. However, it is vital to implement the basic

principles of pain management in order to provide adequate pain relief for patients with addiction or in recovery, or for those with the potential to abuse opioids.

PATIENT PLACEMENT CRITERIA

It is popular to think that treatment for substance abuse and dependence consists of a 28-day inpatient stay that emphasizes the Twelve-Step model. This perception of substance use treatment is a product of the dominance of the Minnesota model that was developed by treatment providers to treat alcoholics. The model, which focuses on detoxification and rehabilitation, implies a biomedical understanding of substance dependence. Consistently, research has demonstrated that substance dependence can and does occur without physiological changes. As a consequence, the World Health

Organization and the American Psychiatric Association have made revisions to the diagnostic criteria for substance dependence to reflect these changes in scientific understanding. Currently, an individual may meet the criteria for substance dependence without exhibiting physiological changes such as tolerance or withdrawal symptoms. The net result of this change is that a variety of substance dependence treatment regimes are available that vary in treatment intensity and type of setting.

The National Institutes of Health recognized that successful treatment requires the matching of treatment settings, interventions, and services to the particular problems and needs of the patient. In the early 1980s, substance dependence treatment providers were increasingly challenged not only to address which type of treatment was best for which kind of patient but also to define criteria that required movement from one level of treatment intensity to another. These questions arose from two different sources. First, funding sources for substance use disorder treatment services (e.g., managed health care organizations and publicly funded health care programs) were tasked with managing and containing health care costs through utilization review processes. During the 1980s, both the cost pressures of treatment and the development of managed care organizations resulted in multiple attempts by insurance organizations and managed care entities to establish treatment matching protocols. Second, substance use treatment providers were tasked with matching patient needs to clinically sound treatment plans and treatment settings. In 1985, at the request of the Minnesota legislature, the commissioner of human services established criteria for determining and placing patients on public assistance in an appropriate level of substance dependency treatment. This legislation marked the first formal effort to match placement to patient needs and spurred other attempts at developing patient placement criteria. The most widely recognized and, in many cases, adopted attempt at treatment matching is the patient placement criteria of the American Society of Addiction Medicine (ASAM).

Development of ASAM Patient Placement Criteria

The patient placement criteria of the ASAM have their origins in a number of earlier efforts to create patient placement criteria. The Cleveland criteria were

designed at the behest of the Northern Ohio Chemical Treatment Directors Association. The publication of the Cleveland criteria for a continuum of care received national attention and served as an initial template for treatment evaluation and assessment. The second effort made use of all the available criteria on patient placement and resulted in the National Association of Addiction Treatment Providers (NAATP) patient placement criteria (PPC). This model was used by a number of publicly and privately funded treatment providers to improve internal review processes and guide clinical decision making.

Although both the Cleveland criteria and the NAATP PPC were steps in the right direction toward comprehensive patient placement criteria, there remained a need for an effective set of criteria that differentiated various levels of care, assessed the need for continued care at a given treatment level, and enhanced the provider's ability to match patient needs to treatment settings and intensity. These needs were addressed through the collaborative efforts of the NAATP and ASAM. This third effort, which was based on revisions of the Cleveland and NAATP criteria, resulted in the *Patient Placement Criteria for the Treatment of Psychoactive Substance Use Disorders* and included both adult and adolescent patient placement criteria within four identified levels of treatment and along six patient dimensions.

Finally, out of ASAM's efforts to broaden stakeholder participation in revising the patient placement criteria, consensus emerged for a national set of placement criteria that could be used by employers, providers, and purchasers of health care. These efforts led to ASAM PPC-2 and its revision: ASAM PPC-2R.

ASAM Patient Placement Criteria-2 Revised

ASAM's current patient placement criteria are in its second edition (ASAM PPC-2R). The ASAM PPC-2R establishes criteria for initial placement in treatment and criteria for continuing treatment, as well as discharge criteria. These criteria assess patient severity and the need for services along six dimensions: dimension 1 (intoxication and/or withdrawal potential), dimension 2 (biomedical conditions and complications), dimension 3 (emotional, behavioral, or cognitive conditions and complications), dimension 4 (readiness to change), dimension 5 (relapse, continued use, or

continued problem potential), and dimension 6 (recovery environment). The ASAM PPC-2R matches these patient dimensions to four primary levels of treatment: Level I (outpatient treatment), Level II (intensive outpatient and partial hospitalization treatment), Level III (medically monitored intensive inpatient treatment, for example, residential treatment), and Level IV (medically managed intensive inpatient treatment, or hospitalization). In addition, the ASAM PPC-2R describes criteria for early intervention services (Level 0.5) and adult opioid maintenance therapy.

At the core of PPC is the assessment of the patient. ASAM defines assessment as a multidimensional procedure that evaluates the patient's strengths, weaknesses, problems, and needs in order to develop an appropriate treatment plan. Patient assessment is consistent with a biopsychosocial perspective that highlights current medical issues, alcohol and other drug use history, psychosocial and socioeconomic factors affecting the patient, and an evaluation of case-management issues and needs ranging from public health and welfare to educational and employment assistance. Both assessment and treatment planning are ongoing and individualized processes that authorize a particular level of treatment and, in many cases, its level of reimbursement. As a patient moves between levels of care, ongoing assessments form a cumulative record of treatment leading to a discharge plan.

Principles and Theoretical Foundations

The development of the ASAM PPC was guided by a number of principles. First, patient placement criteria are designed to be as objective, measurable, and quantifiable as possible. Second, referral to a specific level of care is based on a careful assessment of the patient with the goal of placing the patient in the most appropriate level of treatment. Third, there is an understanding that both substance dependency and treatment exist along continuums of illness severity and treatment intensity. The goal is that the continuum of care will be available for all of those in need. Fourth, treatment failure is not a precondition of a greater intensity of service. In other words, it is not necessary to fail treatment at the outpatient level of service before being placed in an inpatient setting. Fifth, requisite length of stay remains undefined so that medical necessity remains the determining factor for level of

care. Finally, Twelve-Step programs and other recovery groups, though valued, are conceptually different than treatment. Therefore, recovery groups are not considered a part of the continuum of treatment.

The principles just described denote a theoretical formulation of substance dependency and treatment. Treatment should be tailored to address the specific needs of the client in the form of an individualized treatment plan that highlights problems, patient strengths, priorities, goals, and strategies. Patients are informed of the options and availability of treatment modalities, the risks and benefits of such treatments, and the risks of treatment versus no treatment. Judgments regarding the appropriateness of care are based on the concept of *medical necessity*. This term addresses the biopsychosocial aspects of substance dependence and results from an assessment of the extent and severity across the patient's six dimensions. As a patient moves through treatment, his or her progress is continually assessed along the dimensions, and new priorities for recovery are identified. Although patients may deteriorate or fail in any given program or at any level of care, changes in levels of care or service delivery result from a reassessment and modification of the treatment plan in order to enhance a better therapeutic response.

Finally, ASAM recognizes that certain factors potentially take precedent over the patient-treatment match. These include the following: (a) the lack of availability of appropriate, criteria-selected care; (b) failure of a patient to progress at a given level of service such that reassessment recognizes special needs or an intensity of service delivery that does not currently exist within the current PPC levels of care; and (c) state laws that regulate treatment provision requiring a set of placement criteria other than ASAM.

Outcome Research

Limited research on the ASAM criteria has suggested that they provide a reliable means of placing patients at the appropriate level of care. The ASAM criteria are also said to have good concurrent validity. In other words, they correlate well with other protocols for assigning patients to a level of treatment. The criteria's predictive validity or their ability to predict patient outcomes has been minimally researched. However, there is some indication that patients who are properly matched have better outcomes than patients who are mismatched to treatment. A limited number of studies have looked at

the feasibility of matching patients to levels of care according to the ASAM PPC criteria. Early criticism suggested that the ASAM criteria inherently emphasized residential treatment over less restrictive alternatives and suggested that only a small number of substance users could meet the criteria for outpatient treatment. Research on the feasibility of treatment has suggested that this tendency for overtreatment was more common than undertreatment and resulted from the availability of publicly funded inpatient treatment, treatment philosophies that emphasized a gradual step down from inpatient detoxification, and social and legal pressures on the patient that mandated treatment. Undertreatment is often attributed to conflicting demands on the patient (i.e., work schedule conflicts and family or personal responsibilities, patient reluctance, and insurance coverage limitations).

Alternative Forms of Patient Placement

A number of attempts to create alternatives to the ASAM PPC have occurred. Many of these resulted from managed care efforts to more effectively control costs. In most cases, alternative placement criteria have relied heavily on comprehensive patient information similar to the ASAM PPC. The Green Spring Health Services (GSHS) criteria are, perhaps, the most widely known alternative to the ASAM PPC. The GSHS criteria were developed based on years of extensive utilization reviews and provide both psychiatric and substance abuse treatment matching for adults, adolescents, and children. The criteria are based on the severity of illness and the intensity of services along a continuum of care levels.

As previously mentioned, managed care utilization processes emphasize cost containment. In an environment where health care services are often perceived as limited resources, the goal is to balance severity of illness with the potential for restoration of functioning. The GSHS criteria were developed on the assumption that many problems can be addressed effectively and efficiently by levels of care that are the least restrictive and that are less expensive than inpatient settings. GSHS criteria differ from the ASAM criteria primarily by adding an intermediate level of outpatient care that is separate from partial hospitalization and a level of residential care called supervised residential treatment (e.g., halfway houses). In addition, the GSHS criteria emphasize mental competence and restorative

potential as determinants of placement. Therefore, the goal is to match patients not only to levels of care that they can utilize but also to levels that offer the potential for measurable benefit.

Conclusion

Substance abuse disorders are complex combinations of biological, psychological, and social factors. As a result, a continuum of treatment options exists to treat substance abuse and dependency. Patient placement criteria are mechanisms for matching illness severity to levels of treatment intensity in order to maximize treatment outcomes and manage treatment costs. The ASAM PPC-2R is currently the most widely used and researched set of patient placement criteria. These criteria establish four primary placement levels for treatment based on six dimensions of substance use severity. Limited research has suggested that patients that have been properly placed using the ASAM PPC-2R criteria have better outcomes than those that are not matched to treatment. However, research on the ASAM criteria has also suggested that clinicians have a tendency to overtreat by placing patients at higher levels of treatment intensity. Further research on the feasibility of using patient placement criteria, the ASAM PPC-2R in particular, is warranted.

PEER RECOVERY SUPPORT SERVICES

Peer recovery support services are not treatment in the commonly understood clinical sense of the term. Peer recovery support services are designed and delivered by peers in recovery, not by professionals employed in clinical and agency settings. They are grounded in a strength-based approach that focuses on wellness and a full reengagement with the community for recovering individuals and their family members.

Peer recovery support services are available throughout the continuum of care—pretreatment, during treatment, posttreatment, and in some cases, as an alternative to professional treatment. Successful peer initiatives network and build strong and mutually supportive linkages with formal systems of care and with professionals in their communities. However, peer services are largely designed and delivered by individuals and families in recovery to meet the needs of others with similar histories and needs. Many peer leaders donate their time providing recovery support out of a desire to give back to their communities by helping others who are seeking to recover or sustain their recovery. The services are developed and defined in response to needs identified by the recovery community.

Treatment providers and mutual support recovery programs (e.g., Twelve-Step groups) can both provide important help to people seeking long-term recovery. Peers offer their personal experiences of addiction and recovery in a nonprofessional environment. Although many treatment professionals are in

long-term recovery, when they are providing treatment, it is in their prescribed role and responsibility to their employer. Peers are able to connect with individuals seeking recovery or newly in recovery in a less hierarchical manner, although there are ethical guidelines followed by individuals providing peer recovery support services. Mutual support groups can play an essential role in the recovery process. Peers can provide services beyond this support. Therefore, a combination of some or all of these pathways—professional treatment, mutual support groups, and peer recovery support services—may be required for an individual to sustain his or her recovery.

Peer recovery support services are part of a recovery-oriented system of care, helping to prevent relapse and support long-term recovery. The aim of these services is to maximize the opportunities to create a lifetime of recovery and wellness for the individual, family, neighbors, and community. If a person does relapse, peer-to-peer services can help minimize the negative effects through early intervention and timely referral back to treatment. Peers help connect individuals to the recovery community.

Scholars in this field such as William White and Tom McLellan have noted the contribution of holistic, community-based support services to enhancing treatment outcomes and their importance as a response to the challenge of the chronic nature of addiction. In other areas of health, there's a history of effective peer services in the mental health consumer and HIV/AIDS peer communities. The 65-year history of Twelve-Step groups and, more recently, the emergence of other types of support group programs further reinforce the principle that supportive peers can help sustain recovery. Peers can help people move along the continuum by offering hope, motivation, and living proof that recovery is possible. Recovery community organizations providing peer recovery support services recognize that individuals in recovery, their families, and their community allies are critical resources that can effectively extend, enhance, and improve formal treatment.

Peer recovery support services can be delivered by freestanding recovery community organizations or as part of a host agency such as a recovery housing provider or a criminal justice service agency. They are delivered in a variety of settings including recovery community centers, churches, child welfare organizations, recovery homes, drug courts, prerelease jail and prison programs, behavioral health agencies, and HIV/AIDS and social service centers.

Among the growing number of recovery community organizations around the country, many are providing peer recovery support services. Some have established recovery community centers with peer-led recovery support groups or recovery mentorship programs. Others have focused on education, offering classes or coaching in recovery-related topics and basic life skills such as parenting and job hunting. Some projects provide concrete assistance to participants looking for help with housing, employment, parenting, and other everyday tasks, with peers offering assistance with job or school applications, child care, and transportation to support-group meetings. Some organizations offer peer-to-peer services for relatives and friends of people in recovery.

According to Tom Hill, who provides technical assistance to the Recovery Community Services Program (RCSP) grantees funded by the federal Center for Substance Abuse Treatment, peer programs have had to create appropriate roles and peer-based ethical codes. This is due to the fact that organizations providing peer recovery support services establish new kinds of relationships between people at different stages of recovery. Peer leaders have to be well grounded in the nuances of ethical behavior, and there must be systems in place that will allow for close supervision. The RCSP program includes 28 community- and faith-based organizations and has supported 43 projects since it began in 1998.

Peer recovery support services can be targeted to respond to specific cultural or gender-specific needs. They are provided in culturally appropriate and welcoming self-help environments and can include the following:

- assistance in housing, educational, and employment opportunities;
- building constructive family and other personal relationships;
- stress management assistance;
- alcohol- and drug-free social and recreational activities;
- recovery coaching or mentoring to help manage the process of obtaining services from multiple systems, including primary and mental health care, child welfare, and criminal justice systems;
- recovery learning circles and other forms of recovery-related education; and
- peer-led recovery support groups and meetings.

Peer recovery support services provide social support for recovery. They promote engagement in the recovery process and reduce relapse once recovery has been initiated. Because they are designed and delivered by peers, they convey hope as well as experience in sustained, long-term recovery.

PHARMACOLOGICAL APPROACHES TO TREATMENT

Substance abuse treatment providers commonly employ counseling interventions (i.e., individual therapy, group and family therapy, contingency management, motivational interviewing, relapse prevention) when helping patients achieve and maintain sobriety. For patients who abuse substances but who do not show signs of physiological dependence to a substance (i.e., tolerance, withdrawal), these treatment strategies are often employed independently. For patients who present with symptoms of physiological dependence, pharmacological approaches to treatment are commonly utilized in order to help these individuals go through detoxification, decrease drug use, improve the patient's ability to function, and achieve and maintain sobriety. These pharmacological

approaches to treatment may be utilized independently or in conjunction with counseling techniques. The most successful treatment strategies typically begin with medical detoxification, followed by pharmacological maintenance treatment and therapy, and finally by relapse prevention and cessation of pharmacological treatment. This entry describes targets of pharmacological approaches to treatment, provides a brief overview of pharmacological treatments available by category, and highlights the limitations of existing pharmacological treatments and future directions of research in this area.

Targets

Pharmacological approaches to treatment are commonly employed when the physiological dependence symptoms (i.e., tolerance, withdrawal) from a substance may decrease the likelihood of successful cessation (the process of discontinuing substance use). The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* defines tolerance as the need for larger amounts of the substance to obtain a desired effect or lower effects with continued use of the same dosage. The *DSM-IV-TR* defines withdrawal as the development of symptoms due to reducing or discontinuing heavy and prolonged substance use. These symptoms cause clinically significant distress or impairment and would not be due to another medical condition or mental disorder. The presence of physiological dependence often makes it difficult or impossible for the patient to engage in counseling treatments without relapse. For these patients, pharmacological treatments may be used to aid in detoxification or to ease withdrawal symptoms.

Medical detoxification is a common precursor to substance use treatment, particularly for those patients who exhibit severe withdrawal symptoms or who have been unsuccessful at cessation attempts in the past. It may be particularly useful for those patients whose withdrawal symptoms may be medically dangerous. The National Institute on Drug Abuse (NIDA) defines medical detoxification as the systematic withdrawal from an addictive substance, typically conducted in an inpatient or outpatient treatment setting under the direct care of a physician. This precursor to substance abuse treatment is specifically designed to address the acute physiological effects of substance use cessation; however, it

does not address psychological, environmental, or behavioral components of addiction. As such, medical detoxification should be followed by substance use assessment and treatment in order to produce lasting behavioral changes. NIDA reports that medications are currently available for detoxification from opioids, nicotine, benzodiazepines, alcohol, barbiturates, and other sedatives.

Pharmacological approaches to treatment are also employed for sustained periods in order to help the patient reestablish normal levels of functioning, prevent relapse, and diminish cravings. These medications may be used to inhibit or block the effects of a substance (i.e., methadone, buprenorphine), deter substance use (i.e., Antabuse [disulfiram]), alleviate withdrawal symptoms, and provide relief from drug cravings. These medications are useful in conjunction with counseling because they may serve to decrease substance seeking behaviors and increase the patient's compliance to treatment programs. These behavioral changes increase the likelihood that the patient will be able to achieve and maintain sobriety. NIDA reports that medications are currently available for sustained treatment of opioid dependence, nicotine dependence, and alcohol dependence, with treatments for stimulant dependence and cannabis dependence in various stages of development.

Available Treatments

Alcoholism

Pharmacotherapy is commonly employed during alcohol detoxification and treatment due to the severity of withdrawal symptoms that typically accompany sustained alcohol abuse. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) reports that two primary types of medications have been used to reduce alcohol use: medications used to deter alcohol use (i.e., Antabuse) and medications used to reduce alcohol cravings (i.e., acamprosate, naltrexone). Alcohol dependence can vary in severity by patient, with some patients able to cease alcohol use with very little external support and other patients trying unsuccessfully to discontinue use for sustained periods and eventually seeking pharmacological treatment strategies in conjunction with counseling for cessation.

Antabuse is a medication that inhibits aldehyde dehydrogenase, an enzyme that helps break down alcohol. Inhibiting this enzyme interferes with the

body's ability to metabolize alcohol and deters alcohol use by causing an unpleasant physiological reaction when the patient attempts to ingest alcohol. The aversive physiological reaction includes symptoms such as facial flushing, headaches, respiratory difficulty, nausea, vomiting, hyperventilation, and vertigo. The aversive physiological reaction caused by ingesting alcohol while being treated with Antabuse serves to decrease the likelihood that the patient will engage in alcohol use in the future. The use of this pharmacological approach to treatment is commonly accompanied by other interventions (i.e., relapse prevention) that will aid in continued alcohol cessation once the pharmacological treatment has ended.

Naltrexone is an opioid agonist that serves to diminish cravings for alcohol during treatment. Research support for the effectiveness of naltrexone in the treatment of alcohol dependence has been very promising, with some studies indicating that naltrexone reduces the frequency of relapse. Acamprosate acts on the neural pathways that are related to alcohol abuse and was approved by the Food and Drug Administration (FDA) in 2004 for the treatment of alcohol dependence. Early research indicates that acamprosate is most effective with alcohol dependent patients who have completed detoxification prior to beginning this pharmacological treatment. In addition, treatment outcome studies indicate that cessation rates are significantly higher when acamprosate use is paired with other treatment strategies.

Heroin Dependence

Pharmacological treatment strategies are commonly utilized during heroin detoxification and treatment due to the severity of withdrawal symptoms that typically accompany sustained opioid abuse. NIDA divides pharmacological treatment for heroin dependence into two categories: agonist maintenance treatment and antagonist treatment. The primary pharmacological withdrawal method used for the treatment of opioid addiction involves substitution of a comparable drug that produces milder withdrawal symptoms. This medication is gradually reduced over the course of pharmacological treatment.

Agonist maintenance treatment suppresses withdrawal symptoms, reduces cravings, and inhibits drug seeking behaviors. Methadone is the most commonly used agonist maintenance treatment and is taken via oral administration on a daily basis. The dosage is gradually

decreased until the patient is physiologically able to cease methadone use. Levo-alpha acetyl methadol (LAAM) and buprenorphine have more recently been approved for agonist maintenance treatment. These drugs do not require daily administration, which reduces the likelihood of relapse if the patient misses a day of physician supervised treatment. Research on the effectiveness of agonist maintenance treatment has demonstrated the effectiveness of this type of pharmacological treatment, particularly when used in combination with individual and group therapy. NIDA reports that patients who have been stabilized on these medications have a higher probability of engaging in treatment, which increases their likelihood of successful cessation.

Antagonist treatment is commonly initiated after medical detoxification has been completed. Naltrexone (also used for the treatment of alcohol dependence) is typically used during agonist treatment because it has no potential for abuse (unlike agonist maintenance treatments). NIDA reports that naltrexone causes few side effects; however, the use of naltrexone should be initiated after a period of no opioid use in order to prevent complications associated with opioid abstinence syndrome. The continued lack of opioid effects while using naltrexone will gradually cause the patient to stop seeking opioids due to the absence of reinforcing effects. As a caveat, the lack of opioid effects commonly results in treatment noncompliance. For this reason, agonist treatment should be accompanied with counseling in order to produce lasting effects.

Nicotine Dependence

Nicotine withdrawal can vary in severity by patient, with some patients able to cease nicotine use with very little external support and other patients trying unsuccessfully to discontinue use for sustained periods. For severely nicotine dependent patients, pharmacological treatment strategies in conjunction with other treatment strategies may increase their likelihood for successful cessation. NIDA reports that relapse rates for cigarette smoking are highest in the weeks immediately following cessation and tend to decrease substantially after three consecutive months of discontinued use. Several pharmacological treatment options are available to aid in nicotine cessation, including chewing gum, transdermal patches, nicotine sprays and inhalers, and oral medications.

Nicotine replacement options (i.e., chewing gum, transdermal patches) provide gradually decreasing doses of nicotine to decrease withdrawal symptoms during cessation. Both nicotine chewing gum and transdermal patches are approved by the FDA for the pharmacological treatment of nicotine dependence. Nicotine transdermal patches deliver a dose of nicotine that is absorbed through the patient's skin at constant intervals throughout the day. Nicotine chewing gum delivers a dose of nicotine that is absorbed via the patient's salivary glands. Additional oral methods of nicotine administration include sprays and inhalers, and these types of medications also address the need for oral stimulation that commonly accompanies sustained nicotine use (i.e., smoking, chewing). NIDA reports that success rates for nicotine cessation for patients who use nicotine replacement treatments vary widely across studies; however, research suggests that this method of pharmacological treatment is a safe means of helping patients discontinue nicotine use when used properly. In addition to nicotine replacement treatments, some patients find success with oral medications such as Wellbutrin and Zyban. These medications do not function as a nicotine replacement; however, they aid in decreasing nicotine cravings during cessation attempts.

Limitations and Future Directions

Although research on the effectiveness of existing pharmacological approaches to treatment has been mixed in some cases, the reported success of existing treatment strategies suggests that the development of pharmacological treatments for other drugs of abuse should be a focus of future research. Initial explorations into medications to treat cannabis dependence and stimulant dependence have been promising; however, this research is still in the experimental stages. NIDA reports that there are currently no medications approved by the FDA for treating addiction to cocaine, LSD, PCP, marijuana, methamphetamine and other stimulants, inhalants, or anabolic steroids. Currently, NIDA is promoting extensive research toward the development of pharmacological treatments for cocaine dependence. Clinical trials are currently under way for a cocaine vaccine developed by the Xenova Group, a British pharmaceutical company. Research conducted to date has yielded promising results with animals and humans, indicating that

the vaccine produces few side effects and appears to block the effects of cocaine.

Conclusion

Pharmacological approaches to treatment are particularly useful for detoxification and as part of comprehensive treatment strategies. In the case of opioid addiction, pharmacological treatments have been particularly effective and are widely utilized. Anticraving medications have been used for opioid and alcohol dependence. There are several different pharmacological approaches to the treatment of nicotine addiction. Unfortunately, no empirically validated pharmacological approaches have been developed for addiction to other drugs such as marijuana or stimulants.

PHYSIOLOGICAL ASPECTS OF DRUG USE

Mind-altering substances that may result in abuse and dependence are commonly subcategorized into central nervous system (CNS) stimulants (e.g., amphetamine, cocaine, nicotine), CNS depressants (e.g., barbiturates, anxiolytics, alcohol, cannabis), opioids (e.g., heroin, prescription pain medications), and hallucinogens (e.g., LSD, PCP). (It should be noted that cannabis, i.e., marijuana, is often discussed as a separate category.) In the following sections, each of these drug categories are discussed, including their mechanisms of action in the brain, the short-term and long-term physiological effects of abuse, withdrawal symptoms, potential genetic predisposition to abuse, and pharmacological treatments that may assist in their remediation.

Most drugs in the aforementioned categories cause an increase in the neurotransmitter dopamine, particularly within a brain structure called the nucleus accumbens, which is a part of the brain's reward system. Increased dopamine resulting from using these substances exceeds that which is present in response to naturally occurring positive environmental events. In substance dependence, dopamine mechanisms adapt in response to repeated drug use so that eventually the environmental stimulants that were previously pleasurable are no longer sufficient to maintain pleasurable mood states. Though dopamine remains the primary neurotransmitter implicated in drug abuse and dependence, other neurotransmitters are involved with various drugs and so are also briefly discussed.

CNS Stimulants

The physiological changes observed in response to CNS stimulants are characterized by sensorimotor activation in which alertness, arousal, and behavior are all amplified, including increased euphoria and insomnia and a decreased appetite. Methamphetamine is a specific type of amphetamine that is commonly abused and whose effects on the CNS are much stronger than those of other amphetamines. Methamphetamine is usually administered orally, smoked, snorted, or injected. In the brain, methamphetamine vastly increases the release of dopamine, thus causing an elevation in mood and behavioral arousal. As with

other amphetamine use, the physiological effects of methamphetamine use include decreased appetite, irregular heartbeat, hyperthermia, and an increase in blood pressure, heart rate, breathing, physical activity, and alertness. Though amphetamines may affect individuals in idiosyncratic ways to some extent, other less common effects of amphetamine use also may include disrupted sleep patterns, seizures, and violent behavior. Similarly, methamphetamine use may cause sleep abnormalities (i.e., insomnia), as well as confusion, anxiety, irritability, tremors and convulsions, cardiovascular irregularities, and in some instances death. Over a long period of time, chronic use of methamphetamine may result in aggressiveness, dental issues, and impaired cognition, as well as psychotic episodes characterized by paranoia, visual hallucinations, auditory hallucinations, tactile hallucinations, and delusions. There are currently no widely accepted pharmacological treatments for amphetamine and methamphetamine abuse.

Cocaine is another commonly abused CNS stimulant and may be administered intranasally (i.e., snorted), inhaled (i.e., smoked), or injected intravenously. Cocaine affects neurotransmitter activity in the brain in a number of ways. For instance, dopamine is typically released from the terminal button of a neuron into the synapse where it may later bind to a receptor site of another neuron, thus delivering a chemical message that assists in facilitating activity of that neuron. Dopamine that fails to connect with a receptor site is either eliminated as waste or absorbed back into the terminal button where it can be redistributed at a later time. Cocaine interferes with the latter part of this process by restricting dopamine from being able to be reabsorbed by the terminal button so that there is an excessive amount of dopamine that lingers in the synaptic gap. Cocaine also stimulates a rapid release of norepinephrine and serotonin, leading to relatively large amounts of norepinephrine in the synaptic gap. Both processes produce sympathomimetic effects (e.g., increased heart rate, narrowing of the blood vessels, increased blood pressure, dilated pupils, and increased body temperature) and euphoric effects (e.g., elevated mood, decreased fatigue, hyperstimulation, increased mental alertness). The length of time of these euphoric effects varies depending on the chosen route of administration of the drug, lasting 5 to 10 minutes when the drug is smoked, compared with up to 30 minutes when the drug is absorbed intranasally through snorting.

The subsequent depletion of neurotransmitters results in acute and sometimes long-term depressive effects. Another pattern in cocaine use is known as *cocaine binging* in which this substance is ingested repeatedly for extended periods of time with limited sleep. After the binge, the user may feel fatigued, depressed, anxious, and paranoid or evidence intense cravings for this substance. In more extreme cases, the binge can lead to a psychotic episode, complete with hallucinations and paranoid delusions. Long-term negative effects of cocaine abuse include increased risk of stroke, seizure, or heart attack; an irregularity in heart beat; damage to the heart, lungs, kidneys, and gastrointestinal system that can cause nausea and abdominal pain; respiratory problems; malnourishment; a deficit in the sense of smell; a constant runny nose; nosebleeds; difficulty swallowing; and a hoarse voice (resulting from recurrent snorting). At present, the Food and Drug Administration (FDA) has not approved any drugs for the pharmacological treatment of cocaine abuse, though the medications that affect the neurotransmitter GABA (e.g., baclofen, tiagabine, vigabatrin, and topiramate) and agonist replacement therapies (e.g., disulfiram, methylphenidate, and modafinil) show some promise in decreasing cocaine use. Buprenorphine may also be effective in decreasing cocaine use particularly for individuals who are addicted to both cocaine and opioids.

Nicotine is also a stimulant and one of the most commonly abused drugs in our society. One of the primary reinforcing effects of nicotine is rapid stimulation of the CNS followed by negative feelings of depressed mood and fatigue upon termination of use, which motivate future use. Nicotine is an acetylcholine agonist, and its use results in the physiological activation of the sympathetic nervous system, thus leading to the arousal symptoms associated with its use. Frequent use of nicotine via smoking results in a paradox of sorts. Over the course of the day, the user needs increasingly more nicotine to achieve the same stimulating effects. Overnight, however, tolerance that has built up is partially eliminated so that when the user wakes up in the morning, there is a strong craving for tobacco. The first cigarette of the day is often perceived as being the most exhilarating, probably because tolerance from the previous day is no longer present. The primary short-term effects of nicotine on the abuser are based on activation of various systems in the body and include increased heart rate, blood pressure, and metabolic rate; decreased appetite; and

enhanced cognition, especially in attention-related tasks. Long-term physical effects of abuse include the formation of stomach ulcers due to an increase in acid secretion in the stomach during use; an increased risk of chronic diarrhea and colitis as the result of increased muscle contractions of the bowel during use; a lower body weight than nonsmokers due to appetite suppression and increased metabolic rate, often resulting in significant weight gain when abusers drop the habit; an increased risk for cardiovascular disease, heart attacks, and strokes; an increased risk for respiratory disease (i.e., emphysema) and chronic bronchitis; and an increased risk for developing several different types of cancer. Current approved treatments for nicotine abuse include nicotine chewing gum, the nicotine transdermal patch, and the atypical antidepressant bupropion (trade name Zyban). Bupropion is a nicotinic antagonist and inhibits the reuptake of norepinephrine and dopamine.

CNS Depressants

CNS depressants are so identified because of their depressant effects on the nervous system and on behavior. These depressive effects result in a feeling of intoxication and euphoria without the stimulating effects caused by drugs such as methamphetamine and cocaine. This class of drugs includes sedative-hypnotic drugs (i.e., barbiturates), as well as alcohol, benzodiazepines (such as Xanax, Valium, Librium, and Ativan), and sometimes, cannabis.

Alcohol is the most commonly used CNS depressant. Because of its widespread use, the physiological and other effects of alcohol have been extensively investigated. The physiological effects of alcohol are caused by its impact on multiple types of neurotransmitters, namely GABA, glutamate, and dopamine. The depressant effects of alcohol lead to general relaxation, a decrease in social inhibition and judgment, overconfidence, a decrease in coordination and slurring of speech, impairment of fine-motor skills, delayed reaction time, and increased drowsiness. The next-day effects often include nausea and headaches (i.e., hang-over) that are exacerbated by dehydration. At higher doses, or when used in combination with other depressants, alcohol can lead to extreme depression of the CNS, resulting in greatly diminished heart rate and blood pressure, a drop in body temperature, respiratory failure, confusion, and a possible blackout in which the individual will have little or no memory of

the events that took place while he or she was intoxicated. Tolerance occurs with repeated and extended alcohol use and can lead to withdrawal symptoms, including nervousness, excessive perspiration, tremors, nausea, vomiting, abdominal pain, loss of appetite, irritability, confusion, seizures, hallucinations, chills, headaches, a craving for alcohol, depression, asthenia (physical weakness), agitation, and disturbances in sleep. Although alcohol intoxication results in increased confusion and deficits in judgment in the common user, one who abuses alcohol will, over time, experience deficits in verbal learning, memory, visuospatial abilities, visual memory, thought and movement (psychomotor functioning), and abstract thinking. In some extreme cases, heavy users may develop Korsakoff's syndrome, which occurs as a result of malnutrition and a depletion of the body's store of the vitamin thiamin. Malnourishment commonly results from periods of extended and heavy alcohol use during which food consumption is substantially diminished. The syndrome is marked by apathy, a lack of insight, and amnesia. In addition to effects on the brain, alcohol affects multiple organ systems, with the liver being a primary target of its toxic effects. It should also be noted that although there seems to be some genetic predisposition to various forms of drug abuse, genetic influences are particularly strong for alcohol use disorders, with genetic factors accounting for between 50% and 60% of the risk for alcohol dependence and approximately 40% of the risk for abuse. Pharmacological treatment for alcoholism includes disulfiram (Antabuse), which is a drug that interferes with the breakdown of alcohol in the body, resulting in feelings of sickness, nausea, and vomiting when alcohol is ingested. Other drugs currently used to treat alcoholism include acamprosate and naltrexone. Acamprosate has been shown to help decrease the intake of alcohol. Naltrexone, which is an opioid receptor antagonist, has been proven to aid in the maintenance of abstinence.

The sedative-hypnotics (i.e., barbiturates) and anxiolytics (drugs such as benzodiazepines prescribed to treat anxiety) are prescription medications that are subsequently misused by some of those who take them. Such drugs enhance the activity of the neurotransmitter GABA, which is a major inhibitory neurotransmitter in the brain, thus leading to an overall depression of the CNS. Use causes slurred speech, euphoria, disinhibition, and a decrease in both cognitive

and motor functioning. Higher doses of these drugs can lead to psychotic experiences such as hallucinations and paranoia, sedation, and severe coordination problems (known as ataxia). Extremely high doses can lead to a decrease in heart rate and respiratory functions that can lead to coma or death. Tolerance develops to these drugs, leading to withdrawal symptoms that may include restlessness, insomnia, increased levels of anxiety, convulsions, and possibly even death. Heavy, recurrent users may eventually suffer from impairments in coordinated movement. There are no pharmacological treatments currently approved by the FDA for addiction to these drugs, although anxiolytic medications may assist in decreasing anxiety that often triggers substance use. With regard to treatment, it is also important to note that delirium tremens (DTs) can occur during withdrawal from CNS depressants. Because DTs can prove fatal without proper medical management, they are of particular concern to this class of drugs and require medical management. DTs occur in individuals who have a pattern of heavy and chronic use of CNS depressants as a result of the reversal of their sedating effects on neurotransmitter activity in the brain, which causes the brain to become overly excitable. Confusion, disorientation, and agitation are common symptoms, but cardiovascular symptoms (e.g., heart palpitations and tachycardia, increased blood pressure), psychotic symptoms (e.g., paranoia and hallucinations), and seizures can also occur. Benzodiazepines are often administered during withdrawal in order to prevent DTs.

Cannabis, more often known as marijuana, is sometimes classified as a CNS depressant, though it does not neatly fit into this category because it shares a number of features with hallucinogens. It can be administered orally or via smoking, although by far the most common form of administration is through smoking. Delta-9-tetrahydrocannabinol (THC) is the psychoactive substance found in cannabis. Once THC has entered the body, it can decrease the activity of the neurotransmitter acetylcholine, especially in a brain structure called the hippocampus, while simultaneously causing an increase in the release of the neurotransmitter serotonin. THC binds to certain cells in the brain, jump-starting a series of cellular reactions that culminate in the experienced high. The short-term effects of marijuana, which are experienced once one reaches the stage known as being *stoned*, include a calm, relaxed feeling (often described as being in a dreamlike state), sensations of

floating, visual hallucinations, enhanced auditory perception, and a subjective feeling of time passing extremely slowly. Physiological effects include increased heart rate, increased hunger (leading to the “munchies”), and increased blood flow to the skin (leading to a feeling of being flushed). Heavy use is occasionally accompanied by delirium, personality disturbances, and feelings of anxiety, panic, or paranoia. Tolerance does develop in some users, leading to withdrawal symptoms that may include irritability, increased anxiety, a depressed mood, increased aggressiveness, a decrease in appetite, and disturbances in sleep. However, tolerance and withdrawal are rare and typically occur only after very heavy and prolonged use. Possible long-term effects of heavy and repeated use include an increased risk for bronchitis, suppression of the immune system, reduced birthweight in infants when there is heavy maternal use, and an increased risk of cardiovascular events in those with hypertension or clogged arteries. There are currently no FDA approved pharmacological treatments of marijuana addiction.

Opioids

This drug class includes substances that are (a) derived from the naturally occurring alkaloids found in the opium poppy, such as codeine and morphine; (b) semisynthetic substances that are synthesized from natural opioids such as diacetylmorphine (heroin), hydrocodone (Vicodin), oxycodone (OxyContin), and hydromorphone (Dilaudid); and (c) fully synthetic drugs such as methadone, levo-alpha acetyl methadol (LAAM), and meperidine (Pethidine). These drugs can be injected, snorted, inhaled, or swallowed. They are often referred to as narcotics and produce their effects by binding to opioid receptors in the CNS and also by increasing the amount of dopamine in the reward centers of the brain. In their semisynthetic and synthetic forms, most are commonly used for pain relief, and many were developed for this purpose. Some are also used as treatments or replacement therapies for those who have become addicted to opioids (e.g., methadone and LAAM). Because some of these drugs cause intense feelings of euphoria when ingested, they also have a high potential for abuse and addiction. Heroin is a widely abused drug in this classification. The effects of heroin are felt almost immediately upon administration and include a “rush” in which euphoria is experienced very quickly, along

with a flushed feeling, a dry mouth, and a feeling that the extremities are heavier than normal. As the user comes back down from the drug, he or she fluctuates between being awake and asleep (known as being *on the nod*) and mental functioning decreases. Other short-term effects of use may include an overdose (which may lead to death), and an increased risk of contracting infectious diseases due to shared needles. The long-term effects of repeated heavy use include infections of the heart, cellulitis (an infection of the skin), disease of the liver, collapsed veins, and respiratory difficulties. Heroin is a highly addictive drug, and withdrawal symptoms often include intense drug cravings, diarrhea, vomiting, sleep disturbances, muscle and bone pain, and cold flashes. Replacement therapies for opioid dependence include methadone and buprenorphine, both of which are synthetic opioids. The opioid receptor antagonists naloxone and naltrexone, which block the effects of opioids, are also effective for treating those who have overdosed on opioids and may also decrease opioid relapse by decreasing cravings and relieving withdrawal symptoms.

Hallucinogens

The most well-known hallucinogens include lysergic acid diethylamide (LSD) and phencyclidine (PCP), although mescaline and psilocybin are also commonly abused. PCP is usually found in either powdered or pill form and can be taken orally, snorted, or injected into either the veins or the muscles. PCP, in combination with such drugs as tobacco and marijuana, can also be smoked. Once taken, PCP causes a disruption of glutamate and an increased release of dopamine in the brain, specifically in the prefrontal cortex. Individuals on PCP often feel a sense of detachment from the body, as well as sensations of numbness and of floating and sometimes of a dream-like state. Compared with the other hallucinogens, PCP is likely to cause “bad trips” and to result in violence on the part of the user.

LSD is a hallucinogen that exerts its effects by disrupting the neurotransmitter serotonin. An LSD high is characterized by visual hallucinations, a sense of euphoria, increased alertness, an increase in perception, a sense of derealization (the world does not seem real), and an increased tendency to laugh. The physiological effects of the drug include increased heart rate, sweating, a dilation of the pupils, a feeling of nausea,

a loss of appetite, insomnia, dry mouth, and tremors. A third commonly used hallucinogenic is MDMA, better known as *ecstasy*. MDMA stimulates the release of dopamine in the brain, resulting in a mild euphoric experience for the user that is characterized by increased energy levels, increased self-esteem, enhanced sensory perception, and a craving for social interaction (sometimes accompanied by increased sexual arousal). Physiological effects of the drug include increased heart rate, increased body temperature, increased blood pressure, sweating, salivation, tremors, and trismus (a repeated tightening of the jaw muscles) and teeth grinding.

Mescaline is a drug whose structure closely resembles that of amphetamine, but whose effects are like those of LSD in that it causes visual hallucinations. Psilocybin is a hallucinogenic drug that is found in psilocybin mushrooms, commonly known as *magic mushrooms* or *shrooms*. Like LSD, the hallucinogenic effects of psilocybin are due to its mimicking effects of the neurotransmitter serotonin. Its experiential effects resemble also those of LSD.

The long-term effects of these drugs seem to be neuropsychological deficits in various realms as evidenced by performance on neuropsychological tests. Withdrawal symptoms such as depression (PCP) and fatigue, difficulty concentrating, a loss of appetite, and depressed feelings (MDMA) may be experienced. There are typically no withdrawal effects for those who abuse LSD. There are currently no pharmacological treatments for abuse of these drugs.

Conclusion

Although the physiological and psychological effects of many drugs are pleasurable, abuse of these drugs is associated with both short- and long-term negative effects. These negative effects vary by drug, but include and range from addiction to an increased risk of cancer to death. Many also have unpleasant withdrawal symptoms that can often be either reduced or eliminated with appropriate medical interventions. In addition, a number of pharmacological interventions have been developed to treat addiction to these drugs, although continued research is necessary as there are many substances for which pharmacological interventions are absent.

POST-TRAUMATIC STRESS DISORDER

There is an ongoing active and necessary debate in the literature related to the relationship between substance use disorders (SUDs) and post-traumatic stress disorder (PTSD). Certainly, a link between the two has been established with some confidence, but a strict cause-and-effect association has not been established due to the lack of controlled studies. However, several quasi-experimental studies have been published that suggest a strong correlation between SUDs and PTSD. Indeed, some authors suggest that over half of those individuals seeking counseling for a SUD have experienced some level of traumatic exposure in their past, and upwards of three quarters of female addicts seeking counseling can be identified as having had serious traumatic exposures in their pasts.

History and Prevalence

PTSD as a psychiatric diagnosis was first described for veterans who were thought to be suffering from a stress condition as a result of witnessing horrific events. Historically, these stress conditions have been known by a wide selection of terms—for example, *soldier's heart* (a term coined after the U.S. Civil War), *shell shock* (a term coined after World War I), or *combat fatigue* (a term coined after World War II). The underlying condition relevant to all of these conditions was that some soldiers experienced uncomfortable and often debilitating levels of anxiety and ongoing stress resulting from recurrent memories of

their combat experiences. The widespread and heavily publicized experiences of veterans of the Vietnam War brought this disorder to the forefront. However, the name for the condition known today as PTSD was not officially coined until the publication of the third iteration of the *Diagnostic and Statistical Manual of Mental Disorders* by the American Psychiatric Association in 1980. Diagnosis of the disorder has ventured far from combat-related trauma, however, and has been generalized to include essentially any potentially debilitating traumatic exposure.

Estimates vary dramatically as to the number of people who currently suffer from PTSD or who are likely to be diagnosed in their lifetime. Lisa Najavits, a well-known scholar in this area, has stated that over 60% of men will experience trauma in their lifetimes and that about 5% will develop PTSD; over 50% of women will experience trauma during their lives and about 10% will develop PTSD. In terms of the population in SUD treatment programs, between 30% and 60% of women and between 10% and 40% of men could be or are diagnosed with PTSD. This makes PTSD-SUD one of the most common dual diagnoses found in alcohol and other drug treatment settings.

Symptomatology and Diagnosis

Individuals with PTSD have a variety of symptoms that can be generalized into three categories. These categories are (1) *hyperarousal*—generally, this means being on edge and can result in problems with sleep, exaggerations in physiological responses, and problems with concentration; (2) *reexperiencing*—this is often associated with nightmares and flashbacks of traumatic experiences and can occur through direct exposure to a circumstance similar to the original trauma or through proxy exposure to a perceived traumatic trigger; and (3) *psychological numbing*—this is often seen as detachment, as efforts to avoid certain situations or certain people, and changes to affective range (i.e., a generalized and reduced range of appropriate emotional expression). It often appears to observers that someone is like a blank wall. The obvious result of experiencing any or all of these symptoms is lower functioning and a decreased ability to hold a job, have meaningful and productive relationships, and perform in appropriate social roles.

In a more general sense, it is instructive to consider the four major facets of stress responses. These include the following:

- (1) *physical*—feeling fatigued, having a lack of hunger, or sleeplessness. This reaction highlights the importance of ruling out a major depressive disorder and dysthymia, both of which share common physical features often seen in those diagnosed with PTSD;
- (2) *cognitive*—reliving traumatic incidents or having intrusive thoughts related to the traumatic exposure;
- (3) *emotional*—having depressive feelings, anxiety reactions, or unexplained feelings of anger; and
- (4) *behavioral*—withdrawal or acting-out behaviors such as substance use, domestic violence, and/or general aggressive behaviors.

Any combination of PTSD symptoms and stress responses can occur, with the most difficult-to-treat cases being those where PTSD and SUDs are found in combination.

Additional Diagnostic Considerations

Two additional traumatic stress syndromes should also be mentioned, though they are not currently diagnosable disorders. What has been referred to as *secondary PTSD* has been used to describe those who are consistently exposed to someone with PTSD. As an example, the wife of a combat veteran who suffers from PTSD may develop her own mechanisms to deal with the perpetual stress resulting from her husband's condition. As a result, she may develop behaviors such as numbing (e.g., acting detached around her husband when she detects a certain mood) or hypervigilance (e.g., having an exaggerated startle response as if she is walking on eggshells) that greatly affect her own functioning. In other words, by direct exposure to someone suffering from the disorder, she develops PTSD-like symptoms by indirect exposure to the traumatic event.

A second disorder, *complex PTSD*, is currently under consideration as a diagnosable disorder. What separates this disorder from PTSD is that it results from exposure to prolonged interpersonal trauma that leads to a diminished sense of safety, decrease in trust, and demoralization. Due to the resulting changes in self-perception, helplessness and shame increase in victims, and therefore, revictimization is often the result. One may see, for example, that someone who grew up in a household in which he or she witnessed severe domestic violence is being revictimized because

she or he has been in a series of relationships in which domestic violence occurs. Examples of complex traumas include severe neglect, domestic violence, chronic maltreatment, torture, and prolonged solitary confinement in prisons.

Common Precursors to Stress Disorders

Traumatic experiences commonly reported in a treatment setting include combat, severe neglect, sexual and/or physical assault, natural disasters, and near death experiences. Other traumas that have been suggested to be related to PTSD are incarceration, surviving a chronic illness such as cancer, and even LSD flashbacks. Diagnostically, PTSD requires onset of symptoms lasting for longer than 1 month or having symptom onset for the first time at least 6 months after the traumatic experience. Prior to meeting the time required for diagnosis as PTSD, individuals can be diagnosed with acute stress disorder if symptoms develop within the first month after traumatic exposure.

Connecting PTSD and SUDs

SUDs among those suffering from PTSD and other significant traumas are broadly found in the literature. In addition, comorbidity of PTSD and SUDs is well known by clinicians who often provide treatment for those suffering from SUDs, only to discover as treatment progresses that a traumatic experience triggered self-destructive behaviors. Or clinicians work with patients suffering from PTSD who use mind-altering substances as a coping mechanism. Research has suggested that comorbid PTSD and SUDs are often linked to poorer treatment outcomes, though much of this outcome research involves alcohol-use disorders. For example, Jennifer Read, Pamela Brown, and Christopher Kahler found that those who use alcohol report higher levels of reexperiencing PTSD symptoms and that those patients who had PTSD who were in remission had better SUD treatment outcomes. These results are important because they suggest that substance use can aggravate (or potentially be a causative factor for) PTSD symptomatology and that PTSD, when not treated or controlled, leads to poor treatment outcomes for SUD treatment.

Lisa Najavits described several patterns of PTSD-SUDs commonly seen in treatment settings. These include (a) PTSD leading to SUDs in which substances

are used as a way to self-medicate the pain associated with the traumatic experience, (b) SUDs leading to PTSD such that the use of drugs results in a traumatic experience (e.g., date rape), and (c) co-occurrence of PTSD and SUDs (e.g., domestic violence during a drinking episode). Ultimately, any of these patterns can result in a quick and dramatic downward spiral that is both extraordinarily dangerous and difficult to treat.

Examples and At-Risk Groups

Trauma and substance use co-occurrence has been examined extensively for certain populations. Research on the homeless population, for example, often links unresolved past trauma with current SUDs and hence to the profound situational difficulties experienced by this population. Of particular interest is the link between domestic violence and PTSD symptoms, which has been reported in more than 90% of the homeless female population. Co-occurrence of PTSD-SUDs in the homeless population has been estimated to be between 30% and 65%, with treatment outcomes being particularly poor owing to unhealthy environmental conditions and lack of funding for treatment.

Domestic violence, for both the victims and their children, can lead to a variety of PTSD-SUD issues and problems. It is not uncommon for drugs and alcohol to be named as precursors to violence in the home. Indeed, more than 70% of those arrested for domestic violence test positive for alcohol or other drugs. Often, both the victim and perpetrator will test positive. Children witnessing domestic violence often develop PTSD-like symptoms (e.g., complex PTSD) that can lead to risky behaviors such as substance use and abuse later in life. Unfortunately, those with PTSD often use alcohol and other dangerous drugs (e.g., cocaine, methamphetamine, and opioids) on a frequent or chronic basis.

First responders and emergency personnel are groups that have been increasingly studied for PTSD and SUDs. Substance use among police officers is an ever growing concern. The sometimes daily traumatic experiences by officers of the law often result in stress-disorder responses that can lead to substance abuse and dependence as a coping strategy. It has been estimated, for example, that more than 50% of male officers and more than 40% of female officers consume excessive amounts of alcohol on a regular basis. Nurses and physicians also have relatively high rates of SUDs as a result of consistent traumatic exposure. Indeed, use of substances by emergency room nurses is 3.5 times

higher than by nurses of other specialties. Rescue workers such as EMTs and firefighters also develop stress disorder-SUD problems. One study on firefighters indicated that nearly 20% met the diagnostic criteria for PTSD, and some 30% experience problems with alcohol. Studies of rescue workers after large disasters, such as the Oklahoma City bombing and the World Trade Center attack, have been extensively studied, with the common theme being dramatic increases in stress responses and substance abuse.

Traumatic experiences do not always lead simply to a PTSD-SUD relationship. Research indicates that impulse and behavioral disorders also increase with PTSD. These include problem gambling and any number of behavioral addictions (e.g., sexual addiction). Impulse control problems can also contribute to the development of SUDs, which may in turn lead to potentially severe problems in those suffering from PTSD.

Conclusion

Nearly everyone is exposed to a traumatic event at some point in their lives, and an alarming number of people are exposed to multiple or continuous traumatic events and stressors. It remains unclear why some who are exposed do not develop any clear or lasting symptoms, whereas others develop acute or chronic symptoms that are debilitating. Research is beginning to examine this phenomenon, and hopefully much will be learned that will guide professionals in the prevention and treatment of those suffering from trauma-related disorders. Recent research has also begun to highlight the important relationship between trauma and substance use. Given this relationship, practitioners should always remain mindful of the fact that treatment and assessment for trauma must include an assessment for substance use and that severe and persistent substance use may be related to past traumatic events.

PRESCRIPTION DRUGS

The abuse of prescription drugs has increased significantly, with the number of Americans who report abusing controlled prescription drugs more than doubling from 7.8 million to 16.3 million from 1992 to 2006. Examples of commonly used and abused prescription drugs include but are not limited to benzodiazepines (e.g., diazepam [Valium], clonazepam [Klonopin]), stimulants (e.g., methylphenidate [Ritalin], d-amphetamine), opioids (e.g., oxycodone, hydrocodone), and barbiturates (e.g., pentobarbital). In its 2007 report, the International Narcotics Control Board reported that the abuse and trafficking of prescription drugs is set to exceed other illicit drugs. The board noted that medications containing narcotic drugs and/or psychotropic substances have become a drug of first choice for many individuals, rather than being used as a substitute for the more conventional illicit drugs such as cocaine and heroin. This report also noted that many prescription drugs can produce effects similar to illicit drugs when taken in inappropriate quantities and without medical supervision.

Although abuse of prescription drugs has increased in general, the rise has been particularly striking among prescription opioids. As noted in a

comprehensive 2003 review by James Zacny and colleagues from the College on Problems of Drug Dependence, data from the 2001 National Survey on Drug Abuse show that, out of a large number of different psychotherapeutic drug classes, opioids are the class with the greatest nonmedical use, abuse, and dependence. Examples of prescription opioids include morphine (both immediate-release and sustained release, e.g., MS-Contin), levorphanol (Levo-Dromoran), methadone, codeine (opioid constituent in Tylenol-3), hydrocodone (opioid constituent in Vicodin, Lortab), oxycodone (opioid constituent in Percodan, OxyContin), propoxyphene (opioid constituent in Darvon), fentanyl (Duragesic), and hydro-morphone (Dilaudid). These drugs generally are categorized as opioid analgesics, are typically prescribed for the treatment of acute or chronic pain, and are usually ingested orally in pill form. When used appropriately, these medications can be extremely effective in the medical management of pain, and the vast majority of patients receiving prescription opioids for pain management do not develop problematic or excessive use of the medications. However, like other opioid agonists, such as morphine and heroin, prescription opioid pills can be abused. In addition to oral administration, for example, many of these drugs can be crushed and self-administered via injection, inhalation, or snorting.

Opioid Effects

Most of these opioids, regardless of whether they are licit or illicit, primarily bind to the mu-opioid receptors in the nucleus accumbens in the brain and produce an increase in the concentration of dopamine. Effects of prescription opioids are similar to those seen with the larger class of opioid drugs (e.g., heroin) and include analgesia, drowsiness, euphoria, constipation, pupil constriction, clouding of mental function, and depression of the central nervous system and of cardiac activity at high doses. When opioid overdoses occur, they typically result from the respiratory-suppressing effects of opioids. In general, the severity or intensity of opioid effects depends mainly upon the amount or dose of drug and route of administration used.

With repeated use of any opioid, physiological tolerance may develop. Tolerance is typically identified by diminished sensitivity to the drug. For example, it eventually takes a larger amount of the drug to achieve the same effects that were experienced early on. High

levels of tolerance can develop for the respiratory depression, analgesia, sedation, and euphoric effects of opioids. In contrast, little tolerance develops for the pupil constriction or constipation typically seen following opioid administration.

Once an individual becomes physically dependent on opioids, withdrawal will likely occur following a period of drug abstinence. Opioid withdrawal typically begins at the time of the next habitual dose (typically 6–12 hours after last use). The severity and time course of withdrawal is influenced by the type, amount, and formulation of the opioid being used. In general, opioid withdrawal typically peaks in 24 to 48 hours following the last dose, and symptoms include intense craving, tearing eyes, runny nose, yawning, sweating, insomnia, dilated pupils, gooseflesh, irritability, tremor, chills, vomiting, and diarrhea. Although opioid withdrawal symptoms can be extremely uncomfortable and distressing, they are not typically considered life threatening.

Problems Associated With Prescription Opioid Abuse

A whole host of adverse consequences are commonly seen with abuse of prescription opioids, and these adverse effects tend to be the same as those typically associated with opioid dependence in general. Serious health consequences are associated with abuse of prescription opioid drugs, including risk for overdose and hospitalization. Prescription opioid abuse also is associated with extensive use of drugs other than opioids (e.g., alcohol, nicotine, marijuana, cocaine), as well as with an increased involvement in criminal activity. Prescription opioid abusers are also at an elevated risk for contracting or transmitting hepatitis and HIV and for experiencing numerous other medical, employment, legal, financial, and family/social problems.

Prevalence of Prescription Opioid Abuse

The National Survey on Drug Use and Health found that the incidence of nonmedical use of prescription opioids increased by more than 300%, from 628,000 initiates in 1990 to 2.15 million in 2006. About one third of these first-time users were adolescents (ages 12–17). The annual Monitoring the Future survey also provides evidence of increases in prescription opioid abuse among adolescents, with past 30-day nonmedical

use of prescription opioids increasing by over 300% among 12th graders from 1991 to 2007. Prevalence of prescription opioid abuse has tended to be evenly divided by gender, though much still remains unknown about the demographic characteristics of this emerging population.

The alarming increase in prescription opioid abuse is also evident in data from the 2003 Drug Abuse Warning Network report, which documents mentions of specific drugs during emergency department visits. Although emergency department mentions of prescription drugs in general increased by 17% between 1994 and 2002, mentions of prescription opioids increased by 408% during that same period. Among the prescription opioids, specific emergency department mentions of oxycodone and hydrocodone during this period increased by 450% and 170%, respectively.

This rise in prescription opioid abuse and the associated adverse consequences have been followed by sharp increases in the number of individuals seeking treatment for prescription opioid abuse. A 2004 report from the Treatment Episode Data Set, which compiles data on the demographic and drug use characteristics of individuals admitted for substance abuse treatment throughout the United States, indicates that the number of yearly admissions for primary prescription opioid abuse increased by 350% between 1992 and 2002. Of the 40 states that provided data on treatment admissions for 2001, 83% of them reported a significant increase in admissions for prescription opioid abuse.

Treatment of Prescription Opioid Abuse

The striking increase in prescription opioid abuse, along with its associated serious consequences, underscores the importance of efforts to identify and develop effective interventions for prescription opioid abuse. Thus far, there have been no published controlled studies on treatments for prescription opioid abuse. Numerous clinical research trials are currently under way to explore the important components for an effective intervention. Although the most appropriate and effective treatment has not yet been identified, it seems reasonable to expect that treatments for prescription opioid abuse will probably involve some form of opioid detoxification or maintenance using one or more pharmacotherapies currently used in the United States for opioid dependence.

Four medications are approved for the treatment of opioid dependence. Naltrexone was approved by the Food and Drug Administration in 1984. Naltrexone is a long-acting competitive opioid antagonist that, when taken regularly in sufficient doses, can block the reinforcing effects of opioids and markedly diminish or eliminate opioid self-administration. The ability of naltrexone to block the reinforcing effects of opioids can provide protection for patients should they have a brief lapse to opioid use. That is, a sufficient naltrexone dose will prevent subjects from experiencing the euphoric effects typically associated with opioid self-administration, thereby reducing the chance that an isolated slip will become a full relapse. Although clearly shown to be pharmacologically effective in blocking opioid effects, there is often a high dropout rate and compliance problems with naltrexone therapy since the medication does not provide any reinforcing effects on its own. Typically, additional behavioral and psychosocial services are needed to help enhance patient compliance with this treatment.

In terms of opioid agonists, there are three medications that have been approved for use in the treatment of opioid dependence. Methadone is a full opioid agonist and is the most widely used intervention for opioid dependence. Methadone has been used for the treatment of opioid dependence since the mid-1960s and is typically administered orally in liquid form. It functions as a mild reinforcer while suppressing opioid withdrawal for up to 24 hours, so compliance with methadone ingestion is usually not as problematic as with opioid antagonist therapies like naltrexone. Methadone also blocks effects of other opioids, so patients receiving a sufficient dose of methadone will typically stop using other, illicit opioid drugs. In addition to promoting abstinence from illicit opioids, methadone treatment has also been associated with reductions in patients' use of nonopioid drugs (e.g., cocaine, benzodiazepines), in the frequency of drug injections and other high-risk behaviors for contracting HIV, and in many of the other adverse consequences associated with illicit opioid abuse (e.g., criminal activity, social-family problems, employment-financial consequences, medical-health problems).

LAAM (levo-alpha acetyl methadol) is a full mu-opioid agonist that was approved by the Food and Drug Administration in 1993. Although LAAM is longer acting relative to methadone and has been

shown to be effective, it is infrequently used by treatment clinics due largely to regulatory barriers in some states, its higher cost relative to methadone, and some concerns regarding safety.

Buprenorphine is a partial opioid agonist that was approved in 2002 for use in the treatment of opioid dependence in the United States. The medication is typically administered sublingually in tablet form. Unlike methadone, which is only available for opioid treatment in clinics licensed to administer this drug, buprenorphine is available under less rigid regulations and can be provided by certified physicians in office-based medical settings throughout the country. Buprenorphine also has several features that support its use in treating opioid dependence. Like methadone, sufficient maintenance doses of buprenorphine block the effects of other opioids, thereby reducing illicit opioid use during buprenorphine treatment. Buprenorphine also has a ceiling on its agonist activity that may limit its abuse liability and improve its safety profile. Unlike methadone, it also has the potential to be administered less often than daily, though a daily regimen is still most typical in office-based treatment settings. Finally, buprenorphine is associated with a relatively limited withdrawal upon discontinuation of dosing, which also suggests that it may be a good candidate for use in detoxification treatments for opioid-dependent patients.

Although the exact features of opioid treatment are not yet clear for treating prescription opioid abuse, it does appear that most abusers are physically dependent upon opioids and therefore will likely need to receive some form of detoxification or maintenance using an opioid agonist medication. It is also possible that prescription opioid abusers may be good candidates for eventual transition to an opioid antagonist therapy, such as naltrexone. Finally, it is important to note that, in addition to the above pharmacotherapies for treating prescription opioid abuse, any outcome is likely to be enhanced by the addition of ancillary psychosocial or behavioral counseling and other sources of support.

Conclusion

The abuse of prescription drugs has become a serious public health concern in the United States. Prevalence of prescription opioid abuse, in particular, has increased at a striking rate and is associated with a whole host of adverse consequences, including medical, financial, psychosocial, and general societal problems. Future scientific and clinical efforts will be important to fully

characterize the population of prescription opioid abusers and to develop effective treatments for prescription opioid abuse. It will also be critical to learn more about the abuse liability of the various opioid medications currently available and to explore potential strategies for reducing and preventing the abuse of these medications. Development of such strategies will help protect the future availability of use of prescription opioids in the appropriate treatment of pain and other medical issues while minimizing the potential for abuse of prescription opioid drugs.

PREVENTION EDUCATION

Prevention education has a long-standing history in the United States, with a variety of programs created over the years that cater to youth at different age ranges. The Center for Substance Abuse Prevention offers a wide variety of prevention tools for children at different age ranges as well as tips for parents and teachers on educating children about alcohol and other drugs. Also offered are gender- and ethnic-specific prevention programs targeting young girls and Spanish-speaking children. The majority of literature on prevention suggests that it is best to start young with children and offer them prevention education throughout multiple stages of their lives. The majority of prevention programs currently in practice in the United States are based on research and literature from the National Institute on Drug Abuse (NIDA), which identifies risk and protective factors associated with children and principles and application of prevention strategies.

NIDA

According to NIDA, there are several factors that parents and educators should be aware of when considering prevention education. Children face risk factors that differ based on age and that can contribute to drug use or other delinquent behavior. According to NIDA, the more risk factors a child is exposed to while growing up, the more likely it is that he or she will use drugs. However, protective factors are also associated with childhood drug use. These factors serve the opposite function of risk factors in that they serve to protect a child against risk factors and drug use. According to NIDA, risk factors that parents and educators should be aware of include poverty, early aggressive behavior, drug availability, lack of parental supervision, and peer pressure. These risk factors that children experience at different points in their lives can be changed through prevention intervention and education so that they do not cause further drug use or delinquent behavior. NIDA also identifies several protective factors that children develop. These protective factors include self-control, neighborhood attachment, parental monitoring, and academic competence. The risk and protective factors occur in five domains: the individual domain, the family domain, the community domain, the peer domain, and the school domain.

NIDA's Research-Based Prevention Programs

NIDA offers several research-based programs aimed at preventing drug abuse among adolescents. Such programs include the Caring School Community Program, which is geared toward elementary school children in an effort to reduce risk factors associated with drug use and to strengthen protective factors by developing their sense of connection to school. The Life Skills Training (LST) Program is geared toward middle school students in an effort to teach personal skills, social skills, and drug abuse resistant techniques. Project ALERT has elementary school, middle school, and high school components aimed at reducing drug use among children and adolescents by helping children retain prevention information learned early on so that they are able to apply this knowledge through their teenage years. NIDA divides these and all of their other research-based prevention programs into three types: universal programs for all school-age students, selective programs that target specific groups of individuals, and indicated programs that target individuals who have already begun using drugs.

Center for Substance Abuse Prevention (CSAP)

CSAP offers many prevention education programs that target different youths depending on age, gender, and ethnicity. One such program is Building Blocks for a Healthy Future, which offers resources for children, parents, and educators in an effort to prepare children for a drug-free lifestyle. This program is designed for children ages 3 to 6 in hopes of providing them with a foundation so that they are comfortable talking with parents and educators about drugs, alcohol, tobacco, and other sensitive issues that they will encounter while growing up. With a goal of enhancing the protective factors that contribute to a drug-free and safe lifestyle, the program also aims at reducing risk factors for young children.

A second program is Girl Power, aimed at motivating females ages 9 to 13 by focusing on the unique needs and interests of young girls. This program also offers current statistics on females and drug use, depression, suicide, physical activity, and school violence and is based on research suggesting that prevention education may be more effective when it focuses on the gender-specific needs of children. Another program targeting a

specific group is *Hablemos en Confianza*, which targets Spanish-speaking individuals to encourage dialogue between children and their parents about the risks associated with drug use.

CSAP also offers a comprehensive school-based alcohol prevention program called *Reach Out Now*. This program is designed to offer school materials for Alcohol Awareness Month in April and is specifically designed for and geared toward the education of fifth and sixth grade students. It focuses on teaching students how alcohol affects the body, teaching them alternatives to using alcohol, and developing alcohol prevention messages that students can use if faced with peer pressure to drink.

to be used by interested persons for the purposes of program improvement and program assessment. Evaluation serves many purposes, including demonstrating accountability, educating constituents, documenting program components and results, involving stakeholders (key personnel), gaining community support, promoting public relations, and fulfilling agency-funding requirements. Evaluation does not make conclusions about the value of a program, nor of the people involved in the program. It provides information for program improvement and, in many cases, justification for ongoing funding. Although substance abuse prevention theory and practice have evolved, the political context has seen an increase in demands for results (as contrasted with effort) from Congress and other funding sources. The questions often raised include the following: “What results have been achieved with the dollars invested?” or “What evidence is there that what you are doing (or propose to do) will work?” Prevention evaluation is critically important in substance abuse prevention efforts and in all programs designed to reduce the risks for the development of problem behaviors among young people.

Levels of Evaluation and Results

Although textbook definitions and titles may vary, there are three levels or types of prevention evaluation. A comprehensive evaluation includes impact, outcome, and process evaluation. These three levels directly correlate with program goals, objectives, and activities. Impact evaluation involves the long-term, global effects of the program and will include incidence and prevalence data as well as risk and protective factor data. Outcome evaluation describes the immediate or direct effects of the program strategies and includes data on knowledge, awareness, attitudes, and skills. Process evaluation includes any combination of measurements obtained during the implementation of program activities to control, assure, or improve the quality of performance or delivery of strategies that are implemented to achieve established goals and objectives. Data collected will include a description of appropriate educational and other activities, numbers served by the program, participant satisfaction with the activities, and the actual planning process by the sponsors.

PREVENTION EVALUATION

Evaluation is an essential part of any complete prevention program development and implementation model. It is an integral part of program planning and should not be considered an afterthought. Evaluation is a systematic process of obtaining credible information

Evaluation Design

Evaluators or program staff must determine an evaluation design or plan with regard to the time, resources (financial and personnel), population, and setting. Consideration must be given to the type of data (qualitative or quantitative) that is necessary, as well as to what exactly is being evaluated (the variables). Finally, a determination must be made by the evaluator or staff regarding the final audience to receive the evaluation results (e.g., community stakeholders, funding agency).

There are three types of evaluation designs commonly used in health and prevention programs: experimental, quasi-experimental, and nonexperimental. Experimental design has the greatest control over various factors involved with the program that may have an influence on results. Random assignment to two or more groups, either experimental (the groups receiving the program or intervention) or control (a group similar to the experimental group), with measurement in both groups, is the key feature of this design. Measurement will involve a pretest-posttest or a posttest only. This design will produce the most reliable and defensible program results. A quasi-experimental design uses two or more groups also, the experimental and a comparison group. A comparison group is as similar to the experimental group as possible, such as two classrooms of students with similar characteristics. However, there is no random assignment and the program staff cannot control for all factors that may influence the results. A pretest-posttest measurement is used with this design. The nonexperimental design (no comparison or control group) has little control over factors that may affect the results of a program.

The design is critical to the outcomes of a program, but in prevention settings, there are many restraints and limitations that are beyond the control of the evaluator or the staff. For example, random assignment is often not possible because it would be unethical to exclude individuals from a program. There are limitations and constraining factors in most situations. Selection of an optimal evaluation design is key.

Sources of Evaluation Measurements

At the impact level of evaluation, data may be obtained from archival sources, youth surveys, key informants, or focus groups. Key sources of archival data (data that have already been collected) may come from police,

school, health, and social agency records. Youth surveys should be valid and reliable. Examples that can be locally administered by a community group include the Youth Risk Behavior Survey, PRIDE, American Drug and Alcohol Survey, and the Communities That Care survey. When a local survey is not feasible, national measurement may be used to project and justify local program needs. Examples include the Monitoring the Future survey and the National Survey on Drug Use and Health. The Center for Substance Abuse Prevention has published a Core Measurements Initiative that recommends specific measurement instruments for risk and protective factor categories. Key informant data are obtained from individuals in the community who by their position have a sense of community need. Examples include law enforcement officers, school personnel, opinion leaders, and youth services staff. Focus groups conducted with youth are very valuable in the event that youth surveys are not available or permitted in a locality.

Evaluation measurement at the outcome level involves program-specific assessment or survey tools, specifically, pre and post knowledge tests, skills demonstration, or attitude assessment scales. Many model program packages include the outcome measurement instruments for local use. Process level measurement involves participant satisfaction surveys; attendance data; and speaker, material, and logistical data.

Evaluation Planning

Eight steps can be followed to conduct a prevention program evaluation (see Figure 1). Step one is planning. Planning involves formulating the overall evaluation design, determining which instruments will be used, and following all protocols for the protection of human subjects. Following protocols may mean gaining approval by an institutional or community board, as well as parental consent and youth-participant assent. In step one, measurable objectives are established or reviewed. The four levels of objectives are program, behavior, learning, and process. Program objectives address changes in health status, social benefits, or quality of life. They are future oriented and long term.

Behavior objectives are short term and define a specific action or behavior in which the target population will engage to reduce substance abuse or other negative health behaviors. Learning objectives address awareness, knowledge, skills, and attitudes.

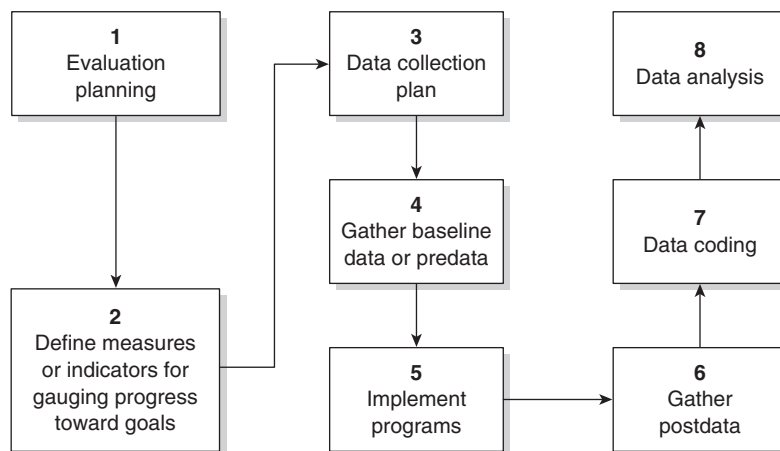

Figure 1 Evaluation Planning Flowchart

Process objectives include the tasks, activities, and plans that lead to accomplishment of all other levels of objectives. In step two, the measures or indicators for gauging progress are determined at the outcome level. During this step, project staff might review already existing instruments, or they might design one. Data collection is step three, and this determines who will collect the data and how data will be collected. Specifically, who will administer surveys and how will they be administered, who will conduct interviews and how will they be conducted, and how will observations be done. Step four is to gather baseline data (i.e., pretest) as determined by the goal and objectives. For example, will the staff have access to a classroom for the pretest? Will observations be done on a playground? Step five is to actually implement the program or intervention. Step six is to collect the postdata. Step seven is coding data that have been collated, cleaning and compiling the data and ensuring that they are accurate, and entering the data into a database or other usable format for analysis.

In step eight, data analysis, the goal is to reduce and organize the quantitative and qualitative data in order to make sense of them. If qualitative data are collected, they are summarized into themes and categories for understanding.

Variables of interest are identified and designated as dependent or independent. Independent variables influence dependent variables. The evaluator controls the independent variables, and examples include exposure to the intervention, gender, ethnicity, and age, while the dependent variables may include awareness, knowledge,

skills, or attitudes. Statistics are used to analyze quantitative data using an appropriate statistical package such as the Statistical Package for the Social Sciences (SPSS). Analysis may be done on one (univariate), two (bivariate), or multiple (multivariate) variables. Descriptive statistics are used to describe characteristics of a group, while inferential statistics are concerned with relationships and causality in order to make generalizations about a population from a sample. The type of analysis performed depends on the evaluation questions and the audience who will receive the evaluation report. Measures of central tendency (median, mode, mean) may be all that is needed in some cases; measures of spread or variation (range) are useful to some audiences. When using bivariate analysis, evaluation questions may be stated in the form of a null or alternative hypotheses, and the evaluator is looking for an observable, measurable difference in two groups. Statistical tests (chi-square, *t*-tests, and analysis of variance) are used to study variable associations, correlations, and group differences. Once statistical tests are completed, the evaluator will determine if there is statistical, program, or practical significance in the results. Then attention turns to interpretation of the data to make sense of them. Key evaluation questions are answered (e.g., What was accomplished? Did it have value? Were the objectives met? How well was the program implemented? Was it culturally appropriate?).

After the data analysis and interpretation are complete, the evaluation results will be reported to an appropriate audience. In many cases, there are multiple audiences who receive an evaluation report.

They can be at the local, regional, state, or national level. They can be the participants of a program, the community in general, stakeholders, a funding agency, advocacy groups, professional colleagues, and school boards or other governing bodies. The report can be verbal or written and prepared differently for each audience. After dissemination of the results, the evaluators and staff determine what to do with the findings; in other words, how to apply the results. Evaluation findings may lead to continuation of a successful effort, some modifications of the program (e.g., small groups, different time frame), or discontinuation of the program. The needs of the target population may have changed, or resources may have been generated for a different approach.

Limitations

There are limitations, barriers, and constraints to any project, and effective prevention evaluation is not immune. Planners may fail to build evaluation into their program, or they may add it as an afterthought. This tendency is happening less frequently due to increased program accountability from funders and agencies. Resources (time, money, personnel) may not be available. Restrictions on data collection from participants, especially minors, exist. Conflict may arise between an external evaluator and an internal staff. Staff or stakeholders may skew findings or selectively report results in order to show program success in order to receive funding. Intervention strategies may not be delivered as intended (with fidelity), and it is sometimes difficult to distinguish between cause and program effect, particularly when there are multiple strategies. Behavior change takes time, and the effects of a program may be hard to detect in the short amount of time that a program is being implemented.

Sustainability

Effective program evaluation can help determine if the project warrants continuation. Evaluation results that are positive lend support for sustaining a program with continued funding and resources. Even if the program results are not showing desired changes or objective attainment, the results may highlight changing needs of the population or program processes that can be improved.

Conclusion

Prevention program evaluation is an integral and important part of a program. Evaluation should be included in the initial stages of program planning and conducted to the best ability of the staff or an external consultant; results should be accurately reported to multiple audiences. Good program evaluation can lead to continued funding and community ownership of a successful effort. Sustained, positive program outcomes and impact can lead to reductions in substance use and to the overall health of individuals and the nation.

PREVENTION POPULATIONS

In many sciences, one learns about the nature of things through classification systems (e.g., Mendelov's Table) and, subsequently, sees patterns among various elements and formulates hypotheses about tendencies. Developing good descriptive systems serve as a "launching pad" of theory creation. As yet, there is no established consensual taxonomy of drug abuse prevention or cessation strategies that segments types of delivery according to the needs of different groups of people. There are, however, the beginnings of different descriptive systems that may

divide programming by community factors, level of risk, or stage of human development.

Community Factors Taxonomy

Communities That Care (CTC) provides research-based tools to help communities promote the positive development of children and youth and prevent adolescent problem behaviors, including substance abuse, delinquency, teen pregnancy, school dropout, and violence. The CTC process, developed by David Hawkins and Richard Catalano, helps communities plan, implement, and evaluate effective prevention programs to meet their needs. Among the phases of the CTC process is the development of a community profile (prioritize community risk and protective factors) and an attempt to address community priorities through the matching of evidence-based programs that address a variety of community units to specific community needs. Such taxonomy may vary by risk, contextual, or developmental factors, for example. The CTC process offers matrices that indicate developmental period, strategies for that period, risk factors for that period, and protective factors provided through the use of designated strategies.

Level of Risk Taxonomy

Another such matrix, provided by Steven Sussman and Susan Ames, divides programming by strategy and level of prevention (universal, selective, indicated). This matrix considers both prevention and cessation. Across any type of programming, there are some common features such as trust building among facilitator and participants, facts about the health behavior and consequences information, knowledge of high-risk situations, general social communication skills enhancement, decision making, and interactive learning. These types of skills bring people together and help individuals understand what they are getting into when participating in risky or healthy behaviors. These strategies are relevant for both prevention and cessation programming.

Some programming strategies might be intrinsically universal, for example, making a public commitment (as opposed to a private commitment) and normative restructuring or prevalence overestimate reduction (in which most of the population demonstrates healthy lifestyles). *Universal programming*

techniques apply to a general population, the assumption being that most exhibit moderate behavior. These strategies seem relevant to prevention or health promotion programming but might not apply to those trying to quit drug use.

Targeted programming involves strategies that address individuals already invested in lifestyles favorable to drug abuse. Strategies include making explicit and resolving equivocation, motivating change, instructing cognitive and behavioral coping, instructing mood management, and providing information on recovery from damage experienced due to lack of healthy behaviors. Many of these strategies are relevant to selective or indicated prevention and cessation programming, but they hardly seem relevant to the general population. Thus, as a start of the development of an explicit taxonomy, researchers could detail program strategies as a function of type of programming (e.g., universal, selective, indicated) or other factors, such as stage of development.

Stage of Human Development (Age of Population) Taxonomy

It is most plausible that different types of programming are relevant across different age groups. Obviously, youth in different age groups demonstrate different reading levels, perceptual-motor development, and level of abstraction. Just as school topics, the media, parenting, and friendship vary across age groups, so would drug education programming. Although it is rare to observe a young child using drugs, there are exceptions (e.g., young inhalant users or cigarette smokers). Other factors tend to differentiate youth at risk for later drug use and abuse.

Young children (under 6 years of age) who tend to blame others in conflict situations and who appear hypersensitive about fulfillment of immediate needs (e.g., food and comfort), and those who are not grounded in ongoing supportive and educative interactions with significant other adults are relatively likely to resort to acting out as a means to express their dissatisfaction. These youth may tend to perceive that their behavior is appropriate. Well-matched prevention or (problem behavior) cessation programming for young children should address developmental limitations as well as correct for behavioral irregularities that might signify a long pathway to drug abuse. For now, it appears that parental education about consistent,

firm, and kind parenting may help in regulating a young child's behavior. In addition, teaching the child self-control and helping the child feel closeness with parents or guardians and first schoolteachers through meetings that provide appropriate feedback may contribute to behavior regulation. Such strategies as complementing the child, but not the behavior; teaching conversation skills and decision making through use of dolls; and proper use of time-out may aid in preventing problem behaviors and the development of prosocial skills. In addition, some work on resource acquisition and early academic preparation skills may help. Programming may be limited or need alteration when applied to children or parents with special needs (traumatized, intellectually challenged).

Older children are more influenced by family than by friends until early adolescence. Elementary school-age youth may have recently heard about some drugs, but probably exhibit little curiosity to try them at the present time. The same types of strategies used for young children may apply to children ages 6 to 11 when provided in a more verbal-based manner (social skills, self-control, academic skills). Some facts about short-term and long-term consequences of drug use may be provided. In addition, a greater emphasis on having the child meet with adults at institutions other than the home may be important at this age (e.g., teachers, counselors). Parents may need to focus on who the child's friends are and take an active role in friendship selection and monitoring. Parents should be good role models as well as agents of socialization.

Young teens (ages 12–15) who are curious about solutions to their sense of dysregulation and who are approached by other teens who share a similar curiosity may seek out or yield to offers to try drugs or may engage in other risky behaviors. Improvement in difficulties in decision making, confrontation of alienation beliefs, and drug prevalence overestimate reduction are strategies that can assist with prevention (initial trial or early use) efforts. For example, drug prevalence overestimate reduction is a prevention strategy that involves teaching youth to understand that they are not the only person in their class who does not use drugs, that their classmates are similar to them, and that few or none of their peers use drugs. This strategy reduces pressure to use in order to conform. Young teens are ideal candidates for comprehensive social influence program materials. Work with family relations is still important, although

parents are relatively unlikely to serve as a mechanism of friendship selection (though they might be trained to do some monitoring). Academic remediation may be important.

Dynamic social changes occur between early adolescence and later adolescence. *Older teens* (ages 16–17) solidify a sense of self and become more resistant to direct influence. Intrapersonal motivations become more important and tend to dominate as precipitants of risky or healthful behaviors throughout adulthood. Substance use may serve more as a stress-coping, intrapersonal function as use enters a more advanced phase. High school-based prevention materials should be provided so that youth will recall and put into practice relevant prevention strategies that are relatively likely to involve stress-coping skills (motivation-skills decision making) as opposed to social influences material. A motivation-skills decision-making model is relevant for both prevention and cessation efforts with older teens. Mentoring type programs that involve older, prosocial adults outside the home may be relevant for elementary age, young teen, and older teen youth. Assistance with employment skills and resource acquisition may become quite relevant for older teens. For some older teens, education in parenting skills may be needed.

The period of *emerging adulthood* (ages 18–25) is one in which youth grapple with the prospects of new opportunities and need to select among opportunities and thereby bypass other opportunities by selecting a subset. Young people leaving high school are expected to seek out and select from among new opportunities, which include (a) assuming career avenues and financial independence, (b) learning skills of independent living (buying or renting a place to live), (c) growth in self-care skills (cooking, cleaning, grooming), and (d) social adventures (e.g., love). Youth may also transition from a relatively high level of family conflict in adolescence to the reduction of such conflict in emerging adulthood as they achieve emotional distance from parental demands and begin to associate more as junior peers. Successful transitioning through emerging adulthood involves being able to view exploration of life options as positive, hold positive general attitudes about life, become increasingly other-oriented (nurturing), and not feel subjectively caught in between adolescence and adulthood. For emerging adults, fear or lack of hope that one will be able to satisfactorily settle down into adult roles is

a driving source of pressure that might lead one to resort to drug use or other self-destructive behavior.

Youth who transition poorly through emerging adulthood may exhibit unconventional behaviors (e.g., drinking alcohol in public), unconventional attitudes (e.g., tolerance of deviance), and poor self-control; they may use anger to cope and may show interpersonal difficulty. These youth tend to enter adult roles early prior to being prepared to take on such roles (e.g., drop out of high school, get married and quickly divorced, exhibit unrestrained drug misuse and abuse). The same motivation-skills decision-making model used with older teens, along with motivational interview strategies and assistance with helping emerging adults find comfortable means to settle down into adulthood, is essential.

Among *adults* (ages 25–50), there may be many movements in personal and work life. Sometimes positive events occur, and at other times negative events transpire. Prevention and cessation strategies that emphasize coping skills, decision making, and provision of legal, medical, and other resources are likely to be relatively important. During this time, group support to help these individuals cope with the grief of losing a parent or other older relative is likely to be important in preventing drug abuse or relapse.

Among *the elderly*, prescription medication misuse is the most common form of drug abuse. Many elderly people frequently ingest multiple prescription medications. In fact, individuals over age 65 average 13 prescriptions each year. Physicians are not always aware of medications prescribed by others or alcohol use patterns among their patients. The rate of elderly drug misuse and abuse of prescription medications is approximately twice as high as that for other adult age groups, but drug problems may be underestimated or not detected because the elderly are stereotyped as nonusers. Relatively lower quantities of drug use among the elderly may qualify as abuse because of the potential for drugs of abuse to exert life-threatening consequences. Drug effects on the elderly may be more long lasting due to slower metabolic rates coupled with ingestion of many medications, resulting in an increase in the likelihood of harmful drug interactions. Older adults experience many significant life changes that put them at risk for drug dependency, including retirement, excessive leisure time, and loss of significant others (i.e., loss of social networks and social support). Other life adjustments that

place the elderly at risk for drug abuse include potential functional loss and deterioration of physical and mental well-being resulting in increased rates of use of prescription medications. For older adults, one's purview of life as one in which to achieve a subjective sense of wisdom versus a subjective sense of despair, as shaped by social-environmental experiences such as amount of free time, lack of structure, and number of significant others remaining in one's social circles, may drive an individual to resort to constructive or destructive behavior. Programming that assists in continuing to help the elderly perceive a sense of social usefulness (e.g., by caretaking for other people or pets, volunteer work, involvement in activism), means of enjoyment at a reasonable cost (e.g., attendance at elder hostels), and sense of independence (e.g., good medical care, supportive caretaking) are essential. In addition, close medical supervision of medicines being used is essential to prevent unwanted addiction and other consequences. In each of the developmental periods noted above, individuals may seek out available resources, logically consider options, and make decisions that are life-fulfilling to self and others.

Conclusion

A taxonomy that combines community factors, risk status, and human development grounded in theoretically based etiologic factors with prevention and cessation strategies and modalities is needed. A broad view of the addictions is needed to be able to do this. This larger view also may need to include other addictions as well, including gambling, overeating, uncontrolled sexual behavior, or danger seeking that may share the same underlying functions and may need to be addressed in similar ways.

PREVENTION PROGRAMS

See EVIDENCE-BASED PREVENTION

PREVENTION RESOURCES

Prevention resources are powerful tools to reduce negative consequences of drug use by preventing initial use. With the capacity to reach mass audiences via a plethora of informational and communication channels, prevention resources serve a pertinent role in the field of substance abuse. The history of prevention itself has influenced the formation of existing resources. Key components leading up to the creation of prevention resources have included the establishment of standard prevention principles and models. This entry covers these critical aspects related to the emergence of resources. Furthermore, although many prevention resources tend to focus on youth, this entry also discusses the range of prevention activities available

across the life span, running from infancy to advanced age. Resources specific to ethnic and gender minorities are also discussed. In addition, a summary of community-based prevention and alternative resources is provided.

Principles of Prevention

Prevention principles have evolved through the synthesis of extensive research conducted in substance abuse treatment and prevention. This evolution has included the collaboration of federal organizations such as the U.S. Departments of Health and Human Services, Education, and Justice. The National Institute on Drug Abuse (NIDA) lists more than 15 principles to guide the creation of prevention programs and, by extension, resources. They can be broadly divided into four major subgroups. The first set involves defining and addressing substance abuse risk factors within a population. Second, the principles indicate that programs that have been shown to be effective in the past should continue to be used. Third, interventions should take place during significant life stages in suitable settings. Finally, programs should be managed effectively such that they undergo continuous monitoring, incorporate staff training, and provide consistency.

Prevention Models

The creation of prevention principles has led to the recognition of several models that encourage the creation of prevention programs and resources. In 1994, the Institute of Medicine proposed a method of categorizing prevention strategies. They suggested moving away from the older model of primary, secondary, and tertiary approaches. Instead, prevention interventions were classified as universal, selective, and indicated. Universal strategies are aimed at large populations and emphasize determent of substance use. Selective strategies work on subsections of the population that may be at increased risk of substance use. Examples include high school dropouts and children from families that have a history of substance abuse. Indicated strategies target specific individuals who may not meet official addiction criteria (i.e., those in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*), but who exhibit early signs of substance

abuse or risk factors for substance use. Prevention resources may be categorized as falling into one of these classifications.

Youth Prevention

One of the most recognized targeted groups with respect to prevention are youth. There is no one method, however, that encompasses the diverse backgrounds and experiences of younger individuals. Accordingly, prevention resources work within a variety of contexts to assist in the prevention of substance abuse. These include school-based programs as well as those aimed toward female, ethnic minority, and incarcerated youth.

School-Based Programs

The overwhelming majority of youth prevention activities occur within the school setting. NIDA provides parents, educators, and community leaders with a guide to the prevention of drug use by children and adolescents. This guide utilizes the universal, selective, and indicated framework to list a host of resources for elementary, middle, and high school students. Universal elementary programs include ones such as Caring School Community Program, Promoting Alternative Thinking Strategies (PATHS), and Skills, Opportunity, and Recognition (SOAR). Universal middle and high school resources include ones such as Life Skills Training programs, Lions-Quest Skills for Adolescence, Project ALERT/ALERT Plus, and the Strengthening Families Program: For Parents and Youth 10–14.

Selective programs for elementary schools include Focus on Families and the Strengthening Families Program. Middle school selective programs include Coping Power and Adolescents. ATLAS (Athletes Training and Learning to Avoid Steroids) is a selective program for high school students. Indicated programs are in place for high school students with programs such as Project Towards No Drug Abuse and the Reconnecting Youth Program.

Although well-known programs such as Drug Abuse Resistance Education (D.A.R.E.) have proven ineffective, the efficacy of the above listed resources have been empirically validated. It is not a comprehensive list, but represents the various programs that

provide youth with resources and tools to be used toward the prevention of substance abuse.

Special Youth Populations

Given the special needs of minority groups, there are also resources available specifically for girls, ethnic minority youth, and youth in the criminal justice system. Programs such as Girls, Inc. and PEERSuasion (GIFP) use life skills and social influences models to encourage girls to avoid substance abuse. Girl Power! provides girls, parents, and educators with a network of books, materials, and other resources.

The UN Office on Drugs and Crime is a source for prevention information on minority youth. Their publication on drug abuse prevention in youth from ethnic and indigenous minorities provides an overview of at-risk ethnic minority literature. Furthermore, it outlines the development, evaluation, and funding of prevention programs. Strategies for connecting with minority youth are also discussed. Aside from youth-specific resources, the United Nations also provides international prevention resources such as links to the Higher Education Center for Alcohol and Other Drug Prevention in the United States and the Drug Abuse Prevention Center in Japan.

A final subset of youth that may require specific programs includes those in the juvenile justice system. The Office of Juvenile Justice and Delinquency Prevention and the National Criminal Justice Reference Service, administered by the Office of Justice Programs, U.S. Department of Justice are groups that provide resources specific to this population. Resources can be found in the format of question-and-answer forums, publications, and fact sheets. These organizations also provide related links on their Web sites to informational clearinghouses, NIDA, and other substance abuse prevention organizations.

Community Prevention

Community prevention resources are available through numerous outlets. These include those produced for families and employees in the workplace. They provide information to people in a range of ages, from pregnant women to the recently retired. In addition, one of the

most visually present community resources comes from advertisements displayed in media campaigns.

Prenatal Prevention

Prevention resources are available throughout nearly all stages of the life cycle beginning at birth. Programs targeted at pregnant women attempt to ensure that newborns are not born drug or alcohol exposed. The Partnership to Prevent Fetal Alcohol Syndrome empowers women to deliver healthy babies by encouraging them to build social supports and avoid alcohol. They provide informational brochures, posters, and prevention toolkits. With the creation of the federal Fetal Alcohol Spectrum Disorders Center for Excellence, prevention resources are available in an increased variety of formats ranging from CD-ROMs and videos to slide shows and magazines.

There are also efforts under way to address pregnant women who are using drugs. However, availability of access to programs such as prenatal substance abuse programs may vary by state. Yet, according to a report by the National Conference of State Legislatures, there have been national steps toward more fully addressing the problem of maternal drug and alcohol use. In 1997, the Substance Abuse Prevention and Treatment Block Grant federally mandated that 5% of grant funds be used to improve services for pregnant women. In addition to federal initiatives toward enhancing prevention resources for pregnant women, various informational posters and charts are available commercially via private corporations that supply health care information to hospitals, clinics, and the general public.

Family Prevention

The U.S. Department of Health and Human Services Substance Abuse and Mental Health Services Administration (SAMHSA) Center for Substance Abuse Prevention provides families with numerous educational tools and resources. These include educational programs such as Building Blocks for a Healthy Future, Too Smart to Start, A Family Guide to Keeping You Mentally Healthy and Drug Free, Stop Underage Drinking, and Partnership to Prevent Fetal Alcohol Syndrome. Other community resources can be found through organizations such as National

Families in Action and Community Anti-Drug Coalitions of America.

Resources exist for ethnic minority families as well. Hablemos en Confianza is a program that seeks to encourage dialogue between Spanish-speaking Hispanic-Latino parents and children regarding the dangers of drug use. Multicultural research conducted with Native American youth has led to the creation of programs such as the Nee-kon Project, while the Family Circles Program has been an effective prevention resource for American Indian families. The Safe Haven Program was created for inner city African American families.

In addition, a number of ethnic minority groups provide family and community prevention resources geared toward the special needs of different cultural groups. The Institute for African-American Mobilization provides a detailed workshop on prevention in the community. The National Asian Pacific American Families Against Substance Abuse, National Latino Behavioral Health Association, and National Hispanic Science Network on Drug Abuse are other examples of organizations providing ethnic minority prevention resources.

Despite gains in prevention resources for minority families, there are still gaps in knowledge. Therefore, the National Institute on Drug Abuse Health Disparities Plan (2004–2008) has proposed to better address ethnic and racial minority substance abuse. Accordingly, more culturally appropriate prevention resources may also emerge with additional research.

Workplace Prevention

The SAMHSA Division of Workplace Programs offers different prevention resources aimed at employees and supervisors. The division provides information on federal drug-free workplace programs as well as how to obtain a drug-free workplace kit. Employee Assistance Program (EAP) resources that focus on drug prevention are also available through SAMHSA. The Center for Substance Abuse Treatment offers an annual Recovery Month kit that promotes drug and alcohol prevention and treatment. Information on workplace prevention and interventions is also available through SAMHSA's National Registry of Evidence-based Programs and Practices.

Resources also exist for retired employees as well as older adults. Surprisingly, many adults use drugs for the first time after their teenage years, often in situations involving life changes (e.g., loss of a spouse) efforts to self-medicate, or a sudden increase in free time that comes with retirement. The Levi-Strauss EAP and the Aetna Human Affairs International Managed Behavioral programs are examples of successful workplace prevention and intervention programs.

Media Campaigns

One of the most readily recognizable prevention resources available to the general public comes from the media. Specifically, television advertisements provide many consumers with visual examples of various forms of addiction and substance abuse. These advertisements frequently conclude with a phone number or Web address for further information and resources. As a part of the government's settlement with the Philip Morris tobacco company, a series of ads sponsored by Philip Morris sought to discourage tobacco usage. However, independent research groups have suggested these ads may have been ineffective and have been potentially more harmful for children through potential glamorization of drugs. A 2002 report from the American Public Health Association provides further discussion of tobacco advertisement effectiveness; however, a 2003 report from the American Legacy Foundation discusses the influence and effectiveness of protobacco messages among young adults.

A series of television advertisements created by the Legacy Foundation was shown to reduce substance usage through Truth television ads and by providing additional resources on a Web site (truth.com). The Office of National Drug Control Policy National Youth Anti-Drug Media Campaign sponsors ads such as Live Above the Influence, and Parents: The Anti-Drug. The Partnership for a Drug-Free America is a nonprofit organization that began as a project of the American Association of Advertising Agencies and that provides media outreach and resources.

Alternative Prevention Resources

Although there has been a tendency to recognize the most effective prevention resources as stemming from national and nonprofit U.S. organizations, there is evidence suggesting that alternate forms of prevention may be just as beneficial as traditional ones. Studies

dating back to the 1970s indicate transcendental meditation may prevent alcohol, nicotine, and drug abuse. The United Nations and the National Association of State Alcohol and Drug Abuse Directors recognize a variety of Eastern medicinal approaches as valid forms of treating and preventing substance abuse.

Holistic approaches to addiction may involve paying particular attention to nutrition or may include usage of biofeedback, homeopathy, yoga, and meditation. Many of the programs that utilize these approaches are independent private organizations. More recently, there has been increased emphasis on the potential for complementary and alternative medicine. The creation of the National Institutes of Health National Center for Complementary and Alternative Medicine (NCCAM) in 1998 has led to further research on alternative practices, including their function in substance abuse. Extant collaborations between NCCAM, NIDA, and the National Institute on Alcohol Abuse and Alcoholism suggest more possibilities for alternative resources for prevention in the future.

Conclusion

Prevention resources are available through a plethora of private, federal, and nonprofit organizations. Prevention resources target universal (general), selective (at-risk), and indicated (symptomatic) populations. In addition, some prevention programs focus primarily on specific populations such as ethnic minorities, pregnant women, or particular age groups. Many groups contribute to prevention research and resources, including the U.S. Department of Health and Human Services SAMHSA National Clearinghouse for Alcohol and Drug Information, the Office of National Drug Control Policy, Join Together, and the National Prevention Network.

PREVENTION STRATEGIES

Drug prevention strategies aimed at delaying, reducing, or preventing the use and abuse of alcohol and illicit drugs are designed to prevent the need for treatment, thus reducing negative health effects, distress, and costs of treatment. This entry describes theoretical approaches to prevention strategies, descriptions of specific prevention strategies, and evaluations and outcomes of effective drug prevention strategies.

Prevention Approaches

There are two primary classification systems that are commonly used to refer to prevention strategies. The first is based on public health models and refers to primary, secondary, and tertiary prevention. Primary

prevention is aimed at preventing the onset of the targeted condition in the general population, and secondary prevention identifies and treats asymptomatic people who have risk factors for the condition. Tertiary prevention involves the treatment of a person with an established condition, including attempting to restore functioning, minimize negative effects, and prevent condition-related complications. Secondary prevention may minimize the impact of conditions through early identification and intervention, even if the individual is eventually treated through tertiary prevention.

A major distinction between primary and secondary prevention measures is that primary prevention seeks to stop not only use-related behaviors themselves (e.g., smoking marijuana), but also risk factors associated with abuse (e.g., lack of supervised social activities for adolescents). Secondary prevention strategies attempt to ameliorate the situation and reduce problematic behaviors when usage has occurred. It seeks to prevent any further damage from occurring and decreases the amount of harm incurred. Furthermore, harm reduction strategies fit into the scheme of tertiary prevention.

The Institute on Medicine (IOM) has updated prevention strategy terminology to a disease model and uses terms of universal, selective, and indicated prevention interventions. Whereas primary, secondary, and tertiary approaches refer to stages of disease development at an individual level (none, risk factors, presence of condition), the IOM model classifies population-level strategies. Universal approaches target the general population, and selective approaches work with subgroups of the general population such as students who are academically failing and at increased risk of engaging in substance abuse. As applied to substance abuse, indicated approaches are those that target individuals who do not meet specific criteria for the diagnosis of substance abuse or dependence, but who may exhibit early signs such as use of gateway drugs.

Applying these models of prevention strategies, the National Institute on Drug Abuse (NIDA), the Center for Substance Abuse Prevention (CSAP), and the Office of National Drug Control Policy (ONDCP) have each established frameworks of prevention strategies.

NIDA Prevention Strategies

In their explication of drug prevention strategies, NIDA utilizes the universal, selected, and indicated prevention approach. The most common interventions for all three of these types of strategies occur in schools, with families,

and in the community. NIDA provides an overview of these strategies targeted at the general population and toward at-risk subgroups and individuals.

According to NIDA, in school settings, universal strategies may convey prevention messages through three main venues: education, skills training, and management. In schools, prevention education information can be provided at school assemblies or within the curriculum itself. Skills training can teach students how to manage stress or make decisions effectively. School management can lead to the implementation of policies that would more fully discourage drug use. Selective school strategies come in the form of alternative programs. These can include after-school programs that provide structured, supervised time or special clubs such as Children of Alcoholics. Competency and skill-building activities may include tutoring or enhancing cultural pride. Indicated prevention measures include mentoring and counseling such as support groups, peer counseling, or crisis hotlines.

In the family context, universal strategies include general parental education, skills training, and involvement programs. Selective measures may assist families through case management and support groups. Indicated prevention strategies can include parental self-help groups as well as family counseling or therapy.

Community universal strategies include community groups such as task forces and religiously oriented youth groups. Public service announcements such as those from media campaigns and information clearinghouses are other strategies. In some cases, health policy may also provide communities with a general incentive toward establishing and maintaining prevention activities. Selective community strategies may encompass teen clubs, mentoring, and tutoring, while indicated approaches can include implementation of gang prevention groups and job skills training.

CSAP's Six Prevention Strategies

In the early 1990s, the CSAP created six strategies for effective substance abuse prevention. These strategies include information dissemination, prevention education, alternative activities, community-based processes, environmental approaches, and problem identification and referral.

Information dissemination includes provision of information on drug use, including its effects on individuals and communities. It also includes providing information on resources and programs aimed at prevention

and treatment services. This strategy involves one-way communication, where information goes from the source to the audience. Forms of dissemination include health fairs, media campaigns and public broadcast announcements, and information clearinghouses.

Prevention education involves a two-way communication process between the information providers and the audience. With this strategy, the focus is placed upon teaching such concepts as refusal skills and critical decision-making and social skills. Competency enhancement approaches teach a combination of problem-solving, cognitive skills for resisting outside influence, skills to increase self-control and self-esteem, adaptive coping strategies, general social skills, and general assertive skills. Prevention education may occur in such contexts as the classroom, parenting classes, and groups for children of substance abusers.

Alternative activities aim to place target populations into more constructive activities such that either the lure of drugs would diminish or the initial need for drugs would be fulfilled in an alternative manner. Forms of promoting alternative activities include creation of drug-free dances for youth, mentoring programs, drug-free recreational activities, and community service projects.

The goal of *community-based processes* is to enhance the ability of communities to provide more effective prevention and treatment services for substance abuse. The utilization of this strategy includes organization, planning, building coalitions, and networking. Community and neighborhood training as well as multi-agency coordination are some of the methods used to implement this prevention strategy.

Environmental approaches seek to establish or change policies, codes, and standards that are either written or unwritten. Through changing or monitoring the effectiveness of these policies, the incidence and prevalence of substance abuse may be influenced. Examination of school drug policies, tobacco and alcohol advertising, and product pricing are forms of implementing this strategy.

Problem identification and referral attempts to identify individuals who have used illegal drugs or engaged in age-inappropriate tobacco or alcohol usage. This strategy aims to evaluate whether the behaviors of these individuals may be reversed through education. Furthermore, it seeks to determine if a referral is appropriate for chemical-dependency assessment. Such practices as employee and student assistance programs are included in this strategy.

ONDCP Prevention Strategies

ONDCP approaches drug abuse prevention through two primary frameworks, demand reduction and supply reduction. In the first, ONDCP recommends prevention strategies established by CSAP and NIDA. Demand can be reduced through bolstering protective factors and decreasing risk factors within the individual to prevent drug use from starting or through treatment that decreases an individual's demand for substances.

Supply reduction refers to activities that attempt to decrease the availability of drugs. Total U.S. national funding for drug control totaled close to \$14 billion in 2008; nearly two thirds of the funding was invested in activities aimed at disrupting the market, or reducing supply, and the rest was divided between stopping use and healing users. Supply reduction may be accomplished through destroying drug crops, confiscating shipments, and imposing criminal penalties. For legal substances such as tobacco and alcohol, supply may be reduced through increased taxation, reducing advertisements, raising age limits for usage, reducing sales outlets, and increasing law enforcement and penalties for those who sell these substances to minors.

The annual National Drug Control Strategy outlines national drug control policy, strategies, and substance usage trends. Published by ONDCP, the National Drug Control Strategy reviews a variety of facets related to drug control including prevention and interventions. A sizable portion of this document also discusses international challenges and strategies for disrupting the illicit drug market. This ONDCP publication also details control strategies across several federal departments (e.g., Department of Homeland Security, Department of Justice, Department of Health and Human Services).

Effectiveness of Prevention Strategies

Prevention strategies are often determined to be effective if they can (a) delay onset of drug use or (b) reduce use. CSAP's High Risk Youth Cross-Site study demonstrated that prevention can decrease use and found differences in how male and female adolescents responded: Males showed an immediate decrease in use that attenuated over time, and females had a delayed but lasting positive response.

In addition to differences in success by gender, specific strategies have varying rates of success. School-based information dissemination has been

unsuccessful, and scare tactics can actually have a detrimental effect. Education that focuses on feelings, self-esteem, social skills, and values has been ineffective, and adding information dissemination increases the amount of knowledge retained, but does not affect drug use. Social resistance skills, especially using peers to teach others how to resist drugs, has been associated with reduction in drug use for several years. Competency enhancement approaches have had generally positive evaluations, reporting reductions in initiation of tobacco, alcohol, and marijuana use. One of the most popular prevention programs, Drug Abuse Resistance Education (D.A.R.E.), has demonstrated limited improvements immediately following the program and no long-term improvements. Environmental approaches, such as increasing alcohol and tobacco taxes or raising the legal drinking age, have a direct impact on use of licit drugs, but have not been effective in influencing illicit drug use.

Conclusion

Prevention strategies encompass a large scope of approaches and methodologies that seek to deter individuals from using illegal substances. They are employed within a variety of contexts, ranging from community neighborhoods to federal policies. With the establishment of an effective means of categorizing strong interventions and strategies, there is continued hope for preventing substance addictions. Although improvements still need to be made at the federal level to ensure optimal balance of costs and maximum benefits and effectiveness, the production of independent reports and analyses may provide governmental officials with the impetus to revise and enhance current national strategies.

PROBLEM IDENTIFICATION AND REFERRAL

According to the Substance Abuse and Mental Health Services Administration's (SAMHSA's) Center for Substance Abuse Prevention (CSAP), there are six interpersonal domains that contribute toward a person's potential for substance abuse or dependence: individual, peer, family, school, community, and societal influences. Not only are risk factors for substance abuse potentially found within each of these six experiential domains, but there are also protective factors within each domain that may reduce the probability of substance use. One of the primary aims of early problem identification and referral is to amplify the protective factors within an individual via education and

targeted intervention and to reduce the risk factors within those six domains wherever feasible.

Problem identification and referral is one of the six substance abuse prevention strategies identified by CSAP. In contrast to the other prevention strategies, problem identification and referral targets those individuals who have already begun to use tobacco, alcohol, or other drugs or who demonstrate behaviors that often are indicative of a potential problem with alcohol or other drugs. For example, a young adolescent who is caught smoking, a chronically truant student, or a worker with sudden performance problems might be targeted for problem identification and referral. Student assistance programs and employee assistance programs are the most common ways that problem identification and referral occurs in the school or work environment.

A core assertion of problem identification and referral is that a successful intervention will address the source of a client's problem, not merely the manifestation of debilitating symptoms. In addiction treatment, this ethos translates to not merely treating the substance abuse or dependence issue, but seeking to determine the events and behaviors that led to choosing to use the substance in the first instance. One effective way to make these determinations is to fully explore and assess both the risk and protective factors within each of the six characteristic domains.

Within the *individual* domain, core substance abuse risk and dependence assessments examine genetic predispositions, based on family history and use patterns, and gauge the potential for increased risk of dependence garnered from research on gender and first age of use. Although these potential risk characteristics are demographic, other intrapersonal attitudes and predispositions are more pliable. These include factors such as an individual's sense of alleged risk when using a substance, a desire to rebel against social norms, feelings of alienation, or impairments in social skills.

Within the *family* domain, risk factors for substance use increase with greater levels of conflict, chronic spousal disputes, experiences of abuse and neglect, and poor discipline and problem-solving skills. Tolerant parental attitudes toward substance use as well as familial modeling are also correlated with a greater likelihood of transgenerational recurrence of substance dependence. From a cultural perspective, a family's level of acculturation or disenfranchisement can also increase the risk factors for use.

For adolescents and young adults, failure to achieve competency in *school*, both academically and

socially, is a significant risk factor in the probability of choosing illicit substance usage. Among those individuals with an external locus of worth, such that peer approval significantly outweighs any consistent, internal sense of positive self-esteem, substance use is also widespread. These developmental risks are further amplified when such individuals align with others who engage in a wide variety of problematic behaviors in addition to drug and alcohol consumption.

From *community* and *society* perspectives, the predilection toward substance abuse increases when neighborhoods and cities are noticeably marginalized due to the forces of poverty, underemployment, segregation and prejudice, or cultural minority status. It is noteworthy, however, that despite these potential high-risk factors, when communities are empowered to set high expectations for behavior and unify to convey messages that substance use will not be tolerated, rates of abuse and addiction decrease.

Effective assessment is an essentially lifelong process of attention, inquiry, and monitoring such that concerned parents and family members, teachers and coaches, spouses and significant others, coworkers and employers, and medical professionals and clergy attend to noticeable changes in an individual. When deleterious symptoms begin to occur, early intervention and referral are critical to aid in the prevention of maladaptive behaviors spiraling into a full-blown problem. Accurate assessment of each domain that is being negatively impacted and referrals and interventions to address the source of these disruptions lead to optimal recovery and a return to healthier functioning.

Effective interventions are both individual and communal. Interventions that attend to individual and intrapersonal concerns may include leadership training, mentoring, self-esteem building, improving communication skills, developing peer-pressure resistance, increasing problem-solving and decision-making skills, substance abuse education, tutoring, and anger management. Communal interventions may include the development of alternative activities for children during off-school hours, violence prevention techniques, development of negotiation and conflict resolution techniques, and providing opportunities for vocational development and employment. Interventions can be provided via individual counseling, group therapy, self-help supports, and classes designed to improve specific skills such as parenting or social skills development. All interventions need to be implemented in culturally specific and culturally responsive ways.

Perhaps the most successful referrals are those targeted to involve the whole family. Recent advances in treatment indicate that when an entire family receives treatment, not only does the individual manifesting harmful behaviors benefit from the intervention, but also the other family members profit from the ensuing education, communication strengthening, and problem-solving and conflict resolution skills building. Whole family interventions can amplify positive bonding between members; decrease negativity, criticism, and defensiveness; reinstitute levels of trust; and reaffirm family values and define expectations of behavior. When implemented consistently, these interventions can act as a prophylactic against further substance abuse and subsequently, significantly diminish the likelihood of the transgenerational transmission of substance dependence and the concomitant costs of social, criminal, and negative health outcomes.

PROBLEM ORIENTED SCREENING INSTRUMENT FOR TEENAGERS

The Problem Oriented Screening Instrument for Teenagers (POSIT) is a self-report screening tool that was developed as part of the Adolescent Assessment/Referral System (AARS) to identify potential problems among adolescent substance users. Elizabeth Rahdert of the National Institute on Drug Abuse designed the AARS as an early intervention system for troubled adolescents. The intervention system provides guidelines to professionals for screening and subsequent in-depth diagnostic evaluations, as well as an index of treatment resources for adolescent populations. The POSIT consists of 139 yes-or-no questions that assess 10 functional areas including the following: (1) Substance Use/Abuse, (2) Physical Health, (3) Mental Health Status, (4) Family Relationships, (5) Peer Relationships, (6) Educational Status, (7) Vocational Status, (8) Social Skills, (9) Leisure and Recreation, and (10) Aggressive Behavior/Delinquency. In general, adolescents who use or abuse substances are likely to exhibit impaired functioning across a variety of domains. In the absence of ongoing substance abuse issues, the POSIT may also be helpful in identifying young people at risk for the development of substance use problems based on distressed responding in other functional domains. The POSIT is not a diagnostic tool but, rather, a probe to determine if a more comprehensive diagnostic evaluation is necessary.

As a screening tool, the POSIT has many advantages. The full measure takes only 30 minutes to complete and assesses a comprehensive range of substance use and abuse and psychosocial domains. Also, no training is required to conduct the assessment, which can be administered as a paper-and-pencil self-report questionnaire, on the computer, or as an interview if the adolescent does not have the necessary comprehension or reading skills (fifth-grade level). Furthermore, as opposed to many screening measures used with adolescents that have been adapted from adult versions, the POSIT was developed specifically for 12- to 19-year-olds and thus is developmentally appropriate. The POSIT can be used in diverse settings, such as in primary care offices, in the juvenile detention system, and with other clinical and nonclinical adolescent populations. In addition, the questionnaire can be scored

in minutes, either by hand or by using the associated computer software. Each subscale is summed to determine if the teen is at low, medium, or high risk for problems in that area based on empirically derived cutoff scores. The measure also includes red flag items that, if endorsed, warrant further assessment. Computerized scoring provides immediate reports comparing the adolescent's score to normative cutoffs for each scale, which may be helpful when discussing what follow-up evaluations are recommended with the adolescent.

Several studies have supported the psychometric properties of the POSIT among a range of clinical and nonclinical populations. For example, Margaret McLaney and colleagues tested the reliability and validity of the measure by comparing results from the POSIT with three widely used adolescent measures with established validity: the Personal Experiences Inventory (PEI), the Diagnostic Interview for Children and Adolescents (DICA), and the Adolescent Diagnostic Interview (ADI). The DICA and the ADI are structured interviews used to determine diagnoses according to the *Diagnostic and Statistical Manual of Mental Disorders*. The study included 234 11- to 20-year-olds who were referred to Youth Evaluation Services for likely substance abuse problems. Results showed that the POSIT scales with the highest reliability were Substance Use/Abuse (.86), Mental Health Status (.84), Family Relations (.72), and Aggressive Behavior/Delinquency (.74). Overall reliability across all 10 scales was .66, with the lowest being Physical Health (.44). In addition, the researchers compared related scales on the POSIT and the PEI and determined the POSIT to have overall good convergent (.46) and divergent (.23) validity. As a screening tool, the POSIT should have good discriminant validity; that is, it has been able to correctly identify adolescents with problems (sensitivity), while not incorrectly flagging adolescents without problems (specificity). Discriminant validity for the Substance Use/Abuse, Mental Health Status, and Aggressive Behavior/Delinquency subscales were calculated based on comparisons with the diagnoses resulting from the DICA and ADI. Although the sensitivities of each of these scales was sufficiently high (.84, .92, and .74, respectively), the specificities fell below what is generally considered to be adequate (.41, .52, and .22, respectively). However, as a screening measure, it is better to have a false positive that can be ruled out upon further evaluation than a false negative that evades appropriate follow-up care. Interestingly, the Substance Use/Abuse domain was significantly related to all but one of the

other subscales, providing further support that teens with substance abuse issues are likely to have other psychosocial problems.

Other studies have tested the utility of using isolated scales to screen for specific problems among adolescents. For instance, John Knight and colleagues evaluated the validity of using the alcohol scale of the POSIT as a brief screener for drinking problems among 538 14- to 18-year-olds in a primary care setting. The researchers tested the sensitivity and specificity of the Substance Use/Abuse scale by dividing the adolescents into three groups on the basis of the severity of their reported alcohol habits during the past year: (1) any problem, (2) any disorder (abuse or dependence), and (3) dependence. Results suggested that the POSIT Substance Use/Abuse scale can be used to successfully identify adolescents in need of further evaluation for substance use issues in non-clinical populations. Moreover, using the POSIT Substance Use/Abuse scale as a screener has the collateral benefit of also screening for other drug use as opposed to using a strictly alcohol-related measure (e.g., the Alcohol Use Disorders Identification Test).

The POSIT can be used in conjunction with the Problem Oriented Screening Instrument for Parents to obtain a corroborative report, or with the POSIT follow-up to detect changes over time. The POSIT is also available in a Spanish version. The paper-and-pencil measure is free and can be obtained by request from the National Clearinghouse for Alcohol and Drug information.

PROJECT MATCH

The Project for Matching Alcoholism Treatments to Client Heterogeneity (Project MATCH), organized by the National Institute on Alcohol Abuse and Alcoholism (NIAAA), was a large-scale multisite clinical trial. This project aimed to test the general assumption that matching patients by their characteristics to particular treatment modalities would improve treatment outcomes. According to this hypothesis, patients who received treatment matched to their characteristics were predicted to be more likely to have better treatment outcomes compared with patients who were not matched or who were mismatched. Such assumptions of treatment matching effects, though long held, had not been stringently tested in a large and representative study prior to the development and implementation of Project MATCH.

In the design of this study, a team of researchers devised specific hypotheses of patient–treatment interactions. Hypotheses were based on previous research findings and theoretical considerations that suggested how patient characteristics were related to treatment outcomes for alcohol problems. This study represented an important clinical trial that aimed to evaluate the utility of matching patients to treatment, and thus has yielded specific and broad-based clinical implications within the field of alcohol treatment outcome research, as well as psychotherapy research in general.

General Information About Project MATCH

To date, Project MATCH is the largest and most statistically powerful trial of psychotherapies undertaken. This study involved 1,726 patients, 22 principal investigators, 80 therapists, 9 communities containing

30 participating institutions and agencies, and many support staff. It was carried out over an 8-year period and was estimated to cost \$27 million to implement.

Treatment within Project MATCH was conducted with clients recruited from two different settings. These included outpatient settings ($N = 952$), as well as patients receiving follow-up treatment subsequent to 3-month-long inpatient care ($N = 774$). From each of these two setting types, patients underwent identical procedures for randomization, assessment, and treatment. These patients will hereafter be referred to as outpatients and aftercare patients, respectively.

All patients were randomly assigned to one of three manual-guided treatment conditions, which were selected on the basis of previously demonstrated efficacy, as well as treatment distinctiveness that would potentially reveal matching effects. All treatment modalities were administered in an individual therapy format and were 12 weeks in duration.

The first treatment modality was a 12-session Twelve-Step Facilitation therapy (TSF), based on Alcoholics Anonymous (AA) principles. The stated objectives in TSF were to foster acceptance of alcoholism as a medical disease and to garner commitment to participate in AA following the TSF. The second treatment modality was Cognitive Behavioral Coping Skills therapy (CBT). The CBT approach, also consisting of 12 sessions, was based on social learning theory principles that are designed to teach skills that target the avoidance of relapse. Finally, Motivational Enhancement Therapy (MET) was tested. MET is based on principles of motivational psychology that help patients to utilize personal resources to make changes. MET conducted within Project MATCH involved four sessions that were spaced over a 12-week period. Twenty-five percent of sessions from each treatment modality were monitored for quality control and adherence to the respective manual.

Patient characteristics that were examined for match with treatment included the following: severity of alcohol use, cognitive impairment, psychiatric severity, conceptual level, gender, meaning-seeking, level of readiness to change, social support for drinking versus abstinence, sociopathy, typology of alcoholism (i.e., Type A vs. Type B), assertion of autonomy, previous involvement in AA, self-efficacy, social functioning, and religiosity. Based on these patient characteristics, the Project MATCH research group predicted contrasts in patient responses to the

individual treatment protocols. For example, it was predicted that patients who demonstrated lower levels of motivation to change in the MET condition, which targeted increasing motivation for change, would have better outcomes as compared with the CBT condition, in which skills for preventing relapse were the focus of treatment. Each treatment was predicted to be matched to specific client characteristics assessed. The main outcome variables of interest were the percentage of days spent abstaining from alcohol use and the average number of drinks per drinking day.

Assessments for Project MATCH were conducted at 3-month intervals for 1 year following the 12-week treatment period. In addition, assessments were conducted at 39-month follow-ups. Changes in drinking patterns, quality of life, and treatment service utilization were also assessed.

Project MATCH Findings

Within Project MATCH, a number of findings specific to the study implementation are notable. First, patients had good overall participation in the study. They attended over two thirds of scheduled appointments, on average, and over 90% of participants provided data for each follow-up assessment. With respect to treatment gains not specific to treatment modality, overall results indicated that participation in treatment within Project MATCH resulted in significant improvements in days of abstinence, as well as decreased number of drinks per drinking day. Furthermore, these significant changes were largely sustained through 1-year and 39-month follow-up assessments. Thus, it appears that, overall, these brief psychotherapies provided significant and persistent reductions in drinking for patients with diagnosed alcohol abuse or dependence.

With regard to findings that were specific to a priori study hypotheses, results confirmed one match for the primary hypotheses. The one significant match finding demonstrated that outpatients without psychopathology did better in the TSF condition as compared with the CBT condition. Specifically, outpatients without psychopathology who were treated in the TSF condition had more days of abstinence compared with patients with low psychopathology severity who received CBT. This effect was maintained through the 1-year follow-up period, although it was no longer significant at the 39-month follow-up assessment. Thus, although the

TSF condition demonstrated stronger benefits for clients without psychopathology through 1 year following treatment termination, this advantage relative to CBT no longer existed by 39 months following treatment termination.

With respect to overall differences between the three treatment modalities, findings demonstrated that outpatients who received TSF therapy were more likely to remain completely abstinent from drinking alcohol in the year following treatment as compared with outpatients who received the other two treatments (CBT and MET). It is noteworthy that there were no significant differences between the treatment groups in the number of meetings attended by clients at the time of the 39-month follow-up, suggesting that the benefits of TSF cannot be attributed to number of AA meetings attended. However, differences between TSF and the other treatment modalities may have contributed to how clients benefited from AA meetings or the number of meetings attended directly following the completion of TSF sessions.

With respect to client characteristics that were prognostic, being an aftercare male patient was predictive of fewer days of abstinence. In addition, severity of psychopathology in both male and female aftercare patients interacted with time to predict the percentage of days abstinent toward the end of the 1-year follow-up period; patients with higher levels of psychiatric severity were more likely to have fewer days of abstinence compared with patients low in psychiatric severity. The following variables were prognostic of drinks per drinking day for aftercare patients such that the presence of these variables resulted in higher likelihood of more drinks per drinking day: higher alcohol involvement, being male, and greater severity of psychopathology. For outpatients only, higher initial motivational readiness and less social support for drinking predicted fewer negative alcohol consequences. Greater sociopathy interacted with time to predict worse outcomes at follow-up for outpatients, although this effect diminished over time in the 1-year follow-up. Specifically, higher levels of sociopathy were predictive of poor treatment outcomes early in the follow-up, but this effect was diminished later in the follow-up period.

An examination of secondary match hypotheses within Project MATCH demonstrated that outpatients with high levels of anger who were treated with MET had greater improvements in posttreatment drinking

compared with outpatients who were treated with CBT. In addition, aftercare patients who were high in alcohol dependence had better treatment outcomes in the TSF treatment relative to aftercare patients receiving CBT; conversely, patients low in alcohol dependence did better in the CBT condition. Finally, with respect to the 39-month follow-up results, patients with social support networks that supported drinking behaviors did better in the TSF condition as compared with the MET condition patients. This final finding was the largest match difference found in the study.

Results from Project MATCH also indicated that patients higher in anger did better in the MET condition at 39-month follow-up compared with the CBT condition. Indeed, anger was the most consistent variable that interacted with treatment at both 1-year and 39-month follow-ups, with the interaction clearly demonstrating an advantage for patients high in anger treated with MET relative to CBT.

With respect to overall outcomes for the three treatment modalities, declines in drinking at 1-year follow-up were generally maintained at the 39-month follow-up assessment. Although there were few differences among outcomes for the three treatments, TSF showed a slight advantage at 39-month follow-up compared with MET and CBT. This advantage was most notable for measures of complete abstinence from drinking.

A number of client attribute predictors of treatment outcome also emerged from Project MATCH. These variables predicted treatment outcome regardless of the type of treatment received. First, there were better outcomes at 39-month follow-up for patients who reported less social support for drinking. In addition, higher initial motivation for change predicted better treatment outcomes at 39-month follow-up. Finally, patients who had more sessions of both the TSF and the CBT conditions had better treatment outcomes. These general results suggest that, across treatment modalities, patients who report less salient social support for behaviors they are trying to change, who are more motivated for treatment, and whose involvement in treatment is more consistent are more likely to have better treatment outcomes.

Conclusions From Project MATCH

Project MATCH lacked the predicted robust findings from the primary hypotheses of patient-treatment

matching effects. Few of the matching hypotheses were borne out, and of those that were, many were not maintained consistently through the 39-month follow-up. Researchers have suggested that it may be that matching is unimportant, or alternatively that variables of importance were not assessed within Project MATCH. Thus, although results from Project MATCH do not demonstrate robust treatment matching effects for patient–treatment, they also do not rule out the possibility of finding effects when matching patients to alternative psychotherapies (e.g., behavioral marital therapy), pharmacotherapies, or means of treatment delivery (e.g., inpatient vs. outpatient).

Despite the lack of empirical support for many of the Project MATCH hypotheses, it is noteworthy that some variables with potential clinical significance for matching purposes may include social support for drinking, anger, and psychiatric severity. In addition, with respect to overall treatment differences, the TSF condition demonstrated a slight advantage over both the CBT and MET conditions.

In sum, although evidence for the efficacy of triaging clients to treatments based on their individual characteristics and the characteristics of the treatment did not receive robust support, there was some evidence for matching that did emerge. In addition, overall results demonstrated that a limited number of high quality sessions of psychotherapy can result in significant improvements for alcohol-dependent patients and that these effects can be maintained for a lengthy follow-up period.

PSYCHOLOGICAL MODELS OF ADDICTION

There are several models that hypothesize that substance use disorders originate as the result of psychological irregularities or abnormalities. Although the concept of an addictive personality that predisposes one to various substance addictions has met with controversy and methodological flaws in much of this body of research, the notion that there are psychological correlates of addiction is still quite prevalent in the literature. These psychological models can best be understood by grouping them according to their major theoretical paradigms as follows: psychoanalytic models, psychopathology models, personality models, behavioral models, and the opponent process model.

Psychoanalytic Models

Although Sigmund Freud did not write extensively on the topic of addictions, he did propose that fixation at the oral stage of psychosexual development could best explain why people would develop addiction to alcohol, food, and smoking. Fixations were thought to result from an infant being either overstimulated or frustrated at the oral stage of psychosexual development. Other psychoanalytic theorists view addictions as resulting from intrapsychic conflict resulting from an overly harsh superego. From this perspective, alcohol or drug use represents an attempt to escape anxiety, fear, or rage.

Neo-Freudians applied psychoanalytic theory to expand their perspective on addictions. For example, the object relations theorists thought that addictions may result from a failure to bond securely with the mother. Other Neo-Freudians thought that individuals who were traumatized may develop addictions as a means of coping with that traumatic event. Evidence of this approach is seen in the high correlations between individuals with posttraumatic stress disorder and substance use disorders. Another approach views addictions as coming about as a result of ego deficits (i.e., personality flaws or character defects). In both of the aforementioned instances, substance abuse and dependence are perceived as attempts to self-medicate, thereby ameliorating the emotional pain caused by the trauma or the ego deficits.

Psychopathology Models

Correlations between substance use disorders and particular types of psychopathology have been well researched. Although correlation does not imply causality, there are some instances where the self-medication hypothesis can also be applied to these models as causal agents. For example, there are several studies that investigate the correlation between childhood attention deficit hyperactivity disorder (ADHD) and substance use disorders. Although not every child or teen diagnosed with ADHD will become an addict or alcoholic, the research suggests a greater propensity toward substance use disorders in this population. Similarly, young people diagnosed with conduct disorders and other oppositional disorders are also at higher risk for developing substance use disorders in adolescence and early adulthood. Mood disorders have also been well researched. Those with bipolar disorders are thought to be at higher risk for substance use disorders, although those with other mood disorders such as major depression are also considered to be at risk when compared with nondepressed individuals. Women with major depression are considered to be at higher risk for substance use disorders than men.

Among Axis II disorders, it appears that antisocial personality disorder correlates most often with substance use disorders. There are instances, however, where antisocial behavior comes about as one's addiction progresses and is not necessarily an antecedent. Narcissistic and borderline personality disorders also correlate with addictions. However, it is often difficult to discern whether the personality disorder exacerbates alcohol and drug use or whether alcohol and drug use plays a causal role or, at the very least, accentuates these personality disorders.

Personality Models

This group of models looks at a variety of personality variables and individual temperaments that are found to correlate with substance use disorders. For example, Cloninger's tri-dimensional model postulates that those with an extremely high need for novelty seeking, harm avoidance, and reward dependence are often overrepresented among alcoholics and those with other substance dependency. In other prospective studies, it was concluded that children

with low ego resiliency and poor ego control are found to be at higher risk for initiating drug use in their teen years. Individuals found to have a low attention span, high emotionality, and low sociability are also considered to be at increased risk. Similarly, those with a high activity level, low flexibility, mood instability, and social withdrawal are also considered at increased risk for developing substance use disorders. Individuals with an external locus of control are often overrepresented among alcoholic and addict populations. Externality is associated with a tendency to blame others or misfortunes for events and a lack of taking personal responsibility for one's behavior. An external locus of control may explain why alcoholics and addicts are so often adept at denying the impact of their addiction on their overall life functioning.

More recently, the personality area of research has focused on the five-factor model of personality. These five factors are considered to be robust personality factors that when combined with one's temperament are thought to have etiological significance. These five factors include (1) neuroticism—tendencies to experience negative emotions; (2) extroversion—sociability or gregariousness; (3) openness to experience—the ability to self-reflect, intellectual curiosity, a need for variety; (4) agreeableness—which includes tendencies to agreeableness and the ability to be emotionally supportive and altruistic; and (5) conscientiousness—the tendency to achieve dependability and responsibility. Studies of individuals at risk for substance use disorders from the perspective of the five-factor model have found that those with family histories of alcoholism were negatively associated with agreeableness and conscientiousness and positively associated with openness. Alcohol use was positively associated with neuroticism and negatively associated with agreeableness and conscientiousness. Some of these findings are similar to Cloninger's tri-dimensional model, discussed earlier.

Behavioral Models

This group of models hypothesizes that substance use disorders are learned behaviors, and therefore, addictions can be learned or maintained through either classical or operant conditioning. In classical conditioning, drug and alcohol problems are facilitated by a pairing of an unconditioned stimulus (UCS), which would be the alcohol or drug use, with a conditioned

stimulus (CS), which might be a particular place where a person uses drugs, or the friends the person associates with or even the music he or she listens to. As with Pavlov's dogs, who once conditioned would respond to the sound of the bell alone (CS) without the pairing with the meat powder (the UCS), so too do addicts and alcoholics respond to conditioned stimuli or triggers in their environment. For example, a cocaine addict may experience a conditioned craving when he or she sees a mirror, sees white powder on a mirror or a rolled-up hundred-dollar bill, or smells the aroma of cocaine. These all become very powerful conditioned cues and often account for relapse.

Operant conditioning models look at the positive and negative reinforcing effects of alcohol and drug use. For example, if an individual takes a drink of alcohol in order to feel elation, his or her drug use is associated with the positively reinforcing effects of drinking, or the high. This is a basic positive reinforcement paradigm. On the other hand, if an individual feels depressed and uses heroin intravenously to alleviate those feelings, his or her drug use is associated both with the reinforcing effects of taking heroin and with the removal of depressed feelings. This would be an example of a negative reinforcement paradigm. In both instances, drug use is facilitated or increased because it is considered reinforcing. From a behavioral perspective, behaviors that are rewarding or positively reinforcing and behaviors that remove uncomfortable or negative mood states will tend to be continued or repeated. The tension reduction hypothesis is a behavioral model that posits that alcohol or drug taking behavior is reinforced by the chemical's ability to reduce anxiety or tension.

Cognitive behavioral theory (CBT) and social learning theory (SLT) models can also be best described under the framework of behavioral models. The CBT model postulates that alcohol and drug use is facilitated by an individual's irrational thoughts or beliefs that in turn may result in feelings of hopelessness or despair that then result in expectations that alcohol or drugs will relieve that emotional discomfort. SLT extends from operant conditioning or instrumental learning but also takes into account the influence of one's capacity to learn from his or her social environment through observation and listening to others. By modeling one's behavior on influential role models and adopting similar behaviors, individuals come to expect that they will reap similar

rewards. SLT therefore focuses on expectancies as well as self-efficacy and attributions, which all facilitate how particular stimuli result in an alcohol or drug-taking behavior as the response. Through repeated exposures to the effects of alcohol or drugs, the individual begins to develop self-efficacy based on his or her expectation and confidence in his or her ability to cope while under the influence of the substance. The perception of one's inability to cope without the substance then reinforces the need for further drug taking, which results in increased use and eventual substance dependency.

Opponent Process Model

This theory was originally put forth to explain *acquired motives* or behaviors that are not necessary for survival but become powerful motivators of behavior nevertheless. Opponent process theory is especially adept at explaining nonchemical addictions or what are sometimes referred to as process addictions (e.g., gambling, sexual addiction, addiction to exercise). However, the model was also found to be useful in explaining chemical or substance dependency. In this two-process theory, it is posited that both positive and negative emotional states underlie all addictions. When one takes a drink or a drug, one first experiences an initial exhilaration, elation, or some other powerful primary emotional response. The secondary process is that which takes place in the hours following alcohol or drug ingestion whereby the person begins to feel discomfort as the drink or drug is metabolized and the substance's effects dissipate. This initiates a pattern whereby the individual then seeks to regain the initial primary process emotional state. This can work in reverse as would be the case with skydiving, which is often used as an example of an acquired motive or process addiction. When a person is preparing to skydive, he or she often develops an intense dread and anxiety. After he or she lands safely, there is an incredible feeling of elation at having survived the ordeal. These opposite or opponent processes then set up a situation whereby the individual often wishes to reexperience the intensity of the high of skydiving. This two-process model goes beyond the tension-reduction hypothesis or the positive reinforcement explanations of the behavioral model in that it takes into account the impact of the aftereffect of the initial high of substance use.

Conclusion

Substance use disorders are complex, multidetermined entities for which multiple etiological factors and processes need to be taken into account. The psychological models of addiction reviewed above suggest that behavioral, cognitive, personality trait, predisposing pathology, and temperament factors all play an important role in either etiology, correlates of addiction, or processes that help to explain how and why addictions are maintained or progress in their severity.

PSYCHOSOCIAL HISTORY

The psychosocial history is a critical component of the assessment of patients with substance abuse, dependence, and related problems. Collection of this information typically occurs during a patient interview, but it may also be gathered using self-report questionnaires and other assessment instruments. There are multiple components of the psychosocial history that collectively contribute to a thorough assessment of the patient's current psychological functioning and future treatment needs. This entry provides a summary of the main components of the psychosocial history and proposes useful strategies to acquire this information during a patient evaluation.

Establishing Rapport

Establishing initial rapport with a patient during an evaluation is essential in gaining a valid, consistent, and thorough psychosocial history. Strategies consistent with motivational interviewing, an approach developed by William Miller and Stephen Rollnick, may be helpful in facilitating a positive relationship between the interviewer and patient. For example, the interviewer should strive to promote a positive relationship throughout the assessment using empathic listening, providing support and encouragement, displaying genuine concern for the patient, responding to patient concerns, and providing needed clarifications and explanations. Interviewers should avoid statements that are likely to elicit resistance, such as confrontation of denial of a substance abuse or dependence problem, excessive questioning, interrupting the participant, and arguing with the participant.

Obtaining an accurate psychosocial history can also be problematic because of the social stigma of alcohol and other drug use. However, there are ongoing efforts by federal agencies, researchers, and advocacy groups for recovering alcoholics and addicts to characterize addiction as a chronic medical condition. As a result, the public perception of addiction may be changing. This change may make it easier to establish rapport and build trust. It may also increase the importance of family history and mental health comorbidities in the psychosocial history.

Demographic Characteristics and Related Issues

Follow-up questions to the patient can target information about specific demographic variables, such as the patient's family constellation, marital status, current employment, educational history, and cultural background. This information will help the interviewer appreciate the patient's background and provide a foundation to understand the effect of substances on the patient's life. For example, some cultures may prohibit the use of alcohol, whereas other cultures embrace it as part of tradition and practice. As a result, patients' attitudes and beliefs about substances may be shaped by their culture and, in turn, can affect their behavior. In addition, age is an important factor that may affect substance use. Experimentation with substances typically occurs during adolescence, so young adults may have different triggers for alcohol and drug use (e.g., peer pressure from friends) than older adults.

In addition to demographic characteristics, patients typically present with issues that may be caused by or related to substance use. These areas include family, social, legal, educational, occupational, and medical issues and are critical to address during the psychosocial history. Assessment of the patient's family history of substance use and other problems (e.g., financial, partner violence) helps to increase understanding of the family of origin and its impact on the patient's substance use. Similarly, the patient's social history can provide information about how the patient may have changed relationships and social activities. For example, a patient may be spending less time with a spouse and more time with friends who use substances more frequently. The assessment of family and social history may also be useful in identifying any codependent relationships.

Although challenging, it is critical to obtain a thorough history of any problems with the law (e.g., report of DUIs or arrests for possession of drugs).

For adolescents, these problems are usually status offenses (e.g., truancy, incorrigibility) and may be warning signs of substance use disorders. Educational history is another important area to assess among adolescents because academic failure has been shown to be associated with substance abuse problems. Similarly, occupational problems are common among adults with substance abuse disorders. Last, a thorough medical history may indicate the abuse of alcohol or drugs. For example, patients with alcohol abuse commonly present with medical problems such as gastritis, peptic ulcers, or a fatty liver. These medical concerns can be severe and often provide the impetus for a patient seeking help.

Substance Use and Related Problems

After building initial rapport, the presenting problem and report of current symptoms is typically the next aspect of psychosocial history assessed. It is important to ask specific questions about the nature, frequency, and duration of the patient's current symptoms for an accurate diagnostic impression. Information about how the substance has negatively impacted the patient's functioning is also critical in making a diagnosis of a substance abuse or dependence disorder according to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*. Although challenging, it is important to directly ask patients about negative effects. For example, one might ask, "What legal problems have you had as a result of your drinking?" or "How has your use of drugs affected you at work?"

Patients with substance use disorders may be guarded and deny any problem with alcohol or drugs, and they may be required to seek mental health services by family or court mandates. Thus, open-ended questions are most effective in gaining reliable information about current symptoms. For example, an examiner may ask, "Can you tell me more about your use of alcohol?" or "What are some of the ways drugs have impacted your life." In interviewing a patient, there is a risk that asking one closed-ended question after another will rapidly train the patient to be passive, answering each question and then quietly waiting for the next. This type of questioning tends to be one-sided, much like a cross-examination during a trial. Although the interviewer guides the direction of the evaluation, the use of open-ended questions will help the patient feel in control, and he or she will be more likely to elaborate responses.

In addition to the assessment of current symptoms, it is necessary to obtain a thorough assessment of the history of the patient's substance use. For example, the examiner should inquire when the patient began the use of the substance or substances that are the presenting problems as well as experimentation and use of other drugs. Information about previous attempts at decreasing or quitting alcohol or other drug use may help identify the patient's strengths. Asking a patient about experiences in previous treatment programs or support groups for substance abuse (e.g., individual therapy, Twelve-Step programs), if applicable, provides useful information for future treatment recommendations. Inquiry about family history of substance abuse and dependence is also important in understanding the development of the illness. Early exposure to alcohol and drugs, for instance, may be a contributing factor to the patient's current substance problem.

Functional Analysis of Substance Use

In conjunction with the assessment of the patient's current symptoms and history of substance use, the interviewer should try to help the patient conduct a functional analysis as part of the behavioral assessment of substance abuse and dependence. The ABC model is typically used, in which the A represents antecedent stimuli that precede the target behavior, B represents the target behavior (i.e., substance use), and C represents consequences that occur after the behavior. Some functional analysis models also include cognitive and emotional components, such as thoughts and feelings, and are located in between the antecedents and the behavior. The functional analysis underscores for the patient the way in which his or her substance use interacts with and is maintained by environmental events. The functional analysis helps conceptualize the individual patient's substance use disorder and develop an appropriate treatment plan and recommendations.

Comorbidity

Substance abuse and dependence disorders often co-occur with other psychiatric disorders, such as depression or anxiety. Assessment of symptoms and diagnoses of other psychiatric disorders helps provide a comprehensive diagnostic impression of the patient and may identify the patient's use of substances as a self-medication strategy. For example, recent research by Rebecca Dodge and colleagues

indicates that patients with more depressive symptoms are less likely to abstain from drugs following discharge from an outpatient substance abuse treatment program. The depressive symptoms predicted treatment success over and above demographic variables, such as age, race, primary drug of choice, and frequency of drug use at admission. Information should also be collected about previous psychiatric hospitalizations, medication trials, and therapy.

Questions about the patient's current emotional state, mood, and sleeping and eating patterns are all useful in the assessment of co-occurring psychiatric disorders. Although difficult, a thorough assessment of current suicidal and homicidal ideation as well as a history of previous suicide attempts is critical in ensuring the safety of the patient. Research has suggested that patients with substance abuse and dependence disorders are at increased risk for suicide, especially adolescents. Additional risk factors of suicide that are important to assess include previous attempts, specific plan, intent, means (e.g., pills, knives), lack of future orientation, and social isolation. Similarly, the interviewer should ask the patient about any previous or current verbal, physical, or sexual abuse.

Methods of Data Collection

In addition to a clinical interview, the psychosocial history may be collected using evidence-based assessment instruments targeting patients with substance abuse and dependence. For example, Marilee Comfort and colleagues developed a 300-item semistructured interview, called the Psychosocial History (PSH), to assess women in substance abuse treatment programs. The interview is designed to describe patient and family characteristics, formulate a treatment plan, and provide a baseline measure of functioning. It has strong psychometric properties and has been used to measure the outcome of treatment. Although evidence-based interviews like the PSH are typically used in research studies, they provide structure and a comprehensive assessment of psychosocial history that may prove valuable in clinical practice.

Special Population Characteristics

When taking a psychosocial history, it is important to understand the characteristics of the population being assessed. There are special populations that have unique issues that need to be considered. For example, women who use drugs during pregnancy are often

difficult to engage because of their fear of losing custody of their children or fear of criminal prosecution. Negative attitudes by treatment providers often drive these women away from the health care system. The psychosocial history needs to be done in a nonjudgmental fashion addressing issues such as health insurance, transportation and child care, the developmental and emotional needs of their children, domestic violence, women's issues, prenatal care, involvement with child welfare and legal systems, poor parenting, and the stigma associated with being a drug-using mother.

Conclusion

The psychosocial history is a critical component of the assessment of individuals with substance abuse and dependence disorders. Information is typically obtained using interviews but can also be collected using self-report questionnaires and other assessment techniques. In addition to establishing initial rapport with the patient, the key components of the psychosocial history include the assessment of demographic variables, current symptoms, previous alcohol and drug use, comorbid psychiatric disorders, and emotional needs. It is also important to understand the unique needs of certain populations (e.g., women who use drugs during pregnancy). Information gathered during the psychosocial history helps to make a thorough assessment of each patient and to determine appropriate treatment needs and recommendations.

PUBLIC POLICY, ALCOHOL

Public policies concerning alcohol use vary widely. Societies that view alcohol use as an immoral act tend to be more punitive toward its use, whereas societies that view alcohol misuse as disordered behavior or a sign of an illness tend to react with policies that focus on public health solutions. Alcohol policies in the United States have developed in the midst of societal tensions between these two very different views of drinking, frequently resulting in contradictory public policies. In addition, many policies regarding alcohol sales, distribution, and use have been left to individual states, resulting in a lack of uniformity of policy within the United States. U.S. governmental funding of prevention and treatment services has been relatively small, contributing to a shortage of services, especially for dispossessed citizens.

International Policy Differences

How a society views alcohol misuse (as a moral or health problem) tends to inform the types of public policies that are developed within that society to legislate the accessibility, marketing, taxation, and sale of alcoholic beverages, as well as the efforts that are placed into policing, preventing, and treating alcohol misuse. In societies with strong moral objections to the use of alcohol, national policies typically have

little to no tolerance for alcohol. Policy is often formulated to control or punish alcohol use in these nations. Many Islamic majority nations, for example, forbid its use or have severe penalties, including capital punishment, for its misuse. At the other extreme of the continuum of public policies, nations in which alcohol use is strongly sanctioned by society generally have more lenient policies regarding the sale, use, and misuse of alcohol. Societies that view alcohol misuse as a health problem formulate policies that emphasize prevention and treatment instead of punishing alcohol's misuse.

Historical U.S. Public Policy

The history of U.S. public policy underscores national tensions regarding the place of alcohol in society. During the U.S. colonial period, alcohol consumption greatly exceeded the per-capita levels observed today, and its use tended to be less regulated. However, isolated settlements banned or highly restricted alcohol use, usually when prevailing religious beliefs were puritanical. During the colonization process, alcohol was often used to make up for the lack of potable water. In addition, the U.S. government sanctioned and encouraged the use of alcohol during treaty negotiations with indigenous peoples in order to gain advantages. In these ways, alcohol use and misuse followed the progress of settlers as they crossed the nation.

Organized prohibitionist movements, such as the Anti-Saloon League and Women's Christian Temperance Union, arose during the 19th century. By the middle part of the 19th century, 13 states had enacted prohibition laws that restricted alcohol sales and use, and in some areas, local governments began to enact drinking age laws to restrict access. Perhaps the most famous of the prohibitionists was Carry A. Nation, who garnered a reputation for vandalizing drinking establishments with a hatchet and using public ostracism as a method to discourage drinking among the citizenry. The results of these efforts peaked in the early 20th century with the enactment of the 18th Amendment to the U.S. Constitution, ushering in the period in U.S. history referred to as prohibition.

Prohibition reduced the per-capita alcohol consumption of the U.S. populace, but it became increasingly unpopular as policy. During prohibition, organized crime began to import or produce illegal alcohol. The federal government, in efforts to enforce prohibition and reduce the influence of organized

crime, enacted policies authorizing federal agencies, such as the Treasury Department and the Federal Bureau of Investigation, to enforce the 18th Amendment. Enforcement became a costly enterprise for the government during this era. Economic consequences occurred, including loss of significant tax revenue for governments and economic losses for citizens associated with the beverage industry. Economic factors and the lack of enforceability contributed to the demise of prohibition as a national policy. The 21st Amendment, enacted in 1933, repealed the 18th Amendment and left the right to legislate most alcohol policies to state and local governments. Many states repealed prohibition outright but left various restrictions in place. Some counties and communities remained *dry* to alcohol. Many states restricted sales through state-owned liquor establishments, opted to enact *blue laws* to restrict or forbid sale of alcohol on Sundays, or used excise taxes to restrict accessibility (and increase revenues) by increasing prices on alcoholic beverages.

Delegating alcohol use legislation to states resulted in a lack of uniformity in legal drinking ages across states. Immediately following prohibition and during the next 2 decades or so, the legal drinking age was essentially 21 years of age with the exception of a lower drinking age for beer in some states. However, during the 1970s, a majority of states lowered the legal age to 18 to 20 years of age. The disparity in drinking ages across states was linked to auto accidents in which young adults drove across state lines to drink legally. Because of these tragic events, Mothers Against Drunk Driving lobbied for a higher and uniform national legal age limit for drinking alcohol. The resulting legislation, called the National Minimum Drinking Age Act of 1984, established a national age limit of age 21, with the stipulation that states that did not abide by this uniform limit would forfeit national highway construction and maintenance funds. Currently, all states are abiding by the age limit. Interestingly, the 21-year U.S. limit is among the highest legal age limits in the world.

Research investigating the effectiveness of the uniform age limit to reduce aversive outcomes has produced equivocal results. Various studies conducted immediately after the adoption of the new age limit showed reductions in drinking-related consequences following the standardization. However, many recent studies have found disturbing trends in underage drinking and its consequences, especially on college

campuses, suggesting that the legal age limit has not dissuaded underage drinking. Critics of the current legal drinking age limit have argued it does not have broad social support. Certainly enforcement of the legal drinking age seems to be rather inconsistent in society, which may be a result of cultural ambivalence about the higher age limit.

Current U.S. Alcohol Sales Policies

Since prohibition, alcohol production and sales have become important industries in the United States. Because of this phenomenon, U.S. trade policies have included protections, often in the form of taxes and import quotas, to control the importation of foreign alcoholic products that would compete with U.S. beverages. Protectionist strategies have trickled down to states that have restricted importation across state lines of alcoholic beverages to protect their own industries. State efforts toward protectionism, however, may be drawing to a close, because a U.S. Supreme Court decision has ruled that interstate free trade cannot be restricted by the enactment of these laws. The catalyst for a challenge to these interstate restrictions of sales and shipment of alcoholic beverages has been the growth of Internet alcoholic beverage sales.

With regard to underage drinking, some local communities have moved toward restricting the number of liquor licenses awarded in college and university neighborhoods. Ethnic minority neighborhood groups also have lobbied local communities to restrict the number of liquor licenses awarded in order to reduce density and access. Local excise taxes have been used to increase the prices of alcoholic beverages in order to dissuade purchasing by underage drinkers with limited incomes. Research supports the efficacy of raising prices to curb consumption on the part of young adult drinkers. Other policies have been enacted, such as placing greater liability upon establishments to protect patrons from being served when intoxicated and offering training to servers to identify underage drinkers and detect intoxication, with mixed results.

U.S. Public Policy, Prevention Efforts, and Research

Prevention campaigns have been hampered by relatively low rates of federal funding in the United States. Advertising campaigns have been used in efforts to discourage abusive drinking such as drinking and driving

or to encourage seeking treatment. Many campaigns have used fear messages to encourage behavior change, but the research suggests that fear messages may not be a particularly effective means to motivate change, especially among young adults. Drinking prevention efforts in the United States have also been conducted within schools by means of health courses, clubs, or school-wide assemblies, sometimes beginning as early as primary school. Many schools now have student and parent organizations that support and promote prevention efforts in schools, and these organizations will sponsor alcohol-free activities, often during high-risk occasions such as prom night.

Recent government funding efforts for preventing alcohol problems have focused primarily on two different areas. The first area has been the development and promulgation of abstinence-based prevention programs, often referred to colloquially as “just say no” programs. These programs were first promoted under the Reagan administration, and support for these programs increased dramatically under the George W. Bush administration. The most famous of the programs, D.A.R.E., has been the preeminent school-based alcohol prevention program in the United States for many years. Unfortunately, researchers have found that abstinence-based prevention programs, including D.A.R.E., do not show good drinking outcomes for participants. Some school districts have begun to reevaluate and restructure their prevention programs because of the research. However, the federal government continues to fund abstinence programs in spite of evidence of poor outcomes.

The second priority area of government funding of prevention efforts has been for genetic research on alcohol dependence. The goal of this research presumably is to identify people at high risk for developing problem drinking and develop genetic or pharmacological cures for the disorder. The research has found some evidence of genetic risk factors for developing alcohol problems, but no obvious pattern can be declared to be the definitive cause of problem drinking.

U.S. Public Policy, Alcohol Treatment, and Research

The U.S. government through the National Institutes of Health (specifically, the National Institute on Alcohol Abuse and Alcoholism) has supported research to determine best practices for treating alcohol use disorders. For many years, treatment services

were developed and implemented in the absence of scientific knowledge about effective practices. It has only been in the last 2 decades or so that researchers have developed and tested effective psychosocial models for treating alcohol problems. Although best practices for treating alcohol problems are being promoted by the federal government, they have been slow to be adopted by practitioners in the field. The net result has been that the use of best treatment practices across the country has been spotty. Many developed nations are far ahead of the United States in using best treatment practices as a matter of public policy.

Government and privately funded research efforts have produced new medicines that help reduce and prevent cravings for alcohol. These pharmaceutical advances have helped improve outcomes for some patients seeking alcohol treatment. The adoption of the use of these pharmaceutical agents to treat alcohol problems has occurred more rapidly than the adoption of research-derived best practices for psychosocial treatment.

One major problem in the United States is treatment inaccessibility. People of low income and certain ethnic minority groups have not accessed treatment services proportionate to their need because of economic and other barriers. Although U.S. public policy has identified specific disparities in delivery of alcohol treatment services, it has not yet responded with sufficient funding or policy changes to measurably reduce these disparities.

Conclusion

There is no worldwide consensus about policies concerning the production, sales, and use of alcohol. In the United States, policies have changed as a function of cultural shifts in attitudes. The United States currently has one of the highest legal drinking ages in the world yet continues to have tremendous problems with underage drinking. Other developed nations with more permissive attitudes toward alcohol use do not show evidence of having greater alcohol-related problems than the United States, suggesting that tight controls may not be the answer to U.S. alcohol problems. American society would likely benefit from public policies that place a higher priority on the use of best practices to intervene in alcohol use, and on increased efforts to develop and implement cost-effective prevention efforts.

PUBLIC POLICY, DRUGS

Drug policies vary by society. In many societies the use of psychoactive substances has been sanctioned and in many instances associated with spiritual and religious practices. In the United States, substance use policies have changed radically over time from a laissez-faire approach to highly regulated and policed policies. U.S. substance use policy began to change in the early 20th century as concerns arose about the morality of drug use. In recent years, the public debate has focused on whether substance abuse is primarily a public health or a legal concern. U.S. public policy today reflects both points of view, contributing to drug policy strategies that are frequently contradictory and at odds in how they function.

International Drug Policies

Psychoactive drug use has been an important part of many civilizations, often done in conjunction with religious and spiritual ceremonies. Many cultures have sanctioned psychoactive substance use, and some of those societies continue to be at the forefront of public policy efforts as exporters of psychoactive substances. In addition, many societies, including the United States, have historically sanctioned public gathering places for the explicit use of psychoactive substances (e.g., opium dens). Although several governments have taken action to reduce or eliminate such establishments, other nations have allowed some types of substance use in public establishments (e.g., the Netherlands).

Laws governing substance use differ greatly around the world. In some societies, substance use or drug trafficking can be punishable by death. Other nations view substance misuse as a public health problem and tend to use legal resources to leverage people into treatment services. Societies can have widely varied responses to different substances that reflect cultural views about the usefulness and risks associated with the substance in question. Furthermore, as societal norms concerning substance use change, policies change as well. The United States is an excellent example of how policies change as attitudes change.

History of Drug Use Policy in the United States

Until the 20th century, drugs were mostly unregulated in the United States. Many consumer products, such as medicines sold over the counter and beverages, included psychoactive substances. Concerns about the purity and safety of food and medicines led to the Pure Food and Drug Act of 1906, the first national effort to make drugs safer. In 1909, because of concerns about the morality of behavior in opium dens, the U.S. federal government banned smoking opium, representing the first national prohibition against any substance. The Harrison Act of 1914 was the first attempt to regulate other opioids and cocaine by requiring distributors to report their activities and pay taxes on their goods. Subsequent regulations and court rulings strengthened the restrictions on these substances during the next couple of decades. Heroin became the third substance banned by the government in 1924 (alcohol was the second).

During the period that resulted in alcohol prohibition, public campaigns initiated by citizens groups concerned about the morality of drug use appealed to the dangers of certain substances, such as marijuana and peyote. Marijuana (or hemp) plants had been used for many years in the United States to create rope; therefore, the plant was widely available. During the 1920s, marijuana use increased, presumably as an alternative to alcohol (which had been banned). The Uniform State Narcotic Act, passed in 1932 to encourage adoption of federal drug legislation by states, also granted (and encouraged) states to ban cannabis use. Public prohibition campaigns used fear messages to dissuade use of marijuana by the public. One by-product of this effort was a motion picture titled

Tell Your Children (more commonly known by its rerelease name of *Reefer Madness*), produced by a religious group in the mid-1930s, which linked marijuana use with loss of control and morally inappropriate behavior. The movie was credited with spawning new legislation in 1937 that required marijuana producers and sellers to purchase federal tax stamps, although no tax stamps were ever produced, effectively banning marijuana use in the United States. Peyote (mescaline), on the other hand, was used primarily by American Indians in religious ceremonies. As part of governmental efforts to outlaw traditional Native practices (for fear of insurrection), peyote was banned by many states around the same time. However, in recent years, freedom of religion legislation has restored the rights of Native Americans to use the psychoactive substance in religious practices.

Beginning in 1938, many substances became subject to regulations of the Federal Food and Drug Administration that required testing for medical efficacy and safety. In 1951, the Boggs Act introduced the concept of mandatory minimum sentences for violations of drug use laws. Perhaps the most influential legislation concerning substances was enacted in 1970 with the passing of the Controlled Substance Act, which instituted the federal schedule of controlled substances. Five schedules were developed by the federal government based upon relative risk for addiction and relative medical usefulness. Schedule I substances, according to the act, constitute the highest risk for addiction and have no medical usefulness, whereas Schedule V substances have been identified as lowest risk for addiction and having the greatest medical usefulness. Examples of substances and their schedules include heroin (Schedule I), cocaine (Schedule II), morphine (Schedule III), benzodiazepines (Schedule IV), and some codeine cough syrups (Schedule V).

However, there is heated debate concerning the accuracy of the federal schedule, with many researchers arguing that the schedules reflect political agendas more than they reflect scientific reality. For example, marijuana is a Schedule I substance but there is evidence that it is much less addictive than other substances scheduled below it and that it may be medically useful. On the other hand, there is growing evidence of widespread abuse of prescription drugs in the United States among all age groups and social classes, especially for Schedule III opioid drugs for pain and for Schedule IV benzodiazepines prescribed

for anxiety. Enforcing policies to control the rising abuse of prescription medicines is complicated by competing interests of pharmaceutical companies that heavily market their products to physicians, other prescribers, and now to the public in mass media.

Prevention Efforts and Research

Before the middle of the 20th century, there was little concerted effort to prevent substance abuse in the United States. Current efforts to prevent drug abuse in the United States focus on promoting abstinence and using interdiction. Government and privately funded advertising campaigns have been used to dissuade adolescents and young adults from initiating substance use. Many of the advertising campaigns use fear or guilt messages in order to prevent substance use or promote abstinence. The research suggests that these efforts have not been particularly successful in reducing substance use in society and that fear messages are not particularly efficacious in modifying substance use, especially among adolescents and young adults. Efforts also have been made to link substance use campaigns with concerns about the spread of HIV, and these campaigns tend to use fear messages to promote abstinence.

School-based campaigns have generally focused on promoting abstinence as a goal. Many of these programs, developed with an eye to the D.A.R.E. model, have promoted a theme of “just say no” to drug use. Researchers who have studied school-based abstinence approaches to substance prevention have found that they are generally not effective. Although researchers have consistently found fault with abstinence-only programs, the federal government continues to favor these initiatives while actively opposing efforts that do not insist on abstinence.

Another major prevention effort by the federal government includes substantial funding of research to identify genetic causes and treatment for people at risk for developing substance use problems. Although evidence of heritability has been revealed by research, progress on identifying genetic markers associated with specific patterns of substance use has been slow. Since there are so many different presentations of substance use, it is highly unlikely that a single pattern will emerge. In addition, money being spent on these efforts will not help to prevent other psychosocial risk factors for drug abuse that have been identified by research (such as interpersonal stress and poverty).

The U.S. War on Drugs

The greatest federal expenditures to curb drug abuse have been earmarked to enforce drug laws and eradicate international production sources. The so-called War on Drugs was initiated by President Nixon when he declared drug abuse to be a security threat to the United States. In 1973, he formed the Drug Enforcement Agency (DEA) to coordinate interdiction efforts. The DEA has worked with other federal agencies to intervene in drug production, sales, and use in the United States and in many other countries. The U.S. government also has used financial incentives, including promises of or threats to decrease foreign aid, to influence drug policies in other countries.

The controversial War on Drugs has not reduced substance use in the United States. The War on Drugs has cost U.S. taxpayers billions of dollars, and the costs are escalating rapidly. Many of the costs are related to incarceration of inmates. More than 1 million inmates are estimated to have substance abuse problems, and a majority of inmates are imprisoned on charges that can be directly or indirectly linked to substance abuse. The incarceration rate for inmates of color is especially high and disproportionate to representation in U.S. society, leading many social scientists to conclude that the War on Drugs is not only ineffective but also biased against people of color.

Partly as a reaction to the War on Drugs, there have been grassroots efforts to decriminalize substance use. These efforts have not produced many changes in policy, but they have resulted in some states enacting laws that allow medical use of marijuana for certain chronic conditions under the supervision of a physician. Twelve states have passed laws to this effect, although the federal government, upheld by the courts, has asserted that federal drug laws supersede states' rights when it comes to legalization of marijuana.

Drug Treatment and Research

Abstinence-based Twelve-Step therapy has been the predominant treatment model for drug problems in the United States. Other best practices for treating drug problems have been developed and empirically tested, including cognitive behavioral therapy and motivational interviewing. Unfortunately, many treatment providers have been slow to embrace best practices. Furthermore, researchers have found evidence that complete abstinence is not necessarily a requirement

for positive outcomes from drug treatment. Pharmacological researchers have developed and empirically tested promising medicines that interfere with substance-induced euphoria and reduce drug cravings that are now used in conjunction with efficacious psychotherapy to successfully treat drug problems.

Many developed nations do not promote abstinence-only goals and commonly utilize harm reduction strategies (e.g., needle exchanges to prevent communicable diseases). Although many harm reduction programs have been shown to improve health outcomes and to reduce health risks among drug users, the United States has been slow to embrace them. In spite of substantial evidence of effectiveness, key U.S. policymakers view harm reduction programs as condoning morally unacceptable drug use.

Conclusion

Drug policies vary widely around the world. In addition, drug policies often vary across substances, with culturally sanctioned substance use dealt with more permissively than substance use that is considered immoral or unhealthy. Drug policies in the United States have not been effective in reducing substance-related problems in the United States. The federal schedule for controlled substances appears to be an obsolete document that does not reflect the current research on risks and benefits of various substances. The War on Drugs has by most accounts been a failure. The net effect of the War on Drugs has been to drive substance use underground, reducing the accessibility of treatment services for substance users because of concerns about legal repercussions, and the war has cost society billions of dollars that have been set aside for law enforcement and corrections efforts in a revolving door system that leaves many incarcerated substance users untreated. Developed nations that have focused on developing public health policies to address drug problems rather than on policing efforts do not have the level of substance abuse problems experienced by the United States. The United States would likely benefit from refocusing its public drug policy from the War on Drugs to public health efforts including use of best prevention and treatment practices.

PUBLIC POLICY, PREVENTION

Prevention programs for substance use problems have several advantages over other interventions, including the potential for higher cost-effectiveness and an opportunity to prevent many of the harmful effects of substance use disorders before they occur. Public policy refers to the laws and regulations provided by the government and can greatly influence how and which prevention programs are implemented. Public policies drive a variety of activities related to prevention, including creating lists of evidence-based practices, implementing prevention programs, and evaluating their effectiveness. In addition, public policies may directly result in environmental prevention efforts through areas such as substance control laws and regulations. However, there have been some criticisms of these policies and their effectiveness in reducing substance use.

Five federal agencies are responsible for the majority of the implementation of substance abuse prevention on a national level: the National Institute on Drug Abuse (NIDA); the Office of Justice Programs (OJP); the U.S. Department of Education; the Substance Abuse and Mental Health Services Administration (SAMHSA); and the Office of National Drug Control Policy (ONDCP). Many of these programs evaluate progress through the Program Assistant Rating Tool (PART),

which rates prevention programs based on four categories (purpose, planning, management, and effectiveness) on a scale of 1 to 100 with scores from 0 to 49 considered ineffective, 50 to 69 considered adequate, 70 to 84 considered moderately effective, and 85 to 100 considered effective. These organizations target substance use prevention in several ways.

Evidence-Based Programs Lists

In order to increase the effectiveness of prevention efforts, several federal agencies require that funded prevention programs be evidence-based. To accomplish this, SAMHSA created a National Registry of Evidence-based Programs and Practices (NREPP) that provides a list of scientifically based substance abuse prevention programs. These programs were evaluated based on the strength of the evidence supporting them and were placed into one of three possible categories: promising, effective, or model. Furthermore, the NREPP considered the ability to disseminate and implement these programs as this is crucial to the actual effectiveness of these programs in the field. Current prevention programs that meet evidence criteria for substance abuse problems cover use of a range of substances that include steroids, diet pills, tobacco, and psychedelics. The Department of Education also created a similar list, identifying promising and exemplary prevention programs. These lists are crucial as many organizations, especially schools, depend on them in order to determine which prevention programs to use.

Community Prevention Programs

The substance abuse prevention efforts of SAMHSA are conducted through its Center for Substance Abuse Prevention (CSAP). The CSAP grants money through the Substance Abuse Prevention and Treatment Block Grant to the individual states. The funds must be used for prevention in some combination of the six following key areas: information dissemination, community-based process, environmental strategies, alternative activities, education, and problem identification and referral. However, the PART system has found this to be ineffective, with a score of only 8 out of 100 on effectiveness.

CSAP funds or directs several other national programs. For example, CSAP funds the Programs of Regional and National Significance project, which

includes the Strategic Prevention Framework State Incentives Grant Program. This program helps communities assess prevention needs, improve the capability of the community to implement these prevention needs, develop strategic plans, implement the plans, and finally, evaluate the effectiveness of the plans. This program assists jurisdictions or communities in implementing evidence-based prevention programs. In addition, the Programs of Regional and National Significance project includes the Substance Abuse Prevention and HIV Prevention in Minority Communities Services Grant, which targets prevention of substance use among individuals diagnosed with HIV. CSAP also funds the Regional Centers for the Application of Prevention Technologies, which consists of five centers specializing in assisting states, jurisdictions, or other communities with the latest evidence-based substance abuse resources. These centers provide training and technical support for those participating in substance abuse prevention work and monitor the results for effectiveness and accountability. When assessed as a group, the Programs of Regional and National Significance have been found to be moderately effective by the PART standards.

The Office of the National Drug Control Policy (ONDCP) reports that public perceptions of substance use, as well as public understanding of negative health effects, greatly impact the trends of drug use. Accordingly, the ONDCP allocates a significant portion of their resources for campaigns like the National Youth Anti-Drug Media Campaign to increase the public perception that drug use is negative and harmful. These media campaigns aim to refute myths regarding drug use as part of an overall antidrug message. This program was found to be ineffective by PART, with an effectiveness rating of 6 out of 100.

The ONDCP has also targeted peer pressure with the Random Student Drug Testing program. The rationale for this program is that it will give students an easy way to say no to drugs. This program is also designed to identify students who are using before abuse becomes a problem. The ONDCP also focuses on forming antidrug coalitions, including the Drug-Free Community Support Program in which community leaders and other groups in the community (such as fraternal organizations) form coalitions. The goals of the coalitions are to identify prevalent drug problems within their individual communities and then to

act together to combat these specific problems. PART found this program adequate.

Another community program run by the ONDCP is the Major Cities Initiative in which cities with high rates of substance abuse are given special attention. The ONDCP encourages local leaders and authorities in the identified urban areas to work toward substance abuse prevention goals, to promote communication and coordination within the community, and to assist in gathering effectiveness data to discover whether the prevention strategies are meeting their intended goal.

The Department of Education also assists in funding and implementing substance use prevention programs through the Safe and Drug Free Schools and Communities Act (SDFSC). The SDFSC provides funds to each state in order to implement evidence-based programs in schools, and by funding larger-scale programs and grants. In addition to being a major source of funds for schools, the SDFSC assists with the training and implementation of school-based programs. PART found the SDFSC to be ineffective.

Environmental Prevention

Several policies aim to prevent substance use directly through laws and regulations that reduce access to specific substances. For example, past policies increasing the legal drinking age to 21 have impacted both the amount of alcohol consumption by young people and the fatalities related to alcohol. Federal programs have also been developed with the goal of increasing the effectiveness of these policies. The Underage Drinking Laws Program, run by OJP, builds upon this prevention strategy through community outreach. The program acts as a liaison with law enforcement and provides information to communities and specifically to youth on the drinking laws. It also offers positive alternative activities to drinking for underage populations. Although the major focus of this initiative is on law enforcement, a wide variety of prevention activities occur under this initiative, including youth-focused campaigns to reduce driving under the influence.

In addition to legal age restrictions, policies may target access by influencing the commercial availability of substances. For example, taxes on alcohol and tobacco are designed to reduce the availability of these substances by increasing their cost. Limitations and regulations regarding liquor licenses

provide another means for public policy to more effectively regulate the supply of alcohol within communities. In regard to illegal substances, several programs have specifically targeted their supply through a variety of activities at both the national and international level. For example, state and federal agencies have worked to limit the precursor ingredients for methamphetamine manufacture in the community by implementing laws that require people purchasing products containing the ingredients to sign a registry and to limit the amount of the product they can purchase at one time.

Problems With Public Policies

Despite the large number of government programs and billions of dollars in funding, there are mixed reviews as to whether there have been reductions in the use of alcohol, cigarettes, and illicit substances. This may be attributed in part to problems with government programs and policies. A major problem is that certain policies lead to the implementation of non-evidence-based programs and to the removal of effective programs. Large-scale programs continue to be implemented, targeting areas such as media campaigns and community coalitions despite their lack of support from research. Furthermore, programs often do not target areas that research would suggest are most important. For example, there is a major focus on preventing illegal drug use, despite the fact that tobacco leads to more annual deaths and that alcohol is the most commonly abused drug. Efforts to specifically target prevention of underage drinking have lost funding, while other programs that research suggests are ineffective, such as drug testing in schools, are on the increase. These inconsistencies may in part be attributable to conflict between policies regarding free trade and access to alcohol and tobacco products and policies attempting to prevent the use of such substances. Overall, discrepancies between research findings and public policy are especially problematic since many prevention programs depend on government funding. This dependency is especially true for prevention efforts in school settings.

Many schools do not implement evidence-based programs for substance use prevention, or when they do, they tend to have low-quality implementation. Among the limitations are a lack of funding and inadequate guidance. Often, the evidence-based

prevention programs that were designed and implemented with well-trained staff and extensive resources are altered to fit available school resources. The alterations result in programs that may lack the efficacy of the original model. Schools with more resources and information about available programs tend to be more successful implementing programs, but few schools have enough resources or information.

Another barrier to implementing evidence-based programs in schools is the variable quality of evidence-based program lists produced by the government. The Education Department no longer provides an updated list of evidence-based programs, leaving many schools to rely on outdated lists or other sources. Other government programs, such as SAMHSA, have attempted to rectify this problem but do not provide sufficient information regarding whether the program is evidence based. The NREPP includes many programs with limited empirical support, leading many schools to assume some programs with limited support are effective due to their inclusion on the list. Some states and programs have attempted to create their own lists to compensate for these deficiencies, but this is difficult due to budget cuts and limited staff resources.

These problems with public policies may be due in part to the lack of accountability regarding PART and Government Performance and Results Act evaluations designed to monitor the activity and effectiveness of these larger government programs. Many of the PART results are not widely available and tend to be excluded from the evaluation reports for prevention programs where one would expect to find them. In addition, some programs have not been evaluated, leading to a lack of accountability or feedback regarding the effectiveness of these programs and their policies.

Conclusion

Public policies are essential to the implementation, regulation, and funding of prevention at the national level. These programs can coordinate funding, provide recommendations regarding effective programs, and implement laws that greatly reduce access to addictive substances. Despite the problems related to the performance of these functions, they allow for the coordination of large-scale, unified programs and initiatives.

PUBLIC POLICY, TREATMENT

The public policy landscape surrounding treatment for substance use disorders within the United States has been shifting continuously for more than 150 years as countervailing scientific, religious, moralistic, and political forces wax and wane. Throughout our nation's history, public perceptions and policy have reflected profound ambivalence regarding substance use disorders. This ambivalence occurs at many levels and cannot simply be reduced to a question of whether addictive disorders are a disease and should be treated as such or whether they are simply a form of moral depravity, hedonism, or selfishness.

Within the various groups that are party to the national policy dialogue, ambivalence is also prevalent. Some advocates of science-based approaches to addictions treatment sometimes still exhibit ambivalence regarding the use of medications for the treatment of addictive disorders or the adoption of harm-reduction approaches despite robust scientific evidence of their clinical efficacy. The popular conception of addictions treatment as a 28-day

residential treatment program with a graduation ceremony—a still common approach—reflects an acute care or cure approach. As William White (a prominent recovery advocate) and others have pointed out, while Americans have long declared addictions chronic, relapsing disorders, Americans still tend to treat them as though they were acute conditions amenable to a time-delimited intervention. Even the paradigm that researchers and policymakers typically adopt when measuring treatment outcomes reflects this paradigm: evaluating treatment effectiveness through pre- and postmeasures. As researchers such as Tom McLellan have pointed out, treatments for other chronic disorders are typically measured during treatment. It is assumed that cessation of treatment for a chronic disorder (e.g., discontinuation of a drug to treat hypertension) will result in relapse. Yet, substance use disorders, while being labeled chronic relapsing disorders, are treated in a manner more akin to physical trauma or acute illness. Ambivalence about treatment and skepticism about its effectiveness have emerged, in part, because of the frequency of posttreatment relapse. Yet relapse is what one would predict even when the best possible approaches are applied.

The stigma associated with addictive disorders may be one factor supporting the continued use of such approaches. To the extent that a disorder can be cured rather than managed and to the extent that treatment can be time-delimited, the individual and society can view addiction as an episode that one can put in the past. This provides a mechanism for disassociating oneself and one's family, community, and the larger society from the issue. The Big Book of Alcoholics Anonymous responds to the tendency to see alcoholism as a transitory condition that can be cured. It characterizes the thought that an alcoholic can someday regain control of his or her drinking as an illusion and compares the likelihood of regaining the ability to drink in moderation once one has become a true alcoholic to that of regrowing severed legs.

There are also those that believe that substance problems are neither diseases nor reflections of moral shortcomings. Among those who argue this position are psychotherapist Stanton Peele, physician Thomas Szasz, and psychologist Jeffrey A. Schaler. Peele specifically argues that the disease concept's position that addictions are necessarily progressive conditions is a reflection of the moralistic perspective once reflected in the Temperance Movement rather than a scientifically based and pragmatic view.

Abstinence as a Policy Goal

The roots of abstinence as a policy goal can be found in the Temperance Movement. White notes that the Temperance Movement evolved from earlier efforts to assist alcoholics in achieving temperance by replacing distilled spirits with beer and wine. This approach failed. Eventually, the focus began to shift from helping alcoholics to preventing the development of new alcoholics through abstinence. This view gained its peak expression in the United States during the prohibition of alcohol through the Volstead Act and the 18th Amendment to the Constitution (1920–1933).

Currently, critics of federal counter-drug policy compare present-day drug prohibition to alcohol prohibition, arguing that there is little if any evidence that interdiction policies have reduced drug use, but that there is ample evidence of harm caused by them, including a thriving black market in drugs, increased violence related to the drug trade, increased mortality and morbidity among drug users, and the incarceration of millions of citizens for drug offenses and consequent costs related to incarceration, fragmented family and social structures, and lost productivity.

Addictions as a Disability

The process for determining eligibility for Social Security disability benefits does not factor in the nature or etiology of a disability, only its impact on the ability to work. Accordingly, individuals who could document a disability caused by an addictive disorder were routinely awarded disability benefits. In 1994, Congress enacted legislation that limited benefits for persons determined disabled due to an addiction (DA&A beneficiaries) to 3 years and mandated participation in addictions treatment as a condition of benefit receipt. Under this law, disability benefits were uniquely circumscribed for persons whose disability stemmed from an addictive disorder. Approximately 2 years after initiating a massive national program to implement the new requirements, Congress specifically excluded disabilities due to addiction from eligibility for Social Security disability benefits.

Elimination of Social Security Insurance or Social Security Disability Insurance benefits drastically reduced access to addictions treatment and other health care services for DA&A beneficiaries while eliminating their sources of income. A National Health Care for the Homeless Council study found that more than three quarters of beneficiaries who had been

paying for their own housing prior to the termination of their benefits lost their housing upon termination of benefits. More than 26% of those who lost benefits were in treatment at the time of benefit termination, and nearly 30% of these individuals were involuntarily discharged due to the loss of medical coverage.

Policy prior to the inception of the DA&A Referral and Monitoring program reflected a de facto acceptance of addictive disorders as a medical condition. The short-lived DA&A Referral and Monitoring program appears to reflect a policy that attempted to reconcile views of addiction as a moral failing with views of it as a disabling medical condition. The elimination of coverage for disabilities arising directly from an addictive disorder reflects a view of addictions as moral failings.

Changes to eligibility requirements for Social Security Insurance and Social Security Disability Insurance benefits, however, did not affect protections for individuals disabled due to addictions under the Americans with Disabilities Act of 1990 (ADA). Under ADA, individuals who are dependent on alcohol, have a history of such dependence, or are perceived to be or have been an alcoholic are protected from discrimination due to their actual or perceived disability. This protection extends to both the active alcoholic and the individual in recovery. In cases of dependence on an illegal drug, however, the historic bifurcation in policy pertaining to alcohol and other drugs emerges clearly. Courts have typically not deemed individuals who are dependent on an illegal drug eligible for protection under the statute unless they have not used the illegal substance for a period of approximately 6 months.

The Language of Addictions Treatment Policy

Language both reflects and informs the policy dialogue. In recent years, the term *behavioral health* has come to be adopted as the preferred term to cover treatment and other clinically managed services provided to address mental health and substance use disorders. This term is considered by some to be stigmatizing because it can be interpreted as making a specious inference that substance use and mental health disorders differ from other chronic disorders in that behavior is a more important factor in their etiology and outcomes. Since behavior can be adjudged to be volitional and therefore the responsibility of the individual with the disorder, some critics argue that the term *behavioral health* can subtly reinforce the notion that substance

use and mental health disorders are the responsibility of the individual with the disorder.

McLellan has argued that there is a widespread perception that addictions treatment is not successful because those in need of its services do not comply with treatment requirements. He documents that, contrary to such perceptions, treatment compliance and outcomes over time for substance use disorders compare favorably with those for hypertension, diabetes, and heart disease. Historically, individuals who do not fully comply with addictions treatment requirements have been described as resistant. As used in the context of the therapeutic relationship between an addiction professional and a client, this term implies an unbalanced power dynamic and places responsibility for treatment failure to some degree on the client, who is deemed to have resisted what presumably would otherwise have been an effective treatment approach. Interestingly, this term would not be used to describe the addictions professional if he or she did not fully comply with a diet and exercise regimen prescribed as part of treatment for hypertension, obesity, or diabetes. Similarly, failure to share the clinician's perception of one's condition as pathological has historically been described as denial. Over the past 15 years, through the gradual adoption of motivational interviewing, and the stages of change theory, the concept of ambivalence has begun to replace the concepts of resistance and denial.

Similar concerns have been raised about the term *substance abuse*, which has been interpreted by some to emphasize behavior by using a term with negative connotations, *abuse*. Recently, the term *medication-assisted treatment* has begun to replace methadone maintenance or methadone treatment and has also been used to describe treatment of opioid dependence in office-based settings with the partial opioid agonist buprenorphine. In addition, White has coined the term *medication-assisted recovery* to describe a recovery path that includes maintenance medication. These terms likely emerged in response to the common descriptor *drug-free treatment*. Some have pointed out that the descriptors *drug-free* or *medication-assisted* would not be applied to the treatment of other chronic conditions, such as hypertension or diabetes. The interventions would simply be described as *treatment*. Some argue, further, that the term *medication-assisted recovery* is only meaningful in the context of a philosophy or worldview in which many view the use of medication to be antithetical to recovery.

The Disease Concept and Policy

The modern history of policy regarding addictions treatment in the United States has been dominated by the disease concept of alcoholism. This concept, in a rudimentary form, extends as far back as historical records. Benjamin Rush, a physician, minister, and lawyer and signer of the Declaration of Independence, was the first American to describe chronic alcohol problems as a disease and to catalogue their symptoms and progression. In 1849, Magnus Huss, a Swedish physician, was the first to systematically classify the physiologic damage caused by alcohol ingestion; he also coined the term *alcoholism*, which he called a chronic, relapsing disease. Later, E. M. Jellinek, who developed the well-known Jellinek's curve, charting the progression of alcoholism, also identified five types of alcoholism, which he defined as abnormal physiologic processes. Three of the five he characterized as actual disease states. Most members of Alcoholics Anonymous, then and now, considered all five categories as a disease.

The definition of addiction as a disease has been supported through the years by major legal, medical, and other professional organizations. Between 1980 and 1991, the American Medical Association and other medical organizations established policies regarding the disease theory. These policies were considered crucial to ensure that third-party reimbursement for treatment would be possible.

Publicly Funded Addictions Treatment

Prior to the 1960s, except for a handful of interested physicians, treatment for alcoholism was difficult to find and was not publicly funded. It was, rather, the province of the voluntary Twelve-Step group Alcoholics Anonymous. Advocates from the National Council on Alcoholism and related organizations, with support from some medical leaders, had been lobbying for the establishment of federal research and treatment support. Treatment began to be studied by the National Institute of Mental Health (NIMH) and a National Center for Prevention and Control of Alcoholism established as a component of NIMH in 1966. The Comprehensive Mental Health Centers Act of 1968—the first of the many failed federal attempts to link mental health and addiction—provided federal funding for the construction of alcoholic treatment centers.

With support from Senator Harold Hughes, a recovering alcoholic, advocates secured passage of

the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment and Rehabilitation Act of 1970, which later came to be known as the Hughes Act. This legislation established the National Institute on Alcohol Abuse and Alcoholism (NIAAA) and provided for formula grants to states to support the development of community-based alcoholism treatment programs. The National Institute on Drug Abuse (NIDA) was established 2 years later. Both centers funded services at the time.

In 1973, a Mental Health Task Force convened by the Department of Housing, Education and Welfare and charged with examining the relationships among alcohol, drug, and mental health (ADM) disorders and how best to organize related research, training, and services activities released its report. The task force concluded that research, training, and services relating to ADM disorders would best be organized under a single organization and that they should be an integrated component of general health care research, training, and services. However, believing that stigma surrounding mental health and substance use disorders made it impossible to integrate these functions at the time, the task force recommended two temporary configurations that would lead to full integration of ADM-related activities over 5 years.

The task force also advocated for gradually combining the then separate alcohol and drug abuse fields because of their similarity, the increasing number of individuals presenting with both alcohol and drug problems, and the increased resources a unified field could bring to alcohol and drug problems. However, the task force also noted important differences between the alcohol and drug fields and mental health.

The task force report was a key element in the 1973 decision to create the Alcohol, Drug Abuse and Mental Health Services Administration (ADAMHA), the precursor to the Substance Abuse and Mental Health Services Administration (SAMHSA). With the creation of ADAMHA, NIMH was stripped of its service funding responsibilities and transferred to the National Institutes of Health (NIH).

Among NIMH's foundational principles was the concept that research, training, and services formed a "three-legged stool" of inherently related disciplines that needed to be effectively coordinated within the same agency in order to drive the advancement of knowledge, systems, and services. This vision conflicted with the organization of federal agencies, which separate research and service functions in distinct agencies. Debate continues today on this topic,

although the current configuration of research agencies (NIDA and NIAAA) as NIH Institutes clearly separates them from the relevant service agency, the Substance Abuse and Mental Health Services Administration (SAMHSA).

The continued existence of separate institutes to support research on alcohol and drug problems reflects a tenuous but so far relatively enduring stasis between countervailing policy agendas. This abandonment of the “three-legged stool” vision is viewed by many as having resulted in a loss of capacity to perform services research and program evaluation and to actively move the behavioral health field ahead.

Under the Ronald Reagan administration, an emphasis on decentralization and state control led to a substantial diminution of direct federal oversight of ADM and to the establishment of a single ADAMHA block grant to the states. With this move, the responsibility for developing, selecting, and monitoring services and service-related programs devolved primarily to the states. The fundamental changes initiated under the Reagan administration are still reflected in the current organization and scope of SAMHSA.

The SAMHSA was established under the ADAMHA Reorganization Act of 1992. With the establishment of SAMHSA, the three research entities of ADAMHA—the NIMH, the NIAAA, and NIDA—were merged into the NIH while the service-oriented arms of ADAMHA became the current SAMHSA.

Emphasis on Recovery and Accountability

Under Charles Curie, SAMHSA administrator from November 2001 to August 2006, the agency adopted a vision of “a life in the community for everyone” and a mission of “building resilience and facilitating recovery.” This mission and vision statement foreshadowed a growing emphasis on recovery. Three strategic goals, accountability, effectiveness, and capacity (ACE), foreshadowed growing emphasis on performance, outcomes, adoption of evidence-based practices, and the development of nontraditional community-based providers as a component of funded service continua, particularly in the addictions treatment and recovery arena.

The vision, mission, and strategic plan developed under Curie and summarized in the SAMHSA Matrix of Priorities provides an overarching framework for the adoption of a more holistic and community-anchored

focus of activities under which recovery receives greater emphasis.

The current SAMHSA focus on recovery was foreshadowed by the Recovery Community Support Program (RCSP). Established by SAMHSA’s Center for Substance Abuse Treatment (CSAT) in 1998, the RCSP was initially focused on mobilizing constituents, achieving visibility, confronting stigma, educating the public, and influencing policymakers. Under Curie, the name of the program was changed to the Recovery Community Services Program, and its focus shifted from advocacy to developing Peer Recovery Support Services (PRSS). The initial motivation for these services was to prevent relapse and support long-term recovery. Conceptually and philosophically, the new RCSP built upon the peer work initiated in mental health and HIV/AIDS consumer communities. PRSS incorporates a system in which individuals in recovery, often referred to as *peer leaders*, act as agents to help others in early recovery, usually in a volunteer capacity. Peer services both support and supersede addiction treatment and mutual support groups.

CSAT has further emphasized recovery through the Partners for Recovery (PFR) Initiative, which emerged under the George W. Bush administration to replace the National Treatment Plan (NTP) initiative that was rolled out under the Bill Clinton administration. Activities related to the NTP were stopped under the Bush administration and references and support materials related to it were purged from the SAMHSA Web site and the National Clearinghouse for Alcohol and Drug Information.

Although distinct from the NTP, PFR rests on the foundation created by the NTP. PFR builds on the guidelines established in the NTP, which were the following: invest for results, no wrong door to treatment, commit to quality, change attitudes, and build partnerships. Like the NTP, PFR focuses on improving the treatment field, but it encompasses a broader vision that engages systems to address, highlight, and support recovery of individuals, families, and communities. PFR has five areas of focus: cross-systems collaboration, recovery, stigma reduction, workforce development, and leadership.

PFR has played a lead role in developing and disseminating the philosophy of recovery-oriented systems of care. It cosponsored a National Summit on Recovery in September 2005. The summit brought together key professionals and community leaders, including representatives of Twelve-Step and other

mutual aid groups to generate ideas for defining and advancing recovery-oriented systems of care (ROSC) in arenas of policy, research, services, and systems. One key output of the summit was a report describing consensus principles of recovery and elements of recovery-oriented systems of care developed by participants. The document also includes a working definition of recovery.

More recently, a series of regional meetings with states to explore strategies for developing ROSC have been convened under PFR. The approaches explored in these sessions include the development of à la carte service continua to support individualized packaging and staging of services and the expansion of nontraditional services, including peer-led and faith-based services. The focus on ROSC nationally is supporting a gradual movement away from traditional program models to individualized services supported by unbundled services.

Under the Access to Recovery (ATR) Program, announced by President George W. Bush in the 2003 State of the Union address, two elements were prominently introduced on the national addictions treatment policy and program landscape: service vouchers and faith-based services. ATR was received with ambivalence at SAMHSA/CSAT and in the field. There was pause among some SAMHSA/CSAT officials regarding the notion of implementing a high-profile administration program that did not appear to reflect the agency's historic emphasis on treatment or the practice models it supported.

Among states there was concern that the creation of voucher systems would increase administrative costs. There was also anxiety about a backlash from treatment providers because of the perception that new faith-based and community-based providers would be competing with them for resources. In addition, some states were anxious that ATR could represent the first step in the conversion of the Substance Abuse Prevention and Treatment Block Grant into a voucher program. In the end, ATR has come to be viewed by many as an exceptional vehicle for driving the development of recovery-oriented systems of care. However, in the face of successive federal fiscal year 2008 and 2009 budgets that propose slashing core CSAT programs while adding close to \$100 million in ATR funding, the program continues to receive a mixed reception.

ATR has also served to foster the adoption of chronic care approaches in substance abuse treatment. A number

of grantees have adopted approaches that were modeled after chronic disease management models. Perhaps the earliest iteration of such an approach, and certainly the best known and widely implemented, is Recovery Management, which was developed in Peoria, Illinois, with funding from the State of Illinois by Chestnut Health Systems and Fayette Companies.

The Bush administration has also emphasized early intervention through the Screening, Brief Intervention and Referral to Treatment (SBIRT) initiative. It has done so, however, while greatly reducing funding for substance abuse prevention. SBIRT is intended to reduce morbidity and mortality due to drug and alcohol use by intervening before potentially problem use progresses to dependence and is also intended to identify individuals who already have diagnosable substance use disorders and to refer them to treatment.

Throughout ATR and SBIRT, accountability and capacity have been emphasized by requirements to serve high numbers of individuals and to collect and report outcome and performance data as tracked through mandatory Government Performance and Results Act data collection. Some have complained that an obsessive focus on numbers served and on collection of data at admission, discharge, and 6 months postadmission reflects greater emphasis on "looking good" than on actually doing good. Others have noted that the administration's support of performance incentive programs and its support of systems and services improvement through support for the Network for the Improvement of Addiction Treatment and for the Advancing Recovery initiative reflects a genuine commitment to quality and performance. The former focuses on improving business practices and on quality at the program level, whereas the latter focuses on improving state systems.

Fiscal Policy and Addictions Treatment

Addictions treatment differs from other forms of health care because of the extent to which it is funded from public rather than private sources. In 2003, 77% of all addictions treatment spending came from public sources. This compares with 58% of mental health and 55% of all health expenditures. Between 1993 and 2003, total spending on the treatment of substance use disorders rose by 1.3% in inflation-adjusted

dollars. Concurrently, mental health and all health expenditures experienced inflation-adjusted increases of 4.3% and 4.6%. Spending for addictions treatment has decreased as a percentage of overall behavioral health spending and of overall health spending. Moreover, from 1993 to 2003, private insurance expenditures for addictions treatment remained essentially flat while private insurance expenditures for all health increased by an average of 7.3% annually. Funding clearly demonstrates that interdiction is a higher priority to the United States than treatment and that it has been given even greater emphasis under the administration of George W. Bush.

Efforts to secure parity of insurance coverage have long been part of the U.S. policy landscape. Legislative history includes more than one failed attempt to achieve this. Most often these efforts have focused on parity for mental health benefits and either excluded addictions treatment benefits or incorporated them as a subset of mental health. Most recently, in March 2008, the House of Representatives passed the Paul Wellstone Mental Health and Addiction Equality Act. However, as of August 2008, this bill had not become law.

The Office of National Drug Control Policy (ONDCP)

The National Survey on Drug Use and Health indicated that 19.1 million Americans over the age of 12 are current illegal drug users while 121 million individuals aged 12 and older were current alcohol users. More than 6 times as many individuals use alcohol as use illegal drugs, and the number of heavy drinkers is nearly as great as the total number of illegal drug users. Despite the difference of magnitude in the alcohol and illegal drug problems in the United States, the history of policy and legislation around substance use generally and treatment specifically has, for the most part, been dominated by a concern about illegal drug use.

Since the ONDCP was established, some argue that alcohol misuse and alcoholism have become less of a national policy priority. ONDCP is the lead executive branch agency charged with advising the President on drug control strategy and implementing federal policy with respect to illegal drug trafficking and use. ONDCP is not charged with responsibility regarding alcohol use. However, through its leadership of the National Drug Control Strategy, ONDCP provides oversight to and approves funding over the

entire continuum of addictions treatment and recovery services. Federal policy regarding addictions treatment is driven almost exclusively by ONDCP.

ONDCP was established by the Anti-Drug Abuse Act of 1988, which charged it with guiding and supporting the United States in achieving the goal of a drug-free America. From its inception, ONDCP was designed as a command-and-control entity. The enacting legislation created three key leadership positions: the ONDCP director, commonly known as the *drug czar*; the deputy director for demand reduction; and the deputy director of supply reduction. The legislation not only established the basic organizational structure of ONDCP, but also ensured that the economic concepts of supply and demand would serve as the organizing principles for its activities and for U.S. drug control policy. Every year, ONDCP releases the National Drug Control Strategy (NDCS), which summarizes past-year activities and trends while outlining planned activities and priorities for the upcoming year. The NDCS summarizes recent and planned activities related to the multibillion-dollar portfolio of coordinated anti-narcotics activities often referred to as the War on Drugs.

Demand reduction funding (prevention and treatment) has declined under the administration of George W. Bush. Despite revised accounting methods that inflate demand reduction activities relative to prior year reports, the most recent NDCS shows that, under the Bush administration, demand reduction funding has declined by 3% while supply reduction increased by 42%. Overall, supply reduction funding increased from 55% to 64% of drug control funding while demand reduction funding went from 45% to 36% of the overall drug control budget.

In 1999, during the Clinton administration, a coalition of drug policy organizations released, as a counterpoint to the NDCS, the Effective National Drug Control Strategy, which recommends that two thirds of the drug control budget be directed to treatment and prevention. Written from a public health and harm reduction perspective, the alternative strategy was developed around two primary goals: (1) reducing the harm caused by drug abuse and (2) reducing the harm caused by existing drug control policies. Advocates have argued that current interdiction policy ignores the lessons learned from Alcohol Prohibition, misdirecting resources to futile interdiction efforts while making possible a thriving black market in illegal substances operated by organized crime and street gangs.

The U.S. drug control policy differs from the policies of Canada, the majority of Western Europe, Australia, and New Zealand in its emphasis on abstinence and its explicit rejection of harm reduction approaches. Although the annual NDCS report and other ONDCP documents and official communications have consistently depicted harm reduction strategies in a negative manner, harm reduction approaches are widely prevalent in the public health arena and even in the addictions treatment field itself. These include noncontroversial policies, such as designated driver programs, and more controversial ones, such as syringe exchanges and condom distribution.

PULSE CHECK

Pulse Check is a report prepared by the Office of National Drug Control Policy (ONDCP) that provides a snapshot of the current drug scene in selected cities across the United States over a 6-month period. *Pulse Check* has been published on either a quarterly or semi-annual basis since 1992 and regularly provides up-to-date information on recent and changing trends in the use of heroin, crack and powder cocaine, marijuana, and methamphetamine. It also monitors any new emerging drugs or trends that appear to be spreading across the country and occasionally reports on special topics, such as the impact of September 11 on drug use.

The report is based on information gathered through 1-hour telephone conversations with four individuals (one ethnographer or one epidemiologist, one law enforcement official, and two treatment providers) knowledgeable about the drug abuse situation in their areas. The interviews generally follow the same guidelines during each reporting period. However, the sources may choose to not report on information or add new information on areas not included in the past. The information from the expert sources is summarized in narrative form in the body of the report and then presented in detailed tables by city or region at the end of the report. For consistency, an attempt has been made to maintain the same law enforcement, ethnographic, and epidemiologic reporters in each interview period. In fact, many of these informants have been consistently reporting on trends in their communities since 1992. On the other hand, the treatment reporters have often changed throughout the years.

The ethnographic sources include trained ethnographers, sociologists, or psychologists who use ethnographic research techniques and epidemiologists with access to ethnographic information. Many of the epidemiologic reporters are also members of the National Institute on Drug Abuse Community Epidemiology Working Group. The law enforcement sources include officials working on special squads or narcotics task forces and Drug Enforcement Agency agents. As mentioned before, an attempt is made to maintain continuity of the informants across issues of the reports. However, if someone is no longer able to be the reporter for his or her area, a replacement will be brought in based on the recommendation of the outgoing *Pulse Check* informant.

The sample of treatment providers are drawn from the Uniform Facility Data Set (UFDS). This is an annual survey conducted by the Substance Abuse and Mental Health Services Administration of facilities providing substance abuse treatment. From about 1992 to 2000 the listings were divided up into four regions and a sample of programs was identified in each region. The samples were then stratified in order to include an equal number of small (fewer than 100 patients) and large (more than 100 patients) programs. Programs that predominantly treated individuals who abuse alcohol were automatically excluded. Eligible programs not selected usually served as replacements if the selected programs were not able to participate. The sample of treatment providers was constantly refreshed for each reporting period so a new group of providers would report on trends in their area for each new issue. But starting with the midyear 2000 issue, ONDCP changed the way the treatment sources were selected. They decided to retain the same treatment sources from the midyear 2000 issue for each new issue in order to preserve continuity. The treatment sources from the 2000 issue were randomly selected from the 1998 UFDS.

Programs that dealt primarily with alcohol users, served a caseload of fewer than 100 clients, or provided only prevention or detoxification services were excluded. The remaining programs were then divided into two groups—methadone and non-methadone treatment programs. This was done to ensure that different types of treatment programs were represented in the sample, since treatment providers from a methadone and nonmethadone program are likely to have clientele with different demographic

characteristics and problems. Therefore, these treatment providers would have different perspectives on drug use in their neighborhoods. If a treatment source could not participate, a replacement was usually made in consultation with experts in the field instead of randomly selecting a new one.

The interview consists of questions about current drug use patterns and changes in the community, demographics of the typical user and seller of each drug, the route of administration for each drug, current patterns of polydrug use, current price and purity levels, and any social or economic factors that may have affected drug use patterns in the previous 6 months. Generally, law enforcement reporters are very knowledgeable about drug availability, trafficking patterns, seller characteristics, and other market activities in their areas. The ethnographic and treatment sources are usually more knowledgeable about the users and the patterns of use. However, the treatment providers' knowledge is, for the most part, limited to the populations targeted by their programs. The ethnographic sources are often able to get information that the other sources cannot because the very nature of their methodology allows them to enter the world of the drug users in their natural setting to observe and obtain an insider's perspective on what is going on in their communities. Even though the ethnographers enter the drug world as researchers, they are usually able to gain the trust of the drug-using population and gain access to information that the other two expert sources cannot.

The information presented in *Pulse Check* is based purely on the observations and perceptions of the expert sources, who may be biased based on their experiences. As a result of this, there is often some variation in the descriptions not only across sites but also between different informants in the same site. Also, even though considerable effort is made to select sites across a broad range of geographic areas, the report cannot be viewed as a national study because the information is only representative of the sites selected to be a part of the *Pulse Check* reports. The purpose of *Pulse Check* is to qualitatively describe trends in drug abuse as they develop before population-based, long-term research is available to policymakers and researchers. The *Pulse Check* reports provide a valuable supplement to the quantitative data provided by the National Institute on Drug Abuse Community Epidemiology Work Group,

the Substance Abuse and Mental Health Services Administration Drug Abuse Warning Network, and the National Institute of Justice Arrestee Drug Abuse Monitoring program. Altogether, the data from these different sources provide policymakers and researchers with a quick assessment and understanding of the emerging trends that are occurring in different parts of the United States so that appropriate and timely action can be taken to address these new trends.

QUALIFIED SERVICES ORGANIZATION AGREEMENTS

A qualified service organization agreement (QSOA) is a binding document between a substance abuse prevention or treatment agency and an organization providing support services to the agency. The purpose of the agreement is to ensure that confidential information of clients seeking substance abuse services remains confidential. QSOAs are integral to the provision of substance abuse prevention and treatment services by establishing and maintaining the privacy of those seeking and receiving substance abuse services. This entry will focus on the purpose of the QSOA, the legal underpinnings of the QSOA, the content of a QSOA, and further readings on this topic.

A substance abuse prevention or treatment agency focuses on specific activities and may have the need to contract with an outside organization to provide support services to its clients, such as transportation, day-care, or medical services. In addition, the substance abuse agency may need to contract with an outside entity for administrative services such as accounting, data management, or data analysis and research. In both instances, the substance abuse agency would execute a QSOA with the outside agency, the qualified service organization, to maintain the confidentiality of clients' information that would be shared in order for the qualified service organization to perform the specified activities. The QSOA may be in addition to a contract for services between the substance abuse agency and the qualified service organization.

Confidentiality in reference to the provision of substance abuse prevention and treatment services is defined in the federal confidentiality law, 42 United States Code (U.S.C.) § 290dd-2. The regulations that implement this law are 42 Code of Federal Regulations (CFR) Part 2. These regulations have been in existence for more than 30 years, since 1975. More recently confidentiality has been addressed in the Health Insurance Portability and Accountability Act (HIPAA) of 1996 that became law in August of 1996—Public Law 104-191. A portion of this law required the U.S. Department of Health and Human Services to create national standards covering the electronic transmission of clients' health care information. The implementing regulations of these standards are found in 45 CFR Parts 160 and 164.

Upon initiation of receipt of substance abuse prevention or treatment services, clients provide consent to receive the indicated services. This signed client consent may also include consent for the agency to use client information for subsequent research after the client has received services. However, the clients' consent regarding the receipt of substance abuse services does not include information found in a QSOA. Therefore, in the clients' consent, they do not provide their consent to share their information with a qualified service organization. QSOAs are separate documents necessary to share pertinent client information with the contracted qualified service organizations.

Once the QSOA is signed by representatives from both entities, only the confidential information needed for the qualified service organization to perform its contracted tasks will be shared. Information can

be shared freely in accordance with the executed agreement. The qualified service organization cannot share confidential information with any other entity, even if the entity has a QSOA with the same substance abuse prevention or treatment agency. Employees within the qualified service organization are to maintain confidential client information by not sharing this information with other employees who are nonessential to the specified task. For example, if the qualified service is data input of client information, all confidential information should only be maintained by the data input staff and direct supervisors.

The existence of a properly executed QSOA provides protection to the substance abuse prevention or treatment agency, the qualified service organization, and most important, the substance abuse clients. A QSOA generally comprises six sections:

1. *Document Title:* Qualified Service Organization Agreement,
2. *Identification of the Entities Entering the Agreement:* the substance abuse prevention or treatment service agency (legal name) and the qualified service organization (legal name),
3. *Services to Be Provided:* the specific services to be provided by the qualified service organization are listed,
4. *Confidentiality Acknowledgments:* the substance abuse agency lists the specific confidentiality rules and regulations the qualified service organization is agreeing to follow in providing the specified services (listed in section 3),
5. *Execution Date:* the date the agreement is executed, and

6. *Signatures:* officials from both entities sign to officially execute the agreement.

These are the basic sections of a QSOA, but it can be altered according to the needs of the entities. The agreement for one agency may be one page, whereas another's may run several pages. For instance, the confidentiality section can simply cite the confidentiality regulations resulting in a short agreement or provide specific language from the regulations with the addition of other language regarding confidentiality in a superseding contract, creating a much longer agreement. The QSOA can also be altered to include an expiration date or consequences of noncompliance, and it may state specific safeguarding actions to be employed by the qualified service organization to keep information confidential. The QSOAs can also be utilized in other fields in addition to substance abuse, where they are essential to maintain the confidentiality of clients' information, such as mental health, child welfare, adult protection, or managed health care.

R

RACIAL AND ETHNIC MINORITIES, ISSUES IN ALCOHOL AND OTHER DRUG USE

Providing quality alcohol and other drug (AOD) prevention and treatment services requires an awareness of the multiple, unique needs of the individuals being served, including an understanding of the sociocultural factors affecting AOD use and abuse patterns. Previous research reveals a complex relationship between race-ethnicity and AOD patterns. For example, a recent study on factors contributing to differences in substance use among African American and White non-Hispanic adolescents suggests an age-related crossover effect. Specifically, African Americans were less likely than Whites to exhibit heavy drinking patterns and drug use during adolescence. However, by age 35 African Americans had higher rates of AOD use and related problems than Whites. The findings from this and similar studies support the notion that for AOD services to be effective in addressing the needs of a diverse population, prevention and treatment professionals need to be knowledgeable about the impact of race, ethnicity, and culture.

According to the revised Culturally and Linguistically Appropriate Services standards from the Office of Minority Health, all individuals should receive understandable and respectful care that is compatible with their cultural health beliefs, practices, and preferred language. To ensure delivery of culturally compatible AOD prevention and treatment services, it is important that staff have the ability to understand how individuals from

different racial and ethnic groups define wellness, illness, and health care. Cultural competence refers to the interpersonal skills that allow people to understand and appreciate cultural differences and similarities between groups as well as within groups. Being culturally competent, which requires acknowledgment of existing cultural biases and how they might influence attitudes and behaviors, is a vital component of staff members' ability to develop client trust.

AOD prevention and treatment programs that are culturally competent recognize and build on the cultural strengths and values of the client and encourage attitudinal and behavioral change. As such, prevention and treatment providers need to be knowledgeable of the beliefs and attitudes regarding AOD use and abuse that guide the behavior of the racially and ethnically diverse clients with whom they work. The remaining sections provide an overview of cultural diversity, ethnicity, and race, followed by a discussion of racial and ethnic group-specific AOD issues.

Defining Culture, Race, and Ethnicity

The definitions of race, ethnicity, and culture often are misconstrued, resulting in the terms being used as if they were interchangeable concepts. Although the differences are subtle, the terms refer to three distinct ways in which individuals identify themselves. As such, the terms will be discussed briefly in this section in order to more clearly depict the levels at which race, ethnicity, and culture contribute to understanding AOD use among different groups.

Culture is best described as the customs, beliefs, values, knowledge, and skills that guide behavior along

a shared direction in life. Broadly defined, cultural diversity refers to any issue in which differences among individuals generate misunderstandings of groups that exhibit those specific differences. Culture is a means by which individuals establish an ancestral group identity for themselves, thereby meeting an essential human need to belong. Individuals' cultural identities may form around any number of circumstances, including but not limited to race, ethnicity, religion, and sexual orientation, and these identities influence the ways in which individuals psychologically relate to the values, symbols, and common histories that make that particular group unique. As such, it is imperative that clinicians and other members of the prevention and treatment community become competent in providing culturally congruent care to a diverse population.

Racial categories typically are biologically defined but often are construed as socially significant. Ethnicity, on the other hand, refers to select social and cultural characteristics by which individuals classify themselves and others into significantly different groups or categories, thereby establishing an ethnic identity. A few of the commonly recognized ethnic groups in the United States include African Americans, American Indians, Asian Americans, and Hispanics-Latinos. In some cases, ethnicity involves merely a loose group identity with few or no cultural traditions in common. This is the case, for example, with many Irish and German Americans. In contrast, some ethnic groups are coherent subcultures with a shared language and body of tradition.

AOD Use Issues Among Specific Racial and Ethnic Groups

As previously stated, the relationship between race-ethnicity and AOD use is complex. This section provides an overview of AOD use patterns by race-ethnicity, followed by a research-based discussion of some of the culture-specific explanations for those patterns.

Race-Ethnic AOD Use Patterns

The Treatment Episode Data Set (TEDS) report provides information on the demographic and substance abuse characteristics of annual admissions to publically funded AOD treatment facilities in the United States. The most recent TEDS report, which highlights the 2006 results, shows that among all racial-ethnic groups (with the exception of Hispanics of Puerto

Rican origin), alcohol was the most frequently reported substance used among individuals admitted for treatment. However, use of substances such as opioids, marijuana, cocaine, and stimulants varied considerably by racial-ethnic group. Specifically, among individuals 12 years of age and older, the rate of illicit drug use was lowest among Asians (3.6%), followed by Hispanics (6.9%), Native Hawaiians–Pacific Islanders (7.5%), Whites (8.5%), multi-ethnic (8.9%), African Americans (9.8%), and Native Americans–Alaska Natives (13.7%). In addition, two thirds (68%) of primary methamphetamine-amphetamine admissions were non-Hispanic Whites, followed by 19% who were of Hispanic origin and 3% each who were Asian-Pacific Islander or non-Hispanic Black. Finally, the rate of current illicit drug use among Native American–Alaska Native youth was 18.7%, which was almost twice the overall rate among all youth ages 12 to 17 years (9.8%). Further examination of AOD use by racial-ethnic group is reported in the following section.

Culture-Specific Factors Related to AOD Use

Understanding the sociocultural factors affecting AOD use and abuse patterns is vital to providing quality services that address the needs of a diverse population. However, providing culturally appropriate services requires increasing the cultural competence of prevention and treatment professionals. For example, two prominent and universal themes for every racial and ethnic group are cultural healing and spiritual beliefs and family structure. However, these themes vary for each racial-ethnic group. An increased knowledge of those group-specific themes among AOD prevention and treatment professionals also increases the likelihood of establishing effective prevention, treatment, and aftercare services to members of racially and ethnically diverse groups.

Several studies have examined how the relationship between race-ethnicity and AOD use is influenced by other factors such as gender, age, economic and social resources, and acculturation. In the following sections, the findings from some of that research will be discussed as it relates to specific ethnic groups.

African Americans

Although adolescent experimentation with alcohol is believed to be a normative event, research reveals that African American youth and young adults are less

likely to use alcohol than Whites in the same age groups. However, African Americans' reported AOD use becomes equivalent to and then exceeds that of Whites as they move into adulthood. Recent research found that sensation-seeking was a significant predictor for 10th grade alcohol, cigarette, and marijuana use for White adolescents, but not for African Americans. In addition, African American high school seniors were reported to have more contextual risk factors than their White peers, such as economic deprivation and academic difficulties. It has been widely published that socioeconomic and cultural barriers faced by African Americans contribute to higher levels of substance abuse in adulthood. However, it has been suggested that in addition to having less disposable income available to purchase AODs, the effects of family and peers on alcohol use differ for African American and White youth. For example, African American youth are less influenced by peers who use AODs and more influenced by strong family relationships, control, and support than are White youth. According to the 2006 National Survey on Drug Use and Health (NSDUH), 43% of African Americans ages 12 years and older reported having used illicit drugs during their lifetime, with 16% having used in the year prior to being surveyed. In addition, the 2006 TEDS report shows that the most frequently reported substance used by non-Hispanic Blacks admitted to treatment was alcohol (31%), followed by cocaine (27%), marijuana (22%), and opioids (15%); for non-Hispanic Whites admitted for treatment, the most frequently reported substance also was alcohol (43%), followed by opioids (18%), marijuana (14%), and cocaine and stimulants (10% each).

Asian Americans–Pacific Islanders

Although typically examined as a single group, the Asian American population actually comprises numerous subgroups with distinct ethnic and cultural backgrounds. Asian American subgroups include people of Chinese, Japanese, Indian, Korean, Filipino, and Southeast Asian origin, whereas Pacific Islanders include Polynesians, Micronesians, and Melanesians. As such, culturally linked differences among these subgroups impact individuals' perception of social norms and adjustment to American mainstream culture. For example, there are two main components involved in the acculturation process: (1) maintaining the traditional culture of one's own group and (2) interacting

with and adapting to the host country's culture. A common cultural pattern in Asian ancestral countries is that smoking is a normative behavior for males but not for females. However, a recent study revealed that the gender gap in smoking rates has become much smaller as Asian Americans have been acculturated into American society and smoking prevalence rates among Asian American females have substantially increased.

According to the 2006 NSDUH, 24% of all Asian Americans ages 12 years and older reported using illicit drugs during their lifetime, with 9% having used in the year prior to being surveyed. Forty-one percent of Native Hawaiians–Pacific Islanders ages 12 years and older reported using illicit drugs during their lifetime, with 13% having used in the year prior to being surveyed. The 2006 TEDS report shows that among all Asian and Pacific Islanders admitted for treatment, alcohol was the most frequently reported substance used (33%), followed by stimulants (27%), marijuana (20%), and opioids and cocaine (9% each). Reports also suggest that Japanese Americans achieve the highest rate for both lifetime and heavy drinking, while Chinese Americans typically have the lowest rates and Korean Americans represent the highest rates of abstainers. In addition, among primary methamphetamine-amphetamine admissions, Asian and Pacific Islanders were most likely to report smoking methamphetamine-amphetamine and less likely to use other routes of administration.

Hispanics-Latinos/Latinas

A racially diverse group, Hispanic-Latino/Latina populations have typically been referred to by governmental institutions as Hispanic. However, this cultural group most often employs the term *Latino* (male) and *Latina* (female), which more accurately depicts a shared sense of ethnicity rather than a racial heritage. Reports on AOD use prevalence rates for Latinos/Latinas are similar to those of the general population. However, recent research suggests that the presence of co-occurring mood and anxiety disorders may be more prevalent among AOD abusing Latinos/Latinas than among the rest of the U.S. population. In addition, cultural norms that discourage AOD use by women may protect Latinas from AOD abuse and related problems. The significance of family in the Hispanic-Latino/Latina community also is critical and often seen as a primary identifier. Family includes a

strong emphasis on both nuclear and extended members and involves strong feelings of loyalty and cohesion. Hispanics-Latinos/Latinas historically value trust, empathy, and mutual community welfare and look within their own group rather than to community services for help with most problems.

According to the 2006 NSDUH, 35% of Hispanics-Latinos/Latinas ages 12 years and older reported using illicit drugs during their lifetime, with 13% having used in the year prior to being surveyed. The 2006 TEDS report shows that among all Hispanics-Latinos/Latinas admitted for treatment, the most frequently reported substance among individuals of Mexican origin was alcohol (36%), followed by stimulants (22%), marijuana (18%), opioids (14%), and cocaine (9%); individuals of Puerto Rican origin most frequently reported using opioids (46%), followed by alcohol (25%) and marijuana and cocaine (13% each); and for individuals of Cuban origin, the most frequently reported substance was alcohol (35%), followed by opioids (31%), cocaine (16%), marijuana (10%), and stimulants (3%).

Native Americans–Alaska Natives

It has been well documented that rates of substance use among Native American youth are consistently higher than those among non-Native youth. In addition, alcohol abuse has been linked to four of the top 10 causes of death among Native Americans (accidents, cirrhosis of the liver, homicide, and suicide). Factors related to increased AOD use among this population are primarily related to (a) decreased economic or educational opportunities and (b) acculturation stress resulting from being raised in two somewhat contradictory cultures and expectations to assimilate and function successfully in both.

Among Alaska Natives, there has been a concerted effort to decrease alcohol use by reducing alcohol sales and possession in the villages. However, this population currently shows the highest prevalence of tobacco use in the United States. In addition to high use and availability of commercial tobacco products, a homemade form of smokeless tobacco known as Iqmik is readily available. Alaska Native women make Iqmik by mixing fire-cured tobacco leaves with the ash generated from burning a woody fungus. Although 100% of the nicotine in Iqmik is in the freebase form, it is perceived by the general public as having few adverse health effects and is frequently given to children as young as 3 years old by parents or family members.

A study of AOD use patterns among adolescents revealed that Iqmik use is considered normative.

According to the 2006 NSDUH, 59% of Native Americans–Alaska Natives ages 12 years and older have reported using illicit drugs during their lifetime, with 20% having used in the year prior to being surveyed. The 2006 TEDS report shows that among Native Americans admitted for treatment, the substance most frequently reported was alcohol (64%), followed by marijuana (13%), stimulants (10%), opioids (6%), and cocaine (5%). For Alaska Natives, the most frequently reported substance used was alcohol (47%), followed by opioids (21%), marijuana (11%), cocaine (10%), and stimulants (9%).

Discussion

Critical to the successful delivery of AOD prevention and treatment services is the providers' understanding of and respect for the client's needs, cultural values, and environment, as well as their ability to build on the cultural strengths and values of each individual being served. The research used in developing this discussion on factors associated with racial and ethnic differences in AOD can be grouped into three general categories: (1) socioeconomic status, (2) strong social (i.e., family and peer) relationships and support, and (3) acculturation and socialization.

Culturally specific training related to these issues is essential to increasing AOD prevention and treatment professionals' understanding of the unique challenges experienced by the various racial-ethnic populations and their ability to establish effective AOD services.

RACIAL AND ETHNIC MINORITIES, ISSUES IN PREVENTION

Demographic trends that emerged in the 20th century have resulted in a large increase in the numbers of individuals in the U.S. population from racial and ethnic minority groups. These demographic trends are projected to continue such that by the year 2100 non-Hispanic Whites are expected to comprise only 40% of the U.S. general population. As the numbers

of individuals from traditional racial and ethnic minorities increases, the need for culturally tailored prevention and intervention for substance abuse issues among individuals from racial and ethnic minority populations increases. This entry presents information on the prevalence of substance use among racial and ethnic minority populations, discusses issues in the prevention of substance abuse among these groups, and presents an introduction to the public health model for prevention of substance use. Although epidemiological data on substance use are presented in aggregate race-ethnicity categories, one should keep in mind that subgroups within each ethnic-racial category may differ and that variation among individuals is also present.

Definitions of Race-Ethnicity

Basic definitions for race and ethnicity were put forward in 1978 by the Office of Management and Budget (OMB) under Statistical Directive No. 15. National-level data on vital statistics and disease surveillance since 1978 followed this directive and employed the following racial categories, with an ethnic category for Hispanics.

Race Categories

American Indian–Alaska Native—a person having origins in any of the original peoples of North America who maintains cultural identification through tribal affiliations or community recognition.

Asian-Pacific Islander—a person having origins in any of the original peoples of the Far East, Southeast Asia, the Indian subcontinent, or the Pacific Islands.

Black or African American—a person having origins in any of the racial groups of Africa.

White—a person having origins in any of the original peoples of Europe, North Africa, or the Middle East.

Ethnic Category

Hispanic—a person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race.

In 1994 the Interagency Committee for the Review of the Racial and Ethnic Standards advised the OMB

to update its minimum categories for data on race and ethnicity and defined the following categories:

American Indian–Alaska Native—a person having origins in any of the original peoples of North and South America (including Central America) who maintains cultural identification through tribal affiliations or community recognition.

Asian-Pacific Islander—a person having origins in any of the original peoples of the Far East, Southeast Asia, the Indian subcontinent, or the Pacific Islands. These areas include, for example, China, India, Japan, Korea, the Philippine Islands, Hawaii, and Samoa.

Black or African American—a person having origins in any of the Black racial groups of Africa.

Hispanic—a person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race.

White—a person having origins in any of the original peoples of Europe, North Africa, or the Middle East.

In addition, the committee recommended that, when race and ethnicity data were collected separately, ethnicity data be collected first with the minimum ethnicity designation being Hispanic origin or not of Hispanic origin. The new standards also allowed for the reporting of more than one race for those of multiracial ancestry.

Prevalence of Drug Use in Various Racial-Ethnic Groups

African Americans

Of African Americans, 6.2% ages 12 and older report past year dependence on or abuse of illicit drugs or alcohol. This number is not far off the average for the general population; however, specific trends are present within the African American community that are important to be aware of in regard to substance-related problems. First, although the rate of illicit drug use among African American high school seniors was lower for all drugs except heroin and marijuana, 1.4% of African Americans ages 35 and older reported past year cocaine use compared with 0.2% of Whites. Second, among African Americans ages 12 to 17, an equal number of individuals compared with Whites reported use of an illicit drug in their lifetime,

past year, or past month. Third, African American women and Hispanic women are more likely to have used crack cocaine compared with White women.

Asian-Pacific Islanders

As a group, Asian-Pacific Islanders report illicit drug use at a lower rate than do non-Hispanic Whites. For example, 6% of Americans 12 and older are current drug users, whereas the rate of current drug users among Asian-Pacific Islanders is just 2.7%. Subgroups of Asian-Pacific Islanders do report drug use comparable to the general population. Specifically, Japanese (5%) and Korean (6.9%) individuals report higher rates of illicit drug use than do members of the Asian-Pacific Islander community in aggregate. Recent increases in sampling of Asian-Pacific Islanders in national surveys have allowed more stable estimates of drug use in the Asian-Pacific Islander community to be promulgated.

Hispanics

Relative to Whites, Hispanics show lower rates of drug use in all categories except crack cocaine and heroin. Data indicate that 22% of Hispanics report lifetime use of marijuana, 71.7% report lifetime use of alcohol, 56.4% report lifetime use of cigarettes, and under 10% report lifetime use of cocaine or hallucinogens. Heroin use is approximately equal to levels for Whites at about 1%, as is crack cocaine use at 2%. Key epidemiological data on drug use among Hispanics has been gathered in the National Survey on Drug Use and Health and in the Hispanic Health and Nutrition Examination Survey conducted between 1982 and 1984. These findings have detailed substance use patterns among subgroups of Hispanics and indicate that there are significant differences between Hispanics from various countries of origin in terms of types of substances used and prevalence of substance use. In addition, studies have indicated that acculturation is an important factor in substance use patterns, with Hispanic individuals of higher acculturation showing higher levels of substance use.

American Indians–Alaska Natives

In general, American Indians and Alaska Natives have been underrepresented in large-scale epidemiologic studies of substance abuse; however, among

Native Americans and Alaska Natives, heavy use of alcohol, tobacco, and other drugs is a major public health problem. The American Indian–Alaska Native population is, on average, younger than the general population, but differences in levels of alcohol, tobacco, and drug use remain even after controlling for age. The rate of illicit drug use and heavy alcohol use among American Indians–Alaska Natives is higher than among any other ethnic-racial group, which suggests a particular need for prevention and intervention in this population. In fact, estimates from data from the 2006 National Survey on Drug Abuse suggest that among individuals 12 years or older, the rate of past month or current illegal drug use is nearly twice that of the general public (8.7% vs. 9.8%, respectively). In addition, American Indians–Alaska Natives, on average, begin use of alcohol, tobacco, and marijuana at younger ages than do Whites. These trends cut across gender and may contribute to economic difficulties.

Public Health Approaches to Prevention

The public health approach to dealing with the drug problem relies heavily on science and medicine rather than on politics and policies. The public health approach seeks to implement drug demand side interventions rather than the supply side reduction approach used in the current drug war. The public health approach recognizes that drugs of abuse and their associated problems are embedded within society and that the use and abuse of drugs has been part of society for centuries. The public health approach avoids the dichotomy of good and bad applied to various substances and to their users. Some classic public health components include community-based interventions such as improved education and health information distribution as well as regulatory approaches to reduce the availability or attractiveness of drugs of abuse, including alcohol and tobacco. Public education campaigns are a major prevention component of a public health approach as would be dealing with the circumstances that may lead to drug use and drug trade.

One issue of importance in understanding substance use among racial-ethnic minorities is the intersection of race-ethnicity and socioeconomic opportunities. Some theorists have noted that minority individuals have not had and do not have access to many of the socioeconomic opportunities in society. The National Institute on Drug Abuse has stated that drug use is the result

of a failure to actualize fundamental human needs; therefore, the lack of access experienced by individuals from racial-ethnic minorities may be an explanation for higher rates of drug use. This explanation is countered, however, by the findings in the Hispanic community that indicate that lower acculturated individuals, who may be less likely to have access to socioeconomic opportunities, actually show lower rates of drug use. It may be that aspects of mainstream U.S. culture encourage substance experimentation, which becomes problematic substance use among culturally and economically marginalized individuals.

Primary prevention measures in minority ethnic and racial communities are virtually nonexistent save those that are conducted in school, and even these have dubious effectiveness (e.g., D.A.R.E.). Science and medicine-based education on the health effects and common consequences of substance use that is culturally tailored and emphasizes specific important components of community values is needed. For example, efforts designed to prevent drug use among African Americans may emphasize community responsibility and traditional family roles, while bolstering access to educational and employment opportunities. Among Asian-Pacific Islanders, school-based preventive interventions appear to be moderately more effective than among other groups; however, specific subgroups of Asian-Pacific Islanders may need to be targeted (e.g., Korean Americans, Japanese Americans) in an effort to reduce drug and alcohol use and their untoward consequences. For American Indians–Alaska Natives it appears that comprehensive, intensive intervention is necessary both to prevent substance use and to intervene once substance use has been initiated. For Hispanics, one issue of importance with regard to prevention is acculturation. Data indicate that as Hispanics acculturate to mainstream U.S. society, their rates of substance use problems increase. Although speculation as to the moderating variables of this increase in substance problems occurs in the literature, little empirical research has identified what aspects of Hispanic culture are protective with regard to substance use and how those aspects may be preserved during the acculturative process to reduce the increase in substance use.

HIV/AIDS is an important issue in substance abuse prevention among ethnic minorities. African Americans and Hispanics are overrepresented among individuals with HIV/AIDS relative to their numbers in the general public. Drug use is implicated in the transmission of the HIV virus through either injection of drugs or risky sex

behavior associated with substance use in minority communities. Secondary prevention measures such as needle cleaning education or needle exchange programs and interventions designed to increase condom use and increase HIV testing and treatment may help reduce the impact of HIV/AIDS on minority communities. Prevention efforts designed to reduce the initiation of substance use would preclude the development of some HIV/AIDS risk behaviors.

Conclusion

Since 1978, revisions in race-ethnicity designations for national-level data have been implemented, which may be in recognition of the increasing proportion of the U.S. population made up of various racial and ethnic minorities. Rates of drug use among Hispanics, African Americans, Asian-Pacific Islanders, and American Indians–Alaska Natives in some cases differ significantly from those of Whites. Hispanics and Asian-Pacific Islanders tend to have somewhat lower rates of substance use than Whites, but segments within these subgroups show high levels of substance use. Among American Indians–Alaska Natives, substance use is a particular problem. Public health interventions may be one prevention measure to reduce drug use initiation. Public health interventions are medicine and science based and address drug demand rather than supply side interventions common to the drug war. There is a need for culturally based prevention interventions and for the recognition of the need to address socioeconomic opportunities in minority populations in order to prevent substance use. HIV/AIDS is more common among African Americans and Hispanics. Preventing drug use in these communities may help reduce the impact of HIV/AIDS in these communities by reducing or eliminating one common route of HIV virus transmission.

RACIAL AND ETHNIC MINORITIES, ISSUES IN TREATMENT

Given recent demographic trends, by the year 2100, non-Hispanic Whites will constitute only 40% of the U.S. population. As the numbers of ethnic and racial minorities increase, careful research to adapt social services, including substance abuse treatment, to the needs of ethnically and racially diverse individuals is necessary. The current entry presents data on treatment admissions by ethnicity-race for the year 2005, discusses service utilization rates for substance abuse treatment, and discusses cultural issues in the treatment of substance use.

Service Utilization

Health services research has examined the extent to which people seek treatment for mental health and substance-related problems. A number of observations can be made regarding the literature on service utilization: (a) It suggests a general underutilization of mental health and substance abuse services nationwide, (b) the problem of underutilization is more pronounced among ethnic minorities, and (c) the pattern of underutilization of mental health and substance abuse services is persistent because studies spanning approximately a third of

a century show similar underutilization rates. Although one might assume that lack of insurance is a major barrier to utilization of services, some research shows that, at least among insured Hispanics working for the federal government, utilization of mental health and substance abuse services is lower than the utilization rates of non-Hispanic Whites.

In 2006, 1,800,717 persons entered treatment for substance abuse in publicly funded treatment. Approximately 35% of these individuals admitted to treatment were ethnic-racial minorities. The largest single ethnic group represented was African Americans (17.7%), followed by Hispanics (12.7%), American Indians–Alaska Natives (2.1%), and Asian-Pacific Islanders (0.7%). Whites comprised 65% of total treatment admissions to publicly funded substance abuse treatment in 2006. As the nation's demographics change in the coming years, it is likely that more and more individuals from traditionally minority ethnic and racial backgrounds will present for treatment in publicly funded substance abuse treatment settings.

Some data suggest, however, that among Hispanics and African American daily drug users, perceived need for treatment is lower than among non-Hispanic Whites. Such differences in perceived need for treatment may serve as a barrier to treatment entry among individuals of minority ethnicity-race. Interventions to change cultural attitudes toward the utility of substance abuse treatment among racial and ethnic minorities may help to reduce the differences in perceived need for treatment among those with substance-related problems. Further, increasing the awareness of and perceived utility of substance abuse treatment services may be part of what is necessary to reduce ethnic disparities in substance abuse treatment services.

Once admitted to treatment, findings in the literature suggest that minority clients may be more likely to leave treatment early, are less likely to complete a course of treatment, and may adhere less to treatment programs than nonminority clients. Early treatment exit is an important issue in that time in treatment is associated with increased gains from treatment (e.g., reductions in drug use and drug-related criminal activity). It is unclear what factors contribute to these differences in treatment outcome; however, it may be that traditional drug treatment interventions, designed primarily for non-Hispanic White males, likely need modifications for use with other ethnic-racial groups. In particular, the incorporation of culturally congruent constructs (e.g., familism for Hispanics, Afrocentrism for African Americans) may make treatment environments

more conducive to retention of racial-ethnic minorities in treatment. With regard to the issue of treatment adherence, the cultural relevance of aspects of substance abuse treatment programs may be important. For example, for African Americans, there may be a preference for church-provided recovery groups over Alcoholics Anonymous (AA). If attendance at AA is part of a treatment program, the program may be less likely to be completed by African American clients.

Cultural Issues

Research suggests that matching on race-ethnicity for counselors and clients may not be significantly related to retention in treatment or to treatment outcomes. What may be more important than the race-ethnicity match is cultural competence coupled with basic clinical skill. The definition of cultural competence is complex and includes awareness of one's own cultural frameworks and the biases inherent in them, as well as an understanding of and acceptance of the fact that differences exist between cultures with regard to their cultural frameworks and biases. Cultural competence may be better conceptualized as a process rather than a state. That is, awareness of one's own cultural context and recognition of other cultural contexts results in the awareness of differences between cultures. Once this awareness has been raised, it seems that the culturally competent therapist works to limit the impact of his or her cultural assumptions on the conceptualization of clients or interaction with the client while striving to clarify understanding of cultural differences and working to incorporate recovery-supportive cultural factors in the therapeutic process.

For example, there is evidence that suggests that differences between cultures exist with regard to the importance of churches and religious organizations in recovery from substance use. African Americans may rely more heavily on church-provided services than on AA. Recognition of the importance of church and religious support services for recovery among African Americans may mean that the culturally competent therapist advocates using church-supportive services in place of AA, despite the fact that the majority of the therapists' clients attend AA meetings. A second example of cultural differences that may impact substance abuse treatment is that of the role of the family. The Hispanic culture emphasizes responsibility to family and may be characterized by more dense and nurturing bonds than non-Hispanic families; therefore, Hispanic clients may want a role for their family

network in the treatment process. With Native American clients, attention to traditional healing practices may be important, depending on the extent to which the client wishes to integrate them into the process of recovery.

Clearly, one major need in the substance abuse treatment field is that of linguistically tailored treatment programs. A treatment staff that speaks the language of its clients reduces miscommunication and the need for translation and increases its clients' levels of comfort. Efforts to recruit and train individuals from various cultural backgrounds and with wide-ranging language skills may help decrease the disparities observed in substance abuse treatment among members of ethnic and racial minorities.

HIV/AIDS

Data indicate that among ethnic minorities, particularly African Americans and Hispanics, HIV/AIDS is having a disproportionate impact. Substance use increases the risk for the transmission of the HIV virus both through risky drug use practices and through substance-related risky sex behavior. Needle use and needle sharing among intravenous drug users in minority populations can act as a vector for the transmission of the HIV virus, which then may be transmitted through sexual contact with others. For Hispanic women, the leading cause of HIV transmission is heterosexual contact with high-risk partners. For Hispanic men, the leading mode of transmission is homosexual contact, and in some urban areas, methamphetamine using subcultures encourage the pairing of methamphetamine use and high-HIV-risk sex behavior.

Aspects of Hispanic culture are important in understanding the risk profiles of Hispanic women for HIV/AIDS. Hispanic males may be viewed more as the sexual decision makers, and women may be expected to be sexually naive. Knowledge about and use of condoms by Hispanic women may violate the assumptions of sexual inexperience and, when discussed in the context of long-term intimate relationships, have implications with regard to assumptions of fidelity. Males, as part of the construct of machismo, may be more likely to have multiple sex partners, a risk factor of HIV contraction. It may be that the interaction of these cultural factors has contributed to the disproportionate rates of HIV/AIDS among Hispanic women, and these women may have been exposed to HIV as a result of sexual relationships with males engaging in risky sex and drug use practices.

The nexus between HIV/AIDS and substance use is of critical importance in reducing the transmission of the HIV virus among both non-Hispanic Whites and members of racial-ethnic minorities. For one population, Hispanics, acculturation may be an important factor in substance-related HIV/AIDS risk because as acculturation to U.S. mainstream culture occurs, the rates of substance use increase. Further, U.S. acculturation may be associated with more permissive attitudes toward sexual behavior than that found in cultures from Hispanics' countries of origin.

Dual Disorders and Ethnic Minorities

As noted above, substance abuse and mental health services are underutilized by ethnic minorities. The stigma associated with mental health and substance-related problems may be one reason that minority individuals do not seek treatment. Minority individuals with co-occurring disorders face a double stigma. When ethnic-racial minority individuals with co-occurring disorders seek treatment, the difficulty of finding culturally or linguistically appropriate treatment is magnified. In addition, the need for cultural competence on the part of the treatment providers is great in that not only must treatment providers be aware of cultural aspects of addictive disorders, but also they must be aware of cultural aspects of psychiatric disorders. For example, among some Hispanic groups, somatization of depressive symptoms has been observed. A counselor who is unaware of this tendency may miss the presence of a mood disorder that could be primary, secondary, or concurrent with a substance disorder. The result may be inappropriate or ineffective treatment for both disorders.

Criminal Justice Involvement

The "get tough" approach to crime in recent decades has resulted in increasing numbers of individuals being incarcerated for drug-related crimes, and a disproportionate number of individuals in the criminal justice system are from minority groups. Criminal justice system involvement is common among substance-involved individuals from all ethnic-racial groups; however, sentencing for minority individuals and those from lower socioeconomic levels tends to be harsher and is more likely to result in incarceration.

In response to the increased numbers of individuals in the criminal justice system for drug-related crimes and due to the association between substance use and

crime, correctional systems across the nation have implemented in-prison or -jail treatment programs. Few culturally tailored or linguistically tailored drug treatment programs have been implemented in the correctional system. Many correctional systems employ therapeutic community treatment models that were developed in the community and have been transplanted to correctional settings with little change.

An approach to nonviolent drug offenders that emerged in the 1980s and is increasingly being implemented is the drug court paradigm. In this approach, nonviolent drug offenders are mandated to receive drug treatment rather than incarceration. Judicial oversight of treatment progress is part of the drug treatment program, and judges can provide positive feedback for treatment progress or can impose legal sanctions for treatment noncompliance, including incarceration. Drug courts are an emerging phenomenon, and the scant evidence on cross-cultural effectiveness of drug courts may suggest that individuals from minority groups show differential outcomes compared with non-Hispanic Whites. It is unclear as to whether these differences in treatment outcome are a function of existing drug treatment programs or are specific to drug court programs.

Conclusion

Demographic trends suggest that, in coming decades, non-Hispanic Whites will constitute only 40% of the U.S. population. The increasing numbers of individuals from traditionally minority ethnic-racial groups will likely result in increasing need for substance abuse services that are adapted to the culture, language, and communities of ethnic-racial minorities. Currently, the single largest ethnic-racial group entering publicly funded substance abuse treatment is non-Hispanic Whites, followed by African Americans and Hispanics. Data suggest that substance abuse and mental health services are underutilized by racial and ethnic minority individuals. This underutilization may, in part, be due to less perception of need for professional treatment for substance-related disorders among different ethnic-racial groups. Once in treatment, individuals from ethnic-racial minority groups may show poorer outcomes than do non-Hispanic Whites. One factor may be the relative lack of culturally and linguistically tailored substance treatment programs. There may be a particular need for such programs given the fact that traditional substance treatment programs were developed

with non-Hispanic White clients. Cultural competence, including recognition of cultural differences and incorporation of recovery-oriented culturally appropriate constructs, may help improve outcomes for minority individuals in substance abuse treatment. Cultural competence may be particularly important in treating individuals with co-occurring disorders. Among the consequences of substance use can be HIV/AIDS. HIV/AIDS has disproportionately affected minority communities, particularly Hispanics and African Americans. Understanding the relationship between substance use and HIV/AIDS in minority communities is vital to reducing HIV/AIDS infection. Criminal justice involvement is also a common consequence of heavy substance involvement. Sentencing disparities have resulted in a disproportionate number of ethnic-racial minority individuals in the correctional system for drug-related crimes. Although drug treatment is increasingly offered in correctional settings, little in the way of culturally or linguistically tailored treatment may be available in correctional settings.

RAPID OPIOID DETOXIFICATION

Epidemiologic studies show that opioid addiction affects nearly one million people and their families a year. This self-destructive public health problem prevails in all socioeconomic classes of American society. Opioid dependency is complex, involving physiological, psychological, genetic, behavioral, and environmental factors. The complicated nature of opioid addiction requires unique treatment approaches and knowledgeable professionals working with substance abuse populations.

Typically, detoxification is a crucial first step in the treatment of opioid dependency. Although risk of death is virtually absent, the withdrawal syndrome from opioids can be intensely symptomatic and drawn out, including when pharmacologic agents are utilized to manage withdrawal. Because withdrawal symptoms can be incredibly distressing, some individuals will terminate the detoxification process, and many will return to illicit opioid use. Other individuals will avoid detoxification entirely because they fear the extreme discomforts of opioid withdrawal.

Traditional methods of treating opioid dependency include discontinuing shorter-acting opioids (e.g., heroin) by substituting a longer-acting opioid (e.g., methadone or buprenorphine) and gradually tapering. In addition, clonidine hydrochloride is a nonopioid approach to opioid detoxification that has been utilized over the past several years. Alternative therapeutic interventions have been created to accelerate opioid detoxification, which aim to minimize the risk of relapse, to quickly begin treatment with naltrexone for maintenance, and to provide suitable psychosocial interventions. Two primary alternative methods include ultra rapid detoxification (UROD) and rapid opioid detoxification (ROD). UROD utilizes general anesthesia along with intravenous opioid antagonists to accelerate the withdrawal process (typically less than 6 hours' duration), while ROD utilizes oral opioid antagonists (such as naltrexone, naloxone, or nalmefene) along with moderate sedation, at a conscious level, orally or intravenously, to precipitate withdrawal (typically 6–72 hours' duration). The opioid receptor antagonist works to abruptly displace the opioid from the receptor site, while the anesthesia is central for the individual to tolerate acute withdrawal symptoms during this accelerated process.

Although rapid opioid detoxification is often presented as a fast and painless way to withdraw from opioids, questions and concerns have been raised mainly regarding adverse events (morbidity and mortality) and the cost associated with the procedure. The following are concerns about risks of ROD: marked increases in plasma corticotrophin (causes the adrenal gland to release cortisol), cortisol (a major stress hormone), respiration, sympathetic activity (opposes the physiological effects of the parasympathetic nervous system by decreasing digestive secretions, speeding the heart rate, and contracting blood vessels), and catecholamines (nerve and adrenal producing hormones that act on blood vessels and the heart); suppression of thyroid hormones; pulmonary distress; pulmonary edema (an accumulation of fluid in the lungs); acute renal failure (sudden and severe decrease in kidney function); ventricular bigeminy (a ventricular premature beat that follows each normal beat); psychosis; delirium; suicide attempts; and deaths associated with the procedure. The above risks are real; however, it is important to again note that the mortality rate for rapid opioid detoxification is minor, while the mortality rate for persons who continue opioid use is significant. Furthermore, it is unlikely that any of the above risks are directly caused by opioid antagonists or general anesthetics, as a variety of different factors contribute to the overall health of the individual receiving ROD. All individuals should be screened for preexisting conditions that could be potentially dangerous for rapid opioid detoxification procedures. Beyond general health concerns, rapid opioid detoxification requires expensive medical facilities, anesthesia equipment, and nursing staff, which cost up to \$7,500 in 1997 and as much as \$15,000 in 2005, and generally, procedures like ROD are not covered by insurance. The possible risks, costs, and benefits should be taken into consideration when individuals and mental health professionals decide on treatment options.

ROD is appropriate for certain individuals looking to detoxify, especially highly motivated, socially stable, low-level opioid users. In addition, this process can be useful for those who do not qualify or care for traditional opioid maintenance treatment methods and for individuals without access to maintenance treatment programs. ROD can be suitable for those who have failed using other methods of detoxification or who desire a speedy detoxification for specific reasons (e.g., family, social reasons, or employment).

The manner in which rapid opioid detoxification is being presented shows how society is urgently looking for answers to the crisis of opioid addiction. The idea that rapid opioid detoxification is a “quick fix” to a huge problem is a highly optimistic outlook. Individuals choosing rapid opioid detoxification should be carefully selected and informed of the available evidence regarding the safety and effectiveness of the procedure. A clear understanding of the power of ongoing treatment should be discussed with individuals in the treatment process. Detoxification is one part of a greater whole to address the chronic dysfunction of addiction, and positive outcomes can result with continued treatment postprocedure. Additional research could provide valuable information on this unique procedure. Because the evidence is unclear about how any specific method of detoxification relates to retention in opioid addiction treatment, some critics suggest the need for more research studies to include randomized controlled trials to compare accelerated methods (e.g., rapid opioid detoxification) with agonist substitution methods (e.g., buprenorphine-assisted detoxification) and with nonopioid-based treatments (e.g., clonidine detoxification). Evaluation of ongoing treatment and additional research regarding the safety of accelerated treatment approaches could be useful for clinicians and opioid-addicted individuals to understand the role of rapid opioid detoxification in the process of treatment.

RATIONAL RECOVERY

Rational Recovery (RR) was developed by clinical social worker Jack Trimpey and his wife, Lois, as a non-spiritual alternative to the Twelve-Step program of recovery. Trimpey was able to overcome his 21-year addiction to alcohol after his wife demanded that he simply stop drinking altogether. Faced with this challenge, Trimpey quit Alcoholics Anonymous (AA) and decided to confront his physical addiction directly. In 1986, Trimpey created a new organization, modeled on AA but emphasizing abstinence through self-reliance and rational thinking. The choice of the name Rational Recovery is a reference to the program’s therapeutic foundation in rational emotive therapy (RET; now called rational emotive behavior therapy, REBT), a cognitive behavioral approach developed by Albert Ellis.

RR philosophy agrees with the Twelve-Step approach in the belief that recovery from alcohol dependency requires complete abstinence. However, RR states that calling alcohol dependence a disease absolves people of much of the responsibility for drinking. In RR, drug and alcohol dependence is defined in terms similar to those in the *Diagnostic and Statistical Manual of Mental Disorders*, but RR does not take a position on the presence or absence of a genetic predisposition for this condition nor does it define chemical dependence as a disease. RR believes that defining alcoholism as a disease is not based on definitive research data. In fact, RR holds that such a position is ultimately irrelevant since the solution to the problem of addiction is the same whether it is considered a disease or the result of genetic predisposition.

RR begins with the belief in unconditional self-acceptance. An assumption of RR, derived from RET-REBT, is that individuals who are alcohol dependent do not need to achieve sobriety in order to build their self-esteem and feel that they are worthwhile. The RR principle is that people achieve sobriety for their own sake because they are inherently worthwhile. Another

important difference between Twelve-Step programs and RR is that the latter involves a process of abstaining from mind-altering substances through the exercise of self-discipline and rational thinking rather than through dependence on a higher power. RR emphasizes personal control versus personal powerlessness. Consistent with the major assumptions of RET-REBT, individuals are encouraged to avoid labeling themselves as alcoholics or drug addicts, as that defines the person's essence. This type of self-labeling indicates that a person has always been and will always be an alcoholic or addict, as that is their nature. According to RR, it is better to view oneself as a person who is currently addicted to alcohol or other drugs but who possesses many positive characteristics, talents, strengths, and limitations and weaknesses. The aspect of being addicted to alcohol or other drugs was not always true and need not be true tomorrow. Therefore, individuals who abstain from alcohol or drugs are considered by RR as *recovered* as opposed to *recovering*.

The major task in recovery from addiction is learning to think rationally, as guided by the cognitive behavioral principles of the ABCs of rational thinking. Briefly, the ABCs of RET-REBT are activating events (this includes describing the specific situation); beliefs, attitudes, and ideas (specifying one's wants, desires, demands, or commands); consequences (specifying both rational and irrational emotions and behaviors); dispute (replacing irrational beliefs with rational ones); and finally, effects (comparing emotional responses tied to one's irrational beliefs with more rational alternatives).

According to RR, sobriety is achieved through a process of education and awareness or recognition. Individuals learn to replace thinking that supports addiction through the addictive voice recognition technique (AVRT). The idea here is that thinking that promotes addiction is the product of the primitive or old brain, which is called the *BEAST*. Whereas the *BEAST* represents survival and pleasure, the cerebral cortex is viewed as the new or higher brain that allows human beings to make choices, to think, and to determine their own actions. From the RR perspective, the old brain needs to be controlled by the new brain if the powerful desire for alcohol and other drugs is to be overcome. Thus, using the AVRT, individuals listen for the voice of the *BEAST* (i.e., the beliefs) promoting alcohol and other drug use and then dispute these messages with more rational thoughts that are in the best interest of the person.

The original version of RR included the Rational Recovery Self-Help Network (RRSN), which consisted

of free groups for individuals who wanted to work on their addictions using RR principles. According to Trimpey, in 1992 there were self-help groups in about 400 cities in the United States and internationally. These RR groups were described as task-oriented self-help groups where individuals develop and utilize RR concepts to deal with common problems in staying sober. In RR groups, individuals are discouraged from presenting stories of drunkenness or drunken behavior (i.e., *drunkalogs*) and instead are asked to focus on thinking of the best ways to change their current thinking, feeling, and behavior.

Several research studies have provided support for RR. Research has shown, for example, that for persons less comfortable with AA's spiritual orientation, RR is a viable alternative since abstinence rates increased with length of time in the group. Other research has demonstrated that RR can be an effective treatment for fostering openness and diminishing denial among addicted individuals.

In 1994, RR dropped the emphasis on self-help groups and replaced it with a preference for emphasizing individual use of AVRT. This emphasis is consistent with the long-standing belief in Twelve-Step programs that meetings do not keep a person sober; working the program is the only effective method in maintaining sobriety. Rational Recovery Systems, Inc. provides training materials and offers courses to promote self-recovery.

A group of individuals who were previously associated with Rational Recovery Systems, Inc. went on to develop an alternate self-help system currently identified as SMART Recovery that includes cognitive behavioral programming, provides training materials, and continues to promote cognitive therapy-based self-help groups. Ellis and others have also outlined rational approaches to overcoming substance dependence in line with the techniques and goals of the RR model.

RECOVERY

Common definitions of the word *recovery* include a return to health or consciousness and regaining a sense of balance, control, or composure. Both descriptions are appropriate when discussing substance use disorders. When consuming drugs or alcohol to excess, a person's health suffers, the person loses the ability to control his or her use, and life is certainly out of balance. Drug and alcohol counselors sometimes talk to substance use disorder clients about being conscious (not under the influence of drugs or alcohol) long enough to seriously engage in treatment. The subject of recovery is appropriate in any volume of substance abuse topics since a return to health is the desired outcome for most individuals with substance use disorders.

From a clinician's perspective, recovery could be equated to remission, which is consistent with other chronic health conditions. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*, there are six different types of remission. The designations closest to the concept of recovery are early full remission (characterized by no criteria met for substance dependence or abuse for at least 1 month but for less than 12), sustained full remission (no criteria met for at least 12 months), and on agonist therapy (medication-assisted treatment). The largest difference between remission and recovery is that remission refers only to not using mood- or mind-altering substances while recovery is abstinence plus a myriad of other life changes.

Overview of Recovery

Many years of research have been done on drug and alcohol dependence, methods and modes of treatment,

and relapse prevention. Up until recently, little research has focused on long-term recovery. Most of the recovery support models existing in the field today are based on experiential knowledge, patterns of belief, and deep-rooted protocol rather than on empirical studies.

Recovery from substance use disorders is generally viewed as a long-term process, although some individuals will speak of themselves as *recovered*, which implies their disorder is *cured*. Since substance use disorders are chronic rather than acute conditions for the purposes of this entry, recovery will be considered a process that lasts a lifetime.

One therapist and writer, Craig Nakken, has addressed the various stages of recovery through his many years of work in the addictions field. According to Nakken, early recovery (the first year or so) focuses on learning tolerance and honesty, middle recovery (generally years 2–5) concentrates on understanding and acceptance, and late recovery (more than 5 years) is focused on love of self, family, and the community. Nakken's interpretation of recovery also emphasizes the need for all family members to be in recovery. A common recommendation is for spouses, significant others, and relatives of people with substance use disorders to attend Al-Anon or Alateen meetings. Addiction affects everyone in the family, and it is often beneficial for all parties to seek support or counseling to deal with feelings and issues that arise whether the person using drugs or alcohol is in recovery or continuing to practice his or her addiction.

Recovery is not synonymous with either sobriety or abstinence. Recovery is commonly thought of as a holistic approach to life where an individual not only ceases using drugs and alcohol but also addresses emotional, social, spiritual, and intellectual needs. It is a commonly held belief that people who use substances to their detriment often have other issues that when left unexamined or unchanged may lead to relapse.

Not using drugs and alcohol is only a small part of the recovery process. Recovery may also involve attending continuing care groups or peer support meetings, returning to church, and any other number of activities to help a person remain free from drugs and alcohol. Recovery also comes in a variety of methods; one size does not fit all. Many people will access recovery through treatment or counseling, by attending Twelve-Step meetings, through Rational Recovery, by participating in the Secular Organization for Sobriety or in Women for Sobriety, as a spiritual or

religious experience, on their own (natural recovery), or some combination of the above. Many Internet sites are now devoted to helping individuals attain and maintain sobriety and recovery.

Changes Made in Recovery

The changes a person makes in recovery can greatly assist in the individual's ability to remain abstinent and subsequently lead a healthier, happier life. For example, to promote physical health, it is recommended that people in treatment or recovery engage in healthy eating habits, increase their fluid intake, increase their physical activity, get adequate rest, take vitamin supplements, decrease their use of caffeine, and stop smoking.

The realms of emotions, the spirit, and the intellect should also be addressed. Those abstaining from drugs and alcohol are often encouraged by treatment professionals and peers to work a program of recovery. This work may include completing the Twelve Steps of Alcoholics Anonymous or Narcotics Anonymous and getting a sponsor, attending other recovery-oriented support groups, participating in a continuing care program, or receiving counseling. Other recommendations could be reestablishing one's spiritual or religious activities, taking responsibility for any criminal justice obligations, honoring commitments to family and employer, and creating a support system so help will be available when needed. People in recovery may also have to make changes regarding where they live, who they socialize with, and where they work.

Although individuals from all walks of life, cultures, and races can be subject to substance use disorders, some people may require additional services and resources to achieve lasting recovery. Employment, housing, childcare, and transportation are just a few areas where accessible, affordable resources can make a huge difference in whether or not a person remains abstinent.

Where a person falls in the life cycle is another consideration; varying age groups have different needs. For example, adolescents in recovery require support from family, friends, school, and frequently, the juvenile justice system. There are evidence-based treatment approaches for adolescents, which emphasize a broad approach to treatment interventions such as including school personnel on the treatment team, having counselors provide in-home

visits, and requiring the family to be involved. From a systems theory perspective, the client is the identified patient and the entire family should participate in order to develop new methods of communication and interaction. All significant people in the adolescent's life are encouraged to be part of developing discharge and recovery plans.

Older adults tend to be more isolated than younger adults, with spouses who may be disabled or deceased, children who are grown and out of the home, and fewer friends because of death or illness. Seniors may require an entirely new support system, which might include a social worker, the local senior center, or in-home visits from health care professionals. Since older adults may be on a variety of medications, their primary care physician should also be involved in the person's recovery. Ensuring that these resources are in place is imperative for continuing abstinence.

Stigma

Although there is a plethora of research supporting addiction as a brain disease, much of the general public continues to view addiction as a result of willful misconduct or as a moral failure. This stigmatizing perspective, combined with the Twelve-Step tradition of anonymity, leads to a perception by the general public that no one (or few people) actually achieves abstinence or recovery. Millions of people in the United States live happy, purposeful lives after ceasing to use mood- or mind-altering substances. Outside of support groups, the majority of these individuals seldom reveal the fact they are in recovery for fear of censorship or even punishment by friends, acquaintances, employers, insurance companies, professional licensing boards, and colleagues. Due to the fear of discrimination, even people who have been in recovery for several years may not admit to having once had a problem with drugs or alcohol when applying for jobs, life insurance, or professional licenses. The practice of stigmatizing recovering individuals has come into question in the past few years and has led to changes in federal law including allowing those with drug convictions to apply for loans to attend college.

Another common misconception is that treatment does not work, and therefore, very few people are in recovery. Many people have known someone who has gone into treatment only to relapse upon discharge. However, according to many researchers, relapse rates

for those who are alcohol or drug dependent are similar to relapse rates for many other chronic conditions including asthma, diabetes, and hypertension.

Trends in Recovery

The movement to emphasize recovery's place in the continuum of care regarding substance use disorders has created more opportunities and greater choices for those in recovery. Initially, this movement began as a grassroots effort by those in recovery and their family members. More recently, the federal government has emphasized the role of recovery in the continuum of care. Traditionally, recovery from drug and alcohol abuse or dependence began (and often ended) with a hospital-based inpatient, residential, or outpatient acute treatment episode generally lasting 28 to 30 days. Some treatment centers provided aftercare groups that implied a period of posttreatment intervention. With the current emphasis on the chronicity of substance use disorders, the term *aftercare* is being gradually being replaced by *continuing care*. The perspective of the field is now more on a recovering individual needing support, assistance, and resources far beyond the acute treatment episode in order to maintain sobriety and prevent relapse. Since it normally takes years for addiction to progress and seriously impact a person's life, it makes sense to view the recovery process as a long-term proposition.

Thomas McLellan and others are advocating for new approaches to treating substance use disorders including recovery management where professional counseling services are less about short-term individual treatment episodes and more about a long-term commitment to maintaining recovery. As William White, a well-known recovery advocate, discusses, recovery is receiving more attention from the federal government especially in the Substance Abuse and Mental Health Services Administration, the National Institute on Drug Abuse, and the National Institute on Alcohol Abuse and Alcoholism. Rather than having the addiction field focused only on the disorder itself and subsequent treatment, federal efforts are emerging to support long-term recovery through publicly funded grant projects such as the Recovery Community Services Program and Access to Recovery. Grassroots organizations like the Faces and Voices of Recovery are advocating for the rights of recovering individuals on Capitol Hill and in state governments. Join Together (online) at Boston University published an article in April 2007 from *The*

New York Times discussing a practice where celebrities and other wealthy individuals in recovery hire sober companions or personal recovery assistants to help them through the first difficult few weeks (or even months) of recovery.

Conclusion

Recovery from substance use disorders is an incredibly complex, long-term process. Many factors contribute to a person's ability to remain drug and alcohol free, including personal commitment and capabilities, access to resources, family and community support, physical and mental health, and the ability to change thoughts, feelings, and behaviors. For most, recovery is abstinence plus the ability to engage in the world differently. When people no longer use substances, all their problems do not magically disappear. However, with the skills and tools learned in Twelve-Step meetings, peer support groups, religious institutions, alternative recovery programs, treatment, counseling, or other drug and alcohol-free systems, recovering individuals can and do lead happier, healthier lives.

RECOVERY COMMUNITY ORGANIZATIONS

Recovery community organizations are independent, not-for-profit, community-based organizations that are led and run by representatives of local communities of recovery on behalf of the recovery community. The broadly defined recovery community (people in long-term recovery and their families, friends, and allies including recovery-focused professionals in the addiction and recovery field) is increasingly composed of discrete segments that span religious, spiritual, and secular pathways of recovery. The sole purpose of a recovery community organization is to mobilize the resources of the recovery community to increase the likelihood that people seeking or needing long-term recovery from addiction get the help that they need to achieve it.

Many times, people in long-term recovery or family members created recovery community organizations in response to unmet needs or crises in their communities. These organizations often existed as voluntary advocacy and service organizations for some time before they secured funding to provide support and carry out mobilizing and organizing activities on a more formal basis.

There are a number of national organizations that address the needs of people who have taken a particular pathway to recovery, and many of these organizations have state and local affiliates. For example, the National Alliance of Methadone Advocates (www.nama.org), Advocates for Recovery through Medicine, the National Alliance of Advocates for Buprenorphine Treatment, and the Opioid Dependence Resource Center all provide assistance for those in medication-assisted recovery. Other national organizations are focused on supporting recovery for particular ethnic groups. An example of such an organization is

White Bison, whose mission is focused on recovery advocacy and support in Native American communities. The National Council on Alcoholism and Drug Dependence has a number of affiliates that have spawned or sponsored the development of local recovery community organizations. At the national level, Faces & Voices of Recovery is an organization representing recovery community organizations and the recovery community. Most local, state, and regional recovery community organizations are part of this national campaign.

Recovery community organizations take many forms. They differ significantly from addiction treatment organizations and recovery mutual aid groups. Recovery community organizations are independent, meaning that they are usually not involved in organizations and activities that go beyond recovery-focused public education, policy advocacy, and the delivery of recovery support services. These organizations are led by individuals chosen by representatives of the recovery community, are committed to recovery-related social change (e.g., recovery-focused community education, advocating prorecovery social policies), and invest considerable resources in organizing recovery resources within their local communities.

Recovery community organizations are not a program of personal recovery. They do not promote a particular pathway to recovery, and their volunteers do not act as Twelve-Step sponsors in their volunteer role. Recovery community organizations celebrate the multiple pathways to recovery and offer resources to people across those frameworks of recovery. If a recovery community organization offers services to individuals and their families, they are peer-based, nonclinical recovery support services. Recovery community organization staff and volunteers do not provide professional assessment, addiction counseling, or related clinical services.

Other distinctive characteristics of recovery community organizations are their conscious effort to achieve cultural diversity, promotion of leadership development within the recovery community, and emphasis on people's recovery potential rather than on their pathologies. These organizations also promote the development of local core recovery values and ethical guidelines to govern the organizational and volunteer decision making in advocacy and peer-support activities.

Recovery community organizations are organized to provide public education, policy advocacy, and peer-based recovery support services. Education and advocacy can take many forms, but all recovery

community organizations seek to put a positive face and voice on recovery using a vanguard of individuals and families willing to offer their lives as testimony that long-term recovery is a reality. This infuses communities with the hope and healing power of recovery. It allows mainstream society a highly visible solution to the staggering problem associated with alcohol and other drug addiction.

Some recovery community organizations bridge the gap between a clinical treatment episode and long-term recovery by providing peer-based recovery support services. These services cover a wide range of activities not generally offered by treatment providers and can include peer support, housing, transportation, vocational training, employment services, recovery coaching, telephone support, support groups, system navigation, recovery resource dissemination, life skills training and other training, and sober social activities. Peer-based recovery support services are available in different locations. Some recovery community organizations are providing these services through drug courts, in jails and prisons, and in recovery community centers. Recovery community centers, which are sprouting up across the country, are set up by recovery community organizations and become the focal point for recovery advocacy, education, and other activities in the community.

In order to support public education, policy advocacy, and peer-based recovery services, recovery community organizations have implemented eight core strategies:

1. *Build strong, grassroots organizations* that develop recovery leaders, offer opportunities for recovering people to express their collective voice, and provide a forum for community service.
2. *Advocate for meaningful representation and voice* for people in long-term recovery and their family members on issues that affect their lives.
3. *Assess needs* related to the adequacy and quality of local treatment and recovery support services.
4. *Educate the public, policymakers, and service providers* about the prevalence and pathways of addiction recovery.
5. *Develop human and fiscal resources* by expanding philanthropic and public support for addiction treatment, recovery support services, and recovery advocacy and by cultivating volunteerism within local communities of recovery.
6. *Advocate for policy changes* at the local, state, and federal levels that promote recovery and remove barriers to recovery.
7. *Celebrate recovery from addiction* through public events that offer living testimony of the transformative power of recovery.
8. *Support research* that illuminates effective strategies and the processes of long-term recovery.

RECOVERY COMMUNITY SERVICES PROGRAM

The Substance Abuse and Mental Health Services Administration's (SAMHSA's) Center for Substance Abuse Treatment (CSAT) established the Recovery Community Services Program (RCSP) in federal

fiscal year 2003 with the award of 10 grants of up to \$325,000 annually to two types of organizations. Five awards were made to recovery community organizations, which are staffed and led primarily by persons in recovery and their family members. These organizations provide peer-to-peer recovery support services. The remaining five awards were made to facilitating organizations to assist recovery groups in forming independent recovery community organizations.

The 2003 cohort of RCSP grantees focused their efforts on engaging and serving a variety of target populations, including adolescents, women, persons with co-occurring substance use and mental health disorders, persons with AIDS, African Americans, Asians and Pacific Island Americans, Hispanics, ex-offenders, homeless persons, and individuals newly in recovery. Since the inception of the program, 33 grants have been awarded. In 2004, \$11,190,236 was awarded to eight organizations over 4 years. Five were recovery organizations, and three were facilitating organizations. In 2006, seven additional 4-year RCSP grants with funding of approximately \$350,000 annually were awarded. In addition, in 2007 SAMHSA-CSAT made available \$2.9 million for up to eight awards of up to \$350,000.

Peer-to-peer recovery support services are the hallmark of the RCSP. Designed and delivered by individuals who are themselves in recovery, peer-to-peer recovery support services are nonclinical and nonprofessional services that support individuals in initiating, consolidating, maintaining, and enhancing recovery. SAMHSA-CSAT described the purpose of the peer-to-peer services provided under RCSP grants as promoting timely reengagement in treatment when relapse occurs and as supporting sustained recovery and improved quality of life. SAMHSA has also noted that peer-to-peer recovery support services are an embodiment of the concept of social support. Both active and perceived social support have been found to be important to recovery, as has the ability to elicit and receive support. The RCSP provides a mechanism for encouraging use of and facilitating access to social support. RCSP grantees are encouraged by SAMHSA to develop a mix of services across four broad categories:

1. emotional support, which is often provided through services such as peer mentoring, peer coaching, and mutual aid groups;
2. informational support, which includes a variety of peer-led services, including life and job skills training, citizenship restoration, educational assistance, and health and wellness information;
3. instrumental support, which includes practical assistance in areas ranging from completing entitlement, employment, or school applications to achieving transportation, clothing and basic needs assistance, or childcare; and
4. affiliated support, which assists individuals in developing social skills and in developing new social networks within the recovering community, faith communities, and broader social groups.

RCSP emerged from a predecessor program, the Recovery Community Support Program, which was established by SAMHSA-CSAT in 1998. The Recovery Community Support Program funded community organizations to mobilize recovering communities at the local, state, or regional levels. Among the goals of the program were raising public awareness about alcohol and drug use disorders, treatment, and recovery; addressing stigma; and improving treatment. SAMHSA-CSAT funded 30 recovery communities during the program's 4 years. Grantees advocated for establishing peer-to-peer recovery support services as an adjunct to treatment, giving rise to the RCSP program in 2003.

Overall, SAMHSA-CSAT established the following goals for the Recovery Community Support Program:

- *build the capacity of recovery organizations* to participate in the planning, delivery, and evaluation of addiction policies, systems, and services so that they become more responsive to the needs of recovering people and their families;
- *promote linkages* among persons in recovery and their family members and allies and facilitate linkages between the recovery community and formal delivery systems;
- *reduce stigma* associated with addiction, treatment, and recovery;
- *foster financial self-sufficiency* and independence of the projects; and
- *document organizational structures and processes* used by RCSP grantees in their organizing and advocacy efforts.

Among key challenges of the 1998 grantees was establishing cohesive recovery communities and

developing a cadre of leaders to inform public dialogue and to foster policy and service systems that would respond to the needs of individuals in recovery. In a document summarizing the accomplishments of the 1998 grantees and the lessons they learned, one grantee indicated that there was not a single recovery community but, rather, a set of diverse communities of recovering individuals. Among these communities, the grantee noted, are many who have the potential to become leaders. Another grantee called for a community-organizing model centered on leadership development and responsibility, and although acknowledging the value of an established agency as a fiduciary agent, the grantee stressed the importance of having autonomous recovery organizations to foster the development of authentic leaders within recovery communities.

Recovery community support programs developed five principles of recovery community organizing, which would later inform the RCSP as its five core values: keeping recovery first, cultural diversity and inclusion, authenticity, participatory process, and leadership. The 1998 RCSP grantee cohort and those that would follow reflect a long-standing tradition of mutual aid among alcoholics and addicts that includes not only Alcoholics Anonymous and the Twelve-Step programs that emerged from it, but also predecessor groups, including the Oxford Group and various temperance leagues. The advocacy tradition from which it emerges includes Marty Mann and the organization she founded, the National Council on Alcohol and Drug Dependence, and Faces & Voices of Recovery.

However, the recovery community organizations that emerged from RCSP are neither mutual aid groups nor public education and advocacy organizations per se. RCSP is rather a vehicle for individual and community empowerment and engagement. It supports the development of policy, systems, and services that support the needs of recovering individuals. RCSP also reflects the mental health consumer movement, which since the late 1970s has advocated for consumer, family, and ally involvement in policy, systems, and services and has advocated for self-managed care. In addition, this movement has sought to address stigma and discrimination, has fostered the development of support groups, and has promoted the concept of recovery from mental illness. This focus on recovering individuals, their families and allies, and the communities they form is also reflected in National Alcohol and Drug Addiction Recovery Month, Access to

Recovery (President George W. Bush's voucher program supporting treatment and recovery support services), and the Partners for Recovery (PFR) Initiative. PFR emerged from the SAMHSA-CSAT National Treatment Plan, offering a broader paradigm for dialogue on the development of services and systems.

In September 2005, RCSP and PFR jointly sponsored the SAMHSA-CSAT National Summit on Recovery through which a working definition of recovery and consensus principles of recovery and elements of recovery-oriented systems of care were developed. The principles and elements of care developed through the summit served as a template for a series of regional meetings with states, researchers, and treatment and recovery support organizations on the planning and implementation of recovery-oriented systems of care sponsored under PFR in 2007. RCSP programs may play a critical role in supporting the development of recovery-oriented systems of care at the state and local levels.

RECOVERY SCHOOLS

Recovery schools are state recognized programs designed for students in recovery from addiction. School-based recovery programs create communities of students in recovery and provide them with professionals, peers, and volunteers who help them work to sustain their recovery and succeed at school. Across the country, recovery schools are being founded to help recovering students increase graduation rates, reduce health care costs, improve academic performance, and transform the culture and environment on campuses. The serious, dangerous level of alcohol and drug problems young adults experience include overdoses, unsafe sex and sexual assault, damaged property, school dropout, injury, death, and addiction. A college environment that includes heavy drinking and drug use is a formidable barrier to students seeking treatment or in recovery from addiction.

Students in recovery have described how dorm life has too many temptations for people in recovery. Students report having their study interrupted with offers of alcohol and other drugs. The “positive” association between college social life and alcohol and drug use is so strong that for students needing or seeking help for alcohol and other drug problems, it seems almost impossible to experience college in a safe, secure, and sober atmosphere. Recovery schools were designed as a solution to this problem.

In response to the growing number of recovery schools, the Association of Recovery Schools (ARS) was organized in 2002. ARS provides support and promotes awareness of school-based programs for students in recovery. Recovery schools can be thought of as part of the continuum of care for students newly in recovery. They increase graduation rates, reduce health care costs, and improve academic performance. ARS members include Texas Tech, Colorado at Boulder, Loyola College in Maryland, and Washington State, to name a few. Their programs range from addiction research to providing Twelve-Step-based meetings and private dorms for students in recovery.

An increasing number of colleges and universities have established programs for students in recovery. To be admitted to most recovery schools, students must have a minimum of 6 months abstinence from their addictive disorder. An example of a recovery school in higher education is Rutgers University in New Jersey,

which pioneered the creation of a specific dormitory for students in recovery. Other schools have initiated full-fledged dual curricula, integrating education, awareness, and support for recovery into liberal arts academia.

Augsburg College is a private liberal arts college in Minneapolis, Minnesota, with a day student population of about 1,700 students. Over the last 8 years, Augsburg College has worked to build a community of recovering students on the campus called StepUP. Of the StepUP students, 80% have maintained abstinence while in the program, and most come to the school because of the large recovery community. The StepUP program works with approximately 55 students per year and provides an additional shadow program of alumni (on and off campus) and support to other recovering students on campus.

Another example of a university-based recovery school is Texas Tech’s Center for the Study of Addiction and Recovery (CSAR) and Recovery College, which was founded in 1986. The program received a \$250,000 federal grant to develop a model that is now being replicated across the country. CSAR provides community support and relapse prevention services to recovery students at Texas Tech University. CSAR works as a source of academic and recovery support for students and assists 70 students from 11 different states in pursuing their dreams of graduating from college. CSAR graduates just over 70% of all enrolled students and maintains a rate of recovery consistently above 90%. The students have a collective grade point average of 3.34.

Recovery schools are not just for college-age students. High schools specifically designed for students in recovery began in the United States in 1989, with two schools in Minnesota. Since then, California, Texas, Massachusetts, and other states have created recovery high schools. The necessity of developing recovery schools in public secondary schools is illustrated by the fact that less than 20% of youth who have completed chemical dependency treatment remain sober after they return home, to school, and to their previous peer group. Recovery schools provide a supportive environment for students. Succeeding academically can help students stay sober, which in turn can help them graduate.

In the fall of 2006, the NorthShore Recovery High School was launched. One of 14 charter schools in the city of Boston, NorthShore is subsidized by the state and provides an environment for high school students who have struggled with drugs and alcohol. The

school helps the students begin their path to recovery and sustain sobriety. To be admitted to the school, students must be sober, agree to random drug testing, pledge to stay sober, and attend two Twelve-Step meetings a week. NorthShore Recovery High School is part of a growing crop of recovery high schools throughout the country.

There's evidence that campus recovery programs (both in high school and in college) can make a difference. For example, at Michigan's Grand Valley State University 5-year-old program, frequent binge drinking has been reduced by 59%. The number of moderate or nondrinking students was up 19%. These successes and the continued availability of public funding will help pave the way for other universities to adopt similar programs. However, with the immense pressure on schools to provide financial aid for tuition and housing, ARS acknowledges that investing in programming for this small number of students can sometimes be difficult. Nevertheless, these programs affect the student bodies as a whole by addressing the problems of alcohol and drug problems.

Administrators, teachers, students, and their families are taking important first steps in developing recovery-friendly learning environments. This development is a different approach than one of sanctions such as suspension and expulsion when dealing with drug and alcohol infractions. Programs to educate students and teachers about addiction and recovery and to support students struggling with addiction to achieve and sustain recovery will make it possible for students to get the help they need at an earlier age, enabling them to focus on school rather than drugs and alcohol.

RECOVERY SUPPORT SERVICES

Recovery support services assist people seeking recovery, newly in recovery, or in long-term recovery. These services support the ability of a person to achieve success in his or her pursuit of sustained, long-term recovery. With the growing understanding that addiction is a chronic illness, there has been a parallel growth in the development and provision of recovery support services by paid and volunteer peers and other professionals. Recovery support services are an adjunct to professional treatment.

Peer and other recovery support services include sustained posttreatment checkups and support that parallels the kinds of posttreatment monitoring used in other chronic disorders like diabetes, heart disease, and cancer. Recovery support services are tailored to fit the needs of each individual. For example, if a person has a criminal record obtained while active in his or her addiction, recovery support services can include navigating the legal system.

Recovery support service providers can be paid or be volunteers, and the essence of their responsibilities is to guide individuals into a life of long-term recovery. According to author William White, these services include stage appropriate recovery education, linkage to communities of recovery, consultation on problems encountered in early recovery, ongoing monitoring of recovery stability, and assistance in reconstructing one's life. Recovery support services can also serve as an early warning system for individuals needing professional treatment.

Recovery support services link individuals to sober housing, recovery-friendly jobs, and health and social services. Individuals providing recovery support services are not Twelve-Step sponsors or counselors and do not seek to duplicate support activities that are already available and under way in the community or in clinical treatment. They seek to work with

Table 1 Rate Ranges for Selected Recovery Support Service Types

<i>Recovery Support Service Type</i>	<i>Unit of Service</i>	<i>Range</i>
Most Common Types		
Transportation	Round trip	\$10–\$14 bus pass
Employment services or job training	Hour	\$10–\$46.79
Case management	Hour	\$10–\$56.89
Housing assistance or services	Daily transitional	\$25–\$33
	Recovery House (monthly)	\$1,359–\$2,000
Childcare	Hour	\$3.85–\$12
Family, marriage counseling, and education	Hour (individual)	\$5–\$81.98
Peer-to-peer services, mentoring, coaching	Hour (individual)	\$10–\$56.89
	Hour (group)	\$15–\$20.50
Other		
Life skills	Hour	\$25–\$30
Spiritual and faith-based support	Hour	\$5–\$10
Education	Hour (individual)	\$20–\$25

an individual to figure out the combination of services and experiences that will help move him or her from recovery initiation to long-term recovery.

There are a number of names or titles that are being developed to reflect the role of a recovery support service provider. They include recovery coach, peer recovery mentor, recovery support specialist, and recovery assistant. Recent news stories have profiled highly paid recovery coaches who accompany celebrities on road trips. Whether well-paid or volunteer, these individuals are building the bridge between professional treatment and long-term recovery for the people they work with.

Frequently, they are directing people newly in recovery into communities of recovery where there is a far greater likelihood of achieving sustained, long-term recovery. Some states, including Arizona, Connecticut, and Vermont and some cities, including Philadelphia, Pennsylvania, have purposefully developed recovery-oriented systems of care that incorporate peer and other recovery support services into a recovery continuum of care.

The growth of peer and other recovery support services has raised issues around reimbursement for these services. The Joint Commission on Accreditation of

Health Care Facilities is issuing standards for peer-based recovery support services. Some states are establishing credentialing systems that set standards for individuals providing recovery support services, and other states are including coverage for recovery support services under Medicaid waivers. Under the federal government's Access to Recovery (ATR) Program, inaugurated in 2004, a rate chart was published that provided guidance for recovery support services (see Table 1). Treatment centers such as the Betty Ford Center and Hazelden are extending their services beyond primary treatment through the use of telephone-based checkups and other supports during the months following treatment.

The ATR program expands access to a comprehensive array of recovery support options, including faith-based options. Under ATR, recovery support services are typically provided by paid staff or volunteers familiar with how their communities can support people seeking to live free of alcohol and drugs and who are often peers of those seeking recovery. Some of these services may require reimbursement, while others may be available in the community free of charge. Some examples of recovery support services under ATR include the following:

- transportation to and from treatment, recovery support activities, employment, and so on;
- employment services and job training;
- case management and/or individual services coordination, providing linkages with other services (legal services, temporary assistance for needy families, social services, food stamps);
- outreach;
- relapse prevention;
- housing assistance and services;
- childcare;
- family and marriage education;
- peer-to-peer services, mentoring, and coaching;
- self-help and support groups, such as Twelve-Step groups, SMART Recovery, Women for Sobriety, and so on;
- life skills;
- spiritual and faith-based support;
- education;
- parent education and child development; and
- substance abuse education.

Recovery support services are a critical part of a recovery-oriented system of care based on building a continuum of care that emphasizes providing care at an appropriate level to maximize individuals' ability to achieve sustained, long-term recovery and to reunite with their families and communities.

behavioral psychologists. Over time, refusal skills training has been incorporated into various programs and interventions aimed at substance use prevention, treatment, relapse prevention, and recovery.

Refusal skills are important because people at risk for substance use often encounter or seek environments where substances are readily available. In addition, people at risk for substance use often find themselves within social groups where substance use is a widely accepted behavior. Therefore, a person with at least some desire not to use substances will be less likely to use alcohol and other drugs if he or she effectively refuses offers for substance use. Yet effective refusal of substances can be complex. As such, refusal skills must often be taught, learned, and practiced explicitly.

In practical terms, counselors are well positioned to teach refusal skills to clients who aim to prevent or stop substance use. Yet refusal skills might be taught and practiced within peer networks. The process of learning and practicing refusal skills involves brainstorming high-risk situations (i.e., situations in which it is likely the person will use alcohol or other drugs), learning skills, practicing through role-playing, and practicing in real-world situations.

To introduce refusal skills training, the counselor asks the client to brainstorm his or her personal high-risk situations. The counselor then asks the client to select one concrete situation. The client is encouraged to specify precise elements of the situation. Who might he or she be with? Where will he or she be? How strong will the temptation to use be? How confident will the client be in his or her ability to refuse the offer?

Once a concrete situation has been identified, the counselor teaches explicit refusal skills. Specifically, effective refusals must first include the act of saying no clearly and firmly to offers to use mind-altering substances. In addition, if the refusing person does not want to be offered alcohol and other drugs in the future, he or she might also firmly state this desire. This request must communicate a strong commitment to avoid substance use. Also, effective messages must be delivered with adequate volume and nonverbal communications. Specifically, it is suggested that the refusing person maintain consistent eye contact and straight posture while refusing. To follow a firm refusal, the refusing person might use other tactics such as switching topics, humor, walking away, or suggesting alternative activities.

REFUSAL SKILLS

Refusal skills involve verbal and nonverbal communications aimed at refusing offers for substances. Refusal skills were first studied and applied by

After explicit refusal skills have been taught and discussed, the next step is to facilitate role-playing exercises to practice refusal skills. The counselor should introduce the role play by explaining that the exercise will be based on the concrete high-risk situations discussed earlier. Then the counselor should play the client (the person being offered substances) and the client should play the person offering substances. In this arrangement, the counselor can first model effective refusal skills. Then the client and the counselor reverse roles so the client practices effective refusal skills in the role of him- or herself (the person being offered alcohol or other drugs). Following the role-play, the counselor should facilitate a discussion and provide coaching on the client's newly acquired skills.

After a client has learned and practiced refusal skills during role plays in session, it is suggested that he or she use the skills in his or her environment to refuse actual offers for substances. Ideally, the client will begin to experience success, or at least become more aware of elements of effective and less-effective attempts to refuse substances in the real world. Optimally, the client will have opportunities to discuss the development of these new skills, as well as setbacks and difficulties, during counseling sessions.

In the realm of substance use prevention, refusal skills have been integrated into drug refusal programs. Although some programs rely solely on didactic processes, researchers suggest the necessity of incorporating rehearsal while learning refusal skills. It is not sufficient to know (intellectually) how to refuse; children and adolescents must have acquired the skills and been provided the opportunity to practice. It is worth noting that refusal skills training is also used in programs targeting adolescent sexual behavior, often in connection with abstinence promotion.

Although refusal skills are touted as preventive tools, these skills are also advocated in substance abuse treatment settings and programs. In fact, the National Institute on Drug Abuse (NIDA) outlines the use of refusal skills in at least two evidence-based treatment manuals. In the NIDA publication *A Community Approach: Treating Cocaine Addiction*, clients are taught to stop abusing cocaine through the use of functional analysis, self-management planning, and drug refusal skills training. Also, refusal skills training is integrated into a module of another NIDA publication, *A Cognitive-Behavioral Approach: Treating Cocaine Addiction*. Although both of these NIDA publications target treatment of cocaine abuse,

many practitioners use the manuals as guides for treating a variety of substance use problems.

Refusal skills are also promoted in the realm of substance abuse relapse prevention and recovery. Relapse prevention and ongoing recovery are times of lifestyle adjustment and maintenance of new behaviors. Yet people who are trying to remain abstinent from alcohol and other drugs may be offered substances or may encounter substances in their social environments. In these cases, well-practiced refusal skills could protect against slips and relapse into further substance use behavior.

RELAPSE

Relapse has been defined in numerous ways in the literature, ranging from any return to substance use after treatment to a return to substance use at a similar or greater level than prior to treatment. In any case, relapse is the modal outcome for individuals who receive substance abuse treatment, with approximately 40% to 60% returning to substance use within 1 year of treatment. Understanding the process of relapse is central to treatment of addictive disorders and can help clinicians and their clients to intervene in the process to guard against relapse or to reduce the severity or length of relapse. The following paragraphs

describe G. Alan Marlatt and associates' cognitive behavioral model of relapse. Relapse to substance use after a period of abstinence, as conceptualized in this model, is a complex and multidetermined event that involves behavioral, cognitive, and affective components. Relapse prevention techniques derived from an understanding of this model have been supported by research and are effective treatment for substance disorders. The relapse prevention model can be employed in both harm reduction and abstinence-oriented treatment.

Elements of Marlatt's Relapse Model

Key elements of Marlatt's relapse model include seemingly irrelevant decisions (SIDS), high-risk situations, coping responses, self-efficacy and outcome expectancies, and the abstinence violation effect. These elements interact in a process resulting in lapses, relapses, or ideally, sustained recovery.

SIDS are relatively innocuous decisions made in the course of daily life that may result in an increased risk of encountering a high-risk situation. High-risk situations are those in which there is an increased desire to use, where the substance of choice may be readily available, or where social pressure to use substances is increased. High-risk situations could be particular environments, cognitive patterns, mood states, or social situations. In fact, the most frequently cited reason for relapse among substance users is a negative mood state.

The goal of relapse prevention is to provide individuals with specific skills to cope with high-risk situations. The extent to which a person feels his or her coping skills are commensurate with particular high-risk situations is reflected in his or her perceptions of self-efficacy for those situations. It is possible that a person could feel quite confident with his or her ability to refuse a drink at a party but has little confidence with his or her ability to refrain from drinking when alone and bored. When faced with a high-risk situation, the skills taught in relapse prevention can reduce the risk of a return to substance use. Relapse prevention skills can be cognitive operations (e.g., choosing to avoid focusing on cravings and urges), thinking about the long-term consequences of a return to substance use (e.g., high blood pressure, marital difficulties), or behavioral strategies (e.g., leaving the location where substances are available, stating an intention clearly to abstain from substance use, seeking social support from sympathetic friends).

Outcome expectancies, or an individual's conceptions regarding the consequences of substance use, can influence substance use behavior. These expectancies include short- and long-term expectancies of both positive and negative outcomes. The short- and long-term consequences of substance use, both positive and negative, may have varying levels of salience to the individual. Research has shown that individuals with substance disorders often prefer immediate, small rewards relative to long-term, larger rewards, and this tendency can influence the conception of the consequences of substance use in a high-risk situation. Short-term reward contingencies can include the reduction of negative mood states, the inducement of euphoria from a psychoactive substance, a shift in cognition toward a more positive sense of self, and stress reduction. Short-term negative consequences include behavioral disinhibition that may result in legal, financial, or social problems, immediate health risks (e.g., overdose), and deficits in role function. Long-term reward contingencies of refraining from substance use can include improved role function, improved health, better interpersonal relations, and greater stability. Situational factors may influence the extent to which short-term rewards predominate over short-term negative consequences or long-term rewards of abstinence. For example, the relative salience of long-term versus short-term rewards may vary with one taking precedence over the other for reasons such as mood state, stress levels, or social pressure. If short-term positive expectancies for substance use are high, the long-term negative expectancies of use remain relatively less salient, and situational factors permit (i.e., a substance of choice is available), the likelihood for a relapse to substance use increases. Motivation, or the extent to which an individual desires to refrain from problematic substance use for internal or external reasons, may mediate the relationship between high-risk situations, expectancies, and a return to substance use.

In addition to the intrapersonal factors discussed above, external interpersonal factors can influence relapse. Social support for sobriety can help to augment motivation for refraining from substance use and can be sought out as one method to deal with internally or externally generated high-risk situations. Often, however, individuals in recovery have substance-using peer groups that either actively discourage sobriety, model continued substance use, or do not possess the skills to help in managing high-risk situations. Careful examination of social support is necessary to support recovery.

The Process of Lapse or Relapse

One potential consequence of the interaction of the factors discussed above is a lapse. Lapses are periods of return to substance use that are short-lived or substance use at a lower level than previous use. Lapses are time limited and have less severe consequences than full-blown relapse. The following is a brief vignette illustrating a lapse.

Bob is a 35-year-old male who is being treated for depression and alcohol abuse. He has been sober for 1 year and he has expressed a desire for abstinence. He has been attending Alcoholics Anonymous (AA) meetings monthly and has a sponsor. He is working full-time as a driver for a delivery company and has been married for 2 years. He has no children. Bob used to drink a 12-pack of beer every night after returning from work while watching sports. In the last week, Bob went to a party with his work friends where they watched college football. He knew that he would be faced with the opportunity to drink beer, but felt that he could refrain from use by clearly stating his intention not to drink to his friends. The game was particularly exciting as it came down to a last minute field goal, which the local university team made to win the game. Bob was excited about the victory, and many of his friends celebrated the victory by taking a shot of tequila. One of Bob's coworkers encouraged Bob to take a shot of tequila, and when Bob refused, he continued to press Bob to drink. Bob, who was frustrated with his coworker's continued pressure, began to feel socially inadequate and decided to take a drink. After the first shot, Bob began drinking beer and eventually had to call his wife to pick him up from the party. After this episode, Bob felt ashamed of his drinking, and he immediately called his AA sponsor to discuss his lapse. At his next therapy session, Bob and his therapist carefully processed the emotions, cognitions, and events leading up to Bob's alcohol use. Bob has refrained from alcohol use since the party, and he continues to express a desire to maintain abstinence. As a result of his lapse, he and his therapist are working on identifying appropriate social support for high-risk situations, and Bob has decided that in the future he will leave situations when he feels social pressure to drink.

Examination of lapses is important clinically in that the precursors to substance use, the consequences

of substance use, and the meaning of substance use with regard to long-term goals can be examined, preferably in a nonjudgmental manner, to identify areas in which an individual may need to improve the skills needed either to maintain abstinence or to refrain from problematic use. The successful clinical processing of a lapse can lead to treatment gains and should not be viewed as treatment failure. Conversely, lapses represent a risk for a return to problematic substance use and therefore should not be dismissed.

A relapse occurs when an individual returns to substance use at a similar or greater level than prior to treatment. Using the above clinical vignette, an alternate ending would describe a relapse.

After returning home with his wife, Bob and she had an intense argument over his drinking. Bob became upset with his wife and felt she was blowing the fact that he had drunk out of proportion since he had been sober for so long. The argument continued for the rest of the night and culminated in Bob's wife issuing an ultimatum that he either maintain his sobriety or leave the house. Bob was ambivalent regarding this ultimatum and began to think that he was unable to change his drinking behavior. The next day he woke and felt that his life was out of control, he was obviously unable to maintain his sobriety since he had drunk the night before, and in general he was demoralized. He called in sick to work, and when his wife left for work, he slipped away to the liquor store to buy a fifth of vodka. He returned to work the next day, but over the course of the next few weeks, he stole secret drinks on the way home from work or on weekends when his wife was away. He sporadically attended therapy and became estranged from his AA sponsor and eventually abandoned therapy altogether. After 3 months of secret drinking, his wife discovered a hidden bottle of scotch in Bob's car and kicked him out of the house. Bob moved in with his brother, who was a heavy drinker, and began to drink daily. Bob's wife filed for divorce. Upon receiving the notification, Bob became despondent. That night he went out with his brother on a "bender" and blacked out, waking up in a stranger's bed. Over the course of the next few months, Bob's drinking escalated. He drank daily and began missing work. He eventually lost his job, which intensified his negative mood, leading to greater drinking. With Bob's continued drinking,

his depression returned. One night Bob reached a crisis point and found that he was contemplating suicide. He felt that he was a failure in work, in his marriage, and in his life due to drinking. After seriously considering suicide, Bob checked himself into an emergency room and was hospitalized on a 72-hour hold for evaluation.

An important factor in the transition from lapse to relapse is the cognitive interpretation of the lapse. Cognitions of this type may be brought on by the abstinence violation effect, which in essence is a cognitive frame that justifies continued substance use based on having initiated any substance use. An example of a thought deriving from the abstinence violation effect might be, "I've had one drink, I might as well get drunk since I've already broken my sobriety."

Conceptualizations of the Interaction of Relapse Factors

Rather than an additive, linear conceptualization of the relapse process, a more accurate description may involve the concurrent occurrence and multiplicative interaction of many factors with the end result being relapse to substance use. In both conceptualizations, intrapersonal and situational factors converge to set the stage for relapse; however, the nonlinear models of relapse appear to fit the existing data on relapse much better than linear models. In fact, the best fitting model of relapse is that of the catastrophe model.

In forming clinical conceptualizations of the relapse process in the real world, it is unlikely that a single, unique stressor will present itself as a high-risk situation. It may be more likely that multiple events may result in the development of internal or external drives to return to substance use. Some characterizations of the relapse process group the risk factors into tonic versus phasic risk factors. Tonic factors are more long-standing and may partially determine the background risk for relapse, but phasic risk factors, which are more situationally bound, may predict when relapse occurs through their interaction with tonic factors. Examples of tonic factors could include personality dimensions such as impulsivity, psychoticism, or neuroticism. Such personality dimensions are related to the ability to resist the impulse to use (impulsivity), a tendency toward wide-ranging and problematic substance use (psychoticism), and the experience of

negative mood states that can precipitate relapse (neuroticism). Phasic factors include social setting, current mood state, social relationships, role function, and stress levels.

Conclusion

Relapse is the most frequent outcome for individuals with substance-related problems. Relapse is a multiply determined event that results from the interaction of internal and external factors. Marlatt and associates have developed a model of relapse based in cognitive behavioral theory that is empirically supported and clinically useful. The goal of relapse prevention is to identify triggers for substance use, both internal and external, and to mitigate the impact of catastrophic thinking (i.e., the abstinence violation effect) on the progression of a lapse to full-blown relapse. Understanding relapse is important to the treatment of substance abuse because it can allow substance abuse professionals working with clients to develop coping skills and plans to intervene before a return to substance use or to reduce the consequences of a relapse.

RELAPSE PREVENTION

Since relapse is a frequent occurrence following treatment, most treatment facilities will have some form of relapse prevention education within the program. Relapse prevention is a process of identifying specific triggers, thoughts, and manifestations of urges (intention to use) and cravings (desire for positive effects of substances) before actual use occurs. Relapse prevention literature indicates that the relapse process can begin long before actual use, when a person falls back into old ways of thinking and behaving.

Viewing addiction as a biopsychosocial disease, relapse falls under the category of returning to the active stage. It is similar to other medical diseases in that the disease manifests itself again. However, given the psychological and social components of addiction, relapse can also be viewed as a return to old patterns of thought (e.g., denial patterns) or to old behaviors (e.g., driving by old places where alcohol and other drugs were used). The general principle of relapse prevention is to assist those in recovery to identify such behaviors and thoughts in order to intervene before substance use resumes.

Some studies on treatment outcomes suggest that individuals who receive treatment but who then relapse generally have relapses that are of shorter duration and intensity than do those individuals who do not receive treatment. Although there are several models of relapse prevention that exist, no single model is superior to another.

Relapse Prevention Models

Two primary models of relapse prevention exist. The CENAPS Model, developed by Terence Gorski, integrates the disease concept of addiction with biopsychosocial strategies to help maintain abstinence and positive changes in recovery. The cognitive-social learning model, developed by Alan Marlatt and Helen Annis, primarily views addiction as overlearned habits, similar to other negative habits individuals may develop (e.g., knuckle cracking, swearing). The goal of this model is to identify reinforcing and inhibiting consequences of the behavior, noting the beliefs and expectations related to the behavior in any situation and analyzing past experiences of success and failure in changing the behavior.

General Principles of Relapse Prevention

Although both these models have different philosophical foundations of the origins of addiction, several general principles can be identified from both models when discussing relapse prevention with patients.

1. *Recognition that relapse is a process and not something that just happens:* Most addicts and alcoholics can begin to identify thoughts, triggers, or warning signs long before resuming substance use. When addicts and alcoholics are educated about this process, they can become aware of how substance use was connected to a range of feelings, situations, people, and events. They also begin to recognize how thoughts of using alcohol and other drugs contribute to the progression of substance use. Thoughts of using can involve denial patterns (e.g., “I only used on weekends, and it’s Wednesday”), self-permission thoughts (e.g., “I haven’t seen this person in weeks, so I can have one or two”), stress relief thoughts (e.g., “I need a drink or line or hit to relax”), or reward thoughts (e.g., “I’ve been doing good for 3 weeks, so I deserve one drink”). Recognizing that relapse is a process of identifiable components, each of which can be managed through interventions and strategies, usually helps those in recovery recognize their unique contributing factors to the process. It is also necessary for individuals to recognize the difference between an active recovery process and sobriety or dry drunk syndrome. Individuals who are in active recovery are in the process of becoming aware of patterns of behaviors and thoughts and they are taking steps to change or manage these behaviors and thoughts. Those individuals who are simply maintaining abstinence or who are manifesting dry drunk syndrome characteristics are not actively changing patterns of thoughts, behaviors, and coping responses. These individuals usually demonstrate behaviors that are similar to the behaviors of people who are actively using.

2. *Awareness:* Relapse prevention involves constant awareness of thoughts, feelings, and physical sensations. Some literature suggests that a portion of individuals have relapsed when their guard was down. By not constantly assessing thoughts, behaviors, motives, and manifestations of urges and cravings, these individuals may miss potential clues or warning signs that

they are slipping into old patterns of thoughts, behaviors, and coping responses. Individuals develop responsibility and accountability for their thoughts and actions when they are working an active recovery and prevention plan. Thus, it is important to recognize and develop a routine for ongoing self-inventory and to determine what is necessary to prevent negative states from building up and erupting into unexpected triggers or high-risk situations.

3. Identification of high-risk triggers: High-risk situations account for a large proportion of relapses. High-risk situations involve a specific category of triggers that are a combination of interactions between people, places, feelings, and thoughts that are cues that trigger urges and cravings to use. Many people in early recovery do not have appropriate coping responses for these high-risk situations. Therefore, when encountering these situations, they experience urges and cravings to use alcohol and other drugs and are often unable to resist. The three most frequent high-risk situations for relapse are negative emotions, peer pressure, and conflict. Negative emotions include a broad range of emotions and mood states such as boredom, loneliness, sadness or depression, disappointment, anger, and resentment. Peer pressure can be a result of overt pressure from using friends or covert pressure within an individual to see or be with old friends. For example, a person in recovery may drive by a bar that he or she once frequented with others. A thought may arise such as, "Gee, I really miss hanging out with those people. I really felt connected with them. Maybe I could go in and see how they are doing . . ." As social beings, this covert pressure can be quite persuasive because individuals need to feel a part of a group, even if it is a group that results in negative personal consequences. Conflict can be a result of interpersonal mishaps that set off the memory of using alcohol or other drugs. When the individual has not developed the skills to manage interpersonal conflict appropriately, the only coping mechanism available is the use of mind-altering substances.

4. Recognition of ongoing recovery management: A newer trend for addicts or alcoholics is recognizing that recovery is an ongoing process. Consistently attending meetings, developing sober networks, and attending professionally facilitated aftercare groups decreases the probability of relapse. Individuals need to recognize that recovery involves the support of others, just as with

any other biopsychosocial disease. Professionals do not recommend that people coping with cancer, diabetes, or AIDS handle these diseases alone. They recommend meetings, peer support, and family involvement. Those in recovery from addiction need to involve significant others, family members, and close friends to help recognize warning signs that the individual may not be cognizant of and for general support in maintaining healthy changes.

5. Change in lifestyle activities and routines: Part of what maintains recovery is learning new activities that do not revolve around substance use. Individuals in recovery need to develop new individual and group activities that they can begin to enjoy. In addition, it is important to recognize that while the routine in recovery changes, balance is important. Individuals need to balance recovery activities with work, family, social groups, and self-development activities in order to have all aspects integrated into their recovery.

6. Development of a relapse prevention plan: Most if not all treatment agencies will assist in the initial development of a relapse prevention plan. It is necessary for this plan to include specific thoughts, triggers, and high-risk factors as well as coping strategies for each. In addition, individuals need to plan what they will do in the event of a lapse or relapse.

7. Understanding the difference between a lapse (i.e., slip) and a relapse: The biopsychosocial model of addiction recognizes that there is a difference between a lapse and a relapse. A lapse is usually of shorter duration, results in few if any consequences, involves less than the usual amount of the substance consumed, and is impulsive. A relapse is usually planned, frequently involves significant consequences, involves a larger amount of the substance used, and is accompanied by defensiveness. It is important for those in recovery to recognize that if they do lapse, "I blew it" thinking (which has been called the abstinence violation effect) can increase the chance of a relapse occurring. However, individuals can usually identify if they have used "I blew it" thinking when they have slipped or if they have planned relapses in their pasts. In addition, it is important to recognize that some individuals may lapse on a substance or behavior that is not their primary drug of choice. For example, if a person's primary drug of choice is alcohol, but he or she starts smoking marijuana,

cross-addiction can occur. In this case, marijuana would become a problem in and of itself, but without any intervention, it would also likely lead the person back to the original drug of choice, alcohol.

Another important aspect of this issue is that Twelve-Step literature does not differentiate between lapses and relapses. This lack may cause some confusion for those in recovery. An individual in recovery who lapses may need to talk with his or her sponsor or other support to help determine what is appropriate for him or her. However, it is important for individuals to recognize that with the biopsychosocial concept of addiction, small setbacks may occur and do not necessarily indicate that the individual has failed or digressed in his or her recovery. Recognizing that lapses or slips can be educational for the individual and focusing on what to do differently the next time a similar situation occurs can be helpful.

8. *Development of coping skills:* The use of alcohol and other drugs is the central coping mechanism for day-to-day life for alcoholics and addicts. Without a repertoire of tools to deal with the everyday stressors encountered in life, individuals will most likely fall back to using alcohol and other drugs to cope. Thus, it is necessary for individuals to identify specific coping mechanisms for different thoughts, feelings or moods, and situations. It is also important for individuals to recognize that certain coping mechanisms may not work in all situations. For example, if a coping mechanism is to speak with one's sponsor when an urge or craving hits, this mechanism may not be the most appropriate tool while sitting in a business meeting. Thus, the individual may use deep breathing while in the meeting and call the sponsor after the meeting.

9. *Combined treatment and aftercare services:* If coexisting psychiatric disorders exist, it is important for individuals in recovery to obtain treatment and adjunct services for these disorders. It is not uncommon, for example, for an individual who is alcohol dependent and who has depression to end up relapsing because the depression was not being treated. Thus, it is important for individuals to obtain services for coexisting psychiatric and medical disorders while receiving treatment for substance use. If this is not possible, it is important that follow-up services be recommended and implemented before an individual is discharged from treatment. Another aspect of adjunct services is the consideration of medication for cravings. Many individuals

in treatment can manage these cravings because they have a place to talk about them and professionals to help them cope. However, if these individuals continue to experience intense cravings at the end of their treatment, medications can be helpful until coping mechanisms to manage these are strengthened, or until social connections (i.e., contacts, sponsor, peer mentors) are developed and strengthened. In addition, individuals will usually have follow-up appointments with the prescribing psychiatrist, appointments which will strengthen the use of outpatient professional supports if other symptoms are demonstrated (e.g., the individual begins to manifest symptoms of depression that were not present or were minimal during treatment).

10. *Relapse prevention plan revisions:* After treatment, it is important for individuals to set aside time on a weekly basis to review their plan and make necessary changes. Some individuals have found that certain situations are harder to handle once they are out of treatment, and they need to change the prevention plan accordingly. Others may find that certain strategies, while effective when in treatment, are not so effective when treatment is complete. Thus, they may need to add new strategies to their plans. Consistent review is important for a relapse prevention plan to be effective.

Conclusion

Relapse prevention planning involves several components necessary for ongoing recovery and recovery maintenance. Individuals need to develop and maintain knowledge and skills related to the biological, psychological, and social components of the disease in recovery. Regardless of the model of relapse prevention used, all of the general principles of relapse prevention are necessary to address in a relapse prevention plan.

RESEARCH ISSUES IN PREVENTION

Substance abuse has consistently been shown to precede, cause, correlate with, exacerbate, or be a consequence of nearly every major mental health, physical health, behavioral, and psychosocial problem. Psychological correlates include cognitive deficits, depression, anxiety, post-traumatic stress disorder, paranoid feelings, and delirium. Physical health correlates are numerous and include, among others, cancer, stroke, and heart disease. Individuals who misuse substances are at a substantially greater risk of having employment difficulties and relationship problems. Further, substance abuse is associated with increased rates of suicide and all forms of interpersonal violence. From an economic standpoint, substance abuse is estimated to cost U.S. society about \$160 billion per year in health care costs. When other costs of substance abuse are expanded to include crime and lost work productivity, this number increases to over \$400 billion.

Based on the health and economic burden of substance abuse, it is clear that it is in the best interest of society to prevent the onset, recurrence, and escalation of this problem. Researchers have estimated that every \$1 invested in prevention of substance abuse translates into a long-term savings of between \$5 and \$10 for the society at large. Despite the clear economic and public health benefits of preventing substance abuse, relatively little research in this area has been conducted. Prevention research is difficult, time consuming, and expensive. Moreover, and as detailed below, efforts to disseminate and implement prevention programs in the community are often unsuccessful.

What Should Substance Abuse Prevention Programs Target?

An inherent difficulty in conducting prevention research is the fact that the problem (substance abuse) has not started, making it difficult to measure the effects of the prevention program. Thus, some prevention studies measure intentions to use, attitudes about substance use, and knowledge of problematic substance use as proxies for behavior. Although this research is important, the link between cognition and behavior is not fully understood, and existing prevention studies have shown that changes in attitudes and beliefs do not necessarily reflect changes in behavior. A more widely accepted method for directing prevention programs and assessing their effectiveness is to focus on the risk and protective factors of substance abuse. Developed by David Hawkins and Richard Catalano and based on years of research, the risk and protective factor theory suggests that problematic behaviors such as substance abuse can be mitigated by limiting the number or preventing the development of risk factors and by bolstering protective factors within individuals. Risk factors are defined as anything within individuals, their families, peers, or communities that increase the likelihood of developing substance abuse.

The majority of individuals exposed to risk factors will not develop problematic substance use. Moreover, individuals exposed to the same risk factors to an equal degree do not necessarily have the same chance of developing problematic substance use. The risk and protective factor theory posits that the individuals who do not develop problems are equipped with factors that buffer or moderate the effect of the risk factors. This notion is analogous to the medical model of human disease: People with a family history of diabetes can offset their increased risk of developing this disease by increasing physical activity and maintaining a healthy diet (both protective factors). Similarly, positive parental attachment can moderate the effects of living in an impoverished neighborhood on the odds of abusing substances. Thus, just as addressing modifiable risk factors may decrease the probability of an individual developing problematic substance use, bolstering their protective factors may be equally influential.

Although the risk and protective factor theory offers a viable approach to designing and researching prevention programs, it has some limitations. First, the effectiveness of the prevention program will

depend entirely on the predictive ability of the chosen factors. Therefore, most risk and protective factor approaches to prevention may result in only small effects, unless careful attention is paid to choosing and targeting factors for prevention programs that may account for relatively more variance in substance use or may be hypothesized to have additive or synergistic effects when other factors are also targeted. Second, choosing the optimal risk and protective factors from a range of domains (community, family, peer, individual) for a given individual (or sample) is far from an exact science. Further, several researchers and policymakers emphasize that for prevention programs to be effective they must target a variety of factors from several different domains. In fact, the quantity of risk factors present may be more important in predicting problematic substance use than the makeup of any one risk factor. However, addressing multiple factors from a range of sources necessitates a lot of research participants, funding, more complex data analyses, and additional informants (e.g., parents, teachers). Third, many risk and protective factors function at the societal and biological levels and are thus difficult or impossible to change. Thus, even the best prevention program delivered under optimal conditions may have to compete against immutable factors.

Who Should Substance Abuse Prevention Programs Target?

One factor that must be considered in designing and researching a prevention program is the target audience, or specifically, whether the program is intended for a universal, selective, or indicated audience. Universal prevention programs are directed to a general population without the consideration of risk level. An example may be a nationwide media campaign highlighting the dangers of drinking and driving. In metaphorical terms, this is akin to casting a large net in the Pacific Ocean in hopes of catching a small number of a particular kind of fish. Although reaching a large number of people is very appealing, universal prevention programs are difficult to implement due to significant costs and issues with feasibility. These concerns are particularly relevant for schools and other communities with limited resources. Further, because only a small fraction of the recipients of universal prevention campaigns will be impacted, the costs and difficulties of implementing them are difficult to justify.

Selective prevention programs are directed toward subsets of individuals who may have an increased likelihood of developing a problematic behavior (e.g., substance abuse) due to the presence of a risk factor. For example, an intervention targeted at children identified as having parents who abuse alcohol would be a selective prevention program. Metaphorically, these programs would be akin to casting a large net in a part of the ocean where the particular fish of interest congregate. Because the ability of any one individual risk factor to predict substance abuse is minimal, targeting this group has some of the same problems, albeit to a lesser extent, as universally applied programs (i.e., only a portion of the participants will be impacted and a large number of participants are required to show an effect). Moreover, by selecting at-risk youth, researchers run the risk of labeling participants. Finally, in working with schools and communities, it may be difficult to justify the recruitment of an at-risk control group who will not be offered the prevention program. This problem can be offset by offering the program to the control group upon completion of the study, but doing this adds another layer of time and cost to a study.

Indicated prevention programs are designed to prevent the continuation or progression of substance abuse in individuals. An example of this type of program would be providing counseling and educational sessions to high school students caught drinking. To continue with the metaphor, implementing these programs would be akin to casting a small net into a part of the ocean where only the fish of interest congregate. The fact that individuals in this group have already exhibited the problematic behavior means that fewer participants are required to demonstrate an effect. Conversely, although indicated prevention programs address individuals most at risk, they do little to prevent the occurrence of problematic substance use in the general population.

Efficacy, Effectiveness, and Dissemination

Prevention research is guided by the goal of reducing the number of substance using and abusing individuals by disseminating evidence-based interventions to communities. However, the urgency of addressing the enormous problem of substance use, coupled with a communication gap between science and practice, has prompted several prevention programs to be widely implemented prematurely, prior to research evidence documenting their efficacy. At worst, this practice can

result in the expenditure of scarce resources on programs that do nothing to prevent—and possibly even exacerbate—the problem. Thus, for society to benefit from research, prevention programs must be found to be efficacious and effective prior to their widespread dissemination and implementation. Efficacy is achieved when a program produces significant results in a tightly controlled environment with highly trained and supervised research staff who are invested in the success of the program. Effectiveness is achieved when a program demonstrates beneficial results in real-world conditions with less trained, supervised, and invested personnel who may also be managing several other demands (e.g., schoolteachers, community organizers).

In addition, prevention programs should demonstrate portability and cost-effectiveness. Hence, evaluation at the effectiveness stage of the research should include measures of the program's fidelity, adaptation, flexibility, and costs, as well as measures to assess standard outcomes. Once programs are shown effective by multiple well-designed studies (preferably by different research groups), they are then ready for wide-scale dissemination. In order to save valuable resources, it is very important that a program's effectiveness be continually monitored throughout implementation.

In all stages of the research, from design to implementation and dissemination, prevention programs should consider the role of gender, ethnicity, age, socioeconomic status, and other relevant variables. A statement reflecting what the program addresses and who it is meant for is a necessary adjunct to any prevention program. For example, a substance abuse prevention program found to benefit adolescent boys should not be haphazardly administered to adolescent girls. Instead, it should first be evaluated for use with adolescent girls until it passes through the appropriate research channels. In fact, any information pertaining to the implementation of a prevention program should be made readily available with appropriate qualifiers, administration guidelines, and a detailed manual to ensure its faithful execution. A growing number of resources, such as the Centers for Application of Prevention Technologies (CAPTs), facilitate the progression of science from clinical research to applied settings by providing resources, guidance, and support in a variety of domains. For example, to increase dissemination of empirically supported prevention research, CAPTs maintain an online library of the current literature in the

substance abuse prevention field and manuals for administering specific protocols.

Conclusion

Substance abuse is endemic and arguably among the nation's most pressing public health problems. There is a critical need for programs that can effectively prevent this problem from escalating and, in turn, reduce the numerous mental, physical, behavioral, social, and economic problems associated with substance abuse. As prevention science has developed, several researchers have argued that the most effective prevention programs (a) address risk and protective factors from multiple levels of social influence (i.e., community, family, peer, and individual) and (b) target universal, selective, and indicated audiences with a particular focus on individuals most at risk. To fulfill these ambitious but necessary goals, increased funding must be made available to allow for the conduct of methodologically rigorous research. Moreover, given the comorbidity and the overlap of risk and protective factors between substance abuse and other psychosocial problems (e.g., aggression, risky sexual behavior), prevention efforts could also be advanced by increased collaboration among experts in related fields.

RESEARCH ISSUES IN TREATMENT

The history of research into the treatment of substance abuse is relatively limited. Prior to the 1930s, drug and alcohol abuse in the United States was primarily viewed as a moral deficit and therefore, a matter of personal choice that was often worthy of contempt. With the advent of Alcoholics Anonymous (AA) in the 1930s, the zeitgeist changed to associate substance abuse, primarily alcohol abuse, with an incurable disease condition that could be arrested only through the cessation of use and the adherence to a strict code of conduct and participation in AA. However, despite the new disease, or biological, conceptualization of substance abuse, the empirical investigation of substance abuse treatment did not receive much attention until several decades later.

In the second half of the 20th century, biological as well as behavioral, social, cognitive, and personality theoretical models were offered to explain substance abuse. Prior to the 1960s, however, few empirical studies were conducted that applied these new models to substance abuse etiology and treatment. Currently, a wealth of studies suggest that each model has relevance for the understanding of substance abuse etiology and for the development of treatment programs.

The Focus of Treatment Research

Characteristics of Research Participants

Initial diagnosis of substance dependence is most often observed in the third through fifth decades of life and is often preceded by the emergence of an array of consequences over time stemming from substance use that are representative of a less severe substance use disorder. Treatments can focus on those with different levels of severity of their substance use problem and those who use different classes of substances (e.g., opioids or alcohol). Thus, treatments can have different goals. For example, for some individuals on the less severe end of the spectrum of substance use problems, goals related to controlled use that do not target abstinence from all substances but instead focus on reducing problematic use may be appropriate. For others on the more severe end of the problem spectrum, abstinence is likely the most appropriate goal. In fact, it is common for treatment providers to regard the more severe diagnosis of substance dependence as a chronic disorder, lasting throughout the lifetimes of individuals who hold the diagnosis, making these individuals prone to periods of remission and relapse to the disorder. Therefore, it is common that individuals with substance dependence diagnoses undergo treatment more than once in their lifetimes.

Background characteristics such as substance of choice, polysubstance use, risk factors such as early age of onset and positive family history of substance abuse, and the existence of co-occurring mental disorders may also influence recommendations for treatment. These characteristics may also portend differential risk for abusive patterns of substance use throughout the life span in terms of clinical course of the disorder and make effective treatment more complicated.

Substance abuse affects males and females at nearly every point across development and across racial, ethnic, and socioeconomic strata, necessitating treatment strategies for adolescents, adults, and the elderly and for strategies that transcend or that are specifically adapted to cultural characteristics of the populations in need of services. Therefore, research should evaluate outcomes of substance abuse treatment for such subpopulations. Treatment research should also attend to individual factors mentioned above, such as substance use characteristics, consequences, and co-occurring psychiatric conditions in the design and evaluation of treatment programs.

Treatment Models

As mentioned previously, many models have been applied to the treatment of substance abuse. For example, through research conducted on social-cognitive characteristics of relapse episodes, Alan Marlatt and colleagues developed a taxonomy of common relapse situations. This taxonomy has been used as a model of treatment that teaches skills to successfully manage high-risk situations for relapse without using substances. Many studies support the efficacy of this relapse prevention treatment. Scott Henggeler and colleagues have investigated substance abuse treatment for adolescents that incorporates multiple systems (e.g., family, school, legal system) into a single treatment program, resulting in successful substance use outcomes for high-risk youth. However, with few exceptions, treatment studies have focused on interventions based on distinct theoretical models and have ignored the integration of divergent treatment modalities.

This is not to say that current approaches to treatment practiced outside of the research context do not frequently employ multiple treatment modalities. However, it is largely unknown whether combined treatment modalities result in similar or better outcomes compared with less eclectic approaches to treatment that stem from one theoretical perspective. It is also largely unknown what mechanisms (e.g., changes in cognitions, reduction in craving) are responsible for positive treatment outcomes and whether different treatment modalities affect different mechanisms associated with substance abuse.

Given a large number of viable mechanisms that may influence substance abuse and that are currently targeted by different treatment approaches, a major issue presented to the research community in subsequent decades will be to investigate similarities and differences in causal mechanisms among current treatment approaches. This may be best approached by simultaneously studying components of competing treatment approaches in order to statistically parcel out independent effects and interactions.

Methodological Issues

Methodological considerations pertinent to the conduct of treatment research for substance abuse include approach to study design, targeted data collection of pre- and posttreatment constructs, and participant

recruitment and assignment to treatment condition. Other methodological issues pertain to the investigation of likely mechanisms of intervention effects and how these specifically relate to treatment outcomes.

Randomized Versus Quasi-Experimental Study Design

The most scientifically rigorous substance abuse treatment studies involve the random assignment of participants to treatment and control group (or comparison group) conditions. Studies that do not employ random assignment are termed *quasi-experimental*. The rigor of these studies depends on the other characteristics of the design. For example, a study that assesses only outcomes for a group of participants receiving treatment cannot reliably ensure that the effects are attributable to the treatment. In contrast, a quasi-experimental study that has a treatment and control group may provide more convincing evidence that outcome effects are attributable to the treatment if the study can show that the treatment and control group were similar in terms of factors that may influence outcomes (e.g., gender, severity of substance abuse prior to treatment). However, a study that uses random assignment increases the likelihood that treatment and control groups are equivalent in terms of background characteristics. Therefore, when a randomized study is implemented with fidelity (e.g., when the treatment is delivered as intended with highly competent treatment providers and no factors other than the treatment differentially influence outcomes for the control and treatment groups) it can be more confidently determined that differences in outcomes between the treatment and control groups result from the treatment.

Ensuring that the treatment is delivered as intended is often achieved by training treatment providers in the appropriate delivery of the treatment and by using a common treatment manual that standardizes the treatment across providers. Methodologically rigorous treatment outcome studies should also employ procedures to periodically monitor the implementation of treatment to ensure that delivery is standardized throughout the study. One particular problem common to randomized treatment outcome studies is the threat to treatment fidelity created by differential attrition. Specifically, differential attrition occurs when participants drop out of the study's treatment and control groups at different rates, or when treatment dropouts in

the treatment and control groups differ on significant characteristics that are associated with treatment outcomes. This differential attrition reduces confidence that study outcomes are due to the effect of treatment.

Treatment outcome studies must monitor differential attrition throughout the conduct of the study before it occurs to a significant extent and cannot be effectively controlled for in statistical analyses. Techniques can be employed during randomization that may make differential attrition less likely to occur. For example, selecting participants and having them agree to participate regardless of the condition they are assigned prior to randomization can help reduce the likelihood that differential attrition occurs, rather than randomizing participants prior to obtaining consent or agreement to participate. Similarly, having an active control or comparison condition that provides an actual treatment to the control group can help ensure that control participants remain in the study. This design has the additional benefit of allowing the outcome effects of the treatment of interest to be directly compared with another existing treatment.

Efficacy Versus Effectiveness

Optimally, the investigation of substance abuse treatment programs follows a progressive line of research in which studies first establish that the treatment is efficacious and then establish that it is effective. An efficacious treatment is one that has demonstrated positive outcomes under optimal study conditions in which the treatment is implemented as intended, participants receive the treatment in a uniform way, and the treatment results in positive changes in substance use behavior or other relevant outcomes. An effective treatment is a treatment with established efficacy that has also been studied under real-world conditions. The real-world conditions likely involve less experimental control with potentially less integrity of treatment delivery and participant compliance with the treatment regimen and greater heterogeneity of the patient population.

Data Collection

Regardless of the goals of treatment (e.g., complete abstinence, reducing negative consequences of substance use), evaluations of treatment programs usually focus on an array of outcomes, such as reductions in substance use, reductions in problems, abstinence,

and quality of life (e.g., maintaining employment, relationship satisfaction). Treatment evaluations often focus on mechanisms that explain the dimensions of a treatment that account for positive outcomes and for whom these outcomes are most likely to be elicited. Therefore, it is beneficial to assess treatment participants prior to the beginning of treatment as well as at specific points following treatment initiation and after treatment ends.

The determination of when to collect outcome data often involves several considerations. It is expensive to collect data; thus, it is important to select the most appropriate data collection time points. These are, optimally, consistent with theoretical assumptions of the treatment model and goals of the study. Often, it is expected that the treatment will exert the largest effect on substance use immediately after treatment ends, and then the effects will dissipate over time. Therefore, it is common that treatment studies will employ multiple outcome assessments that correspond to immediately after treatment ends and to a later time point (or time points) to assess the longevity of treatment effects. However, this strategy is not the only one. It may be that other treatment models may expect the greatest effect to occur at a later time point, and this possibility should be considered in the timing of outcome assessments. Further, studies that investigate how a treatment works (i.e., active mechanisms of treatment) may assess participants both during treatment and following completion to determine whether changes in participant characteristics (e.g., motivation) are responsible for treatment outcomes related to substance use.

Pretest data collected prior to the beginning of treatment provides an opportunity to obtain baseline information on participants. This information can serve as comparison data to assess whether the control or comparison and treatment groups are equivalent in terms of background (e.g., gender, age, severity of substance use) and to statistically control for differences if desired or necessary. Collecting pretest data also enables the investigation of change in substance use behaviors or mutable characteristics (i.e., characteristics other than substance abuse that may change as a result of the intervention) over the course of treatment. Mutable characteristics may include factors that inform how the treatment works to change substance use behaviors or other outcomes (e.g., health). For example, some treatments, such as cognitive behavioral therapy, may be expected to influence substance

use by changing the expectations participants hold regarding the use of substances (e.g., outcome expectancies such as tension reduction, increased productivity). Other treatments, such as Motivational Enhancement Therapy, may influence substance use behaviors by reducing ambivalence regarding the negative effects that substance use creates and the need for behavioral change. Therefore, to investigate these potential mechanisms, studies of cognitive behavioral and Motivational Enhancement Therapy should, respectively, assess outcome expectancies and ambivalence toward the necessity of change in substance use behaviors.

Ideally, pretest and outcomes assessments (i.e., data collected after treatment ends and during treatment if desired) will include identical or equivalent measures to assess change in substance use behaviors or other mutable characteristics. In addition, pretest data can include measures of characteristics, or covariates, that may differentially relate to the success of treatment (e.g., gender, age, severity of substance use), and these data can then be used in outcome analyses to determine whether the success of treatment differs for those with different characteristics. Thus, the collection of outcome data and pretest data is often intricately intertwined.

Ability to Detect Whether a Treatment Works

A major issue relevant to substance abuse treatment research is ensuring that a study possesses the characteristics needed to detect that a treatment works if, in fact, it does. Several considerations described above, such as random versus quasi-experimental studies and treatment fidelity, are important to achieve valid study results. In addition, ensuring that an adequate study sample size has been obtained is also necessary to have confidence that a treatment effect will be statistically detected if it has occurred. This study characteristic is called *statistical power* and is a major study design issue that must be addressed in the conduct of substance abuse treatment research.

Briefly, the power a treatment outcome study has to detect a true treatment effect is impacted by several characteristics of the study. The most relevant characteristics include the study sample size, the size of the treatment effect, and the reliability and validity of the measures used. In general, the larger the size of the treatment effect, and the more reliable and

valid the measures, the smaller the study sample size needed to detect a statistically significant effect. Many statistical packages are available for purchase and for free on the Internet that will estimate power for a treatment outcome study.

Optimally, the sample size needed for a particular study will be determined prior to the recruitment of participants and the conduct of the study. This planning requires knowledge of the likely size of the treatment effect, which is often unattainable in the beginning stages of research. Therefore, pilot studies are often conducted prior to an efficacy (or effectiveness) study to obtain an estimate of the treatment effect. This estimate is then used to determine the size of the sample needed. In practice, obtaining a sample of participants for treatment research is often a difficult task. Acquiring access to and recruiting a sufficient number of participants from the population of interest is often difficult and becomes more problematic when the research is focused on more distinct subpopulations of treatment participants (e.g., pregnant women substance abusers).

Ethical Considerations

There are many ethical issues that must be taken into consideration when conducting scientific research on human participants. These considerations also hold for substance abuse treatment research. Current ethical guidelines that relate to the conduct of substance abuse treatment research are codified into the U.S. Federal Regulations and are based on previous declarations and reports on the criteria for the ethical conduct of research from legal and scientific communities worldwide, such as the Nuremberg Code, the Declaration of Helsinki, and the *Belmont Report: Ethical Principles and Guidelines for the Protection of Human Subjects of Research*. Most recently added to this list, and the most influential to current ethical viewpoints related to research with human participants, is the *Belmont Report*.

The *Belmont Report* established three broad ethical principles for research on human participants: respect for persons, beneficence, and justice. In summary, the principle of respect for persons proposed that research participants should be allowed to make decisions and act of their own accord, and those who are unable to do this must be protected. At a minimum, respect for persons holds that voluntary informed consent must be acquired to participate in research. Beneficence

requires that research participants be allowed to make their own decisions and must be protected from harm from the conduct of research. In this regard, the report highlighted the necessity of researchers to maximize benefits and minimize research-related risks. The principle of justice concerned the fairness of distribution of research-related risks and benefits. The principle of justice refers to the selection of research subjects. On this point, research must ensure that the reason participants are included in research directly relates to the problem being studied and that subjects are not included in research simply because they are readily available or easily manipulated.

To ensure that ethical guidelines are adhered to in the conduct of treatment research, treatment outcome studies must undergo ethical review by a research institutional review board (IRB). In addition to considering the ethical issues mentioned above, one major concern common to IRB review of substance abuse treatment studies involves issues related to confidentiality. Minimizing the risk of violations of confidentiality is important due to substance use often being an illegal or embarrassing behavior. Often, to minimize risk of research-related harm to participants, treatment studies will acquire a federal certificate of confidentiality that protects data from the possibility of a court subpoena. Other safeguards, such as the creation of a study data safety monitoring board, are also common to include in the conduct of treatment research.

Conclusion

Substance abuse treatment research optimally involves the consideration of many methodological and ethical issues, as well as the integration of theoretical knowledge into the development of treatment models and the investigation of study goals. Studies of existing treatment modalities over the past several decades have established the efficacy of several treatments (e.g., relapse prevention therapy). The investigation of causal mechanisms of treatment effects have received less attention overall; however, recent trends in research point to the investigation of causal treatment mechanisms as a current focus of study that will inform substance abuse treatments over the upcoming decades. In addition, more research is needed that investigates participant characteristics that are associated with better or worse response to treatment and whether response to treatment differs for these

participants based on the treatment components employed (i.e., treatment matching).

RESIDENTIAL TREATMENT

Substance-related residential treatment is characterized by service facilities that offer supervised, structured care 24 hours per day, 7 days per week to individuals seeking assistance with overcoming addiction. These facilities exist within a continuum of care, and it is assumed that individuals with severe addictions will

benefit from a stable and controlled environment that removes the client from maladaptive lifestyles. Residential facilities are usually operated by either non-profit organizations or private for-profit organizations, and payment for services can be made by clients as self-payers or from publicly funded sources (e.g., Medicaid). Individuals may enter residential treatment by self-referral or by referral from another party, such as an employer, physician, or social service agency.

Although there are several similarities across various programs, there are also many differences. For example, many residential programs are similar in that they are abstinence-based and require detoxification from alcohol and other drugs prior to admission. On the other hand, some programs support the harm reduction model and allow clients to attend treatment while engaged in a medically supervised methadone maintenance program. Furthermore, some residential programs operate an ongoing intake process, and others are closed programs where groups of clients start and complete the program together. The number of participants in a residential treatment facility depends on the bed capacity and staffing of the facility, and programs can range from 10 to 30 clients or more. The length of stay can also vary across facilities, with many programs lasting 4 weeks in duration and other programs lasting up to a year or longer. In the event that a client lapses during his or her treatment, some facilities will automatically discharge the client from the program, and others may attempt to work with the client to reassess his or her treatment plan and to retain the individual in residential treatment if appropriate (e.g., if the safety of the community is not severely compromised).

Many residential programs employ a multidisciplinary staff that may include physicians, psychiatrists, psychologists, nurses, addiction counselors, family counselors, clergy, and other support staff in varying degrees. In most cases, some form of counseling (e.g., individual, group, family) is the predominant professional activity in treatment, and this service can be provided by professional counselors or by informal counselors (who may be in recovery from addiction themselves). In addition, many residential facilities require clients to participate in general activities, such as household chores (e.g., cleaning, meal preparation) and recreation, and these activities are intended to contribute to the development of a sense of community, cooperation, and support.

Throughout the entire process of residential treatment, there are a number of therapeutic modalities

that can be employed. One fundamental distinction is whether or not a program utilizes the Twelve-Step philosophy (e.g., Alcoholics Anonymous, Narcotics Anonymous) as a framework to guide its activities. Another distinction could be the level of intensity that a residential program may provide, with some programs engaging in methods such as confrontation and experiential techniques (e.g., role play and self-disclosure), which may lead to strong emotional expressions or catharsis. Most programs incorporate didactic lectures to educate clients on addiction-related issues, such as the effects of alcohol and other drugs on the body, HIV/AIDS, nutrition, and exercise. Finally, many programs utilize cognitive and behavioral methods, such as desensitization, operant conditioning, assertiveness training, stress management training (e.g., progressive relaxation), and social skills training (e.g., drink or drug refusal skills).

Residential treatment facilities have other common characteristics in terms of the contexts in which treatment is delivered. For instance, in many programs, treatment is primarily delivered in a group context where clients learn and progress in their recovery through interpersonal interaction and shared experience. Although some programs utilize the group context exclusively, treatment can be augmented with individual services where clients receive personalized attention such as medical care and private counseling sessions. In some facilities, family treatment is also offered, and family members are invited to attend individual sessions, group sessions, or graduation ceremonies, although this involvement can be difficult if the facility is located in a remote setting (some facilities are purposely situated in pristine rural environments to contrast with clients' past lifestyles of addiction). At the completion of a treatment episode, many programs celebrate their clients' success through a graduation ceremony that is attended by staff, other clients, and in some cases, significant others. These events serve as a rite of passage that signifies a person's transition toward a healthy lifestyle and reintegration into his or her home community.

Treatment Objectives in Residential Treatment

The domains of clinical focus in residential treatment are typically associated with the client's length of stay in a residential facility. For example, a client may undergo various forms of assessment early in his or

her residential treatment experience, such as a review of his or her life history, an examination of alcohol or other drug use history and the consequences of this behavior, and an assessment of concurrent disorders. Other areas of focus in early treatment include establishing rapport, providing individuals with support as they integrate into the residential therapeutic setting, working with clients to strengthen their motivations toward making positive change, and developing treatment goals.

As clients progress in a residential program, clinical attention may shift toward assisting them with the achievement of broader treatment objectives. Treatment plans and interventions differ by client and facility, and progress can be assessed by staff, client self-assessment, or some combination of the two. For instance, clients may work toward the goals of improving self-efficacy and self-esteem, improving interpersonal relationships, and developing behavioral or life skills. In some treatment programs, clients address complex matters such as unresolved childhood issues, guilt and shame, problems relating to sex, and psychiatric conditions like depression, anxiety, and personality disorders.

As a client approaches the completion of a residential program, the clinical focus is usually oriented toward themes such as relapse prevention and aftercare. In relapse prevention, staff members work with clients toward maintaining their achievements and continuing along a path toward increased health. Clients may learn to identify triggers that put them at risk for relapse and to develop skills in managing cravings as well as in deploying action plans that are healthy alternatives to alcohol or other drug use. Aftercare planning may involve procuring employment or housing and setting up ongoing support in the form of outpatient counseling or other appropriate support services (e.g., support groups or social services). Clients may also focus on generalizing new skills and insights learned in treatment in preparation for their return to their home communities.

Common Models of Residential Treatment

One of the most well-recognized residential treatment modalities is practiced at Hazelden in Minnesota and is known as the Minnesota model. This approach was designed to improve outcomes in the area of addiction treatment as compared with medical detoxification,

which was the predominant method of treatment at the time of the program's inception in the early 1950s. Hazelden and the Minnesota model are based on the philosophy of the Twelve-Step program of recovery that is the hallmark of Alcoholics Anonymous, with abstinence as the ultimate treatment goal. The Minnesota model promotes group affiliation as an effective therapeutic process. Clients regularly attend meetings with other residents where the focus is on overcoming denial, practicing the Twelve Steps of recovery, and gaining increased confidence and personal responsibility.

Another popular format for residential treatment is known as the therapeutic community. Therapeutic communities originally emerged in Europe around World War II, and U.S. adaptations soon followed. In general, this mode of treatment arose in reaction to the psychiatric treatment of addiction, and its programs are designed to offer a communal, structured, and alcohol and other drug-free environment where positive change is promoted in the humanistic tradition of openness, honesty, and relationships among people. An example of the application of the therapeutic community model is Walden House, a community-based agency located in San Francisco, California. Clients at Walden House act as surrogate family members to other clients in an attempt to build self-esteem, develop self-reliance and personal responsibility, and cease behaviors that are related to substance use.

A third noteworthy model of residential treatment transitions clients through phases or tiers of the program. Typically, programs organized in this fashion incorporate three phases that are separated according to levels of intensity or program content. A facility may incorporate an introductory phase, for instance, where clients participate in education sessions that focus on addiction issues, followed by more advanced phases of treatment where clients engage in psychotherapeutic interventions such as trauma work, interpersonal development, and skill building. A final phase of treatment may focus on solidifying skills learned during treatment and transitioning the client back to his or her home community. At each phase of transition, staff members evaluate the client according to explicit criteria to determine the client's suitability and preparedness for progression to the next level of treatment (or the client may self-assess his or her progress). In some cases, clients may be expected to remain in a particular phase of treatment for an extended period of time to further develop their skills before proceeding to the next level.

Specialized Programs

It is important to note that residential treatment programs are usually comprised of a combination of intervention techniques that are based in a variety of theoretical orientations, and programs do not rely on singular approaches or theories regarding addiction. Moreover, residential treatment facilities may design services exclusively for special populations or offer specialized programs on an intermittent basis. For example, there are programs that are specifically designed for adolescents as well as for seniors. Programs may also focus on treatment for alcohol addiction or on another particular drug. Other examples of specialty residential treatment programs include those that focus on men, women, women with children, those involved with the criminal justice system, and homeless people and individuals with HIV, post-traumatic stress disorder, or other concurrent disorders.

The Effectiveness of Residential Treatment

In considering the effectiveness of residential treatment, research has been hindered by vague descriptions of treatment programs, the instability of participants in studies, problems with random group assignment, difficulties in ensuring equivalency of groups, and a lack of agreement as to what constitutes success in addiction treatment. It is difficult to locate scientifically sound research that evaluates the outcome of residential treatment programs. Nonetheless, there are proponents on both sides of the debate over the relative effectiveness of residential versus outpatient treatment programs. For example, in a methodologically strong research study published in 1977, Griffith Edwards and colleagues randomly assigned problem drinkers to one of two groups: a treatment group that included a specialized inpatient alcoholism unit (which resembled many components of residential treatment) and a group that received a single counseling session but no further intervention. At a 12-month follow-up, the researchers concluded that there were no significant differences between groups on any measure of improvement, such as self-reported drinking behavior, self-rated severity of drinking problem, or indices of social adjustment. Although this research did not compare a traditional residential program with outpatient treatment, this well-cited study implied that more intense intervention does not necessarily result in better client outcomes.

In contrast, Joseph Gudysh and colleagues (published in 1998) randomly assigned participants to either day treatment or residential treatment and found that residential treatment participants showed more improvement in terms of social problem severity and psychiatric symptoms at a 6-month follow-up. In an extension of their first study, Gudysh and colleagues (published in 1999) conducted a 12- and 18-month follow-up and again found the residential treatment clients to demonstrate better outcomes in terms of social problem severity and psychiatric symptoms (and also suggested better outcomes in the area of social support and early treatment retention for the residential clients).

Despite the fact that research has not unequivocally proven the superiority of residential or outpatient treatment, it may be possible to conclude that residential treatment may be the more effective option for individuals with high levels of comorbid psychiatric severity or severe social problems.

RESISTANCE IN TREATMENT

Resistance is generally defined as client opposition or ambivalence to treatment or refusal to participate in treatment. Clients may exhibit resistant behavior for various reasons including but not limited to a client's own motivation, program inflexibility, the level of counselor competence, or poor provider–client communication. Resistance can be tied to a client's belief that treatment for substance use disorders necessitates a loss of personal freedom or that substance use disorder treatment does not work. Whatever the reason for the behavior, resistance is an expected component of treatment that providers will inevitably have to address.

It is important that practitioners address resistance in some way because studies have shown that if resistance persists, it can prevent full client engagement and may lead to a client's early exit from treatment, both of which can and do lead to poorer outcomes than if a client were fully engaged and remained in treatment for a professionally recommended length of time. This finding does not imply that clients who are coerced into treatment will not be successful in treatment. In fact, studies by John Kelly and colleagues, Douglas Young and colleagues, Steven Belenko, and many others indicate that clients who are coerced into treatment have the same or better outcomes compared with those who have not been coerced. This finding is an especially important point as more correctional systems embrace mandatory treatment instead of incarceration for individuals who commit substance-use-related crimes. However, research conducted by Robert Shearer and colleagues indicated that at least 25% of inmates screened for substance use do not enter treatment due to motivational factors and that resistance tends to be higher among individuals in the correctional setting, especially among ethnic and cultural minorities within the correctional setting. With growing concern about increasing prison populations and studies indicating

the effectiveness of in-prison substance use disorder treatment in reducing subsequent crime and costs to society, resistance is a prominent obstacle providers must assist individuals in overcoming in order for treatment to be maximally effective. These concerns hold true even outside the correctional setting when cultural, racial, and ethnic factors form the basis for powerful feelings of resistance to treatment among members of minority communities. Fortunately, there are many therapeutic options providers can use to deal with resistance in treatment.

Resistance and Change

Historically, resistance was viewed as the result of character defects, unwillingness to change, and even a lack of willpower. Confrontational approaches and negative responses to people with drug and alcohol problems were the norm. It was not uncommon to hear providers invoke maxims such as “no pain, no gain” or “you've got to hit bottom before you are ready to make serious changes.” Certainly pain and discomfort are catalysts for change; however, as research in addictions has grown, it is clear that together they are just one aspect to change. Just as addiction treatment as a whole has moved beyond a one-size-fits-all mentality, so too have providers moved beyond pain and discomfort as the only motivators for change.

Often clients can be encouraged to overcome resistance if they feel they will lose something of value such as family, health, or a job. Even if a provider can use these as motivating factors to encourage change, a client may still feel apprehensive about ceasing alcohol or other drug use immediately. Just as resistance in general is an expected part of treatment, so too are the stages of change an individual experiences when entering into the treatment process.

The Stages of Change

James Prochaska and Carlo DiClemente developed a model to help providers understand a client's readiness to change. The stages of change model classifies clients' readiness into one of five categories: precontemplation, contemplation, preparation, action, and maintenance. This model has been used to address a variety of unhealthy behaviors such as smoking, unnecessary or extreme weight loss, and alcohol and drug use. Study after study using this model indicates that there is a predictable sequence of thoughts and

feelings as a client progresses from precontemplation, when he or she does not recognize the negative consequences of his or her behavior, to maintenance, when he or she can sustain new, healthy behavior. On the path from precontemplation to maintenance, when a client is experimenting with new and healthier behavior, he or she will often experience loops of lapses (one or a few episodes) or relapses (returning to the initial behavior) before change is sustained. Cigarette smokers, for example, cycle through the stages an average of seven times before maintaining complete abstinence from smoking.

The strength of this model lies in the fact that if a client is not ready to change but is forced into a treatment that does not match his or her stage of change, the treatment will inevitably lead to resistance. However, if a provider uses strategies appropriate to a client's level of change, there is a much greater chance that the individual will become engaged and remain in treatment. For example, if a provider identifies that a client is contemplating change in his or her use but is not yet ready for action, that provider can assist the client by offering educational information about the harmful effects of substance use and also help the client identify the pros and cons of his or her use.

Tools to Assess Client Readiness

Because the change process is complex and cyclical, it is helpful to assess the levels of readiness and change throughout the treatment process. A provider's goal is to help clients identify reasons for change and choose an appropriate pathway to make such changes. Providers have a number of clinical tools available to them that can be used to identify a client's stage of change and level of readiness. For example, the Recovery Attitude and Treatment Evaluator, developed by David Mee-Lee and colleagues, measures client status on five dimensions including resistance to treatment and resistance to continuing care; the University of Rhode Island Change Assessment provides a score on each stage of change and an overall motivation measure. In this way, providers can better understand the nature of a client's resistance—that is, whether the client is resistant to the content of treatment or the process of treatment, or exhibits resistance as a result of a mental health disorder such as borderline personality disorder—and offer a treatment that will best meet the client's needs, thereby reducing resistance.

Dealing With Resistance

It is important to remember that despite the appearance of resistance, clients may already be weighing their options and considering change because the path to behavioral change is not straightforward. People seeking to change their drug and alcohol using behavior may slowly taper their use of one substance while still using another. Some consider complete abstinence or quitting cold turkey, while others choose to use medications to aid them in the treatment process. Whichever method works best for a client, providers will have the most success when they access treatment options that aid the client in tapping into his or her own motivation and decision-making process and meeting the client where he or she is in the stages of change.

There are a number of widely used approaches that providers can employ to specifically address resistance in treatment and to encourage a client's motivation. These approaches have been developed and refined over time and are designed to enhance clients' intrinsic and extrinsic motivation. Research has found that strategies promoting personal responsibility (intrinsic motivation) are the most promising for treatment involvement and retention and for sustained change. On the other hand, interventions that offer financial incentives to patients (extrinsic motivation) who accomplish a specific behavior such as submitting drug-free urine samples have been found to be significantly more effective than standard treatment without financial incentives, especially in early treatment when drug and alcohol cessation is the most difficult. Common treatments that address each form of motivation are described below.

Motivational interviewing (MI), developed by William Miller and Stephen Rollnick, is an evidence-based approach used to help clients overcome their ambivalence toward changing any unhealthy behavior. Based on motivational psychology, MI is a client-centered approach that focuses on enhancing a client's internal motivation to make changes. MI provides a framework in which providers collaborate with clients by recognizing their experiences and foster an atmosphere conducive to change; draw on the client's own perceptions, goals, and values to highlight the discrepancy between present behavior and goals; roll with the resistance by allowing the client to direct change and to offer new perspectives without imposing them; and supporting the client in choosing and

carrying out his or her own change. Overall, Miller characterizes MI not as a set of counseling techniques, but as a way of being with people, and it is often the underlying idea for many motivational techniques.

Brief intervention, a resistance-reducing technique that may include MI, uses straightforward advice and information on the negative consequences of alcohol and drug use to motivate patients to reduce or stop drinking. According to the National Institute on Alcohol Abuse and Alcoholism, brief interventions typically consist of one to four short counseling sessions with a trained interventionist. Brief interventions can be offered in non-substance-use-disorder specialty settings such as primary health care offices or trauma centers. According to Miller, brief interventions include six key elements summarized by the acronym FRAMES: feedback, responsibility, advice, menu of strategies, empathy, and self-efficacy. Research indicates that even one or two sessions of such brief counseling can lead to behavioral change.

Another resistance-reducing technique, Motivational Enhancement Therapy (MET), combines motivational techniques in a series of short treatment sessions over 3-months. Although MET can be considered a brief intervention, it is distinguished from them because it typically takes place over a longer period of time. In MET, an extensive evaluation is conducted, and patients are given clear, structured feedback about the consequences related to the quantity, frequency, and duration of their current use patterns. Providers share specific information each week for the 3-month period including how the patient relates to the average individual, information to help enhance motivation, and ideas to assist in developing a plan of action for change. Project MATCH, a study matching different treatments for alcoholism to a variety of client characteristics, examined the effects of four 1-hour sessions of MET and found that at 1-year and 3-year follow-ups, participants reported drinking less often and consuming fewer drinks per drinking day compared with their drinking behavior before treatment. The conclusion that the combination of educating patients while using motivational strategies results in positive behavioral change is borne out by many subsequent studies.

Contingency management (CM), also referred to as motivational incentives, is based on operant conditioning therapy and focuses on enhancing a patient's extrinsic motivation. Like MI, the use of incentives

addresses a patient's ambivalence, but through external means. CM works by reinforcing small positive behaviors in the treatment process with the ultimate goal of complete and sustained abstinence. Implementation of CM includes offering an immediate incentive for the specified changes in behavior and is based on the principle that if a good behavior is rewarded, it is more likely to be repeated. Especially during the early stages of treatment, a reward or reinforcement for drug-free behavior can be a powerful motivator. For example, a person is given an incentive—money or goods—when submitting a negative urine screen for his or her specific drug. Over 40 years of research support the success of this method and specifically support CM's effectiveness in reducing alcohol and drug use and increasing attendance in treatment.

Benefits of Resistance

Despite the barriers it creates in treatment, resistance can sometimes be a useful tool for providers. For example, a client may exhibit resistance if he or she is uncomfortable with a specific treatment approach or is not yet ready to make a specific behavioral change suggested by the practitioner. In this instance, resistance behavior acts as an indicator to the provider that the patient is unhappy with some aspect of treatment. When providers alter the specific treatment method in response to client feedback (resistance), clients report feeling more respected, a feeling which has a direct and positive effect on engagement and retention in treatment. This result is supported by research conducted by Roy Futterman and colleagues that highlights the success providers have when they focus on the process of treatment—that is, the interaction between client and provider—rather than on emphasizing specific behavioral changes (e.g., immediately stopping substance use).

Conclusion

Resistance in treatment is an expected and integral part of the change process. Resistance is a signal that lets providers know whether to proceed, slow down, or change the course of the change process. Although resistance by definition is considered an unwillingness to change, its occurrence is a result of the counselor-client relationship. There is an opportunity for the provider to recognize this resistance as a signal, to contemplate

the reason for resistance, and to address it in ways that engage patients to become less defensive. It can and should be used as a routine communication tool to assess where the patient is located in the stages of change and in the treatment process. Research has offered evidence that strategies can be used to assist in this change talk and to help reduce resistance and initiate and encourage motivation for more favorable change and progress in treatment. Utilizing proven strategies to enhance extrinsic and intrinsic motivation are promising practices to positively address resistance in treatment.

REVERSE TOLERANCE

When a drug is repeatedly administered, tolerance may develop to certain effects of the drug so that larger doses are needed to achieve the same effects. Reverse tolerance, also known as sensitization or behavioral sensitization, occurs when an effect of a drug increases with repeated administration. Reverse tolerance occurs less frequently than tolerance and happens only with particular effects of certain drugs. Reverse tolerance is not fully understood, but most of the research in this area focuses on the stimulating effects of drugs such as cocaine, amphetamines, and alcohol. These drugs produce activating effects in the dopaminergic system of the brain and effect the behavior of animals and humans; even when low doses are repeatedly administered, there is a progressive increase in activation with each dose. Although tolerance to certain effects of a drug diminishes over time if the drug is not administered, sensitization appears to continue long after the drug use has been stopped.

Unlike tolerance, sensitization has been shown to be particularly strong when the drug is repeatedly consumed in the same environment. For example, if an individual frequently uses cocaine in the bathroom, sensitization to its effects is augmented because of the environmental cue of the location—that is, the bathroom itself acts as a prompt for sensitization to occur. In contrast, sensitization to the drug's effects is likely to decrease if the drug is administered in a different environment. It appears that the environment with which the drug is associated becomes a cue in itself so that sensitization is produced in that environment, even in the absence of the drug being consumed.

Sensitization occurs in the mesolimbic dopamine system, which is responsible for the reinforcing effects of drugs and alcohol. The sensitization of the dopamine system in the brain is thought to be partially responsible for drug addiction and drug craving. One potential explanation for the mechanism underlying reverse tolerance can be derived from incentive sensitization theory. This theory postulates that the change in sensitivity of the dopamine system accounts for the craving of a specific drug; when a drug with reinforcing effects, such as cocaine, is administered, the dopamine system is activated. If a drug is administered repeatedly, the

mesolimbic dopamine system becomes sensitized to the effects of the drug, and consequently, the drug will have a greater reinforcing effect with each dose. When a drug with reinforcing effects is taken, the dopamine system is activated in the brain, producing a craving for the drug and a motivation to consume the drug again. According to the incentive sensitization theory, this succession of events describes the progression from intermittent drug use to addiction and dependence.

Sensitization is characterized by two distinct components: initiation and expression. Initiation of sensitization to a drug occurs when dopamine and glutamate receptors are activated in the brain as a result of the initial administration of a drug. The activation of these receptors then causes transient neurochemical changes in the brain. Expression occurs when, subsequent to the transient changes from drug initiation, a lasting change in neuronal function appears, which is expressed as a sensitization to specific effects of a drug.

Sensitization to Specific Drugs

Research has shown that sensitization occurs in response to only specific substances. Central nervous system stimulants, such as cocaine, have been shown to produce reverse tolerance. Tolerance develops quickly to some effects of cocaine—that is, more dosage is required to produce the desired effect. However, there is a reverse tolerance to other effects of cocaine. In other words, these effects are enhanced with recurrent administration. Stereotyped behaviors (e.g., searching, sorting, examining behaviors), spontaneous motor activity, and psychotic behaviors are quickly sensitized in humans. A recent study using positron-emission tomography (PET) scans examined the process of sensitization to stimulants in humans and found that sensitization could be achieved in a laboratory setting and that specific personality traits predicted proneness to sensitization. Results indicated that repeated administration of amphetamines led to a persistent sensitization illustrated by increased psychomotor activity, energy, eye blink rate, agreeableness, and alertness to responses. Furthermore, the PET scans revealed that dopamine release increased proportionally to the frequency of administration. Results from the follow-up administrations indicated that sensitization remained active for up to 1 year after the initial sensitization was produced. In addition, researchers found a relationship

between proneness to sensitization and novelty-seeking personality traits, suggesting a link between temperament and vulnerability to addiction.

The research regarding reverse tolerance to marijuana is equivocal. There have been many clinical observations that report a sensitization to the drug with repeated use, as well as several research studies conducted in the 1970s that suggest that a heavy marijuana user is more sensitive to the high, requiring less of the drug to achieve the same effects relative to an infrequent user. In contrast, several studies have found that there is no sensitization to the effects of the drug with repeated administration; in fact, more recent research has shown that daily users of marijuana develop a tolerance to its effects.

Understanding the process by which reverse tolerance develops and persists for certain drugs has implications for the treatment of addictions. Specifically, identifying ways to block the sensitization of drug effects may provide a way to prevent cravings for a drug. One study of alcoholism attempted to block sensitization to alcohol by using NMDA receptor antagonists (specifically MK-801), an endogenous subtype of glutamate receptors found in the brain. NMDA receptors have been shown to be extremely sensitive to low doses of alcohol, and there is evidence that alcohol may directly interact with NMDA receptors in the brain. Results indicated that NMDA receptor antagonists diminish the sensitizing effects of alcohol. Moreover, other studies have found that the NMDA antagonist MK-801 blocks the development of reverse tolerance to the stimulating effects of cocaine and amphetamines in rats. These findings further illustrate the potential usefulness of NMDA antagonists in the treatment of various drug addictions. The ability of other antagonists to pharmacologically reduce drug cravings has also been demonstrated with naloxone, an opioid antagonist used to treat opioid overdose. Naloxone has been shown to block the sensitizing effects of amphetamines and cocaine in several controlled laboratory studies, providing another example of how understanding the mechanisms of reverse tolerance may facilitate the development of pharmacological treatments for drug addiction.

RISK AND PROTECTIVE FACTOR THEORY

David Hawkins and Richard Catalano developed the risk and protective factor theory on the basis of an extensive review of research on substance use and other problem behaviors among youth. Analogous to the medical model of human disease, this theory suggests that substance abuse and other problem behaviors can be mitigated by limiting the number or preventing the development of risk factors and by bolstering protective factors within individuals. Risk factors are defined as anything within an individual or the individual's family, peers, or community that increases the likelihood of developing a problem with substance use. Conversely, protective factors are defined as anything that decreases the probability of developing problematic substance use. To be included as a risk or protective factor, variables of interest had to be associated with an increase (risk factor) or decrease (protective factor) in the problem behavior and had to be empirically validated and replicated with longitudinal studies. A summary of the risk and protective factors that have been shown to predict substance abuse (and many other problem behaviors) among youth follows.

Risk Factors

Research has consistently demonstrated that exposure to multiple risk factors is strongly predictive of later substance abuse. In fact, the quantity of risk factors present may be more important in predicting problematic behavior than the makeup of any one risk factor. Thus, several researchers and policymakers emphasize that for prevention and intervention

programs to be effective they must target a variety of risk factors from several different domains.

Individual-Level Risk Factors

Because all levels of social influence ultimately filter down to the individual level, risk factors within the individual may be particularly important to consider. Moreover, these factors may be the most amenable to change on an individual level. Research has consistently shown that youth who exhibit other antisocial behaviors such as aggression or rebelliousness have an increased risk of developing problems with substance use. Similarly, youth with favorable attitudes toward problematic behaviors (including substance use) are more likely to use drugs and alcohol than are youth with less favorable attitudes. Specific characteristics that frequently coexist with antisocial behavior, including impulsiveness, poor coping skills, and sensation seeking, have also been shown to be predictive of substance misuse. Finally, the earlier youth begin to use substances, the more likely they will be to develop a substance-related problem.

Family-Level Risk Factors

Previous research has documented a strong association between several family risk factors and the development of substance abuse problems in youth. For example, consistent with social learning theory, a history of substance misuse and other deviant behaviors within the family, along with parental attitudes that are favorable to or dismissive of drug and alcohol use, is an often cited risk factor. Moreover, growing up in a home environment characterized by stress, conflict, or mental illness has been shown to predict substance use in youth. Parenting styles (e.g., severe or inconsistent punishment, lack of clear expectations), low parental supervision, lack of parental attachment, and parental inattention have also been found to be associated with the likelihood that adolescents will become involved in problematic substance use.

Peer-Level Risk Factors

A substantial body of evidence consistently suggests that having and spending time with delinquent and substance-using peers is strongly associated with whether or not youth will develop a problem with drugs or alcohol. In fact, this factor is one of the few

risk factors that independently predict future substance abuse—that is, even in the absence of other risk factors, associating with substance-using peers substantially increases one's risk of using substances. Similarly, previous research has shown that adolescents are more likely to use substances if they associate with friends and peers who are supportive of, justify, or reward deviant behaviors such as drug or alcohol use.

Community and School-Level Risk Factors

The literature is replete with studies demonstrating the increased odds of developing a host of behavior problems based on where one lives and learns. For example, extreme poverty, living in a disadvantaged neighborhood with little community organization or neighborhood attachment, and a general acceptance of or passive resistance to substance use have all been found to put youth at risk for abusing drugs and alcohol. One of the more robust risk factors in the community is the presence and availability of substances. Indeed, research has demonstrated that the mere perception of the availability of drugs and alcohol is a risk factor for substance abuse. It is likely that this availability (or perceived availability) normalizes substance use for the developing youth (i.e., it promotes an “everyone else is doing it” attitude).

Protective Factors

A majority of people exposed to the risk factors outlined above do not develop problems with alcohol or drugs. Moreover, youth exposed to the same risk factors, and to an equal degree, do not necessarily have the same chance of developing the problematic behavior in question. The risk and protective factor theory would posit that the individuals who do not develop problems are equipped with factors that buffer or moderate the effect of the risk factors. This notion is consistent with the medical model of human disease. For example, someone with a family history of diabetes can offset his or her increased risk of developing this disease by increasing his or her amount of physical activity and by maintaining a healthy diet (both protective factors). Similarly, positive parental attachment can moderate the effects of living in an impoverished neighborhood.

Despite having tremendous promise for substance abuse prevention and intervention programs and being equally important as risk factors in predicting

problematic behaviors, relatively little research has been conducted on protective factors. However, one protective factor that has consistently been associated with a decreased likelihood of engaging in substance use and other problem behaviors is bonding. Specifically, youth with positive attachments to their family, peers, neighborhood, school, and community are significantly less likely to engage in deviant behaviors than are youth who lack these positive attachments. Importantly, for these attachments to be productive, they must be characterized by healthy, prosocial beliefs and by clear and disapproving standards about drug and alcohol use. Certain individual characteristics such as intelligence (high) and gender (female) also appear to offer a certain amount of protection against the abuse of drugs and alcohol.

Social Development Research Group

The Social Development Research Group at the University of Washington has been responsible for a substantial amount of the research on risk and protective factors. For example, in a recent cross-cultural study, this research group compared the similarities and differences of multiple risk and protective factors for adolescent substance abuse in the United States (Maine and Oregon) and in Australia (Victoria). Three noteworthy outcomes of this study include the following: (1) The group was able to replicate previous research on the association between risk and protective factors and increased or decreased substance abuse, respectively; (2) risk and protective factors were more similar than different across cultures; and (3) peer and individual and family factors were the strongest and most consistent predictors of substance misuse.

This group of researchers also developed the Communities That Care (CTC) Youth Survey to identify risk and protective factors from all domains of influence (i.e., individual and peer, family, community, and school) that have been shown to predict adolescent problem behaviors. Based on the social development model, the CTC Youth Survey contains 31 scales, 22 of which assess risk factors and nine of which assess protective factors. This survey has been administered in several states (e.g., Maine, Oregon, Pennsylvania, Utah, Washington) with a variety of students. The adequate reliability, strong validity, and ability to assess a broad scope of risk and protective factors have made the CTC survey an important component to prevention planning. In fact, a major advantage of this survey is its

ability to locate elevated risk factors and depressed protective factors in a given population. By identifying the most prevalent risk and protective factors associated with problem behaviors (including substance use), schools and communities can tailor their individual programs to address their respective priority areas. It is worth noting that some have criticized the complexity and practical limitations associated with analyzing and interpreting 31 different factors. Using CTC Youth Survey data collected from Pennsylvania public schools, Mark Feinberg and colleagues at Pennsylvania State University analyzed and found support for aggregating the risk and protective factor scales to create eight indices. The researchers suggested that this method of analyzing and examining the survey data would facilitate increased understanding and usage by community organizations in their decisions to parcel out resources for prevention and intervention programs.

Conclusion

Numerous factors are responsible for the development of problematic behaviors among youth, making it imperative that multiple levels of influence are considered when identifying factors related to the onset and escalation or de-escalation of alcohol and drug use. Specifically, modifiable risk and protective factors within the individual, family, peer, school, and community should all be included in prevention and intervention programs. The consideration of multiple risk and protective factors is important for several reasons. First, it is unlikely that a single risk factor is responsible for youths' participation in problem behaviors. In fact, previous research suggests that the number of risk factors an adolescent is exposed to is positively related to the likelihood of substance abuse and other delinquent behavior. Second, certain risk factors may be more difficult to change than others. For example, exposure to stress or community disorganization may require a long-term societal change. Thus, by addressing other modifiable risk factors (e.g., peer group, parental attitudes), a more immediate impact can be made on lessening the probability of youth becoming involved with substances. Similarly, modifiable protective factors can be bolstered to help offset the negative effects of the stable and difficult-to-change risk factors.

The risk and protective factors identified by the research teams of Hawkins and Catalano have

consistently been associated with substance abuse among youth and have provided a wealth of valuable information. Research has solidified the notion that identifying and addressing risk and protective factors is a viable and necessary method for preventing and intervening in substance abuse and other problem behaviors.

RISK FACTORS FOR ADDICTION

Prevention focused on risk and protective factors is based on a simple premise: To prevent a problem from happening, one needs to identify the factors that increase the risk of that problem developing and then find ways to reduce the risk. At the same time, one must also identify those factors that buffer individuals from the risk factors present in their environments and then find ways to increase the protection. The risk and protective factor approach is similar to the medical model for heart disease. The medical model for heart disease advances the idea that there are several factors that put adults at risk of heart disease, such as eating fatty foods and smoking. In addition, several protective factors exist that have been shown to shield adults from acquiring heart disease, such as eating diets low in fat and getting plenty of exercise. The same model works in understanding substance abuse prevention. There are some factors that put youth at risk of using substances and some factors that protect or shield youth from using substances. It is this theoretical approach that will be explored first.

Prevention based on risk and protective factors is based on the work of David Hawkins, Richard F. Catalano, and a team of researchers at the University of Washington in Seattle. In the early 1980s, they conducted a review of 30 years of youth substance abuse and delinquency research and identified risk factors for adolescent substance abuse and delinquency. They have continually updated this review.

The primary focus of substance abuse prevention programs is reducing or preventing substance abuse; however, since problem behaviors—including substance abuse, violence, delinquency, teenage pregnancy, and school dropout—share many common risk factors, reducing these risk factors is likely to reduce multiple problem behaviors. Because both risk factors and protective factors are observable, they lend themselves to interventions. The following is a summary of the research-based risk factors and the problem behaviors they predict (in parentheses). Please note that the research is divided into four domains: community, family, school, and individual-peer risk factors.

Community Risk Factors

The following are the risk factors that fall within the community domain. In other words, these factors

reside in the larger community, neighborhood, or school environment:

Availability of Drugs (Substance Abuse and Violence): The more available drugs are in a community, the higher the risk that young people will abuse drugs in the community. Perceived availability of drugs is also associated with risk.

Community Laws and Norms Favorable Toward Drug Use, Firearms, and Crime (Substance Abuse, Delinquency, and Violence): Community norms—the attitudes and policies a community holds about substance use and crime—are communicated in a variety of ways: through laws and written policies, through informal social practices, and through the expectations parents and other members of the community have of young people. When these laws and norms are favorable toward drug use, they constitute a risk factor for use.

Transitions and Mobility (Substance Abuse, Delinquency, School Dropout): With the risk factor of transitions and mobility, one needs to look at both the school and community domains. In the school domain, even normal school transitions can predict increases in problem behaviors. When children move from elementary school to middle school or from middle school to high school, significant increases in the rate of drug use, school dropout, and antisocial behavior may occur.

Low Neighborhood Attachment and Community Disorganization (Substance Abuse, Delinquency, and Violence): Higher rates of drug problems, delinquency, violence, and drug trafficking occur in communities or neighborhoods where people have little attachment to the community, where the rates of vandalism are high and where there is low surveillance of public places. These conditions are not limited to low-income neighborhoods; they can also be found in higher-income neighborhoods.

Extreme Economic Deprivation (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Children who live in deteriorating and crime-ridden neighborhoods characterized by extreme poverty are more likely to develop problems with delinquency, teen pregnancy, school dropout, and violence. Children who live in these areas and have behavior and adjustment problems early in life are also more likely to have problems with drugs later on.

Family Risk Factors

The following risk factors reside in the family domain. The family domain can include traditional and nontraditional, nuclear, extended, or other forms of family found in contemporary society:

Family History of the Problem Behavior (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): If children are raised in a family with a history of addiction to alcohol or other drugs, the risk of having alcohol and other drug problems themselves increases. If children are born or raised in a family with a history of criminal activity, the risk of juvenile delinquency increases.

Family Management Problems (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): This risk factor has been shown to increase the risk of substance abuse, delinquency, teen pregnancy, school dropout, and violence. Poor family management practices include lack of clear expectations for behavior, failure of parents to monitor their children (knowing where they are and with whom they are), and excessively severe or inconsistent punishment.

Family Conflict (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Persistent, serious conflict between primary caregivers or between caregivers and children appears to enhance risk for children raised in these families. Conflict between family members appears to be more important than family structure.

Parental Attitudes and Involvement in Drug Use, Crime, and Violence (Substance Abuse, Delinquency, and Violence): Parents' attitudes and behavior toward drugs, crime, and violence influence the attitudes and behavior of their children. Parental approval of young people's moderate drinking, even under parental supervision, increases the risk of the young person using marijuana.

School Risk Factors

The following risk factors are found within the school domain. These schools can be public or private and range from elementary to high school environments:

Early and Persistent Antisocial Behavior (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Boys who are aggressive in Grades

K through 3 are at higher risk of substance abuse and juvenile delinquency. Young people, both girls and boys, who engage in antisocial behavior during early adolescence are at increased risk for substance abuse, juvenile delinquency, violence, school dropout, and teen pregnancy.

Academic Failure Beginning in Elementary School (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Beginning in the late elementary grades (Grades 4–6), academic failure increases the risk of substance abuse, delinquency, violence, pregnancy, and school dropout. Children fail for many reasons. It appears that the experience of failure—not necessarily ability—increases the risk of problem behaviors.

Lack of Commitment to School (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Low commitment to school means the young person has ceased to see the role of student as a viable one. Young people who have lost this commitment to school are at higher risk for substance abuse, delinquency, teen pregnancy, and school dropout.

Individual-Peer Risk Factors

The following risk factors fall in the individual and peer domains, meaning that the risk factors operate in both intrapersonal and interpersonal spheres. This set of risk factors is particularly potent and has demonstrated a strong correlation to substance use, especially the “friends who engage in the problem behavior” risk factor.

Alienation-Rebelliousness (Substance Abuse, Delinquency, and School Dropout): Young people who feel they are not part of society, who are not bound by rules, who do not believe in trying to be successful or responsible, or who take an active rebellious stance toward society are at higher risk of substance abuse, delinquency, and school dropout.

Friends Who Engage in the Problem Behavior (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): Young people who associate with peers who engage in problem behavior—delinquency, substance abuse, violent activity, sexual activity, or school dropout—are much more likely to engage in the same problem behavior. This factor is one

of the most consistent predictors that research has identified. Even when young people come from well-managed families and do not experience other risk factors, just hanging out with friends who engage in the problem behavior greatly increases the child's risk of that problem. However, young people who experience a low number of risk factors are less likely to associate with friends who are involved in the problem behavior.

Favorable Attitudes Toward the Problem Behavior (Substance Abuse, Delinquency, Teen Pregnancy, and School Dropout): During the elementary school years, children usually express antidrug, anticrime, and prosocial attitudes. They have difficulty imagining why people use drugs, commit crimes, and drop out of school. However, in middle school, as others they know begin to participate in such activities, their attitudes often shift toward greater acceptance of these behaviors. This acceptance places them at higher risk because a shift in attitudes precedes a shift in behavior.

Early Initiation of the Problem Behavior (Substance Abuse, Delinquency, Violence, Teen Pregnancy, and School Dropout): The earlier young people begin using drugs, committing crimes, engaging in violent activity, dropping out of school, and becoming sexually active, the greater the likelihood that they will have problems with these behaviors later on. For example, research shows that young people who initiate drug use before the age of 15 are at twice the risk of having drug problems as those who wait until after the age of 19.

Constitutional Factors (Substance Abuse, Delinquency, and Violence): Constitutional factors are factors that may have a biological or physiological basis. These factors are often seen in young people with behaviors such as high sensation-seeking, low harm-avoidance, and lack of impulse control. Brain trauma at birth or later in life also increases a child's risk. These factors appear to increase the risk of young people abusing drugs, engaging in delinquent behavior, and committing violent acts.

Generalizations About Risks

There are a number of generalizations that can be made about the risk factors presented in this theoretical perspective. First, risks exist in multiple domains, meaning that risk factors exist across all four categories including community, family, school, and individual-

peer. If a single risk factor is addressed in a single area, problem behaviors may not be significantly reduced. Communities should focus on reducing risks across several areas or domains.

Second, the more risk factors, the greater the risk. Although exposure to one risk factor does not condemn a child to problems later in life, exposure to a greater number of risk factors increases a young person's risk exponentially. Even if a community cannot eliminate all the risk factors that are present, reducing or eliminating even a few risk factors may significantly decrease problem behaviors for young people.

Third, common risk factors predict diverse problem behaviors. Since many individual risk factors predict multiple problems, the reduction of risk factors is likely to affect a number of different problems in the community. The same is true for the heart disease model. When a person reduces a single risk factor, such as smoking, the risk decreases for lung, throat, and mouth cancers as well as heart disease.

Fourth, risk factors show much consistency in effects across different races and cultures. Although levels of risk may vary in different racial or cultural groups, the way in which these risk factors work does not appear to vary. One implication for community prevention is to prioritize prevention efforts for groups with higher levels of risk exposure.

Fifth, protective factors may buffer exposure to risk. Protective factors are conditions that buffer young people from the negative consequences of exposure to risks by either reducing the impact of the risk or changing the way a person responds to the risk. Consequently, enhancing protective factors can reduce the likelihood of problem behaviors arising.

S

SCHOOL-BASED PREVENTION PROGRAMS

School-based prevention programs have historically been a key component of a comprehensive prevention system. Epidemiological evidence suggests the age of onset for substance abuse is in early adolescence, and peers are a primary influence on adolescent behavior. Schools reach many adolescents in a single location while providing a controlled environment for delivery of prevention curricula and nonuse norms, policies, and practices. Schools not only can provide a solid academic foundation for students and teach skills that enable them to make choices about healthy lifestyles throughout their lives but can create an environment where substance use is either a norm or not acceptable.

According to the Education Development Center, Inc., in a document titled *School-Based Prevention: Critical Components*, schools can enhance their efforts to reduce or prevent substance abuse by implementing 11 key strategies. These strategies are organized according to changes at three levels: individual students, schools and classrooms, and the larger community.

Individual Strategies

Historically, the most common prevention activity has been targeted to the individual students. Teachers delivered curricula in hopes of teaching students about the dangers of substances and teaching resistance skills (e.g., “say no” to drugs). Key strategy number one includes instructional approaches that

combine social and thinking skills. Certain skills are emerging as critical to preventing and reducing substance abuse, including empathy and perspective taking, social problem solving, anger management or impulse control, communication, stress management and coping, media resistance, assertiveness, character and belief development, and resistance training. Programs should include, among other things, adequate “dosage” of at least 10 to 15 sessions per year and another 10 to 15 booster sessions one to several years after the original program, reaching children from kindergarten through high school, and using age-appropriate interactive teaching methods.

Key strategy number two includes early identification, referral, and intervention with students and parents at risk. One of the most common activities in this area is student assistance programs. However, this strategy requires further, more rigorous evaluation before it can be considered a key activity. Strategies designed to identify students and parents at risk and refer them to appropriate educational or therapeutic programs have been more successful at reducing substance abuse. Programs that target at-risk families and provide skills training, family in-home support, and family therapy have been shown to improve communication, foster attachment, improve parenting skills, reduce parents’ substance abuse, improve child behavior, and reduce children’s levels of substance abuse. Programs should include, among other things, components for both parents and children, identification of and expansion upon strengths of the family, and groups of no more than 15 families per cohort.

Key strategy number three is to provide safe and supervised alternatives for students at risk. As an

alternative to substance use, options are offered that include recreational, enrichment, and leisure activities. These may include community service, mentoring programs, cultural activities, school-to-work assignments, internships, and tutoring. Alternative strategies alone have not been proven to reduce substance abuse. Therefore, these activities may be included as part of a comprehensive prevention program that incorporates other strategies that have been proven effective. Alternative activities are more likely to be effective if they provide intensive approaches that include many hours of involvement, incorporate skill building, and target young people at risk who may not have adequate adult supervision.

School and Classroom Strategies

Changing schools and classroom environments includes making comprehensive and integrated changes in the operation and organization of the school or school system.

Key strategy number four is about school–community collaboration in program planning and delivery. In schools where open and healthy communication between parents, students, community members, and faculty exists, there is higher teacher morale and less student disorder. Some key factors involved in changing policies and practices to promote health include having a clear vision for promoting health, well-being, and social competence among young people; having devoted leaders to guide planning and deliver ongoing professional development for school faculty, parents, and other community members; and combining what is needed at the school level with what is happening politically, economically, and socially at the national and local levels.

Key strategy number five is to provide clear school policies to prohibit substance use. This strategy is supported by perhaps the largest amount of scientific evidence. Examples of school policies that promote a no-use norm and have a large impact on reducing and preventing substance use include drug-free zones, dress codes, random inspections, increased supervision of all areas, eliminating smoking areas for faculty and students, having a clean school environment, reducing class size, installing adequate lighting, clearly communicating expectations for behavior, and applying school policies fairly to all students. To help ensure effectiveness, schools should include a rationale for their policies, clear and positive statements about

behaviors the school expects students to exhibit and specification of consequences for infractions, and rewards and recognition for compliance.

Key strategy number six is to enforce school policies with clear reward structures and unambiguous sanctions. Schools with such governance experience less disorder. Effective enforcement should include promotion and enforcement of specific rules or policies regarding discipline, smoking, and alcohol use. These rules and policies should be paired with communication strategies that emphasize changing certain norms about substance use and disruptive behavior and that offer deterrents to substance use and disruptive behavior. Further, enforcement may include rewards and recognition for those who behave appropriately.

Key strategy number seven is to communicate and influence school norms about substance use. Schools can communicate a nonuse norm regarding the harm and unacceptability of teen alcohol, tobacco, and other drug use through newsletters, posters, educational campaigns, presentations, articles in the school and community newspapers, and ceremonies. Influencing school norms through organized campaigns tends to be more effective when an assessment is conducted to measure awareness and knowledge about the problem; a committee or task group is formed to coordinate campaign activities; students' misperceptions about the prevalence of the problem are corrected; and parents, teachers, and students are involved.

Key strategy number eight is to restructure the classroom for a more engaging and interactive educational environment. Certain classroom management and teaching strategies are showing promise in reducing risk factors and increasing protective factors associated with substance use. These strategies include classroom rule enforcement, use of rewards and punishments, cooperative learning, smaller class sizes, nongraded elementary schools, continuous progress instruction, and computer-assisted instruction. Strategies to create a more engaging interactive class include using classroom control and transition methods that maintain a positive classroom environment and maximize the amount of time students spend on learning, defining rules clearly at the beginning of the year and teaching these rules during structured lessons, and incorporating and providing opportunities for teamwork and cooperative learning in lesson plans. Further, to promote more engaging classes, the progress of each student should be continually monitored, and the student or group of students should be

advanced when they achieve mastery. Furthermore, students must be regrouped in different ways to achieve smaller, less alienating, and more suitable environments.

Community Strategies

Schools can also play a major role in changing the community environment. The norms that can increase or decrease the likelihood of student substance abuse are largely influenced by the larger community environment, and schools can work to change policies and change community norms that encourage underage drinking, underage smoking, and other unhealthy behaviors. Combining community-level changes with school activities is crucial in reducing and preventing youth substance use.

Key strategy number nine is to limit availability of alcohol, tobacco, and other drugs to youth. The most potent strategy is to pass laws and institute rules and regulations that control availability through pricing, provide deterrence for using or incentives for not using, and impose restrictions on both availability and use. Schools can play a major role in making changes at the community level that can affect the behaviors of the young people they serve. Schools can impact the environment and community policies in the following ways: support legislation, including local ordinances that reduce availability of alcohol, tobacco, and other drugs; track and document substance abuse indicators in the community; provide expert or public testimony at local and state levels; discuss key legislative issues regarding substance use among youth at faculty and staff meetings; endorse official reports, initiatives, and position papers on preventing youth substance use; adapt or pass policy statements or resolutions on limiting youth access to alcohol, tobacco, and other drugs; and involve students in letter writing campaigns to lobby local, state, or national decision makers about specific policy changes.

Key strategy number ten is the enforcement of community policies to limit youth access to alcohol, tobacco, and other drugs. Oftentimes, there are laws, policies, rules, and regulations in place that are intended to discourage youth use. However, if they are not enforced, the pro-use message communicates a tolerance and acceptance of youth substance use. Existing and new policies regarding substance use must be consistently enforced in order to be effective in preventing or reducing youth use. Schools can

work with community members to enforce communitywide policies. Police officers, as important leaders in enforcing laws, should be represented on community advisory boards or coalitions. Youth, parents, and other community members can also play an important role in collaboration with law enforcement. For example, parents can pressure alcohol and tobacco outlets to check identification. Task forces can be established to conduct undercover community buying operations that provide positive and negative feedback to merchants. Community members can advocate for server training and increased enforcement of laws against serving intoxicated patrons and selling alcoholic beverages to minors. Further, they can identify and report illegal drug activities, including underage drinking.

Key strategy number eleven is to implement communitywide communication campaigns to influence community norms about substance use. Communities must realize there is a problem in order to accept, promote, and enforce a specific policy or regulation and must be ready to change. A communitywide campaign can inform the public and bring support for specific policies. Schools can lead or participate in activities such as promotional or educational videos, fliers, and posters; alcohol-free events; town meetings; press conferences; speeches; educational workshops; news stories or features; letters to the editor; and interviews on radio or television. These approaches are more effective when (a) they are combined with more intensive and interactive prevention approaches (i.e., reducing availability or implementing evidence-based school curricula that build social and thinking skills), (b) messages are located where young people actually view and hear them, (c) messages are tailored to a specific audience, (d) the use of authority figures is avoided, and (e) demonstrations of harmful substances are avoided.

Conclusion

Researchers and practitioners have a greater understanding of how prevention strategies work, for whom they work, and how they work together in the community to create positive behavioral change. Schools will continue to play a pivotal role in prevention, and, by implementing these 11 strategies as well as other effective ones, they will enhance their chances of success at preventing and reducing substance use among youth.

SCHOOL DRUG POLICIES

Young people, in particular those under the age of 25, can suffer far-reaching mental, physical, social, and legal consequences for substance use. The responsibility for assisting them to make healthy choices is best

approached with multifaceted strategies that include the family, school, and community. A school's alcohol and other drug policy represents the framework for efforts in the school to address student alcohol and other drug use; serves to guide prevention efforts; establishes boundaries of application, expectations, and normative values for student behavior; details the school's procedures in handling incidents with consequences; and empowers adults responsible for students in the district. It is essential that the school send the message to young people and adults alike that the use, possession, and intent to supply illegal and unauthorized drugs within the realm of the school will not be tolerated.

There is great differentiation in the content, application, and enforcement of school alcohol and other drug policies. Neither federal government nor individual states mandate a single course of action for all school districts to follow in creating and enforcing drug policies. For this reason, policies and procedures vary between districts. Schools within a district do well to maintain a single policy with procedures that apply to all students within the district. The creation of policies and procedures must balance what is best for the individual and what is most desirable for the total school population, necessitating the inclusion of prevention, intervention, and support as well as consequences for violations. Policies of record encompass the district's policies and procedures of which school drug policies are part. These include procedures implemented by staff for prevention efforts and incident management as well as violations and consequences published in student handbooks and posted on Web sites.

Policy and Procedure Development

The opening section of a written policy typically includes a brief description of the policy development process along with the philosophy and purpose statement. The development description includes the date of approval and adoption as well as implementation dates. This section contains a statement indicating that policies will be reviewed on an ongoing basis with revisions made as necessary. Classification of those included in the development working group (e.g., staff, parents, administrators, students, business owners) is also included in the development description.

Board of education approval must be given prior to policy being implemented, and district residents must be given the opportunity to review and respond. A typical protocol for board of education approval includes

a newspaper Notice of Hearing inviting residents of the district to attend one of three public meetings conducted by the board of education with intent to review and discuss the policy.

Boundaries and Jurisdiction

To whom, when, and where the policy and procedures apply must be stated. Prevention jurisdiction should include all students to whom programs and curricula will apply. A range of incidents and consequences for the possession, use, and distribution of alcohol and other drugs on school property, during the school day and at events both on and off school property, on school property when school is not in session, and off school property when school is not in session but when co-curricular contracts are in place are also included in this section. Incidents and consequences for adults who violate the policy must also be covered.

Definitions and Terminology

Alcohol and other drug incident management clearly defines terms related to the policy. Terms such as *use*, *misuse*, *drugs* (including *illegal* and *misused legal*), *paraphernalia*, *medicines*, *medical paraphernalia*, *volatile substances*, and *medical emergencies* are frequently addressed terms in the definition section of the school's drug policy. Legal counsel should be involved in defining terms covered in the policy.

Prevention Policies and Procedures

School alcohol and other drug policies and procedures serve both preventive and consequential purposes. Prevention policies address the alcohol and other drug education practices implemented within the school. At a minimum, the policy statement clarifies the school's responsibility and legal requirements to address educational needs of youth about alcohol and other drug problems. The internal policy and procedures give guidance to each school on prevention curriculum, program development, implementation, monitoring, and evaluation.

The U.S. Department of Education's Title IV Safe and Drug-Free Schools and Communities Act, which funds many of the nation's school-based prevention programs, requires schools receiving those funds to

implement prevention programs that meet certain standards of practice. The act's principles of effectiveness require that funds be administered in a manner that supports evidence-based prevention programs and practices. The U.S. Department of Education's list of 9 exemplary and 33 promising programs and the National Institute on Drug Abuse prevention principles offer more extensive information sources for substance abuse prevention planning.

Prevention policy and procedures include who is responsible for planning and implementing prevention education activities and events. The policy includes how needs assessment, program monitoring, and program evaluation will be handled by the district. Parent involvement in planning and implementing prevention strategies is included in this segment.

Incidents and Consequences

The policy must state that alcohol and other illegal drugs, as well as nonmedical use of drugs intended for use in medical treatment and use of drugs having no accepted medical purpose, are unauthorized and unacceptable in the school.

Incident management includes the scope and extent of policy violations on and off school property (including on school trips) and codes of conduct for co-curricular and extracurricular events. Typical facets found under incident management in the school drug policy are as follows:

- The range of incidents covered by the policy and consequences for being under the influence, as well as the possession, use, transfer, and distribution, of alcohol and other drugs along with a range of options for responding fairly to alcohol and other drug policy violations
- Searches, including school property, personal property, personal search procedures, and canine searches
- The school's response to student self-disclosure of use not in violation of school drug policies
- Under what conditions and how law enforcement is involved
- Under what conditions and how parents are notified and involved
- Implementation and maintenance of confidentiality procedures
- Custody or control of prescription drugs, equipment necessary to administer the drugs as prescribed, and equipment necessary to monitor illness

Procedures Involving Suspension, Expulsion, and Readmission

Most school drug policies implement a graduated system of consequences rather than apply an expulsion practice for all violations. Consequences applied include suspension from all school activities for an extended period of time (one to two semesters), expulsion, mandatory participation in a drug education program for the student and family, or submission to a professional substance use assessment and compliance to recommendations for treatment.

An abeyance contract may be implemented after an expulsion whereby the student and family participate in requirements for (a) drug testing at the family's expense, (b) recommendations for getting help for the student, and (c) completing additional restrictions over a specified period of time. These restrictions most often include no further violations of any area of school policy.

Medical Emergencies

Steps the school will implement when an incident constituting a medical emergency arises are part of school drug policy. A medical emergency involving substances may include a student or staff member who is unconscious, is having trouble breathing, is seriously confused or disoriented, or has taken a harmful toxic substance. The medical emergency section of the school drug policy often includes the protocol for rapid communication in the building and district, a coordinated and rapid response plan including securing internal and external medical resources, ensuring the safety and well-being of others in the building, appropriate precautions to minimize further risk, and identification of available medical equipment with proper training. Because the procedures involving law enforcement and parental notification will differ from those applied to nonemergency incidents (both in the context of medical emergencies), these procedures are detailed in this segment of the policy.

Intervention and Support Services

Expulsion alone does not typically motivate an adolescent to stop alcohol and other drug use. The school drug policies serve a key role in providing protocol implemented through early intervention processes that assist students and families in accessing alcohol and other drug assessment, treatment, support, and additional resources. Early intervention services in

the policy often include a student assistance program utilizing a student assistance counselor and a student assistance core team. The school drug policies and the school Web site typically include a list of national help lines, national Web sites, and local treatment and support services.

Policy Implementation

Most school policies state that the principal is the ultimate authority on school discipline and may interpret the policy as it relates to pupils and circumstances. In light of that authority, the principal must also see that all incidents and consequences, including those for alcohol and other drugs, are applied fairly across the student population.

Policy implementation guidelines are typically part of the policy of record and are not distributed to students and parents. These guidelines prescribe staff protocol in handling incidents including alcohol and other drugs. Consistent protocol must be applied to handling incidents such as the discovery of substances or drug paraphernalia, suspicion of being under the influence, and observance of substance transfer. Documentation also must be handled in a consistent manner. Prescribed protocol for staff handling of incidents both empowers staff to respond in appropriate and consistent modes and assists administration in policy interpretation.

Policy Dissemination, Training, and Support

A school's drug policies constitute a section of the school's comprehensive policies and procedures that govern all district operations. Because alcohol and other drug policies are not developed in isolation from other policy aspects, development and dissemination of school drug policies are related to all parts of the district's policy and procedures.

The least substantial approach to policy dissemination is achieved through creating accessibility for families, students, and staff. Copies of record are typically kept in the library of each school and the district's central office with announcement to those residing and working within the school district that these are permanent copies available for review.

A more commonly implemented protocol for distributing the school's drug policies in addition to posting copies of record is inclusion of behavior expectations

and consequences in the school's student handbook. Another widespread practice is inclusion of policy sections in the student and family information packet distributed at the opening of school. A fourth dissemination method gaining popularity is posting of the school's policy and procedures on the school's Web site. Each method accomplishes dissemination objectives.

For schools intending the policy and procedures to have a preventive impact, dissemination strategies need to be accompanied by training and support. Reactive training presented through opportunities to correct infractions offers only sporadic and often incomplete messages about the policy and procedures. Planned training through a variety of channels to students, parents, and staff creates stronger preventive opportunities. A training and support plan identifies a variety of communication channels that allow staff, students, and parents to dialogue about the rationale of items contained in the policy and procedures concerning implementation. Administrators must also be mindful of policy training and support needs of new staff, substitute teachers, and volunteers.

Conclusion

School alcohol and other drug policies are necessary for the safety and well-being of all students and adults in the building. Sound, defensible policy serves as a strong preventive component along with defining expected behavior and consequences for violations. Although the responsibility for equitably implementing the policy and procedures rests with the school, the responsibility for creating the policy and educating others about its use remains with families and communities as well.

SCOPE OF PRACTICE

See ETHICAL STANDARDS FOR ADDICTION PROFESSIONALS

SCREENING

As applied to substance abuse prevention, treatment, and recovery, screening may generally be defined as the systematic assessment of an individual, or group of individuals, for the purpose of intervention. This assessment may take the form of a structured interview tool, a urine toxicology test (or the toxicology test of another biological specimen), or both. Because substance abuse is a major health care problem and is often characterized by compulsive drug-seeking behavior, denial, short-term breaks of recovery, and almost certain relapses, screening is an important tool at all levels. Screening may be further defined in terms of when to screen, who to screen, how and what to use for screening, and where to screen.

Screening of biological specimens for alcohol and other drugs falls most commonly into one of two categories: forensic or clinical. A forensic test is conducted for legal reasons, with analytical toxicology results that may likely come under scrutiny in a court of law. A clinical laboratory performs drug testing for medical reasons in support of patient care.

When to Screen

Screening for intervention can be regarded as an effort in prevention, treatment, and recovery from substance abuse. As a primary prevention effort, screening takes on the role of protecting and maintaining the health of an individual by identifying those who are at risk for

substance abuse. This typically happens through the use of a brief interview tool such as a survey. A survey used in this manner may provide an opportunity for immediate prevention education to be put into place. Preventive screening generally targets a specific group such as teenagers or may be used in pre-employment testing.

Screening during treatment and recovery is routinely accomplished through the use of a urine toxicology test. This may be in addition to a structured psychosocial assessment tool or a treatment plan. A psychosocial assessment tool may also be used for screening during the follow-up or recovery stage of the treatment program. The monitoring of recovering addicts using a dual system is an important step in supporting and encouraging the successful maintenance of sobriety.

Workplace drug screening most often occurs as a pre-employment test. It may also occur during random drug testing of current employees. During the investigation of a workplace accident or on-the-job injury, risk management will likely request a urine drug test of the employee(s) involved, particularly if drug use is suspected.

The success of a urine drug screen depends heavily on the substance used and the time frame from last use to the time of specimen collection. Many drugs are quickly metabolized and excreted from the body, whereas others stay in the body for several days. It is important to have some understanding of the nature of drug metabolism and excretion so that the collection of a urine specimen coincides with an optimal detection window.

Who Should Be Screened?

Toxicology screening tests, such as urine drug testing, are used on a regular basis in common venues such as admission to a drug treatment program or job entrance. The federal government, the military, and many private industries require urine drug testing on workplace employees on a random basis, a “for cause” basis, or both.

These urine tests may target employees of sensitive occupations such as drivers and pilots of public transportation or medical practitioners such as doctors, nurses, or dentists. Because many professional sports associations prohibit the use of performance-enhancing drugs, urine screening for drug abuse or drug presence is common among athletes. Urine screening may be forensic in nature when used for probation and parole.

Parole officers monitor ex-drug offenders for drug use. A drug positive screening test could become a violation of probation or parole and result in reincarceration.

Screening may be conducted on a specific targeted group at risk, such as pregnant women, abusers at high risk for relapse, or an inmate population. It also may be conducted on those who endanger themselves or others through their drug use, such as professional athletes, doctors, nurses, dentists, pilots, taxi and bus drivers, grade school teachers, bankers, stockbrokers, professional gambling dealers, railroad engineers, police officers, armed forces personnel, high-rise construction workers, heavy-load operators, and firemen.

Pre-employment screening using both a urine drug test and an interview assessment tool may be commonly used on job applicants for sensitive positions such as in the casino industry, police officer training, and for stockbrokers.

How Is Screening Conducted?

The most commonly collected biological specimen for screening is urine because it is relatively easy to obtain and the collection of a urine specimen is considered noninvasive. Alternative specimens collected and tested may also include blood, hair, saliva, sweat, and breath (for alcohol).

Through the use of modern technology, screening of biological specimens for alcohol and other drugs may be accomplished by using a quick and inexpensive on-site urine test, an oral saliva test, or a sweat patch test, or it may be conducted by laboratory-based instrumentation such as that used on blood or hair. On-site test kits now available can provide presumptive identification of drugs in as little as 5 minutes and are as sensitive and reliable as a laboratory screening procedure. Laboratory-based instrument screening may take 12 hours to several days to obtain results but may offer both presumptive and confirmatory results.

Because drug addiction involves multiple biological, sociological, and physiological causes, a clinical approach to screening consisting of a physical examination and the use of a structured interview or a brief survey, in addition to the drug test, is most useful. This will provide a tool by which the clinician can draw a differential diagnosis, assess the level of drug addiction, and develop a treatment plan.

Structured interview tools (or surveys) for substance abuse may take the form of a simple one-page

survey document that takes 10 minutes to a 102-page comprehensive psychosocial assessment of participant needs that may take 2 to 3 hours to complete. A survey may be completed by the participant, or it may be administered by a trained assessor. To be most useful, the assessment tool used should be standardized to the population for which it is intended. Participants completing an assessment tool should always be afforded a private confidential area in which to answer the questions.

Because screening questions can be embarrassing or uncomfortable, the participant should be informed that questions about alcohol and substance use are asked of all participants and that the information collected will be kept confidential. Self-reported drug use is not always completely reliable; therefore, routine history-taking should be included in the assessment questionnaire. History screening tools can often provide evidence of substance use and add valuable information and reliability to the assessment process.

Where Is Screening Conducted?

On-site urine drug testing kits are used primarily at the point of collection of the specimen. Therefore, urine screening may take place anywhere that provides a private area specifically designed, usually with specific regulatory criteria, for the collection of a urine specimen. One such example is the use of a law enforcement mobile unit (converted recreational vehicle or trailer) at the roadside scene of the arrest of a driver suspected to be under the influence of alcohol or other drugs. On-site screening kits make it no longer necessary to transport either the specimen or the subject to a laboratory for collection or testing.

However, it is still common and perfectly acceptable to collect a urine specimen at any facility designated as a collection site and then prepare the specimen for transport to a laboratory for testing.

Any site used for the collection of urine specimens should provide a private area for collection following specific guidelines mandated by the protocol that established collection criteria. The collection of a urine specimen must be supervised to ensure donor identity and to guarantee the integrity of the specimen. This supervision may occur by direct observation of the donor giving the specimen. It is not unusual for a donor to substitute or dilute the urine specimen if the collection is not supervised. However, specimens are more commonly collected through direct supervision and indirect observation.

Limitations of Screening

Screening in and of itself does not confirm a diagnosis of substance abuse. The presence of a drug or drug metabolite in a urine specimen is only an indication of a prior exposure to the drug in question. It does not prove impairment at the time of the specimen collection. Urine screening tests are considered presumptive evidence of substance use and should be used in conjunction with additional evidence to draw specific conclusions.

Urine screening tests are subject to false positives (drugs incorrectly identified as being present) and false negatives (drugs incorrectly identified as being not present). It is extremely important that urine test results be interpreted by experts trained in toxicology and pharmacology and urine drug testing.

SCREENING INSTRUMENTS

Multiple screening tools exist to detect alcohol and drug use, abuse, and addiction. Screening instruments are usually brief in nature, generally require limited training, and can be either self-administered or given in the context of an interview. Even though no screening measure can identify all substance abuse problems, the selection of well-established instruments with consideration to setting, population, and related factors can increase the likelihood of early detection.

Numerous well-established substance abuse screening instruments have been developed over the years and share many commonalities. The questions or items in screening instruments attempt to uncover characteristics associated with substance use such as efforts to cut down or quit, concern expressed by others, negative consequences, blackouts, and issues involving control of alcohol and drug use. The scoring of screening instruments typically involves a tally or sum with a cutoff point indicating the probability of abuse or addiction and providing insight to the severity level of substance abuse.

The instruments described in this entry have a long history of use in screening for substance use and abuse and are associated with a significant number of research and outcome studies. Although this is not an all-inclusive list, the following screening instruments are frequently used in the field of addictions counseling. In addition, these screening instruments are used by other mental health practitioners to determine if substance use problems are related to presenting issues.

Screening Instruments for Substance Use Disorders

Perhaps one of the simplest and best-known screening tools is the CAGE questionnaire. This four-item questionnaire is easily incorporated into an initial counseling session and is useful to quickly screen individuals for alcohol problems. Questions are as follows: (1) Have you ever felt the need to **C**ut down on your drinking? (2) Do you ever feel **A**nnoyed by people complaining about your drinking? (3) Do you ever feel **G**uilty about drinking? (4) Do you ever feel the need for an **E**ye-opener in the morning? Two responses of “yes” indicate the likelihood of a problem and the need for further evaluation. The CAGE questionnaire has been extensively researched and

validated for use in identifying alcoholism. A modified version of the CAGE, the CAGE-AID (Adapted to Include Drugs), can be used for diagnosis of other substance use disorders. The CAGE questions are widely available in the public domain, free of charge.

The Alcohol Use Disorders Identification Test (AUDIT), developed by the World Health Organization, is a widely used screening questionnaire that has been translated into multiple languages and used internationally. The AUDIT consists of 10 items: three questions pertaining to the amount and frequency of drinking, three questions on alcohol dependence, and four on problems caused by alcohol. The core questions can be reproduced without use of a copyright. The AUDIT should be administered by a trained professional during an interview; it takes about 5 minutes to complete and has high levels of reliability and validity. Like the CAGE questionnaire, it uses a simple set of questions with higher scores indicating the need for deeper investigation.

The Michigan Alcohol Screening Test (MAST) is a 25-item questionnaire, either self-administered or used during an interview, to screen for alcohol abuse and dependence. Underlying questions assess symptoms and consequences of alcohol abuse in the areas of guilt; blackouts; delirium tremens; loss of control; family, social, employment, and legal problems; and attempts to seek help for drinking. The MAST provides quick and effective screening for lifetime alcohol-related problems and alcoholism. Several modified versions of the MAST have been developed for use with specific populations. In addition, the DAST (Drug Abuse Screening Questionnaire) and the MAST-AD (Alcohol-Drug) have been developed to screen for drug abuse. All versions of the MAST are available in the public domain. There is also a geriatric version of the MAST.

The Substance Abuse Subtle Screening Inventory-3 (SASSI-3) is a brief screening measure to help identify individuals with a high probability of having a substance use disorder. The SASSI-3 consists of a two-sided questionnaire and takes about 15 minutes to complete. On one side are 52 true/false questions seemingly unrelated to substance abuse. The other side consists of risk prediction scales that allow clients to self-report on 12 alcohol-related and 14 drug-related items. The SASSI-3 includes subtests with subtle attributes to assist in the identification of individuals who are unwilling or unable to acknowledge misuse of substances. Adult, adolescent, and gender-specific forms have been developed. Paper, audio, and computerized versions of the test are

offered, as well as versions in other languages. The SASSI-3 is a commercial product that must be purchased, and training is required to administer and interpret the test.

Screening Instruments for Special Populations

Adolescents and Young Adults

Due to the multiple variables such as development and consideration of the right to consent, adolescents and young adults are a particularly challenging group to screen. In addition to the adolescent version of the SASSI-3, the CRAFFT and the Problem Oriented Screening Instrument for Teenagers (POSIT) are frequently used with younger populations, while the Drug Use Screening Inventory-Revised (DUSI-R) is useful for college-age and young adults.

The CRAFFT is a screening instrument for alcohol and other drugs, generally administered through an interview format. The name is based on a mnemonic, and the test is widely available on the Internet. The questions cover the following six items: (1) Have you ever ridden in a **C**ar driven by someone (including yourself) who was high or had been using alcohol or drugs? (2) Do you ever use alcohol or drugs to **R**elax, feel better about yourself, or fit in? (3) Do you ever use alcohol or drugs while you are by yourself (**A**lone)? (4) Do you ever **F**orget things you did while using alcohol or drugs? (5) Do family or **F**riends ever tell you that you should cut down on your drinking or drug use? (6) Have you ever gotten into **T**rouble while using alcohol or drugs? The six items evaluate certain events or behaviors over the entire lifetime, irrespective of when they occurred. A positive response to two or more items is indicative of substance abuse or dependence.

Another well-known screening instrument for use with adolescents is the POSIT. Longer than the CRAFFT, it is useful in identifying potential concerns in 10 problem areas needing further assessment. The POSIT is a self-administered, 139-item “yes/no” screening that takes approximately 20 to 30 minutes to complete. A computerized version for administering and scoring has been developed, as well as a Spanish version. Questions involve substance abuse, mental and physical health, social relations (including peers, family), school, leisure, and delinquency behaviors. The POSIT is not copyrighted and is available in the public domain.

The DUSI-R is useful for young adults and college-age students. The DUSI-R is a comprehensive screening for use with individuals suspected of drug use and to “flag” problem areas similar to those outlined in the POSIT. Areas addressed include substance use, behavior patterns, health, psychiatric disorders, social skills, family system, school, peers, leisure activities, and recreation. The instrument is a 159-item self-administered instrument, requiring approximately 20 to 40 minutes to complete. The DUSI-R holds a copyright and has a minimal fee for each paper version and a cost associated with available software.

The Adolescent Drinking Index, Teen Addiction Severity Index, and Rutgers Alcohol Problem Index are other instruments useful with this population.

Pregnant Women

Women who drink while pregnant place their unborn babies at significant risk for developing fetal alcohol syndrome. To reduce this risk, all women should be screened for substance use while pregnant.

In clinical settings, the TWEAK is a quick and easy screen used during an interview for assessing risk of use during preconception and pregnancy. The TWEAK is a five-item scale with the acronym for the following questions: **T**olerance: How many drinks can you hold? (or How many drinks does it take to make you feel high?). **W**orried: Have close friends or relatives Worried or Complained about your drinking in the past year? **E**ye-openers: Do you sometimes take a drink in the morning when you first get up? **A**mnesia (blackouts): Has a friend or family member ever told you about things you said or did while you were drinking that you could not remember? **K**(C) = Cut Down: Do you sometimes feel the need to cut down on your drinking? Although originally developed for women, the TWEAK is not gender specific and can be used with either men or women. The TWEAK takes less than 2 minutes and can be administered by pencil and paper, by computer, or in interview formats. No fee exists for use, and questions are widely available in the public domain.

Geriatric

Senior citizens and older adults are a growing population requiring special attention for screening. Warning signs of substance abuse (e.g., sleep problems,

falls, or cognitive confusion) can be confounded with, or masked by, other illnesses or chronic conditions associated with aging. Additionally, the possibility of mixing alcohol with prescription medication is a significant concern. Based on a modified version of the MAST, discussed earlier, a geriatric version, the MAST-G, was developed for use specifically with older adults. The MAST-G is a 24-item test with high sensitivity and specificity among older adults. It typically is administered by a clinician upon intake in a wide range of settings, including primary care clinics, nursing homes, and other older adult housing locations. A response of “yes” to six or more questions indicates the need for additional follow-up. The MAST-G is copyrighted but is available free of charge.

Screening Instruments: Levels of Dependence

Another group of screening instruments are helpful for assessing the level of dependence rather than only the existence of a problem. Two screening instruments for use with adults seeking help with a drinking problem are the Short Alcohol Dependence Data (SADD) and the Severity of Alcohol Dependence Questionnaire (SADQ). Both of these instruments focus on problematic drinking and are suitable for persons who are able or willing to acknowledge existing drinking problems. The SADD questionnaire consists of 15 items and is useful for assessing level of dependence, with a focus on mild to moderate dependence. The SADQ consists of 20 items designed to measure the degree to which drinkers seeking help experience alcohol dependence. Both instruments are useful for determining the client’s receptiveness to change and readiness for treatment. No fee is associated with either instrument.

Selecting Screening Instruments

Multiple considerations should be taken into account when deciding which instrument is most appropriate for use. First, the purpose and need for screening should be established. As discussed, various screening instruments exist based on the population group (e.g., adult, college-age, adolescent, geriatric) and purpose of instrument (e.g., problem identification, preliminary diagnosis, treatment planning).

Second, selected instruments should be based on proven clinical utility and well-established outcome research. As with most instruments that rely on self-report information, reliability and validity of screening are in part dependent on the willingness and ability of the individual to answer items truthfully. The specificity and sensitivity of screening instruments to ethnicity, gender, and relevance should be considered when selecting an appropriate tool.

Third, the logistics of implementation and interpretation of screening instruments needs to be considered. Information about recommended level of training for administration and time for completion and scoring should be an appropriate match to the agency or setting. Some instruments are copyrighted and have associated costs to obtain and score. The format for administration (e.g., self, paper and pencil, computer, or clinician interview), reading level, and availability of multiple languages are additional considerations.

Fourth, screening should never be used in isolation to diagnose or treat a substance use disorder. Instead, if a screening is indicative of a substance use problem, it is necessary to follow up with a comprehensive assessment.

Finally, in addition to the instruments already discussed, a multitude of additional screening tools exist, and instruments continue to be developed and modified. Continual education and training on most current approaches and effectiveness of screening are essential.

SECULAR ORGANIZATIONS FOR SOBRIETY/SAVE OUR SELVES

Secular Organizations for Sobriety/Save Our Selves (SOS), a nonprofit organization serving chemically dependent individuals and their families, was founded in 1985 by James Christopher as a nonspiritual alternative to traditional Twelve-Step recovery programs such as Alcoholics Anonymous. SOS comprises a network of autonomous self-help groups coordinated by the SOS clearinghouse. These self-help groups address a wide range of issues related to addiction, including overeating, gambling, smoking, and co-occurring psychiatric disorders.

In 1985, Christopher published an article titled “Sobriety Without Superstition,” which is an account of the course he, as a self-described “free thinker,” took to rational sobriety. This article is credited by SOS itself as being the founding document of the organization. With its first self-help support group held in 1986 in North Hollywood, California, SOS has become a recovery method for alcoholics and drug addicts and their families that has expanded to more than 1,000 meetings and more than 20,000 members in the United States. With its current international affiliations, SOS numbers over 5,000 meetings and 100,000 members worldwide.

SOS emphasizes its status as a secular recovery program that holds that sobriety is an issue separate from religion or spirituality. SOS, therefore, credits the individual for achieving and maintaining sobriety, without reliance on, or appeal to, a “Higher Power.” Similarly, SOS supports skepticism and encourages the use of the scientific method to understand chemical dependence. Other general principles of SOS

include the belief that support of other chemically dependent persons is an important adjunct to recovery, that group meetings are best conducted in an anonymous manner, that SOS groups are self-supporting through contributions from members, and that SOS does not limit its approach to chemical dependence to one theory or area of knowledge.

SOS views sobriety as the top priority in an individual’s life and insists on its members’ own responsibility for abstinence from drugs and alcohol. SOS refers to the individual’s responsibility for remaining clean and sober as a lifelong “sobriety priority.” This commitment to sobriety is viewed by SOS as an ethical responsibility involving an obligation to no longer put oneself or others at risk from the behaviors associated with chemical dependence. SOS emphasizes the power of persons to make a choice concerning their sobriety and acknowledges that this choice must be reaffirmed continually. SOS views chemical dependence as mainly physiological in nature, and as such, this “cellular addiction” must be curtailed with the continual acknowledgment that one is an alcoholic or addict for whom sobriety is the top priority. Despite an emphasis on the physiological nature of addiction, SOS does not adhere to a single point of view or theory and honors the individual’s own approach to his or her addiction, whether the cause is attributed to nature or nurture.

SOS provides suggested guidelines for sobriety. These guidelines are not steps offered as a program but are to be used by the individual to craft his or her own program for the achievement of sobriety. The guidelines encompass a daily reaffirmation of one’s commitment not to drink or use drugs under any condition; a commitment to take any necessary steps to achieve lifelong sobriety; a decision to not drink or use for reasons based on emotions, external circumstances, or conflicts; a commitment to sharing thoughts and feelings with others as sober, clean individuals; and an affirmation that a person is responsible for his or her own life and sobriety. These guidelines are read by a member at the beginning of each SOS meeting.

SOS provides assistance for family members and friends of chemically dependent individuals by opening meetings to them. At the meetings, family members and friends are educated about the nature of addiction and learn to recognize the phases of the chemically dependent person’s self-crafted program for sobriety. SOS believes that, while sobriety is the responsibility of the addicted person, the family has its own recovery cycle that involves recovering from

the feelings of being responsible for the addictive behavior. SOS groups also afford an opportunity for family and friends to gain insight from listening to the experiences, strengths, and encouragements offered by other recovering individuals in a supportive environment.

Research concerning the characteristics of participants in SOS found that the three things they most liked about SOS were its independence from religion; its openness, or comfortable environment; and its lack of rigidity and procedures. Of the elements participants found most helpful, people and interpersonal factors, the format and content of the meetings, and the focus or emphases of SOS were rated the highest. This research suggests similarities in the persons drawn to SOS and those drawn to other nonreligious recovery programs, such as Rational Recovery. Research concerning the effectiveness of SOS is scarce, but a recent national survey of people in recovery conducted by the Walsh Group found a positive relationship between good recovery outcomes and good recovery group matches. People whose personal philosophy was well matched with the philosophy of SOS were more likely to have a better recovery outcome than people who were not well matched. Of the factors determining whether a person was well matched with the group, religiosity was a key dimension.

SELF-REPORT INVENTORIES

The purpose of psychological assessment is to provide helpful information to the clinician with regard to diagnosing substance-related disorders and issues relevant to intervention. Substance abuse assessment includes various techniques, such as clinical interviewing, medical testing (e.g., toxicology screens), collateral information gathered from family members, and psychological testing. Psychological testing can include wide-band measures such as the Minnesota Multiphasic Personality Inventory-2 (MMPI-2) that require substantial time and effort to complete, score, and interpret, as well as self-report inventories used for screening purposes. As the name implies, self-report inventories are completed by the client and generally ask for information on alcohol and other drug use, as well as information related to substance abuse (e.g., consequences).

This entry provides a framework for understanding self-report inventories, their purpose, and how their effectiveness is determined. Descriptions of several widely used inventories are provided. The terms *self-report inventory*, *screening measure*, and *screener* are used interchangeably throughout this entry.

Effectiveness of Self-Report Inventories

Self-report inventories have often been viewed with suspicion, especially in light of the apparent ease with which such measures can be “faked.” However, research does not support this contention. Though self-report inventories on drinking patterns and problems are potentially subject to intentional modification and to forgetting (especially after periods of prolonged or abusive drinking patterns), research on the use of these inventories has consistently found the following: When clients take the inventories in a sober state, and when there are no negative consequences as a result of honest disclosure (e.g., legal consequences), self-report inventories are likely to yield

accurate information. In fact, research on the accuracy of self-report inventories indicates that they are at least as effective, if not more so, than other methods such as collateral reports, physical examinations, and laboratory tests.

Self-Report Inventories and the Psychological Assessment Process

Self-report inventories are frequently used as screening measures (screeners) in psychological assessment. Screening is a process that involves an initial and usually brief assessment of a client to determine the presence or absence of a given problem. Thus, screening measures are relatively fast and easy to administer. In the substance abuse field, screeners consist of a brief series of questions that are often used to determine whether a particular problem (such as alcohol abuse) is likely to be present. Thus, the critical element of screening measures is that they reveal if there is a high *likelihood* that a substance-related problem is present; they do not actually diagnose a substance use disorder. Instead, screeners provide a quick (usually completed within several minutes) and convenient method to determine whether a person has a high likelihood of falling into a certain category of substance-related problems such as alcohol abuse. If the results of a screening measure are positive, the next step is often to perform a more complete assessment to determine if diagnostic criteria for a substance use disorder are met. Any mental health professional (e.g., psychologist, psychiatrist, social worker, counselor, therapist) can use most self-report inventories.

Self-report inventories frequently are utilized to screen for diagnosable substance abuse disorders as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, the professional resource that defines and describes all mental health disorders and symptoms of these disorders. In this context, self-report inventories are used as quick and efficient tools to determine the likelihood that a substance-related disorder is present. Thus, self-report inventories have been created to screen for the presence or absence of some particular substance-related disorder, including alcohol problems, drug use, and abuse of prescription medications.

Additionally, self-report inventories have been created to measure aspects of substance use other than presence of a substance-related problem. Such

inventories tap important concepts in substance abuse work, such as readiness to change and self-efficacy with regard to changing substance use. This entry focuses on self-report inventories of substance use, abuse, and dependence.

Validity of Self-Report Inventories: Sensitivity and Specificity

The value of a self-report inventory lies in its ability to predict whether a patient meets some defined category, such as substance abuse or substance dependence. To determine the value of self-report inventories, they must undergo thorough testing prior to their distribution to professionals in the field. The most important issue in terms of how valuable the test is lies in its validity, and specifically, the criterion-related validity of the test. Criterion-related validity examines how well the self-report inventory (test) predicts some criterion (diagnosis of alcohol abuse). In this sense, prediction does not refer to some future event. Rather, it is a term referring to statistical prediction of some category. This issue can be illustrated in the following way. How well does the self-report inventory predict a diagnosis made concurrently by a mental health professional? That is, what is being predicted from the self-report inventory is whether a person falls into category A (no alcohol problem) or category B (alcohol abuse) as determined by some criterion, such as a comprehensive interview.

The criterion-related validity of a self-report inventory is determined using two concepts: sensitivity and specificity. *Sensitivity* is the percentage of true positive cases that the test identifies as positive. *Specificity* is the percentage of true negative cases that the test identifies as negative. A full review of sensitivity, specificity, and predictive value of a self-report inventory is beyond the scope of this entry. However, a brief example is provided for illustration. Assume a counselor working in probation and parole decides to administer a self-report inventory to 100 probationers. Assume that 70 of the 100 have actual substance abuse disorders. Conceptually, sensitivity is the percentage of the 70 abusers who were correctly identified as positive on the screener. So if the counselor administers the self-report inventory and 65 of the 70 abusers were correctly identified, sensitivity would be 92.9% (65/70). Specificity would be the percentage of the remaining 30 individuals without substance abuse problems who were correctly identified as nonabusers. If the test identified 20 of the 30 individuals

as nonabusers, then the specificity would be 66.7% (20/30). Thus, an essential part of evaluating self-report inventories is determining statistically how well they actually work. When test designers take on the task of creating new self-report inventories, their test creation must follow guidelines created by the American Psychological Association, which include adhering to principles of validating the new inventory.

Validity of Self-Report Inventories for Different Groups

An important aspect of the appropriate use of self-report inventories has to do with the populations of interest. For example, a certain screening measure of alcohol abuse might work well and be worded for a certain group of people (e.g., adolescents or young adults) but not for others (e.g., pregnant women, senior citizens). Thus, it is imperative that, when choosing a measure, the user determine the best measure based on whether the self-report inventory has been tested and shown to have adequate validity with the particular population of interest (e.g., adolescents, Latinos/Latinas).

Examples of Self-Report Inventories

There are numerous validated self-report inventories available for use by substance use professionals. They are generally categorized by type of substance assessed for (alcohol, drugs), degree of substance-related problem (e.g., at-risk use, abuse, or dependence), or both. The self-report inventories reviewed in this section are among the most widely used in the alcohol and other drug field. However, there are many others, including the Problem Oriented Screening Instrument for Teenagers (POSIT), the Substance Abuse Subtle Screening Inventory-3 (SASSI-3), and the Alcohol Use Disorders Identification Test (AUDIT).

The CAGE

The CAGE is one of the most widely used screening measures and contains four interview questions. The name comes from the first letter of the key word in each question (Cut down; Annoyed; Guilty; and Eye-opener). The four questions are Have you ever felt you should cut down on your drinking? Have people

annoyed you by criticizing your drinking? Have you ever felt bad or guilty about your drinking? Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover (eye-opener)?

The CAGE is widely used in applied clinical settings in part because it is much briefer than other measures of alcohol abuse. Thus, it can be used by both health and mental health professionals for a very quick screening measure (1–2 minutes) embedded in other standard interview questions. One criticism of the CAGE is that it does not specify time frame, so a client with a past history of alcohol abuse may have a positive CAGE despite being abstinent currently. One way to address this problem is to ask the client to specify the time frame in question for any positive answers.

The CAGE also can be used in questionnaire format, and it appears to be similar in accuracy in this format as in interview format. Affirmative responses are summed so that total scores range from 0 (zero) to 4. A score of 2 or higher indicates a high probability of an alcohol problem. Many studies of the sensitivity and specificity of the CAGE have been conducted with numerous populations. Sensitivity generally has been found to be strong, though research has found quite a range for the sensitivity of the measure (often ranging from 43% to 94%) with specificity also being impressive (ranging from 78% to 96%) across numerous studies. Overall, the CAGE is easy to utilize because it consists of only four questions, and it appears to have good sensitivity and specificity for detecting alcohol dependence.

The MAST

The Michigan Alcoholism Screening Test (MAST) is one of the most widely used self-report inventories to screen for alcoholism and alcohol problems. It has been examined in numerous research studies and has been adapted for use in many different languages. It consists of 25 items and provides a convenient measure of lifetime alcohol-related problems and alcoholism. The MAST is intended to screen for alcohol problems and therefore is not a stand-alone diagnostic measure of alcoholism. Each item is responded to in a “yes” or “no” format. Items are differentially weighted with fewer points for less-severe problems (Do friends or relatives think you are a normal drinker?) and more points for more-severe problems (Have you ever been arrested for drunk driving or driving after drinking?). A total score is provided

by summing all 25 items. Higher scores (possible range 0 to 53) indicate a greater likelihood of alcohol problems. Items tap areas of functioning including drinking behavior, consequences that occur from drinking, and prior attempts to seek or receive help for drinking and drinking-related problems.

The MAST can be administered in either oral or written format. The validity of oral and written formats appears roughly equivalent. Though several different scoring schemes exist for the MAST, the method outlined by the inventory's creator appears to be the most widely used. Accordingly, a score of 3 or less indicates no problems with alcohol, a score of 4 suggests possible problems with alcohol, and a score of 5 indicates a strong possibility of alcohol problems or alcoholism. The main disadvantage to using the MAST as a screening measure is its length. Numerous studies on the MAST have found sensitivities that range from 84% to 100% and specificities that range from 87% to 95% in assessing alcohol abuse and dependence.

The DAST

The best-known self-report inventory of drug abuse is the 28-item Drug Abuse Screening Test (DAST), a self-report measure. The DAST provides a total score based on data gathered about psychosocial, medical, and legal effects of possible drug use. Questions are responded to in a yes/no format. Sample questions include the following: Have you used drugs other than those required for medical reasons? Have you abused prescription drugs? Do you feel bad about your drug use? Have you been in trouble at work because of drug use? Have you ever been arrested for possession of illegal drugs? Higher scores indicate more problems with substance abuse. A cutoff score of 8 has been recommended; using this criterion, sensitivity has been found to be 93% and specificity 88%.

The TICS

Some screening instruments combine aspects of a brief screening tool with assessment of multiple substance use problems, namely, alcohol and drugs. One such brief inventory is the TICS (Two-Item Conjoint Screener). The TICS is a two-item screening tool to assess for alcohol and drug abuse problems intended to be used in primary care medical settings. The two items are the following: In the last year, have you ever drunk

or used drugs more than you meant to? Have you felt you need to cut down on your drinking or drug use in the last year? Using a positive score defined as two positive responses, the TICS has been found to have roughly 80% sensitivity and 80% specificity.

Conclusion

Self-report inventories are widely used to screen for substance use problems. The purpose of screening is to provide a cost-effective and time-efficient method of gathering data about the possibility of a substance-related problem. The validity of these measures is determined by the sensitivity and specificity of the measures. Numerous measures of substance-related problems exist to aid clinicians. Among the most effective measures are the self-report inventories CAGE, MAST, DAST, and TICS.

SEX ADDICTION

Sexuality is a fundamental part of living and one of several defining components of personal identity. Most people indicate that sexual pleasure augments their life. Sexual interactions provide an opportunity to share one's body and emotions with another person while supplying personal pleasure and a release for physical tensions that have built up within the individual organism. For many people the bond that emerges from jointly sharing their sexual lives affords a commitment to protect and continue their unique individual and family characteristics. It also assures the survival of the human species. Sex, like food and sleep, is considered a basic urge that most people seek and find enhancing. Yet, what happens when this basic urge spirals out of control?

Experts in the field estimate that up to 6% of the population are afflicted with a compulsion to engage in sexual activities beyond what is considered "normal" or socially acceptable. As the sexual behaviors increase and become a persistent focus, they are experienced as "unmanageable" and lead to distress for the person engaging in the activities and for their significant others. Such sexual practices may incorporate compulsively seeking sexual gratification in conventional ways, such as with consenting adult partners, or from more unconventional ways, such as with non-human objects. For example, sexual compulsions may include excessive masturbation or sexual partnering, a preoccupation with pornography, telephone sex, or fetishes and engaging in illegal activities such as voyeurism, exhibitionism, or prostitution.

Diagnostic Criteria

Although the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* does not have a distinct code for all forms of excessive sexual activities, three classifications are typically used. When the compulsion is considered more culturally common (i.e., masturbation,

serial sex partners, viewing pornography, paying consenting adults for liaisons), the disorder is typically diagnosed as either an impulse control disorder, not otherwise specified or a sexual disorder, not otherwise specified. More unconventional sexual obsessions are defined under the title of paraphilias (i.e., fetishism, voyeurism, sexual sadism or masochism). It is anticipated that the fifth edition of the *DSM* may create a new category of disorders under the heading of behavioral and substance addictions. If that were to occur, it is expected that many sexual compulsions would be determined as sexual addictions and, thus, would be included with such impulse control disorders as pathological gambling, compulsive buying or spending, and Internet addiction.

Despite the endless debates as to whether behavioral compulsions are truly addictions, the addiction model is clearly a useful viewpoint for understanding, assessing, and treating compulsive sexual behaviors. Consistent with other behavioral compulsions, sexual addiction is defined as an excessive involvement in specific or various practices that disrupt normal daily living and impede healthy functioning. A loss of time and perspective emerges from the preoccupation to satisfy cravings, rituals develop which reinforce the behavior, cravings intensify, and the ability to control thoughts and behaviors progressively decreases as pleasure-seeking behaviors become primary.

As with other addictions, a person's mood is altered by the planning, pursuit, and attainment of sexual gratification. Tolerance and withdrawal experiences develop as the person chases the original excitement; yet, the person only finds temporary relief and soon is seeking additional sexual pleasure. As the addictive cycle progresses, the compulsive sexual behavior becomes a coping mechanism for anxiety, stress, loneliness, and other negative experiences, until finally, the individual is "addicted" to the pleasure-giving neurotransmitters released during the sexual activity. The obsessive pursuit of sexual satisfaction begins to dominate while leaving the person's home and work life neglected and at risk.

A fundamental aspect of the addictive process is the sense of powerlessness to disrupt the obsessive-compulsive behavior. In this case, sex, or the pursuit of sexual activities, becomes an all-consuming priority. As efforts are made by the individual to stop the behavior, it continues despite the negative consequences. The sexually addicted individual sacrifices important people and things and often his or her own

sense of identity. Unmanageable compulsions cause some people to engage in riskier and riskier behaviors that endanger their relationships, their reputations, their careers, and even their physical survival. Clearly, the brink of disaster looms ahead for any person traversing the path of sexual addiction.

Escalating Realities

Religious doctrine, cultural mores, and personal preference typically guide sexual behavior. Yet, what is considered normal in one society may be determined as abnormal in a different one. In Western civilization, sexual activities between consenting adults are usually legally tolerated if they occur in private and without the exchange of money. It is unacceptable, however, if the pursuit of sexual gratification occurs with nonconsenting partners (children or adults), and, in fact, such behaviors are labeled crimes of violence or abuse. Because in some other societies, acceptable sexual conduct is not determined by age or by consent, societal taboos often become the ruler by which specific behaviors are judged.

Aside from sexual assault crimes, cultural variation and societal change demand that sexual addiction be defined not by the specific behavior but by the escalating process and its interference with culturally normative relationships. For example, as Internet activities expand into “real-time” engagement, it is easier for a compulsion to take hold of a person’s time, attention, and intimacies. Easy access provides new and extended opportunities for viewing pornography, seeking anonymous sexual liaisons, and supporting excessive self-stimulation. For most people, it is not the behavior of looking at sexually provocative pictures or masturbation that is problematic but the inability to stop doing so when the behavior becomes self-defeating.

As indicated earlier, the continuum from normal sexual activity to pathological sexual addiction follows a similar continuum as found with social drinking to alcoholism or recreational gambling to pathological gambling. Initially, engagement in the behavior is culturally acceptable and only one of many activities enjoyed. As the behavior progresses into an addiction, losses supersede benefits and collateral damage occurs. Compulsive sexual behaviors dismantle the addict’s self-esteem and create many conflicted emotions. Unhealthy relationships replace healthy ones, and the quest for immediate sexual satisfaction replaces the desire for emotional intimacy.

These changes catapult the sexual addict into a secret world where there is a constant fear of discovery. The guilt and shame felt for acting out sexually may become so unbearable that the addict attempts to ameliorate the pain through acting out again. As the sexual addict is trapped by the addictive cycle, personal and familial destruction soars. Secrets add to the distress about the addictive behavior itself, enlarge the feelings of shame and confusion, and damage loved ones. The secret life that develops with sexual addictions is typically more profound than that found with other “hidden” addictions.

This secrecy makes it difficult to determine accurately the prevalence of such problems. It is clear that individuals struggling with a sexual addiction begin living a distorted life. As the secret life becomes more primary than the public life, fantasy becomes reality and the problem becomes the solution. The secondary identity that develops allows sexual addicts to retreat into a world of seclusion or private engagements where sex becomes the organizing principle of life—no matter the cost. The trance-like behavior and impaired thinking found in sexual addictions creates situations where a person may misread cues, ignore risk, and expose him- or herself or significant others to embarrassment or public humiliation.

Obviously, intimate relationships suffer from the secret keeping found with sexually compulsive behavior; yet, the consequences often go well beyond the destruction of primary relationships. As news reports consistently attest, sexually addictive behaviors can create legal difficulties, endanger health, and jeopardize careers. Engaging in lewd behavior, soliciting prostitutes, or violating societal taboos may make for interesting story lines, but such activities frequently attest to the possibility of a sexual compulsion. Such reports suggest the devastation encountered from sexual addiction but generally do not discuss the possibility of multiple addictions.

Comorbidity

Numerous studies and national surveys confirm what addiction treatment providers know: Sexual addiction typically coexists with other chemical and behavioral addictions. The Society for the Advancement of Sexual Health reported in 2005 that many individuals suffering with sexual compulsivity have overlapping symptoms with alcohol and drug addiction, food addiction, and pathological gambling. Because of

Patrick Carnes's seminal work with individuals and families suffering from sexual addictions, his studies and understanding of the interrelated issues in multiple addictions are most quoted. As other researchers and treatment providers review Carnes's numbers and do their own studies, the following comorbidity rates are consistently detailed: More than 40% of individuals struggling with sexual compulsivity also have a chemical dependency; approximately 38% indicate an eating disorder; slightly more than 25% specify problems with compulsive working or compulsive spending; and 5% suffer from compulsive gambling.

Whether these numbers will remain consistent as cyber-sex addiction grows is uncertain. What is clear is that the Internet has decreased inhibitions and made shopping, gambling, and sexual voyeurism readily obtainable. These thriving "businesses" have decreased barriers, encouraged compulsivity, and connected differing addictions more closely together while subtly suggesting their normalcy. The anonymity and availability creates a belief that most people are engaging in such behaviors, making it easier for addicted individuals to go further into their compulsions. The advent of the Internet sex business, specifically, provides increased opportunities for seeking arousal without as much societal inhibition.

The reality of multiple addictions reinforces the need to look at the scope of compulsive behaviors and substance abuse. Because addicted individuals often exchange one addiction for another, it is critical to understand the overlapping symptoms and prevalence factors. In addition, because sexual addiction is highly correlated with the likelihood of childhood emotional, sexual, and physical abuse, multiple addictions and psychological difficulties run rampant. Trauma histories, fear of discovery, and shame leave many sexual addicts extremely distraught. It is not uncommon to discover sexual addiction co-occurring with other psychiatric disorders. Similar to alcohol and drug abuse or dependency, mood disorders of depression, dysthymia, and anxiety are extremely widespread. Consideration must be given to these concomitant issues, or unrecognized problems can remain hidden, magnifying the potential for relapse.

Treatment

Due to the overlap of addictive problems, it would not be uncommon for individuals dealing with several addictive issues to present with the problem

they perceive as more socially acceptable. While the stigma of chemical dependency and some behavioral addictions is lessening, the stigma of sexual addiction remains strong. Because of this stigma, sexual addiction is frequently discussed only when a person has already entered substance abuse treatment or the sexual compulsivity has become severe enough to come out of hiding. With this in mind, it is critical to assist sufferers in revealing this issue so that it can be treated concomitantly and not become either a replacement addiction or a vehicle for relapse of the initial addiction.

In 1983 Patrick Carnes's book *Out of the Shadows: Understanding Sexual Addiction* helped illuminate this hidden addiction, propelling addiction counselors to begin discussing more openly this major concern of many clients. Since that time, it has become clear that the addictive and debilitating journey of sexual compulsions is as damaging to the individual and his or her family as are drug and alcohol problems. It has also become clear that attention to this compulsion encourages individuals to face their problem, enter treatment, and develop effective methods for changing their lives.

The similarities found across substance and behavioral addictions have given some direction to sexual addiction treatment considerations. For example, early treatment of any addictive disorder typically includes a combination of psychotherapy, education, and a Twelve-Step program. Attention is given to abstaining from the dysfunctional behavior by understanding when danger is lurking and how to change the situation or the learned response to something new. As the addicted person realizes relapse risks, his or her self-awareness increases. Self-understanding often allows for an improvement in communication skills and the ability to regulate affect. Later recovery brings deeper insights, improved relationships, increased self-esteem, and a new ability to deal with lifelong issues.

In the case of sexual addiction, individual, group, and family counseling, in concert with a variation of the Twelve-Step approach, appears to be the most useful. Involvement in groups (whether self-help or professionally led) provides an opportunity to reduce the isolation and secrecy inherent in sexual compulsivity. In therapy, group members challenge each other's perceptions of "normal" thoughts and behaviors while providing support for, and understanding of, the need to find healthier outlets for sexual desire. Through self-help,

people engaged in recovery advocate facing addiction honestly, seeking spiritual rather than sexual connections, and discovering tools for shame reduction.

Whether individuals with a sexual addiction enter treatment voluntarily or due to legal sanctions, therapeutic needs demand a multimodality approach. Cognitive-behavioral tools help identify and manage relapse triggers, reduce anxiety, and teach skills to deter acting out sexual compulsions. These tools are frequently taught in psychoeducational groups and utilized in individual counseling. As recovery extends, insight-oriented or existential approaches assist individuals to deal with some of the underlying issues that have made them more vulnerable to the development and the continuation of this specific addiction. These approaches provide avenues for addressing emotional residue and distorted thinking left behind by childhood traumas or their own past actions.

Finally, family treatment is critical to healing the many wounds of sexual addiction. The betrayal and sense of powerlessness that significant others suffer must be addressed if they or the addicted person is to achieve any resolution. Such efforts propel recovery whether these relationships continue intact or not. Most important, understanding that compulsive behaviors are not the fault of the family member reduces dysfunctional patterns that hinder the development of healthy and loving relationships for all.

Twelve-Step fellowships have formed for many addictive concerns. Support groups that have organized to assist people affected by sexual addictions include Sex Addicts Anonymous, Sexaholics Anonymous, Sexual Compulsiveness Anonymous, Sex and Love Addicts Anonymous, S-Anon/S-Ateen International Family Groups, and Codependents of Sex Addicts. The fact that so many groups have been established to help those dealing with sexual addictions suggests the value that is placed on finding a network of support when facing this difficult issue.

Recovery from sexual addictions, like recovery from substance addictions, is a lifelong process. Interrupting the behavior and providing informed treatment opportunities for those afflicted with such a devastating problem requires everyone to emerge from the veil of secrecy. Clearly, understanding and addressing the many factors that lead to such an addiction provide the best defense against its escalation in our communities, our families, and our individual lives.

SEXUALLY TRANSMITTED DISEASES

Sexually transmitted diseases (STDs) are infections that are transmitted from one person to another primarily through sexual contact. However, these diseases can also result from the use of contaminated drug injection equipment and in utero. Researchers have identified more than 20 different STDs, which are categorized into two main groups. STDs caused by bacteria can be treated and often cured with antibiotics. Some bacterial STDs include chlamydia, gonorrhea, syphilis, and trichomoniasis. STDs caused by viruses can be controlled but not cured. Viral STDs remain in the human body permanently. Some viral STDs include cytomegalovirus, genital herpes, genital warts, hepatitis B virus, HIV/AIDS, and human papilloma virus (HPV).

The use of alcohol and other illicit drugs has a tremendous impact on the rate of transmission of STDs. Individuals who are heavy or binge drinkers or use other illicit drugs are more likely than their sober counterparts to contract STDs. Binge drinking is defined as the consumption of more than five alcoholic beverages within a few hours. Heavy alcohol use, which includes binge drinking, is defined by consumption of five or more alcoholic beverages on the same occasion on 5 or more days within the past 30 days. Illicit drug use refers to the use of any inhalants, hallucinogens, nonmedical use of prescription or over-the-counter medications, cocaine and cocaine derivatives, methamphetamines, opioids, and marijuana. People who use drugs, alcohol, or both are more likely to engage in the following high-risk behaviors due to lowered inhibitions: unprotected sex, multiple sex partners, intercourse with prostitutes or injection drug users, and the exchange of sex for drugs or money. Additionally, the effects of drug or alcohol abuse may be used to reduce conscious awareness of risk for individuals who would not participate in such activities in an unadulterated state.

Comorbidity of mental health and substance abuse issues has been linked to increased levels of transmission of STDs due to an increase in high-risk behaviors. Mental health factors such as manic episodes, depression, and delusional thoughts may inhibit a person's decision-making processes and alter their normative responses. Hypersexuality, a behavior commonly associated with substance abuse, has a direct impact on the rates of infection in populations affected with comorbid conditions. Consequently, substance use may be used to minimize the adverse psychological effects of shame-based behavior of impulsive sexual experiences.

In 2005, the Centers for Disease Control and Prevention reported more than 976,445 new cases of chlamydia, 339,593 new cases of gonorrhea, 266,000 new cases of herpes, and 8,724 new cases of syphilis. There are numerous research studies that report that younger adults who consume illicit drugs or alcohol, ages 18 to 25, are more likely to contract a sexually transmitted disease than are older adults. It has been estimated that more than half of the new HIV infections are among people under the age of 25. Since the HIV/AIDS epidemic began, intravenous drug use has accounted for more than 36% of all new infections. Racial minorities in the United States are the most heavily affected population by AIDS resulting from IV drug use. Forty-three percent of cumulative AIDS cases reported among adult and adolescent Hispanic

males were directly or indirectly related to injection drug use, as were 43% among African American males. The female population infection rates surpass their male counterparts. Fifty-eight percent of cumulative AIDS cases reported among adult and adolescent Hispanic females were directly or indirectly related to injection drug use, as were 57% of cases reported among White females and 51% among African American females. By comparison, only 18% of the cumulative AIDS cases reported through 2002 among White males were directly or indirectly related to injection drug use. Noninjection drugs (such as "crack" cocaine) also contribute to the spread of the epidemic when users trade sex for money or when they engage in high-risk sexual behaviors while under the influence of drugs. One study of more than 2,000 young adults conducted by the Centers for Disease Control and Prevention in three inner-city neighborhoods found that crack smokers were 3 times more likely to be infected with HIV than nonsmokers.

Substance abusers, who are often struggling with legal and financial concerns, are more likely to be carrying an STD, because they tend to be avoidant of health care services. A large percentage of substance abusers are of low socioeconomic status and are less likely to have access to quality health care. Female substance abusers are less likely to have regular gynecological exams or physicals. High-risk pregnancies are associated with substance abusers. Many women neglect to get the proper prenatal care. At times, STDs are diagnosed at the latter stages of pregnancies and therefore the fetus can be affected with birth defects and physical ailments.

Both males and females engaged in heavy substance use are also likely to ignore the physical symptoms of STDs and are often unaware of the diseases that they carry. Altered mental states due to substance abuse and unprotected sex often go hand in hand, but access to adequate health care is usually not a priority for those in the drug culture. There are many programs that provide condoms, birth control, and clean needles to substance users. However, sobriety is often the prerequisite for individuals to decrease high-risk behavior. Safe sex education and relapse prevention are crucial to the decline in the transmission of STDs for those grappling with substance abuse.

SHOPPING ADDICTION

For some people, shopping is a necessary evil, to be done only when cupboards are bare and clothes have holes. Others find shopping for a “bargain” to be a fun and energizing activity that brings a sense of accomplishment. Yet, according to a 2006 study reported in the *American Journal of Psychiatry*, nearly 6% of the population indicate they have difficulty resisting shopping to the point that it creates financial and emotional problems. When people buy items they don’t need or can’t afford frequently enough to bring negative consequences into their lives, it can be termed an addiction.

Compulsive buying (oniomania) is diagnostically classified in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* as an impulse control disorder, not otherwise specified. This category includes other compulsive behaviors, such as obsessive Internet use and sexual addictions. The criterion of increasing physiological and emotional arousal prior to the act with a decrease in arousal and feelings of guilt after the act certainly reflects many compulsive shoppers’ experiences. Such shoppers state that they have an increasing sense of excitement during shopping, then feel exhilarated with the purchase, and have an expectation of feeling better after returning from their adventure. Most, however, indicate that the aftereffects include feelings of anxiety, remorse, and worry. The intensity of emotions that are activated by a shopping experience helps explain the difficulty in managing the impulse.

Another criterion for the diagnosis of an impulse control or addictive disorder is the recurrent failure to resist doing the behavior even though to continue to do so has become harmful to one’s life. Many compulsive buyers indicate that their efforts to stop the behavior are frequently unsuccessful even as negative consequences increase. Continual spending in the face of financial problems, marital distress, guilty feelings, and irritable behavior at work and home confirm compulsive shopping’s classification as an addiction.

Individuals with an addiction look to their substance or behavior of choice to feel better. Although compulsive shoppers might celebrate a good event in their life by buying a special item, they are more likely to go on a spree when they are feeling down. The distraction of shopping allows feelings of loneliness, depression, and anger to be temporarily dissipated and ignored. Many feel a rush of excitement when they are “on the hunt,” and the immediate gratification of buying can be fulfilling and create a sense of relief. This relief from negative feelings is intensified by the thrill of having something new to enjoy.

The ability to temporarily change one’s mood when feeling sad or bored can become quite enticing. The fantasy world that is created when shopping adds to its addictive quality. Similar to gambling, shopping often provides opportunities for a person to feel “special.” The relationship that develops between the shopper and the salesperson is one-sided but intimate. The salesperson waits on the shopper, shows respect, listens, and attempts to find things that please the shopper. The sense of importance and significance that such attention can create in the shopper counters negative feelings and adds to his or her self-esteem. To complete the social transaction and the aggrandized sense of self, the shopper makes the purchase. Many shoppers report the sense of pressure they feel to complete this interaction with the salesperson. Buying the items also supports their new, idealized sense of self.

If the compulsive buyers’ fantasy is to see themselves as stylish, for example, they might become obsessed with buying clothes, shoes, or jewelry. If they view their ideal self as active, they might obsessively purchase new sports equipment. If they idealize benevolence or affluence, they might buy extravagant gifts for friends and relatives. Frequently, shopping and spending, not the item purchased, becomes the desired goal. In fact, it is not uncommon for compulsive buyers to purchase items that they never use or for which they actually have little need. The purchases reinforce the fantasized self, thus making it difficult to return the item after purchase.

Compulsive shopping and spending has previously been viewed more as a disorder of women. Recent studies have shown, however, that both men and women appear to be affected equally. Although compulsive buying can occur whenever someone wants to change his or her mood, winter and the holiday season frequently bring an increase in overspending.

The holidays can trigger shopping binges among many noncompulsive buyers, but “shopaholics” are even more in jeopardy of getting caught up in impulse buying. Loneliness and depression, at higher rates during the winter, are exaggerated by the expectations of the holidays. It is no surprise then that the fantasy world of shopping would call to the addicted individual. Escape is just inside the next store.

As stated previously, shopping addiction has many parallels with pathological gambling. Both provide easy access to the desired outcome (i.e., escape, excitement, attachment) in the moment but wreak havoc on one’s emotional, financial, and relationship health in the long run. The resulting debt only adds to the original feelings of depression and disappointment with one’s life or one’s self. Additionally, compulsive shoppers and gamblers often have other addictive behaviors. It is not surprising that the vicious cycle is hard to break.

Because addictive behaviors tend to congregate and many compulsions have co-occurring stressors, it is useful for the compulsive shopper to seek professional help or attend support groups. For example, strategies aimed at stopping gambling or drinking can also be useful to a person attempting to stop impulse buying. The fellowships of Alcoholics Anonymous and Gamblers Anonymous, as well as the availability of meetings, provide alternatives to trying to get a “quick fix” at the retail store. As many compulsive shoppers are attempting to soothe their unhappy feelings, treating the mood and interpersonal issues that surround shopping binges helps many impulse buyers. Psychological and family treatment can assist with changing the factors that trigger some shoppers’ binges. Another option, credit counseling, can provide a direction to remedying the financial component caused by the excess spending while helping a person begin anew.

Most important, developing a plan of action aimed specifically at compulsive buying is crucial to fighting the intense impulse of this addiction. Activities that decrease access, availability, and opportunity are most useful. For example, getting rid of credit cards and leaving checks at home so that purchases can be made only with cash decreases the ability to buy impulsively. Avoiding discount stores, large shopping malls, and advertisement catalogues decreases availability. Window shopping after hours or without a wallet eliminates access. Finding replacement activities that change one’s mood without the detrimental consequences focuses a person on new opportunities.

Finally, making a list of what is needed prior to shopping and limiting the amount of time set aside for shopping provides a structure to the outing.

Although excessive shopping and spending is a behavior that can become addictive, change is possible. Treatment and conscientious attention to methods of eradicating compulsive spending can help life become more manageable. As a person determines the triggers that engage his or her interest in shopping and understands the emotions underpinning the impulse, he or she will be able to address change directly.

SINGLE STATE AUTHORITIES

Federal legislation requires each state to have a single state authority (SSA) responsible for coordinating alcohol and drug prevention and treatment activities for the state. This entry describes the development of the SSA concept and outlines the relationships with the Hughes Act and the Uniform Act.

Development

In the 1960s, community responses to chronic alcoholics relied on jails and imprisonment—detoxification in drunk tanks and sentences to county workhouses for drying out. Systems for rehabilitation and treatment developed only after laws that permitted incarceration of individuals for public drunkenness were challenged in court and found to be unconstitutional. Following U.S. circuit court (*Easter v. District of Columbia*; *Driver v.*

Hinnant) and Supreme Court (*Powell v. Texas*) rulings that homeless individuals could not be convicted for public inebriation, states decriminalized public inebriation and developed systems of care for individuals with alcohol disorders. The Comprehensive Alcohol Abuse and Alcoholism Prevention and Treatment Act of 1970 (P.L. 91-616; also known as the Hughes Act after its chief sponsor, Senator Harold Hughes, a recovering alcoholic and former governor of Iowa) required states to prepare comprehensive plans for the treatment of alcoholism and created a federal agency (the National Institute on Alcohol Abuse and Alcoholism) to support and promote alcoholism prevention and treatment services and research. The Hughes Act also amended federal legislation to require that state health plans include services for the prevention and treatment of alcohol disorders. SSAs were mandated as the mechanism for the coordination of services and the distribution of federal resources for alcohol and drug treatment.

The legislation that led to the establishment of state alcoholism prevention and treatment authorities was frequently based on the 1971 Uniform Act (model legislation that decriminalized public inebriation and established a state infrastructure for the treatment of alcohol disorders).

SSAs were authorized to plan and establish treatment and prevention programs, contract for services, accept federal funds, and conduct research. Specific duties include developing state and regional plans, coordinating services with other state agencies, sponsoring education and training, collaborating with persons in recovery to promote voluntary treatment admissions, promoting employee assistance services, developing interventions for drunken driving, promoting inclusion of alcohol treatment benefits in health insurance, and discouraging discrimination against alcoholics in hospital admissions. The Uniform Act created a governor's advisory council on alcoholism to advise the state authority on broad policy goals. The state authority is required to establish comprehensive treatment services with regional access, including inpatient, residential, outpatient, and follow-up services. The state authority is mandated to develop program standards and to inspect services to assure continued compliance with the standards; the standards include requirements to submit annual data on services provided. Although the Uniform Act has a clear preference for voluntary treatment, the state authority is also empowered to provide services for involuntary commitments.

Reauthorizations of the Hughes Act created incentives and encouraged states to adopt the Uniform Act and increased resources for the SSAs. An evaluation of the Uniform Act and its implementation noted that the most important facet of the act was the establishment of a state alcoholism authority with explicit powers and responsibilities. The structure of the alcoholism authority was replicated when the National Institute on Drug Abuse was created and mandated a state authority for the treatment and prevention of drug disorders. Over time the alcohol and drug authorities have been integrated and, in many states, further merged into mental health services. In the process, some state authority planning and research functions have withered or been abandoned. Join Together reviewed how states organize and deliver alcohol and drug prevention and treatment services in 2006 and recommended that states revisit and update authorizing legislation to maintain a strong and effective state authority for the prevention and treatment of alcohol and drug problems.

Provisions of the Uniform Act Related to the State Authority

A "division of alcoholism" was created within the state's department of health or mental health (Section 3 of the Uniform Act). Eight broad powers were specified in Section 4:

1. Plan and maintain treatment programs.
2. Contract for services.
3. Solicit resources from the federal government.
4. Administer state plans submitted to the federal government.
5. Coordinate with treatment services in the state and other states.
6. Keep records and conduct research.
7. Perform other necessary activities.
8. Acquire and dispose of property for treatment facilities.

Section 5 articulated 17 duties:

1. Develop state, regional, and local plans for prevention and treatment of alcohol disorders.

2. Coordinate public and private agencies interested in prevention and treatment of alcohol disorders.
3. Cooperate with the departments of corrections and parole to establish and conduct programs to treat alcoholics and intoxicated individuals in penal institutions or on parole.
4. Cooperate with the department of education, schools, police, courts, and other interested parties to establish prevention and treatment services and to develop prevention curricula for all levels of school education.
5. Prepare and disseminate educational materials.
6. Develop and disseminate information concerning the effects of alcohol.
7. Organize training programs for persons treating alcohol disorders.
8. Sponsor and encourage research on alcoholism and treatment and serve as a clearinghouse for information on alcoholism.
9. Specify methods for keeping and collect statistical information on treatment services, including number treated, frequency of admission and readmission, and duration of treatment.
10. Advise the governor and prepare a comprehensive plan for treatment of alcohol disorders to be included in the state's health plan.
11. Review all state plans submitted for federal funding and advise the governor on provisions related to alcohol disorders.
12. Cooperate with alcohol treatment services for employees of state and local governments and business and services in the state.
13. Work with individuals in recovery to encourage voluntary admissions to treatment.
14. Cooperate with public safety to address drunken driving.
15. Encourage general hospitals to admit intoxicated individuals and to treat them appropriately.
16. Encourage insurance programs to include alcohol treatment benefits.
17. Submit an annual report on activities.

The SSA remains the primary mechanism for planning and coordinating addiction prevention and treatment services in each state. The state authority is the

conduit for federal funding for alcohol and drug abuse prevention and treatment services; it prepares the Substance Abuse Prevention and Treatment Block Grant application and distributes the funding throughout the state.

SOBRIETY

The term *sobriety* is commonly used to express the idea of abstinence from the consumption of alcohol, drugs, or both. However, in its Latin roots (*sobrius*, *sobrietas*) and continuing in its Medieval and Renaissance uses, the definition of sobriety is to be temperate and moderate in the indulgence of appetite. In the 16th century, *Sobrietie* was defined as “a bridelyng by discrecion the wilfulnesse of desire.” By the mid-20th century, sobriety came to mean total abstinence from any consumption of drugs, especially alcohol. The American Society of Addiction Medicine defines recovery as a state of “complete abstinence” from all psychoactive substances combined with a satisfactory quality of life. This shifting definition, from one of temperance to one of abstinence, is indicative of a larger issue concerning the history of substance use in the United States: Ideas of how to conceptualize drug use have remained inextricably intertwined with judgments about the morality of the user. In turn, such ideas have also framed our understanding of what counts as sobriety and, more broadly, recovery.

A comprehensive look at the history of substance use in the United States reveals that different moral judgments have been placed on (a) the substances that addicts use, (b) the people who consume them, and (c) whether those substances are consumed for

medicinal purposes or in the pursuit of pleasure. This latter distinction functioned in the 19th century to frame the issue of drug consumption in a manner that put the nonmedical uses of addictive substances in contention with moral values. At that time, addiction was viewed as an acquiescence of rationality to the indulgence of habit. However, the concept of “habit” in the 19th century was more in reference to the weak will of the individual than to the pharmacological properties of drugs and medicines. Persistent Christian and Victorian values in the American cultural tradition have resulted in a tendency to frame the pursuit of pleasure as sinful, and the taking of drugs for nonmedical reasons was seen as an indulgence in the pursuit of pleasure. Another factor at play is the Western European intellectual tradition that has stigmatized the pursuit of pleasure as evidence of one’s primal instincts exercising dominance over one’s intellect. This history has helped frame substance use, sobriety, and recovery often as moral issues.

Consequently, there is a current lack of consensus over how to define sobriety and recovery from substance use disorders. Among treatment professionals and “sober” and “recovered” persons, there is confusion and contention over when and how sobriety or recovery is achieved, lost, and regained. This entry discusses the most common paradigms of sobriety as related to the broader objective of recovery and discusses the pros and cons of each.

The Abstinence Model

When addiction first came to be a widely acknowledged problem in the United States in the late 19th century, drugs of abuse were not illegal, and there was no national ethos stressing total abstinence as a morally superior state of being. On the contrary, in the late 18th and early 19th centuries, many temperance associations stressing moderation in consumption arose in the newly united colonial states. Alcohol was considered one of the many gifts God had bestowed upon humankind; only its abuse was considered the work of the devil. However, with the advent of the Progressive movement, the 1914 passage of the Harrison Narcotics Act banning nonmedically prescribed drug use, and the beginning of Prohibition in 1920, a new cultural ethos insisting on total abstinence from drug consumption took hold and the meaning of sobriety took on this new definition as well.

Framing drug use and recovery as a medical issue has its roots in the struggle to classify alcoholism as a disease rather than a vice or moral failing. When alcohol was viewed as a vice, those who indulged in such sinful behavior were said to be deserving of punishment, not treatment. Organizations created to help alcoholics (such as Alcoholics Anonymous [AA], created in 1935 shortly after the fall of Prohibition in 1933) realized that to escape social stigma, gain acceptance for the idea of compassionate treatment rather than punishment, and raise funding for such treatment, alcoholism needed to be reconceptualized as a disease resulting in behaviors beyond the control of the afflicted individual.

In the early years of the organization, members of AA internally debated which strategy was most efficacious toward their recovery: reduced, moderate consumption or total abstinence. For those whose problem drinking was most severe, total abstinence seemed the only successful approach for long-term successful management of their condition. They did not deny that those with less-severe drinking problems could return to moderate respectable “social” drinking. However, those persons were not the ones who most frequently went to AA for support. The organization therefore evolved to be of the most use to those with the most-severe drinking problems, and thus the total abstinence model of sobriety became AA’s standard.

A complicating but noteworthy factor in this history is the severe cultural stigma that was attached to being an alcoholic and how that social stigma had to be politically negotiated. What helped the AA campaign reconceptualize alcoholism as a disease was the fact that many alcoholics were prominent White professional men with great influence. Through an extensive lobbying campaign, support was gradually gathered for the reconceptualization of problem drinking. The powerlessness of the individual to make decisions to control drinking was emphasized as the only way to convince the general public as well as politicians that alcoholism could only be treated effectively with medical intervention rather than penal sanctions. This lobbying resulted in the decision taken by the World Health Organization in 1951 to classify alcoholism as a disease, done mainly to combat the idea that alcoholism and drunkenness were immoral vices.

Following AA’s lead, many other substance use disorder treatment organizations—whose clients tend to present problems of greatest severity—have also come to rely on the total abstinence model of sobriety

as their standard. Most recently, the Betty Ford Institute published a working definition of recovery, defining it as a voluntarily maintained lifestyle of sobriety, personal health, and citizenship, where sobriety was defined as complete abstinence from alcohol and all nonprescribed drugs.

However, this definition of sobriety as used by many treatment and recovery organizations is inconsistent with the published literature from addiction researchers which suggests that among all persons with substance use disorders, at least three levels of sobriety could be considered successful: (1) those who observe total abstinence, (2) those who consume very little on rare occasions without negative consequences, and (3) those who have shifted to maintenance use and are still dependent but have managed to mitigate the negative consequences of their use. The latter are examples of the harm reduction model. Consistent with the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* definition of addiction—compulsive drug seeking and use, despite harmful consequences—harm reduction models of sobriety and recovery take as their approach managing and eliminating the harmful consequences of substance use and avoid placing a value judgment on the continuation or discontinuation of drug use.

The Harm Reduction Model

The introduction of methadone maintenance treatment for heroin abusers in the 1960s—championed by Marie Nyswander and Vincent Dole—ushered in a new counter-model of harm reduction among treatment professionals. This model has its roots in the mid-20th-century history of drug prohibition. Early 20th-century treatment centers dispensed opioids, with gradually decreasing doses, to prevent negative withdrawal symptoms. However, the U.S. government feared that addicts continued to enjoy open-ended use because of inconsistent monitoring. This led federal authorities to shut down most private addiction treatment facilities for continuing to dispense opioids as part of their treatment. In the 1930s and 1940s, two federal substance abuse treatment prisons, at Lexington, Kentucky, and Fort Worth, Texas, called “narcotics farms,” were established to deal with the rising number of addicts being arrested and incarcerated. These were run by the National Institute for Mental Health (NIMH) under the direction of the Public Health Service (PHS). The NIMH

standard treatment philosophy was that recovery meant abstinence: Addicts were to be treated by giving them gradually decreasing doses of opioids through withdrawal until they reached total abstinence, followed by psychiatric treatment.

With the fall of Germany in World War II, the United States gained access to a new synthetic opioid developed by German scientists called methadone. The U.S. narcotics farms began using methadone regularly to wean addicts off of other drugs while Nyswander was stationed at Lexington as a physician between 1945 and 1950. Methadone showed great promise because it could satisfy drug craving without delivering euphoria. This took the addict’s mind off of drug craving and seeking the next “hit,” which allowed persons being treated with methadone to resume somewhat normal life routines. But methadone fell out of favor with PHS researchers because they found it to be just as addictive as any other opioid. They were troubled by the fact that there could be no end to methadone administrations without the threat that the addict being treated might resume intense drug craving.

The problem of chronic relapse was the primary concern of all treatment professionals. When Nyswander left the PHS and teamed with Dole to research innovative addiction treatment in the early 1960s, the two hypothesized that the constant use of a drug to the point of dependence caused a permanent and irreversible metabolic change in the nervous system of the addict. The implication of this hypothesis was that a recovering addict needed some form or kind of opioid in his or her system to compensate for this metabolic disease and reach a point of normalcy. Nyswander thought back to the Lexington methadone trials and reconsidered the PHS view that continued opioid maintenance as a form of treatment was immoral because it did not lead to abstinence. If a substance such as methadone could be administered regularly to addicts seeking recovery, it would allow them to resume a nearly normal lifestyle and thus reduce the harm caused by their addiction. They reasoned that this approach was surely no less moral than other treatment approaches that showed high rates of relapse.

The Bureau of Narcotics and Dangerous Drugs, which oversaw all addiction research during this period, was vehemently against maintenance programs that supplied addicts regular doses of opioids. However, heroin abuse was such a problem at the time and the initial research findings of Nyswander and Dole were

so promising that they were allowed to continue. By the late 1960s, methadone maintenance programs had shown so much success in reducing crime by drug addicts in major U.S. cities—principally New York and Washington, D.C.—that it became the major part of President Richard Nixon’s original War on Drugs launched in 1972. The research efforts of Nyswander and Dole helped bring the treatment of addiction back into the medical profession where it had waned over the previous 40 years, and their hypothesis that addiction was a metabolic disease helped lead to the discovery of opioid receptors, central to the present medical understanding of addiction. Their efforts also made the harm reduction model a viable option for substance abuse treatment professionals.

Today there remains widespread use of the harm reduction model. There is no agreement as to whether alcoholics whose current use of alcohol is blocked by taking naltrexone, acamprosate, or disulfiram constitute persons in recovery. Similarly, there remains no consensus whether those in treatment for opioid addictions with the aid of taking buprenorphine or methadone constitute persons in recovery. Internationally, such substitute opioid maintenance programs are less stigmatized and accepted as viable recovery options. Many treatment professionals continue to operate treatment programs where the reduction of drug use, criminal involvement, unemployment, and other related negative consequences are the standards for successful recovery. There remains, however, widespread disagreement among treatment professionals whether the harm reduction model, meaning temperate controlled drug use without the negative consequences, constitutes true sobriety or recovery.

Present Conceptions and Continuing Controversies

The current prevailing biomedical model of addiction, according to the National Institute on Drug Abuse, defines addiction as a chronic, relapsing brain disease characterized by compulsive drug seeking and use, despite harmful consequences. This model is largely the result of new scanning and imaging technologies (e.g., magnetic resonance imaging) that have provided evidence of how drugs change the brain in both structure and function. These brain changes can be long lasting and are correlated with harmful behaviors seen in people who abuse drugs. Paradoxically, the defining

of drug addiction as a disease predated the technological advancements in neurological study on which the brain disease model is based.

This paradox highlights the fact that defining substance use disorders as a disease has been part political strategy to circumvent the moral debate over the behavior of those who consume substances of abuse and win broad support for their treatment rather than punishment and social stigmatization. In doing so, however, advocates for the disease model of addiction have often insisted upon the powerlessness of the individual to control his or her behavior. This also contradicts substantial evidence that getting on the path to recovery from addiction is sometimes instigated by a critical event that changes the addict’s perspective and motivation to pursue sobriety with vigor and a determination that yields very low relapse rates. Also, substance abuse is a disease for which both etiology and cure are profoundly dependent upon social, economic, and cultural variables.

Evidence suggests that the total abstinence model of sobriety yields the most successful results, avoiding relapse for those whose substance use disorder is the most severe. Analogously, the harm reduction approach to sobriety and recovery can, and often does, yield successful results for those whose substance use disorder is less severe.

Like diabetes, hypertension, cardiovascular disease, and the other chronic diseases that ail the American public and which are also heavily influenced by social variables, our understanding of substance use disorders as diseases must not allow our society to explain away or obscure the major underlying problems and thus disregard and fail to deal with the cultural, social, psychological, and economic factors that contribute to drug abuse. As a society our contemporary understanding of sobriety should not simply focus on the abstinence from or moderation of consumption of substances of abuse. Instead, working toward sobriety should encompass working to address those underlying problems.

Practical Resources Guide to Achieve Sobriety

The history and definition of sobriety are philosophical and complicated. In the United States, abstinence has been the predominant goal of addiction recovery, whereas in Europe, harm reduction has more adherents. The future goals for substance use treatment professionals should integrate harm reduction and abstinence into

a multifaceted spectrum of recovery, starting with educating drug users about safer drug use to reduce negative consequences, then to manage drug use, and ultimately to achieve a healthy lifestyle. Any change of drug-using behavior should be a good start for an individual to achieve sobriety and eventually become a productive citizen of society. Contemporary treatment professionals utilize many different pathways to achieve sobriety, such as faith based, spiritual based, nonfaith or nonspiritual based, holistic, and harm reduction. Persons on the road to recovery will need to find the right program(s) or treatment(s) to fit their needs.

SOCIAL DRINKING

Social drinking is the consumption of alcohol within limits to induce socialization and to participate in cultural norms. Individuals partaking in social drinking

do so for many reasons, including as a social lubricant at parties or bars, with meals, at family functions, among friends, on a date, or as part of cultural traditions. The consumption of alcohol in a safe, legal, and responsible manner and keeping one's blood alcohol level lower than legal limits are within the realm of social drinking. Social drinking does not include consumption of excessive amounts of alcohol. Obviously, if a drinker experiences negative consequences from alcohol consumption (e.g., being arrested for driving under the influence [DUI], vomiting, blackout), this is not considered social drinking. Social drinking is also referred to as moderate drinking. The commonly accepted definition of moderate drinking is consumption of two drinks per day for men and one drink per day for women. Social drinking is prevalent throughout society, and patterns are often determined by family and peer influence, socioeconomic factors, cultural and demographic factors, and alcohol advertisements.

Family and peer attitudes toward alcohol and societal norms affect individuals' social drinking patterns. Social drinking behaviors can begin as early as adolescence and evolve throughout one's life. Young people's alcohol use is often modeled after parental drinking behaviors, alcohol expectancies, and peer influences. The need to facilitate peer interactions and foster socialization may increase an adolescent's probability of participating in social drinking. In addition, misconceptions about alcohol use among peers influence adolescent and young adult social drinking behaviors. Adolescents' perceptions of quantity, type, and setting of alcohol consumption among peers may determine drinking patterns. Social drinking attitudes may also shift because of life-changing events, including increased responsibility, career changes and promotions, new financial obligations, marriage, and parenthood.

Socioeconomic status is also related to alcohol consumption. Individuals from different socioeconomic groups may have different attitudes toward alcohol consumption. Socioeconomic status can also be a determinate of type of alcohol consumed and manner in which it is consumed. Types of bars, parties, and events may determine the type of social drinking that occurs, and the motive for consumption can often be linked to socioeconomic status.

Cultural norms describe the function of social drinking and often set limits for individuals to abide by these norms. Narrowing down drinking patterns among ethnic minorities in the United States is difficult because

of the many subgroups within each population. Moreover, a number of influences affect the drinking patterns of each ethnic minority group. These may include cultural norms, attitudes toward drinking, socioeconomic stress, historical factors, racial tensions, availability of alcohol, regional norms, local laws, employment, marital status, and personal values.

Traditional Hispanic cultural norms, although not representative of all subgroups, endorse alcohol consumption by males and promote abstention among females. The “machismo” cultural norms describe the behavior of Hispanic males as more likely to partake in social drinking. African Americans report higher rates of abstinence from drinking than do Caucasians. As in the Hispanic population, there is no clear sense regarding drinking patterns among the diverse subgroups of Asian Americans. Low levels of alcohol consumption among Asians are linked to ancient Confucian and Taoist philosophies focusing on harmony. Other Asian cultural influences stress responsibility and promote moderate drinking behaviors. In addition, drinking in many Asian cultures takes place in social situations in which it is expected that moderate drinking will occur. Native American social drinking behaviors vary from tribe to tribe. Many Native Americans abstain from alcohol use, while others partake only in social contexts. In many instances Native Americans may refrain from consumption and reduce alcohol consumption as they assume tribal responsibilities. In other instances members of this population may consume at dangerous levels.

The mass media in the United States populates billboards, magazines, and television with individuals participating in alcohol consumption. Media portrayals often include attractive, successful, adventurous individuals enjoying the perceived positive benefits of alcohol consumption, including social acceptance, romantic attraction, camaraderie, and general pleasure. Pro-alcohol media never include images of the negative consequences of consumption. This positive image affects the social drinking attitudes and perceived social drinking patterns that individuals may strive to adopt. Media portrayals can greatly impact how adolescents and young adults view drinking behaviors and perceived results of social acceptance. In addition, social drinking behaviors and cultural norms are not always accurately represented in the media.

Social drinking attitudes and behaviors include the responsible intake of alcohol to increase social interactions. Social drinking may also be associated with moderate drinking or the consumption of safe levels

of alcohol (i.e., two drinks for men and one drink for women per day). Social drinking behaviors are influenced by a number of factors, including family and peers, socioeconomic status, demographic and cultural norms, and the media.

SOCIAL LEARNING MODEL OF ADDICTIVE BEHAVIORS

The social learning model posits that behavior is learned and can be explained by the reciprocal interactions among behavioral, cognitive, and environmental or situational determinants. Key concepts in the social learning model include learning via direct experience and through indirect means of modeling and the idea that learning experiences are mediated

through cognitive processes. Applied to addictions, the social learning model suggests that drug and alcohol use are learned behaviors and that such behaviors persist because of differential reinforcement from other individuals, from the environment, from thoughts and feelings, and from the direct consequences of drug or alcohol use. Within the social learning model of addictive behaviors, treatment of alcohol and drug use behaviors focuses on how individuals might unlearn addictive behaviors. Moreover, treatment may target the learning of alternative or replacement behaviors (i.e., through behavioral modification).

History of the Social Learning Model

The social learning model was pioneered by Albert Bandura in books published in 1969, 1977, and 1986. Bandura laid out a theory of learning that involved behavior, influences of the environment, and cognitive processes. Bandura suggested that cognitions act to mediate environmental events and patterns of behaviors and thus play a key role in determining overt behaviors. He argued for the importance of cognitive processes and placed greater emphasis on the individual than the environment in determining behavior. In his 1969 book, Bandura argued that alcohol use is learned in a social context and is negatively reinforced through pharmacological consequences of stress reduction. According to Bandura's social learning model of addictive behaviors, alcohol use may become problematic if, under conditions of stress, alcohol use prevails over more constructive forms of coping behaviors.

Since Bandura's initial presentation of the social learning model and its application to substance use, a number of models utilizing its components to explain addictive behaviors and disorders have been developed. Some applications have taken the form of developing a broad theoretical understanding of the addiction process. In addition, more focused models, also drawing from Bandura's conceptual framework, have been developed to understand key parts of addictive disorders, and to identify domains that may be particularly important for clinical intervention.

Learning Through Experience

The social learning model utilizes operant conditioning principles to explain learning by direct experience. According to social learning theory, response consequences, including both reinforcement and punishment,

provide information to an individual that contributes to the evolution of behaviors. Similarly, that information may also provide motivational influences as individuals develop expectations of behavioral outcomes. Through the process of learning via response consequences, behaviors that are successful are selected and those that are unsuccessful are discarded. These processes can occur both consciously and unconsciously and automatically or with volitional effort. As applied within the social learning model of addictive behaviors, alcohol and drug use behaviors that are reinforced by positive consequences (e.g., pleasurable feelings of intoxication) may consequently increase in frequency, whereas substance use behaviors like abstinence that are punished (e.g., via withdrawal symptoms) may decrease in frequency.

Learning Through Modeling

Learning can also occur indirectly through modeling, also called vicarious learning. Indeed, learning via modeling is less labor intensive, as it does not require direct experience. According to social learning theory, four component conditions are necessary for vicarious learning to occur: attention to the behavior being modeled, retention of observed information, motor reproduction, and motivation to engage in the learned behavior.

First, individuals must pay attention to the model or modeled events to accurately gather information about a modeled behavior. Attention to models may be greater when the model is perceived as being attractive and as having engaging qualities. In this vein, peer groups that are highly valued may robustly preserve the attention of individuals, particularly adolescents, who are observing. This influence is of particular note given the demonstrated influences of peer groups on drinking and drug use behaviors, especially among younger populations.

Second, retention of observed information is required such that the individual is able to recall what has been observed. Retention can occur through encoding, cognitive organization, or rehearsal, and may take the form of imagery or of verbal representational systems. Memory codes, once formulated, then act to guide performance. For example, after viewing a movie that exhibits a main character who smokes, an individual may recall the steps for smoking in images and may then translate that sequence into images in his or her memory stores.

The third required condition for learning through modeling is motor reproduction. Specifically, an individual must have the ability to mechanically duplicate the observed behavior. According to tenets of social learning theory, for motor reproduction to occur, individuals need first to select and organize behaviors cognitively. Engaging in those behaviors is also highly dependent upon the availability of skills. Even with available skills, first attempts at behaviors are rarely completed without error. To perfect most behaviors, individuals must practice what has been observed, retained, and attempted. In the example of an individual learning to smoke, the first attempt at smoking a cigarette may occur with difficulty, despite observed and retained information about the steps to smoking. However, after a number of attempts, an individual may modify his or her behavior to become increasingly adept at smoking.

Finally, the fourth component condition of learning through social modeling is that individuals must be motivated to display what has been learned. This step differentiates between the acquisition and performance of behaviors. Individuals do not engage in every behavior they have learned but rather are likely to perform behaviors that result in valued outcomes. Motivation may be garnered through external, vicarious, or self-reinforcement, or through punishment. For example, the physical, psychological, and social consequences that result from drinking and drug use play an integral role in affecting an individual's motivation to engage in those behaviors.

Cognitive Factors

Although much evidence suggests a powerful role for the influence of the environment on individual behaviors, it is also clear that people are not wholly compliant to the influences of external factors, but instead hold their own moral positions, temperaments, and genetic and physical predispositions that influence their behaviors. Because of cognitive and self-regulatory influences, humans may depend less on environmental determinants than on their internal processes to direct their behaviors. Indeed, social learning theory of addictive behaviors places high importance on self-regulation, including the cognitive processes that direct alcohol and drug use behaviors.

Central to social learning theory, self-efficacy and outcome expectancies operate to influence behavior. Self-efficacy is defined as the belief that one is capable of engaging in particular behaviors. Individuals are

more likely to choose and persist in activities that they believe themselves to be capable of doing. While self-efficacy beliefs may be based in past experience of success or failure in engaging in particular behaviors (e.g., the ability to quit smoking), they may also be associated with one's beliefs about future behaviors (e.g., I know I *can* quit). Self-efficacy is not static; rather, it changes over time with new experiences or situational demands. According to the social learning model, self-efficacy beliefs mediate behavior change and thus are particularly important during the modification (e.g., initiation, termination) of behaviors.

Outcome expectancies are beliefs about the likely consequences of engaging in a particular behavior. In other words, outcome expectancies represent if-then contingencies about engaging in behaviors. It has been noted that expectancies need not be accurate to motivate behaviors, provided that the individual believes these contingency statements to be true. If people hold both high self-efficacy beliefs and high outcome expectancies, they are likely to be highly motivated toward that behavior. For example, if individuals believe that substance use will relieve psychological distress and that they are highly capable of obtaining and using substances, they may be more likely to use a substance as compared with individuals who do not hold such beliefs.

Social-Environmental Factors

The social learning model of addictive behaviors places emphasis on the reciprocal nature of the individual and situation. Environmental influences and constraints can be operationalized in a number of ways. For example, the peer environment may significantly impact alcohol and drug use. The drinking behavior of an individual in a group of heavy drinkers is likely to be different from an individual's drinking behavior when that person is alone. Social norms, or the commonly held views about drinking or substance use, influence an individual's behaviors.

In addition, situational factors, like the craving of substances, may be triggered by environmental cues. For example, environmental cues, such as going to a party where alcohol is readily available, may provide a salient trigger for drinking behaviors. Situational factors may also act as reinforcers, such as the festive mood that often occurs at a party in which alcohol is available; positive mood induction at parties may consequently be associated with drinking and may then be a reinforcer for drinking behaviors.

Treatment

Specific treatment interventions based on the principles of the social learning model of addictive behaviors have been developed through a number of models that identify etiological pathways of particular addictive behaviors. For example, according to Alan Marlatt and Judith Gordon's relapse model, relapse from alcohol abstinence may result from immediate determinants, including high-risk situations or outcome expectancies, as well as covert antecedents like cravings. Based on this model, treatment interventions focus on identification of high-risk situations, increasing self-efficacy for managing high-risk situations, and supporting the development of alternative behaviors and coping skills that can replace addictive behaviors.

Interventions relying on operant learning concepts may also include use of contracts for specific behaviors, which can be utilized to reward clients when they adhere to the treatment plan and, possibly, to punish clients when they deviate from the plan. Interventions such as these fall under the category of behavioral modification. Within behavioral modification, therapists and patients can tailor reinforcement or punishment to apply to their own preferences most saliently. The application of behavioral modification strategies can be initiated in the context of treatment, but it can be continued independently by the patient. An evidence-based treatment approach, the Community Reinforcement Approach, is based on operant learning principles.

In addition to direct learning strategies, treatment interventions relying on vicarious learning can also be used. Modeling therapy, for example, involves having a target person observe another individual who is constructively dealing with an addiction so that the target person can learn appropriate and adaptive coping mechanisms. For example, in addiction treatment programs, substance refusal skills are often modeled and practiced with patients.

Conclusion

The social learning model of addictive behaviors explains the learning of alcohol and drug use behaviors via direct and indirect learning experiences, as well as through environmental and cognitive influences. The model explains learning through one's own experience, through viewing the experiences of others, and via social and environmental influences. It also emphasizes

the important role played by cognition. Furthermore, this model underscores the importance of the reciprocal nature of each of these factors within the learning process. In contributing to the understanding of alcohol and drug use through the development of models of specific behaviors, social learning theory constructs have also provided information for the development of a number of useful treatment interventions.

SOCIAL NORMS MARKETING

Commercial marketing promotes goods and services for a profit. Social marketing promotes ideas designed to influence the voluntary behavior of the target audience. Social norms marketing is a focused application of social marketing based on applying social marketing techniques to social norms theory, which suggests that much of people's behavior is strongly influenced by their perceptions of what is "normal" or "typical." However, it has been shown that people often overestimate what they perceive others think and do and sometimes underestimate what they themselves do. In the case of substance abuse, many overestimate the number of people who drink or use other drugs, thereby creating the perception that alcohol and other drug use is normal behavior, and therefore, it must be acceptable. Social norms marketing is designed to educate the target audience about the actual substance

use attitudes and behaviors of their peers based on empirical data. By viewing a realistic picture of what their peers believe and do, members of the target audience may be influenced to adopt positive attitudes and choose healthy behaviors.

Development of Social Norms Marketing

Social norms marketing was proposed in 1986 by H. Wesley Perkins and Alan D. Berkowitz when they analyzed the alcohol use patterns of students. Perkins and Berkowitz found that misperceptions of peer norms about alcohol consumption may increase tolerance for, and actual use of, alcohol. Consequently, they recommended that prevention efforts focus on providing students with accurate information on peer drinking attitudes and behavior. Students typically overestimate substance use and overestimate the permissiveness of their peers. Students, in reality, are more moderate in both use and attitudes, and more students abstain than others think. However, some alcohol consumption among young people may be perpetuated by the belief that “everybody does it.”

Since the mid-1980s, there has been an increased application of social norms marketing programs to prevent or reduce alcohol use. Programs have been funded by federal and state agencies, nonprofit organizations, consortia, and, on occasion, the alcohol beverage industry. Social norms marketing programs have reported success in reducing alcohol use by as much as 20%, and at least two programs have been identified as model programs by the Center for Substance Abuse Prevention.

In addition to addressing alcohol use with social norms marketing campaigns, other programs have demonstrated the effectiveness of social norms marketing in reducing or preventing cigarette smoking, reducing drinking and driving, and reducing sexual assault.

Types of Misperceptions

Social norms marketing is used to correct the misperceptions or gaps in what people perceive are the attitudes and behaviors of others with empirical data regarding their actual attitudes and behaviors. There are three main types of misperceptions: pluralistic ignorance (i.e., the majority of people falsely assume that others think or behave differently than they do),

false consensus (i.e., the minority of people with unhealthy attitudes and behaviors have the incorrect belief that many others think and behave as they do), and false uniqueness (i.e., the misperception of people who think there are fewer people who behave as they do or that their behavior is unique compared with the behavior of others). Social norms marketing has been shown to be effective in changing the behavior of the moderately drinking majority (*pluralistic ignorance*) and the heavy drinking minority (*false consensus*), and in maintaining or increasing the number of abstainers or infrequent drinkers (*false uniqueness*).

Use of Social Norms Marketing for Multiple Levels of Prevention

Social norms marketing has been used to focus on the three levels of prevention audiences: universal, selective, and indicated. Universal prevention is directed at all members of a target population without identifying those at risk. Selective prevention is directed at members of a group who may have risk factors for a behavior. Indicated prevention is directed at individuals who already exhibit the problem behavior.

Use of social norms marketing targeted to universal populations is most common. A number of secondary schools, colleges, and universities have developed and implemented communitywide electronic or print media campaigns that promote accurate norms for drinking and abstaining. They have reported success in reducing drinking and increasing positive attitudes toward nonuse.

Selective or targeted social norms marketing campaigns have focused on particular groups, such as first-year college students, fraternity and sorority members, athletes, or members of an academic class, to specifically address members of the group who may be at risk for substance abuse. In these types of social marketing campaigns, norms specific to the targeted groups have been promoted in small groups, workshops, or classes to change unhealthy behaviors.

Use of social norms marketing is not typically identified as a prevention strategy for individuals. However, normative data about drinking can be presented to high-risk drinkers and other drug abusers as part of individual counseling interventions. Because substance abusers tend to underestimate or deny their problem, sharing normative data can be a nonjudgmental way to stimulate change.

Characteristics of Successful Social Norms Marketing Programs

Social norms marketing programs frequently follow a five-step model to ensure systematic program development and implementation. The five-step model builds upon the data obtained from the previous step or steps and includes the following steps: (1) Gather baseline data, (2) develop the message, (3) ensure message credibility, (4) deliver the message, and (5) support message retention.

Those social norms marketing programs reporting success often conducted effective assessments of the target audience's needs and were based on standard marketing techniques, such as incentive programs, which were employed throughout the programs to increase the likelihood of message retention and behavior change. For example, movie tickets and key chains have been popular incentives. They can be given as rewards for correct quiz answers about the content of messages in the program. The success and sustainability of a number of programs depended upon the extent to which the target audience, in most cases students, led changes. Most successful programs have been those that are facilitated and directed by students.

Advocates of social norms marketing have used the approach in secondary schools, in communities, and on college and university campuses with reported success. It has been referred to as an extremely powerful approach that applies marketing techniques developed in the commercial sector to improve consumers' (students, community members) physical and mental health. Social norms marketing can be an effective substance abuse prevention strategy. In fact, some evaluation research suggests that when social norms marketing is incorporated into comprehensive prevention efforts, the social norms marketing component can be one of the important ingredients associated with program effectiveness.

SOCIAL SKILLS TRAINING

Social skills training forms an integral part of both prevention and intervention efforts in addressing the negative effects of substance use. Although former First Lady Nancy Reagan adopted the simplistic slogan “Just Say No” as the centerpiece of her efforts to prevent the initiation of young people into alcohol and other drug use, for many young people and their older adult counterparts, avoiding first or continued substance use is not that simple. The ability to effectively interact with others in an assertive fashion is critical to avoidance of substance use initiation as well as to the process of beginning to change substance use or remain abstinent following a decision to do so.

Social skills training arises from a cognitive social-learning theory perspective that holds that substance use is largely a learned behavior and that changes in this learned behavior can be made through use of behavioral rehearsal, modeling, and changes in how the individual views and evaluates situations in which substance use is likely.

For example, for a young person to avoid initiation into substance use, he or she must be able to effectively refuse the initial offering of substances, feel

comfortable doing so, and believe that such refusals will be effective. For an older person already using substances who has made the decision to change that use, the ability to effectively interact with others takes on a more complex importance. It is known, for example, that for many individuals who have decided to reduce or stop substance use, poorly handling interpersonal conflict situations can constitute a trigger of return to previous, undesired levels of substance use. Thus, ineffectively handling an argument with a spouse or other significant person may lead to a sense of discouragement and negative self-image that triggers negative affect, which in turn triggers increased substance use. In addition, the ability to effectively resist perceived or actual social pressure to violate self-imposed use limits (whether they be reduced use limits or abstinence) is often critical to effectively maintaining behavior change. It is not uncommon, for example, for newly abstinent problem drinkers to express concerns about how they will address questions from drinking friends about their shift to abstinence and how they will resist social pressure from those friends to “just have one.”

Many individuals in society suffer from deficits in their ability to engage in effective assertive behavior. Deficits take two primary forms, both focusing on an inability of the individual to effectively assert his or her wishes and rights in the face of attempts by others to induce behavior the individual does not want to engage in. The first form is an inability to be forceful and determined in one's assertions (underassertiveness) or a tendency to be overly aggressive in one's assertions (aggressiveness). Both forms of social skill deficits can interfere with effective behavior with respect to alcohol and other drugs.

These deficits may result from either or both of two sources. The first is simply a lack of the requisite skills to engage in effective assertive behavior; the second is a lack of motivation to do so. The latter may take the form of beliefs that assertive behavior will be ineffective or that one lacks the skills to be assertive when one actually possesses them. Skill deficits require training to alleviate the deficits. Motivational deficits require addressing the thoughts and expectations that drive the avoidance of effective assertive behavior. Social skills training approaches have addressed both of these sources of deficit in assertive behavior.

In general, social skills training programs consist of one or more of three major components: assertiveness and communication training, social problem

solving, and critical thinking. Taken together, these components have been shown to be effective tools in assisting in the prevention of the onset of substance use and in helping people attempting to change substance use make those changes effectively.

Assertiveness and communication training focuses on teaching the individual how to effectively communicate his or her wants, needs, and desires in a non-passive as well as nonaggressive fashion. Teaching individuals how to differentiate assertive behavior from both passive and aggressive behavior and then providing them with opportunities to practice (usually in group role-play situations or in individual counseling sessions) have resulted not only in increased appropriate assertiveness and more effective communication but also in reduced likelihood of substance use. In the typical training program, the counselor or other group participants first model effective assertiveness and communication skills and then role-play with other participants how to enact these skills in a variety of situations.

Social problem solving training focuses on teaching the individual how to recognize potentially problematic social situations and devise an appropriate strategy for responding to those situations from among a repertoire of skills that typically have been learned in the type of assertiveness and communication training described in the previous paragraph. Teaching individuals increased flexibility in identifying and responding to situations in which the risk for substance use is increased sets the stage for those individuals to apply those skills appropriately to situations in which they have the greatest likelihood of a positive effect.

Critical thinking about social situations and training in how to clearly understand the pros and cons of a particular course of action is also an important skill in effective social interaction. Critical thinking may be extended to planning how individuals will address particular high-likelihood situations that may arise in their daily lives and developing a plan that will guide the enactment of the social skills learned in other components of social skills training.

Despite the efficacy of social skills training approaches in promoting initial delay of substance use initiation and in assisting in relapse prevention for substance users, there is evidence that the effects of social skills training may erode over time. This has led to a recommendation that booster sessions be provided to enhance retention and generalization of skills learned.

Research has strongly supported the use of the broader form of social skills training that includes the three components described earlier. In prevention work and in therapeutic intervention, social skills training is an important part of the intervention armamentarium. An added benefit of social skills training is that it assists individuals who undergo it in becoming more effective in other areas of their lives that require effective social interaction skills. Research has also demonstrated that persons who undergo social skills training and integrate those skills into their daily lives experience heightened levels of self-efficacy and self-esteem that extend beyond coping with issues surrounding substance use.

SOCIOCULTURAL MODELS OF ADDICTION

Substance use disorders do not occur in a vacuum; therefore, social and environmental influences must be taken into account as causal factors or factors that place individuals and, in some instances, entire communities at risk for these disorders. Several social and environmental features have been identified as having

greater influence on those who develop addictions. For example, it is not unusual to find that substance use disorders are more prevalent in areas that are gripped by poverty, racism, and a lack of occupational and educational opportunities. It is also known that role models have a great impact on alcohol and drug use. Several influential sociocultural models are described in this entry.

Peer Models

Individuals who abuse substances will often have greater social contact with those who also abuse similar substances. The old saying “Birds of a feather flock together” aptly describes this phenomenon. For example, alcoholics tend to socialize with, and feel more accepted by, other alcoholics. Although peer pressure from other drug-using adolescents to initiate drug use was thought to influence initial drug-taking behavior, research suggests that adolescents are more likely to initiate drug use in order to “fit in” or gain acceptance by a peer group that they view as being desirable. Peer role models who abuse alcohol or drugs are often perceived as being more powerful or admired. Therefore, some teenagers will initiate drug use to become more like the peers they envy.

Family and Socialization Models

Families are considered of paramount importance in the transmission of societal norms, values, and religious and political beliefs. Thus families are influential in how their children develop attitudes and beliefs about alcohol and drugs. Through observation of alcohol and drug use of parents and other extended family members, as well as parental approval of deviant behavior (e.g., stealing, carrying weapons, defiant behavior), children and teens are often influenced as to how they will use substances. Similar to peer models, an important factor in familial influence is that the substance-using parent is perceived as a powerful or enviable role model.

Another subgroup of family models recognizes that families often influence the course of alcoholism or addiction. Although these models do not contend that families cause addiction, they posit that families often organize in particular ways, which may unintentionally allow the addiction to progress. For example, the family systems model claims that, when addiction is evident in a family member, the other family members

organize around the addict or alcoholic in such a way as to maintain homeostasis or balance. This model explains why family members often take on certain roles (e.g., family hero, scapegoat, lost child, mascot) in response to the substance use disorder.

Cultural Models

Rates of alcoholism are higher in some countries than in others. Given this observation, it has been understandable that researchers look to certain environmental and cultural influences that might promote alcohol abuse. Similar to how binge drinking is common among college students in spite of attempts by college administrators to discourage such behavior, many countries experience increased rates of alcoholism in spite of public policy attempts to curb excessive drinking. Social health policy can have an influence on rates of addiction. This is evident in recent changes in laws regarding smoking in public places like office buildings and restaurants. Higher taxation rates on alcohol and tobacco also have an influence on lowering the overall rates of substance use.

Researchers have looked the variable rates of alcoholism in countries such as Australia, England, Ireland, Italy, and Israel, with a focus on discerning sociocultural differences that may influence those rates. For example, Australia, England, and Ireland have higher rates of alcoholism, which is hypothesized to result from being pub cultures. Pubs are central places of socialization and community life, much in the way taverns dominated American culture as places of communal gathering for information sharing and political discussion in the 18th and 19th centuries. Although Italy and Israel also are alcohol-consuming countries, they tend to have low rates of alcoholism. The key difference appears to be whether alcohol consumption is done as part of family, ceremonial, or religious ritual or whether it is done apart from families. Alcohol consumed with family and as part of a holiday or religious ritual tends to have a buffering effect on excessive drinking. In Australia, for example, many pubs still have separate sections where men drink apart from women and children. Another factor that supports the influence of culture on alcohol consumption is that many immigrant groups who relocate to countries with higher rates of alcoholism tend to have low rates of substance abuse when they initially relocate. However, several years after relocation, their rates of substance abuse increase.

Another example of cultural influence is found in religious groups, especially fundamentalist religious groups that discourage and prohibit substance use. These groups usually socialize their children that alcohol and drug use is considered deviant and sinful.

The Vietnam War is often cited as an example of the tremendous impact environment can have on addiction. Researchers suggest that Vietnam had all of the conditions that would encourage addiction: consistent availability of high-grade heroin and other drugs such as marijuana, inconsistent but tremendous levels of stress (hours of boredom punctuated by moments of life-threatening fear), and lack of social support created by the military policy of shifting troops back home after serving a year overseas. Follow-up studies suggest that whereas some returning soldiers continued their heroin addiction once they returned to the United States, the majority did not. These findings are cited as prime examples of how influential environment can be.

Impact of Racism, Social Class, and Poverty

Substance use is most prevalent and most devastating in areas of the United States that are impacted the most by poverty, racism, and a lack of educational and occupational opportunity. This is most evident in the urban ghettos but also in poor rural areas. Although the dynamics that promote drug use are similar from city to country, the drug availability may vary. For example, the abuse of inhalants is more widespread in rural areas, often because of the lack of availability of other drugs.

Alcoholism has been problematic within the African American community. However, this was not always the case. Historically, alcohol was used as part of ceremonial and religious rituals in Africa. Even during years of slavery and during the Reconstruction era, drunkenness was rare, although many states had enacted laws prohibiting the use of alcohol by freed slaves. With the passage of time, many of these laws were abolished and African Americans gained their right to drink, although most did so at home, at neighborhood bars, and mostly on the weekend. Because of these historical influences, it was thought that African Americans did not perceive alcoholism to be a danger. From a religious perspective, however, drunkenness was considered to be sinful. Given the struggles of African Americans to gain basic rights and given the lack of educational and job opportunities, this is thought to have contributed to a perception that alcohol

is a reward for living a hard life and that life's hardships entitle one to drink. Therefore, it is hypothesized that drinking in the African American community came to be perceived as a means of coping with life's hardships rather than as a cause of problems. Rates of addiction in Hispanic and Latino barrios also provide evidence of how cultural influences, in combination with poverty and the lack of economic and educational opportunity, can impact on rates of addiction.

Similarly, Native American reservations have high rates of unemployment, school dropout, poverty, welfare dependence, and alcoholism. Deaths due to alcoholism are 5 times higher for Native American adults and 17 times higher for Native American adolescents when compared with national averages. It is noteworthy that in those Tribal Nations where casino gaming has been endorsed, this has resulted not only in economic and community growth but also in the amelioration of many health and social problems such as domestic violence, crime rates, and suicide rates, all of which are correlated with alcoholism. Overall, the positive social impact of legally sanctioned gaming has been demonstrated most dramatically with the Pequot and Mohegan Tribal nations in Connecticut.

Many researchers conclude that it is impossible to lessen the prevalence of addiction within impoverished communities without first addressing the issues of racism, poverty, and lack of educational and occupational opportunity. It should be noted, however, that in many countries, including the United States, greater socioeconomic status and affluence have also been associated with increases in alcohol and drug use. Therefore, although affluence is generally seen as affording individuals better access to education and health care, it does not immunize individuals from substance use disorders.

Diathesis Stress Model

This model is unique in that it is considered to be a compromise of the nature–nurture debate, which has dominated the social sciences. The diathesis stress model concludes that addictions result from both biological and environmental influences. Therefore, one may be genetically predisposed (biological—nature) toward addiction. However, the individual may not manifest addiction unless there are social conditions (environmental—nurture) that promote or encourage substance use. A saying best captures the essence of this model: “If biology loads the gun, environment pulls the trigger.”

Conclusion

Although there have been many recent advances in both genetic research and neurobiology of substance use disorders, it is still important to take environmental, social, and cultural factors into account when examining the etiology and influences on addictive behaviors. It is important not to dismiss the influence of peers, culture, ethnicity, race, and socioeconomic status when examining the etiology and factors influencing the perpetuation of addictions.

SOLUTION-FOCUSED THERAPY

Increased costs for substance-related mental health services and the consequent rise of managed health care has facilitated the rise of time-limited (i.e., brief) counseling and psychotherapy approaches, such as solution-focused therapy (SFT). SFT has thus emerged as a popular approach to working with substance-related issues, despite its opposition to a disease model of addictions. SFT was developed almost 25 years ago at the Brief Family Therapy Center in Milwaukee, Wisconsin. Some significant figures in its origin and development include Steve deShazer, Insoo K. Berg, Scott D. Miller, William O'Hanlon, and Michelle Weiner-Davis.

The essence of SFT and its theoretical perspective on human nature, mental health, psychopathology, change, and the therapeutic mandate is captured within the following nine central principles (eight of which are outlined by Berg and Miller in their book *Working With the Problem Drinker*).

1. *Emphasize mental health over psychopathology.* Mental health professionals need to look for what is functional and how to use it rather than what is less functional and how to fix it. In other words, counseling and psychotherapy should accentuate clients' strengths, resources, and abilities and minimize discussion of shortcomings, disadvantages, and deficiencies, as the former are much more important in facilitating change in the lives of individuals.

2. *Utilize what the individual already has or can do.* Each individual is unique, and counseling and psychotherapy should attempt to maximize the use of each individual's personal idiosyncrasies, including (but not limited to) values, religious beliefs, cultural customs, distinctive habits, perceived strengths, personal theories, and even symptoms, to assist in the formulation of an individualized change plan. For example, as discussed widely by Berg and Miller, Buddhist philosophy can be used to translate the Twelve Steps of Alcoholics Anonymous for use with a Buddhist individual seeking counseling to help stop misusing alcohol.

3. *No single change plan works for everyone.* There is no one absolute and unconditionally correct way to

view a problem or a solution across all individuals. Different perspectives might be just as valid in providing coherent meaning to the facts, and different solutions might be differentially valued across individuals.

4. *Parsimony.* Complex solutions should be a last resort. Often, a simple and minimally invasive solution is at least sufficiently functional. Such a small change also holds great potential to result in a "snowball" effect, leading to further and bigger changes, as success with small endeavors can create optimism, hope, and motivation for future change.

5. *Change is inevitable.* Considering that no situation is exactly the same and that life therefore requires constant adaptation, personal adjustments (and therefore change) can be perceived as expected. If change can be perceived as expected, then it can also be understood as inevitable.

6. *Focus on the present and the future because insight into the cause of the problem is not necessary for change to occur.* Extensive exploration of the past or even a comprehensive definition of the presenting concern is often not necessary because solutions do not need to be directly related to the problematic situations that they are intended to resolve. Also, what initially caused the problem is not necessarily the same as what has maintained it, which further supports focusing on the present. As an analogy, the solution to terminating a headache is taking aspirin, independent of whether the headache was caused by head trauma, stress, or fatigue—causes completely unrelated to the pharmacological change mechanism of aspirin. Furthermore, assuming the headache was caused by an acute stressor, it is possible that the acute stressor can pass but the headache be maintained by lack of adequate sleep.

7. *There is not necessarily a deep, underlying cause for the client's current symptoms.* Oftentimes, change can be facilitated by treating the presenting concern as the real issue in need of resolution. This is in contrast to many other therapeutic approaches that assume resolution of the overt presenting issue will result in an underlying problem emerging in another way.

8. *Cooperate with the client as much as possible.* Within legal and ethical bounds, mental health professionals should cooperate with the client. This includes validating the client and his or her feelings (but not necessarily his or her behavior) when the client wishes to continue the so-called problem behavior. It also includes working on the issue, as defined by the client. For example, in working with a

youth pressured by his or her parents to attend substance abuse counseling, a counselor practicing SFT may work with the youth on decreasing parental “nagging” (a goal the youth will most likely endorse), and, in doing so, the youth may inadvertently positively alter his or her drinking behavior.

9. *Three underlying guidelines for clients.* (1) “If it ain’t broke, don’t fix it” (i.e., do not label it as a problem if the individual does not). (2) Once you know what works, do more of it (i.e., focus on what has already changed and how, as well as what is possible and changeable). (3) If it does not work, then do not do it again; try something different (i.e., persistence will eventually result in the discovery of a functional solution).

According to SFT, the problem can often be reconceptualized as (a) the current methods used to deal with the presenting issue and (b) the pathologizing and disempowering way that the problem is being talked about and understood. Unlike most other approaches, SFT does not propose any overarching therapeutic goals. Instead, any goal, regardless of its content, that meets certain process criteria can be one of the appropriate goals of counseling. These process criteria include the following: (a) The goal must be really important to the client (i.e., not a goal forced upon the client by others), (b) the broader goal should be broken down into smaller steps, (c) the goal should be translatable into observable and quantifiable terms (because this makes it easier to evaluate progress and determine future steps), (d) the

Table 1 Common Solution-Focused Strategies

<i>Question</i>	<i>Description</i>	<i>Example(s)</i>
Pre-session change	Ask clients what changes or differences have already occurred. Designed to increase awareness of current successes and highlight that the client has already begun the process of change.	What has been different about your drinking in the week before you came to see a counselor?
Exception	Ask clients to describe times when the complaint is absent, less intense, or dealt with in an acceptable manner. Designed to orient the discussion toward solutions and the identification of patterns related to solutions.	Can you tell me about the last time you went a day without using drugs? Has it always been this severe? When did your problematic alcohol use first start?
Outcome (miracle)	Ask clients to describe what will be different when the problem has been successfully dealt with. Designed to engender a focus on the future and assist in the formation of goals.	If you woke up tomorrow and all of a sudden quit drinking, tell me, in as much detail as possible, what would your day be like?
Scaling	Ask clients to rate something on a numerical scale. Designed to establish a phenomenological rating system for assessing progress and success and for stimulating micro-goal setting.	On a scale of 1 to 10, how could you decrease the severity of your drug abuse from 5 to 4?
Coping	Ask clients to describe how they have managed to endure the problem thus far and successfully prevented it from getting worse. Designed to increase awareness of current and past successes and acknowledge the coping skills of the individual.	How have you managed to cope with your spouse’s drinking for so long?

goal should encourage active behavior in that it can be stated in terms of what to do rather than what not to do, and (e) the goal should be under one's control and be reasonably achievable. For example, an inappropriate goal would be to ensure that alcohol is not served at a friend's upcoming social gathering; an appropriate goal would be requesting alcohol not be served and having a contingency plan if alcohol is served (as the friend's agreement is beyond the control of the client). Once counseling goals have been established, SFT therapeutic strategies are employed to assist the client in goal attainment. SFT strategies revolve around five key questions. These are presented in Table 1 along with examples. Although these are the most frequently used strategies, other therapeutic strategies are also available to the mental health professional practicing SFT.

SFT has advanced itself primarily through the backing of anecdotal case reports and follow-up client satisfaction surveys. A recent review of controlled studies of SFT conducted by Wallace J. Gingerich and Sheri Eisengart in 2000 identified 15 empirical studies assessing the efficacy and empirical effectiveness of SFT (but only five were highly controlled efficacy studies). All 15 studies demonstrated positive outcomes for SFT versus either control groups or other theoretical orientations. Out of the five highly controlled studies, four found SFT to be better than no counseling at all or standard institutional treatment and the other found SFT to be comparably effective to another approach that is well supported by research. Gingerich and Eisengart concluded that preliminary support does exist for the effectiveness of SFT but that additional controlled research is needed to make more definitive conclusions.

SPECIAL POPULATIONS

The concept of “special populations” (SPs) was created as a contrast to *mainstream population*, a term generally defined as a group of people who are numerically in the majority or who are a dominant group in power. Historically, the dominant groups in America tend to be males, Caucasians, and heterosexual individuals. The corresponding SPs, therefore, are women; racial/ethnic minorities; and gays, lesbians, and other nonheterosexual individuals. Traditionally, major health studies, including alcohol and other drug (AOD) research, generally focused on the needs of dominant groups. Since the 1970s and 1980s, clinicians and researchers have gradually realized that research results obtained from the dominant groups are not necessarily generalizable to SPs and that model treatment programs designed for the mainstream population do not necessarily work for SPs. SPs may have a different biopsychosocial background, specific AOD etiologies and protective and risk factors, and distinct treatment issues and needs compared with those of the mainstream population, all of which may demand modifications of mainstream treatment models. This entry covers a brief historical development of the SP concept, definitions of and characteristics involved with the concept, three SP examples presenting their special needs and practice strategies for helping them, an examination of the actual implementation of SP-specific practice, and a conclusion discussing challenges facing the implementation of SP-specific practice and tactics to overcome them.

Historical Background

In 1977, Eric Josephson and the National Institute on Drug Abuse first used the term *special population* to address the specific treatment needs of substance-abusing adolescents. In 1985, Stanley Einstein stated that no longer should we continue to use the term *drug user* because there is a difference between younger and older drug users, African American and White drug users, and male and female drug users. It

was not until the 1990s that more systematic studies were conducted on various SPs.

Definitions

Today, the term *special population* has been expanded to cover many different groups. It can be based on gender (e.g., women), ethnicity (e.g., ethnic/racial minorities), developmental stage (e.g., older persons), sexual orientation (e.g., gays and lesbians), socioeconomic status (e.g., the homeless), occupation (e.g., athletes, veterans), health status (e.g., HIV-positive substance abusers), incarceration status (e.g., inmates), physical status (e.g., physically disabled), dual diagnosis (e.g., substance abusers with a bipolar diagnosis or an eating disorder), geographical areas (rural vs. urban residents), level of acculturation (new immigrants vs. American-born first or second generation), and so on. Because all of these factors are not necessarily mutually exclusive, certain special subpopulations may be further developed, such as adolescent girls (gender plus developmental stage) or homeless veterans with post-traumatic stress disorder (socioeconomic status plus occupation plus dual diagnosis).

The classification of SPs, or the attachment of “SP” to a group, is somewhat arbitrary and flexible. One criterion could be that SP members possess distinct biopsychosocial backgrounds, which differentiates them from mainstream population members and has direct or indirect implications for AOD treatment. Two other characteristics are as follows:

1. The term *special population* may connote a sense of being “underserved” or “unserved.” For example, substance abuse is traditionally considered a men’s disease in the United States, and most treatment programs target men despite the fact that women were the primary group of morphine and opium addicts during the 19th century. Likewise, rural residents have traditionally received less attention and have had less access to AOD treatment than urban residents despite the fact that the AOD prevalence gap between the two has been closing.

2. Some SPs may have a higher AOD prevalence rate or be more vulnerable to AOD impact than the mainstream population. For example, gays and lesbians tend to have a moderately higher AOD rate than heterosexual people, and homeless women are likelier to have a higher AOD rate than housed women. Older persons and adolescents may be more vulnerable to the negative consequences of AOD abuse than the mainstream

group (i.e., the young or middle-aged adults) because of the developmental stages they are in.

Practice Strategies for Helping Three Special Populations

The following includes three well-known SPs, which serve as examples to highlight the unique needs of and treatment strategies for SPs.

Women

Studies show that women suffer more severe AOD consequences than do men. It takes a shorter time for a woman than for a man who consumes a similar level of alcohol to deteriorate from normal drinking to dependence. Women tend to develop more severe liver and other physical problems than men after exposure to an equivalent amount of alcohol or length of time drinking because of women’s lower enzyme and higher fat levels. Further, women are more likely than men to be subjected to physical harm or sexual assaults when drinking.

Studies also indicate that women may be more vulnerable to certain risk factors than men. Although both sexes may use AOD to self-medicate negative emotions, substance-abusing female clients (the “clinical” rather than “community” population) are more likely than their male counterparts to do so. Numerous studies also show a significant link between women’s childhood sexual or physical abuse history and their later development of substance abuse, although the link is not necessarily causal. On the other hand, many studies show that although both sexes may use AOD to enhance positive emotions or occasions and to seek pleasure, men are more likely to do so. Literature also suggests that substance-abusing women are more likely to come from substance-abusing families of origin than are their male counterparts. Studies report consistently that women tend to engage in AOD use and abuse more often through their male partners’ AOD-using behaviors than vice versa. This not only demonstrates the relevance of their male partners’ AOD-using behavior when helping women but also highlights the possibility of domestic violence as AOD tends to precipitate violence. Another gender-specific factor is women’s concerns about weight. Studies have revealed that women are more likely than men to use methamphetamine (meth) to lose weight, to relapse to smoking because of weight concerns, and to develop disordered eating problems owing to weight concerns.

Effective practice should help substance-abusing women deal with the previously mentioned issues. In addition, studies have shown that women may be more likely than men to feel shame and guilt and, therefore, may be more receptive to a nonconfrontational (vs. the traditional confrontational) treatment approach and an individual (vs. group) counseling modality compared with men, particularly during the initial treatment stage. Further, because they are more likely to assume the primary childcare role and less likely to have vehicles or be employed than are men, women may be more motivated for treatment if the program provides case management (childcare, transportation, employment training).

Racial/Ethnic Minorities

African Americans and other racial/ethnic minorities in the United States experience more severe negative AOD outcomes. They have had up to 5 times higher levels of alcohol morbidity and mortality than Whites despite their similar levels of lifetime heavy drinking. Despite the limited AOD research on racial/ethnic minorities, some elements have begun to emerge, including the observation of their lower treatment retention and engagement rates compared with Whites and two factors explaining such low rates. For example, Ashley Austin and colleagues' study shows that White adolescents completed an average of 89% of the required sessions, compared with 74% for the U.S.-born Hispanic adolescents, 70% for the foreign-born Hispanic adolescents, and 58% for African American adolescents.

The two factors used to explain the low retention and engagement rates of racial/ethnic minorities are an economic and logistical factor and a cultural factor. Because of a lower socioeconomic status and employment of a temporary nature, racial/ethnic minorities, particularly Latinos/Latinas, are less likely to have health insurance. Researchers have found that, at more severe levels of an alcohol problem, both African Americans and Latinos/Latinas are less likely to use services than are Whites, and Latinos/Latinas are especially likely to cite economic and logistical factors as reasons for not getting treatment.

The cultural factor may include four elements: inconsistent worldviews between the original and the dominant cultures, varying levels of acculturation, varying degree of ethnic identity, and diverse subgroups within each racial/ethnic minority group. Researchers suggest that programs designed for the

dominant group may hold different worldviews regarding life, human social behavior, and the world compared with various racial/ethnic minorities. Felipe Castro and Julie Garfinkle presented three cultural conflicts: (1) The client may be looking for concrete directions from a counselor trained to be nondirective; (2) the client may be expected to take some responsibilities, but he or she wishes to be healed by the counselor; or (3) the client's disorganized or informal lifestyle may be incompatible with the agency's demands for planning and scheduling. Another example is that the "disease concept" originating from the Caucasian mainstream population may not be as readily acceptable as the "moral model" to some immigrant families of substance abusers.

Research results on acculturation and racial identity are still equivocal. Some show that a higher acculturation is associated with a higher substance abuse rate among adolescents; others show a lower acculturation linked with a higher substance abuse rate or no association between the two among adolescents. Research has shown that both the Hispanic students communicating with parents in English only and those communicating bilingually with parents appeared to have a higher alcohol initiation rate than those who communicated with parents in Spanish only; however, the bilingual students appeared to have a higher alcohol initiation rate than the English-only students. A possible explanation could be that higher acculturation increases exposure and access to alcohol and thus both the English-only and bilingual students have a higher alcohol initiation rate than Spanish-only students. However, being in two cultures may bring conflicts and struggle for adaptation, heightening the risk for drinking. Thus the bilingual students have a higher alcohol initiation rate than the English-only students. Likewise, studies' results on racial identity are inconsistent, with some showing a negative relationship and some a positive relationship between racial identity and substance abuse.

Multiple subpopulations are subsumed under the "Latino/Latina" population and the "Asian American" population. The subpopulations may be impacted differently by AOD problems and the various cultural elements. For example, research has found no relationship between alcohol use and acculturation for Latino American men (ages 20–74) but a positive relationship between the two for Latina American women. Researchers have suggested that this result may be due to acculturation causing Latina women to adopt American gender roles and drinking norms,

whereas Latino men do not need to change their drinking behavior much to agree with the drinking behavior of the men in the United States. Asian American adolescents are known to have a lower substance abuse rate than other adolescents, but an examination of the subpopulations revealed that the Japanese American and Filipino American adolescents shared a similar lifetime alcohol use rate with the Whites, although the Chinese, Korean, and Vietnamese American adolescents had lower rates.

To recruit and retain racial/ethnic minority clients, treatment programs should emphasize case management and culturally responsive practices. They may need to maximize those clients' access to AOD treatment (e.g., through Medicaid application and flexible office hours), and they must consider the previously mentioned four cultural elements. More research should be conducted to reconcile the inconsistent findings and confirm practice strategies.

Gays and Lesbians

Gays and lesbians experience not only the same daily life stress as heterosexual people do but also pressures and challenges specific to being a gay or lesbian. Gays and lesbians may be afflicted with AOD problems for different reasons during the different stages of coming out. In the early stages, they may suffer internalized heterosexism and experience overwhelming identity confusion, guilt and shame, and low self-esteem, or they may worry about rejection from their family and friends and fear losing their jobs. They, subsequently, may use AOD to self-medicate all these negative feelings. In the latter stages of coming out, they may become more involved with the gay/lesbian/bisexual community and may be more likely to socialize in gay or lesbian bars, which also increases the risk of AOD use and abuse. For gay and lesbian individuals who have matured in their coming-out process and fully embraced their true sex identity, the issues that trigger AOD abuse may include couple relationship problems or workplace discrimination problems.

Survey findings on substance-abusing gays' and lesbians' perceptions of successful AOD treatment programs emphasized practitioners' ability to provide affirmative treatment, including adopting an inclusive language (e.g., not assuming the client is heterosexual), addressing environmental heterosexism and homophobia issues with clients when appropriate, and helping clients connect with the gay/lesbian/bisexual

community. Affirmative treatment may also include a program's clear policy on protecting a client's confidentiality, equal treatment, and safety and nonharassment rights, regardless of a client's sexual orientation. Various studies have indicated the importance of bringing forth the client's true sexual orientation and helping the client transition through the coming-out process smoothly. However, such action must be handled following the client's own pace. Other issues may include suicide prevention, interpersonal relationships with families of origin, legal issues, and childhood and lifetime sexual and other abuse.

Infusion of harm reduction content—for example, safe sex—into AOD treatment is also critical. It is well established that drug use is associated with risky sexual behavior and HIV/AIDS risk among gay/bisexual men. Recent studies show that this association is even more pronounced among urban gay and bisexual men who abuse methamphetamine. Meth is viewed as providing the modality for gay and bisexual men to engage in sex in continuous encounters and with multiple partners, especially those who trade sex for money or drugs. Lesbians also may be at high risk for HIV/AIDS. Research has shown that female injection drug users having sex with other women are likelier to employ risky drug-using behavior and to have a higher HIV rate than female injection drug users having sex only with men. Lesbians and other nonheterosexual women are likelier than heterosexual women to have gay or bisexual men as sexual partners.

Actual Implementation of Special Population-Specific Practice

To what degree are the current AOD treatment programs serving SP clients? To what degree are the programs that accept SP clients actually providing the “best” or “better” practice to them? Margaret Polinsky, Yih-Ing Hser, and Christine Grella's survey of treatment programs in Los Angeles County found that an overall high percentage of programs are able to meet the needs of various SP clients. For example, 42.5% of them said they were able to meet the needs of mentally impaired clients; 63.3%, the needs of dually diagnosed clients; 75.5%, the needs of AIDS patients; and 89.1%, the needs of women clients.

Programs' self-reporting capability to serve SPs may be one thing; whether they actually provide SP-specific key services could be another. Examining the 2000 National Survey of Substance Abuse

Treatment Services data, Todd Olmstead and Jody Sindelar found that fewer than half of the treatment facilities with special programs for women actually offered women-specific key services. Only 19% of them offered childcare; 45%, transportation assistance; and 40%, housing assistance. The rates were even lower for those accepting women but containing no special programs for women: 4% provided childcare; 28%, transportation assistance; and 24%, housing assistance. Likewise, only 43% of the AOD treatment programs with special programs for gays and lesbians offered HIV testing, and 71% provided HIV education/counseling/support. Again, the rates for those accepting gays and lesbians but not containing gay- or lesbian-specific programs are lower: 30% offered HIV testing and 51% had HIV education/counseling/support.

Conclusion

The concept of SPs began in the 1970s, and the AOD treatment and research community has, since the 1990s, paid greater attention to the various SPs. The responsiveness of the AOD treatment and research community has ignited the hope of improving treatment engagement, retention, and effectiveness among various SPs, many of whom are vulnerable in various ways, experience disadvantageous social reality, and have traditionally been underserved or unserved. Attention to SPs benefits not only the SPs but also society in general in the long run.

The usage of the concept of SPs, however, has not been embraced by all people. An individual may simultaneously belong to multiple SPs (e.g., an African American, disabled, gay man), and an arbitrary compartmentalization of the individual into one single category (e.g., gay population) may result in a neglect of the person's multiple other needs. Thus, practitioners must not use their knowledge about SPs in stereotypical ways but as a means for understanding one or more aspect(s) of the client. Members of a SP can be stratified by various factors. For example, within a racial/ethnic minority, within-group differences may be examined through gender, age, or generation. Knowledge about a SP should never sacrifice individualization when it comes down to assessment and treatment of an individual. The initial intention of the concept is to go beyond a client's AOD problems and to treat the client as a whole person; a misuse of the concept may do just the opposite.

The implementation of SP-specific services has not been without challenges. Although a specialized treatment program provides specific services to a SP, it limits clients' geographic accessibility because of the infeasibility of establishing specialized programs in all locations. A general and nonspecialized program offers a much wider accessibility. For larger facilities that house both the specialized and nonspecialized programs, difficulties still exist. Research shows that although AOD treatment facilities with special programs are more likely to provide key services to SPs, less than half of them offer most key services. More research exploring causes of the gap is needed. It may be that the gap is related to the fact that key services to SPs are expensive and the programs are underfunded. This suggests that the programs should conduct cost-benefit analyses to show the long-term benefits if special services are provided and thus attract more funding.

SPIRITUAL ISSUES

The treatment of, and recovery from, alcohol and other drug addiction has historically been intrinsically connected with spirituality and spiritual growth. Twelve-Step programs, arising from Alcoholics Anonymous, have always understood recovery from addiction in fundamentally spiritual terms. Likewise, a growing body of research around the use of spiritual concepts in the treatment of alcohol and drug addiction shows the value of spirituality as the central curative factor in recovery and its importance in maintaining treatment gains.

Defining Spirituality

Those undertaking an extensive review of the literature on this topic may find the research difficult to decipher. Although the word *spirituality* has been used in the literature of the health and social sciences, the variations in how this word is defined and measured are highly problematic in making sense of the results.

The term *spirituality* generally refers to the human longing for a sense of meaning and fulfillment through morally satisfying relationships among individuals, families, communities, cultures, and religions. Although often viewed in a religious context, spirituality is not necessarily about being religious.

Spirituality is about responding to the deepest questions posed by an individual's existence with a whole heart. *Religion* refers to organized structures that center on particular beliefs, behaviors, rituals, ceremonies, and traditions.

During the past 5 years, several expert committees from the addiction and health fields have grappled with a scientific conception of spirituality. In 2003, William R. Miller summarized the findings of these committees into several working assumptions about spirituality:

1. Spirituality is not interchangeable with religion; it is one principal area of concern for religion, but religions also have other nonspiritual goals and purposes.
2. Spirituality is best understood as a characteristic of individuals. It includes the individual's "religion," or religiousness, but is not defined in relation to religion.
3. Spirituality is not a commodity that is present or absent, or one that is possessed in amount.
4. Spirituality is multidimensional and is best understood as comprised of multiple dimensions including behavior and practices, beliefs, motivations and values, and subjective experience.
5. Every person can be located somewhere within the multidimensional space of spirituality.

A recent review of the spirituality and substance abuse literature found a diversity of definitions and a lack of clarity in references to spiritual concepts. Christopher Cook's analysis, conducted in 2004, identified 13 conceptual components or dimensions within the definitions and descriptions of spirituality:

1. Relatedness—interpersonal relationships*
2. Core/force/soul—the inner core, force, or soul of a person*
3. Meaning/purpose—meaning and purpose in life*
4. Transcendence—recognition of a transcendent dimension to life*
5. Humanity—the distinctiveness of humanity
6. Authenticity/truth—authenticity and truth
7. Values—importance and worth

8. Nonmateriality—opposition of the spiritual to the material
9. (Non)religiousness—opposition of spirituality to, or identity with, religion
10. Wholeness—holistic wellness, wholeness, or health
11. Self-knowledge—self-knowledge and self-actualization
12. Creativity—creativity of the human agent
13. Consciousness—consciousness and awareness

Items followed by an asterisk are the most frequently identified conceptual components of definitions and descriptions of spirituality.

These specific components provide an organizing framework for examining research and understanding the constructs that can be incorporated into spiritually focused treatment practices.

Research on Spirituality and Religion in Addiction Treatment

Research to date on addiction supports the notion that spirituality is an important topic to include in addiction treatment. Much of the research on this topic has been concentrated in a few areas. Principal among them are correlational studies examining relationships between substance use and religiosity in youth and adults, studies of Twelve-Step program involvement and Twelve Step–based interventions, and nonempirical commentaries. The research to date supports the notion that spirituality is an important topic to include in addiction treatment. For example, in a 2002 study of 237 recovering substance abusers, Dustin A. Pardini and colleagues found that higher levels of religious faith and spirituality predicted a more optimistic life orientation, greater perceived social support, higher resilience to stress, and lower levels of anxiety. Many large-scale studies have focused on the use of spiritual principles in Alcoholics Anonymous (AA), finding that substance abusers who practice the Twelve Steps are more likely to remain abstinent than those treated with other types of nonspiritual therapy, and individuals who reported a spiritual awakening as a result of their AA involvement were nearly 4 times more likely to be abstinent 3 years post treatment than individuals

who reported never having had a spiritual awakening. In a large meta-analytic study conducted by the National Institute on Alcohol Abuse and Alcoholism in 1999, the Fetzer Institute found strong support for the protective nature of spirituality and religion (110 studies), of AA involvement (51 studies), and of spiritual/religious interventions (26 studies).

Spirituality has also been cited as an influence on recovery itself. The sense of meaning and purpose in life is often at a low ebb during addiction treatment, but it tends to increase during recovery. In its large-scale clinical trial, Project MATCH found that higher baseline scores on the Religious Background and Behavior Scale predicted better outcomes in the reduction of drinking at the 1-year follow-up. Other research studies have shown that increased spiritual practices have been associated with improved addiction treatment outcomes, that spirituality has played a role in maintaining treatment gains, and that recovering individuals show more evidence of spirituality than those who relapse.

Integrating Spiritually Based Strategies

People, for as long as history has been recorded, have found spirituality to be a significant source of healing, and a large proportion of people continue to find spirituality, including religious involvement, to be an important source of meaning and sustenance. Many strategies are used every day in addiction treatment and health care that incorporate essentially spiritual material. The themes of these strategies are rooted in fostering a sense of direction; engendering meaning and purpose in life; developing feelings of connectedness with oneself, with others, and with God or a higher power; clarifying what is trivial and what is truly vital in life; fostering love, compassion, and forgiveness; and defining personal values related to an individual's philosophy of life. Likewise, the key principles of Twelve-Step programs—spiritual discipline and character development, including humility, making amends, forgiveness, acceptance, submission to a higher power, ongoing personal moral inventory, and service to others—have been emphasized for many years and are familiar to most addiction counselors.

There exists a variety of spiritual issues, assessments, and strategies that can be incorporated into addiction treatment. Several useful and well-tested assessment

instruments, examined in 1999 by Richard L. Gorsuch and William R. Miller, are available and can be used to provide a reliable assessment of a client's spirituality. Formal religious activities, such as prayer and the reengagement of clients with religious traditions, are strategy options for those who desire them. Other spiritually focused practices, such as values clarification, activities that provide humanistic connections, contemplation, yoga, Zen, and transcendental meditation have been effectively applied to addiction treatment. For example, the outcome of meditation is generally related to the earlier mentioned construct of *mindfulness*, defined as having an awareness of the full range of experiences that exist and bringing one's complete attention to the present experience on a moment-to-moment basis. This outcome is important in its application to clinical practice as it is said to foster the ability to observe one's thoughts and feelings as they occur in the present moment, allowing for self-monitoring or cognitive techniques aimed at changing thought patterns.

Familiarity with a range of spiritual and religious perspectives and strategies is limited for many counselors. This is not to suggest that each counselor should be proficient in these areas or step outside of the limits of his or her professional competence. Rather, it is important to have a fundamental knowledge of this vital aspect of human nature. Using counseling techniques with a wider inclusion of spiritual issues may be a difficult task for counselors who may feel unprepared both educationally and experientially. Accomplishing this task requires a willingness by counselors to reflect on the role their own belief systems play in their work, as well as a desire to have a dialogue with clients on spiritual and religious issues.

It is important that counselors be sensitive to how spiritual and religious beliefs are approached within a cultural context. Not only do religious traditions and values constitute an integral part of culture, but spiritual experiences and practices have an important place in the psychological reality of many people. Religion and spirituality in many cultural groups are deemed important for the provision of comfort, joy, pleasure, and meaning to life as well as the means to deal with death, suffering, pain, injustice, tragedy, and stressful experiences in the life of an individual or family. Counselors should be careful, however, in making assumptions regarding the spiritual or religious dimension of a client's life based upon racial/ethnic or cultural backgrounds. Even when a client self-identifies as being of a particular culture and spiritual or religious group, the counselor needs to

explore that identification for that particular client, as many factors can impact a client's beliefs and values, as well as the application of those beliefs and values.

William R. Miller, in *Integrating Spirituality Into Treatment: Resources for Practitioners*, asserts that one need not be a believer (religiously speaking) to help clients discuss spiritual features of their condition and their care. Rather, a profound respect for spiritual, religious, and cultural diversity is what is called for here. Fundamentally, a clinician needs a set of proficiencies that are sensitive not only to culture but also to a client's spiritual needs, such as having a nonjudgmental, accepting, and empathic relationship with the client and an openness and willingness to take time to understand the client's spirituality as it may relate to health-related issues.

In conclusion, research has shown that treatment of, and recovery from, addiction is paralleled by spiritual growth. A variety of spiritually focused strategies are available that can serve as either a central or complementary therapeutic pathway for facilitating lasting change in clients.

STAGES OF CHANGE MODEL

The stages of change model provides the theoretical framework for understanding the stages and processes of behavioral change. This model offers an explanation for *how* people change, with or without treatment, with important implications for changing substance abusing behavior. The stages of change model represents a series of five stages through which people pass as they change a behavior: precontemplation, contemplation, preparation, action, and maintenance. In this model, change is viewed as a progression from precontemplation, where there is no intention to change within the foreseeable future, to maintenance, where change in behavior is sustained for at least 6 months. The stages are not linear, and any one person may cycle several times through each stage before sustainable behavioral change occurs. This entry includes a summary of the stages of change with relevance to treatment engagement for substance use disorders. An integration of the stages and processes of change is discussed in relation to treatment engagement and relapse prevention.

Stage Model

Precontemplation

Individuals in this stage do not recognize that they have a problem and are not seeking to change their substance abusing behavior. Resistance to change is the hallmark of this stage. Precontemplation is

described as “seeing solutions but not seeing the problem.” Precontemplators are often pressured into treatment by family members and friends, who are well aware of their problems and often frustrated with their drug use. If referred, the precontemplators may benefit from nonthreatening information to raise awareness of a possible problem, or potential for change, or to provide other support for change.

Contemplation

A person in this stage is aware of a problem, and is seriously thinking of overcoming it, but shows no commitment to change as of yet. Contemplators can often get “stuck” in this stage for quite some time while they are evaluating the pros and cons of their problems and the possible solutions. Contemplation is described as “knowing where you want to go but not quite ready yet.” Many contemplators are ambivalent concerning change and have indefinite plans to take action in the next 6 months. Client education is an effective tool for contemplation and ambivalence.

Preparation

At this stage, individuals are intending to take action in the next month but have unsuccessfully taken action over the past year. Individuals are prepared for action in this stage, with some small behavioral changes, like drinking less or smoking less, but they have not quite reached their goal. They may seek treatment and ask for help to reach these goals.

Action

In this stage, people modify their behavior, experiences, or environment to overcome problems. Action involves *overt* behavior change and requires considerable commitment, time, and energy. Modification of targeted behavior to an acceptable criterion and significant overt efforts to change are the hallmarks of action. Individuals in this stage make comments such as “I am really working hard at change.”

Maintenance

In this stage, individuals are working to prevent relapse and to consolidate the gains attained during action. Maintenance is continuation of change, and for addictions, maintenance must be sustained for at least

6 months. Stabilizing behavior change and avoiding relapse are the hallmarks of this stage. Individuals in this stage may make comments such as “I may need a boost right now to help me maintain the changes I’ve already made.”

Recycling

In addictions, many people cycle through these stages before change is maintained for at least 6 months. One may repeat oneself through the stages or may be “stuck” in a particular stage for long periods of time before moving to the next stage or relapsing to the previous stage. As a result, there is a great deal of “learning from mistakes,” but through each cycle, the more “action” the client takes, the better the prognosis will be.

Research Findings

Research has demonstrated the application of the stages and processes of change with many different targets of change including smoking cessation, dietary modification, gambling, alcohol consumption, drug use, smoking, condom use, and pregnancy prevention. Research demonstrated that matching treatment with an individual’s state of change and key client characteristics is associated with lower relapse rates and improved treatment engagement.

Processes of Change

The processes of change are a second major dimension of how change happens. Change processes are activities that individuals engage in when they attempt to modify problem behaviors. These processes are powerful predictors of change for both therapeutic and self changes. Whether or not a client will complete treatment can be predicted by a combination of the client’s stage of change and engagement in the processes of change.

Research suggests that cognitive and experiential processes of change are more important during the earlier stages of change, and behavioral processes appear to be more salient in the latter stages. For example, in the precontemplation stage, examples of processes important to change include (a) consciousness raising or increasing information about oneself and the problem, (b) dramatic relief or experiencing and expressing feelings about problems and solutions, and (c) environmental reevaluation or assessment of how the problem

affects the physical environment. The contemplation stage matches well with educational techniques and processes that increase awareness and encourage self-evaluation of existing problems. The action stage is characterized by more behavioral processes. Some examples cited include the following: (a) counterconditioning or substituting alternatives for problem behaviors, such as relaxation, desensitization, assertion, and positive self-statements; (b) stimulus control or avoiding stimuli that elicit problem behaviors, such as environmental restructuring, avoiding high-risk cues, and fading; (c) reinforcement management or rewarding self for change and contingency contracts; and (d) helping relationships or being open and trusting about problems with others, including therapeutic alliance, social support, and self-help groups.

Future Directions

Research suggests a transtheoretical model of change, which includes cyclical patterns of movement through the stages of change, a common set of processes of change, and an integration of the stages and the processes of change to prevent relapse and improve treatment retention. For addictions, successful change involves recycling through the stages of change and matching treatment to an individual’s stage of change to increase motivation for change and treatment engagement.

STATE PROVIDER ASSOCIATIONS

Addiction counseling originated in a service vacuum. In the 1960s, mental health professionals (psychologists, psychiatrists, social workers) avoided the substance abuse client population. As the addiction counseling profession grew in size and stature, state associations for addiction counselors became an important component of the profession. Considerable progress has been made in the counseling and addiction counseling professions. Licensed counselor laws exist in nearly all 50 states, and addiction counseling certification is being mandated by more states every year. For many years, the various treatment facilities have operated independently, often competing with each other for much-needed grant funding. However, the growth of state provider associations has fostered productive consortium relationships and supported yearly conferences with training in current practices.

At the present time, state associations offer organization, assistance, training, and advocacy. The associations are able to work with state legislatures to bring parity to the field. The associations are continually evolving organizations. Considering change inherent within the addiction counseling profession itself, this entry provides a general overview of state associations. Specific information can be obtained by contacting specific state associations.

Certification and Training

National organizations such as the International Certification & Reciprocity Consortium/Alcohol and Other Drug Abuse, Inc. (IC&RC) and NAADAC (the Association for Addiction Professionals) oversee the certification of addiction counselors. State associations are affiliated and/or work with one or both of these organizations. For instance, IC&RC is affiliated with 44 states, and NAADAC is affiliated with 46 states.

Considering the past and current status of addiction counseling education and training, state associations linked with these certification bodies play a crucial role in the quality control of the profession.

MaryLouise Kerwin, Katherine Walker-Smith, and Kimberly Kirby reviewed state requirements for addiction counselors and uncovered the following statistics. Forty-five percent of states currently do not even require a college degree to qualify as an addiction counselor, and only 3% require a graduate degree. However, as of 2007, 50% of states mandate credentialing to practice addiction counseling (e.g., passing a professional examination). More and more states require some form of credentialing every year. Some states require the equivalent of six college courses worth of training (i.e., 270 hours or more). When compared with mental health counseling peers, addiction counselors are mandated to fewer classroom hours of instruction but must complete 1,000 more hours of supervised training. Therefore, the state associations (as they work with the IC&RC or NAADAC) assist in the quality control of the profession by organizing the professional credentials that are voluntary or mandated in the state.

Addiction counseling has traditionally operated via the “apprentice model,” wherein supervision stresses tasks and a “how to” model as opposed to a conceptual training model focus. Consequently, addiction counseling practices become facility or region specific. For instance, many addiction counselors in traditional therapeutic communities return to the same facility where they received treatment to work as counselors.

State associations combat this quality control issue by offering workshops, continuing education, training, and statewide conferences on issues such as counseling practices, addiction, assessment and evaluation, HIV/AIDS, violence, co-occurring disorders, and poly-substance disorders. State association-sponsored conferences typically draw regionally and nationally respected speakers while offering most, if not all, of the continuing education credits required each year. Thus, addiction counselors from facilities and private practices all throughout a state can gather, learn, and network while maintaining their professional credentials.

Advocacy

State associations advocate for the addiction counseling profession at the regional, county, state, and national levels. States affiliated with IC&RC or NAADAC

receive all of the benefits of the national reach of these organizations. Important issues include the practice of addiction counseling, reciprocity for certification credentials, working relationships with other human service and mental health professions, and legal issues relevant to addiction and counseling. Associations now represent licensed professional counselors, social workers, and addiction counselors and lobby for third-party reimbursement.

Importance of State Associations

Addiction counseling is a profession currently in transition toward more formal credentialing and education. In addition, the public is in need of information on the various forms of addiction and treatment options. In sum, state associations provide a key resource for counselor training and advocacy. Because the states vary in their efforts and self-defined responsibilities, consultation with a specific state association will enable counselors (or counselors-in-training) to take full advantage of all the opportunities and support available to them statewide.

STIGMA

In the substance abuse field, stigma refers to widely held negative opinions of drugs of abuse, those who use them, and those who are addicted to them. Although the degree of stigmatization of drug use and dependence has varied over time and with drug

and user characteristics, stigma has been strongly associated with those who lose control over drug use. Stigma has a profound impact on drug-dependent individuals and those associated with them, including family members, neighborhoods, treatment professionals and programs, and treatment and recovery advocates. Stigma delays treatment seeking and influences treatment effectiveness.

In November 2000, the Center for Substance Abuse Treatment addressed the issue of stigma in its publication *Changing the Conversation, Improving Substance Abuse Treatment: The National Treatment Plan Initiative*. The consensus panel delineated a five-point definition of stigma as it relates to drug use and addiction. The first point acknowledges that stigma is a powerful, shame-based mark of disgrace and reproach; the second, that stigma arises from, and is perpetuated by, prejudicial attitudes and beliefs; the third, that these attitudes and beliefs give rise to discrimination against addicted and recovering people; the fourth, that such discrimination deprives addicted and recovering people of basic human rights; and the fifth, that addicted and recovering people often internalize prejudicial beliefs and discriminatory practices.

History of Stigma

Stigmatizing of drug use and addiction is hardly new. Historically, most addictive drugs and their users have been seen in both positive and negative lights. Alcohol, tobacco, opium, cocaine, cannabis, and various hallucinogens have all been praised for their medical, spiritual, and societal benefits. Opium offered effective relief of pain, diarrhea, and cough for centuries when few other medicines were available, and those who used it for pleasure were extravagant in their praise of the opium experience. However, those who became addicted to opium (and later, heroin) were, and are, intensely stigmatized, being described as degenerates; those who provided the opium were characterized as predatory “Chinamen,” adding racial bias to drug-associated stigma. Likewise, light to moderate use of alcohol has long been accepted in many cultures, with various alcoholic beverages being seen as essential to celebrations, fine dining, and social relaxation. This acceptance disappears with regard to individuals who are dependent on alcohol. The word *alcoholic* continues to be strongly associated with being weak-willed, of poor moral character, homeless, and jobless.

Periodically throughout history, the association of addicted people with low morality has devolved into stigmatizing the substances themselves. Many examples of this can be drawn from the history of the United States in the 19th and 20th centuries. The temperance movement, which initially urged people to abstain from liquor and drink beer and wine only in moderation, became the Prohibition movement, which advocated enforced abstinence via legislation. It is well known that nationwide Prohibition was a short-lived phenomenon, but the portrayal of alcohol and alcoholism as societal evils remained. Over the same period of time, heroin, cocaine, and marijuana were all viewed as threats to decency and stability, and the legal use of these drugs has remained highly restricted since that time.

The intersection of stigma with racism and oppression is worth noting. Opium trafficking was associated with Chinese individuals in Europe and the United States, and the racist term *yellow peril* derived in part from this association. Both African-descent slaves and Native American individuals were viewed as unable to “hold their liquor,” one more bit of evidence that they were inferior to the dominant White culture. Many in the Prohibition movement warned against drunken, dirty immigrants—Irish, Italian, and Eastern European people who were generally Catholic or Orthodox—not fitting in with the prevailing White Protestant sensibility. Both cocaine and marijuana were condemned, in part, due to hysteria over the image of Black men who got high, engaged in violent crime, and raped White women. This image is echoed in the current differential sentencing for crack cocaine versus powder cocaine offenses, which has been shown to disproportionately affect African American individuals. This phenomenon is not exclusive to the United States. Peoples who suffer some of the worst oppression in the world—Roma (Gypsy) people in Eastern Europe, Aboriginal people in Australia, Dalit (Untouchable) people in India—have been seen as inferior to most of humanity, with high rates of alcoholism being evidence of their degenerate natures (rather than a consequence of the oppression they experience). In all of the previously mentioned cases and others, the effect is to deepen the disempowerment of oppressed peoples by judging them as weak and immoral. This shows up at the public policy level as well. For example, much of the effort to control drug use in the United States is put into supply reduction, in which the blame for “the drug problem” is placed on Latin American and West Asian countries.

The demonizing of substances themselves, however, is by no means the most destructive aspect of drug-related stigma. Those addicted to alcohol or illicit drugs are described in various pejorative terms—*drunk, lush, junkie, crackhead* (or *pothead* or *methhead*), *dope fiend, freak*—which generally connote that the individual is simply evil, weak, or both. Common public perceptions are that addicted people don’t care about anyone but themselves, that they are routinely involved in criminal activity, that they make no useful contribution to society and are a constant drain on the welfare system, that they go to treatment only to escape the consequences of their actions, and, perhaps most damaging of all, that they “did it to themselves.” This seems to be the crux of much of the stigmatization of addicted people: that they irresponsibly chose to drink too much or use illegal substances, and they deserve the ruin they have brought on themselves.

Consequences of Stigma

The consequences of these stigmatizing beliefs for addicted and recovering people are manifold. Out of shame and fear, addicted individuals often feel the need to remain silent about their experiences; this not only delays or prevents them from seeking help but also, should they find the help they need, makes them hesitant to share positive messages of recovery. In some places, pregnant women who are addicted and who use drugs or alcohol while pregnant are subject not only to vilification but to arrest and conviction for child abuse. A single positive result on a urine drug screen is often grounds for immediate dismissal from work or school rather than an opportunity for effective intervention. Addicted and recovering people are routinely denied work, housing, health benefits, and alternatives to incarceration and are subject to many other forms of ostracism and discrimination. Worse yet, the shame created by these conditions often causes addicted people to mistrust and avoid the very systems designed to provide them with the treatment and other services that they need and deserve.

Among the most tragic aspects of this internalization of stigma is that it is sometimes found in treatment programs and recovery groups. When an individual does not adhere to treatment, or attains but is unable to maintain abstinence, others will often refer to this individual as “just not ready.” This fails to acknowledge the reality of addiction, a chronic condition characterized by

relapse; one can bring a great deal of readiness to recovery efforts, yet find staying abstinent extremely challenging. Likewise, those whose recovery includes opioid maintenance medication (such as methadone or buprenorphine) may encounter prejudicial attitudes from those in Twelve-Step recovery programs because they are “still using.”

Stigma presents barriers to treatment at every level. For the individual, as noted earlier, acknowledging that drug use is a problem and asking for help is made much more difficult by the shame fostered by constant negative messages about drug use and addiction. Many people simply do not know what to expect when they request help from a trusted friend, physician, clinic, or hotline. They may fear that they will be forced into rehab, arrested, or in danger of losing family or livelihood. Some issues are culture specific. Survey data from Latinas entering treatment in the United States indicate that they typically postpone seeking help because they fear intense scorn from their peers; this is true especially if the women needing help are mothers. Likewise, research among Asian immigrants and first-generation Asian Americans in the United States indicates that some hesitate to request assistance in order to avoid disrupting the image of Asians as “model immigrants.”

Another layer of stigma-induced barriers to treatment is seen in the poor funding of addiction services. In many parts of the world, those seeking treatment far outnumber the number of treatment slots available. Many of the agencies responsible for providing services are unable to maintain adequate staffing or infrastructure. If an individual is covered by health insurance or a national medical system, the carrier or system may be unwilling to provide the necessary length or intensity of treatment that is appropriate to that individual. If the individual does not have these advantages, the wait for services might be days or weeks, or even longer, often resulting in the loss of the therapeutic opportunity.

The consequences of stigma reach beyond the experiences of addicted people to those associated with them—everyone from family, friends, and neighbors to treatment professionals, advocates, and researchers. In July 1985, a telling editorial appeared in the *American Journal of Psychiatry*. Its title was “The Ultimate Stigma: Inadequate Funding for Research on Mental Illness and Addictive Disorders,” and it encapsulated findings from a report by the Institute of Medicine. Although funding for addictive disorders has expanded

enormously since 1985, it is still by no means in proportion to the large-scale health and economic consequences of addiction. The point of the editorial remains relevant: In the realm of public policy, as elsewhere, it is considered acceptable to question whether addicted people really deserve adequate attention and assistance.

Efforts to Reduce Stigma

The current understanding of addiction as a chronic medical illness stands in direct contrast to the moralistic view that underlies so much stigma and discrimination. Many of the current efforts at stigma reduction are geared toward fostering a public understanding of the nature of addiction, including the neurobiological and other physiological factors that play into the development and maintenance of the illness. In particular, efforts are under way to educate medical professionals, lawmakers, judges, and journalists into the reality of addictive disease.

Stigma reduction, in general, has become essential to ongoing efforts to help addicted individuals, their families, and their communities. In its 2004 publication *Neuroscience of Psychoactive Substance Abuse and Dependence*, the World Health Organization (WHO) makes 10 public policy recommendations. In addressing stigma, the WHO’s recommendation states, “One of the main barriers to treatment and care of people with substance dependence and related problems is the stigma and discrimination against them. Regardless of the level of substance use and which substance an individual takes, they have the same rights to health, education, work opportunities and reintegration into society, as does any other individual” (p. 33). The governments of many countries have implemented stigma reduction programs, and there are also many non-governmental organizations that advocate for addicted people and for treatment and recovery.

In the United States, the Substance Abuse and Mental Health Services Administration (SAMHSA) supports National Alcohol and Drug Addiction Recovery Month each year in September. Recovery Month brings together state and local agencies, treatment providers, public figures, community groups, and recovering people and their allies to celebrate recovery and foster stigma reduction. Such efforts routinely include political action, with individuals and organizations lobbying their legislators for increased funding for treatment and other essential programs; visibility events such as walks, rallies, and concerts; culture-specific ceremonies, arts presentations,

and gatherings; and conferences for professional and public education. SAMHSA has also published *Are You in Recovery From Alcohol or Drug Problems? Know Your Rights* as a guide for those who may be experiencing discrimination due to their history or recovery status. Among nonprofit entities in the United States, Faces and Voices of Recovery, Join Together, and NAADAC, the Association for Addiction Professionals, are among those who are constantly engaging in political action, public awareness campaigns, and other advocacy efforts. NAADAC, in particular, engages treatment professionals and recovery advocates in an annual political action conference in Washington, D.C., at which attendees are trained and rallied in addressing public policy issues. Groups such as these also publicly applaud accurate news stories and media representations of addiction and recovery and confront portrayals that are stigmatizing and sensationalized. Efforts such as these are making some inroads into the stigma that surrounds drugs and addiction.

STUDENT ASSISTANCE PROGRAM

A student assistance program (SAP) consists of a set of practices implementing a systematic professional process in a school that frames an infrastructure for organizing the services existing in that school. This framework addresses barriers to learning, such as substance abuse, mental health concerns, and violence problems, through a continuum of prevention, early identification, intervention, and support services through universal, selective, and indicated strategies. The framework includes utilization of school-based resources and connections to community resources and services that assist in providing prevention services to the entire school population, addressing selective student population needs based on common risk factors, or working with indicated individual students and their families. Student assistance services are structured through the nine components of a comprehensive SAP and delivered through a combination of targeted strategies using one or more SAP approaches.

Barriers to Learning

Student assistance has historically focused on dealing with behavioral health issues that impact the individual student, family, and school. Students impacted by individual, family, and community stressors such as mental health issues, substance use, and violence are at greater risk for socioemotional and behavioral health concerns as well as lowered academic achievement and reduced graduation rates. Schools that are impacted by these stressors and that lack adequate measures of support are at greater risk of fostering climates that produce fewer students achieving their potential. These stressors, called “barriers to learning,” can occur to students of all ages. Student assistance programs are specifically targeted to address these barriers.

Student assistance has been shown to reduce behavioral problems, increase academic performance, and increase school attendance for all students. Student assistance partners with parents, students, school resource officers, other school faculty, community coalitions, and agencies in seeking to mitigate these barriers.

Scope of Student Assistance

Student assistance is not a special education initiative. Student assistance services focus on the needs of every child in the school as well as serving the school as a whole through system enhancement and change. Student assistance exists in schools in all 50 states serving students in Grades K(indergarten) through 12 focusing and organizing prevention, early intervention, and support services. Although a comprehensive prevalence picture of student assistance does not currently exist, a number of states report hundreds of SAPs functioning within their state.

Development of the Student Assistance Field

Student assistance emerged in the early 1970s and was patterned after the successful approach of employee assistance programs as a way to assist secondary schools in dealing with alcohol and other drug problems at a time when there were no historical programs or strategies on which to build. The focus was on formalized intervention processes with goals of addressing adolescent alcohol and other drug use intended to get individuals into treatment programs. The Reagan administration's Chemical People program enhanced community awareness of adolescent substance use and prompted a number of hospital-based treatment centers to initiate "care team" training to engage schools in moving adolescents toward treatment. These care teams became the groundwork for a number of future SAPs that would expand efforts to address all barriers to learning.

Simultaneously, prevention efforts grew in schools and social service organizations. By the late 1970s, student assistance responded to the prevention movement and shifted from an intervention-only approach to encompass prevention, intervention, and support efforts expanding strategies for other behavioral health and school-based issues.

Student assistance emerged as a field of study in the mid-1980s with the development of the National Student Assistance Association, which polarized

individual states' efforts to advance SAP strategies. The student assistance field adopted evidence-based prevention principles in the mid-1990s and promoted evidence-based implementation practices following published literature in 2000.

The most recent study conducted by the Center for Substance Abuse Prevention, in cooperation with the National Student Assistance Association, confirmed that students going through the student assistance process were connected with behavioral health care services at a rate 4 times higher than is noted nationally and complied with recommendations at a higher rate as well. Study results showed that students involved with student assistance increased attendance at school, decreased behavioral referrals, and improved academically.

Approaches to the Delivery of Student Assistance Services

Delivery of student assistance services has historically been categorized into the external approach, the internal approach, and the core team approach. Often, for sustainability reasons, schools will implement a combined approach to avoid the SAP being constituted by a single individual who is subject to personnel changes.

External Approach

The external SAP counselor or coordinator is an agency-based individual typically contracted part-time to a district to provide on-site services. The external SAP counselor responsibilities may include planning and delivery of prevention services, conducting educational support groups, and conducting initial screening and assessment primarily for substance abuse, mental health, and violence problems. The external SAP coordinator or counselor's certification in working with behavioral health issues serves intervention needs well, but may not be able to fully address the prevention needs of the school. The approach is often limited by funding for both the number of hours per week allotted to work directly with students and elimination when budgets grow smaller and contracts with outside providers must be cut.

Internal Approach

The internal SAP counselor or coordinator approach consists of an individual employed by the district to coordinate prevention efforts for all students, conduct educational support groups, and work directly with individual

students. The SAP coordinator may provide direct student services, supervise others providing the services, or utilize a combination of both. The internal SAP coordinator or counselor often has specialized training, including a background in counseling. Unfortunately, many internal SAP coordinators are subject to the same limitations as external SAP coordinators.

Core Team Approach

The most widely implemented SAP approach involves a team of individuals representing a variety of disciplines including the building administrator, school nurse, guidance counselor, and classroom teachers working with students to implement school-based strategies and connect students and families to community resources. SAP core team members often volunteer the extra time needed for SAP work; this results in the approach not being vulnerable to outside funding for services. However, dedicated time for working with students may be limited.

The Student Assistance Continuum of Care

Prevention

Prevention includes evidence-based programs and practices that offer age-appropriate alcohol, tobacco, and other drug education; interpersonal and behavioral skills training; violence prevention strategies; and social norming strategies. Prevention efforts may also include creating effective policies and procedures that clearly spell out consequences for violations and ways of obtaining help. The SAPs often work collaboratively with community prevention partners implementing strategies focused on increasing understanding of risk and protective factors; increasing awareness of alcohol, tobacco, and other drug use; and providing positive youth activities and service opportunities.

Identification and Referral

Adults in the school community are trained to identify common warning signs of barriers to learning so that students may be referred to the SAP. Warning signs include declining academic performance and attendance, increased behavioral problems, and possible health concerns. Identification may also come through referral by students and parents, policy violations, or possession of common risk factors such as teen pregnancy or geographic location.

Early Intervention

The SAP gathers relevant information in a fact-finding screening process to determine whether the referred student is appropriate for student assistance services or would benefit from non-SAP-focused services. Typically, parents are also contacted as part of the fact-finding process, and the student is interviewed to understand his or her perception of the problem.

Problem Solving and Recommendations

The SAP develops a plan to help the student and family reduce the barriers to learning and improve the student's chances for success. The plan attempts to link the student to appropriate in-school resources such as meeting with the school counselor, tutoring, mentoring, peer mediation, or participation in a life skills education or support group. When deemed appropriate, the plan may also include linking the student and family with needed community resources to assist with problems beyond the scope of school services. A few areas of the country are beginning to implement a brief intervention school-based substance abuse treatment process conducted by licensed or certified individuals as part of SAP services.

Support and Follow-Up

As students receive school or community services, SAP can coordinate the exchange of important information to increase the probability of success. For those students receiving treatment and support from community agencies, a school support plan may be implemented as well. SAP typically provides monitoring of the student's progress along with additional strategies over a period of time to facilitate continued progress.

Student Assistance Targeted Strategies

SAP aligns strategies with the Institute of Medicine's universal, selective, and indicated population delineations. Universal SAP strategies are directed to the entire student population and include prevention programs, policy and procedures, and environmental changes affecting all students. Selected SAP strategies focus on students deemed at higher risk by virtue of their membership in a particular population segment, such as children of alcoholics, students with anger or grief issues, students who violate school policy, or students

who are failing academically. Education-based support groups, mentoring, tutoring programs, and targeted after-school programs focusing on life skills development are commonly used strategies in the selective population.

Indicated SAP strategies are designed for individuals who do not meet the *Diagnostic and Statistical Manual, Fourth Edition, Text Revision* criteria for addiction or mental health problems but who are showing early danger signs such as failing grades, negative individual and peer behaviors, or using alcohol and other drugs. The mission of indicated SAP services is to identify individuals who are exhibiting early signs of problem behaviors and target them with special programs and services.

Components of a Comprehensive Student Assistance Program

The nine components, distributed in 1997 by the National Student Assistance Association, are considered the foundational pillars and serve as the minimum standards for implementing a school-based SAP. An abbreviated description of the components follows.

School Board Policy

Alcohol and other drug policies define the school's role in creating a safe, disciplined, and drug-free learning community. Policies should clearly communicate both the prevention strategies and behavioral expectations with consequences as well as foundations for students with policy violations and those voluntarily seeking assistance.

Staff Development

Provide all school employees with the necessary attitudes and skills to appropriately identify students whose academics, behavior, and health may indicate problems. Staff development should also build skills to increase protective factors and foster resilience through SAP services.

Program Awareness

Provide information about student assistance services educating parents, students, agencies, and the community about how to access SAP, community resources, and the school policy on alcohol, tobacco, other drugs, disruptive behavior, and violence in relationship to SAP prevention, intervention, and support.

Internal Referral Process

Provide a systematic process that identifies and refers students with behavior, academic, attendance, health, and social concerns to a multidisciplinary problem-solving and case management team (core team) or student assistance coordinator.

Problem Solving Team and Case Management

Conduct the screening process to identify needs and barriers, and create solution-focused strategies to allow schools to best serve students.

SAP Evaluation

Conduct ongoing process and outcome evaluation of strategies and services to ensure continuous quality improvement of student assistance services and outcomes.

Educational Student Support Groups

Provide education-based skill building through information, support, and problem solving with students who are experiencing academic, behavior, attendance, health, or social problems.

Cooperation and Collaboration With Community Agencies and Resources

Build bridges between schools, parents, and communities through prevention services, screening and assessment services, treatment resources, and shared case management.

Integration With Other School-Based Programs

Integrate student assistance services with other school-based programs and services, optimizing resources to improve academic performance, school attendance, behavior, and social skills, while reducing student risk for alcohol, tobacco, and other drug use and violence.

Conclusion

Although student assistance is a relatively young field, research and practitioner support documenting student assistance practices and strategies continues to

grow, enhancing the desirability and effectiveness of implementation.

across countries, and there is some question as to how much of this variance can be attributed to incongruent definitions (some of which are rooted in cultural customs) rather than actual differences. According to the 2005 National Survey on Drug Use and Health, nearly 12 million Americans met the criteria for substance abuse (including abuse of alcohol); this figure represents more than 5% of the United States population over the age of 12. When including the more severe condition of substance dependence, it was estimated that a total of 22.2 million Americans over the age of 12 (about 9.1%) met the criteria for a substance use problem. In addition, males were about twice as likely as females to be diagnosable for substance abuse.

There are significant economic costs associated with the abuse of alcohol and other substances. According to the Office of National Drug Control Policy, in 2002, the overall cost of abuse of substances other than alcohol in the United States approximated \$181 billion. More than 20% of these costs were related to incarceration, and nearly another 20% were related to drug-related illnesses. Furthermore, the National Institute on Alcohol Abuse and Alcoholism estimated that, in 1998, the costs related to alcohol abuse alone were nearly \$185 billion. The majority of these costs (about 66%) were related to lost current or future earnings due to alcohol-related illness or premature death.

SUBSTANCE ABUSE

Many definitions of substance abuse exist. For example, legal statutes can be interpreted to support the position that the mere use of illegal substances is abuse, whereas adaptation perspectives may stipulate that substance abuse occurs only when the negative consequences of using outweigh the benefits. Over time, the establishment of a singular definition of substance abuse has been further confused by changes in social, legal, and cultural norms related to substance use. Nevertheless, substance abuse can generally be defined as the detrimental or risky use of legal or illegal substances or the use of legal substances in a manner or amount inconsistent with medical recommendations.

Because many definitions and methods for measuring substance abuse exist, agreement on the incidence and prevalence of substance abuse has proven difficult. Moreover, prevalence estimates vary greatly

Theories of Substance Abuse

Although the etiology of substance abuse is widely disputed, several theories have gained prominence. The moral, disease, and biological models contend that substance abuse results from individual factors, whereas social learning, systems, and sociocultural theories argue that social and cultural factors are the fundamental cause of substance abuse. More recently, a biopsychosocial approach has been suggested as a way to integrate elements from several of these theories into one unified approach.

Individual Theories

The moral model claims that substance abuse is a choice and that individuals are personally and morally responsible for the use of substances (and the problems that result from them). Alternately, the disease model posits that substance abuse is a progressive and permanent disease with biological origins.

This model is the foundation of many support groups, such as Alcoholics Anonymous, Narcotics Anonymous, and Al-Anon. The biogenetic model argues that substance abuse is largely a result of genetic and neurological processes and that, although initial use may be voluntary, the ensuing abuse or dependence of substances is driven by biological predispositions and changes that occur in the brain.

Social Theories

Social-cognitive learning theories, when applied to substance abuse, assert that substance abuse results from complex learning, including learning from observing others and reinforcement processes. In contrast, systems theory places greater emphasis on interactional processes that occur in families (and other such systems) and can lead to substance abuse. The sociocultural model proposes that substance abuse is a predictable consequence of the specific social norms, laws, and economic systems of many societies, cultures, and subcultures.

Integrated Approaches

The biopsychosocial perspective is an integrative model that amalgamates three major domains known to influence human behavior: the biological, the psychological, and the social. The biopsychosocial model contends that each of these factors contributes in some interactional way to substance abuse. Although this model is more complex than the other major theories, many argue that it more accurately reflects the multifaceted dynamics of substance abuse.

Risk Factors for Substance Abuse

Although research has identified many risk factors for substance abuse, no single variable has been consistently found to predict who will go on to abuse substances across all contexts and circumstances. Instead, risk factors are thought to be interactive and multiplicative. The Center for Substance Abuse and Prevention (part of the U.S. Department of Health and Human Services) currently organizes risk factors for substance abuse into four categories: community, family, school, and individual/peer. Community factors include drug availability, laws, social norms, media portrayals, and community

disorganization. Family factors include family history of substance abuse, family conflict, abuse (physical, emotional, and sexual abuse), and favorable parent attitudes. School factors include academic failure and lack of commitment to school. Individual/peer factors include psychopathology, substance-abusing peers, and gang involvement. Knowledge of risk factors such as these can help in the early identification of individuals likely to begin abusing or to continue abusing substances.

Diagnosis of Substance Abuse

The abuse of substances is often difficult to assess because many individuals are unaware of their true levels of use, deny the seriousness of their problems, or fear the legal and social ramifications of disclosure. The most widely accepted method of diagnostic classification in North America is the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, published by the American Psychiatric Association.

According to the *DSM-IV-TR*, substance abuse falls under the grouping of substance use disorders, which in turn falls under the larger category of substance-related disorders. According to this diagnostic system, substance abuse requires clinical impairment or distress and is evidenced by the presence of at least one of the following symptoms for 12 months or more: (a) repeated failure to fulfill major work, school, or home obligations; (b) frequent use in physically hazardous circumstances (such as driving under the influence); (c) persistent legal problems related to substance use; or (d) continued use in the face of continuing or reoccurring social or interpersonal problems caused by or worsened by substance use. The *DSM-IV-TR* specifies that the term *substance* can refer to a drug of abuse, a medication, or a toxin. Categories of substances that qualify for a diagnosis of substance abuse by the *DSM-IV-TR* include alcohol, amphetamines, cannabis, cocaine, hallucinogens, inhalants, opioids, phencyclidine, and the category of substances comprising sedatives, hypnotics, and anxiolytics. Substances of abuse that do not fit into any of the above categories (such as steroids, cortisol, or antihistamines) are classified as abuse of other substances. Although the *DSM-IV-TR* acknowledges that use of caffeine and nicotine can result in substance-related psychiatric disorders, nicotine abuse and

caffeine abuse are not listed as diagnostic categories in their own right.

Used in many countries outside of North America, the *International Statistical Classification of Diseases and Related Health Problems, Version 10 (ICD-10)* is a diagnostic system developed by the World Health Organization. Instead of the term *substance abuse*, the *ICD-10* uses the term *harmful substance use*, which falls under the classification of mental and behavioral disorders due to psychoactive substance use. Harmful substance use is defined as a pattern of psychoactive substance use that results in actual physical or psychological damage to one's health above and beyond acute intoxication or withdrawal effects. The *ICD-10* employs the following categories of substances that are potentially harmful: alcohol, opioids, cannabinoids, sedatives or hypnotics, cocaine, other stimulants (including caffeine), hallucinogens, tobacco, and volatile solvents. There is also a classification for harmful substance use characterized by multiple drug use and one for other psychoactive substances. Unlike the *DSM-IV-TR*, the *ICD-10* does not consider social or occupational impairment as part of the criteria for diagnosing harmful substance use. Nevertheless, like the *DSM-IV-TR*, use of a substance (whether legal or illegal) in and of itself does not constitute abuse or harmful use unless there are significant consequences. The *ICD-10* also includes a diagnostic category called abuse of non-dependence-producing substances, which includes harm caused by the misuse of antidepressants, neuroleptics, laxatives, over-the-counter pain relievers, steroids and other hormones, and vitamins.

Treatment of Substance Abuse

Although some of those who abuse substances resolve their problem spontaneously and without professional assistance, formal treatment has been shown to be helpful for many individuals. There is evidence that those who receive substance-related counseling tend to reduce their use of substances and show more improvement in other areas of functioning than those not seeking treatment services. Treatment of substance abuse can be facilitated in a variety of settings but is usually conducted on an outpatient basis. This type of treatment can vary from short-term, full-day treatment to weekly or biweekly counseling sessions. Counseling may also be provided on an as-needed basis.

Consistent evidence has been found supporting the effectiveness of a number of specific treatment approaches, including social skills training, self-control training, brief motivational counseling, behavioral marital therapy, stress management training, and community reinforcement. Some evidence of positive outcomes has also been found for covert sensitization, behavioral contracting, the medication disulfiram (brand name Antabuse), and some antidepressants.

Best-Practice Guidelines

Health Canada and the U.S. National Institute on Drug Abuse have both independently developed research-driven best-practice guidelines for substance abuse treatment. A summary integrating these two sets of best practices is as follows:

1. The use of medications (such as methadone and disulfiram) can be effective as supplemental treatments when carefully administered and monitored.
2. Behavioral therapies, such as relapse prevention programs, behavioral self-control therapy, and behavioral contracting, have been shown to be useful in both individual and group counseling approaches.
3. A community reinforcement approach has been shown to be especially effective for individuals who severely abuse alcohol and have poor social networks.
4. Marital therapy and social skills training are both well supported by research in the treatment of substance abuse.
5. Stress management interventions have been shown to be effective elements of alcohol treatment programs.
6. Treatment services should be flexible and tailored to each individual. No single treatment is appropriate for all individuals, and treatment requirements will likely change as treatment progresses.
7. Group therapy is often preferable to individual treatment, unless contraindicated.
8. Although research supports the cost-effectiveness of outpatient treatment, some individuals may also benefit from residential programs.
9. Treatment is most effective when the individual is considered holistically and the multiple needs of the individual are simultaneously addressed.

10. Brief interventions of up to eight sessions have been shown to be as effective as treatments of longer duration for socially stable individuals who abuse alcohol and are slightly or moderately dependent.
11. A strong therapeutic relationship between the counselor and individuals in treatment is essential to positive treatment outcomes.

Prevention of Substance Abuse

Several models applicable to substance abuse prevention exist. A perspective that is widely endorsed at the current time was developed by the Committee on Prevention of Mental Disorders, a subcommittee commissioned by the Institute of Medicine. Their prevention model is grounded in three types of prevention: universal, selective, and indicated. Universal prevention targets an entire population (neighborhood, school, local community, state, country) without considering risk level of developing substance abuse. Nationwide media campaigns educating the general population about the consequences of using particular drugs are an example of universal prevention. Selective prevention targets groups of individuals who are at above-average risk for substance abuse due to characteristically possessing specific biopsychosocial risk factors (e.g., children of parents who are dependent on substances, high school dropouts). University-sponsored education campaigns directed at students living on campus (who have been found to have higher levels of substance abuse than comparable students living off campus) are an example of selective prevention. Indicated prevention targets specific individuals who present with obvious signs or symptoms related to progression into substance abuse but who do not currently meet diagnostic criteria. Mandated counseling for an underage individual caught by the authorities using alcohol in a public place would be an example of indicated prevention.

Conclusion

Most individuals have either directly or indirectly suffered the biopsychosocial consequences related to the abuse of alcohol and other substances. Furthermore, escalating costs related to substance abuse (e.g., medical consequences, lost earnings, judicial costs, incarceration) have fueled shifts in government policies. Nevertheless, evidence-based treatment approaches

and best-practice guidelines have emerged and hold the potential to dramatically increase the efficacy and effectiveness of the treatment services that are provided for individuals struggling with substance abuse issues.

SUBSTANCE ABUSE AND MENTAL HEALTH SERVICES ADMINISTRATION

The Substance Abuse and Mental Health Services Administration (SAMHSA) is a federal agency in the U.S. Department of Health and Human Services. SAMHSA's primary goal is to improve the quality and availability of substance abuse prevention and treatment and mental health services. Since its establishment as a services agency in 1992, SAMHSA has been appropriated annual budgets of nearly \$3 billion in order to support grant programs and contracts that improve the quality, availability, and variety of substance abuse and mental health treatment services at local, state, and regional levels. SAMHSA administers grant programs and contracts, coordinates data collection and evaluation, and provides technical

assistance activities to local and regional programs through its three centers and Office of Applied Studies. The three centers are the Center for Mental Health Services, the Center for Substance Abuse Prevention, and the Center for Substance Abuse Treatment. SAMHSA is the lead governmental agency supporting substance abuse treatment and prevention and mental health initiatives.

Structure, Mission, and Vision

SAMHSA's mission is to build resilience and facilitate recovery for individuals with a substance abuse problem or mental illness, in addition to guiding prevention efforts for those individuals who may be at risk for a substance abuse problem or mental illness. In line with this mission, SAMHSA's resources, contracts, and demonstration projects were created to promote service capacity expansion and address existing prevention and treatment service delivery gaps. SAMHSA provides direct support, in the form of grants and contracts, to states and community service entities, thus encouraging best practices in treatment and prevention programming. SAMHSA also provides support for prevention and treatment program improvement via federal leadership and policy initiatives.

Commensurate with SAMHSA's mission is its vision—a life in the community for everyone. The vision acknowledges that Americans of all ages who have, or may be at risk for developing, a mental illness or substance abuse disorder should be allowed a fulfilled life. SAMHSA envisions this fulfilled life to include achievements in obtaining an education, housing, a job, and meaningful social relationships, all within the context of a supportive community. SAMHSA promotes attainment of this vision by supporting services that yield improvement outcomes focusing on these salient areas, namely, having safe and steady housing, attaining an adequate education, gaining the necessary job skills for employability, and improving the quality of life within the context of a compassionate and life-enhancing community.

All SAMHSA-funded initiatives serve to attain three primary goals: accountability, capacity, and effectiveness. The main objective of the accountability goal is to track national trends of substance use and mental illness, establish measurement and reporting systems to be used by SAMHSA-sponsored projects, and achieve excellence in management practices regarding grantees and fiscal matters. Tracking

national trends is achieved by many of the major SAMHSA-sponsored surveys such as the National Survey of Drug Use and Health, which serves as a surveillance tool that tracks and describes the extent of substance abuse and mental illness rates in the United States. Additionally, SAMHSA has established a standardized measurement and reporting system, required as of 2006 for all SAMHSA-supported grants, called the National Outcome Measures (NOMS). NOMS is a set of indices or domains that index key data outcomes for projects (e.g., decreased justice involvement, increased housing stability, increased retention in substance abuse treatment services). All projects are required to report these outcome data and use them in grant-sponsored treatment provision.

A second goal of SAMHSA involves building or expanding capacity and infrastructure of service availability and delivery for people with, or at risk for, a mental illness or substance abuse disorder. This is the heart of SAMHSA's programming, as many SAMHSA-sponsored programs target groups with special needs (e.g., indigent, ethnically diverse). Capacity-building state grants and programs include Access to Recovery, Mental Health Transformation, Strategic Prevention Framework, and Co-occurring Disorders, all of which began in 2005. Preliminary data from these programs have shown positive results in increasing service availability and capacity. The ultimate goal of these grants involves a focus on changing the structural aspects of programs to ensure implementation of evidence-based practices, enhanced competency levels of the professionals in these prevention and treatment arenas, and effective and efficient treatment and prevention service delivery. To gauge the success of these capacity-building initiatives, Government Performance and Results Act (GPRA) performance measures are required to be submitted by SAMHSA-sponsored programs. For example, grantees report the number of clients served in their program (broken down by ethnicity, gender, and age) and the number of treatment providers trained, as well as other measures. These GPRA measures are used in setting goals within the project-funded period.

One of the largest single expenditures in SAMHSA's budget is the block grant. The Substance Abuse Prevention and Treatment Block Grant is the government's primary source of funding to states for drug and alcohol treatment and prevention programs. The Mental Health Block Grant provides funds to states to create comprehensive, community-based systems of

mental health care. Although it is not a requirement of these grant programs that the funds be used to support homeless individuals, many states have devised ways to garner block grant funds to provide both homeless services and innovative programming in substance abuse and mental health treatment.

SAMHSA's effectiveness goal centers on improving service quality across SAMHSA-supported programs. The effectiveness goal is primarily assessed through grantee-provided NOMS and by encouraging treatment and prevention programs to apply to SAMHSA's National Registry of Evidence-based Programs and Practices, a registry indicating that a given prevention or treatment program has produced successful outcomes and has demonstrated this success through research and evaluation.

SAMHSA also administers the National Clearinghouse for Alcohol and Drug Information, a repository of prevention, treatment, and recovery publications and media available free of charge or at a low cost recovery rate.

The four administrative entities within SAMHSA are described as follows.

Center for Mental Health Services (CMHS)

The CMHS provides national leadership in the application of best practices, evidence-based programming, and knowledge concerning the prevention and treatment of mental illness. Priorities of the CMHS include supporting programs whose goals are to improve accessibility to mental illness prevention and treatment by removing obstacles, while providing effective services and programs for those affected by, or at risk for, a mental illness. The overarching goal of CMHS is to improve the mental health status among all individuals in the United States and provide rehabilitative treatment services to those suffering from a mental illness. Ongoing programs fitting CMHS's scope include the Protection and Advocacy for Individuals With Mental Illness Program, Comprehensive Mental Health Services for Children and Their Families Programs, and the Projects for Assistance in Transition From Homelessness Program. Sample CMHS programs that have attained significance at the national and regional levels include Safe Schools/Healthy Students National Evaluation, Cross-Site Evaluation of the National Child Traumatic Stress Initiative, and the Garrett Lee Smith Memorial Suicide Prevention National

Cross-Site Evaluation. In addition, a host of campaigns and programmatic literature to increase knowledge and awareness derived from CMHS is available to the public on the Web (e.g., a family guide to keeping youth mentally healthy and drug free, Mental Health Services Locator).

Center for Substance Abuse Prevention (CSAP)

CSAP provides leadership in the development of effective and efficient prevention programs, policies, and dissemination of best practices. Programs falling under CSAP's priorities for funding include Strategic Prevention Framework State Incentive Grants, Drug-Free Communities Support Program, HIV Grants, Methamphetamine Grants, and the Centers for the Application of Prevention Technologies. Campaigns supporting CSAP's mission include the StopAlcoholAbuse.Gov Web site, Too Smart To Start, and Building Blocks for a Healthy Future.

Center for Substance Abuse Treatment (CSAT)

CSAT's mission is to promote the quality and availability of community-based substance abuse treatment services and to support free treatment referral services to link people with the community-based substance abuse services they need. Sample programs funded under CSAT include the Screening, Brief Intervention, Referral, and Treatment program; the Family Treatment Drug Courts Program; the Opioid Treatment Program; Access to Recovery; the Drug Addiction Treatment Waiver Program; Recovery Community Services Program; and the Addiction Technology Transfer Centers. Examples of campaigns and programs supported by CSAT include Recovery Month, Partners for Recovery, and the Substance Abuse Treatment Facility Locator Service.

Office of Applied Studies (OAS)

The OAS is responsible for providing national data on alcohol, tobacco, marijuana, and other drug abuse; drug-related emergency room events and medical examiner cases related to alcohol or drug mortality; and treatment program indicators. Data surveillance systems sources include the Drug and Alcohol Services Information System, Drug Abuse Warning Network, and the National Survey on Drug Use and

Health. Reports are prepared based on demographic variables, such as gender, occupational categories, and age groups, and treatment variables, such as annual admissions and length of stay in treatment programs.

SUBSTANCE ABUSE SUBTLE SCREENING INVENTORY-3

The Substance Abuse Subtle Screening Inventory-3 (SASSI-3) is one of many instruments designed to screen for substance use. As a screening instrument, its purpose is to indicate whether there is sufficient indication of risk to warrant more thorough evaluation.

A unique attraction of the SASSI is its claim to detect risk of substance use disorders regardless of the respondent's honesty or motivation, based on the inclusion of indirect or "subtle" scales. As described in this entry, independent research on the SASSI has not supported this claim.

The SASSI-3 is the third version of this series of measures. The first SASSI was released in 1985. With two new scales (the Correctional and Random Answering Pattern scales) and one reformulated scale (the ALD scale differentiating alcohol from drug abusers was transformed into the Supplemental Addictions Measure), the SASSI-2 was published in 1994. However, this version was found to have a high false positive rate (15.5%), resulting in many people who were not using substances at problematic levels being highlighted as having a high probability for substance dependence. In an attempt to reduce this false positive rate, the SASSI-3 was developed and was released in 1999.

The SASSI-3 contains 93 questions on two sides of a single sheet. Like its predecessors, it contains a combination of indirect and direct scales. Indirect or subtle scales contain questions that do not obviously relate to a person's substance use (i.e., "I am rarely at a loss for words"), whereas direct scales ask directly about substance use (i.e., "I have used alcohol or 'pot' too much or too often"). The front side of the SASSI-3 contains both indirect and direct items, whereas the second side contains only direct items.

The SASSI-3 contains 10 subscales. Three of these subscales are direct, containing items that obviously ask about a person's use of alcohol and other drugs and substance-related causes, consequences, and correlates. They include the Face-Valid Alcohol, Face-Valid Other Drug, and Symptoms subscales. Four of the SASSI-3 scales are described as "subtle," including low-face-validity items intended to collect information about characteristics and personality styles associated with substance use and a person's level of defensiveness. They include the Obvious Attributes, Subtle Attributes, Defensiveness, and Supplemental Addiction Measure scales. (The results derived from the Supplemental Addiction Measure subscale are not used in clinical interpretation.) The remaining three subscales—Random Answering Pattern, Family Versus Control Subjects, and Correctional—are intended to reflect the meaningfulness of participants' responses, the similarity of participants' responses to people who have substance-using family members, and the similarity of participants' responses to people with legal problems.

Identification of a person's likelihood of having a "high probability of having a substance dependence disorder" is made when a person scores at or beyond the specified cutoffs on any one or more of nine decision rules. The SASSI-3 rules also indicate that an elevated defensiveness score signals a possible false negative. Therefore, a respondent is judged to have a "low probability of a substance dependence disorder" only if all nine criteria and the defensiveness score are below designated cutoffs.

In addition to the adult SASSI series, there is a parallel instrument (SASSI-A2) for use with adolescents. The original SASSI for use with adolescents, SASSI-A, was released in 1990. A revised SASSI for adolescents, SASSI-A2, was released in 2001 and contained three new direct scales (Attitudes, Family-Friends Risk, and Symptoms scales). Unlike the adult SASSI, the SASSI-A2 screens for both substance dependence and substance abuse.

The test manual states that the SASSI-3 is a psychometrically sound, valid measure. It is described as having high rates of accuracy (94%), sensitivity (94%), specificity (94%), positive predictive power (98%), negative predictive power (80%), and low false positive (6%) and false negative (6%) rates. In addition, the SASSI is claimed to be robust, unaffected by demographic variables (such as race/ethnicity, gender, age, level of education) or co-occurring psychopathology.

However, a recent review of published research on the SASSI-3 did not support these claims. Independent studies that were not conducted by the authors of the SASSI-3 found that the direct scales perform on par with, or better than, the entire SASSI-3 measure, and that the subtle scales did not enhance the detection of substance use disorders. Validated public domain screening instruments, available free of charge, were found to be at least as effective as the SASSI-3.

Although a screening instrument is intended to identify the need for further evaluation, the SASSI instruments are sometimes used as the primary or sole measure to determine substance use disorder diagnoses or to negate self-report. The test manual provides guidelines to inform treatment decisions and correctional dispositions based on the SASSI, which are not appropriate uses of a screening instrument. Based on independent research to date, the SASSI appears to perform no better than other substance abuse screening instruments that are available free of charge in the public domain.

SUBSTANCE DEPENDENCE

Substance dependence refers to a physiological and psychological dependency on a drug. Various drug categories are associated with a unique set of potential consequences and dependence potential. For example, some drugs are likely to have lethal consequences (e.g., opioids) and high potential for biological dependence, whereas others generally do not (e.g., hallucinogens). Alternatively, some drugs that are physiologically addictive generally are not abused (e.g., caffeine) but are used by many individuals across cultures. Many, if not most, drugs can result in an acquired psychological dependence on the drug. Almost all drugs of abuse are highly rewarding because of their influence on reinforcing neurobiological systems, but they do not necessarily result in the experience of "biologically" related withdrawal symptoms, such as physical pain, vomiting, diarrhea, and tremors. However, cessation of many drugs may lead to subjective cravings, affected by neurobiological processes as a result of prior drug conditioning or associative learning processes (e.g., likely true of cocaine use), and these cravings are more readily evoked among some individuals than among others.

Tolerance to the Effects of Drugs

Tolerance to drug effects and experiencing withdrawal symptoms after sudden cessation of use are characteristics of drug dependence. Tolerance to drug

effects involves adjustments in the body to the presence of the drug. For example, metabolic tolerance may involve faster metabolism of alcohol in the liver with repeated alcohol intake. Neural adaptations that occur as a result of repetitive drug use or cellular tolerance may involve postsynaptic receptors becoming less sensitive to the drug; presynaptic sites manufacturing less of the naturally occurring neurotransmitter to compensate for the introduction of the drug that mimics its effects; or, for a drug that blocks transmission, a greater number of receptor sites being manufactured or a greater amount of the naturally occurring neurotransmitter being supplied, which could affect the lethal dose.

Withdrawal From Drug Dependency

Withdrawal symptoms vary in length and severity of withdrawal reactions from drug to drug. These symptoms consist of readjustments in physical functioning and behavior attributed to the overactivity of the nervous system. Also referred to as an “abstinence syndrome,” withdrawal symptoms are experienced when physically dependent individuals stop using drugs, particularly when cessation is abrupt. Some drugs result in more severe physiological reactivity. For example, withdrawal from alcohol, sedatives, hypnotics, or anxiolytics may involve such autonomic reactivity as hand tremors, insomnia, nausea or vomiting, transient illusions or hallucinations, psychomotor agitation, anxiety, or grand mal seizures. Alternatively, stimulant withdrawal (e.g., amphetamines, cocaine) includes symptoms of fatigue or exhaustion, depression, unpleasant and vivid dreams, insomnia or hypersomnia, increased appetite, and psychomotor retardation or agitation. Opioid withdrawal includes dysphoric mood, anxiety, nausea or vomiting, muscle aches, abdominal cramping, tearing, rhinorrhea (i.e., runny nose), sweating, diarrhea, yawning, fever, and insomnia. Nicotine withdrawal includes depressed, anxious, or irritable mood; insomnia; difficulty concentrating; restlessness; decreased heart rate; constipation; sweating; and increased appetite. PCP has no or few withdrawal symptoms. Caffeine has a few withdrawal symptoms, including headaches, some fatigue, and difficulty concentrating. Not recognized until recently, cannabis also has a few withdrawal symptoms, including fatigue, difficulty concentrating, stomach pains, some agitation, perhaps anger,

and vivid dreams, especially among chronic users. Hallucinogens are not known to have withdrawal symptoms, although there have been occasional reports of flashbacks (high-like states) in some people who have stopped using these drugs.

Various medications are used to help medically manage the withdrawal process of some of the more physically dependent drugs (e.g., alcohol, benzodiazepines, opioids) and to reduce discomfort and sleep deprivation. However, many individuals go through acute withdrawal from a drug in private, without medical intervention or formalized treatment. Others enter formalized treatment to better reduce potential for medical complications (e.g., seizures) or to be monitored so as to successfully complete the withdrawal process instead of opting for continued use of a drug or drugs. As an institutionalized process, withdrawal generally involves a 3- to 5-day inpatient stay at a detoxification facility with 24-hour intensive medical management. Unfortunately, recovery from acute withdrawal is only the first step in overcoming drug dependency for many individuals.

Drug Action

The varieties of drugs that produce dependency through direct or indirect effects on neurotransmitter function in the brain are of primary interest in this encyclopedia. These drugs are processed by the body through administration, distribution, metabolism, and elimination. *Administration* refers to the various means by which a drug enters the body, that is, through ingestion, inhalation, injection, and absorption. In addition to these forms of administration, there are several alternative methods; for example, heroin and cocaine may be sniffed or smoked. Depending on the method of administration, drugs generally exert their effects within an hour of intake (e.g., through ingestion) or within minutes or seconds of use (e.g., through injection).

Distribution refers to how efficiently a drug moves throughout the body. Distribution is influenced by, among other factors, the size of the various drug molecules and their solubility—protein, water, and fat-bound. In general, the rate of entry of a drug into the brain is dependent on the fat solubility of the drug. The greater the fat solubility is, the faster the rate of entry will be. Conversely, highly ionized drugs, such as penicillin, penetrate the blood–brain barrier poorly.

Metabolism refers to the effects or action of the drug. All drugs of abuse “feel good” in different ways; for example, the drug user may feel more alert, relaxed, or happy. Almost all drugs of abuse affect mesolimbic reward pathways. However, each drug also may have specific target receptor sites in the brain and affect different neurotransmitter pathways. When two or more drugs are used together, various interaction effects can take place, either additive (effects simply add up), synergic (effects are much stronger when drugs are used together), potentiating (having effects only in conjunction with the use of another drug), or antagonistic (drugs may cancel each other out).

Elimination refers to the breakdown and excretion of drugs from the body. Drugs are excreted in time primarily through the skin (by sweating) or through the kidneys (by urination). Drugs have measurable and differential distribution and elimination half-lives (i.e., the amount of time it takes for half of the drug to reach sites of action and be eliminated from the body). Nicotine, for example, when smoked in a cigarette, has a 9-minute distribution half-life (very fast) and a 2-hour elimination half-life. As a general rule, regular interval dosing results in a relatively steady blood level concentration of the drug that is reached after approximately six elimination half-lives.

Assessment of Substance Dependence

The primary method of assessing substance dependence is through a clinical interview, self-reports of the behavior, or both. A formal definition of substance abuse disorder, based on the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, is as follows:

Drug abuse is a maladaptive pattern of drug use leading to clinically significant impairment or distress, as manifested by one or more of four symptoms or criteria in a 12-month period.

1. Recurrent drug use may result in a *failure to fulfill major role obligations* at work, school, or home. Repeated absences, tardiness, poor performance, suspensions, or neglect of duties in major life domains suggests that use has crossed over into abuse.
2. Recurrent drug use in situations in which it is *physically hazardous* is a sign of abuse. Operating

machinery, driving a car, swimming, or walking in a dangerous area while under the influence indicates drug abuse.

3. Recurrent drug-related *legal problems*, such as arrests for disorderly conduct or DUI [driving under the influence] arrests, are indicative of abuse.
4. Recurrent use, despite having persistent or recurrent *social or interpersonal problems* caused or exacerbated by the effects of the drug, is indicative of abuse. For example, getting into arguments or fights with others, passing out at others' houses, or acting inappropriately in front of others (which is disapproved of) is indicative of abuse.

In summary, drug use that leads to decrements in performance of major life roles, dangerous action, legal problems, or social problems indicates a substance abuse disorder.

Alternatively, a diagnosis of substance dependence, a more severe disorder, subsumes a diagnosis of substance abuse. There are seven other criteria that, if met, constitute substance dependence.

The criteria for substance dependence, provided by the *DSM-IV-TR*, include a maladaptive pattern of drug use leading to clinically significant impairment or distress, as manifested by three or more of the following seven symptoms occurring in the same 12-month period.

1. *Tolerance is experienced*. Tolerance entails a need for markedly increased amounts of a drug to achieve the desired drug effect or a markedly diminished effect with continued use of the same amount of the drug.
2. *Withdrawal is experienced*. Either a characteristic withdrawal syndrome occurs when one terminates using the drug, or the same or a similar drug is taken to relieve or avoid the syndrome.
3. *Larger amounts of the drug are taken over a longer period* than was intended. For example, an alcohol-dependent individual may intend to drink only two drinks on a given evening but ends up having 15 drinks, or to “party” over the weekend but the party lasts for 2 weeks until there is no more money for alcohol.
4. *There exists a persistent desire or unsuccessful effort to cut down or control drug use*. For example, a drug-dependent individual may decide to control his or her use but ends up abstaining on some evenings and using in excess on other evenings.

5. *A great deal of time is spent on activities needed to obtain the drug, use the drug, or recover from its effects.* For example, a person may travel long distances or search all day to obtain cocaine, use the drug that night, and miss work the next day to recover and catch some rest. In this scenario, 2 days were spent for 1 night of “getting high.”
6. *Important social, occupational, or recreational activities are given up or reduced because of drug use.* For example, the drug abuser may be very high, passed out, or hung over much of the time and thus may not spend time with family and friends like he or she did before becoming dependent.
7. *Drug use continues despite knowledge of having a persistent or recurrent physical or psychological problem* that is likely to have been caused or worsened by the drug. For example, someone who becomes paranoid after continued methamphetamine use and is hospitalized but continues to use it after release from the hospital exhibits this symptom.
6. *Psychotic disorder* may occur during or following drug use and is characterized by hallucinations, delusions (e.g., paranoia), excitement or stupor, and extreme affect.
7. *Amnesic syndrome* is associated with chronic prominent impairment of recent and remote memory caused by drug use.
8. *Residual or late-onset psychotic disorder* may occur that is directly related to drug use but persists beyond the period in which a direct drug effect is occurring.

In sum, substance dependence may be simplified as being composed of any or all of three primary characteristics based on recurrent drug use. First, if the drug user stops using a drug abruptly, he or she typically suffers withdrawal symptoms. Second, substance dependence reflects an intraindividual-based increase in frequency, duration, and amount of intake. This increase in time spent using a drug may reflect tolerance to drug use effects or an increasing behavioral involvement with drug use across situations. Third, either this preoccupation with drug use intrudes on other life contexts or else other lifestyle situations and some life roles are terminated.

Alternatively, the 10th revision of the *International Statistical Classification of Diseases and Related Health Problems (ICD-10)* provides eight classifications of consequences from the use of a substance in its section on mental and behavioral disorders due to psychoactive substance use (Chapter 5; F10–F19). The *ICD-10* definition focuses more on the mental or physical health complications and not social, legal, or environmentally hazardous consequences of abuse, as does the *DSM-IV-TR*. The *ICD-10* classifications of consequences from use are as follows:

1. *Acute intoxication* includes disturbances in brain function or behavior, or complications (e.g., coma) related to the effects of a drug.
2. *Harmful use* refers to a pattern of use that is damaging to one’s physical or mental health.
3. *Dependence syndrome* is defined by a strong desire to take the drug, difficulties controlling use, persisting in use despite harmful consequences, a higher priority given to drug use than other activities, increased tolerance, and withdrawal.
4. *Withdrawal* refers to the time-limited effects of lowering dosage or stopping use of a drug.
5. *Delirium* may or may not occur.

Conclusion

The development and maintenance of drug dependency involves multiple pathways and levels of influence within biological, psychological, and sociological domains. Some individuals who repetitively use, or even abuse, drugs may experience a variety of negative consequences, such as disease states associated with use (e.g., cirrhosis of the liver) that become apparent over time, but these individuals may not become dependent on the drug or engage in compulsive drug taking. Other individuals seemingly lose control the first time (or few times) they use a drug, rapidly engaging in more compulsive drug taking, despite consequences of use. For these individuals, drug use is somewhat like a toggle switch that is either on or off. For them, total abstinence is likely the only choice because they have few inhibitory or control processes once the switch is turned on. It is not entirely clear what causes the difference in loss of control among some individuals and not others, resulting in drug dependency. However, there are many factors that exacerbate the process, including biologically based differences in metabolic processes, different levels of

susceptibility to the reinforcing effects of drugs, affective disorders, personality disorders, cognitive disorders, and an inability to tolerate frustration or emotional discomfort. Some of these processes are under individual control (e.g., spending time with drug-using peers), but many are not (e.g., genetics or neurobiological variations).

suicide, and other problem behaviors that extensively tax the health care system. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* includes a general category for these disorders called substance related disorders, which is further broken down into two general categories: substance use disorders and substance-induced disorders. Substance use disorders include the diagnoses of substance abuse and substance dependence, while substance-induced disorders include substance intoxication, substance withdrawal, and eight additional substance-induced mental disorders. These substance-induced mental disorders include substance-induced delirium, substance-induced persisting dementia, substance-induced persisting amnesic disorder, substance-induced psychotic disorder, substance-induced mood disorder, substance-induced anxiety disorder, substance-induced sexual dysfunction, and substance-induced sleep disorder.

In addition to specific disorders, the *DSM-IV-TR* divides substances into the following categories: alcohol; cannabis; cocaine; opioids; amphetamines; hallucinogens; caffeine; inhalants; nicotine; phencyclidine; sedatives, anxiolytics, or hypnotics; and other. The specific diagnosis of a substance-induced disorder is based on both the disorder itself and the substance thought to be involved. For example, a diagnosis of intoxication will always be associated with a substance, such as cocaine intoxication or cannabis intoxication. Whereas all categories of substances listed in the *DSM-IV-TR* have at least one associated substance-induced disorder, each substance-induced disorder may not apply to all types of substances. For example, cannabis can cause intoxication but not persisting dementia or persisting amnesic disorder. The "other" category can be used to diagnose substance-induced disorders occurring as a side effect of prescription medication, for example, sexual dysfunction resulting from antidepressant therapies, or those related to toxin exposure.

SUBSTANCE-INDUCED DISORDERS

Mental and physical disorders resulting from the use of drugs and alcohol are highly prevalent in the United States, with males affected 2 to 3 times more frequently than females. These disorders have debilitating effects, as they are associated with increased mortality rates, homelessness, child maltreatment, homicide,

Assessment of Substance-Induced Disorders

The diagnosis of substance-induced disorders often involves obtaining an extensive psychosocial, and sometimes medical, history by a qualified mental health and medical professional. Psychosocial factors relevant to the disorders may be obtained by a variety of professionals, such as psychologists, psychiatrists,

physicians, licensed or certified addiction counselors, or licensed clinical social workers, although the specific qualifications required to make diagnoses may vary by state. For some disorders, such as persisting dementia or persisting amnesic disorder, more specialized training is required to make the diagnosis because it not only is based on the psychosocial interview but may also require specialized physical and neurological examinations (e.g., brain imaging procedures), neuropsychological testing to document deficits in memory and other cognitive abilities, and assessment of functional outcomes. Thus, for some of the substance-induced disorders, the diagnosis is made after extensive evaluation by an interdisciplinary team of professionals, each of whom is specialized to evaluate a specific aspect of the disorder in question. It can often be difficult to assess individuals with substance-induced disorders because there may be strong incentives for them to underreport or deny substance use. It is also the case that because some substances can cause deficits in cognitive abilities such as memory, individuals with long histories of use may simply be unable to accurately remember the details of prior use. This is particularly true for substance-induced dementia or amnesic disorder, where memory deficits are required in order to make these diagnoses. Even when sufficient symptoms are present to make a diagnosis, it is often difficult to clearly establish a link between the symptoms and the substance use. For example, in the case of an individual with a history of heavy methamphetamine use and psychotic episodes, it is not always clear whether the methamphetamine use preceded the psychotic episode or, alternatively, if the methamphetamine was used in an attempt to cope with the preexisting psychotic symptoms. In these instances, history of substance use onset and offset in relation to symptom onset and offset is crucial in determining whether the disorder is substance induced or not. This temporal relationship is especially difficult to determine when mental symptoms continue after intoxication and withdrawal, and clinical judgment is needed to determine whether a substance-induced persisting disorder should be diagnosed or whether a primary mental disorder should be diagnosed.

As a result, in many cases an initial suspicion of substance use will require supplemental information in addition to the client's self-reported use. In this regard, it is helpful to obtain collateral reports from significant others, to perform drug screening, and to review available medical records with special attention

given to patterns of medical problems that are consistent with substance use and also whether the client is prescribed medications that have a high potential for abuse and dependence (e.g., benzodiazepines). Assessment with specialized psychological tests may also be necessary to evaluate the frequency, severity, and type of use, as well as to identify psychological disorders that may be induced by the substance or that may exist in addition to the substance-induced disorder. For example, depression and anxiety disorders are very common in those who abuse substances, as are various personality disorders. Examples of psychometrically sound assessment procedures include the Timeline Followback assessment procedure, which is used to document substance use over the past 4 months; the Substance Abuse Subtle Screening Inventory-3, which is useful for identifying individuals at risk for substance use disorders; and the Addiction Severity Index, which assesses the impact that drug use and alcohol use have on various areas of functioning, such as medical status, employment status, family and social relationships, legal status, and psychiatric/psychological status.

The following sections provide an overview of the substance-induced disorders that accompany the *DSM-IV-TR* substance categories, with special attention given to the most commonly used drugs, including cannabis, cocaine, amphetamines, opioids, and benzodiazepines, which are classified as sedatives.

Substance Intoxication

Substance intoxication is a reversible disorder that results from the ingestion of a substance. It is characterized by maladaptive behavioral or psychological changes that are due to the direct physiological effects of the substance on the central nervous system and develop shortly after use. Substance intoxication applies to the substance categories of alcohol, amphetamines, caffeine, cannabis, cocaine, hallucinogens, inhalants, opioids, phencyclidine, and sedatives. The physiological symptoms of cannabis intoxication include bloodshot eyes, increased appetite, and dry mouth. Psychological symptoms may include impaired cognitive abilities (e.g., sensory perception, memory, and judgment), fluctuations in mood state (anxiety or euphoria), and psychotic symptoms (paranoia, grandiosity, hallucinations). Cocaine intoxication is accompanied by physiological, behavioral, and psychological symptoms. Physiological symptoms of

intoxication include pupil dilation, increased blood pressure, tachycardia, and perspiration, among others. Behavioral changes induced by cocaine include restlessness, hyperactivity, and stereotyped behaviors (i.e., repetition and perseveration). Psychological symptoms induced by cocaine include euphoria, increased alertness, anxiety, depression, and grandiosity. Physiological dependence typically develops after heavy, chronic use. Common physiological symptoms of amphetamine intoxication include increased heart rate, blood pressure, and body temperature, tachycardia, cardiac arrhythmias, and pupillary dilation. Psychological symptoms include elevated mood, perceptual alterations, impaired judgment, and decreased concentration. Opioid intoxication is characterized by feelings of euphoria, impaired attention and judgment, lethargy, slurred speech, and constriction of the pupils. Dysphoria (unpleasant mood) often follows the initial euphoria. Less common symptoms include hallucinations and delirium. Physiological intoxication effects of benzodiazepine use include ataxia (incoordination), dysarthria (poor articulation), diplopia (blurred vision), vertigo, and dizziness. Benzodiazepines also induce relaxation, calmness, euphoria, and, less frequently, feelings of hostility and depression.

Substance Withdrawal

Substance withdrawal is a syndrome associated with a specific substance that is due to the cessation or reduction of its heavy and prolonged use. It causes significant distress or impairments in important areas of a person's life. A general principle is that the withdrawal effects of a particular substance are the opposites of its intoxication effects, so that a drug with calming effects during intoxication will have withdrawal effects characterized by anxiety, drugs that induce feelings of euphoria during intoxication are associated with feelings of depression during withdrawal, and so forth. The diagnosis of withdrawal applies to the substance categories of alcohol, amphetamines, cocaine, nicotine, opioids, and sedatives. During cocaine withdrawal, physiological symptoms including disrupted sleep, appetite, and psychomotor functioning are common. These physiological symptoms are often accompanied by feelings of depression, sadness, and anxiety. Whereas many of the symptoms abate after physiological withdrawal is complete (1–5 days), some may last much longer. For example, some individuals continue to report

anhedonic (inability to experience pleasure) symptoms for up to 10 weeks following cessation of heavy use. For chronic heavy amphetamine users, cessation of use causes withdrawal symptoms to occur within a few hours or a few days. Dysphoria is common during withdrawal, as is disrupted sleep, fatigue, increased appetite, psychomotor agitation or retardation, and anhedonia. Withdrawal symptoms from opioids such as heroin typically occur within 24 hours of cessation. During withdrawal, dysphoric feelings of anxiety and depression are common, as are physical symptoms such as malaise, nausea, dilation of pupils, sweating, insomnia, and muscle aches. Most withdrawal symptoms resolve within a week, but some can continue for several months (e.g., dysphoria). Symptoms of withdrawal from benzodiazepines can include anxiety, irritability, insomnia, muscle twitching or aching, sweating, concentration difficulties, depression, and derealization (alteration in perception). More severe withdrawal symptoms include seizures, delirium, and confusion. Withdrawal symptoms may be more intense when shorter-acting benzodiazepines are discontinued. However, abrupt discontinuance of benzodiazepines that have long half-lives (e.g., Valium) can cause seizures within 3 days of discontinuation.

Substance-Induced Mental Disorders

The eight types of substance-induced mental disorders have symptoms that are characteristic of specific mental disorder diagnoses described elsewhere in the *DSM-IV-TR* (e.g., major depressive disorder) but that are due to the direct effects of a substance. These mental disorders can occur in relation to substance intoxication or substance withdrawal, or they can continue even after prolonged abstinence from the substance. These latter conditions, referred to as substance-induced persisting disorders, include substance-induced persisting dementia, substance-induced persisting amnesic disorder, and hallucinogen persisting perception disorder. As previously discussed, substance intoxication and withdrawal syndromes are characterized by a number of psychological symptoms including psychosis, mood disturbance, anxiety, sexual dysfunction, and sleep difficulties. However, if these symptoms are in excess of, or more severe than, what is expected to result from the intoxication or withdrawal syndrome or are severe enough to warrant independent clinical attention, then an additional diagnosis of one of the aforementioned

substance-induced disorders should be made. Finally, an examination of psychological symptom severity and persistence, as well as the temporal relationship with substance use, is necessary to determine whether a primary diagnosis of a mental disorder is more suitable.

Substance-Induced Delirium

Substance-induced delirium can develop during substance intoxication or during substance withdrawal. Delirium is a disturbance in consciousness and cognition or thinking abilities, which develops over a short period of time (hours to days) and fluctuates during the course of a day. The disturbance in consciousness includes reduced awareness of the environment, disorientation, and difficulty in focusing, sustaining, or shifting attention. Disturbance in memory, language, and perception can also occur, and so sometimes the differentiation between substance-induced delirium and substance-induced dementia can be difficult to make, requiring specialized assessment procedures. Substance intoxication delirium applies to the substance categories of alcohol, amphetamines, cannabis, cocaine, hallucinogens, inhalants, opioids, phencyclidine, and sedatives. Substance withdrawal delirium applies only to alcohol (delirium tremens) and sedatives. Delirium that occurs during substance intoxication resolves as the intoxication ends or within a few hours to days. Substance withdrawal delirium is more varied depending on the action of the specific substance: Longer-acting substances are associated with longer withdrawal periods and lengthier delirium. It is vital that an individual who is experiencing delirium receive immediate medical attention, as delirium is often indicative of an underlying life-threatening medical condition.

Substance-Induced Persisting Dementia

Similar to substance-induced delirium, substance-induced persisting dementia is characterized by deficits in cognition etiologically related to the effects of a substance. This type of dementia has symptoms that are similar to other dementias, such as dementia of the Alzheimer's type, and include memory impairment and at least another cognitive disturbance, such as aphasia (difficulties with language), apraxia (difficulties executing complex motor functions), agnosia (difficulties recognizing or identifying objects), or executive functioning (difficulties in the ability to plan, initiate,

sequence, monitor, and stop complex behaviors). These cognitive deficits must impair the person's ability to function and represent a decline from previous levels of functioning. Substance-induced persisting dementia applies to the substance classes of alcohol, inhalants, and sedatives, as well as certain types of medications and toxins. Onset of the disorder is slow, and cognitive deficits are usually permanent.

Substance-Induced Persisting Amnestic Disorder

Substance-induced persisting amnestic disorder is characterized by memory difficulties that cause significant impairment in a person's social or occupational functioning and represent a decline from previous functioning. It does not occur exclusively during delirium, dementia, substance intoxication, or substance withdrawal. Unlike delirium or dementia, amnestic disorder does not include impairment of other cognitive abilities; only memory abilities are affected. Additionally, blackouts or memory disturbance associated only with substance intoxication or substance withdrawal should be diagnosed as such, rather than as substance-induced persisting amnestic disorder. The distinction between dementia and amnestic disorder is at times a difficult one to make, and accurate diagnosis often requires thorough neuropsychological evaluation. The memory impairment persists long after abstinence from the substance and may remain stable or worsen with the passage of time. The following categories of substances apply to substance-induced persisting amnestic disorder: alcohol (Wernicke-Korsakoff syndrome) and sedatives.

Substance-Induced Psychotic Disorder

In substance-induced psychotic disorder, psychotic symptoms of delusions and hallucinations occur and are determined to be due to the direct effect of a substance arising during intoxication or withdrawal. Delusions are erroneous beliefs that involve a misinterpretation of normal everyday experiences. For example, individuals would be exhibiting delusional thinking if they misinterpreted their neighbor's car parked across the street as evidence that someone is following them or spying on them. Delusions can be categorized into types based on the theme of the content; common types are persecutory, referential, somatic, religious, and grandiose. On the other hand, hallucinations are distortions in perception

that can occur in any sensory modality, with auditory hallucinations being the most common in non-substance-induced psychosis (e.g., hearing voices when no one is talking). Hallucinations resulting from the effects of a substance can be auditory, but they can also be tactile or visual in nature. Tactile hallucinations can include the sensation of something crawling on or under the skin (called *formication*), and visual hallucinations may include seeing insects, snakes, rats, or the stereotypical “pink elephants” associated with alcohol withdrawal. In fact some evidence suggests that 9 out of 10 nonauditory hallucinations are related to substance use. An important distinction is that if the individual realizes hallucinations are substance induced, then a diagnosis of substance intoxication or substance withdrawal would be given, rather than substance-induced psychotic disorder. Substance-induced psychotic disorders can persist for days or weeks after the substance is removed but will subside with sustained abstinence. If the psychotic symptoms persist long after the substance has been discontinued, then a diagnosis of a primary psychotic disorder may be appropriate, such as schizophrenia. In these cases, the substance is viewed as a risk factor, which causes the onset of primary psychotic disorders in individuals who, because of environmental and genetic factors, are predisposed to develop these psychotic disorders. Substance-induced psychotic disorders associated with substance intoxication may be diagnosed for alcohol, amphetamines, cannabis, cocaine, hallucinogens, inhalants, opioids, phencyclidine, and sedatives. Substance-induced psychotic disorders occurring in association with withdrawal are diagnosed only for alcohol and sedatives.

Substance-Induced Mood Disorder

Substance-induced mood disorder is characterized by a disturbance in mood due to the direct effects of a substance that causes significant impairment in a person’s social or occupational functioning. The mood disturbance typically resembles a mood episode, such as a major depressive episode (characterized by depressed mood or diminished interest or pleasure), a manic episode (characterized by elevated and expansive mood or irritable mood), or a mixed episode (symptoms of both major depressive and manic episodes occurring at the same time). However, substance-induced mood disorders may not contain all the symptoms of these mood episodes. Rather, a substance-induced mood disorder is diagnosed when onset of mood symptoms occurs during either intoxication or withdrawal, and the symptoms are

in excess of those mood symptoms usually associated with an intoxication or withdrawal diagnosis. Substance-induced mood disorders can last as long as 4 weeks after discontinuing the substance (and at times longer), and the type of substance and the length of the withdrawal period determine the time frame of symptom resolution. The diagnosis of substance-induced mood disorder occurring in association with intoxication applies to the following classes of substances: alcohol; amphetamines; cocaine; hallucinogens; inhalants; opioids; phencyclidine; and sedatives, anxiolytics, or hypnotics. The diagnosis of substance-induced mood disorder occurring in association with withdrawal applies to alcohol, amphetamines, cocaine, and sedatives.

Substance-Induced Anxiety Disorder

The main feature of a substance-induced anxiety disorder is anxiety symptoms (due to the direct effects of a substance) that cause significant distress or impairment to a person’s social or occupational functioning. The anxiety symptoms may come in the form of generalized anxiety (excessive worry about a number of events), panic attacks (sudden onset of intense fear and physical symptoms of anxiety), phobias (anxiety provoked by exposure to a specific stimuli such as a dog, a high place, or an airplane ride), or obsessions and compulsions (intrusive anxiety-provoking thoughts and repetitive behaviors that are attempts to reduce this anxiety). The onset of substance-induced anxiety disorder occurs in association with intoxication or withdrawal from a substance, and in some cases (e.g., for substances with long withdrawal periods) it may not arise until 4 weeks after cessation of the substance. The anxiety symptoms subside after the substance is discontinued and, if applicable, after acute withdrawal ends. Substance-induced anxiety disorders occurring in association with intoxication apply to alcohol, amphetamines, caffeine, cannabis, cocaine, hallucinogens, inhalants, and phencyclidine. Substance-induced anxiety disorders occurring in association with withdrawal apply to alcohol, cocaine, and sedatives.

Substance-Induced Sexual Dysfunction

Substance-induced sexual dysfunction is characterized by a sexual dysfunction that is the direct result of substance use and causes marked distress or interpersonal difficulty. The sexual dysfunction varies depending on the substance involved and may entail impaired desire, impaired arousal, impaired

orgasm, or sexual pain. The dysfunction has also been found to generalize and is not limited to certain types of stimulation, situations, or partners. Substance-induced sexual dysfunction arises in association with intoxication and subsides after cessation of the substance. Substance-induced sexual dysfunction applies to the substance classes of alcohol, amphetamines, caffeine, cocaine, opioids, and sedatives.

Substance-Induced Sleep Disorder

Substance-induced sleep disorder is a clinically significant disturbance in sleep that is the direct result of the physiological effects of a substance and that causes impairment in social or occupational functioning. There are four types of sleep disturbances that can occur: insomnia, hypersomnia, parasomnia, and mixed type. Insomnia and hypersomnia are the most common. Insomnia is characterized by difficulty falling asleep or remaining asleep or by having nonrestorative sleep, whereas hypersomnia is characterized by excessively long sleep or sleepiness during waking hours. Parasomnia is distinguished by abnormal behavioral events that occur during sleep or sleep-wake transitions, such as sleepwalking. The mixed type designates multiple types of sleep disturbances. Substance-induced sleep disorders occur during intoxication and withdrawal. Substance-induced sleep disorders occurring in association with intoxication apply to alcohol; amphetamines; caffeine; cocaine; opioids; and sedatives, anxiolytics, and hypnotics. Substance-induced sleep disorders occurring in association with withdrawal are diagnosed for the substance classes of alcohol, amphetamines, cocaine, opioids, and sedatives.

Conclusion

The substance-induced disorders represent a heterogeneous collection of disorders that are grouped together in the *DSM-IV-TR* by the primary causative factor, substance use. These disorders encompass changes in mood, cognition, and behavior. Some are transient in nature, whereas others may persist indefinitely. Some are life threatening and require medical attention, whereas others are less severe and resolve without treatment. Although many of the substance-induced disorders are less well understood than their counterparts, the substance use disorders (i.e., substance abuse and dependence), service providers should be aware of their diagnostic criteria because they can significantly impair functioning, interfere with the effectiveness of substance abuse treatment, and negatively impact

adjustment following cessation of substance use. Because some are complex in nature, multimethod assessments conducted by interdisciplinary teams may be required to arrive at a final diagnosis.

SUBSTANCE-INDUCED WITHDRAWAL DELIRIUM

Sometimes referred to as the “DTs,” “the shakes,” or “the horrors,” substance-induced withdrawal delirium, or delirium tremens (DTs), are an acute episodic delirium that can prove fatal without proper medical management. DTs can occur during withdrawal from tranquilizers, such as barbiturates and benzodiazepines, but more commonly occur during alcohol withdrawal induced by a period of abstinence following excessive and habitual alcohol use. DTs are the most severe of the alcohol withdrawal syndromes. The

most common symptoms of DTs are confusion, disorientation, and agitation. However, symptoms can also include tremors, anxiety and restlessness, irritability, emotional lability, depression, fatigue, clouded thinking, hyperreflexia (overexaggeration of reflexes), heart palpitations and tachycardia (excessively rapid heartbeat), high blood pressure, diaphoresis (excessive perspiration), nausea and vomiting, insomnia, paranoia, visual hallucinations (often insects, snakes, rats, stereotypical “pink elephants”), auditory hallucinations, tactile hallucinations (sensation of something crawling on the skin, called *formication*), sensitivity to light, sensitivity to sound, sensitivity to touch, fever, and seizures.

The symptoms of DTs result from the chronic effects of alcohol on the brain. Chronic heavy alcohol use sedates the brain by causing a downregulation of the inhibitory neurotransmitter GABA, as well as the upregulation of excitatory neurotransmitters, such as glutamate. Cessation of alcohol use removes its sedating effects and causes the brain to become overly excitable, which, in turn, results in autonomic nervous system arousal and neurotoxicity. Following cessation of alcohol use, withdrawal symptoms may be initially mild but can rapidly worsen. Within 3 to 6 hours following cessation of alcohol use, minor alcohol withdrawal can begin, with symptoms including insomnia, anxiety, tremor, hyperreflexia, hypertension, tachycardia, diaphoresis, nausea, vomiting, and alcohol cravings. Within 24 hours after cessation, major alcohol withdrawal may begin, which can last from 1 to 3 days and include auditory hallucinations, visual hallucinations, anxiety, and hyperactivity. When DTs occur, they occur most often between 3 and 5 hours after cessation of alcohol use. With regard to duration, 62% of episodes last no longer than 5 days, although in some cases they can last much longer.

DTs occur in approximately 5% to 10% of individuals with alcohol dependency and in roughly 5% to 20% of those hospitalized for alcohol withdrawal. It most commonly occurs in people with a history of chronic and excessive alcohol use over many years, for example, consumption of 16 ounces of 80-proof alcohol each day for a period of 10 or more years. However, DTs can occur after heavy use of only a few months duration. It may be triggered by infection, head injury, or another medical illness. Those with a history of alcohol withdrawal may be particularly prone to DTs, as might those with a history of seizure or those who are malnourished.

For an accurate diagnosis of DTs to be made, other similarly presenting conditions should be carefully ruled out. A number of brain disorders have symptoms similar to DTs, including brain tumors (neoplasms), brain infections, and seizure disorders. Endocrine and metabolic disorders can also cause symptoms similar to those of DTs, as can more generalized infection, nutritional deficiency, cardiopulmonary disease, and exposure to toxic agents other than alcohol.

Reports of the mortality rate associated with DTs vary widely, with estimates ranging from 5% to 35% when DTs are left untreated and from 1% to 15% when treatment is promptly administered. Treatment typically consists of administration of benzodiazepines to ease symptoms of withdrawal, with the dose being tapered over several days. Because of the high potential for mortality, DTs are viewed as a medical emergency and require immediate hospitalization for adequate treatment. During treatment, vital signs such as temperature, pulse, respiration, and blood pressure are monitored, as are fluid and electrolyte levels, with appropriate interventions applied to correct abnormalities that may be present. Treatment also includes pharmacotherapy to manage symptoms, with the therapeutic aim being to provide support, prevent medical complications, and prevent death. Treatment with benzodiazepines may decrease the rate of seizures in DTs. As such, treatment almost always includes keeping the individual sedated with benzodiazepines until symptoms subside to protect against withdrawal seizures, reduce agitation, and manage hyperactivity of autonomic responses. In severe cases, antipsychotic medications may also be administered in small doses to manage psychosis-related agitation, although these drugs are used with caution, as they can lower the seizure threshold. Anticonvulsant (antiseizure) medications are currently under investigation for their potential in the treatment of DTs, and preliminary results are promising. Controlling environmental stimuli (muted lighting, absence of loud noises) can also help to minimize the frequency and intensity of visual and auditory hallucinations. Individuals presenting with symptoms of DTs should always be tested and, if necessary, treated for other medical problems associated with alcohol use. Among these problems are sepsis (whole body inflammation due to infection), closed head injury, shock, blood-clotting disorders, alcoholic liver disease, alcoholic

neuropathy (disease of the peripheral nerves), alcoholic cardiomyopathy (heart disease), and Wernicke-Korsakoff syndrome.

After recovery from the acute symptoms associated with DTs, long-term preventive treatment can begin. This often includes a “drying out” period, wherein complete alcohol abstinence is required, and after which treatment for alcohol use or alcoholism begins. Such treatment might include psychological counseling, support group attendance, behavior modification, and pharmacological intervention.

SUBSTANCE USE DISORDERS

Substance-related disorders, as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, include both substance-induced disorders and substance use disorders. Substance use disorders include the subcategories of substance abuse and substance dependence, and these two subcategories constitute the most common

substance-related disorder diagnoses, with a prevalence rate of 9.2% in the United States.

Substance Abuse

Substance abuse is diagnosed when substance use leads to significant problems in one or more of the following four domains within a 12-month period: (1) legal, (2) interpersonal, (3) work or school, or (4) hazardous behaviors. Individuals with a substance abuse diagnosis may exhibit a failure to fulfill major role obligations, repeatedly use substances in situations where it is dangerous to do so, and experience recurrent interpersonal problems despite these problems being exacerbated by the substance use. Substance abuse thus constitutes a pattern of recurrent negative consequences associated with the substance use, but does not include tolerance, withdrawal, or a pattern of compulsive use, which are characteristic of substance dependence. Substance abuse is more likely to be diagnosed in individuals who have recently started using the substance; many of these individuals will progress to substance dependence.

Substance Dependence

The diagnosis of substance dependence is made when substance use is persistent, leading to the development of three or more cognitive, behavioral, or physiological symptoms within a 12-month period. These symptoms may include failed attempts to decrease use of the substance; tolerance; withdrawal; or impairment in social, occupational, or recreational functioning as a direct result of substance use or behaviors involving pursuit of the substance. Tolerance is defined as either needing a substantially increased amount of the substance to achieve intoxication effects than what was previously necessary or having a substantially decreased intoxication effect from the substance with continued use of the same amount of the substance. Withdrawal includes physiological changes that occur when a substance has been used over a prolonged period of time and then the substance use is either stopped or reduced. Withdrawal is defined as either experiencing a characteristic withdrawal for the substance or if the same (or a similar) substance is taken to reduce withdrawal symptoms. Withdrawal syndromes for particular substances include symptoms that are typically the opposite of the effects of the substance itself.

The diagnosis of substance dependence may include, but does not require, physical dependence on

the substance, as would be evidenced by the presence of increased tolerance or withdrawal symptoms. However, a primary distinction between the diagnoses of substance abuse and substance dependence is that, with substance abuse, the criteria do not include withdrawal, tolerance, or symptoms of compulsive use. If an individual meets criteria for substance dependence, then it is important to specify whether or not physiological dependence is associated with tolerance or withdrawal symptoms. This is indicated with the specifiers “with physiological dependence” and “without physiological dependence.” If tolerance or withdrawal symptoms are present, then the specifier “with physiological dependence” is used. If there is no evidence of either tolerance or withdrawal symptoms, then the specifier “without physiological dependence” is used.

Substance dependence criteria have a total of six course specifiers, four of which specify different states of remission; the other two indicate whether the individual is on agonist therapy or in a controlled environment. An individual is considered to be in remission from substance dependence only after the criteria for substance dependence or abuse have been absent for 1 month or longer. There are four qualifiers for remission, which are determined by the period of time that has elapsed since the cessation of dependence (early or sustained remission) as well as by the continued presence or complete absence of one or more of the substance dependence or abuse criteria (partial or full remission). The four remission specifiers are “early full remission,” “early partial remission,” “sustained full remission,” and “sustained partial remission.” Early full remission is specified if an individual has not met criteria for dependence or abuse for at least 1 month but less than 12 months. Early partial remission occurs when an individual has not met criteria for dependence or abuse for at least 1 month but less than 12 months. Additionally, for the specifier “early partial remission,” following at least a 1-month period of sobriety, the individual meets one or more criteria for dependence or abuse but does not meet full criteria for dependence. The specifier “sustained full remission” is obtained when an individual has not met any criteria for dependence or abuse at any time in the past 12 months or longer. “Sustained partial remission” is a specifier used to describe individuals who have not met full criteria for dependence for a period of 12 months or longer but have met one or more criteria for dependence or abuse. Two other course

specifiers are whether the individual is on agonist therapy or whether he or she is in a controlled environment. The specifier “on agonist therapy” applies to individuals who are prescribed an agonist medication, such as methadone for an opioid addiction, and who have not met criteria for dependence or abuse in the past month. This excludes the development of tolerance to or withdrawal due to the agonist medication. The course specifier “in a controlled environment” is used when an individual is currently living in a controlled environment with no access to any substances of abuse (e.g., incarceration) and has not exhibited symptoms of dependence or abuse for at least the past month.

The descriptions of substance dependence and abuse disorders also apply to specific substances. Substances that have dependence and abuse diagnoses in the *DSM-IV-TR* are alcohol; amphetamines; cannabis; cocaine; hallucinogens; inhalants; opioids; phencyclidine; and sedatives, hypnotics, and anxiolytics. The *DSM-IV-TR* includes a diagnosis for nicotine dependence but not for nicotine abuse. For each substance, the *DSM-IV-TR* includes information on characteristic signs and symptoms for diagnostic decision making.

Assessment

Effective assessment and diagnosis of substance use disorders involves obtaining a psychosocial history by a qualified mental health professional. This may include a psychologist, psychiatrist, physician, other health care professional, addiction counselor, professional counselor, or social worker, although qualifications for which mental health professionals can make diagnoses may vary from state to state. Obtaining an accurate psychosocial history can be difficult because individuals with substance use disorders often have a strong motivation to keep substance use private. Neurocognitive deficits caused by substance use can create further complications with regard to obtaining accurate histories because the individual is unable to accurately report details of previous use. In fact, when compared with individuals with no cognitive impairment, individuals with cognitive deficits are more likely to deny substance use. Additionally, individual substances are associated with unique symptomatology and phenomenology, which can further obscure the clinical picture.

In many cases, substance use will only be suspected, and clinicians may doubt the validity of patient

self-report. However, several methods can be used to improve the utility of patient self-report. For instance, it is helpful to obtain information from significant others and to perform drug screening. Medical records may assist in determining if physical problems are consistent with substance use or if the individual has access to medications with high potential for abuse. In addition to an accurate history and routine laboratory tests, sound psychometric assessment and screening are necessary to evaluate the frequency of use, the severity and chronicity of the disorder, and the possibility of use of multiple substances and coexisting psychological disorders. Structured procedures, such as the Timeline Followback assessment procedure, which has been used to document both alcohol and substance use over the past 4 months, is particularly beneficial for those with substance use disorders, by providing a visual and structured format to recall instances of substance use. Self-report measures, such as the Substance Abuse Subtle Screening Inventory-3 (SASSI-3), may also be useful in identifying individuals at risk for substance use disorders. Measures such as the SASSI-3 are brief and provide information about a range of alcohol and drug use behaviors using established cutoff scores to determine level of risk for substance use disorders. Another measure that is often used in both clinical and research settings is the Addiction Severity Index (ASI). The ASI is a structured interview that assesses the severity of an individual's use of drugs and alcohol. It also provides information regarding areas of an individual's life that may be affected by drug and alcohol use, such as medical status, employment status, family and social relationships, legal status, and psychiatric/psychological status.

Polysubstance Dependence

Polysubstance dependence requires the use of three groups of substances (excluding caffeine and nicotine) over a 1-year period. The pattern of symptomatology produced must meet criteria for substance dependence due to the combined use of the various drugs. Under conditions where criteria for substance dependence are met for one or more substances, diagnoses of dependence would be made for those specific drugs, as opposed to a diagnosis of polysubstance dependence. The symptoms of intoxication and withdrawal in polysubstance use reflect the specific symptoms associated with the particular substances being used. Due to interaction and potentiation effects, specific symptoms of withdrawal

and intoxication can be difficult to predict when multiple substances are used.

Detoxification with polysubstance dependence can be difficult as the clinical picture becomes obscured. Under conditions where drug use includes central nervous system (CNS) depressants and opioids, detoxification of CNS depressants is the priority because the withdrawal from CNS depressants can be life threatening. Engaging in the simultaneous detoxification of different drug classes can compound physical and psychological discomfort and potentially increase risk for relapse.

Conclusion

The individual diagnosed with a substance use disorder rarely presents with a single causal factor. Difficulties in providing a thorough assessment and accurate diagnosis may include the wide variations in use, the high rate of polysubstance use, and comorbidity of diagnoses. Clinicians should take care to conduct an evaluation that relies on a multimethod approach. This evaluation should include a reasonable assessment of physical, psychiatric, and psychosocial domains of functioning. Ideally, assessment and diagnosis by clinicians would incorporate a methodology that allows examination of the interaction of factors that occur in an individual diagnosed with a substance use disorder including comorbid substance use, as well as medical and psychiatric disorders.

SUBSTITUTE ADDICTIONS

The term *substitute addictions* is used when an individual replaces one addiction with another. These addictions encompass using another substance to replace the original addiction, as well as behaviors that are compulsive. Research suggests that as many as 76% of people in recovery relapse with other substances or behaviors that are equally harmful, if not more so, than their original addiction.

Some of these “addictions” may manifest themselves in the form of compulsive behaviors, such as work, gambling, eating, sex, Internet use, and spending. It is difficult to specifically determine what factors lead to substitute addictions, but the common conception is that they are caused by various biological, psychological, and social factors.

Theories

One theory that addresses substitute addiction issues is the self-regulation systems model, where the current state experienced and set point on arousal or affect are chronically apart. This theory points out that biological factors, such as neurotransmitter imbalances, as well as problems with cognitive development, may lead individuals to self-regulate or “balance” their mood using substances or other behaviors that may be considered addictions.

Bidirectional theory contends that substance use and abuse occur when coping strategies to remain sober fail, mainly because of a combination of psychological and sociological factors that impact an individual. This theory implies that outside factors, such as income, community resources, and family support systems, as well as psychological factors, such as cognitive and internal demands, influence a person to seek substances or other addictions as a way of coping with stressful events.

A biological basis for substitute addictions can be explained by the lack of dopamine receptor sites within the brain. Dopamine is the chemical within the human brain that provides pleasure. When psychoactive or illicit drugs are introduced into the body,

dopamine receptors are stimulated and individuals feel pleasurable sensations. After an individual has been using drugs for extended periods of time, the brain adapts to the increase in dopamine by reducing the receptor sites in the brain where dopamine chemical reactions take place, known as the neural synapse. Because there are fewer receptor sites in the brain because of prolonged drug use, an individual often experiences depression and feelings of lethargy because dopamine uptake is restricted.

Substitute addictions may be adopted to stimulate dopamine production for many individuals because the substitute behavior produces dopamine and therefore elicits feelings of pleasure for the individual. For example, eating food stimulates dopamine, as does having an orgasm or exercising vigorously. Although the previous examples do not stimulate as much dopamine in the brain as do most illicit drugs, the effect is still one of positive reinforcement.

Treatment

Educational approaches may help clients become aware of the dangers of substituting addictions. During treatment, it is important for providers to assess the probability of a client developing a substitute addiction by reviewing the psychosocial history and other information gathered during treatment. The issue of substitute addictions can be discussed with the client and the client’s significant others and included in the relapse prevention plan. In addition, the client and the client’s significant others should be informed of the symptoms of a substitute addiction and guided to seek immediate assistance if they see evidence of a substitute addiction.

Cognitive behavioral therapy has been especially successful in the treatment of addictions, where thoughts and impulses are identified for the client and subsequently extinguished by the use of more positive means of dealing with the underlying emotions. Treatment with this technique may help clients recognize that the thoughts and impulses associated with a new addiction are similar to those that they had previously associated with their substance use addiction. The therapist would then work with the client to form new beliefs and thoughts regarding the addiction.

Behavioral self-control techniques using contingency management can be helpful by emphasizing moderation of a behavior rather than abstinence. Contingency management involves a gift or other reward system for appropriate behavior. For example,

a client may receive a favorite food once a week for eating healthy foods during the rest of the week; another client may receive a gourmet dinner when he or she doesn't gamble for a set period of time. Contingency management techniques are easy to learn and help to initiate and maintain positive behavioral changes. In addition, contingency management has been shown to retain clients in treatment for longer periods than counseling alone.

Behavioral self-control training reinforces desirable behavior through practice and repetition until the client learns to moderate and eventually extinguish maladaptive behaviors. This type of therapy is designed to reinforce small steps. The therapy builds upon these smaller steps so that later on, clients can implement these same components into larger goals and achievements. These approaches may be helpful for some clients because they offer positive reinforcement, can appear more flexible, and emphasize reduction of behavior rather than total abstinence.

Other substitute addiction therapies may emphasize relaxation training designed to help some clients recognize that they may feel more prone to a compulsive behavior when experiencing high levels of anxiety and stress. By recognizing the signs and symptoms of stress or anxiety, clients may be able to use deep breathing techniques, visualization, and meditation to focus on more positive behaviors rather than engaging in compulsive behaviors.

Conclusion

Clients with addictive disorders will usually incorporate some new behaviors to replace the old behaviors of their addiction. In fact, treatment providers encourage these clients to find alternative behaviors. The key is to replace the addiction with prosocial activities rather than a substitute addiction that is detrimental to the client's well-being. Treatment providers often stress the importance of getting people involved with peers and social groups that can lend support and a healthy environment. Many clients find that when they discontinue their use of alcohol and other drugs, they are cut off from their social support system. Therefore, helping clients find positive support groups may be part of building a solid foundation for recovery from any addiction.

SUICIDE

Suicide is defined as intentional death by one's own hand. According to the World Health Organization, approximately 1 million people die by suicide worldwide each year. In the United States, suicide is the 11th leading cause of death; according to the Centers for Disease Control and Prevention, more than 30,000 people commit suicide each year. The suicide rate in the United States is approximately 1.5 times the rate of homicide deaths and twice the rate of HIV/AIDS-related deaths.

Other terms have been used to describe various nonlethal self-harming behaviors. *Attempted suicide*, for example, is any act in which an individual intends to take his or her own life but survives. *Suicidal ideation* involves thoughts about killing oneself and can range from passive thoughts about one's own death to more active planning for a suicide attempt. Suicidal ideation can also be limited to a particular time in a person's life, or it can persist through several years. Approximately 1,900 emergency department visits are made each day in the United States to treat self-inflicted injuries.

Drug and alcohol use play a major role in many nonlethal suicide attempts and suicide deaths. According to the Department of Health and Human Service's National Strategy for Suicide Prevention program, between 40% and 60% of individuals who die by suicide are intoxicated, and up to 66% have some alcohol in their system at the time of death. Approximately 1% to 6% of alcohol-dependent individuals will die by suicide. That number jumps to 50% to 75% of individuals who have concurrent alcohol dependence and depression. Further, alcohol use frequently immediately precedes suicide attempts, suggesting that alcohol plays a causal role in suicide. Less is known about illicit drug use or abuse and suicide, but having a substance use disorder does significantly increase one's risk of suicidal ideation, suicide attempt, and death by suicide. As in the general

population, substance-abusing men are about 3 times more likely to die by suicide than are substance-abusing women, and substance-abusing women are approximately 3 times more likely to attempt suicide than are substance-abusing men.

Risk of suicide is also elevated among adolescent substance abusers. Suicide is the third leading cause of death among U.S. teens and young adults ages 15 to 24. According to the Youth Risk Behavior Survey, approximately 8.8% of high school students attempt suicide each year. Although research on substance use and suicide in teens is sometimes inconsistent and the exact relationship is not yet known, several studies have demonstrated a relationship between suicidality and use of various substances among adolescents. The 2000 National Survey on Drug Use and Health found that one quarter of illicit substance-using adolescents (ages 12–17 years) contemplated or attempted suicide compared with only 9% of non-substance-using adolescents.

The exact nature of the association between substance use disorders and suicide is unclear, and the evidence for a common etiology of substance use disorders and suicide risk remains elusive. There may be a genetic vulnerability to suicide risk that is more prevalent in substance-dependent individuals, or these individuals may be at greater risk because of the inherent stress associated with addiction. Although more prospective studies of suicide risk have been conducted recently, it remains unclear whether suicide risk precedes substance use or substance use precedes suicide risk. Three possibilities have been proposed: (1) Substance use is a precipitant of later suicide risk; (2) individuals use drugs and alcohol to self-medicate because they are suicidal and experiencing severe distress; or (3) some other factor (e.g., early trauma, depression) is a common cause of both suicide and substance use disorder. The evidence to date suggests that there may be more than one trajectory for suicide risk and addiction and that the various risk factors may have reciprocal influence on each other.

Several environmental and individual risk factors have been proposed to mediate the relationship between suicidality and substance abuse, including depression, history of trauma or abuse, problems in relationships and with social support, low self-esteem, severity of drug or alcohol dependence, polysubstance use, and impulsiveness. Trauma, for example, places individuals at high risk for substance use disorders and increased risk for suicide, attempted suicide, and suicidal ideation. The reverse may also be true; that is, substance abuse may place one at greater risk of experiencing trauma.

Additionally, loss of a caregiver or significant other has also been identified as a risk factor for suicide.

Depression is perhaps the most common psychiatric diagnosis associated with suicide risk in individuals with and without substance use disorders. Nearly 20% of individuals with untreated major depressive disorder will eventually commit suicide. Rates of depression have consistently been found to be higher in people with drug and alcohol disorders. Hopelessness is a factor related to depression that appears to place individuals at particularly high risk of suicide.

Another factor common to both substance use disorder and suicide risk is behavioral disinhibition, which has been measured as impulsivity, or as executive function difficulties, and involves problems maintaining control over one's behavior and emotions. Recent research, for example, has identified early childhood behavioral disinhibition as a risk factor for both substance use disorder and suicidality in late adolescence and early adulthood.

With regard to the suicidal act itself, substance use may decrease one's inhibitions, making it more likely that an individual who is already vulnerable—for example, because of a co-occurring depression—will take his or her own life. Alcohol use is frequently found to be an immediate precipitant in attempted and completed suicides. Alcohol itself has been found to be a disinhibiting factor in lethal and nearly lethal suicide attempts, and alcohol is often consumed within a few hours of a suicide attempt.

In summary, risk of suicide, suicide attempt, and suicidal ideation is significantly elevated in adults and adolescents with substance use disorders. Several risk factors for suicide have been identified, and in many cases, the risk factors for suicide among substance users are similar to those in the general population. However, individuals who use or abuse substances appear to also have higher rates of the factors that place them at risk for suicide.

SUPPLY REDUCTION

The U.S. National Drug Control Strategy developed by the Office of National Drug Control Policy has two components: supply reduction and demand reduction. As the term implies, *supply reduction* refers to efforts to decrease the availability of illegal drugs in the United States. According to the U.S. federal government, the strategy behind supply reduction is to disrupt the market for illegal drugs in order to reduce the profitability of the drug trade and increase the costs of drugs to consumers.

In other words, if there is a reduced quantity of illegal drugs available for purchase, the price will increase and the purity will decrease. This might discourage casual drug users from continuing to purchase illegal drugs and might encourage drug abusers to seek treatment. Over \$117 billion has been spent on supply reduction efforts from 1996 to 2008, and 63.5% of the national drug control budget was allocated to supply reduction in 2008.

Supply reduction is generally divided among three different initiatives: domestic law enforcement, interdiction, and international efforts.

Domestic Law Enforcement

Domestic law enforcement comprises the largest expenditure of the three areas. As the name implies, these are all of the federal activities involved in the investigation, arrest, and prosecution of people and organizations that grow, manufacture, transport, and distribute illegal drugs in the United States. Domestic law enforcement also includes operations involving money laundering from the proceeds of selling illegal

drugs. Nearly \$3.5 billion, or 26.7% of the entire federal drug control budget, was devoted to this area in fiscal year (FY) 2006. That was increased to nearly \$3.6 billion (27.4%) in FY 2007, and over \$3.8 billion (27.8%) for FY 2008.

The federal agency with major responsibility in the domestic law enforcement area is the Department of Justice, specifically the Drug Enforcement Administration (DEA). The mission of the DEA is to enforce the controlled substances laws and regulations of the United States and apprehend individuals and organizations involved in the growing, manufacturing, or distribution of illicit drugs. Most people are familiar with DEA “drug busts” shown on TV or depicted in other media. The DEA’s budget was nearly \$2.1 billion in FY 2008.

The Department of Justice also includes the Interagency Crime and Drug Enforcement. The mission of this agency, according to the Department of Justice, is to identify, dismantle, and disrupt sophisticated national and international drug trafficking and money laundering organizations. As the mission implies, some of these activities go beyond domestic law enforcement and are included in other supply reduction initiatives. The Interagency Crime and Drug Enforcement is allocated almost \$500 million a year.

The High Intensity Drug Trafficking Area Program (HIDTA) was established by the Anti-Drug Abuse Act of 1988 and is administered by the Office of National Drug Control Policy. With 32 locations throughout the country, HIDTA is designed to bring together representatives from law enforcement, criminal justice, and demand reduction disciplines to create partnerships for developing effective multiagency, multidisciplinary responses to regional drug problems. The program generally receives about \$225 million per year.

There are other parts of domestic law enforcement in the budgets of other agencies. For example, the Customs and Border Protection agency in the Department of Homeland Security has some domestic law enforcement responsibility. However, the federal government does not make it clear as to the proportion of the budget devoted to domestic law enforcement as opposed to other initiatives in supply reduction.

Interdiction

Interdiction is the second largest area of expenditures in the supply reduction budget. The activities in this area involve disrupting the transportation, by land,

sea, and air, of illegal drugs into the United States. Nearly \$3.3 billion, or 25.3% of the entire federal drug control budget, was devoted to this area in FY 2006. That was increased to nearly \$3.4 billion (25.7%) in FY 2007. In FY 2008, interdiction was allocated more than \$3.2 billion (23.5%).

Most of the interdiction funds in the National Drug Control budget are allocated to the Coast Guard, Immigration and Customs Enforcement, and Customs and Border Protection, all part of the Department of Homeland Security. The U.S. Coast Guard is responsible for reducing the flow of illegal drugs entering the United States by denying smugglers their maritime routes. From FY 2006 to FY 2008, the Coast Guard budget was reduced slightly, from over \$1.2 billion to a little over \$1.0 billion. Nearly all of the funding for Immigration and Customs Enforcement is devoted to investigations concerning the movement of carriers, persons, and commodities between the United States and other nations. Many of the investigations involve money laundering and the interdiction of large amounts of currency. Immigration and Customs Enforcement's budget increased from less than \$400 million in FY 2006 to nearly \$423 million in FY 2007. In FY 2008, the budget was reduced to \$412 million. The Customs and Border Protection agency implements enforcement strategies that are designed to interdict and disrupt the flow of illegal drugs across the nation's borders and dismantle the related smuggling organizations. With the federal attention on the United States–Mexico border, the budget for Customs and Border Protection increased from a little more than \$1.6 billion in FY 2006 to more than \$2.1 billion in the 2008 budget.

International Efforts

Although international efforts comprise the smallest percentage of the supply reduction budget, the initiatives in this area frequently receive a great deal of media attention. The efforts to disrupt the growth of poppies (used to make heroin) in Afghanistan and of coca plants (used to make cocaine) in Colombia are well known. More than \$1.4 billion, or 11.0% of the entire federal drug control budget, was devoted to this area in FY 2006. That was increased by more than \$600 million in FY 2007, due to special allocations to combat poppy growing in Afghanistan. Nearly \$1.7 billion (12.2%) was budgeted for FY 2008, although there was also a budget for "emergency designation" in the

Department of Defense, if money is needed again in Afghanistan.

The State Department and Department of Defense are largely responsible for international efforts. International efforts include spraying coca and poppy fields, alternative crop development programs (i.e., encouraging poor farmers to grow crops other than coca and poppy plants), and assisting foreign governments to investigate, disrupt, and prosecute drug trafficking organizations. The budgets for the State Department and the Department of Defense are generally around \$1 billion each. Some of the funds in the Department of Defense are considered to be in the interdiction area and for demand reduction (e.g., drug prevention and treatment for military personnel).

One of the most highly publicized international supply reduction programs was called Plan Colombia. This effort was started during the Clinton administration and continued during George W. Bush's presidency. It involved the defoliation of more than 1 million acres of coca fields, encouraging farmers to grow alternative crops, and helping the government disrupt drug cartels. Nearly \$4 billion has been spent on this initiative. Similarly, the United States is attempting to assist the government of Afghanistan in slowing the cultivation of poppy plants, used to make heroin. It is estimated that 60% of the national economy of this country comes from the production of heroin, and Afghanistan is the leading source of this drug in the world.

Effectiveness of Supply Reduction

The effectiveness of supply reduction efforts is questionable. The federal government reports on the price and purity of illegal drugs on a quarterly basis. Since 1996 to the second quarter of 2003 (last available data), the price of cocaine has dropped 48% with virtually no change in purity. Neither the price nor purity of crack cocaine has changed significantly. The price of heroin has dropped nearly 30% with purity relatively stable. Methamphetamine prices have decreased nearly 30%, and purity has increased by nearly 25%. The price of marijuana has increased more than 12%, but the TCH content of marijuana (the active ingredient of marijuana that determines potency) has increased more than 58%. In addition, since 2001, the Department of Justice has published a National Drug Threat Assessment regarding the availability of illegal drugs. The availability of cocaine,

heroin, methamphetamine, and marijuana has remained stable or increased. In fact, according to the National Drug Threat Assessment, there have been record interdictions of cocaine, but that has not changed the availability of this drug in the United States. The result of Plan Colombia has been to force growers to cultivate coca plants in nontraditional growing areas of Colombia.

The simplest explanation for the lack of effectiveness of supply reduction efforts is money. According to a UN report, the value of the global illegal drug market in 2003 was \$13 billion at the production level, \$94 billion at the wholesale level, and \$322 billion at the retail level. This is higher than the gross domestic product (GDP) of 88% of the countries in the world. That means there is a 623% markup from the production to the wholesale levels and a 243% increase from the wholesale to retail levels.

In 2003, the worldwide retail market value of marijuana products was \$142 billion, cocaine was \$71 billion, opioids (primarily heroin) was \$65 billion, and methamphetamine, amphetamine, and ecstasy combined was \$44 billion. Although the UN report does not give a breakdown of expenditures for illegal drugs by country, there are estimates by continent. North America spent \$144 billion (retail), or 44% of the world's total, on illegal drugs. North America's share of cocaine expenditures was 62%; opioids, 14%; marijuana, 55%; and methamphetamine, amphetamine, and ecstasy, 57%. In sum, more than half of the world's retail expenditures on cocaine, marijuana, and stimulant drugs come from North America.

At least with regard to cocaine and heroin, the vast majority of the money spent on these illegal drugs in the United States is by chronic users (those people with abuse or dependence disorders). According to a report prepared for the Office of National Drug Control Policy, 84.4% of the expenditures for cocaine were spent by chronic users of this drug, and 94% of the money spent on heroin was by chronic users.

There are two huge forces that maintain the supply of illegal drugs in this country regardless of efforts to control it: the tremendous money that is made from the wholesale and retail distribution of illegal drugs and the demand for illegal drugs created by chronic users.

Conclusion

Supply reduction activities comprise the largest percentage of the National Drug Control budget. In addition,

this percentage is increasing from 63.0% of the budget in 2006 to a proposed 65.2% in FY 2009. The activities in supply reduction (domestic law enforcement, interdiction, international efforts) reflect a military, punitive, and criminal justice orientation to drug control, and the budgetary allocations are reflective of the philosophical orientation of the federal government with regard to drug policy. Unfortunately, there is virtually no evidence that the expenditures of funds for supply reduction have had the desired impact. Clearly, supply reduction is an area of national drug control policy that has failed.

SUPPORT GROUPS

A support group is a community created by people who have something in common and a task to perform. Generally that task involves information exchange, achievement of a goal, personal growth, or healing on the part of group members.

The group itself is both a vehicle for achieving group goals and a resource for individual members to

rely on for help in meeting their changing needs over time. The ideas and issues of the group thus flow normally from the needs of the members.

The creation of support structures based on common issues and concerns is natural to the human experience. Birds of a feather flock together for a reason. Over the past 50 years, research on support groups and self-help groups has consistently reported that support group participants experience fewer feelings of isolation, improved coping skills, increased practical knowledge, enhanced self-confidence, and increased hope for the future.

Support groups can be led by a peer or facilitated by a professional or objective person from outside the group, who may act as an administrator, a leader, a guide, a mentor, or a broker of resources. Important elements that provide structure and a process for change include membership feedback, use of the membership as role models, open communication, purposeful relationships, shared norms and values, and the use of the collective body for guiding individual change.

Successful support groups are dynamic and possess a great deal of energy. This energy comes in part from the group's shared search for meaning; from the practice of admonishing and challenging each other with love; from the individual's accountability to the community; from the public but safe disclosure of acts, fears, hopes, and guilt; and from the leadership by the elders in the group.

Because the group can be a microcosm of society in general, the group member may develop a wider perspective and realization that he or she is not alone. In addition, the group provides a society where the member can practice new cognitive and behavioral habits. Members may find that the relationships in the group can mimic or remind them of their own family experiences and give them an opportunity to correct negative relationships. It is more difficult to manipulate one's peers in a support group than it is to manipulate family members or acquaintances. Finally, the members find that sharing in the group increases self-knowledge, and everyone learns from the modeling of others.

Mutual Aid Groups

Mutual aid groups (also referred to as self-help groups) are a special type of support group and are

almost always peer led rather than professionally led. Mutual aid generally refers to groups or meetings that involve people with similar or common needs, which are facilitated by one of the members who may be a consumer, survivor, or fellow sufferer. Generally the group task is to help people deal with a major life issue such as death, abuse, addiction, disability, or other serious condition. Hallmarks of these groups are that they are informal, nonprofit, voluntary, and usually anonymous and confidential. Although they may vary in approach, philosophy, size, governance structure, and organizational traditions, they generally do not charge fees, require appointments, or place limits on the number of visits a member can make. Members can therefore attend these group meetings indefinitely if they choose. This point is especially important when substance use disorders are accepted and treated as chronic health problems akin to diabetes and hypertension. Even though acute care interventions, such as primary treatment, are important for addressing immediate medical needs, for stabilization, and for encouraging engagement in continuing care, the acute care episodes do not, by themselves, cure chronic health problems.

Organized mutual aid or self-help has a long history and has become a part of the social landscape in Western culture, with an estimated 2% to 3% of the general population involved in self-help at any given time and with 18% of American adults having attended a self-help group at some point in their life. In fact, Americans make more visits to mutual aid groups for substance abuse and psychiatric problems than they do to all mental health professionals combined.

There is some discussion that the term *self-help* incorrectly describes groups that form to address the recovery issues of people who have substance use disorders. The argument is that *self-help* connotes a person's overcoming the disease alone, perhaps through insight, revelation, or increased willpower to stop using. Proponents who believe these groups are more accurately described as "recovery mutual aid groups" maintain that these are not self-help groups. Achieving and sustaining recovery in these groups involves the utilization of resources and relationships beyond the self. Therefore, for purposes of this discussion, the term *recovery mutual aid groups* will be

used to describe groups promoting recovery from substance use disorders.

Twelve-Step Groups

Since the early 20th century, Alcoholics Anonymous (AA) has been one of the best-known and most successful networks of local recovery mutual aid groups. Founded in 1935 by a New York stockbroker and an Ohio physician, AA is built on a foundation of 12 steps and 12 traditions. The essence of the Twelve Steps embodies peer support, honest self-reflection, public acknowledgment of shortcomings, and acceptance of a “higher power.” Sponsorship, or mentoring by someone successful in the program, is also a critical component. Whereas the Twelve Steps provide guidance to the individual, the Twelve Traditions of AA outline guiding organizational principles. These principles instruct the membership to recruit new members through “attraction rather than promotion,” to have no opinions on issues other than those affecting AA as a whole, to see each AA group as autonomous, and to decline outside contributions which could influence the mission of the organization. Of course, one of the cornerstones of AA is found in the name itself. Members are expected to honor the right for each person to remain *anonymous*. To that end, no membership information is sought, no roll call or attendance is taken, and no records are kept pertaining to any individual.

The success of AA spawned a number of other Twelve-Step groups dealing with a variety of life difficulties. By the early 1950s, meetings of recovering narcotics addicts were emerging in the Los Angeles area, adapting the original steps and organization of AA from the late 1940s. Narcotics Anonymous (NA) was officially founded in 1953, starting as a small movement and growing into the world’s second largest Twelve-Step organization based on the Twelve Steps and Twelve Traditions adopted from AA.

Al-Anon Family Groups was founded in 1951 as an outgrowth of the AA program. In the early years of AA, family members also attended AA meetings, and soon “family groups” began to form spontaneously. These groups asked for guidance from AA. In May 1951, Lois W. (the wife of Bill W., who was the cofounder of AA) and her friend Anne B. formalized these groups, and via correspondence the name Al-Anon Family Groups was selected. Approximately

200,000 family members now attend meetings of Al-Anon in the United States.

Gamblers Anonymous (GA) is the outgrowth of a chance meeting between two men during the month of January in 1957. These men had a truly baffling history of trouble and misery caused by their obsession with gambling. They began to meet regularly, and as the months passed, neither returned to gambling. GA also adapted the Twelve Steps of AA.

Overeaters Anonymous (OA) was founded in January 1960. Its membership is estimated to be about 70,000 in more than 70 countries. OA has created its own literature but also uses the books *Alcoholics Anonymous* and *Twelve Steps and Twelve Traditions* from AA.

Cocaine Anonymous (CA) began in Los Angeles in 1982. Since that time, chapters have been started throughout the United States, Canada, and Europe. CA literature is available in English, French, and Spanish. In 1994, CA’s first book, *Hope, Faith, and Courage: Stories From the Fellowship of Cocaine Anonymous*, was published. The organization estimated in 1996 that its membership comprised 30,000 members in more than 2,000 groups.

In the United States there are more than 20 other “anonymous” mutual aid group organizations dealing with issues ranging from sex to debt and spending to violence and abuse to general relationships and mental health.

Alternative Support Groups

Not all support groups dealing with addiction issues follow the Twelve-Step model. For decades, an ever increasing number of mutual aid support groups have helped individuals and families overcome addictions through use of other approaches, sometimes in direct opposition to the Twelve-Step approach.

Since 1987, Addicts Victorious has provided support group meetings in an Evangelical Christian environment. In addition to the support groups, individual counseling and a 5-day biblical counseling program are elements of the program.

Founded in 1948, Alcoholics Victorious support groups offer a secure atmosphere for recovering people who recognize Jesus Christ as their “higher power” to assemble and share their experience, strength, and hope. Alcoholics Victorious meetings use both the Twelve Steps of AA and the Alcoholics Victorious Creed.

Moderation Management is a support group and nine-step program with a focus on helping individuals identify their own risky drinking behaviors, make decisions, and then take action to either abstain or moderate their alcohol use.

Rational Recovery is a for-profit organization founded in 1986 by a licensed clinical social worker. It offers counseling, guidance, and instruction on self-recovery from various addictions through planned, permanent abstinence and acts as an alternative to AA and other Twelve-Step programs.

Secular Organizations for Sobriety (SOS) is an alternative recovery method for alcoholics or drug addicts who are uncomfortable with, or who cannot accept, the spiritual orientation of Twelve-Step programs. SOS's approach to recovery is strictly secular and maintains that sobriety is a separate issue from religion or spirituality. SOS credits the individual for achieving and maintaining his or her own sobriety, without reliance on any "Higher Power."

SMART (Self Management and Recovery Training) includes both in-person and online mutual self-help groups. SMART's focus is on all types of addictive behaviors, including substance use disorders, gambling addiction, cocaine addiction, and other substance and activity addictions. SMART Recovery promotes abstinence and is based on Rational Emotive Behavior Therapy, developed by psychologist Albert Ellis in the 1950s.

Women for Sobriety (WFS) began in 1976, emerging from one woman's struggle with alcoholism and search for a support system specific to the needs of women. WFS bases itself on a Thirteen Statement Program that encourages emotional and spiritual growth. Primary activities of WFS are the establishment of self-help groups and the distribution of literature to women asking for help.

Role of Mutual Aid Groups in Treatment and Recovery

Although a medical basis for alcoholism has been discussed since Benjamin Rush wrote about it in the 18th century, formal treatment of addiction is a recent development and is accompanied by significant ambivalence and reluctance to support care on the part of the health care system. This is the result of substantial public stigma against the behavior of persons with an addiction and strong social attitudes about personal choice and self-inflicted disease.

As a result, for 200 years recovery from addiction has been primarily peer-driven through various mutual aid or self-help support groups and consumer-led organizations. For many years AA and other Twelve-Step groups were practically the only recovery option for people with substance use disorders. In fact, many of those recovering from an addiction have overcome active use solely through recovery mutual aid groups, without any formal treatment or medical supports. Estimates are that today more than 6 million adults a year have contact with recovery mutual aid groups.

Thus, a first and important role for recovery mutual aid groups is to function as an available stand-alone intervention that meets the needs of those with substance use disorders who never enter treatment. Also, there is a need for community-based recovery mutual aid groups to remain available on a voluntary basis for those approximately 50% of recovering people who leave treatment before completing the full course of treatment. As a general rule, however, mutual aid groups are best viewed as a form of continuing care rather than as a substitute for acute treatment services.

A second crucial role for recovery mutual aid groups in treatment and recovery is to enhance and complement professional treatment programs. Research has shown that peer-to-peer services and mutual support groups help prevent relapse and promote long-term recovery and that support groups combined with professional treatment are superior to support groups alone. Because this adjunctive support also reduces utilization and demand on the treatment system, many managed care programs tend to minimize available medical and professional counseling interventions covered by insurance and instead require referral to support groups for ongoing and continuing recovery.

Formal therapy or treatment offers a safe and professional environment where people can address issues of motivation, build substance use resistance skills, learn to replace self-defeating activities with positive activities, and develop insight into their own behavior. Treatment also focuses on improving interpersonal relationships.

However, addiction is a lifelong illness with a vulnerability to relapse. The skills and relationships developed in treatment must be continued, practiced, and reinforced if relapse is to be prevented. Continued involvement in recovery mutual aid offers this reinforcement and support. In addition to the gains made in treatment and formal aftercare, mutual aid groups provide members with a setting in which they can replace

antisocial attitudes with prosocial values and attitudes, shift affiliation from negative influencing peers to prosocial peers and mentors, and develop ways to reconnect with family and significant others. By working the “steps” inherent in most mutual aid groups, the member also finds ways to gain self-control and improve problem solving, increase empathy for others, and resolve resentments over past relationships.

Participation in Twelve-Step programs can also be combined with brief outpatient treatment, in which the therapist facilitates the patient’s involvement in the self-help group. In the mid-1990s the National Institute on Alcohol Abuse and Alcoholism sponsored Project MATCH, a multisite clinical trial to test the patient–treatment matching approaches to the clinical management of alcoholism. One of the standardized, documented intervention tools to come out of the clinical trial was *The Twelve Step Facilitation Therapy Manual*, which outlines a process for integrating outpatient treatment with active involvement in AA. The program consists of 12 structured weekly sessions. Each session includes a specific agenda and pattern and suggested “recovery tasks” for completion between sessions, including reading AA literature and attending several AA meetings. The facilitation manual contains worksheets, session agendas, topics for each session, and methods for reviewing and evaluating the patient’s progress. In this approach, mutual aid becomes more than an adjunct or support to treatment; it becomes an integral and critical component of the treatment process itself.

Conclusion

Support groups, particularly recovery mutual aid groups, are part of the American social landscape and have become an important aspect of life for millions of individuals. Support groups are available for myriad conditions and concerns. All are based on a mutual support philosophy, and participants share personal experiences, serve as role models to facilitate the learning of problem-solving skills, and provide hope to each other for the future. Mutual aid groups, in particular, are an effective way for individuals in pain or discomfort to make changes in themselves. Usually these changes are guided by a mentor, or “sponsor,” and are based on following specific steps or a specific plan of action. The difficult work of making changes is done in the protection and safety of anonymity.

The task of the support group is not to treat or change people but to create a setting and an environment in which individuals can change themselves. Beyond the transformation that comes from participating in these mutual aid groups, individuals also enhance their friendship networks and improve their ability to cope with stress. Professional counselors and therapists working with troubled individuals and families can improve the predicted outcomes of their clients by engaging recovery mutual aid and other community support groups as complements and adjuncts to the treatment process. On the other hand, if professional treatment and intervention is not accessible for whatever reason, these mutual aid groups may be the only resource available to help individuals change their lives for the better.

SYNANON

The creation of addiction treatment programs was heavily influenced by two very different peer-based methodologies: Alcoholics Anonymous (AA; a support group format) and therapeutic communities (TCs; a long-term residential format). The original TC was named Synanon and was the brainchild of charismatic ex-addict Charles Dederich. Synanon flourished in the 1960s in California as a residential community for addicts who were seeking to become drug-free.

AA and TCs were models for the development of early treatment programs funded directly by the federal government. The National Institute on Alcohol Abuse and Alcoholism fostered the expansion of AA-derived treatment programs, and the National Institute on Drug Abuse funded many TC-based treatment programs. The success of these peer-based approaches contrasted sharply with the failures of physicians and psychiatrists who attempted to treat patients addicted to alcohol or other drugs.

In Synanon, addicts recovered through rigorous self-directed and group-supported change processes in which individuals drew from internal strengths in a self-reclamation process. The success of recovering addicts as counselors fostered the struggle that continues today in the tension between credentials and experience as qualifications for treatment providers. Throughout the history of treatment and the current rise of recovery support services, many have argued that those who have experienced addiction are the best source of help for individuals seeking recovery.

Charles Dederich was a recovering alcoholic, drug addict, and college dropout who was disappointed by the failure of professionals to successfully treat addiction and by the use of medications, notably methadone, as therapeutic tools. He developed a form of confrontational and transformational therapy grounded in the achievement of complete honesty about one's personal flaws and failures. Each newcomer to Synanon was assigned a "buddy" to accompany him or her through withdrawal, encouraging the newcomer that detoxification

could be achieved by relying on one's internal strengths. After an initial recovery period, the newcomer participated 3 times weekly in what came to be called "the game" or "marathons," often lasting several hours. In this group activity, people attacked each other, pointing out the weaknesses that had led to drinking or drug using and that were making recovery difficult. The attacks were intended to break down participants' defenses so that the personal restructuring could begin.

Synanon soon became a halfway house in Santa Monica, in which residents performed household chores in a highly structured and disciplined system. They rose in rank over time, as they became better equipped to deal with society. Dederich's program was seen by many as a process of human change achieved through a new kind of nonprofessional therapy. From 1959 through the mid-1960s, Synanon claimed many successes among more than 500 addicts who overcame their compulsive use of drugs and became sober. Making personal adjustments, they found their place in society and rebuilt their health.

These successes were considered quite remarkable, in part because Synanon's clients were hardened long-term drug users who had failed repeatedly to overcome their addictions; the majority were well known by the criminal justice system. The program attracted much attention. The media and state and federal legislators praised it highly and a movie titled *Synanon* was made by Columbia Pictures, with Edmund O'Brien playing Dederich.

During these years, drug treatment programs started by ex-addicts, modeled after Synanon and funded by the Office of Economic Opportunity and National Institute on Drug Abuse, appeared across the country: Daytop Village and Phoenix House in the New York City and New Jersey area; Morrisania in the Bronx; R.A.P., Inc., in Washington, D.C.; and Rubicon in Richmond, Virginia. Many still exist, practicing a highly modified and improved form of therapeutic communities, in which professionals have an important role. TCs, though criticized initially, have become an accepted and honored pathway to recovery.

Unfortunately, by the time studies were done, Synanon was in decline and had changed direction. Dederich's original goal had been to return addicts to society. However, he became convinced that recovering addicts needed to remain within the TC permanently. Turning his attention away from addiction, he began to apply the principles he had used with addicts

to Americans who desired more fulfilling lives. He described Synanon as a social movement.

Building on the public's positive perception of his method of rehabilitation, he began attracting large contributions from Fortune 500 companies. Many people attached themselves to him as a guru, contributing huge sums of money to participate in the game and in the hierarchically constructed society. Many who came to live at Synanon brought their children with them. Synanon became revolutionary in nature, hoping to change the world and joining the human potential movement of the 1970s.

Syanon's ex-addicts had engaged in small cottage industries to gain job experience and raise funds. Dederich expanded on these methods, building up an office supplies company, in which the *dope fiends* (a term used to refer to addicts) and *lifestylers* (people who participated in Synanon but who did not have drug problems) worked side by side. Employees earned little, while Dederich and his staff and supporters received high salaries and bonuses. Tensions developed between the dope fiends and lifestylers, especially when the game was played.

Dederich declared Synanon a religion, and even wrote a catechism, in order to achieve tax-exempt status. However, internal disarray and lawsuits over problems such as child abuse were filed by disgruntled lifestylers. In addition, a small California newspaper won a Pulitzer Prize for its exposé of the program. Eventually, the Internal Revenue Service revoked Synanon's tax-exempt status and confiscated its assets and real estate holdings. Unfortunately, Dederich returned to drinking and, following his death in 1979, the program slowly died. Today, the Synanon-style movement is criticized by those who see it as the forerunner of boot-camp approaches to addiction treatment.

SYNAR AMENDMENT

The Synar Amendment is the name commonly given to Section 1926 of the Alcohol, Drug Abuse, and Mental Health Administration Reorganization Act (Public Law 102-321), which was passed by the U.S. Congress in 1992. Its nickname is taken from one of the bill's cosponsors, Representative Michael Synar, who was a Democratic congressman from Oklahoma. The amendment contains provisions to reduce the use of tobacco products among minors by requiring all 50 states, the District of Columbia, and all U.S. territories to pass and enforce legislation that prohibits the sale or distribution of such products to individuals under the age of 18. The Synar Amendment also provides sanctions that may be handed down to states that fail to meet its requirements. Several key aspects of the Synar Amendment include its oversight, assessment of compliance, and effectiveness in reducing tobacco sales to minors.

Oversight

Oversight and enforcement of the Synar Amendment is carried out by the Center for Substance Abuse Prevention (CSAP). CSAP is a part of the Substance Abuse and Mental Health Services Administration (SAMHSA), which is housed within the U.S. Department of Health and Human Services. Synar is one of only two federal programs identified by the U.S. General Accounting Office that focuses solely on the reduction of tobacco use, and it is the only program whose single aim is to reduce the use of tobacco products among minors.

To implement the Synar Amendment, SAMHSA issued what is known as the Synar Regulation in 1996 to serve as a benchmark for determining whether states and territories are in compliance with the amendment. The Synar Regulation consists of five requirements. These requirements instruct states to (1) enact a law that prohibits the sale or distribution of tobacco products to individuals under the age of 18 by any tobacco distributor, manufacturer, or retailer; (2) provide reasonable enforcement of these laws to reduce the number of tobacco sales to minors; (3) devise a strategy for reducing the statewide retailer violation rate (RVR) to 20% or less and to consult with SAMHSA on a time frame for accomplishing this goal; (4) assess compliance with the state law(s)

through the use of random, unannounced inspections of tobacco retailers and vending machines on an annual basis; and (5) provide an annual written report to SAMHSA that describes the efforts made by the state to enforce its tobacco law(s), the methods used to select outlets for inspection and inspection procedures, the success of the state in reducing the RVR over the past fiscal year, and strategies for enforcing its law(s) during the next fiscal year.

Assessment and Sanctions

To be in compliance with the Synar Amendment, a state must demonstrate that less than 20% of attempted tobacco purchases by individuals under the age of 18 are successful. The text of the Synar Amendment states that all states were to have enacted a law by (a) 1994 or (b) 1995 (for states whose legislatures were not scheduled to convene in 1994), and that states were to achieve the minimum RVR by 2003. Although all 50 states had enacted laws prohibiting the sale of tobacco to minors by 1995, the RVR requirement was not achieved nationally until 2006.

States that fail to enact a law prohibiting tobacco sales to minors are ineligible to apply for Federal Substance Abuse Prevention and Treatment (SAPT) block grant funding as provided for in Section 1921 of Public Law 102-321. Further, if a state fails to adequately enforce its law, it is subject to having its SAPT funding reduced. The percentage of reduction is regulated by the amendment and depends on the number of years a state has been out of compliance with the regulations. A noncompliant state can avoid having SAPT funding withheld, however, if it agrees to enforce tobacco laws using state funds.

Compliance with Synar is assessed through the use of annual statewide inspections of tobacco retail outlets and tobacco vending machines by each state. These inspections, known as Synar surveys, are random and unannounced, and the results are reported to the Secretary of the Department of Health and Human Services via an annual Synar report. While each state is responsible for developing its own survey methods, CSAP requires uniformity of protocols across years and within each state so that valid comparisons can be made from year to year. In addition, CSAP provides guidance and technical assistance in developing and implementing inspection protocols and in structuring the annual report to the Department of Health and Human Services.

With respect to data collection, the guidelines provided by CSAP list the following as valid inspection methods: having minors buy or attempt to buy tobacco products, having youthful-looking adults buy tobacco products, placing an inspector in a tobacco outlet to passively observe sales to minors, administering surveys to minors and tobacco merchants, and inspecting legal records to determine which outlets have documented violations. Inspections are not carried out for all tobacco outlets within a state. Rather, CSAP requires that a valid probability sample of statewide outlets be drawn annually for assessment. To do this, a state must ensure that each tobacco outlet has a known, nonzero probability of being selected for inspection. Selection of outlets is done by drawing a sample from what is known as a "list frame," or a list of all tobacco outlets within a state that are eligible for inspection. States not only are required to compile a list frame but must also ensure that a minimum of 80% of all eligible outlets are included in the list. States are compelled by CSAP to conduct coverage studies every 3 to 5 years to demonstrate that this requirement is being met. Instructions for designing and implementing such coverage studies are provided by CSAP.

Trends in Youth Tobacco Sales

The 2006 Youth Tobacco Sales report published by SAMHSA reported that, prior to 1996, RVRs were between 60% and 90% in many states. This meant that two thirds or more of all attempted tobacco purchases by minors were successful. Data collected in 1997 via Synar surveys indicated that the highest statewide RVR was 74.6%, whereas the national RVR was 40.1% (this figure is used as a baseline by which SAMHSA gauges changes in national trends). By 1998, the national RVR decreased by almost 40%, and youth tobacco sales have declined every year since then. By 2006, the national RVR was reduced to 10.9%, with 46 states reporting RVRs of 15% or less. Further, this was the first year since Synar's inception that all states had an RVR below 20% (i.e., all states were in compliance with the amendment). The declining reported rates of tobacco sales to minors since the passing of the Synar Amendment suggests that it has been successful in curbing tobacco sales to minors.

THERAPEUTIC COMMUNITIES

The therapeutic community refers to a range of residential approaches to the treatment of substance abuse and addiction. Although most therapeutic communities share essential components, several variations of the approach exist. A typical therapeutic community involves a drug-free residential setting in which the staff and residents work together to encourage movement through a series of hierarchical treatment stages. Each new stage represents individual growth and increased responsibility. This entry explores essential components of therapeutic communities as well as current modifications of the approach, including its use with special populations. Further, the entry includes a discussion of factors related to the effectiveness of therapeutic communities.

Basic Principles

The ultimate goal of therapeutic communities is lasting lifestyle change for the participants. An assumption of the therapeutic community philosophy is that substance abuse is deviant behavior caused by incomplete personality development and skills deficits. As such, therapeutic communities strive to assist residents in the development of social, economic, and educational skills and facilitate prosocial change in substance abuse-related attitudes and behaviors. Two principles, *community as method* and *self-help*, are employed to aid in the accomplishment of these goals.

Community as method refers to the purposive socialization of participants through both formal and

informal interactions with other residents and staff members. Because therapeutic communities are residential in nature, participants spend most of their time and have most of their needs met on site. The other residents and the staff, then, compose the community in which participants live. Norms that discourage alcohol and other drug use and participation in prosocial behavior are developed via group processes in the community. Newer members are socialized to the group norms through daily unstructured interaction (e.g., eating dinner or doing laundry) with residents and staff in the living unit as well as through structured group meetings and therapy sessions. Punishment and reward systems are central in helping residents adopt and internalize community norms. Members who adopt prosocial attitudes and behavior regarding substance abuse are rewarded with community acceptance and access to social privileges. Further, when members drift toward antisocial attitudes or behaviors, community norms are reinforced via loss of privileges, responsibility, and acceptance.

The *self-help* approach of therapeutic communities focuses on the resident as a primary agent of change. As members progress through the hierarchical stages of treatment, they are expected to take on new roles and to model appropriate behavior for their fellow residents. Members take control of their situation by learning and adopting concepts of “right living” and “acting as if.” *Right living* refers to behaviors which facilitate responsible and ethical ways of living. *Acting as if* refers to behaving in ways that correspond with the ways in which one should or would like to live as opposed to behaving in ways associated with how one used to live.

Stages of Treatment

As mentioned above, therapeutic communities are based on a hierarchical treatment model in which participants move through different stages. The first stage of treatment lasts approximately 30 days and consists of induction and early treatment. During this time, the resident is expected to assimilate to community life as he or she is introduced to important community policies and procedures. In this early stage, the resident is asked to participate in various self-assessment processes. The resident begins to learn about the nature of addiction and hopefully commits to recovery as he or she works to gain the trust of fellow residents and staff members. This stage of treatment may be especially important to the success of therapeutic communities. In at least one documented case, induction was related to retention such that getting rid of this phase of treatment reduced the likelihood of long-term retention in the program.

The second stage is the primary treatment phase. It is during this phase that most of the work on attitude and behavior change takes place. As participants take ownership of their attitudes and conform to group norms, they are rewarded with increased privilege and responsibility. It is also during this stage that social and psychological needs and educational, vocational, and familial deficits are addressed. Residents may participate in tailored interventions to address specific needs or receive training to improve educational or vocational skills, for example.

Reentry into the larger community makes up the final stage of therapeutic communities treatment. Ideally, residents leave the therapeutic community drug-free, and they rejoin society employed or enrolled in school. Various aftercare opportunities, including individual and family counseling, may be available to help with the transition. Some communities even offer a formal outpatient component upon completion of the residential treatment component. Finally, if residents attended Alcoholics or Narcotics Anonymous meetings during their residence, they are encouraged to continue to do so once they have transitioned back into the community.

Modifications

Therapeutic communities have been implemented with a number of populations with unique issues and needs. Because one of the primary goals of therapeutic communities is to assist residents in building skills

and supports necessary for a drug-free life upon reentry into the community, they can easily be tailored to fit the specific needs of diverse populations. Therapeutic communities are often used with criminal justice populations and have been implemented both inside and outside prison walls. The prosocial norm-building process seems especially effective with these populations as it involves assimilation to norms that discourage not only drug abuse but all antisocial behavior in which residents may be involved. Therapeutic communities have also been tailored to meet the specific needs of women with children, adolescents, persons with co-occurring disorders, and HIV/AIDS populations.

In addition to slight modifications or adjustments for special populations, therapeutic communities have adapted in accordance with societal changes and organizational pressures. One notable modification of therapeutic communities is reduced length of stays. The original therapeutic communities had an indeterminate length of stay with the assumption that longer stays were more conducive to positive long-term outcomes, including abstinence. Cost, however, is an issue when trying to justify any type of long-term residential treatment, especially under current constraints of managed health care. As a result, many modifications of therapeutic communities have involved testing the feasibility and effectiveness of shorter stays. Completing treatment in therapeutic communities today could mean a residence of anywhere from 90 days to 24 months. In an effort to use funds efficiently, many communities have experimented with shorter residential stays combined with longer-term outpatient aftercare. Further, some communities have adopted a day-treatment, outpatient approach to therapeutic communities. Although day-treatment communities do not seem to be as successful for participants with severe social and psychiatric problems, they may be a cost-effective alternative for patients with less severe functioning problems.

Other recent modifications to therapeutic communities are a bit more controversial because they are thought to contradict some of the primary concepts of the traditional therapeutic community philosophy. Two specific issues include the partnership between therapeutic communities and methadone clinics and the continuing use and influence of professional mental health services and practitioners. Although the use of methadone actually contradicts the traditional “drug-free” philosophy of therapeutic communities, it

has been met with some success. The first therapeutic communities to adopt methadone as part of the treatment regimen did so in an effort to comply with regulations prohibiting public substance abuse treatment providers from discriminating against methadone patients. Another modification relates to the continuing increase of patients entering communities with co-occurring disorders. To address comorbidity issues, many communities have adopted mental health interventions or hired on-site or visiting psychologists and psychiatrists. This approach deviates slightly from the traditional community which relied primarily on staff persons who were ex-addicts with prior experience in similar communities. Further, the increasing use of mental health services has led to the introduction and consistent use of psychotropic medications within therapeutic communities. Future research and conversations are likely to focus on resolving such controversies and striking an appropriate balance between adaptations motivated by societal change and commitments to preserving the unique characteristics of the traditional therapeutic community.

Effectiveness

Therapeutic communities have a long tradition in the treatment of substance abuse, though the history of research on the effectiveness of therapeutic communities and related modifications is not as long-lived. Nonetheless, a full review of the efficacy and effectiveness research on therapeutic communities is outside the scope of this encyclopedia entry. Instead, retention and readiness, two effectiveness-related issues that have received attention, will be briefly reviewed.

Given the long-term nature of treatment in therapeutic communities, retention seems an extremely relevant issue. The types of normative changes expected from participants are not likely to happen and be maintained with much less than 90 days of ongoing treatment. There seems to be a positive relationship between time in treatment and positive outcomes post-treatment, with those continuing through completion having the best outcomes. Research suggests that the first 30 days of treatment may be important in predicting longer-term retention especially as dropout is highest during the early treatment days. Participants who are adequately orientated to the program and who start to see positive changes during the orientation period may be most likely to recognize the benefits of long-term persistence in the program. In the early

therapeutic communities, dropout was not necessarily a concern to program staff. It was generally believed that those clients who dropped out were least likely to be successful and that losing them was healthier for the remaining residents. Recent research, however, has been less concerned with blaming the patient for early dropout and, instead, concerned with exploring systemic or programmatic issues that could be improved to facilitate client readiness, motivation, and persistence.

Treatment readiness is another element of therapeutic communities that has attracted attention. Readiness has been linked to retention, which, as mentioned above, is ultimately linked to longer-term treatment outcomes. One focus of readiness research is on identifying, developing, and exploring the reliability and validity of instruments intended to tap client readiness for treatment. Current and future research is likely to focus on identifying practices for classifying treatment readiness and then tailoring community progress and interventions to fit the client's stage of readiness upon entrance. For clients who are ready for change, focused interventions may be implemented right away, whereas more time may be spent on self-assessment and orientation for clients who are less convinced of their need or capacity for change.

Conclusion

Therapeutic communities have a long history in the field of substance abuse treatment, and for many clients the history is a successful one. The long-term nature of treatment seems beneficial to those who are able to persist, and the highly adaptable nature of the therapeutic community makes it useful for diverse populations with unique needs and issues. Like many substance abuse treatments, though, the nature of therapeutic communities is such that the treatment was developed prior to related theory and research. The atheoretical nature of therapeutic communities means that research has been forced to develop after-the-fact explanations regarding the hows and whys behind the success, or lack thereof, of these communities. Current research explores the already established communities to determine client and staff characteristics and treatment components most closely linked to positive treatment outcomes. As the nature of funding becomes increasingly evidence-based, and health care systems change and evolve, tradition-based programs such as the therapeutic community must participate in evaluation to identify those

precedents which must be maintained and those which must be humbled by the research. This means that therapeutic communities will find it necessary to continue to flesh out and embrace the most efficacious and cost-effective components of treatment and expel any unnecessary mechanisms.

TIMELINE FOLLOWBACK

Efficient and standardized measures of substance abuse and dependence are needed to assist in treatment planning, as well as to measure treatment outcomes. When assessing for substance abuse and dependence, it is imperative to employ standardized measures of alcohol and drug use frequency across an extended time, so patterns of use can be better understood. The Timeline Followback (TLFB) procedure is the most widely employed standardized measure that assesses retrospective self-report estimates of substance use. The TLFB method was originally developed in the 1970s to assess alcohol frequency. Since its original development, the TLFB has developed into an assessment measure that

can be utilized in a variety of settings and formats. This procedure can also be utilized to assess the frequency of a wide variety of substances and measurable behaviors related to commonly co-occurring problems and treatment goals associated with substance abuse.

In this procedure, the assessment professional presents the substance abuser with a calendar that includes commonly experienced significant events (e.g., holidays, disastrous weather, professional sporting events, elections, accidents with mass casualties). Next the individual is instructed to record memorable personal events on their retrospective date of occurrence (e.g., anniversaries, birthdays, work-related events, funerals, arrests, celebrations, hospitalizations). These common and idiosyncratic events serve as anchor points to assist the respondent in remembering his or her substance use patterns during these time periods. The respondent is then instructed to estimate his or her daily substance use consumption for a specified time period ranging up to the past 12 months. Whenever possible, a standard drink and drug conversion chart should be utilized to assist the respondent in estimating the approximate amount of substances consumed during a particular occurrence.

If desired, the assessor can also utilize several memory aids or techniques to assist the respondent in accurately recalling substance use patterns. The interviewer can instruct the respondent to record black and white days. This technique involves querying the individual for extended periods of continuous substance use (i.e., black) and abstinence (i.e., white). Similarly, the interviewer can query for periods of heavy and light substance use. To establish boundaries on the amounts of substances used, the assessor can begin the interview by querying the respondent on the most and/or least amount of substance(s) consumed on any single day during the specified reporting period. To avoid vague quantity consumption reports (e.g., smoked a lot or a little, drank too much), the interviewer can provide more appropriate examples to assist in more accurately specifying the quantity of substances used. Additionally, when scheduling the initial assessment, the interviewer can instruct the individual to bring his or her own memory aids (e.g., appointment and schedule books, planners, diaries, calendars) to the interview.

Several versions of the TLFB procedure are currently available; these include a paper-and-pencil method, a computerized version, and a telephone

interview. The TLFB procedure can be self-administered or administered by an assessor individually or in group formats. Administration times vary depending on the format that is utilized and the time interval that is assessed. Typical administration times are approximately 10 to 15 minutes for the 90-day TLFB and 25 minutes for the 12-month procedure. Group administration times may require more time.

The TLFB procedure has demonstrated good reliability and validity in a variety of populations (e.g., substance abusing adults and adolescents from inpatient and outpatient settings, conduct-disordered adolescents, college students, pregnant women, psychiatric outpatients, males seeking outpatient treatment for domestic violence). Additionally, the TLFB procedure has been successfully employed with alcohol abusers across four countries (i.e., Australia, Canada, Mexico, Sweden) and has been translated into three languages (i.e., Swedish, Spanish, and English). The procedure has demonstrated good agreement with collateral informants (e.g., parents, spouses, roommates) and additional substance use detection methods (e.g., urine analyses). Therefore, if desired, the assessor can perform the TLFB procedure with additional informants and in corroboration with other assessment measures to increase the likelihood of substance use detection and accurate quantity and frequency reports. The TLFB method can also be easily adapted to assess the frequency and severity of additional behaviors related to commonly co-occurring problems and treatment goals associated with substance abuse (e.g., number of days institutionalized, employed, in inpatient and outpatient settings, incarcerated, attending school, smoking cigarettes, seeking treatment and aftercare contacts, exposed to domestic violence, driving under the influence, spent gambling, engaging in sexual risk behaviors). This information can be utilized by treatment providers to assist in determining diagnoses, treatment planning, and the assessment of the relationship between substance abuse and other behaviors.

A significant advantage of the TLFB procedure includes the ability to provide detailed estimates of substance use and other treatment-interfering behaviors. These detailed estimates allow clinicians to analyze substance use patterns with particular emphasis on relapse triggers, antecedents, and consequences of substance-related behaviors. The telephone and computerized versions of the TLFB interview also offer

several advantages. The telephone interview is cost and time efficient, and the computerized assessment provides easy storage and retrieval of assessment results, instant feedback, and a nonthreatening and nonjudgmental administration format.

TOBACCO

In 1964, the surgeon general issued the first *Report on Smoking and Health* to review and evaluate the health consequences of tobacco use. Since that landmark report, tobacco has become increasingly recognized as the leading cause of preventable illness and death in our society. Tobacco use is directly linked to cancers, cardiovascular disease, pulmonary disease, stroke, and pregnancy complications. According to the Centers for Disease Control and Prevention, smoking accounts for more than 435,000 deaths and an estimated \$193 billion in direct and indirect medical costs each year in the United States. Despite the well-known health risks and cost of smoking, approximately 21% of U.S. adults still smoke tobacco products, and an additional 3% currently use smokeless tobacco products. It is estimated that each day about 4,000 adolescents between the ages of 12 and 17 will try their first cigarette. Many of them will develop lifelong dependency for tobacco.

Understanding tobacco dependence as a chronic, biopsychosocial disease is important for prevention and treatment. There is no doubt that psychosocial pressures influence the initiation of tobacco use, but it is the reinforcement and dependency produced by nicotine in the brain that fuels the addiction. Understanding the physiological effects of tobacco, and especially nicotine, is helpful in identifying specific populations at risk for dependence as well as in the development of effective pharmacological therapies.

Pharmacology of Tobacco

Tobacco and its by-product, tobacco smoke, contain hundreds of physiologically active and psychoactive compounds, each with differing effect on the human body. Nicotine is the chemical in tobacco that is chiefly responsible for producing the reinforcing effects responsible for smoking dependence and is likely responsible for similar dependency in smokeless (spit) tobacco. It is also responsible for many of the somatic and subjective effects observed by the tobacco user.

Pharmacology of Nicotine

Nicotine is a naturally occurring chemical found in the tobacco plant. It absorbs easily through the lungs, the lining of the mouth, the skin, and, to a lesser

extent, the gastrointestinal tract. Nicotine quickly distributes through the bloodstream and easily crosses the blood-brain barrier, allowing it to act directly on the brain. The dose and bioavailability of nicotine (fraction of administered dose reaching systemic circulation unchanged) depends on the method by which nicotine is delivered to the body.

The average cigarette contains 6 to 11 milligrams (mg) of pure nicotine of which only a fraction, 1 to 3 mg, enters into the bloodstream. The bioavailability of nicotine can be increased up to threefold depending on the inhalation technique of the smoker. In comparison, the nicotine absorbed from the average dose of smokeless tobacco is equivalent to three to four cigarettes.

Nicotine from tobacco smoke is quickly absorbed through the lungs and distributed throughout the body. It is estimated that nicotine from smoked tobacco reaches the brain within seven seconds of inhalation. The nicotine found in smokeless tobacco is absorbed through the buccal membranes of the mouth and through the small intestine if tobacco juices are swallowed. Although both smoked tobacco and smokeless tobacco have similar peak concentrations in the venous blood, the absorption of nicotine from smokeless tobacco occurs much more slowly than that of smoked tobacco. Consequently, smokeless tobacco has a longer duration of effect which may persist for some time after the tobacco is removed.

Once in the bloodstream, nicotine has a half-life (amount of time for half of the nicotine in the body to be metabolized or excreted) of approximately 2 hours. It undergoes metabolism by liver enzymes (cytochrome P450) and, to a lesser extent, in the kidney and lung. Variations in liver enzymes may account for variable clearance time between individuals. Of the nicotine in the bloodstream, 80% to 90% is metabolized to the chemical cotinine before excretion by the kidney into the urine.

Nicotine readily crosses the placenta in pregnant women and into the fetal bloodstream. Relatively high doses of nicotine can be excreted in the milk of lactating women.

Pharmacodynamics of Nicotine

Nicotine produces a number of physical and mood-altering effects in the brain. The drug's actions are biphasic, stimulatory initially and inhibitory later, allowing it to act as both a stimulant and a depressant.

Nicotine affects nearly every major organ system, most notably the cardiovascular system, gastrointestinal tract, and exocrine and endocrine tissues. In addition to direct effects, nicotine can also act indirectly by stimulating the release of chemical transmitters (dopamine, norepinephrine, epinephrine) in the brain and nerves. These chemicals act as neuromodulators in the central nervous system and as hormones in the bloodstream.

The effects of nicotine on the cardiovascular system are due primarily to the release of stimulating chemicals (catecholamines) from both the nervous system and the adrenal glands. Additionally, nicotine produces a reflex response with narrowing of blood vessels, increased heart rate, and elevated blood pressure by binding to tissue in the aorta and carotid arteries of the heart.

In the gastrointestinal tract, nicotine increases muscle tone and motility in the bowels. Nausea, vomiting, and diarrhea often occur the first few times a person uses tobacco. Therefore, peer reinforcement of tobacco use may be a needed element in the development of nicotine dependency.

Nicotine also affects hormone-producing tissues. It causes the release of glucose into the bloodstream and a concomitant inhibition of insulin. Together, these actions lead to a rise in blood sugar (hyperglycemia). Smokers who are used to the hyperglycemic effects of nicotine can have profound withdrawal effects in the form of low blood sugar (hypoglycemia) and experience cravings during quit attempts.

Nicotine is extremely toxic at high concentrations. Consumption by children or exposure to nicotine-containing insecticides can result in nicotine poisoning. Nausea, vomiting, diarrhea, cold sweats, headache, dizziness, disturbed hearing and vision, mental confusion, and weakness are all possible presentations of nicotine poisoning. Over time, the effects of nicotine poisoning are weak heart rate, low blood pressure, and possibly death due to respiratory failure.

Nicotine, carbon monoxide, and the damaging effects of smoke on the cells lining blood vessel cells contribute to a strong association of blood clots with smoking. Blood clots can lead to heart attack or stroke.

The toxic and damaging effects of tobacco are well known, yet tobacco use remains a chronic problem for more than 20% of the U.S. population. Most people make many attempts to quit and relapse. Nicotine sustains their tobacco use through positive and reinforcing effects on the brain.

Current evidence points to nicotine's stimulation of the release of the chemical transmitters dopamine and norepinephrine in the brain as the primary reinforcing action. Mood-elevating drugs such as amphetamine stimulate the same catecholamines. The effects of dopamine target the part of the brain (nucleus accumbens) that is responsible for perceiving pleasure and reward. Additional compounds found in tobacco smoke (but not smokeless tobacco) inhibit enzymes in the same areas of the brain. These enzymes break down the neurotransmitters norepinephrine and serotonin. These are the same neurotransmitters targeted by antidepressant medications. The inhibitory effect of cigarette smoke on brain enzymes and consequent improvement of depressed mood contributes to the positive reinforcing (addictive) properties of nicotine.

The immediate, pleasurable effects of nicotine are short-lived. As a result, continuous dosing is observed in many smokers.

Nicotine dependence is the most common form of chemical dependence in the United States. It has been suggested that the addictive properties of nicotine are as strong as heroin, cocaine, and alcohol. The effects of nicotine include both tolerance and withdrawal, making dependence a chronic condition and making cessation difficult.

Withdrawal symptoms generally peak at 48 hours and generally disappear after 6 months.

Epidemiology and Comorbidities

Differing social pressures, physiology, genetics, and comorbid disease states may all contribute to the varying incidence of tobacco use across different populations. According to the Centers for Disease Control and Prevention, tobacco use among men (22.7%) is more common than among women (17.4%). Its use is closely correlated with an individual's level of education and socioeconomic status; those living in poverty and with lower levels of education are at higher risk for tobacco dependence. American Indians/Alaska natives have the highest incidence of smoking, and Asians have the lowest incidence. Caucasians, African Americans, and Hispanics have smoking rates that are only slightly above the national average (21%). Tobacco use varies depending upon the method of consumption as well. Caucasian males ages 18 to 25 have the highest incidence of using smokeless tobacco.

There is a strong link between tobacco use and mental illness. A study by Karen Lasser and her colleagues found that those with mental illness were about twice as likely to smoke as were people with no diagnosed mental illness. Patients with psychiatric diagnoses such as depression, bipolar disorder, and schizophrenia have more difficulty with smoking cessation than do individuals without mental illness. Additional support for the link between tobacco use and mental illness is provided by data showing that drug and alcohol addiction frequently co-occur with the use of tobacco.

The finding that smoking is more common in those with mental illness is quite significant. Smoking itself complicates treatment of psychiatric illness by decreasing the blood levels of some psychiatric drugs; thus larger doses are required to achieve therapeutic doses. Some studies report a higher incidence of adverse drug reactions such as tardive dyskinesia (involuntary movements) in patients who use both neuroleptic drugs and tobacco. Researchers are looking for pathways that link psychiatric illnesses and nicotine dependence in hope of developing effective treatments for both disorders.

Treatment

According to the Department of Health and Human Services, at least 70% of today's smokers in the United States would like to quit smoking. Each year, 44% of smokers attempt to quit, but only 4% to 7% are likely to succeed. These data helped motivate the Department of Health and Human Services to offer the evidence-based *Clinical Practice Guideline for Treating Tobacco Use and Dependence* (see <http://www.surgeongeneral.gov/tobacco>).

The 2008 guideline describes current treatment recommendations for tobacco dependence. It encourages clinicians to use the "5 A's approach" with smokers. Health care providers are encouraged to *Ask* about tobacco use and to address myths about quitting, to *Advise* users to stop smoking and to address the health benefits of doing so, to *Assess* the user's willingness to quit, and to *Assist* the user in quitting and to *Arrange* for follow-up. The first three A's are for all tobacco users regardless of their willingness to quit. Those who are unwilling to quit should be provided motivational interventions. These interventions are aimed at increasing the individual's awareness of the health risks of smoking, promoting the benefits of

quitting, and addressing any fears or concerns the individual may have about quitting or previous relapses. The preferred technique is a directive, patient-centered form of counseling known as *motivational interviewing*. The technique is designed to unmask the patient's internal motivation to quit using tobacco.

A number of behavioral therapies are available for tobacco cessation; these include self-help materials such as pamphlets and cessation-promoting Web sites, group therapy and social support, aversive conditioning, and counseling. There is a strong dose-response relationship between intensity of counseling and quitting outcomes for individuals with motivation to quit. This finding has helped to establish person-to-person counseling as a primary treatment modality for tobacco dependence. Whether an individual receives personal counseling, group counseling, or counseling by telephone, the duration and frequency of encounters appears to have the greatest impact on quitting outcomes. Four or more treatment sessions of at least 10 minutes' duration have produced the best quitting outcomes. Even brief interventions (less than 3 minutes with a physician) nearly double the rate of quitting in smokers. High-intensity treatment (more than 10 minutes per session) such as practical counseling (cognitive behavioral therapy, problem solving, skills training) combined with social support and encouragement have resulted in higher abstinence rates and are currently recommended for all tobacco cessation interventions. Cognitive behavioral therapy is a popular first-line treatment that identifies both the triggers and consequences of smoking and helps tobacco-dependent people develop adaptive behaviors for managing triggers and craving.

In addition to these interventions, three pharmacological therapies are approved by the Food and Drug Administration for the treatment of nicotine dependence. Nicotine-replacement therapy (NRT), bupropion (Zyban), and varenicline (Chantix) are pharmacological interventions for individuals who smoke on a regular basis and who exhibit a strong desire to quit. All three treatments are presumed to be effective in the cessation of smokeless tobacco use as well. The research studies that support the use of medications for smoking cessation typically include a behavioral treatment or support group.

Nicotine-replacement therapy is intended to decrease the withdrawal symptoms following smoking cessation. This is accomplished by replacing a portion

of the chemical stimulation but removing the harmful content of tobacco. NRT is generally well tolerated by patients and is available in several different forms to meet the patient's needs. Options include a transdermal patch (Nicoderm, Habitrol), gum (Nicorette), nasal spray (Nicotrol NS), inhaler (Nicotrol Inhaler), tablet, and lozenge (Commit). Each option has a distinctly different pharmacokinetic profile. The patch provides the highest dose of nicotine, which is delivered over a continuous 16- to 24-hour period, whereas the inhaler is shown to reach peak blood levels of nicotine within 5 to 10 minutes. Patches and gums produce smaller subjective effects than cigarette smoking and do not have the same potential for abuse. Nasal sprays deliver the highest concentration of nicotine, so they have the highest potential for abuse. Generally, NRT starts with higher doses and tapers down over the course of an 8- to 12-week treatment period. If necessary, NRT continues over longer periods of time (more than 6 months). The method of delivery and dose depend on the level of nicotine dependence. High-dose nicotine replacement has been shown to be effective in heavy smokers, whereas light smokers generally do not receive benefit from NRT.

Bupropion is an antidepressant medication that was found to be effective for nicotine dependence. It inhibits the reuptake and increases the concentration of dopamine and norepinephrine in the reward center of the brain. This leads to decreased withdrawal symptoms and cravings. Some smokers note that they no longer enjoy the taste of tobacco. Patients usually start this medication 1 to 2 weeks prior to a designated quit date. This medication has some side effects; the most worrisome is an increased risk of seizures.

Varenicline partially binds nicotine receptors in the pleasure and reward pathways of the brain. It selectively stimulates receptors at dramatically reduced nicotine levels in the blood. This helps to eliminate some of the negative symptoms, such as cravings, of withdrawal. Typically, varenicline treatment starts 1 week prior to a decided quit date. The dose increases during the first week and then stays at a therapeutic dose for a 12-week period.

Other medications have shown modest effectiveness for treating tobacco dependence. These nonapproved agents include clonidine (Catapres) and nortriptyline (Pamelor, Aventyl). Clonidine is usually prescribed as an antihypertensive agent. Nortriptyline is a tricyclic antidepressant which has also been used to treat nicotine dependence. These medications,

which carry significant side effect profiles, have rarely been used since the advent of approved prescription medications for tobacco dependence.

Conclusion

Tobacco use and dependency present a unique health concern. The issue is characterized by a recognized health and economic burden which is paralleled by a lack of consistent intervention despite the availability of effective treatment regimes. The history of tobacco use on this continent dates back more than 2,000 years, yet the recognition of its consequences on the health of the human body have really only come to light within the past 50 years. These newly established data on the negative health impacts of tobacco now provide the drive to research and discover the mechanisms and means by which tobacco takes hold of its user and creates an addiction to this product.

TOBACCO CESSATION PROGRAMS AND TREATMENTS

Although the dangers of tobacco use are well documented, the Centers for Disease Control and Prevention (CDC) reported that approximately 46 million adults in the United States smoke cigarettes. Perhaps the most central reason that smoking remains such a common phenomenon is that persons who become daily users are unable to quit easily or for long periods of time. For example, the CDC estimates that although approximately 15 million adult smokers attempt to quit smoking each year, only approximately 5% are abstinent 1 year later. Unless

the prevalence of tobacco use is reduced in a meaningful fashion, according to the CDC, 1 out of every 2 smokers in the United States will die prematurely. The purpose of this entry is to overview (1) the nature of tobacco use, (2) the major treatment programs designed for smoking cessation, and (3) the core elements of the clinical practice guidelines for tobacco dependence.

Nature of Tobacco Use

Cigarette Smoking

Cigarette smoking is widely recognized as the most popular form of tobacco use and as a major public health problem. Indeed, cigarette smoking remains a leading preventable cause of death and disability in the United States. Smoking is considered a key factor in various types of medical illness, including heart disease, a variety of pulmonary diseases (e.g., chronic obstructive pulmonary disease), and many types of cancer. For instance, the American Cancer Society reported that smoking is responsible for almost 30% of all cancer-related deaths. Although smoking increases the risk for developing many of these lethal medical diseases, quitting smoking decreases the risk of developing such problems and may increase the survival time among persons who have already developed such medical problems.

Despite a reduction in smoking prevalence over the past 25 years, approximately 22% to 25% of adults in the United States currently smoke, which translates into 45 million to 48 million Americans. Though nearly 70% of these smokers are motivated to quit, approximately 90% to 95% of smokers who do try to quit smoking on their own, and 60% to 80% of those who attend treatment programs, relapse to smoking, according to the CDC. Additional work suggests that 64% of youth (adolescents) report having tried cigarettes, and 14% have smoked frequently in the past month (i.e., 20 out of the past 30 days). Thus, there is evidence not only that smoking is a major source of death and disability but that once started, it is often difficult to stop.

Smokeless Tobacco

Although cigarette smoking is the most common type of tobacco use, there also is a significant population of smokeless tobacco users in the United States and the world. Epidemiological data in the United

States reported by the American Cancer Society, for example, suggest that approximately 3% of individuals have used some form of smokeless tobacco—either snuff (finely ground, shredded tobacco) or chewing tobacco—in the past month. These rates of use are higher among young Caucasian males compared with females, among those in southeastern and north central states compared with other regions, and in rural compared with urban settings. For example, past work reported by the CDC suggests that the highest rates of current use (16.6%) are among Caucasian males 18 to 25 years of age.

In general, rates of smokeless tobacco use are noteworthy because smokeless tobacco contains carcinogens (e.g., tobacco-specific nitrosamines) known to be causal agents in lung, oral, esophageal, liver, and pancreatic cancer. In addition, smokeless tobacco use is associated with greater nicotine absorption than cigarette smoking. Smokeless tobacco also stays in the bloodstream for greater durations of time than cigarette smoking. Similar to cigarettes, smokeless tobacco use can lead to increased rates of physical disease (e.g., oral cancer, gum disease) and nicotine addiction. Whereas the risks associated with cigarette use have become well publicized in the United States, public awareness about the dangers of smokeless tobacco remains limited. Indeed, many perceive smokeless tobacco as a “risk-free alternative” to cigarette smoking. Although as many as 50% of smokeless tobacco users report wanting to quit, as with cigarettes, rates of relapse remain high. In a recent review of smokeless tobacco treatment programs, Dorothy Hatsukami and Herbert Severson estimated a 3- to 6-month abstinence rate of 12% to 30%, with intensive behavioral treatments faring better than other intervention options. Thus, similar to cigarette use, smokeless tobacco use is an addictive behavior that is difficult to quit, and more intensive treatment approaches appear to yield relatively better outcomes.

Treatment of Tobacco Use Disorders

Smoking cessation has been shown to yield rapid and lasting health benefits. Since the surgeon general’s 1964 report on the detrimental effects of tobacco use, a body of work has been dedicated to treatment for smoking cessation. Treatment for tobacco use includes pharmacological therapy, behavioral therapy, and some alternative therapies.

Pharmacological Approaches

Pharmacological therapy offers a range of treatments that allow for tailored doses based on the smoker’s level of tolerance and dependence. These treatments include nicotine replacement therapy (NRT) and the drugs bupropion and varenicline. NRT is commonly used and easily available as it is offered over the counter. This therapy is available in nasal spray, tablets, gum, patches, lozenges, and inhalers. NRT works by supplying the body with nicotine, which helps alleviate adverse withdrawal symptoms. NRT has been shown to be effective as its different forms show an increase in quit rates. For example, Ludmila Cofta-Woerpel and colleagues reviewed the use of NRT based on the *Treating Tobacco Use and Dependence Clinical Practice Guideline* and found that NRT, in the form of gum, inhalers, nasal spray, and transdermal patch, roughly doubled long-term rates of abstinence relative to a placebo. This review also noted that the use of multiple forms of NRT increases abstinence rates above and beyond a single treatment of NRT.

Along with nicotine replacement therapy, the drug bupropion has also shown to be effective as drug therapy for smoking cessation. Bupropion was originally used to treat depression and was expected to aid in smoking cessation by targeting withdrawal symptoms connected to negative affect. The *Treating Tobacco Use and Dependence Clinical Practice Guideline* authors found that bupropion doubles long-term abstinence rates compared with a placebo. Furthermore, other research has shown bupropion to be superior to NRT. In research conducted by Douglas Jorenby and colleagues, participants using bupropion had a 1-year quit rate of 30%, which was twice as high as the quit rate in participants using nicotine replacement therapy.

Varenicline is another drug used in treatment for smoking cessation. It was designed specifically for this purpose. Approved by the Food and Drug Administration in the United States in May of 2006, varenicline works by reducing nicotine cravings felt by quitting smokers. David Gonzales and colleagues conducted a randomized clinical trial in which they compared the effects of varenicline, sustained release bupropion, and placebo in 1,025 smokers. Across the 12 weeks of the study, abstinence rates were highest for varenicline (21%) as compared with bupropion (16.1%) and the placebo (8.4%). In two double-blind randomized studies conducted by Gillian Keating and

colleagues, abstinence rates were significantly higher in participants receiving varenicline as compared with bupropion. Even when administering lower doses of varenicline as compared with higher doses of sustained release bupropion, varenicline was superior to bupropion, showing its value for use in treatment for smoking cessation.

Behavioral Approaches

Although pharmacological therapy is effective in the treatment of cigarette smoking, there is evidence that behavioral therapy also enhances quit rates. Behavioral approaches provide tobacco users with important skills needed to quit and remain abstinent. Moreover, some individuals cannot afford the drugs or nicotine replacement therapies used to treat nicotine dependence or cannot use the medications due to health risks (e.g., pregnancy or other contraindications). Behavioral approaches to smoking cessation typically draw upon past theories, including Albert Bandura's social learning theory and models such as Alan Marlatt and Judith Gordon's relapse prevention model and James Prochaska and Carlo DiClemente's transtheoretical model.

For example, the relapse prevention model advocates addressing affect, behaviors, and cognitions and teaching tobacco users to anticipate and then cope with obstacles preventing them from remaining abstinent. This model helps tobacco users to identify the situations that put them at high risk for relapse and also provides them with problem-solving strategies that can help them plan for and cope with these situations. In addition, the relapse prevention model helps tobacco users recognize the cravings and cognitions surrounding their tobacco use. In a review of controlled clinical trials adhering to the relapse prevention model and the use of its recommended strategies on adult smokers, Kathleen Carroll and colleagues found that 9 out of the 12 studies evaluated revealed significant main effects at follow-ups and posttreatment. In one study completed by Victor Stevens and Jack Hollis, 1-month follow-up abstinence rates were significantly higher in participants (people who were already abstinent from nicotine) who received relapse prevention skills training (83.6%) relative to a discussion control (77.4%) and a no-treatment control (65.4%). This study also revealed superior long-term abstinence at the 1-year follow-up for participants receiving relapse prevention

(41.3% in the relapse prevention skills training group, 34.1% in the discussion control group, and 33.3% in the no-treatment control group).

Motivational interviewing (MI) also has been used as a form of behavioral treatment for smoking cessation. This treatment attempts to enhance motivation to quit smoking. It can include an assessment of the health effects and the social consequences of tobacco use as well as financial costs. Motivational interviewing can also address the level of dependence and addiction of tobacco users and then help them identify goals for behavior change and challenges to making such change. Both MI and brief advice to stop smoking have been shown to increase quit attempts and lead to reductions in smoking. In one sample of teen smokers, Suzanne Colby and colleagues found that at a 3-month follow-up, 20% of participants receiving MI were abstinent from cigarettes as compared with 10% of those in the brief advice group. Moreover, 72% of participants receiving MI made a serious quit attempt compared with 60% of those in the brief advice group. This research highlights the efficacy of motivational interviewing as well as the significant effect that brief advice to quit can have on smoking cessation and quit attempts.

To further assess the efficacy of behavioral approaches, Jennifer Vidrine and colleagues reviewed behavioral treatments for smoking cessation and provided recommendations on the basis of the *Treating Tobacco Use and Dependence Clinical Practice Guideline*. These guidelines suggest that practical counseling and both intratreatment and extratreatment social support are effective in behavioral counseling for smoking cessation. Practical counseling involves problem-solving and skills training, which includes identifying and coping with smoking triggers. The clinician's concern, positive reinforcement, and encouragement constitute intratreatment social support. Extratreatment social support refers to outside care and concern for the tobacco user (e.g., community resources, family, and friends). Furthermore, research conducted on the use of stage-of-change-based letters, written feedback, and stage-matched coping strategies, based on the transtheoretical model and as reviewed by the *Treating Tobacco Use and Dependence Clinical Practice Guideline* authors, found that these methods also enhance smoking cessation rates.

The intensity of treatment should also be taken into account when reviewing behavioral approaches for

smoking cessation. Intensity refers to the duration as well as the frequency of the intervention with the clinician. Vidrine and colleagues noted that interventions lasting as short as 3 minutes showed an increase in abstinence rates. However, they also found that longer duration and more sessions of behavioral therapy were more effective than brief sessions of shorter duration.

Combined Behavioral and Pharmacological Approaches

Even though there has been substantial evidence supporting the use of various forms of behavioral and pharmacological therapy individually, it is important to note the enhanced effects of combined therapy on rates of smoking cessation. Maxine Stitzer found that treatment combining behavioral therapy and nicotine replacement therapy has an additive effect on abstinence rates, particularly in early postquit follow-ups. In one study completed by Nina Schneider and colleagues, 80% of the subjects receiving nicotine replacement therapy (gum) and intensive counseling were abstinent from smoking at 1-week follow-up as compared with 66% of participants receiving a placebo gum combined with behavioral therapy and 35% of participants receiving the placebo gum and no behavioral therapy. Ludmila Cofta-Woerpel and colleagues suggest that combined interventions may be more effective than either approach alone because each therapy has a different target (e.g., withdrawal symptoms and cravings for drug therapy and skills training to cope with high risk situations for behavioral therapy). Alternative approaches, such as acupuncture and hypnosis, to smoking cessation have also been proposed. According to Vidrine and colleagues, further investigation of these approaches should be conducted to assess their efficacy. In addition, Vidrine and colleagues found support for the efficacy of aversive smoking approaches such as rapid puffing. Nevertheless, aversive smoking approaches can have associated health risks as well as uncomfortable side effects and should be used with caution.

Clinical Practice Guidelines

It is optimal for clinicians to offer a combination of pharmacological and behavioral therapies for treatment of tobacco dependence. Nevertheless, it is important to note that some tobacco users should not use pharmaceuticals in their attempt to quit due to

health contraindications. Health status and financial concerns should be taken into consideration when selecting the most suitable approach for smoking cessation. Similarly, clinicians should assess all aspects of the client's tobacco use to cater to individual needs and choose the most appropriate treatment.

According to a review conducted by Ludmila Cofta-Woerpel and colleagues, authors of the *Treating Tobacco Use and Dependence Clinical Practice Guideline*, tobacco users who have quit recently should receive relapse prevention intervention, and current smokers should be assessed on their motivation to quit and directed accordingly. Tobacco users who appear to be unwilling to quit should be given an intervention designed to motivate them to become abstinent.

As it has been shown that therapy lasting only 3 minutes is effective in increasing smoking cessation rates, Ludmila Cofta-Woerpel and colleagues developed a brief intervention model, known as "the 5 As," for clinicians. According to this model, clinicians should assess their clients' smoking status, advise them to quit, assess their willingness to quit, assist them in quitting (which includes negotiating a quit date), and arrange follow-ups with their clients.

Cofta-Woerpel and colleagues also developed another model to aid clinicians in providing guidance for tobacco users during their quit attempts. This model is known as the Multiple Session Program Model, and it begins with the clinician helping the tobacco user set a quit date and enhancing his or her motivation to quit or remain abstinent. The clinician also provides basic information about smoking and about the benefits of quitting. With the input of the client, the clinician develops a quit plan and provides both external and internal social support to the client throughout the duration of the quit attempt. This model also suggests that the clinician should offer practical counseling which helps the client develop skills to avoid smoking triggers and cope with symptoms of withdrawal. Finally, the clinician should plan a follow-up session with the client after therapy is finished.

Although many of the current treatments for tobacco cessation are shown to be effective, there are barriers to the implementation of these treatments. In 2003, the chief of the National Cancer Institute's Tobacco Control Research Branch reported that high relapse rates and the costs of nicotine replacement therapy (some costing \$15 a day) can deter patients from receiving treatment. The 2003 National Institute

on Drug Abuse symposium also focused on the need for insurance and health care to cover the costs of pharmacological and behavioral therapy for smoking cessation to allow more patients to receive treatment.

In the meantime, it is important for clinicians to offer nicotine replacement therapies as well as other drug therapy and discuss how these medications have been proven to aid in quitting. Clinicians should strongly consider implementing combination therapy in their approach to smoking cessation intervention.

Conclusion

The evidence for smoking-related illness and deaths reveals the crucial need for effective tobacco cessation treatments. Pharmacological therapies such as bupropion and varenicline, as well as nicotine replacement therapy, have been shown to be effective smoking cessation treatments in past research. Additionally, the use of behavioral therapy, including motivational interviewing, relapse prevention, and practical counseling, has been shown to increase abstinence rates. Combining both forms of therapy can have an additive effect and can further increase these rates. Clinicians should cater to each person's individual needs when selecting which form of therapy to use. The body of research dedicated to tobacco cessation treatment continues to expand; keeping up-to-date with the latest and most effective approaches will help clinicians to make informed decisions when choosing the appropriate care for their patients.

TOBACCO MARKETING AND COUNTERMARKETING

Tobacco marketing includes all efforts of the industry to promote tobacco products. Industry marketing has been linked to a variety of smoking behaviors among both adults and youth and has been found to encourage smoking initiation among youth. Tobacco industry documents uncovered as a result of recent litigation provide factual information on the industry's intent to target certain groups, including women, racial/ethnic minorities, and youth. Countermarketing is a strategy used by public health agencies to protect individuals who may be susceptible to the influence of tobacco industry marketing—particularly youth—by responding directly to that marketing. The best countermarketing campaigns utilize key practices of modern marketing, including branding and audience segmentation. Because most smokers have their first cigarette before age 18, and because one-third of youth who begin smoking will progress to established smoking, reducing the influence of tobacco industry marketing on youth is an important public health goal. Examples of successful state and national countermarketing campaigns are discussed.

Tobacco Industry Marketing

For decades, the tobacco industry has used their substantial financial resources and state-of-the-art marketing techniques to promote the use of cigarettes and other tobacco products. As a result, some of the most recognized advertising campaigns in history have been sponsored by the tobacco industry. Present-day tobacco marketing takes the form of print ads in newspapers and magazines; posters and displays at retail establishments; sponsorship of sporting events or nightclub events; and distribution of branded promotional items and cigarette samples. Prior to 1998, the tobacco industry had access to a greater array of communication

channels, including outdoor advertising; television and radio commercials; a greater number of sports sponsorships; product placement in movies and television; and greater leeway in the distribution of branded promotional items, including candy cigarettes and toys. These marketing channels increase product awareness and build consumer demand among many audiences, including youth who have never smoked.

Two important marketing strategies employed by the tobacco industry are branding and market segmentation. Branding confers meaning to a product or company beyond tangibles such as product name or packaging. People, teens in particular, use brands as a means of self-expression. Market segmentation is the segmentation of a market into distinct subsets that have similar needs and desires to increase the likelihood that individuals will respond favorably to a given marketing strategy. By conducting in-depth consumer research to understand the motivations and desires of target audiences, the industry developed specific campaigns to appeal to different audiences. For example, in the early 1960s, Phillip Morris created the “Marlboro Man,” an iconic figure designed to tie tobacco use to ideas of masculinity, independence, and freedom. Its rugged images of cowboys resonated effectively with males and helped make Marlboro the top-selling brand of cigarettes in the United States and the world. Its images also resonated with youth, and it became the number one youth-initiation brand soon after the campaign was launched. These marketing efforts helped normalize tobacco use within American society even after the health threats were known.

Women

Women have also been targeted by the tobacco industry, and the industry has developed brands specifically for women. In 1968, Phillip Morris introduced a cigarette brand named “Virginia Slims”; these narrow cigarettes were packaged in a white box with the tagline, “You’ve come a long way, baby.” This slogan encouraged an association between smoking and women’s newfound freedom, which was garnered from the women’s liberation movement. Other brands targeted at women included cigarettes with perfumed scents and exotic flavors and packaging illustrated with flowers, pastels, and watercolors. More recently, ads have been appearing online since fall 2006, and in magazines and stores since January 2007, for a new R. J. Reynolds (RJR) tobacco product in black and hot

pink packaging called “Camel No. 9”—a name reminiscent of the famous perfume, Chanel No. 5, and evocative of femininity and fashion. Branded items such as compact mirrors and cell phone charms are being used to promote the brand; critics argue that they are designed to appeal to young girls. Unfortunately, lung cancer has now become the leading cause of cancer death among women, having increased by nearly 400% in the past 20 years. That statistic has led experts to comment that “the Virginia Slims Woman is catching up to the Marlboro Man.”

Youth

Newly uncovered tobacco industry documents show that tobacco companies have thought of youth as “replacement smokers”: an important audience that must be cultivated to replace adult smokers who quit smoking or die. Countless images of tobacco advertising in the media serve to normalize smoking behavior and, some say, increase the perception that smoking is more prevalent among youth and young adults than it really is. Tobacco companies often sponsor promotional events, such as bar nights and parties on college campuses, where free cigarettes are distributed. One of the most memorable campaigns, the now-defunct “Joe Camel” campaign, was particularly effective with young audiences. This campaign proved so successful in generating awareness and brand receptivity that youth were found to be more familiar with the Joe Camel figure than with some well-known Disney characters. RJR drew serious criticism from the public for its use of this cartoon character to promote tobacco products. Although the company denied allegations that the campaign was intended to target youth, internal documents demonstrated its interest in children as the target audience. Under intense pressure from impending litigation, RJR voluntarily ended the campaign in 1997.

In October 1999, RJR began selling candy flavored versions of the Camel brand, featuring flavors such as Twista Lime and Kauai Kolada during the summer and Warm Winter Toffee and Winter MochaMint in the winter. Brown and Williamson, which has since merged with RJR under the name Reynolds America, also introduced new flavors of their menthol brand KOOL in four flavors: Mocha Taboo, Caribbean Chill, Midnight Berry, and Mintrigue. Although cigarette companies deny attempting to attract youth smokers, an examination of cigarette brand and type preferences

demonstrated that some have a stronger appeal than others among youth. In October 2006, RJR reached an agreement with 38 state attorneys general to discontinue sales of most flavored cigarettes in response to public outcry that these brands were highly appealing to youth. Just 7 months later, however, RJR brought a new line of flavored cigarettes to the market: “Camel Signature Blends” in Robust, Mellow, Frost, and Infused. Given the persistence of the industry in marketing cigarette products with presumed youth appeal, it should be no surprise that, despite knowing the health threats of tobacco use, approximately 4,000 youth begin smoking each day.

Racial and Ethnic Minority Groups

Studies have also documented the industry’s use of marketing approaches to target racial and ethnic minority groups to promote tobacco use. For example, in 1989, RJR planned to test-market a new brand of cigarette called “Uptown” in Philadelphia. This mentholated brand, designed to appeal to African American smokers’ preference for menthol, was packaged with stylish black and gold writing. Advertising for this product planned to take advantage of channels that were particularly effective in reaching African Americans including billboards, transit advertising, bus shelters, point-of-purchase signage, and advertisements in African American-oriented newspapers and magazines. However, due to opposition from numerous leading public health groups and from African American civil rights organizations, RJR cancelled test marketing activities before any cigarettes were sold. In 1998, The Surgeon General’s Report on Tobacco Use Among U.S. Racial/Ethnic Minority Groups noted that the tobacco industry’s long history of providing funding for cultural and community-service organizations and events for some racial/ethnic groups may undermine tobacco prevention and control efforts.

The Master Settlement Agreement

The industry’s ability to advertise has been constrained by the 1998 Master Settlement Agreement (MSA), a settlement agreement between the four major tobacco manufacturers and the attorneys general of 46 states. Under the MSA, seven tobacco companies agreed to change the way tobacco products are marketed as well as provide substantial funds to states for Medicaid health care expenditures caused by

tobacco-related disease. The agreement indicated that cigarette companies may not target youth in the advertising, promotion, or marketing of tobacco products. This restriction is critical because national estimates indicate that each day more than 4,000 people under age 18 try their first cigarette, and between one-third and one-half of youth who try a cigarette will go on to become daily smokers. However, the tobacco industry continues to spend billions of dollars on advertising and promotional activities to promote tobacco use. Expenditures for tobacco advertising and promotion rose from slightly over \$2 billion annually in 1985 to more than \$13 billion in 2005. The industry claims that the objective of their marketing efforts is to maintain brand market share, but in reality, these marketing efforts influence teens and young adults to initiate and continue smoking. A 2001 study showed that cigarette companies increased their advertising in youth-oriented magazines after the MSA was signed, especially for the three brands most popular with youth—Marlboro, Camel, and Newport.

Tobacco Countermarketing

Tobacco countermarketing employs conventional advertising and promotion strategies but acts to discourage tobacco use rather than promote it. Multiple message strategies communicated through numerous venues have helped increase awareness of the health effects and social consequences of tobacco use as well as of the deceptive and manipulative marketing practices of the tobacco industry. At both the national and state level, countermarketing campaigns have been found to be effective in reducing adult and youth smoking prevalence.

Perhaps the first example of tobacco countermarketing occurred from 1967 through 1971, when the Federal Communication Commission Fairness Doctrine required broadcasters to show approximately one public service anti-tobacco ad for every three tobacco ads they aired. Although the advertisements were not designed specifically for youth and represented a variety of messages, during the period of the campaign per capita cigarette sales decreased, youth smoking decreased, and youth who reported watching more television during this period were found to be less likely to smoke. Another study concluded that smoking rates among adults would have been significantly higher from 1964 to 1978 had it not been for the Fairness Doctrine campaign.

Resources became available for states to develop their own tobacco countermarketing campaigns as MSA monies and other litigation monies were paid to the states by the industry. State-based campaigns in Florida, California, and Massachusetts are exemplary in their implementation as well as their attention to rigorous evaluation.

In 1997, Florida developed a youth-focused campaign called “Truth” targeted to teens ages 12 to 17. It employed an anti-tobacco industry approach as a primary message strategy. Many of their ads depicted youth directly confronting the tobacco industry, and promotional activities included teen events, merchandising, and media outreach. The marketing plan also included using teen input in every phase of the development to add style and legitimacy and to empower the teen movement. Its strategy was to reposition tobacco control as a hip, rebellious youth movement with the message that tobacco is an addictive drug marketed by callous adult corporate entities. A variety of studies demonstrated that the campaign reduced smoking, the risk of initiation, and the likelihood of progressing to established smoking. Nearly all youth in Florida (92% of 12- to 17-year-olds) could accurately describe one of the campaign advertisements in the year after the campaign launched. From 1998 to 2000, smoking prevalence among students in Florida underwent a statistically significant decline, from 18.5% to 11.1% among middle school students and from 27.4% to 22.6% among high school students. A longitudinal study showed that exposure to the campaign lowered the risk of smoking initiation and, among current smokers, the likelihood of progressing to established smoking. Moreover, the campaign had a dose-response effect; higher levels of campaign exposure were associated with lower likelihood of smoking initiation and progression to established smoking.

California’s campaign is one of the longest running countermarketing campaigns and is primarily focused on adults; however, it is designed so that youth are also exposed to campaign media messages. This campaign also employs an anti-industry approach to convey messages about the health consequences of tobacco use. Among adults, the campaign reduced smoking rates and per capita consumption and increased cessation; however, there is evidence that the campaign also reduced youth smoking rates and increased the proportion of youth who report never having smoked. Among youth ages 12 to 17, the proportion who had never

smoked increased from 1990 to 1999. Respondents were more likely to be “never smokers” if they were 12 years or younger in 1990, when most program components were put in place. Although adolescent smoking increased in the earliest years of the campaign, this trend began to change in 1996. From 1996 to 1999, the proportion of youth reporting established smoking declined from 9.9% to 8.0%. The California Department of Public Health reports declines in youth smoking from 1996 to 2002.

The Massachusetts anti-smoking media campaign consisted of television, radio, and billboard advertising designed to reach youth and adults. Campaign advertisements focused largely on tobacco industry practices and the health effects of tobacco use. The media campaign was considered “emotionally arousing,” was fairly intense (costing \$8 per capita over 4 years), and took place in the context of newly established state taxes on cigarettes. A large proportion of youth (71%) reported exposure to the television component of the media campaign. A longitudinal study showed that 12- and 13-year-old youth who were exposed to the campaign in 1993 were 50% less likely to progress to established smoking over the next 4 years. These youth were also less likely to have an inflated perception of peer smoking rates, a perception associated with an increased likelihood of smoking.

The largest anti-tobacco campaign ever conducted in the United States is the national truth campaign. It is focused on high-sensation-seeking youth ages 12 to 17, though there is a known impact among older youth and young adults. Primarily a media campaign, truth employs an anti-tobacco industry message theme. The edgy ads also highlight the health consequences of tobacco use. In the first 9 months of the campaign, 75% of all 12- to 17-year-old youth nationwide could accurately describe at least one truth ad. In the same period, truth influenced key youth attitudes toward tobacco in the expected direction and was associated with lower intentions to smoke. A 2002 study showed that truth was equally appealing to both smokers and nonsmokers and across race/ethnicity. Later studies demonstrated that the truth campaign was responsible for an estimated 22% of the nationwide decline in youth smoking from 1999 to 2002 and that there was a dose-response relationship between campaign exposure and smoking prevalence among youth in Grades 8 through 12. Recently, campaign exposure has been negatively and statistically significantly associated

with lower perceived smoking prevalence among youth, suggesting that the campaign may reduce smoking by correcting youth misperceptions about the prevalence of smoking among their peers.

Conclusion

Despite tobacco’s proven health consequences, which were first put forth by the U.S. surgeon general in 1964, tobacco use remains one of the most critical public health threats in the world today and is the leading preventable cause of death in the United States. Tobacco industry marketing plays a large role in shaping public perceptions about the acceptability of tobacco use and encourages youth in particular to use tobacco brands as a means of self-expression. Countermarketing is a public health strategy which can be used to inoculate at-risk populations to tobacco industry marketing. A growing body of literature demonstrates that national and state-level countermarketing campaigns can be effectively used to reduce smoking rates among both adults and youth. Additionally, countermarketing campaigns can reduce the likelihood of youth smoking initiation and, among those youth who already smoke, progression from occasional to established smoking. Countermarketing campaigns can also reduce the likelihood that youth will perceive smoking rates among their peers to be higher than they actually are, thereby countering the “normalizing” effect of industry tobacco marketing.

attorneys general from individual states and other jurisdictional entities. These conditions, of course, not only helped to shape many of the final terms and conditions of the negotiated multistate agreement but significantly directed the course of many of its resulting main and secondary effects.

Background

In 1994, four states—Massachusetts, Mississippi, Minnesota, and West Virginia—filed separate lawsuits in their respective state courts against individual tobacco companies in order to seek compensation for the health care costs of dealing with conditions resulting from the use and abuse of tobacco. Florida subsequently filed a similarly crafted lawsuit in 1995. Most other states and jurisdictions soon took similar steps to join in this emerging litigation trend. Thus, on June 20, 1997, a group of state attorneys general presented a proposed settlement to cover this pending and growing body of class action suits against tobacco manufacturers, also covering other pending actions brought by states and other governmental entities. It was hoped that a substantial proportion of the funds from such a settlement would also be allocated for state and local tobacco control efforts to support strategies by governmental officials, public health professionals, and other advocates to reduce youth tobacco access, to limit exposure of environmental tobacco smoke to nonsmokers, and to assist with smoking cessation programs and other treatment services. The considerable economic burden borne by the individual states and jurisdictions in providing Medicaid and other health care services for treating diseases associated with the use and abuse of tobacco served as the primary economic rationale by the attorneys general for initiating the multistate tobacco master settlement agreement.

TOBACCO MASTER SETTLEMENT AGREEMENT

The tobacco master settlement agreement was a major landmark in tobacco control. The attorneys general from nearly every state joined together and were able to win agreement from the major tobacco companies to provide financial compensation to individual states and participating jurisdictions for the health-related costs of smoking. The scope of the multistate tobacco master settlement agreement was rather broad, and its ramifications were far-reaching. Accordingly, it is important to understand some of the general background factors that contributed to the subsequent forging of the tobacco master settlement agreement by respective

Overview of the Tobacco Master Settlement Agreement

The tobacco master settlement agreement was concluded on November 23, 1998. The state attorneys general of 46 states, the District of Columbia, and five U.S. territories (Puerto Rico, the U.S. Virgin Islands, Guam, American Samoa, and the Northern Mariana Islands) signed this agreement with the major American tobacco companies (Brown & Williamson Tobacco Corporation, Lorillard Tobacco Company,

Philip Morris Incorporated, R. J. Reynolds Tobacco Company, Commonwealth Tobacco, and Liggett & Myers). The four other states (Florida, Minnesota, Mississippi, and Texas) settled individual agreements with the tobacco industry totaling \$40 billion. The tobacco master settlement agreement settled all consumer protection claims, antitrust claims, and claims for equitable, monetary, restitutionary, and injunctive relief sought by any of the participating states and other covered entities for the settlement year and for all previous years. State legislatures were encouraged, but not required, to establish a version of the model statute that dealt with a method for tobacco manufacturers not participating in the master settlement agreement to make payments to a reserve fund to cover possible future claims. This was intended to level the playing field between participating and nonparticipating tobacco manufacturers. However, not all states and jurisdictions have passed such proposed legislation.

The foundation of the tobacco master settlement agreement was that the tobacco industry would reimburse the respective states and other participating jurisdictions for the costs of providing Medicaid and other health care services to individuals with tobacco-related illnesses. This move was designed to settle pending lawsuits that held the tobacco industry accountable for decades of wrongful deeds. The general goals of this multistate master settlement agreement were to reduce the exposure of youth to tobacco marketing, to support comprehensive tobacco prevention efforts in each settling state, and to counter the industry effects of tobacco marketing on youth and children. Although the tobacco master settlement agreement restricts certain industry practices, it leaves many others unregulated, including tobacco cessation assistance for adults and other users of tobacco products. This has proven to be a major shortcoming of the master settlement agreement.

The multistate tobacco master settlement agreement forced the tobacco companies to share their internal documents. Another result was the creation of the American Legacy Foundation with its popular “truth” campaign intended to combat tobacco use in the United States. Smoking prevention efforts by the American Legacy Foundation have been cited as contributing significantly to the achieved declines in tobacco use by Americans.

Both the actual text of the tobacco master settlement agreement and a revised and updated summary of the attorneys general master tobacco settlement agreement can be found online.

It is estimated that the tobacco master settlement agreement will generate about \$206 billion over the first 25 years for state-based tobacco control efforts. This, in effect, makes the 1998 multistate tobacco master settlement agreement the largest civil settlement in American history. Nevertheless, annual allotments to states are subject to several adjustments, reductions, and offsets. The federal government, for instance, claimed about half the monetary sum agreed upon in the settlement in order to recoup, as required, third-party recovery payments of the federal Medicaid matching percentage. This federal move significantly impacted the potential effects of the multistate tobacco master settlement agreement.

The state attorneys general reached a similar but separate agreement with the U.S. Tobacco Company concerning smokeless tobacco products. The Smokeless Tobacco Settlement will result in the payment of up to \$400 million over 10 years to the National Public Education Fund. This separate smokeless tobacco settlement was an associated achievement directly attributable to the multistate tobacco master settlement agreement.

Selected Conditions of the Tobacco Master Settlement Agreement

There are many specific terms and conditions covered by the multistate tobacco master settlement agreement. Many of these terms and conditions serve to impose specific restrictions upon the tobacco industry, such as prohibiting certain marketing practices as well as limiting the option of tobacco manufacturers to oppose potential legislation to curb tobacco use, particularly by youth. Additional terms and conditions cover many other related issues, including those involved in administering and implementing the multistate tobacco master settlement agreement.

The tobacco master settlement agreement places several voluntary restrictions upon the production and marketing of tobacco products in the United States. For example, there are limitations on third-party use of tobacco brand names; bans on outdoor advertising and transit advertising of tobacco products; prohibitions on obtaining naming rights for any stadium or arena; prohibition of sponsorship of activities where contestants or paid participants are under the legal purchase age; bans on the future use of nontobacco brand names or trade names, recognized athletic teams, entertainment groups, or individual celebrities

for tobacco products; a ban on youth access to free samples; and limitations on lobbying. The distribution and sale of nontobacco merchandise, such as T-shirts, caps, and backpacks, with tobacco brand names and logos is also banned. There is also a ban on the promotion of tobacco products in videos and video games, on television shows, in movies, and at theater productions and other live performances.

Tobacco manufacturers are prohibited by the tobacco master settlement agreement from opposing, directly or indirectly, several different forms of potential legislation that may be proposed. For example, there can be no opposition to state legislative bans on the making and selling of cigarette packs containing less than 20 cigarettes. There can be no industry opposition to moves to limit access to vending machines for tobacco products, nor can there be any tobacco industry opposition to moves to use additional technologies to increase the effectiveness of age-of-purchase laws for tobacco products, such as the use of programmable scanners to read drivers' licenses, or use of other ID or age databases. The American tobacco industry is also prohibited from opposing, in the future, any potential legislation that might enhance enforcement efforts to identify and prosecute violations of restrictions on retail sales to youth or of penalties for youth possession or use of tobacco products. The tobacco manufacturers are also prevented from opposing any legislation that would place limitations upon nontobacco products designed to look like tobacco products, such as candy cigarettes or bubble gum cigars. It was hoped that these prohibitions on future opposition to additional legislation directed against tobacco industry practices would cancel efforts to circumvent the terms and conditions of the agreement as well as its fundamental intent.

Consideration for Agricultural and Rural Community Assistance is included in the tobacco master settlement agreement to help mitigate the economic impacts to tobacco-producing states and communities. On February 4, 1999, the 14 tobacco-producing states and the participating tobacco manufacturers tentatively agreed to a formula based on the U.S. Department of Agriculture's quota system to distribute a \$5.15 billion trust fund to the tobacco-producing states for economic assistance to tobacco farmers and communities in those states. This concession to tobacco farmer assistance demonstrates the continuing substantial economic role that the tobacco industry has played in local, state, and national politics in the United States.

The tobacco master settlement agreement was crafted with the intent of changing the corporate tobacco culture. It requires that tobacco manufacturers become committed to reducing youth access to tobacco products and to reducing current and future tobacco consumption. There were also measures to disband tobacco trade associations and to restrict lobbying efforts by tobacco manufacturers.

There is provision for public access to documents of the tobacco manufacturers and those of tobacco-related organizations. This has already resulted in the public disclosure of more than 40 million pages of previously confidential documents. It has been noted that this disclosure has proven highly useful to tobacco prevention efforts, such as those by the American Legacy Foundation and other, similar organizations. The tobacco industry is also prohibited from suppressing or limiting research on the relationships between smoking and health. Conditions and terms are also provided for enforcement of the tobacco master settlement agreement, including court jurisdiction and a state-by-state enforcement fund, as well as guidelines for payments (both up-front payments and subsequent annual payments), attorney fees, and auditing. There are several other, miscellaneous provisions contained within the multistate tobacco master settlement agreement.

Effects of the Tobacco Master Settlement Agreement

The 1998 multistate tobacco master settlement agreement was intended to place restrictions on advertising and promotions for tobacco products. However, the amount the tobacco industry expends on advertising and promotional strategies appears to have shifted. Although there have been reductions in total expenditures on outdoor advertising, on public entertainment, and on brand-identified specialty promotional items, there have been large increases in marketing expenditures related to retail value added and incentive to merchant categories, possibly to offset the higher prices of cigarettes. It has been noted that the tobacco industry has expanded its direct marketing practices, such as direct mail, coupons, event sponsorship, brand loyalty campaigns, sweepstakes, and tobacco industry magazines, all of which circumvent the marketing restrictions of the tobacco master settlement agreement. For instance, bar and nightclub promotions are not directly regulated by the master settlement agreement. Another strategy successfully employed by the

tobacco industry to circumvent the advertising restrictions of the tobacco master settlement agreement is the sponsorship of motor sports and other activities; this type of sponsorship allows tobacco manufacturers to obtain substantial television advertising. This critical area of restricting the marketing of tobacco products has been cited as one of the serious failures of the 1998 multistate tobacco master settlement agreement.

There has been a significant reduction in youth exposure to tobacco advertising since the multistate tobacco master settlement agreement prohibited advertising and other marketing activities targeted at youth, as well as the elimination of the use of cartoons in marketing. In fact, the tobacco master settlement agreement has served as an effective device that permits state officials to address marketing practices of the tobacco industry that could potentially increase underage smoking. For instance, subsequent court decisions have supported the enforcement mechanisms of the agreement and found that R. J. Reynolds violated the prohibition on targeting youth by its advertising of tobacco products in national magazines.

Although it is not possible to establish a clear cause-and-effect relationship between the tobacco master settlement agreement and associated rates of youth smoking, there has been a significant decrease since 1998. According to the annual Monitoring the Future Survey, the percentage of young people who reported smoking cigarettes in the past month decreased nearly 50% between 1998 and 2006. These general trends of declining tobacco use have been reported in many other studies. However, the decreases have declined in recent years, especially among the youngest groups, as the tobacco industry has successfully adapted its marketing strategies. Critics have noted that state allocations of funds from the tobacco master settlement agreement have been diverse, with substantial amounts diverted to areas other than tobacco control and health, including covering state budget shortfalls and capital projects. These moves, of course, are contrary to the original intent of the multistate tobacco master settlement. This apparently reflects the lack of consistent public support for tobacco control efforts. In fact, fiscal crises in respective settling states appear to significantly impact the use of master settlement funds, as does the possibility of securitizing future funds. It has further been observed that most states are not yet meeting even the minimum levels of support for tobacco prevention and cessation programs recommended by the U.S. Centers for Disease Control and Prevention.

Analysis has indicated that the tobacco master settlement agreement has not done serious harm to the participating tobacco companies and has actually increased the value and profitability of the companies. There clearly was an increase in the average price of cigarettes after the settlement, which probably negatively influenced smoking prevalence rates. State cigarette excise taxes have also risen substantially. Increased expenditures for state tobacco control programs with master settlement funding have effectively reduced tobacco use, but these initial gains appear to be declining, particularly as more states and jurisdictions have diverted these funds to cover non-tobacco-related areas within their budgets.

Conclusion

The 1998 multistate tobacco master settlement agreement crafted by respective state attorneys general has proven to be somewhat effective in delivering on its originally intended mission of placing restrictions on advertising and promotions for tobacco products, in particular those marketing efforts directed at youthful consumers. Further, considerable financial compensation was in fact obtained from the tobacco manufacturing industry for use by participating states and other jurisdictions. On the other hand, the tobacco manufacturing industry has appeared to be extremely resourceful in devising strategies to circumvent the overall intended effects of the master settlement. This has been most clearly evident in marketing strategies by the industry designed to attract the youngest tobacco consumers where initial gains appear to be decreasing in effectiveness. Similarly, tobacco cessation initiatives—initially begun with great promise and substantial funding after the conclusion of the master settlement agreement—have also frequently been scaled back as resources are increasingly diverted elsewhere by respective state governments. Likewise, comprehensive tobacco prevention efforts initiated by states and participating jurisdictions after the acceptance of the settlement agreement have more recently been curtailed. Nevertheless, the multistate tobacco master settlement agreement has served as a model tobacco control initiative whose effects have profoundly altered the nature and extent of tobacco marketing, which, in turn, is already proving to have resulted in dramatic reductions in tobacco use in this country. It is fully expected that these public health gains, particularly those concerned with restricting

youth marketing exposure, will continue to demonstrate significant benefits well into the future. Renewed resolve and more finely tuned initiatives are needed to advance collective tobacco prevention control efforts.

TOLERANCE

Tolerance occurs when the body adapts to drug usage, reducing the expected or desired effects. This means an increase in dosage is needed to produce the same effects. Tolerance depends on a number of things, most importantly dosage, the type of drug, and how often the drug is used. Drug tolerance can involve both psychological and physiological factors. *Tachyphylaxis* is a medical term used to describe a rapid onset of drug tolerance. Tachyphylaxis can occur so quickly it may only take a few separate uses of the drug within a few hours before the user has built a tolerance. It is important to note that although a higher dosage of a drug may be needed to achieve the desired effects, the amount needed for a fatal overdose does not necessarily need to

be higher. Even when users cannot feel the effects of a drug as strongly as they once could, the increase in dosage may still be too much for their system to handle. Additionally, overdoses can happen when users have gone through an abstinent period, such as a drug rehabilitation program or time in prison. When they begin to use again, they may assume their tolerance is the same when, in reality, their bodies have readjusted and the same dosage is not needed to gain the desired effects.

Genetics may play a role in tolerance. It is often thought that some people are born with a naturally higher tolerance for certain drugs, in particular alcohol, than others. These people may be able to naturally metabolize alcohol faster than others, even if they have never had alcohol before. Dependence, addiction, and tolerance are three separate issues. Dependence brings about symptoms of withdrawal when a substance is discontinued. Dependence also entails an intense craving for the effects of a drug. Addiction is the uncontrollable and unmanageable use of a drug. Tolerance arises when a given amount of a substance loses its potency over time. Although addiction and tolerance can take place at the same time, one can occur without the other. Also, developing tolerance to a drug does not mean that all effects of the drug decrease at the same pace. Users may never develop a tolerance to some effects of a drug, but at the same time, other effects will show a tolerance almost immediately. Codeine, for example, is a pain-relieving medication produced from opium. Codeine can have common side effects like nausea, vomiting, and dry mouth. A frequent user's body may adapt so that the dosage of codeine no longer makes the user ill but is still effective as a pain reliever. Tolerance, though a separate issue, is often associated with addiction or substance dependence. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, substance dependence may be diagnosed when, over a period of 12 months, the user displays at least three of the following symptoms: tolerance; withdrawal; spending an enormous amount of time in an effort to get, use, or recover from the drug; being unsuccessful in controlling or cutting down drug use; and pushing aside, or cutting out, normal and important activities in order to use the drug.

Tolerance is frequently considered by health care professionals who are assessing substance abuse problems of older patients. However, a few factors may cause a clinician to misinterpret the tolerance

of a patient. In older patients, as a result of the aging process and common diseases that can be found in people beyond middle age, physiological reactions and dependence to certain drugs may automatically lower the natural threshold for tolerance. Also, because an older user has become accustomed to the drug and its effects, reverse tolerance may be present. This happens most often in cases of addicts who have abused alcohol for years. Their liver is so damaged by the years of abuse that it is no longer able to metabolize the same amount of alcohol; this leads to a higher blood alcohol level in a smaller amount of time than the user is used to. Therefore, considering only the development of tolerance among older adults is not enough to diagnose substance abuse or dependence. Similarly, the simple fact that a user does not exhibit tolerance does not mean that he or she is not addicted. In cases where alcoholism develops later in life, older users may not have had the opportunity to fully develop tolerance to the drug and may not even experience the symptoms of withdrawal upon stopping.

Types of Tolerance

Pharmacological

Pharmacological tolerance occurs when the body adapts or makes up for the presence of a certain drug in the body's systems. This can happen through excretion of drugs or a fast deactivation of the active ingredients in the drug. The liver adapts and can synthesize a greater number than normal of drug-metabolizing enzymes. The liver essentially speeds up its normal actions, and the drug passes through the system more quickly. It is important to note that this form of tolerance may be affected by the way the drug is administered. The liver is a major part of this mechanism. Therefore, oral administration is the route most affected because the drug must pass through the liver to be metabolized.

Another way in which pharmacological dependence can develop is by modification of the user's neurotransmitters. Once certain drugs cross the blood-brain barrier, they match up with specific neurotransmitters and either increase the release of the transmitters or impede their reuptake, subsequently amplifying the access to receptors. Tolerance occurs when fewer transmitters exist and more of the drug is needed for the same effect.

Most drugs interact with a specific neurotransmitter called dopamine. This neurotransmitter is found in areas of the brain that are responsible for emotions, motivation, feeling pleasure, and movement. Substances that are being abused are found to release too much dopamine, to the point of overstimulation. This is where euphoric effects that are associated with specific drugs originate. This overstimulation of dopamine is rewarding and pleasurable, but it can mark the beginning of the drug abuse cycle. As abuse continues, the overstimulation of dopamine in the brain causes it to adjust and subsequently start to reduce the number of dopamine receptors or reduce the amount of dopamine itself. When this happens, the effects of a drug are less pleasurable, and the user cannot reach the same level of euphoria as before. To reach the level of pleasure previously enjoyed, users will abuse more and more of the drug, trying to reinstate their usual dopamine levels. When users are at this stage, they have clearly developed a tolerance to their drug of choice. Once a patient has developed tolerance to a prescription drug, health care professionals can usually increase the dosage to adapt to the current level of tolerance or use a different drug entirely.

Tolerance to alcohol is easy to develop. Alcohol users who drink a consistent amount over a period of time will no longer feel the same effects as they once did. To feel the same level of intoxication, they will need to drink a greater number of drinks. It is important to note that although tolerance may increase, blood alcohol levels will stay the same. For someone who has a high tolerance, five alcoholic drinks may have no effect on them physically, but their blood alcohol concentration may still be .10, which is above .08, the legal limit to drive in all states.

Behavioral

Behavioral tolerance occurs when users train themselves to adapt to a drug. An example of this is someone who regularly drinks alcohol but is able to function extremely well even though he or she is under the influence. Such individuals have become accustomed to the effects the alcohol has on their bodies so that it seems as though they are completely sober. They have conditioned themselves for a certain response based on the drug and dosage. Behavioral tolerance usually develops in experienced drug users. They can modify their behaviors more easily than can first-time users.

It has also been said that Pavlovian conditioning can be responsible for behavioral tolerance. When the presence of a stimulus can bring about a response, conditioning has taken place. For example, just the sight of a syringe (presence of a stimulus) may cause a brief sense of euphoria in a user, similar to the euphoria experienced after an injection of heroin.

Cross-Tolerance

Cross-tolerance occurs when a tolerance to one drug causes a tolerance to a related drug. Normally the related drugs are similar chemically. The most common cases of cross-tolerance involve alcohol, barbiturates, and benzodiazepines. Cross-tolerance occurs because drugs in the same family share a brain mechanism. Frequent users of barbiturates can develop a tolerance to other depressants, namely, alcohol and anesthetics. Conversely, heavy drinkers can develop a tolerance to other depressants, barbiturates, and anesthetics. This is because the drug of choice, in this case alcohol, stimulates the hepatic metabolic enzymes of the user, and other drugs such as barbiturates, depressants, and anesthetics will be inactivated more quickly. So an alcohol abuser who is used to, or tolerant of, the sleep effects of alcohol may be unphased when taking a barbiturate that usually has strong effects on the average person.

Reverse Tolerance

Reverse tolerance involves a user feeling the desired effects but from a lesser amount of a certain drug. People with late stages of alcoholism often exhibit reverse tolerance because hepatic enzymes are increasingly unable to metabolize alcohol. Therefore, less alcohol is actually needed before a user can feel the desired effects.

Tolerance to Alcohol

Cross-tolerance, behavioral tolerance, and reverse tolerance are all possible outcomes of alcohol abuse. Additionally, many of alcohol's pharmacological effects will be diminished with consistent or increased use of alcohol. This can lead to an increase in usage, which may also be tied to a psychological attachment or physical dependence on alcohol. Behavioral tolerance is most often observed with alcohol abusers. Moving cautiously, talking slowly,

and walking with greater concentration are all ways users may change their behavior to adjust to their alcohol intake.

Tolerance to Marijuana

A tolerance to the effects of marijuana has been documented in humans and animals. Tetrahydrocannabinol, or THC, is the active ingredient found in marijuana. Users must increase the dosage to gain the same effects as they could previously with smaller doses. THC may also be connected to a physical dependence in the user. This physical dependence, with symptoms such as weight loss, sweating, and irritability, is dependent on the user, and not all users will experience it.

Psychological dependence is much more prevalent and entails a craving for the drug that is brought on by a need and connection the user has to the pleasurable effects of THC. Although the psychological effects vary from user to user, they may include distortion of the senses and mood swings.

Tolerance to Opioids

It is possible for users of opioids to develop a tolerance in a short amount of time. Because opioids affect users differently, it is impossible to predict which aspects of the drug a user will become tolerant to. Opioid abusers who have become tolerant can ingest larger and larger amounts of a drug, at a rate and quantity that would be lethal to nonusers.

Conclusion

Tolerance is a complex issue that affects the use and abuse of drugs. Intentionally or unintentionally, tolerance can have a major impact on the health of drug users. Tolerance puts the user at risk for a dangerous and potentially harmful withdrawal of a drug, as well as physical discomfort and pain. No matter the type of tolerance that develops, users must be aware that even though they may be adapting to a certain drug, they are still putting themselves at risk.

TREATMENT, HISTORY OF

Written records pertaining to addictions to alcohol and other drugs have existed since at least the colonial period in America. Society's reactions to addiction have varied widely from benign neglect to religious or moral sermonizing to attempts at scientific and medical treatments. As addictions take a large toll on the social and economic aspects of the community, treatment of addictions in modern America has become a societal imperative as well as part of government programming and big business. It is useful to realize how the understanding and treatment of addictions have evolved over time and how this evolution has led the country to its current approaches.

Early America

Alcohol use was fairly common throughout colonial America with many people, including children, drinking a little every day without many reported ill effects. After the Revolutionary War, distillation and production of spirits went up and drinking increased, especially of stronger drinks like whiskey. The harmful and addictive effects of alcohol were being observed more often. In 1784, Benjamin Rush published a pamphlet called "Inquiry Into the Effects of Ardent Spirits

on the Human Mind and Body." This publication was the first to propose the idea that alcoholism was a medical disease and should be treated as such. Rush noted the characteristics of alcohol dependency that could qualify it as a disease. These included its progressive nature, chronicity, and adverse effects on the body. He called for the establishment of special hospitals for the afflicted, which he called Sober Houses.

During this time period, people also used opium, morphine, chloroform, ether, and cocaine without much ill effect and mostly for medicinal purposes. Marijuana was often planted as a cash crop and was used in making rope and other consumer products. By the 1820s, however, the Temperance Movement against the use of alcohol was gaining strength in the country. This movement did what was called "rescue work" in trying to save alcoholics from their affliction. They set up "inebriate houses" to help sober up heavy drinkers and instill in them some moral changes. The stays in these houses were voluntary and of short duration. Residents were then released back into the community and referred to local support groups to help them stay sober. Some of these temperance groups evolved into, and survived as, the Salvation Army.

Some local support groups included the Washington Movement, the Fraternal Temperance Society, the Ribbon Reform Club, and the Drunkards' Club. These groups collapsed later in the century as many of the inpatient asylums did. The first publicly funded hospital opened in New York in 1864 as an Inebriate Asylum. Patients sent there were often legally coerced and required to stay for years.

A Swedish doctor, Magnus Huss, first coined the term *alcoholism* in 1849. He used it to describe a group of drinking behaviors that he called a disease and called for medical treatment of those afflicted. These qualities included a hereditary predisposition, loss of control, craving, tolerance, and progression.

Early Government Actions

During the 1870s, for-profit asylums like the Keeley Institutes and the Gatlin Institute opened to aid those suffering from the disease of alcohol dependency. These organizations also sold patent medicines they called "cures" for addiction. An exposé in 1905 revealed that most of these potions contained cocaine, alcohol, or morphine and that the "cure" was indeed worse than the disease.

Between 1900 and 1920, most addiction treatment facilities closed. Factors that led to these closings include ethical abuses, a lack of proven effectiveness, disagreements in the field about proper treatment, economic downturns, and a reduction of supporting funds from the government and other institutions. Alcoholics seeking help were often left to the common psychiatric treatments of the day, such as electroconvulsive therapy and bromide injections.

The federal government began its ongoing attempts to control the distribution and use of drugs in 1906 with the Pure Food and Drug Act, which required the labeling of all goods that contained alcohol, cocaine, and opioids. This seemed to lead to a decrease in the number of addictions in the United States. In 1914, Congress passed the Harrison Narcotics Act, which mandated that only physicians and approved pharmacists with doctors' prescriptions could sell opioids and cocaine. Many doctors at the time were using opioids to help their patients detoxify from morphine addictions. This law was also interpreted to mean that doctors could not prescribe these drugs to active addicts. From 1919 to 1935, 2,500 doctors were jailed for violations of the Harrison Narcotics Act. Other "morphine maintenance clinics" closed during the 1920s under the threat of legal action by the federal government. From about 1924 to 1935, there was little formal treatment of alcoholics or other addicts.

The U.S. Government tried to manage alcohol abuse by passing the 18th Amendment to the Constitution in 1919, which prohibited the sale and manufacture of alcohol. This broad social experiment in "controlling" alcohol abuse ended in failure in 1933 when Congress passed the 21st Amendment, repealing the 18th.

Alcoholics Anonymous

In the spirit of prior rescue missions and support groups, organized intervention for alcoholics was rekindled in 1935 with the founding of Alcoholics Anonymous (AA). The founding members were Bill Wilson and Dr. Bob Smith, commonly called Bill W. and Dr. Bob. Bill W. was an alcoholic seeking desperately to remain sober. While on a business trip, he met another alcoholic, Dr. Bob, and started to talk to him about trying to stay abstinent. The two of them joined forces and looked for other alcoholics who were willing to help each other stay away from alcohol and support each other to rebuild their lives.

AA recognizes alcoholism as a disease with physical, psychological, and spiritual components. Mutual support, anonymity, the Twelve Steps, and a commitment to staying 100% alcohol free are the main foundations of the organization. AA meetings are run not by mental health or addictions professionals but by the recovering alcoholics themselves. As such, this intervention is often seen not as "treatment" but rather as a crucial adjunct to professional treatment. Most alcohol rehabilitation centers and outpatient agencies use the AA philosophy and meetings as part of the treatment.

AA meetings spread to all 50 states and are now held worldwide. Support groups for other addictive behaviors have developed following the AA model.

Late-20th-Century Trends

In 1949, the Hazelden Treatment Center was established in Minnesota to treat alcoholics. It used an interdisciplinary approach to treatment that included understanding alcoholism as a disease rather than seeing it as a moral failing. Hazelden was also known for its confrontational approach to getting people to change and for using AA meetings as support for treatment. This Minnesota Model, as it is called, became the predominant method for the inpatient treatment of alcoholism and other addictions throughout the 20th century. Hazelden is still a vibrant treatment center, which also publishes many books, pamphlets, articles, and posters on addictions and recovery.

E. M. Jellinek was instrumental in researching the disease of alcoholism and in getting the American Medical Association to recognize it as such in 1956. Jellinek studied alcoholics around the world, especially the male participants of AA. He described five increasingly harmful kinds of alcohol abuse that he named after the first five letters of the Greek alphabet: alpha, beta, gamma, delta, and epsilon. Jellinek described only the gamma and delta levels of heavier drinking and their consequences. He considered alcoholism to be a disease because it has characteristics similar to those of other biological diseases. These characteristics include loss of control, chronicity, and a worsening progression of symptoms that can lead to death. The epsilon level correlates with what is now called "binge drinking," and some include it within the disease category. The World Health Organization declared alcoholism a health problem in 1951.

In 1958 in California, Synanon was established as the first treatment community for addicts, a new concept in treatment history. These organizations were self-help communities composed of other addicts at various stages of recovery who would live together for 12 to 18 months. A full-time living arrangement was seen as the best way to get addicts to make all of the psychological and social changes necessary to remain clean. It looked to change the whole person by making all members of the community responsible for each other. These centers sustained a high dropout rate; however, those addicts who stayed the longest were shown to have the best success in staying clean and sober.

In 1966, Congress passed the Narcotics Addicts Rehabilitation Act, which provided treatment alternatives for those arrested on drug charges rather than just sending them to jail. In 1970, Congress passed the Hughes Act, which set up a system for the governmental funding of research and treatment for alcoholics. The official title of the act was the Comprehensive Alcoholism Prevention and Treatment Act, and it created the National Institute of Alcohol Abuse and Alcoholism. Later, the National Institute on Drug Abuse was also established to research and treat other drug addictions and abuses.

Many of the paths in the history of addictions treatment parallel the history of psychological treatments in general. For much of the early 20th century, Sigmund Freud's psychoanalytic tradition dominated the psychotherapy field. Later behavioral treatments developed from the work of people like Ivan Pavlov, John Watson, and B. F. Skinner. Then, counseling approaches developed by Aaron Beck and Albert Ellis treated the thoughts and belief systems of people as the causes of their psychological difficulties. These main psychological schools of thought came to be applied to addictions treatment as well.

Psychoanalytical Approaches

The psychoanalytic tradition of psychotherapy, as founded by Sigmund Freud and his followers, has been used to treat substance abuse. Substance abuse is seen as a symptom of other unconscious psychological conflicts that are either being coped with or defended against by chemical abuse. For example, the anxiety surrounding a repressed aggressive urge could be defused or denied by escape into a drug or alcoholic high.

This tradition may also include the idea of "self-medicating" painful feelings. People struggling with deep emotions about abandonment, rejection, or low self-worth may cope with these attacks on the ego by "medicating" the disturbing feelings with a chemical. Individuals coping with the pain of childhood abuse or other trauma also may self-medicate.

Cognitive and Behavioral Approaches

Albert Ellis, a former psychoanalyst, led the treatment of addictions in another direction with the development of Rational Emotive Therapy, later called Rational Emotive Behavior Therapy. The theory advances the idea that dysfunctional behaviors, including addictive ones, are caused by irrational or dysfunctional beliefs in the individual. For example, a person may believe "I can't cope without a drink" or "I can't talk to a possible date unless I'm high." These thoughts lead directly to the behavior. Treatment includes the identification and changing of these beliefs.

Some of Ellis's followers have been investigating and promoting the idea of natural recovery from addictions. This concept notes that many people recover from addictions on their own. Professionals following this model investigate the qualities or processes that enable a person to do this.

Behavioral treatments were developed during the 1970s and 1980s. Reward systems and token economies were used to help clients change their addictive behaviors. Some interesting experiments with rewards paid subjects not to drink. The more they were paid, the more abstinent they remained. These approaches are often called contingency management, in which the client agrees to a system of rewards and punishments to help shape his or her behavior toward the desired outcome. There were also successful experiments in getting addicts to stop using cocaine by paying them to stay sober.

The Community Reinforcement Approach brings a variety of factors to bear on the client to help shape behavior toward abstinence. Social, vocational, and recreational forces could all be used to reinforce abstinent and productive behaviors. Behavioral treatments also began to include training recovering addicts in the development of skills they may never have developed because of their addiction. Social skills were taught to those in need of them; refusal skills and assertive behaviors were taught to help addicts and alcoholics stay sober and get their needs met in

healthier ways. Because relapse is seen as a part of the recovery process, recovering clients were also taught healthier ways to cope with the urges and cravings to use. These healthier ways to cope might include relaxation training, stress reduction, imagery, and the development of alternative behaviors and good social supports.

Harm Reduction Approaches

In the 1980s a treatment philosophy called “harm reduction” emerged in Holland. The central idea was to try to reduce the harmful effects of the behaviors of addicts without necessarily trying to stop the addictive behaviors. Public policy was to lessen the self-inflicted damage of addicts while allowing the dysfunctional actions to continue on some level. This led to the first U.S. needle exchange program in Tacoma, Washington, in August 1988. David Purchase, a common citizen with an interest in the field, started giving away clean needles to the addicts in Tacoma. He was attempting to slow the spread of HIV by supplying sterilized needles to intravenous drug abusers. Although his actions were potentially in violation of the drug paraphernalia laws of the state, he had the support of local health and law enforcement agencies. The program grew and spread to other states but remained controversial among some law enforcement and governmental bodies. Designated driver programs are another example of harm reduction because they do not try to stop abusive drinking but rather to reduce or eliminate the dangers of driving under the influence.

Methadone maintenance, which was started in the United States in the 1970s, can be viewed as a harm reduction program. The idea is to substitute a less harmful and addictive drug, methadone, for the potentially deadly and life-destroying drugs that a heroin or morphine addict is injecting. Using the methadone under a controlled program allowed the motivated addict to avoid the feared pains of heroin withdrawal. It also allowed the addict to function more productively without the constant effects of heroin numbing the brain and without the need to commit crimes to earn money for the heroin. Methadone programs have been shown to reduce deaths due to heroin addiction.

Harm reduction programs and methadone maintenance programs are still controversial in the United States. Some segments of society, especially law enforcement, see this as coddling criminals and potentially even encouraging more drug or alcohol use

because the user does not feel all the consequences of his or her actions. This debate parallels the ongoing one in American society between those who see addiction as a treatable disease and those who see it as a criminal activity requiring a law enforcement response.

Motivational Approaches

Over time, many therapists found the approaches associated with the Minnesota Model too confrontational and, worse yet, ineffective. Recidivism and relapse rates for addicts and alcoholics going through rehabilitation were always high, even approaching 90%. In response to this, Stephen Rollnick and William Miller developed a style of addictions treatment they called motivational interviewing. The idea was to avoid confrontation with the addict about the behavior and find a more cooperative way to motivate the client to change. The approach has often been described as a more directed version of Rogerian or client-centered therapy. Again, addiction treatment parallels the paths of traditional psychotherapy by working from the original ideas of the psychologist Carl Rogers.

This therapy includes the ideas of forming an empathetic, therapeutic relationship, rolling with the resistance, accepting ambiguity, developing discrepancy between the client’s goals and behaviors, and helping the person develop self-efficacy or the belief in his or her own ability to effect change in life. The approach allows the client to talk about the positive changes in getting clean and sober rather than having the therapist lecture him or her about such benefits. The client is also encouraged to compare the benefits of using substances with the costs. Research so far on this approach has been fairly positive.

Pharmacological Approaches

Various medications have been tried to help addicts control or manage their addictions. Naltrexone hydrochloride was approved by the Food and Drug Administration in 1995 to help alcoholics by blocking some of the craving and pleasurable effects of the alcohol. It also seems to help block the euphoric effects of various opioids. Acamprosate is used to reduce the craving for alcohol by blocking neurotransmitters in the brain. Antabuse, commonly used to treat alcoholics, acts by interfering with the body’s ability

to metabolize alcohol. When a person on Antabuse drinks alcohol, he or she gets extremely ill. The effectiveness of this drug relies on the cooperation and willingness of the client to take it when home.

Buprenorphine hydrochloride was approved in 2002 to help treat narcotics addiction by blocking the pleasurable effects in the brain. Levo-alpha acetyl methadol, or LAAM, is a drug similar to methadone and is being used in some clinics to block the symptoms of withdrawal from heroin or other narcotics. Its effects in the body last about twice as long as those of methadone.

Treatment Settings

After the development of the Minnesota Model, most drug or alcohol treatment took place in inpatient rehabilitation centers. This inpatient model included similar components in various centers around the country: detoxification, education in the disease concept and the effects of the drugs used, goal setting, group meetings, family therapy, introduction to the AA and NA (Narcotics Anonymous) support groups, and some individual therapy. The inpatient model also provided the unique and effective experience of being totally away from the triggers to using, such as friends, neighborhood, and other stresses. Before a client was released back home, he or she would be given an aftercare plan that asked him or her to follow up on the goals of treatment through other agencies, fellowship groups, and therapists.

During the 1960s, aftercare facilities developed to help people remain sober when released back into the community. These included halfway houses, which were homes established in the community and occupied by recovering clients and some professional personnel. They were temporary homes somewhat safe from the temptations of the drug lifestyle that were a step “halfway” between rehab and going home totally. These houses helped people in recovery follow up on the goals set while undergoing inpatient treatment and helped stabilize them by giving them a safe environment in which to reacquire some of the skills needed to live a drug-free life. These skills included things like finding a job, learning to cook, establishing healthier relationships with family members, or managing money.

Inpatient facilities often had a high rate of relapse and recidivism. As health insurance companies became more involved in paying for these stays in rehab, they also became more disgruntled with the high costs and high rates of people returning to this treatment over and

over again. Partly as a response to pressure over costs, treatment facilities developed programs that came to be called intensive outpatient programs or sometimes “after work” or “after school” programs.

These programs allowed the teenager or adult to remain at home, in school, or at work during the day while attending treatment after work and school hours for 3- or 4-hour blocks of time. These programs meet 4 nights a week but usually not during the weekends. The treatment aspects of the programs are the same or similar to those of the inpatient programs, just more compressed. The programs counted on the person’s attendance at school or work as a way for him or her to stay clean during the day while being in treatment at night. Many studies showed this format to be as effective as a complete inpatient stay for substantially lower costs.

Another step in the history of addictions treatment in America was the development of drug courts. The system attempts to integrate treatment into the legal system by offering nonviolent offenders with drug problems the choice of prison time or treatment. The drug court program provides incentives for cooperation with, and completion of, treatment as well as legal sanctions if this is not done. The requirements are fairly strict, and there is a strong enforcement to ensure compliance with the judge’s orders for treatment.

Conclusion

The history of drug and alcohol abuse in America has undergone many changes over the years, and yet some ideas have recycled in and out of the popular mind and the professional paradigms. Support groups have existed for much of the time, as well as the concept of addiction as a disease. The amount and availability of drugs and alcohol has increased in U.S. society, bringing the development of new, effective treatments. Millions of dollars of government and private funds have gone into the research and treatment of these diseases. There finally seems to be a real attempt at bridging the gap between scientific research and those called to treat drug and alcohol dependency. No one talks of a cure for this disease, but most believe it can be manageable, much like other chronic diseases.

TREATMENT, NONTRADITIONAL APPROACHES

Nontraditional treatments refer to the treatment methods used by individuals to treat substance abuse that fall outside of the traditional range of treatments. Typically, there are very few published studies in peer-reviewed journals on the effectiveness of these methods, which vary in popularity, rate of use, and efficacy. Additionally, the formal study of the efficacy of these methods is diffuse. However, because nontraditional approaches are used by a substantial number of individuals, formal evaluation is strongly needed. It is important to note that nontraditional therapies often do not have concrete clinical practice guidelines. Thus, it is not possible to determine if nontraditional approaches are applied consistently across different treatment providers and settings. More extensive formal evaluation will not only determine the efficacy of these methods but also establish specific practice guidelines for these treatments. Examples of nontraditional treatments include hypnosis, exercise, acupuncture, aversion therapy, self-monitoring, sensory deprivation, antidepressant medication, calcium carbimide, and developmental counseling.

Hypnosis

The studies examining the efficacy of hypnosis in substance abuse treatment are at least 30 years old. More recently published research has not been conducted, even though this technique is still widely used. There are various ways researchers have used

hypnosis to treat substance abuse. Some individuals have used hypnosis to encourage participation in treatment, and some have used it to induce an aversive reaction to a particular substance.

Hypnosis has primarily been used in the treatment of alcohol and nicotine addiction and is usually one component of the treatment, embedded within a larger program. The research on hypnosis as a treatment for alcohol abuse has had mixed outcomes. In 1973, researchers used hypnosis for five 15- to 30-minute sessions aimed at inducing indifference to alcohol, increasing relaxation, increasing a sense of well-being caused by sobriety, and encouraging the patients to find help following their first drink. They found no significant difference in the outcomes between the control group and the group that received hypnosis. Other researchers compiled a comprehensive review of both case studies and experimental research prior to 1980. They reported that the majority of experimental studies found no significant difference between the experimental and control groups.

The research on hypnosis as a treatment for smoking is also mixed. There is a wide variation in the reported effectiveness of the treatment procedures, ranging from 94% success to 0% success. Additionally, the number of studies that have found hypnosis to have significant effects on smoking behavior is much lower than the number of studies that report hypnosis has no effect on smoking behavior.

Exercise

Exercise is another nontraditional approach that has been used to treat substance abuse, specifically for alcohol and nicotine addiction. The exercise treatments described in the studies available vary in intensity and expectations. There is not a substantial amount of research on exercise treatments for alcohol dependence. Although most of the studies report some positive effects, overall results indicate that exercise does not have a significant impact on drinking behavior. In fact, only one study reported positive results; researchers found that in comparison to a control group, participants who engaged in a running regimen significantly reduced their alcohol consumption.

Exercise as a treatment for nicotine addiction is more promising. Three early evaluations of exercise therapy indicated that it was either ineffective or possibly counterproductive to smoking-cessation efforts in terms of increased anxiety and sleep disturbances,

but more recently researchers reported that aerobic exercise, when combined with behavioral counseling, was more effective than both standard education alone and behavioral counseling combined with nicotine gum therapy on measures of posttreatment abstinence. It is important to note that this advantage was not maintained at either 6- or 12-month follow-up assessments.

Acupuncture

Acupuncture is a technique that involves the stimulation of particular external body regions, usually through needle insertion. The philosophy underlying acupuncture is that the body consists of energy, called chi. Chi flows through the body in channels, called meridians. Disease, according to Chinese medicine, is a result of an imbalance of chi in the meridians. Acupuncture is used to stimulate regions of the body in order to correct the flow of chi. As a substance abuse treatment method, it has been used primarily for relapse prevention with alcohol addiction, smoking cessation for nicotine addiction, and detoxification for opioid addiction. Typically, acupuncturists use auricular (ear) acupuncture to treat addiction.

Despite its use, acupuncture as a substance abuse treatment approach is controversial. In a technical review on acupuncture sponsored by the National Institute on Drug Abuse, the authors concluded that there was no evidence that acupuncture is an effective treatment for substance abuse. Mirroring this conclusion, individual studies have produced insignificant results. Out of eight studies on acupuncture in the treatment of nicotine addiction, two studies reported initial reductions in smoking (but the significance did not continue at additional follow-up periods), and the remaining studies found little, if any, effect. Studies addressing the effect of acupuncture on alcohol and opioid dependency also found little, if any, effect. Despite these results, acupuncture is widely used as a treatment for substance abuse in the United States and Europe. Research has shown that auricular acupuncture is one of the most widely used treatments for cocaine addiction, and more than 300 substance abuse clinics throughout the United States and Europe offer acupuncture treatment. In addition, auricular acupuncture is also a treatment component in many drug court programs.

Aversion Therapy, Apneic

The goal of aversion therapy, in general, is to condition an individual to experience aversive reactions to substances when exposed to cues associated with drinking. With the apneic aversion therapy, the aversive reaction is produced by pairing the substance being abused with induced breathing paralysis. Thus, the high that the patient feels is coupled with a strong negative, unpleasant experience. One common way breathing is disturbed is through administration of the drug Scoline. The efficacy of apneic aversion therapy is poor. Researchers have determined that other types of aversion therapy, such as nausea aversion therapy, are more effective as substance abuse treatments.

Self-Monitoring

Self-monitoring is a cognitive-behavioral technique that involves reflecting on, and providing self-reports about, a specific behavior, regardless of the mode of reporting. The resulting record may only be to remind individuals of their internal states at a particular time when they engaged in the behavior. As a treatment, it is usually coupled with other cognitive-behavioral techniques and is favored because it is inexpensive and convenient and requires little equipment. Most research utilizing frequent self-monitoring for substance abuse indicates that participant compliance is very good across a variety of monitoring methodologies when incentives are offered. When incentives are not offered, however, researchers have found poor self-reporting compliance.

Typically, self-monitoring is incorporated into treatment programs that address nicotine and alcohol abuse. Research has found that self-monitoring, when combined with other approaches, effectively reduces substance abuse behavior. For example, in an early study examining the efficacy of self-monitoring on smoking behavior, researchers assigned participants to three groups—a nicotine fading group (where individuals gradually reduced the amount of nicotine in their cigarettes), a self-monitoring group, and a combined self-monitoring/nicotine fading group. The researchers found that, at a 6-month follow-up, the self-monitoring/nicotine fading group had reduced their nicotine level and cigarette intake more than the other two groups.

There are a few criticisms associated with self-monitoring. Specifically, critics say that the process itself may affect the behaviors being monitored (measurement reactivity). In addition, many researchers report poor self-monitoring adherence rates.

Sensory Deprivation

Sensory deprivation is the deliberate withholding of stimuli from affecting one or more of the senses. The conceptual basis of this approach relies on the effectiveness of stimulus-reducing environments in facilitating self-motivated attitude and behavior change, openness to new information, and reduced defensiveness, among other factors.

In terms of substance abuse, this technique has been used to produce attitudinal and behavioral change through persuasion. It is important to note that most of the research on sensory deprivation and substance abuse is very old. Early sensory deprivation researchers determined that deprived participants showed more attitude change than controls in response to persuasive messages. Most of the research conducted on sensory deprivation as a substance abuse treatment technique has been limited to smoking behavior. Overall, results of these studies indicate that sensory deprivation is successful in changing attitudes and, thus, in reducing smoking behavior. Reliable data on the prevalence of this technique as a substance abuse treatment are not available.

Antidepressant Medication

Antidepressant medication has been prescribed as a treatment for substance abuse. Depression and substance dependencies have been found to frequently co-occur. It has been suggested that individuals with psychiatric problems, including depression, become dependent on substances as a way to self-medicate. Thus, drugs that effectively treat the underlying problem may reduce an individual's need for certain substances. Despite the need, research has found that clinicians treating individuals with substance dependencies are reluctant to prescribe antidepressants because they do not want to confuse substance-induced depressive symptoms with actual depressive disorders. Results of a 2004 study published in the *Journal of the American Medical*

Association indicated that antidepressant medication had a moderate beneficial effect on patients with co-occurring substance abuse and depressive disorders. The researchers specify, however, that antidepressant medication cannot be the only treatment administered and that the individual needs concurrent therapy directly treating the addiction.

Calcium Carbimide

Calcium carbimide is a citrate salt used to treat alcoholism. It is sold under the name Temposil and is similar to disulfiram (Antabuse) in its effects. Specifically, calcium carbimide inhibits the metabolism of alcohol, and when ingested, it causes the alcohol user to experience sweating, difficulty breathing, rapid heartbeat, rash, headache, nausea, and vomiting. Research results indicate that calcium carbimide may be effective in treating alcoholism, but only when paired with additional therapy. Alcoholics often discontinue use in order to continue drinking.

Developmental Counseling

Developmental counseling is a therapy style that is based most prominently on Jean Piaget's stage theory. The theory concerns the emergence of schemata, which determine the ways in which people perceive the world. Piaget divided his theory into cognitive stages (e.g., the sensorimotor period, the preoperational period, the concrete operational period, and the formal operational period), which correspond to the acquisition of different abilities. The goal of developmental counseling therapy is to assess the level of cognitive developmental functioning and select interventions based on this functioning. The therapy encompasses developmental orientations similar to Piaget's—sensorimotor, concrete, formal operations, and dialectic/systemic. Researchers have not formally studied the efficacy of this therapy as a substance abuse treatment method, despite its use in treatment settings.

Conclusion

As mentioned previously, these substance abuse treatment methodologies—hypnosis, exercise, acupuncture, aversion therapy, self-monitoring, sensory deprivation, antidepressant medication, calcium carbimide, and

developmental counseling—are considered to be non-traditional. This is due to the fact that there are very few published studies concerning their efficacy. As a result, substance abuse treatment providers should focus on evidence-based approaches and strategies.

TREATMENT ACCESS AND RETENTION

Although it has been shown that individuals with substance use disorders can often benefit from treatment, only an estimated 1 in 10 persons needing addiction treatment actually receives it. Further, fewer than half of those who enter treatment stay long enough in a treatment program to benefit from it. Some people with problems from substance use do not seek treatment because they feel they are able to resolve their problems within their communities or recover on their own, but a larger proportion of individuals do not seek treatment because of barriers to treatment access. Individuals in treatment also experience additional barriers that prevent them from staying in treatment.

Issues of treatment access and retention are currently very important. As the public substance use treatment system shifts from self-help models to more formal systems of care, it faces many challenges including inadequate funding, recruitment of appropriately trained staff, and a patient population with complex needs. In addition, a lack of integration exists between substance use, mental health, and primary medical care services. This lack of resources and integration of care is especially problematic as substance use clients tend to present with complicated comorbid medical and psychiatric conditions that, if treated, are treated independently and inefficiently. Collectively, these organizational challenges directly impact treatment access and retention.

Research has shown that individuals who complete treatment tend to have improved substance use and lifestyle outcomes. Therefore, understanding the barriers to treatment access and problems of retention in treatment programs—whether they be a result of societal factors or other systemic, organizational, or individual factors—can help facilitate treatment utilization among those in need. This entry reviews key issues related to substance use treatment access and retention and summarizes some current efforts to improve access and retention in substance use treatment.

Issues of Access

Access to treatment can be understood at the socio-cultural, systemic, organizational, and individual levels. First, sociocultural factors may contribute to treatment

access. The current social and political climate regarding substance use treatment can influence community perceptions and decision making about funding and supporting treatment. Social stigma and decreased public funding for treatment can dissuade individuals from seeking treatment. Treatment access can also be conceptualized at the system level, where various community health care agencies interact to provide treatment. These agencies may include methadone maintenance clinics and recovery homes but also health clinics, prisons, workplaces, and welfare programs, which serve as entry points for treatment. Individuals may have greater access to treatment if these systems collaborate effectively. For example, in some states, individuals arrested for drug-related offenses may be diverted to substance use treatment instead of incarceration. Through this approach, treatment access is provided to clients who might not otherwise seek treatment due to lack of finances or low treatment motivation.

A recent view of treatment access that focuses on the organizational level of analysis suggests that issues of treatment access can be attributed to the health care system. These issues include policies on the amount of funding that goes toward substance use treatment services. Lack of public funding for treatment can alter the services available, result in less space for additional clients and staff, and inflate treatment costs for clients. There have also been cutbacks to treatment availability in the private sector. The rise in managed care has also led to reductions in access to inpatient care with an increasing reliance on outpatient treatment. Characteristics of treatment programs that may affect treatment entry include long waiting

lists for appointments, complex eligibility and admission requirements, lack of cooperation between service organizations, residential treatment facility rule compliance (e.g., restrictions on what residents can bring with them to treatment, lack of contact with family), and absence of appropriate treatment for certain groups (e.g., lack of cultural appropriateness to diverse groups, treatment in other languages, or child-care services for parents with children). System redesign may help to remove barriers for individuals who want to access the care they need.

Individual characteristics play an important role in determining access to substance use treatment as well. According to 2004–2006 data from the Substance Abuse and Mental Health Services Administration, about two thirds of individuals who needed treatment for illegal drug use did not access treatment because they could not afford it or were not ready to stop using substances (Figure 1). Research has shown that cost is a significant barrier to accessing treatment. In cases where coupons for free treatment have been offered to individuals on the street, large increases in the number of individuals entering treatment have occurred; many of these were entering treatment for the first time. Other common barriers to treatment access for those who need it include not knowing where to go for treatment, concern about social stigma or negative opinion by neighbors and their community, and the potential negative impact on personal employment. Individuals may also not access treatment because they feel they can handle their substance use without attending a treatment program. For some individuals, multiple factors may contribute to their reasons for not receiving treatment.

Figure 1 Six Most Often Reported Reasons for Not Receiving Treatment for Illegal Drug Use

Source: Office of Applied Studies, Substance Abuse and Mental Health Association (2004–2006 combined data).

Additional individual obstacles to treatment access include pragmatic limitations (e.g., money, transportation, schedule), emotional factors (e.g., fears, beliefs about substance use treatment, negative past experiences in treatment), instability (e.g., homelessness), physical and mental health (e.g., HIV-positive status, co-occurring mental health disorder), and environmental factors (e.g., negative social support, employment). Other predisposing personal characteristics such as race/ethnicity and gender are not barriers; however, they have been linked with factors (e.g., stigma, perceived discrimination, lack of awareness of alternatives, lack of financial resources, language difficulties) that influence whether one seeks and stays in treatment. For instance, African Americans and Hispanics are less likely to receive treatment than Whites and are more likely to receive care primarily in public settings because of income disparities. Women, along with African Americans and Hispanics, enter treatment later in their disease progression and drop out sooner. Individual-level barriers, whether emotional, medical, cultural, or practical, have an important impact on whether clients seek services.

The interplay between organizational and individual factors significantly impacts treatment access. The ability of an individual to access substance use treatment when ready and willing is an essential component of effective medical care and may make the difference between relapse and recovery. Not receiving treatment right away may negatively affect an individual's perception of the effectiveness of treatment and may serve to worsen his or her substance use problems. The ability to access treatment when ready may directly change the course of an individual's struggle with substance use and prevent health and social consequences from becoming pronounced.

Issues of Retention

Treatment retention is the propensity of an individual to stay in treatment long enough to experience improvement. It is required for an individual to receive the benefits of treatment rehabilitation. Barriers that influence access to treatment (e.g., cost, stigma, capacity) continue to play a role while an individual is in treatment. Similar to treatment access, treatment retention can be conceptualized in different ways. Systemic-, organizational-, and individual-level characteristics can again affect the ability of individuals to

stay in treatment and are helpful to recognize in order to improve the standard of substance use treatment.

Characteristics of the health care system can impede treatment retention. With a system of care that is largely fragmented and far from comprehensive in its offerings, substance use clients lack a wide range of treatment options to serve their multidimensional problems. A range of treatment types and formats would be helpful in order to match client needs and severity of substance use disorder with intensity and style of treatment. In this way, treatment may be more likely to provide services that will effectively meet client needs, increasing an individual's level of satisfaction and the likelihood that he or she will remain in treatment. Strong client-counselor relationships also have been linked with treatment completion. For instance, providers who demonstrate strong interpersonal skills (e.g., clarify misunderstandings, help clients speak up in treatment) and openness to discussing treatment progress and barriers in a nonjudgmental and nonconfrontational manner with the client may enhance the therapeutic relationship. Using evidence-based practices may also provide more effective tools for helping clients decrease client substance use and related problems. Increased cultural sensitivity to groups such as homeless individuals; adolescents; older adults; ethnic minorities; gay, lesbian, bisexual, and transgendered individuals; pregnant women; and women, in general, may also enhance the services being provided to the client. Efforts to improve the therapeutic relationship, provide effective treatments, and enhance cultural sensitivity may directly or indirectly impact a client's retention in treatment.

Many individual-level factors create barriers to treatment retention. Staying in treatment is often affected by a client's readiness and motivation to change. This readiness requires taking action steps toward recovery and resolving the barriers that may have prevented access to treatment (e.g., fear of treatment or privacy concerns). How individuals view their own addiction and the severity of their disorder may also determine their willingness and ability to stay in treatment. The presence of co-occurring disorders (e.g., substance use disorder with depression or other mental health disorder) has been associated with higher rates of suicide, greater impairment, poorer substance use disorder and mental health treatment outcomes, and death. Depressed mood frequently leads to substance use relapse. In people with depression, even low levels of alcohol use are associated with more depression and decreased antidepressant response. Assessing and integrating client

preferences into treatment plans helps clients identify the best treatment for them and increases the likelihood they will stay in treatment. For example, a client may prefer treatment that involves family members or a spiritual component. Other individual factors such as recovery environment (i.e., the stability of an individual's current living situation and other social supports), Twelve-Step meeting attendance, and high spirituality have also been shown to enhance treatment retention.

Research suggests that staying in treatment correlates directly with improvements in outcomes such as being able to manage alcohol or drug use in the long term. Retention can also be used as a manageable and measurable short-term goal for clients while they work toward meeting longer-term goals. Treatment retention rates differ with situational factors such as treatment type (e.g., whether the individual is in inpatient vs. outpatient treatment), primary drug of choice, current episode, and criminal justice system involvement. As with issues of access, health care system characteristics as well as individual determinants can both help promote and impede treatment retention.

Improvement Efforts in Access and Retention

Health care organizations, government agencies, and foundations have undertaken many efforts to improve access and retention in substance use treatment. Health care organizations have changed procedures and processes as a way to help address individual, organizational, and systemic level barriers. For example, health care organizations have started to offer treatment in alternative formats such as computer-assisted or Web-based arrangements so individuals who cannot regularly access services on-site can access treatment at home or another location at low or no cost. Availability of treatment is therefore greatly increased. Another alternative format for treatment that may help increase access and retention are home-based visits whereby the treatment provider visits the client in his or her own home. This can address individual-level barriers to treatment such as lack of transportation, time, and childcare, as well as scheduling problems. To help with issues of retention, health care organizations have used behavioral enhancement practices (such as incentives) to help clients stay in treatment.

According to the American Psychological Association's practice guidelines, a client-centered behavioral technique known as motivational interviewing can work to improve retention by exploring and resolving ambivalence with

the client and increasing motivation to stay in treatment. Similarly, contingency management, which rewards or reinforces positive behavior modifications (e.g., through visits with family, monetary vouchers, and other privileges), has also been suggested as a way to increase treatment retention. Another practice to improve treatment retention has been to survey clients at intake about probable barriers to remaining in treatment. Taking the time to understand barriers from the start may help adequately identify individual and system barriers that can be addressed and resolved in treatment. To the extent that substance use treatment programs can be integrated with mental health care, couples or family counseling, day care, vocational training, medical and dental care, legal services, and HIV testing and counseling, the more likely it is that a complicated population can have a diversity of needs met.

Government policy changes have helped improve treatment access and retention as well. A recent example to improve treatment access was the implementation of the Drug Addiction Treatment Act of 2000. This policy allows qualified primary care physicians (i.e., those who complete specified training requirements) to administer certain narcotic medications for the treatment of opioid addiction in their offices rather than having clients travel to separate opioid agonist treatment centers. This policy change helped move treatment out of stigmatized treatment facilities into primary care offices, thereby offering substance use treatment in a more mainstream medical context. This change could potentially reduce issues of stigma, lack of financial resources, and treatment availability. Although issues such as lack of access to physician services and limited number of providers who can prescribe this treatment offer continued barriers to treatment for many individuals, the movement toward a more integrated system of care and "one-stop shopping" is a way to greatly enhance an individual's ability to access care that is needed.

Finally, a national, federally funded large-scale effort to improve treatment access and retention via foundation-level change has been undertaken by the Network for the Improvement of Addiction Treatment (NIATx). NIATx, a partnership between the Robert Wood Johnson Foundation, the Center for Substance Abuse Treatment, and numerous independent treatment organizations across the United States, focuses on making small, incremental procedural improvements in the structure of treatment delivery. That is, NIATx aims to improve everyday processes of care in order to better

serve clients. Using a “plan-do-study-act” cycle approach, each process in treatment is examined to identify problems and solutions (plan), implement new processes (do), measure outcomes (study), and institutionalize and make additional changes (act). For example, NIATx aimed to make process improvement part of the culture of treatment delivery. One of the biggest outcomes of the project has been quicker access to treatment in residential, intensive outpatient, and outpatient care. Process changes that were made that contributed to this reduction in waiting lists were on-demand scheduling and next-day admissions, simplification of intake and assessment procedures, more phone responsiveness, cross-training of staff, and reduced paperwork. Efforts that were made to increase retention included expanded hours of operation, reminder calls, staff training to utilize motivational interviewing, and introductions to counselors prior to first treatment session. Improved treatment access and retention may result from examining, changing, and institutionalizing everyday organizational processes that act as barriers to treatment.

Conclusion

Treatment access and retention are a function of many interacting organizational and individual variables. Several improvements are currently under way to enhance treatment access and retention. Dissemination of these improvements nationally is needed for systemic change. As rates of substance use disorders continue to be prevalent and formal treatment is needed, improvement efforts will need to address systemic, organizational, and individual barriers in order to meet the demand of this population in need.

TREATMENT APPROACHES AND STRATEGIES

Alcohol and other drug treatment approaches and strategies are dependent upon the model of addiction adopted by the particular treatment program. However, there is a growing trend toward more eclectic approaches to treatment that combine aspects of different treatment models. Although this is certainly good practice, it has also been driven by financial concerns, particularly in for-profit treatment programs. For example, some insurance companies pay for substance abuse treatment only if there is another mental disorder as well. This consideration has resulted in treatment programs developing “co-occurring disorders” programs and using components from a variety of treatment approaches.

Although it would be expected that all treatment programs utilize evidence-based practices (i.e., approaches and strategies validated by research), this is not always the case. Therefore, the treatment approaches and strategies described in this entry are not necessarily “evidence based” but are those most often used in both public-sector and private substance abuse treatment programs.

Treatment Approaches

Minnesota Model

Perhaps the best-known and most widely emulated approach to treatment is the Minnesota Model, developed by the Hazelden Foundation in the 1940s and 1950s. The philosophy of the Minnesota Model can be described by four components. The first is the belief that clients can change attitudes, beliefs, and behaviors. Famous people who have completed the program, such as Betty Ford, Elizabeth Taylor, and Anthony Hopkins, are used as models to illustrate this belief. Second, the Minnesota Model adheres to the disease concept of addiction. The term *chemical dependency* is preferred to *addiction* or *alcoholism* and is seen as a physical, psychological, social, and spiritual illness. The major characteristics of the disease concept are taught. That is, chemical dependency is seen as a primary disease that is chronic, progressive, and potentially fatal. The focus of treatment is the disease and not secondary characteristics.

The third philosophical component is illustrated by the long-term treatment goals of the Minnesota Model: abstinence from all mood-altering chemicals and improvement of lifestyle. Clients are not considered cured, because the disease is incurable. However, through abstinence and personal growth, a chemically dependent individual can be in the process of recovery. Finally, the Minnesota Model uses the principles of Alcoholics Anonymous (AA) and Narcotics Anonymous (NA) in treatment, implying a heavy spiritual component to treatment.

The continuum of care includes assessment and diagnosis, detoxification, inpatient care, therapeutic communities, halfway houses, outpatient care, and aftercare. Group therapy is used and is concerned with present and future behavior as opposed to past causal factors. Groups are often confrontational. The family also receives therapy. Didactic experiences, including lectures and videotapes, are used to educate clients about the disease of chemical dependency and the consequences of the disease. The staff is composed of professionals from a number of disciplines (physicians, social workers, psychologists, nurses, and clergy), and recovering addicts and alcoholics are also used as counselors. Clients have reading and writing assignments, such as reading the AA Twelve Steps and Twelve Traditions and writing their life histories. Attendance at AA or NA meetings is required, and clients are expected to work through the first three to

five steps of AA while in treatment. There also may be work assignments and recreational activities, depending on the treatment setting. Aftercare includes attendance at AA or NA.

Behavioral Approaches

In contrast to the disease model of treatment exemplified by the Minnesota Model, behavioral models of treatment use techniques of classical and operant conditioning in the treatment of alcohol and other drug problems. Perhaps the best-known behavioral technique applied to alcohol problems is aversive conditioning, which is designed to reduce or eliminate the client's desire for alcohol or drugs by pairing unpleasant stimuli or images with substances. The unpleasant stimuli most widely used are nausea, apnea (paralysis of breathing), electric shock, and various images. Nausea is the oldest and most commonly used of these stimuli, with fairly wide use in the former Soviet Union and in some hospitals in the United States. The process is to give the client a drug that, when combined with alcohol, produces severe nausea. In a supervised setting, the client is then allowed to drink. In the classical conditioning paradigm, the feeling of severe nausea should quickly become associated with drinking alcohol. Electric shock can also be administered when the client drinks, or a drug can be administered that produces apnea when alcohol is consumed. Because these procedures are painful, stressful, and potentially dangerous, careful screening of clients and medical supervision are necessary. Although electric shock can be used in the treatment of addiction to drugs other than alcohol, most references to aversive conditioning are related to the treatment of alcoholism.

Covert sensitization has major advantages over other forms of aversive conditioning techniques. This process involves pairing the consumption of the drug of choice with aversive images, such as nausea or negative consequences of alcohol or other drug use. The advantages are obvious. Because clients do not experience physical nausea, electric shock, or apnea, there are no medical dangers. Therefore, clients would also be less likely to discontinue treatment.

Additional behavioral techniques have been used in treatment. Contingency contracting has been used, wherein clients make monetary deposits that are forfeited if they do not complete the treatment program. Behavioral Self-Control Training involves setting goals, self-monitoring, managing consumption,

rewarding goal attainment, analyzing drinking situations, and learning coping skills. These techniques have been used to achieve abstinence or controlled use.

Another form of a behavioral approach to treatment is the Community Reinforcement Approach (CRA). Although there are a variety of “twists” to this approach, the basic idea is to provide tangible rewards for achieving successful treatment goals. For example, CRA was applied in a 24-week outpatient program for cocaine addicts. For each “clean” urine sample, clients were given vouchers for retail goods that increased in value with consecutive cocaine-free samples.

Pharmacological Approaches

Pharmacological procedures are also used in treatment. However, it is rare to find these procedures as the only intervention. Rather, they are usually used in conjunction with other treatment methods. The philosophy of treatment and the treatment setting may also determine whether drugs are used to treat alcohol and other drug problems. Treatment programs in non-hospital settings without medical staff obviously should not use drugs in treatment.

Detoxification, the period of time in which a client is withdrawing from alcohol or other drugs, is frequently a time when medication is used. In the past, this process occurred in an inpatient, hospital setting. However, because of the high costs of hospitalization, outpatient detoxification is now a common practice. In the detoxification process for alcohol and other central nervous system depressants, minor tranquilizers such as Valium or Xanax are often used to reduce the danger of seizures and other uncomfortable and dangerous withdrawal symptoms. Careful medical supervision with a gradually decreasing dosage is necessary, as these minor tranquilizers are in the same drug classification as alcohol.

Methadone is widely known for its use in treating opioid addiction. Methadone is a synthetic narcotic with a longer duration of effect than heroin, and ingestion blocks the euphoric effects of opioids. Once a client is stabilized on a particular dose, he or she takes it to reduce or eliminate any withdrawal symptoms from heroin abstinence. The client usually must visit a methadone clinic to receive the dose. Once a client is stabilized on methadone, he or she can function normally.

In 2002, buprenorphine was approved for use in treating opioid addiction. Buprenorphine is an opioid

that has proved to be as effective in treating opioid addiction as methadone. The advantages of buprenorphine are that it is taken in tablet form, daily doses do not appear to be necessary, and it has relatively mild withdrawal symptoms. In the pill form administered to opioid addicts, naloxone is added to buprenorphine (the combination of which is available under the trade name Suboxone). The naloxone decreases the likelihood of abuse, because it blocks the “high” that could be achieved by injecting buprenorphine alone. In addition, buprenorphine can be administered by general physicians in outpatient clinics rather than in specialty clinics, as is the case with methadone. The approval of buprenorphine by the Food and Drug Administration has greatly increased the access to opioid agonist treatment for heroin addicts.

Antabuse (disulfiram) has been used in conjunction with other forms of alcohol treatment. When Antabuse is taken and alcohol is ingested during the following 24- to 48-hour period, the client experiences facial flushing, heart palpitations and rapid heart rate, difficulty in breathing, nausea, and vomiting. Because Antabuse takes 30 minutes to work after ingestion, it has been of limited value in aversive conditioning. The client must take Antabuse on a daily basis, and this raises the issue of the need for such medication. If an individual were motivated to take Antabuse daily, it would seem that he or she would probably be motivated to remain abstinent without Antabuse. However, some alcoholics, when tempted to use alcohol, are comforted by the fact that Antabuse will result in an unpleasant reaction if they drink. This awareness often reduces or eliminates the urge to use. Clients who use Antabuse must be warned against using over-the-counter products that contain alcohol, because the Antabuse will cause a reaction from the use of these products.

In the past several years, there has been considerable publicity on the use of naltrexone in alcoholism treatment. Naltrexone is an opioid antagonist (i.e., a drug that blocks the effects of other drugs). However, it has also been found to reduce the craving for alcohol. Therefore, it is recommended as one strategy in a comprehensive treatment program but not as the only strategy.

Other Approaches

A comprehensive treatment approach for stimulant abuse was developed by researchers at the University of California, Los Angeles. The Matrix Model includes elements of group and family therapies, education,

support groups, and relapse prevention. There is an emphasis on the relationship between the counselor and the client, with the counselor utilizing the relationship to reinforce positive behavior change. The approach is not confrontational and seeks to promote self-esteem, dignity, and self-worth. Detailed manuals have been developed to guide this approach.

The National Institute on Alcohol Abuse and Alcoholism has developed treatment manuals for three very different approaches to alcohol treatment. The manuals were used in a large-scale study to investigate the effects of matching clients to treatment approaches. The first approach is called Twelve-Step Facilitation Therapy and is based on the principles of AA. The treatment protocol familiarizes clients with the AA philosophy and encourages participation in AA. This approach is similar to the Minnesota Model. The second manual is called Cognitive Behavioral Therapy and is based on a social-learning-theory model. Skills to avoid relapse are taught. The third approach is Motivational Enhancement Therapy and is designed to help clients identify and utilize personal resources to effect change. This approach is based on motivational psychology and is related to motivational interviewing.

Treatment Strategies

The strategies that are used in treatment vary depending upon the approach of the treatment program and the treatment setting (e.g., outpatient or residential). Not all of these strategies are (or should be) applied to every client. A treatment plan must be developed that is individualized according to the needs of the client. The following are the most widely used strategies.

Individual, Group, and Family Counseling

The frequency, intensity, and approach to individual counseling varies widely among treatment programs. This is dependent on the staffing model of the treatment program and the credentials of the professional staff. Thus, a treatment program that employs mainly addiction counselors who are not trained at the master's level limits both the types of issues that can be addressed in individual counseling and the philosophical orientations that are used. Obviously, programs employing master's- and doctoral-level addiction counselors and other mental health professionals can offer more extensive individual counseling services.

Traditionally, group counseling is often the primary approach of both residential and outpatient treatment programs. However, in many treatment programs, group counseling may actually be a confrontation of individuals in the group who are not "working the program," or it may be dissemination of educational information. It would be more useful for group work to help clients to develop concrete usable skills and to rehearse these behaviors in the group. In addition, such group counseling can be used to analyze drinking and drug-taking behaviors and to develop methods of coping, problem solving, and assertiveness, rather than being focused on gaining client compliance to admit to having a disease.

There has been an increasing use of family counseling in treatment programs. As with group counseling, what is sometimes called family counseling is actually education about the disease concept and the family's role in the disease process. However, family counseling is an essential component of treatment. Clearly, the family system can serve to support or sabotage recovery, and addiction almost always creates significant problems within families. It is essential that family counseling be conducted by qualified mental health professionals.

Support Groups

Although support groups should not be considered a treatment "strategy," they are so frequently a part of traditional treatment programs that they must be mentioned. The use of Twelve-Step meetings as a treatment strategy and the utilization of the Twelve-Step philosophy in treatment programs are consistent with the disease model of addiction and thus are a central component of treatment programs utilizing the Minnesota Model.

AA and NA are usually recommended for the alcoholic or addict, and family members are encouraged to attend either Al-Anon or Alateen meetings. This is to introduce family members to the potential support available through Al-Anon or Alateen while the client is still in treatment. Clients and family members may also be referred to ACOA (Twelve-Step support for adult children of alcoholics) or CODA (Twelve-Step support for codependents).

There are alternative support groups to those that use the Twelve-Step model, but the acceptance of these alternatives in disease-model treatment programs may be resisted.

Lifestyle Changes

Irrespective of the orientation of the treatment program, treatment strategies designed to bring about changes in the lifestyle of the client are essential. For example, if clients return to the same friends and activities that were a part of their lives prior to treatment, relapse is highly probable. The range of lifestyle changes that must be addressed illustrates the complexity of comprehensive treatment and the need for long-term interventions for alcoholic and addicted individuals. The lifestyle areas that should receive attention for a particular client should be determined during the assessment of the client and should then be included in the treatment plan.

The issue of friends, lovers, family members, and acquaintances is a focus of treatment. If a client has close associations with individuals who use alcohol or other drugs, some difficult and painful decisions must be made. These topics may be discussed in individual, group, and family counseling. In addition, clients may need assistance with social skills in order to enhance their ability to make new friends. Many alcoholic or addicted individuals have relied on the use of alcohol and other drugs to feel comfortable in social situations or as a common bond to those with whom they spend time. The difficulty of this particular area is clearly illustrated by an adolescent who is told during treatment to avoid contact with friends who use. The adolescent returns to school after treatment and perceives his or her options as returning to a previous social group or having no friends at all. If relapse is to be avoided, the adolescent who is treated for an alcohol or other drug problem clearly needs continued support and assistance to help develop a new social group.

Because many individuals with substance abuse problems have used these substances to avoid negative emotions or to manage stress and pain, alternative methods of dealing with common life problems must also be taught in treatment. Strategies may involve stress management techniques, relaxation procedures, and assertiveness training. The intent of such training is to provide the client with skills to use in situations or in response to situations in which alcohol or other drug use was the only perceived option available. If the client is not taught alternative methods for managing stress and tension, along with techniques to relax that do not involve drugs, relapse is a predictable response. Other lifestyle areas that may be a focus of intervention include vocational and educational planning, financial planning, living environment, and nutrition.

Education

Many treatment programs, particularly those using a disease-concept model, use lectures and films to provide clients with information on the disease concept, family issues, and the social, medical, and psychological consequences of alcohol and other drug use. Although the teaching of educational information is a commonly used strategy in treatment, there is no evidence that providing information to alcoholics and addicts changes their behavior. However, as part of a comprehensive treatment program, it certainly makes sense to provide information to clients and family members. But education and information dissemination should not be expected to produce miraculous changes; thus, these activities should not be conducted at the expense of more useful treatment strategies.

Aftercare

For those individuals who enter treatment, recovery can be conceptualized as a three-stage process. The first stage is formal treatment, the second stage is aftercare, and the third stage is ongoing recovery. Aftercare refers to the interventions and strategies that will be implemented after formal treatment is completed. However, it more accurately should be called "continuing care," as such programs are usually continuations of many of the strategies from formal treatment. The focus should be on the issues that require attention following discharge from formal treatment.

Conclusion

Treatment approaches and treatment strategies may vary according to the philosophical orientation of the program, the intensity of treatment setting, and the level of qualifications of the treatment staff. Although it would be preferable for all treatment approaches to incorporate evidence-based approaches and strategies, the reality is that not all treatment facilities and programs have achieved this goal. What is most important is that treatment programs develop individualized treatment plans that are based on the individual needs of the clients and use strategies designed to meet these needs.

TREATMENT EFFECTIVENESS

Does treatment work? This issue is complex but extremely important, given the time and expense of alcohol and other drug treatment and the costs to society when people continue abusing alcohol and other drugs following treatment. Although numerous studies have examined treatment effectiveness, making sense of the results is difficult because of several underlying problems.

Problems

Treatment programs, for the most part, are not designed to scientifically evaluate the aspects of treatment that are most effective. This makes research immediately problematic, as there is no control over the many variables that may affect results. The numerous client variables that may impact treatment effectiveness include age, gender, duration of use, type of substances used, life problems experienced, voluntary or involuntary admission to treatment, prior treatment, client health, psychological problems, criminal activity, level of education, and income. The type of treatment environment (e.g., private, for profit; public, nonprofit; hospital inpatient; free-standing outpatient; therapeutic community) may impact effectiveness. To adequately research the effectiveness of a treatment

program or treatment approach, a control group is necessary. Ethical (and practical) issues in the random assignment of clients to treatment must be considered when the researcher hypothesizes that one form of treatment is superior to another.

Equally as important to the issues that create barriers to well-designed research studies are the types of outcomes in effectiveness studies. Is client success defined by program completion, abstinence, length of sobriety, reduction in life problems, or all of these factors? What if a client completes a program, relapses, goes to a different program, and then remains abstinent? Does that mean the first program was a failure, or, on the contrary, did it contribute to the client's eventual sobriety?

Treatment Outcome Studies

Fortunately, major long-term studies have been completed to help answer the question "Does treatment work?" The Center for Substance Abuse Treatment sponsored a congressionally mandated study of treatment outcomes for clients in public-sector treatment programs. The National Treatment Improvement Evaluation Study followed 4,411 clients in 78 treatment sites across the country for 5 years; the results were first published by Dean Gerstein in 1997. Clients were from vulnerable and underserved populations, such as minorities, pregnant women, youth, public housing residents, welfare recipients, and those involved in the criminal justice system. Many of the people studied did not complete treatment, which would tend to depress any positive results. In spite of these factors, there were significant reductions in alcohol and other drug use 1 year after treatment regardless of the amount of time spent in treatment or the amount of treatment received. In addition, positive outcomes were found in employment income, mental and physical health, criminal activity, homelessness, and high-risk behaviors for HIV infection. This study also demonstrated that the average savings per client in the year after treatment was \$9,177, which is more than three times the average cost of one treatment episode. The savings were a result of reduced health care, reduced crime-related costs, and increased earnings by clients. Outpatient and long-term residential treatment showed the largest cost savings, but short-term residential treatment and outpatient methadone also were cost-effective.

The National Institute on Drug Abuse followed more than 10,000 clients in nearly 100 treatment programs for 2 years and published initial results in 1997. The Drug Abuse Treatment Outcome Studies (DATOS) involved four types of treatment programs: outpatient methadone, outpatient drug-free, long-term residential, and short-term inpatient. In all treatment modalities, significant reductions occurred in the use of heroin, cocaine, marijuana, and alcohol 1 year following treatment. Positive outcomes were noted in criminal activity, depression, and employment. The outcomes were most pronounced for clients in long-term treatment but were significant for short-term clients as well.

Five-year follow-up data were gathered on 708 subjects from 45 programs in eight cities who met *DSM-IV-TR* criteria for cocaine dependence and have been reported by Dwayne Simpson and colleagues beginning in 2002. There were large decreases in cocaine use in the first year after treatment discharge, which were maintained at the 5-year follow-up. Similarly, improvements in heavy alcohol use and criminal activity continued. The level of severity of drug use and psychosocial problems at treatment entry were predictive of long-term outcomes. However, outcomes improved in direct relationship to the level of treatment exposure (i.e., those who were in treatment longer did better).

Furthermore, data on 1,167 adolescents from the DATOS sample were also analyzed by Yih-Ing Hser and colleagues. At 1-year post treatment, there were significant reductions in marijuana use, heavy drinking, use of illicit drugs, and criminal involvement. The clients also reported better psychological adjustment and better school performance.

A third study, conducted by the National Institute on Alcohol Abuse and Alcoholism, was called Project MATCH. The results were first published by the Project MATCH research group in 1997. This study was designed to determine if different types of alcoholics respond differently to specific treatment approaches. More than 1,700 alcoholics in outpatient treatment or aftercare were studied. The clients were matched with one of three treatment approaches based on client characteristics, including severity of alcohol involvement, cognitive impairment, psychiatric severity, conceptual level, gender, meaning-seeking, motivational readiness to change, social support for drinking versus abstinence, sociopathy, and typology of alcoholism. The three treatment approaches were Twelve-Step Facilitation, Cognitive-Behavioral

Coping Skills, and Motivational Enhancement Therapy. Overall, the clients in this study demonstrated significant improvement in increased percentage of abstinent days and decreased number of drinks per drinking day. There were few differences among the treatment approaches. In spite of many efforts, researchers have been unable to identify the reasons why one approach was superior to another in the rare instances where differences were noted. Positive outcomes were also noted in the use of other drugs, depression, and alcohol-related problems.

Finally, there have been outcome studies on the use of pharmacological approaches to treatment. For example, the Center for Substance Abuse Treatment found that naltrexone reduced the percentage of days a client spends drinking, the amount of alcohol consumed on a drinking occasion, and the relapse to excessive and destructive drinking. John Ball and colleagues have shown that methadone is an extremely effective treatment for opioid addiction. For example, researchers found that over 92% of methadone maintenance clients were abstinent from other opioids after 4.5 years on methadone. Improved social functioning, reduced mortality and morbidity, and decreased criminal activity have also been demonstrated. Methadone treatment is also extremely cost-effective, with \$4 in economic benefits for every \$1 spent for treatment.

Research Summaries

In 2002, Michael Prendergast and his colleagues conducted a meta-analysis of 78 studies of drug treatment that were conducted between 1965 and 1996. This analysis included statistical controls for methodological variables that impacted the size of treatment effects. Of the studies analyzed, nearly two thirds assessed some type of treatment technique. The remaining studies evaluated methadone maintenance, therapeutic communities, drug-free outpatient programs, or detoxification. Nearly 80% of the studies included an active comparison group (i.e., routine treatment, placebo treatment, or alternative treatment), and almost 60% of the studies used random or quasi-random procedures to assign subjects to treatment conditions. About 70% of the studies were funded by federal sources.

The outcome variables in this meta-analysis were drug use and criminal behavior. Drug use was assessed by drug testing, self-report, or both. Criminal behavior was determined by self-report or official records. The

analysis showed that clients who participated in treatment had better outcomes for drug use and criminal behavior than those who received no or minimal treatment. The authors (Prendergast and colleagues) described the outcome results as not large but not trivial. The drug use outcomes were largest in studies where the implementation of treatment was judged to be high, when the degree of theoretical development of the treatment was rated low, or where the allegiance of the researcher to the treatment was viewed as favorable. Treatment with younger adults had a positive impact on criminal behavior to a greater degree compared with older adults. Treatment modality was not related to drug use or criminal behavior outcomes.

In 2005, Steven Belenko and his colleagues at the Treatment Research Institute published a comprehensive review of studies on the economic benefits of drug treatment. They concluded that substance abuse treatment, particularly treatment that incorporated evidence-based practices, had positive outcomes on alcohol and other drug use, criminal behavior, health, and social functioning. The primary economic benefits of treatment were the result of reduced crime and reduced health care utilization. Outpatient treatment was more cost-effective than residential treatment, although the residential services may be more effective for higher-risk populations. With regard to outpatient programs, enhanced services were more cost-effective than standard services. Furthermore, brief interventions were shown to be cost-effective for alcohol-involved clients in certain settings. For incarcerated populations, residential prison treatment combined with postrelease aftercare services was cost-effective. The cost-benefit ratio was highest for high-risk inmates who received treatment and aftercare.

Conclusion

Although it is not possible to comprehensively review all treatment effectiveness research, several conclusions can be reached. Treatment does appear to have a beneficial, long-term effect on a variety of client behaviors, including alcohol and other drug use. Treatment length may be related to improved outcomes, but even short-term treatment is helpful. A variety of treatment approaches and treatment settings have proven effective, and even the most vulnerable clients benefit from treatment.

TREATMENT FACILITIES

Facilities intended specifically for the treatment of alcohol and substance use began to be developed approximately half a century ago. The rise in the number of treatment facilities may be attributable to an increase in the prevalence of addictions in the United States, as well as the proliferation of funding institutions, such as insurance companies, that provide payment for the treatment of addictions. Until such treatment centers were developed, individuals who

experienced problems with alcohol or drug use were treated primarily with outpatient psychotherapy or through attendance at Alcoholics Anonymous.

Treatment facilities initially were based on the Twelve-Step principles of Alcoholics Anonymous. Although such centers provided good successes for individuals experiencing addictions to alcohol, they were less effective for individuals struggling with addictions to other types of substances. In addition, the Twelve-Step approach to the treatment of addictions was often not sufficient to meet the needs of severe addictions that frequently involved multiple diagnoses and also was often not sufficient to meet the needs of special populations. More recently, treatment facilities targeting addictions to a number of different substances, as well as special populations, have begun to emerge.

Treatment Facility Goals

The main goals of treatment facilities are to rehabilitate patients who are addicted to alcohol or other drugs. Rehabilitation may involve a number of components, including evaluation, psychoeducation, and counseling in individual, family, or group formats. Rehabilitation programs often target behaviors associated with alcohol and drug use and offer training and reinforcement of skills necessary to maintain abstinence in the face of obstacles. However, rehabilitation programs may also intervene on psychological components of addictions (e.g., denial and isolation) or on enhancing strengths of patients (e.g., resiliency or self-efficacy beliefs).

Inpatient Versus Outpatient Treatment

The most basic decision patients need to make when selecting a treatment facility is whether inpatient or outpatient treatment is appropriate. Those who may be well suited for outpatient treatment are willing and able to attend sessions consistently and are able to abstain from drug use for 48 hours at a time with minimal support. Conversely, individuals who cannot meet these criteria are likely to benefit from inpatient treatment. Inpatient treatment is typically more intensive and structured and often involves isolation from family, friends, and the community during the initial phases of recovery from an alcohol or other drug addiction. Inpatient treatment facilities are often used to provide detoxification from substances as well.

Types of Programs

According to a recent national survey of treatment facilities conducted by the Substance Abuse and Mental Health Services Administration, there are 13,371 facilities providing services for substance abuse treatment. Most treatment (89%) is conducted in an outpatient setting, with the remaining facilities operating as residential or inpatient facilities. Treatment facilities vary greatly in the services they provide, the style in which services are provided, and the clientele served. Although the major categories of treatment facilities are reviewed here, this is not an exhaustive list of the types of facilities that are available to individuals seeking treatment for alcohol or drug addictions.

Detoxification

Detoxification centers provide an environment in which the first few hours or days of abstinence and withdrawal can take place. Of course, detoxification is not a necessary component for all individuals who are beginning their recovery from alcohol or drug addictions, but it may be a necessary step for some. Of note, although detoxification centers target the first, and most difficult, brief period of time following the initiation of abstinence, complete detoxification may need to occur over a longer period of time (e.g., months). Services provided within detoxification centers are important because withdrawal is both physically and psychologically taxing and even potentially dangerous. Given the dangers and the discomfort of withdrawal from alcohol, sedatives, and opioids, a medical setting may be a good place for detoxification because of its available medical backup. However, many free-standing rehabilitation programs make detoxification services available, and this is being done increasingly on an outpatient basis.

Primary Treatment

Primary treatment facilities are often the first step in treatment (following detoxification, if necessary). Time spent in a primary treatment facility is variable and can range from several days to several months in length. Primary treatment facilities may exist within a hospital-based rehabilitation unit. Indeed, some insurance policies may reimburse for primary treatment only if it is provided in a hospital setting. Hospital-based rehabilitation units may in fact be more suitable than free-standing primary treatment facilities for those with

co-occurring mental illnesses. However, numerous nonhospital primary treatment facilities are equipped with medical staff and can provide care for individuals recovering from alcohol or other drug addictions that range from medical to psychological care. Thus, both hospitals and private treatment facilities may be able to provide primary treatment services necessary for more complex cases. Primary treatment facilities may include residential, outpatient, and/or intensive outpatient services.

Extended Care

Extended care refers to the care obtained during the first months following primary treatment. Extended care may vary in length from 2 months to 2 years. Such treatment may take the form of a long-term residential program, or it may be conducted on an outpatient basis. Residential programs are well suited for patients who are impulsive or lack other skills that would permit successful maintenance of their recovery in the outside community, as well as for those who have completed rehabilitation but are not yet ready to return to their communities. In this vein, residential programs provide support and structure geared to prevent relapse. However, extended care in the form of outpatient services may be a good form of care for individuals who need a moderate amount of maintenance treatment to sustain their recovery.

Therapeutic Communities

Therapeutic communities are similar to residential programs but differ in that they provide services that target early treatment, primary treatment, and support for reintegration into one's former community. Therapeutic communities rely primarily on the residential community as the vehicle of change and maintenance of abstinence. The focus of therapeutic communities is on reestablishing, or establishing for the first time, healthy and functional living skills, attitudes, and values with a particular emphasis on self-control and responsibility. Therapeutic communities also encourage a self-help attitude in the residents, as well as mutual help attitudes such that patients are encouraged to participate in the recovery of other residents. Stays in therapeutic communities typically vary from 18 to 24 months. This type of program is particularly well suited for individuals with multiple drug problems or diagnoses.

Sober Houses

Sober houses also provide a drug-free residence but are intended for individuals who are already stable in the recovery phase of their addiction. Sober houses are typically unstructured environments in which residents are expected to maintain personal hygiene and employment and are permitted to see family and friends outside the sober house community. Sober houses are intended to provide stability as individuals recovering from alcohol or drug addictions are learning once more how to live outside of a structured environment.

Transitional Living

Transitional living treatment facilities provide support that largely focuses on the recovering individual's reintegration into his or her community. Facilities that fit into this category include halfway houses, which are residences for individuals who have already completed their treatment but are not ready to return to their community. Halfway house treatment goals may include providing assistance in gaining employment and living more independently. Thus, services provided within transitional living facilities may include vocational or social-skills training that facilitates the transition back into the community.

Treatment Facilities for Special Populations

As noted earlier, there are treatment facilities that are available to patients in various stages of recovery. In addition, treatment facilities that provide services for specific populations trying to rehabilitate from alcohol or other drug problems are also available.

Faith-based treatment facilities provide rehabilitation services that utilize religious principles to help patients overcome alcohol and drug addictions. Such programs incorporate time for religious practice and education and integrate this with a focus on addiction. Individuals with strong religious convictions may find programs that are faith-based to be particularly in line with their recovery needs.

Exclusive rehabilitation centers provide services for high-profile clients. Such centers boast an array of upscale living accommodations, including luxurious housing units, on-site massage therapists, gourmet cooking, and leisure activities. In addition, exclusive rehabilitation centers provide extra attention to maintaining client privacy.

A vast array of special population programs target populations of specific age ranges. For example, programs for teenagers experiencing addictions exist in a variety of formats, including wilderness camps. Such programs provide teenagers with an opportunity to develop social ties within a new peer group. Programs also exist that provide services for young adults, middle-aged populations, and mature adults. Similar to teen programs, these programs provide opportunities for individuals to recover in an environment that promotes the development of a new peer group and social support network.

Similar to programs targeting particular age ranges, programs also exist that are gender specific. Women-only programs may be particularly well suited for individuals who have a history of sexual or physical trauma. In addition, same-sex groups (i.e., women's or men's treatment facilities) provide an opportunity to recover in an environment that feels safe and permits the forging of new social connections. Analogous to same-sex treatment facilities, facilities that provide services for gay, lesbian, bisexual, or transgendered (GLBT) patients also provide a safe environment for individuals recovering from alcohol or drug addictions. GLBT-oriented treatment facilities focus on clinical issues that may be of particular importance to this population, including homophobia, coming out, feelings of shame, and the development of a new support system in the context of a drug- and alcohol-free lifestyle.

Co-occurring disorders (also referred to as "dual diagnosis") programs serve patients with both diagnosable alcohol or substance use disorders and one or more other diagnosable psychiatric disorders. Patients with co-occurring disorders may be served in either residential or outpatient settings. Treatment facilities that supply services for co-occurring disorders are likely to integrate multiple resources and treatments within the same site.

Although the treatment of opioid addictions can occur in a variety of settings, including hospitals, private physicians' offices, and community mental health centers, methadone clinics also exist that specialize in methadone maintenance treatment. In addition, numerous treatment facilities provide services that are specialized for different substances, including cocaine and marijuana.

Conclusion

Although the majority of patients recovering from alcohol or drug addictions seek treatment in the form

of outpatient services, an impressive range of treatment facilities exist that provide a broad assortment of services. Facilities exist that target the needs of patients in varying degrees of recovery from detoxification to services for individuals that are independently sustaining their recovery. In addition, treatment facilities exist that target the needs of various special populations. Given the number of services that are available for special needs, it is important to seek information that will determine patient/client needs and thus the type of treatment facility that will best meet those treatment needs.

TREATMENT IN JAILS AND PRISONS

Treatment programs are currently a part of normal operations in most Western prisons and jails. Societies have realized that there are compelling problems that lead people to become criminals, and the best way to minimize the probability of future offenses is through structured treatment programs that address the causes of the crime, rather than the crime itself. For many offenders, problems with drugs or alcohol led directly or indirectly to the criminal behavior, and treating the drug or alcohol problem may significantly reduce the chances of future crime. Although there are many other causes, ranging from educational to psychological to emotional, which result in crime, the most common treatment programs in prison and jail facilities deal with substance abuse as a precursor to criminality.

Before a discussion of treatment programs in prisons and jails can occur, it is first necessary to briefly review the history of corrections and the structure of modern correctional operations.

Corrections Overview

In modern society it is common to refer to *jails* and *prisons* interchangeably. The media may report that a person “spent five years in jail for a crime he did not commit,” or that a “prisoner” escaped from the county jail work program. Although these types of statements are common, they are technically incorrect and they serve to blur the distinctions between prisons and jails. The structural and operational distinctions between these very different institutions must be understood before an accurate discussion of treatment programs in these respective institutions can occur.

Jails are typically county- or city-level institutions. They tend to be small (although there are exceptions to this rule), and they hold inmates who have been sentenced to serve time in the jail as well as inmates who are considered unsentenced. Unsented inmates may be in the jail for a number of reasons. They may be there after they have been arrested while they are awaiting trial or an appearance before a judge. They may be awaiting sentencing after the trial has occurred, or they may be awaiting the posting of their bail so they can return home until their trial date.

Sentenced inmates are usually sent to the jail for misdemeanor crimes or for low-level felonies. This is because virtually all jails in the United States are limited in the time they can hold an inmate. Jails are limited to sentences of 1 year or less, which eliminates from the jail those persons who are sentenced to middle- and high-level felonies that receive sentences in excess of 1 year. Inmates can only serve more than a year in jail if they are being held without bail while a case is being prepared against them, or if a judge sentences them to multiple sentences of 1 year or less which must be served consecutively. Jails are usually operated by the county sheriff and are staffed by deputy sheriffs, who are typically sworn officers who have completed training at a law enforcement academy and who are also able to serve as street-level officers.

In contrast, prisons are operated by state or federal governments, and they are larger institutions. Prisons typically hold more serious offenders (persons guilty of middle- to high-level felonies) and hold them for longer

periods of time. Prisons are operated by correctional officers, who typically have not completed a police officer type of training academy but rather have completed a correctional officer training program that has prepared them to work as officers in a correctional institution.

Because of these different criminal populations, the average time spent in each of these institutions, their diverse institutional goals, and the different administrative and funding controls of these institutions, jails and prisons are asked to offer very different types of treatment programming.

Prisons and Correctional Institutions

For centuries there were no prisons. Jails were used to hold those who were awaiting trial. If convicted, the person on trial would typically receive a punishment, which was either corporal or capital. Imprisonment as a punishment was limited to religious criminals or the nobility, and churches and monasteries served as prisons for this small fragment of offenders. In fact, monasteries still refer to the rooms where the monks and sisters live as “cells.” Prisons developed from the influence of religious practitioners who sought to provide a safe place for their offenders, while at the same time creating a place where these offenders could consider the errors they had made and resolve to never commit such crimes in the future. These prisons were called *penitentiaries*, based on the belief that these were places where offenders could experience true penitence and feel remorse for their actions.

As a result of this new ideology, prisons in the United States and Europe began to change their perspectives along with their names. They began to be called penitentiaries, from the Quaker belief in the power of penitence. Later, these former prisons became *correctional institutions*, and the state agencies that operated them changed from Departments of Prisons to Departments of Corrections. In contrast, jails remained facilities to hold persons temporarily, and treatment, penitence, and corrections remained a goal in the far periphery of the focus of the institution. Whereas prisons were increasing in size and diversity (in terms of the programs offered), jails remained more custodial institutions. Whether it was because of the nature of the population served (low-level offenders) or the limited time the person served in the jail (less than 1 year), these facilities remained focused on the care and custody of inmates rather than on their reform and rehabilitation.

This situation changed as the operators of these facilities and the public began to fully realize the significance of the drug-crime relationship. The Bureau of Justice Statistics reported in 2004 that 56% of all state-level prison inmates had used drugs in the month before their offense, and 72% of property offenders had used in the month prior to their offense. Overall, approximately 17% of prisoners committed their crimes to obtain money for drugs, and 83% of state inmates reported that they used drugs regularly, with marijuana (77.6%) and cocaine or crack cocaine (46.8%) being the two most commonly used. There were few differences among racial/ethnic groups, and males and females were quite similar in overall use patterns. Age, however, showed some distinct differences, with 66% of the 24 years and younger group and 60% of the 25- to 34-year-old group reporting use in the month prior to the offense. This difference was mirrored in the patterns of use in the month prior to the offense. Younger inmates reported the greatest levels of use, and older inmates, although not as frequent in their usage, had increased their use patterns nearly 10% between 1997 and 2004. The same survey found that over 26% of state inmates reported use patterns that placed them in the drug abuse category, and an additional 33% reported use patterns consistent with drug dependence.

Based upon these findings and similar data over the past 30 years, the correctional community realized that prisons and jails were appropriate places to initiate or continue treatment programs, especially for younger offenders with dependence issues that contributed to their crimes. There were, however, significant issues to be considered before it would be appropriate to expect successful treatment in a correctional environment. The first of these considerations involved the appropriateness of forcing a person into a treatment program. The prior mind-set was that individuals needed to want help before help would be effective. Studies and anecdotal evidence indicated, however, that most individuals who were participating in treatment programming due to legal or custodial pressures still experienced positive outcomes. How and why they attended treatment programs mattered less than had been previously believed; what mattered was that they attended the program.

A second concern involved the realities of treatment programming faced by most jail facilities. As jails are short-term custodial settings, there are limitations on the programming options available. Many of the inmates are either awaiting trial or awaiting sentencing, and some will be transferred to a prison environment as soon as transportation can be arranged or space

becomes available. Consequently, the question of the cost-effectiveness of short-term treatment programming had to be addressed. The answer to this dilemma was contingent on the type of treatment needed and the ability to order the offender to participate in treatment programs once released from the custodial environment. Certain offenders, such as those who are charged with crimes like spousal abuse or domestic battery, can receive effective short-term treatment in the area of anger management. Treatment for chronic problems, such as addiction, is not as successful in a short-term environment, but it can begin in a custodial environment, and the offender can be ordered (in some cases) to continue once released.

Prisons, because they hold offenders for longer periods and have more corrections-related officers, are much more interested in the outcome of the offender. When offenders re-offend upon release, it is the prison that is criticized for not correcting the behavior of the offender. Consequently, prisons take their role as correctional institutions very seriously and dedicate many resources to the goal of rehabilitation.

Types of Treatment Programming in Prisons and Jails

Because jails hold inmates for relatively short terms, the goal of the treatment programming is usually to get the inmate acquainted with a treatment environment and then connect the inmate to similar programs (sometimes with the same therapist) on the outside. Some inmates are able to complete their respective programs while in the jail, but this is usually limited to programs with well-defined goals, such as GED (General Education Development or high school academic equivalency) programs or anger management training. For problems of a more chronic nature, like substance abuse and addiction, long-term treatment is usually offered first through the jail, then later through the local probation office, which in most cases continues supervision of the inmate for a time specified by the court following release. It is this aftercare and supervision that often make the process begun by the counselors in the jail successful. Should the person on probation test positive for drug use or be found in possession of drugs, the probation officer and the probation supervisor can decide if a brief period in jail might convey the seriousness of the offense and the disapproval of the judge. It is common that after a brief stay in the jail, the offender will be released back to society and to the treatment program outside the jail.

Prisons, unlike jails, hold an inmate for a longer period, and consequently they have more treatment opportunities to offer and greater potential for success. Prison treatment programs can range from education and support group programs to group therapy and total immersion programs like therapeutic communities. As a rule, when an inmate is sent to a prison, the first stop is the classification unit. While in this unit, the inmate is evaluated in several areas (education, vocational skills, substance abuse issues, and psychological issues), and a treatment program is created to manage those areas of deficiency or need. These various treatments are usually timed to correspond with the projected release date for the inmate.

Treatment in a prison environment is challenging at best and difficult at worst. Inmate behavioral norms (commonly referred to as the “convict code”) do not allow inmates to show weakness, cooperate with the prison administration, or pry into the business of other inmates. Therapeutic settings demand a level of trust and sharing among the participants and trust in the clinician, who is endeavoring to create personal change in a therapeutic environment. So, to be effective in therapy, an inmate has to violate the convict code, and staying true to the convict code means failure in the therapeutic situation. This paradox is made even more problematic by the use of indeterminate sentences, which allow inmates to be released prior to the expiration of their sentence if they participate in programs and earn “good time” credits. In such situations, staying true to the convict code means that an inmate will serve every day of his or her sentence and likely leave the prison with worse prospects for law-abiding behavior than were present upon entry into the prison system.

To combat this paradox, some prisons have created “therapeutic communities” (TCs), where the entire inmate population in a specific area of the prison is committed to creating an environment where personal change and accountability can flourish. Inmates in TCs can feel free to discuss their problems and confront others about their behavior without ridicule or threat. The environment is not hostile, but it is not to be taken lightly either. The most noteworthy TC, Delancey Street in California, is based on the ideals of “complete accountability, mastery of life and career skill, empowering everyone to learn, earn and lead.”

Placement in the TC represents a time commitment, which, if not completed, will not count toward good time or, in some cases, toward the sentence at

all. That means that if the inmate leaves the TC prior to the completion of the 1-year minimum commitment, the time spent will be lost and will not count toward the sentence imposed by the court; it will just be wasted time. Placement in the TC must also be done to coincide with the completion of the prison sentence. Inmates who complete their time within the TC should be released directly from the TC to the outside, preferably on parole so a parole officer can monitor their progress and behavior. Placing the inmate back in the general population of the prison may quickly undo the progress made in the TC and may prove unhealthy for the inmate. The confrontation and personal responsibility considered necessary for a TC to operate effectively and therapeutically may not be received well by inmates who have not participated in the TC environment, and they may react violently to the same requirements of personal responsibility that are encouraged within the TC.

Conclusion

Although there are distinct advantages to running treatment programs through correctional agencies, there are also drawbacks. Programs run through court-ordered incarcerative settings allow the justice system to constantly monitor the offender, to follow up with the offender to make sure, for example, that restitution is being paid, and to offer the threat of return to an incarcerative setting if the requirements of the court order are not followed. The advantages to the offender are things like group support from others in similar situations and decreased cost because the state often covers some of the costs. For society, the advantages are decreased chances for new offenses and improved public safety brought about by the supervision the offender receives. Disadvantages to the process are primarily in the area of financial costs to operate these programs in both prisons and jails and in the society at large.

TREATMENT OF ALCOHOL AND DRUG USE DISORDERS

Alcohol and drug use disorders, often referred to as substance use disorders, are chronic and frequently require multiple episodes of treatment. These conditions are prevalent in the United States. According to the Substance Abuse and Mental Health Services Administration, an estimated 22.6 million people in 2006 were affected by substance use disorders, but national data analyzed by Emily Cohen and colleagues estimate that only about 15% of the general population that experiences alcohol abuse or dependence in their lifetime ever seeks treatment or attends support groups. Although individuals with substance use disorders may recover on their own, a concept known as natural recovery, Cohen and colleagues found that those who receive treatment tend to experience better substance use and lifestyle outcomes compared with individuals who recover naturally.

Barriers to treatment, such as stigma or shame associated with seeking help, difficulty with accessing services, and little social and financial support for attending treatment, may contribute to these low rates of treatment utilization. Misrepresentations of what

substance abuse treatment consists of and involves are often portrayed in the media (e.g., treatment is lying on a couch and talking about family history, or it involves a straightjacket and medication). Such media portrayals may result in misperceptions about treatment that pose additional barriers to seeking help. This entry discusses various forms of treatment, including the settings where treatment is delivered, the major components of treatment, and the characteristics of effective treatment. The entry also includes issues important to consider in treatment, including the use of evidence-based practices (e.g., using current and best evidence to make decisions about client care), the necessity of ongoing training and supervision of treatment providers, and working with special populations.

The treatment of substance use disorders aims to manage an individual's alcohol and/or drug use. Treatment goals may vary by client preference, counselor philosophy, and institutional policy. Goals may range from obtaining abstinence (no use of alcohol or drugs) to moderation (some use, but within a range that does not produce problems). Individuals from a variety of educational backgrounds deliver treatment, including certified or licensed addiction counselors, social workers, nurses, physicians, and psychologists. It is important to note that specialized training and continued supervision is needed and is essential to delivering high-quality care to clients. Treatment should be delivered by qualified professionals who are certified or licensed and attend ongoing educational courses, including continuing education courses, on evidence-based practices and advances in substance use etiology.

Substance abuse treatment is only one component of services provided to individuals with substance use disorders. Consistent with the stepped-care model approach offered by Mark Sobell and Linda Sobell, clients are offered less intense and restrictive forms of services before more costly and intense services or treatments. For example, an individual identified for at-risk drinking may receive a one-session brief intervention initially and be recommended to outpatient treatment if his or her problems persist. This method allows for clients to receive a range of services depending on their severity level.

Treatment Settings

Treatment settings vary by cost, time, intensity, and goal of treatment. In outpatient treatment, clients may receive services on a daily or weekly basis, but they

do not spend the night in a treatment center. Thus, clients can continue with their daily activities as they normally would by attending daily or weekly counseling while also fulfilling work and other life responsibilities. Outpatient treatment is most suited for individuals who are least likely to suffer from withdrawal symptoms and who have a stable recovery or living environment, such as supportive family and friends and reliable transportation to counseling.

Outpatient services can be obtained from a variety of sources, including employee assistance programs, mental health clinics, hospitals, and counseling centers. These services are delivered by a certified or licensed professional. The purpose of outpatient treatment is for the client to make personal changes leading to abstinence, moderation, harm reduction, or relapse prevention, depending on the client's goals and institutional philosophy. Outpatient treatment can also include visits to a methadone clinic to treat opioid dependence or individual or group psychotherapy. The Center for Substance Abuse Treatment states that the frequency of outpatient treatment sessions can range from once a week to daily, and the length of treatment lasts between 2 months and 1 year depending on the severity of the client's problem and the availability of services.

Intensive outpatient treatment and partial hospitalization are appropriate for individuals needing a more structured treatment program and who are more likely to relapse without closer monitoring and support. In these programs, the client attends treatment (e.g., 4 to 8 hours per day), which may be offered during the day, in the evening, or on the weekend. According to the American Society of Addiction Medicine (ASAM) patient placement criteria, intensive outpatient programs generally offer 9 or more hours per week of recovery education and treatment; partial hospitalization programs generally provide 20 or more hours of clinically intensive programming per week, and clients have more access to ongoing medical services.

Inpatient or residential treatment is a more intensive form of treatment, where clients stay in a designated inpatient unit of a hospital or clinic overnight for 24-hour care. The ASAM criteria suggest that inpatient treatment is ideal for individuals who have poor recovery or living environments (e.g., individuals who are homeless) and those with psychiatric comorbidity (e.g., a coexisting psychiatric disorder, such as major depression or schizophrenia). These clients

may need to be medically monitored in the early stages of abstinence through detoxification, a stable living environment in which to work on their substance use problems, or both. For example, clients with recovery environments that are unsafe or involve other substance-using peers may warrant an inpatient stay. In addition, some clients may face serious medical consequences from withdrawal from central nervous system depressants (e.g., alcohol) and, thus, need medically supervised detoxification in an inpatient setting.

Last, therapeutic communities and community residential facilities (also known as "halfway houses" or "sober houses") are residential programs with planned lengths of stay of up to 1 year. Residents in these facilities practice everyday living and carry out responsibilities, as they would in the "real world," within their community of staff and other residents. For example, clients are given daily chores, attend Twelve-Step meetings, and convene in community meetings to discuss group dynamics, interpersonal difficulties, and responsibilities of the house. These highly structured and substance-free programs provide residents with a transition from treatment to living on their own. The focus of these programs is on resocialization, which re-trains residents to examine patterns of their current behavior and develop the skills needed to live responsibly in society.

Major Components of Treatment

Assessment

Treatment services begin with a comprehensive assessment of an individual's drug and alcohol use. A trained counselor conducts a semistructured interview in which a standardized set of questions are asked of the client and discussed collaboratively in order to assess standard elements of the client's substance use including consumption patterns, relapse history, prior treatment, and associated biopsychosocial consequences (e.g., liver disease, difficulty with anger and impulsivity, relationship problems); occupational, housing, and legal status; social and family support; co-occurring psychiatric diagnoses; physical disorders; and motivation to change. Assessment in these areas is essential and designed to highlight the client's strengths that will support his or her recovery and the high-risk areas that could trigger relapse.

Treatment Plan

Using information collected from the assessment, the counselor and client work collaboratively to create a treatment plan that details how a client will achieve specific, manageable, and measurable goals while in treatment (e.g., abstinence, attending weekly groups, obtaining a physical exam, applying for supported housing). These goals should be important and meaningful to the client and his or her recovery, while also addressing the problems and high-risk situations gathered from the assessment.

Treatment objectives are prioritized and divided into short-term goals (immediate goals while in treatment) and long-term goals (goals after treatment). For each goal, there is a corresponding plan to achieve it. Some goals and plans may require the client to work with professionals from various disciplines (e.g., working with a psychologist through weekly counseling to increase interpersonal skills, a vocational rehabilitation counselor to find a part-time job, and a social worker to apply for housing benefits). Ideally, each goal is matched with a timeline of when the goal is expected to be completed. The treatment plan is viewed as a changing document that is monitored and modified regularly as a method of assessing treatment progress over time.

Treatment Sessions

The format of treatment or therapy sessions can be individual, group, marital or couple, or family. Group formats are most commonly used in community and hospital settings because groups are more cost-effective than individual sessions. There are therapeutic advantages to group therapy over individual therapy. Groups consist of other members working on their recovery, which can normalize the stigma and shame often associated with having a substance use disorder. The group climate also creates an environment where members share insights and advice, encourage and hold each other accountable, and validate the difficulties of recovery. Group members also work on their interpersonal skills through communicating and participating in discussions. Group session content varies and can range from purely educational, where a counselor provides didactics to the group, to a more process-oriented group that allows group members to discuss issues important to them in an

unstructured format. In this latter example, a counselor may act as a moderator by guiding the session with summaries, thought-provoking questions, or insights while allowing the group members to lead in talking about issues important to them. Due to the nature of these process groups, clients are encouraged to self-disclose and share their struggles with group members, which is in contrast to more educational groups where the counselor's role may be more didactic and less collaborative. Therapists must decide whether the clients can join the group at any time or if the group is exclusive. They must also monitor the phases of recovery among the clients and assess whether a new member would be a good match for the group. For example, a client farther along in his or her recovery may be better matched in a group with clients in their later stages of recovery than in a group with members ambivalent about change.

In addition to, or in lieu of, group treatment, individualized treatment provides one-on-one counseling with a therapist and offers privacy and confidentiality for clients to discuss sensitive issues more openly. This treatment can be very beneficial. Clients are able to work with a counselor on individualized topics and goals, and clients move at their own pace, both of which allow for more flexibility and greater attention to client needs. Individualized treatment is qualitatively different from case management alone. In individualized treatment, the counselor and client work collaboratively on short- and long-term therapeutic goals, and case management tends to focus on problem-solving, practical here-and-now issues such as providing referrals to housing or coordinating what type of treatment the client will go to.

Marital, couple, or family treatment is often used in conjunction with group or individualized therapy when interpersonal relationships are identified as part of the problem. The source of distress can be viewed as multidirectional and systemic, where the individual with substance use issues and the family impact each other, instead of the source of all problems being attributed to any one individual. Marital, couple, and family therapies have the goals of improving personal and family functioning and supporting the client's treatment plan and goals for recovery. Family Twelve-Step mutual-support groups are also available, including Al-Anon, Alateen, and Nar-Anon, and serve to support family members of substance abusers whether

or not the substance abusers themselves are seeking treatment.

The Role of Other Treatment Strategies

Education about substance abuse can play an important role in treatment. There are several effective methods. Normative feedback, often used in brief interventions, is designed to present clients with summary information about how their use of alcohol and other substance use compares with that of their peers. This concept is based on cognitive dissonance, a state in which the client's current behaviors are in conflict with his or her personal values and life goals. This ambivalence or discrepancy may encourage clients to evaluate how their current behaviors fit with the type of person they see themselves becoming. An example of normative feedback may be to say that "compared to men your age in the United States, your drinking ranks in the 88th percentile, which means that you drink more than 88% of your peers." Providing this feedback may generate ambivalence in the client toward his current drinking behavior if his values include not drinking more than most men.

Another type of feedback is providing clients with education about how to understand and calculate their blood alcohol concentration. In doing so, individuals are able to recognize levels of alcohol intoxication and become more knowledgeable about how many drinks over certain periods of time it takes to reach different levels of impairment. This information educates clients on what their consumption would be like if they reached illegal limits of intoxication, and this education may increase their self-monitoring of drinking.

Lifestyle changes are also associated with increased treatment adherence and recovery. Substance abuse treatment may also include coping and interpersonal skills training, vocational guidance, and financial planning and address topics of assertiveness, recovery environment, coping with cravings, reducing risk of HIV, balancing personal time, and meditation.

Mutual support programs, such as Alcoholics Anonymous, exist to assist individuals in coping with a substance use problem. Members of support programs tend to be substance users in recovery, and meetings are designed so that attendees can share experiences with other addicts and alcoholics. Unlike group treatment, Twelve-Step or mutual support programs are not run by professionals. Thus, mutual

support or Twelve-Step programs are best supplemented by ongoing outpatient or inpatient treatment. These programs can also be helpful during aftercare or follow-up care after a treatment episode. In their research, Jennifer Boyd Ritsher and colleagues found that individuals with greater Twelve-Step involvement during the first two years following treatment had greater remission or absence of symptoms 5 years after treatment compared with those with less Twelve-Step involvement.

National Institute on Drug Abuse Principles of Effective Treatment

Not all substance abuse treatment is equally helpful. The most effective substance abuse treatments can be characterized by some basic treatment components. The National Institute on Drug Abuse offers a set of overarching principles for effective drug abuse treatment and implementation based on a review of several decades of scientific research and clinical practice. To be effective, treatment must accommodate the needs of the individual, for example, by matching treatment settings, interventions, and services to the individual's particular problems and needs. Treatment must be readily available, assessed, and continually modified and be of an adequate length of time to be effective (a threshold at about 3 months in treatment is typical).

Effective treatment should include counseling to address issues of motivation and resistance. Therapy also helps clients build problem-solving skills to resist or reduce drug use and take steps toward participating in constructive sober activities. Medications combined with counseling can help addicted individuals stabilize co-occurring mental and physical conditions and reduce their substance use. Individuals with co-occurring substance use and mental disorders should have integrated care that treats both conditions simultaneously.

Treatment should also consider associated medical, psychological, social, vocational, and legal problems and provide assessment and counseling for HIV/AIDS, hepatitis B, tuberculosis, and other infectious diseases. Possible drug use during treatment must be continuously monitored through objective drug testing (e.g., urinalysis or other tests); such testing can help the client withstand urges to relapse and give early evidence of setbacks. It is not uncommon for

substance-using individuals to require multiple episodes of treatment; thus, aftercare and continuing care are important components of the treatment process.

Treatment Effectiveness

Studies evaluating the effectiveness of substance abuse treatment provide scientific evidence for improving and designing new treatment programs as well as implications for treatment policy. Major studies include Project MATCH, the Drug Abuse Treatment Outcome Studies project, and the National Treatment Improvement Evaluation Study. These comprehensive undertakings have provided such key themes in treatment as the following: Retention in treatment is related to posttreatment outcomes; support (e.g., counseling, support groups) after treatment prevents relapse; and brief motivational therapy is a safe and cost-effective starting point to more intensive interventions.

Issues for Special Populations

Substance abusers are as widely diverse as the population at large. They differ in demographic characteristics, substance use problems, motivation for change, and barriers to treatment. Many subgroups are underrepresented and underserved in substance abuse treatment and present specific needs to treatment programs. The American Psychiatric Association identifies subgroups with unique concerns regarding treatment. These include individuals with severe mental illness, HIV/AIDS, multiple substance use, co-occurring medical and psychiatric diagnoses, and legal problems. Homeless individuals, adolescents, older adults, ethnic minorities, gay/lesbian/bisexual/transgendered individuals, and women or pregnant women may also have unique needs in treatment. For example, adolescents may not seek help because of stigma or confidentiality concerns, and substance use disorders among older adults are often undiagnosed and undertreated. Ethnic minorities bring their own special history and traditions to treatment, and practical barriers (such as not speaking English) may present challenges to treatment. Women have greater perceived social stigma associated with their substance use and may be more likely to experience particular barriers to treatment (e.g., lack of childcare or health insurance). Treatment of substance abuse in the gay/lesbian/bisexual/transgender community must address issues of homophobia. Derald Wing Sue and David Sue advise that

caregivers be trained in cultural competency and that facilities include minorities and special populations among their treatment staff to attract and help maintain minority populations in treatment.

Conclusion

Substance use treatment is diverse, varying in setting, approach, format, and effectiveness. A variety of certified and licensed professionals provide treatment, and the type of treatment provided should be a decision made collaboratively by the professional and the client, based on the client's preferences and treatment goals. A comprehensive assessment and treatment plan allows for the client and counselor to create structured goals for measuring treatment progress and provides them with a roadmap early in therapy. Treatment is not prescriptive and should be customized to each client's problem severity and motivation to change. Special populations may benefit from this approach where treatment goals are tied with values important to them. Research continues to find support for certain types of treatments over others, and professionals that provide clinical treatment to clients should aim to learn the latest evidence-based practices.

TREATMENT PLANS AND TREATMENT PLANNING

Treatment planning is a collaborative process in which a professional and the client develop a written document that identifies important treatment goals; describes measurable, time-sensitive action steps toward achieving those goals with expected outcomes; and reflects a verbal agreement between a counselor and client. At a minimum, an individualized treatment plan addresses the identified substance use disorder(s), as well as issues related to treatment progress, including relationships with family and significant others, potential mental conditions, employment, education, spirituality, health concerns, and social and legal needs.

Types of Treatment Plans

An *initial treatment plan* focuses on the client's short-term or preliminary goals and objectives and guides

the initial course of treatment. Elements of an initial plan include reason(s) treatment is indicated, a preliminary diagnosis or diagnostic impression, the client's presenting problems, client symptoms, and initial methods or services that will be used to address those problems. A treatment program may require a preliminary treatment plan at admission, followed by a comprehensive, individualized treatment plan shortly thereafter.

A *program-driven plan* reflects the components or standard activities and services available within the context of a particular treatment regimen. This outdated, "one-size-fits-all" method of treatment planning provides insufficient information to differentiate between clients' unique problems and needs. Program-driven statements are commonly overused. Examples of program-driven statements include the following:

- Client will refrain from using all mood-altering substances now and in the future.
- Client will participate in the outpatient program.
- Client will attend three AA meetings a week.

An *individualized treatment plan* is a written document that identifies important treatment goals relative to those problems identified in the screening and assessment process. The plan identifies important treatment goals; describes measurable, time-sensitive action steps toward achieving those goals with expected outcomes; and reflects the verbal agreement between the counselor and the client. Information is gathered systematically from the client and other available collateral sources. Validated screening and assessment instruments used in combination with a structured interview format of both closed- and open-ended questions elicit information regarding the client's current situation, symptoms, perceptions of his or her problems, strengths, needs, and readiness to engage in treatment. The counselor assesses the severity of the client's problems and uses clinical judgment to prioritize problems appropriately. The plan is continually updated and revised throughout the course of treatment. Timing of revisions and updates is guided by regulatory and credentialing requirements.

Treatment plan reviews or *continued stay reviews* reflect client progress in relation to the problems and goals identified in the most current treatment plan and may also adjust the level of care.

Historical Aspects in Substance Abuse Treatment

Until recently, the field of substance abuse treatment operated from a “one-size-fits-all” treatment philosophy. Typically, one approach to treating individuals with substance use disorders was considered superior. Focus was placed on a limited number of tools and strategies that had worked with some consistency. Programs used the same tools, in the same way, with everyone, regardless of clients’ specific problems. Unique aspects of clients’ problems and treatment needs were not reflected in program-driven plans and were often developed without client or collateral party involvement. In the event the client’s situation indicated the need for additional services, plans did not reflect referrals to community service providers, psychiatric clinics, or vocational rehabilitation services. There was little difference among clients’ treatment plans. The written document was frequently viewed as necessary, useless paperwork and was filed in the client chart for the duration of the treatment episode.

In 2003, R. K. Hester and W. R. Miller conducted a seminal review of treatment outcome literature regarding alcohol treatment interventions and concluded that there is no single treatment intervention that works for all clients. Rather, there are several evidence-based practices that demonstrate efficacy for a variety of clients in multiple settings and levels of care. Research studies have also concluded that *individualized treatment planning* methods lead to increased client retention. Retention is important because many clients terminate treatment prematurely. This paradigm shift away from a philosophy of one-size-fits-all treatment recognizes that clients have different and unique abilities, goals, lifestyles, socioeconomic realities, work histories, educational and vocational experiences, and cultural backgrounds. Similar to medication dosing, no two clients should have the “same dose of treatment” just as no two clients present with identical problems or strengths.

Client Role in the Process of Treatment Planning

A treatment plan defines the therapeutic contract between the client and counselor. It provides the client with a sense of ownership and responsibility in the treatment process. It keeps all parties accountable, focused, and goal oriented. A well-constructed plan can turn paperwork that might seem meaningless into

a useful activity, and it can maximize identified problems and counseling sessions by keeping the client and the provider focused on identified problems and agreed-upon goals.

It is simply not enough to provide the client with a copy of his or her plan. Studies suggest client retention improves when the counselor accurately assesses and reflects the client’s perceptions of his or her problems in the plan. Key to the successful treatment planning process is that the client (a) understand the treatment care instructions, (b) be allowed the opportunity to give feedback to the counselor, and (c) can state other specific problems, goals, or needs he or she may want addressed.

Treatment Plan Components and Examples

The terminology used to convey the more specific components of a treatment plan are not consistently defined or applied. Terminology may vary by profession, by program, by agency, and by region. Terms such as *action step*, *treatment approach*, *task*, *measurable goal*, *treatment strategy*, *benchmark*, *milestone*, and *solution* are often used to indicate components of a treatment plan. Sample definitions of treatment plan components follow:

Problem statements are based on the information gathered in the screening and assessment. For example,

- Megan reports regular, daily use of methamphetamine during the past year.
- James stated that he has significant family problems related to past month’s alcohol use.

Goal statements are based on the problem statement. Goals should be reasonably achievable in the active treatment phase. For example:

- Megan will address her use of methamphetamine and consider the pros and cons of continued use.
- James will explore his recent episodes of drinking and consider how alcohol has contributed to his current family problems.

Objectives reflect what the client will do to meet the treatment goals. For example,

- Megan will list the pros and cons of using methamphetamine and use this list to complete “A Using Timeline” exercise.

- John will attend 90% of the weekend family education classes and complete 80% of the “Catch Your Spouse Doing Something Good” assignments.

Interventions reflect what the clinicians will do to assist the client. For example,

- Counselor will review and discuss Megan’s “Using Timeline” in individual sessions.
- Marriage and family counselor will educate James and his wife on ways to appropriately express anger and frustrations.

Characteristics of Goal, Objective, and Intervention Statements: SMART

S = Specific

- Objectives and interventions should be specific and goal-focused, allowing both client and counselor to note progress (or lack of progress). Specific behaviors are targeted that will help clients reduce their symptoms and improve their level of functioning.

M = Measurable

- Objectives are measurable so that the client and counselor can document change. Interventions are measurable and hold the counselor and treatment program accountable.
- Objectives and interventions include measurable indicators of client progress. These indicators can include client self-reports, comparing baseline data to current data, dates, occasions of behavior, and rating scale scores.

A = Attainable

- Goals, objectives, and interventions should be achievable by the client in the active treatment phase.
- Focus on improved functioning rather than the “end” or “cure” of the problem (e.g., fill out a job application vs. become employed full-time).
- Identify those goals that can be attained in the level of care provided.
- Identify clients that need referrals to outside agencies.
- Objectives and interventions may need to be revised when the client moves from one level of care to another.

R = Realistic

- Be realistic. While the objective should require client effort, it must be reasonable to expect that the client can attain the objective in a specific time period.
- Goals and objectives should be achievable given the client environment, supports, diagnosis, level of functioning, or level of functional impairment. Counselors must also have a realistic expectation that a client is able to achieve the goals and take steps on his or her own behalf.

T = Time Limited

- Focus on time-limited or short-term goals and objectives. Achievement of goals, objectives, and interventions can be reviewed within a specific time period. Target dates help clients understand how long they must continue with a new behavior.

Guidelines in Writing Effective Plans

Quality treatment plans address both the alcohol or drug problem and how the drug or alcohol use impacts the client’s life and his or her ability to perform in various arenas (e.g., health, family, legal, financial, employment, school, or relationships). Drug or alcohol use by itself does not denote addiction or alcoholism or even a problem. Drug or alcohol use must be linked to some sort of impairment in functioning that creates problems; otherwise, it simply is a poor choice made by the client. If this link cannot be substantiated, then a diagnosis of substance abuse or substance dependence will be difficult or impossible to determine. Thus, treatment plans need to include the substance use problem and the problems caused by the substance use (functional impairment).

It is equally important to accurately assess and reflect the client’s readiness to change and take it into consideration before treatment recommendations are developed. In 1982, Prochaska and DiClemente introduced a transtheoretical model of change. This model proposes that behavior change follows a series of predictable stages of readiness to change. Once the client’s stage of change is determined, the counselor tailors the goals, objectives, and interventions to “fit” the client’s readiness.

Generally prescribed guidelines include the following:

1. The substance use disorder and the problems caused by the disorder should be addressed.
2. Services provided by the counselor (or treatment staff) and other outside agencies need to be included.
3. The plan needs to be individualized and reflect evidence-based practices.
4. Written statements must be nonjudgmental. Avoid jargon (e.g., Client is in denial, client is codependent). Terms such as *low self-esteem*, *denial*, or *codependent* do not describe the behavior that is causing the problem. These labels are more than descriptions of behavior and can be construed as judgmental.
5. Complete sentence structure should be used, and the problem should be expressed in one clear, concise statement.
6. Goals and objectives should be phrased in a positive manner so that the client's focus is on practicing new behavior rather than stopping or avoiding an old behavior. An example of a positive statement: "Client will attend 90% of all scheduled classes in the next 30 days." An example of the *same statement* written in a more negative tone: "Client will not miss more than 10% of all scheduled classes in the next 30 days." Although the distinction may be small, goal and objective statements written in a positive manner promote behavioral changes. It is also much easier to follow up by asking clients about what they did as opposed to what they didn't do.

Conclusion

Treatment planning begins and ends as a collaborative planning process between the client and a clinical team or counselor. It clarifies the potential problem areas necessary for designing an individualized treatment plan and helps with retention of clients in treatment. Problem, goal, objective, and intervention statements are all part of one continuous therapeutic thread that ties together the delivery of treatment services.

TREATMENT PROGRAMS FOR ALCOHOL OR DRUG ABUSE

Treatment programs for individuals with alcohol or other drug (AOD) problems were once very limited. However, many years of scientific research and clinical practice have informed the field and have guided the development of a variety of addiction treatment approaches and programs. Individuals may now choose among these options depending on the severity of their problems and their individual needs. AOD treatment program philosophies, goals, and methods vary, but all aim to help individuals decrease or eliminate substance use and to ultimately establish healthy, productive, and satisfying lives.

Research and clinical data demonstrate that treatment for substance addiction is similarly effective when compared with treatment for comparably chronic medical conditions. Like people in treatment for chronic medical conditions, individuals in AOD addiction treatment learn behavioral changes, often take medications, and might need sustained and repeated treatment episodes over time in order to recover and to achieve a desired outcome. In addition, a person's expectations about treatment effectiveness also influence success or failure. The expectation of a sudden or easy "cure" might result in disappointment or discouragement and a tendency to leave treatment too early.

Ideally, AOD treatment programs adjust to reflect the current state of the science and art of the field. Research has revealed a set of overarching principles that characterize the most effective drug abuse and addiction treatments and their implementation. First, treatment should be readily available because individuals seeking treatment might be ambivalent and discouraged if care opportunities are not easily accessible. In addition, treatment professionals should

recognize that no single plan or type of therapy is effective for everyone, and effective care entails the continuous assessment and modification of an integrated plan that attends to the multiple and changing needs of the individual. Needs that should be addressed include not only AOD addiction but also coexisting mental disorders, social and emotional health, economic stability, and physical health including infectious diseases such as HIV/AIDS. Furthermore, effective treatment may include individual or group counseling, medications, behavioral change therapies, cognitive-behavioral therapies, and monitoring for AOD use during treatment. Finally, treatment does not need to be voluntary to be effective; however, it is critical that a person be engaged in treatment for an adequate period of time, as recovery from drug addiction can be a long-term process and often requires multiple episodes of treatment. Indeed, one of the best predictors of treatment effectiveness is the duration of treatment. People who stay in treatment longer than 3 months usually have better outcomes than those who do not.

The following section describes several types of AOD treatment programs. Such programs may be found in hospitals, medical facilities, specialized treatment centers, and the community, with services delivered by a variety of practitioners, including certified alcohol and drug counselors, psychologists, psychiatrists, nurses, social workers, and other trained professionals. Although the list is not exhaustive, it provides a general idea of what treatment program options are available.

Types of AOD Treatment Programs

Medical Detoxification Programs

Detoxification is often a first step in treatment or is considered a pretreatment. It is recommended for people who are unable to stop use on their own, who experience severe withdrawal symptoms, or who have medical problems that should be monitored. “Detox” is a medically supervised process of allowing the body to eliminate alcohol or other drugs over several days. Because this process may be medically dangerous and is often difficult and uncomfortable, it should take place in a medical or outpatient facility. Depending on the length and severity of AOD use, physical and psychological dependence on a substance may develop, leading to withdrawal symptoms

in the absence of the substance. Symptoms may include sweats; cramps; depression; anxiety; and difficulty eating, sleeping, and concentrating. Seizures or hallucinations may also occur. Although detoxification may be an important first step toward recovery, it is not effective alone without immediate referral to additional AOD treatment.

Outpatient, Partial Hospitalization, and Inpatient Programs

Outpatient, partial hospitalization, and inpatient programs share many programmatic characteristics. Typically, all include education about the nature of addiction, some combination of individual and group therapy, relapse prevention, case management or care coordination, medications when indicated, monitoring of substance use during treatment, and supportive group therapy. Because the severity of addiction, individual needs, and life circumstances require more or less intense treatment, people may choose to spend more or less time in the treatment facility.

Outpatient treatment programs are chosen by the vast majority of people seeking AOD addiction treatment. Most outpatient programs provide about 2 to 6 hours of care per week, which may be most suitable for people who do not want interruption in their daily work schedule, who do not require a more intense treatment regimen, who are unable to pay for inpatient treatment (which is considerably more expensive), who are unwilling or unable to be away from family, or who will experience a supportive environment outside of the program without exposure to substance use or pressure to use from others. Many people who have completed more intensive outpatient or inpatient treatment may opt to continue on a lighter outpatient schedule for maintenance in recovery, perhaps attending for an hour per week or per month, depending on individual needs and program requirements.

Partial hospitalization involves a more intensive outpatient treatment schedule and environment while participants live at home and attend treatment for 3 to 12 hours per day, 3 to 7 days per week. This type of program is more expensive than outpatient but less costly than inpatient care. As with any program, it is most suitable for someone who would benefit from this level of treatment and can afford the time and cost. It will also be most effective if the home environment is supportive of the individual’s recovery

and does not expose or pressure the individual to use substances.

Inpatient programs are more intensive than either outpatient or partial hospitalization programs but with similar treatment components, and participants reside within the facility for an extended period of time, usually 3 to 6 weeks. These programs may also be referred to as short-term residential programs or chemical dependency units. For some people, being away from their usual environment is most effective for them at the beginning of the recovery process. For instance, this may be the best option for individuals who have not been successful in less-intensive programs, who live far away from alternative programs and cannot travel on a regular basis, or who have medical or psychological conditions that should be monitored, or when the living environment is not supportive and not conducive to recovery. Following inpatient treatment, it is important that the individual be immediately connected with outpatient or extended care in order to continue recovery.

Long-Term Residential Programs

Residential treatment programs provide 24-hour care in a nonmedical setting for people who need additional, extended time and support in a structured setting to promote successful recovery from AOD use. The best-known model for residential treatment is the therapeutic community (TC). The TC focuses on resocializing individuals who have had relatively long AOD use histories, impaired social functioning, or chronic criminal recidivism. Length of treatment usually ranges from 6 to 12 months. In addition to addiction treatment in the form of education, counseling, AOD use monitoring, and behavioral training, vocational, social, and other services may be provided.

Opioid Addiction Programs

Because of the effects of opioid addiction on the brain, opioid dependency results in a severe withdrawal syndrome in the absence of the substance. This not only is a hindrance to the person seeking treatment but also requires a carefully planned treatment program. Programs include medication to alleviate withdrawal symptoms and strong cravings for the substance and are typically provided on an outpatient basis.

Depending on the severity and duration of opioid use, a short- or long-term process of detoxification may be most effective. Detoxification alone is not considered treatment for opioid addiction, but rather a way to relieve withdrawal symptoms while the individual adjusts to being substance-free. An effective program will also include individual or group therapy, monitoring of illicit drug use, relapse prevention, bolstering of support systems, substance education, and other components common in treatment for any other substance.

Medications used to treat opioid addiction include methadone, buprenorphine, and naltrexone. Methadone maintenance treatment is the best known and most widely used method for people who have more severe opioid dependency. Participants are administered methadone, a synthetic opioid that blocks the effects of other opioids, eliminates withdrawal symptoms, relieves drug craving, and helps to stabilize the person. Because there is potential for abuse or resale of methadone, it is dispensed in a carefully controlled environment, usually by a pharmacist. Contrary to the misperception that methadone replaces one drug of abuse with another, methadone is administered in doses that do not produce intoxication. Many adhere to methadone maintenance treatment programs for long periods of time, over several months or years. Buprenorphine is more an option for people with mild to moderate opioid addiction or who have tapered down from methadone treatment. This medication acts similarly to methadone but has a “ceiling” effect in that it does not have additional opioid effects beyond a certain level; this prevents accidental overdose and reduces the possibility of abuse. Finally, naltrexone blocks the effects of opioids, so it may be beneficial (when taken as indicated) to prevent relapse in individuals who have achieved abstinence from opioids and who are highly motivated not to return to opioid use.

Twelve-Step and Self-Help Groups

Although not considered formal treatment programs per se, consumer-developed groups are an important adjunct to addiction treatment programs. These include Twelve-Step support groups such as Alcoholics Anonymous and Narcotics Anonymous, as well as self-help groups such as Smart Recovery. Groups are usually organized and run by people who have recovered from addiction or who are in the

process of recovery. Participants in these types of groups often feel more comfortable with, and give more credibility to, those who have experienced similar struggles and who are personally familiar with the recovery process. Consumer-driven services are widespread nationally and internationally, easily available, and cost-free, making them convenient to attend.

Potential difficulties with these types of groups are the possibility of giving or receiving inappropriate advice and of not agreeing with a particular group's philosophy or not finding that philosophy to be helpful. For instance, Twelve-Step groups view abstinence as the only viable option, consider addiction a disease, and incorporate spiritual values into their philosophy. Smart Recovery, on the other hand, emphasizes self-reliance instead of reliance on a higher power and views addiction as a complex maladaptive behavior pattern over which a person has control and can change. As with any type of recovery assistance or program, one must consider the costs and benefits and the goodness of fit.

Conclusion

With all of the treatment program options, how does the consumer know which is best? First, the consumer should be educated about the options available and, by discussing an appropriate plan with a treatment provider, decide on the best course of action to take in recovery. Every person seeking treatment has varying levels of addiction, motivation, resources, and availability, and thus no program is perfect for everyone. Furthermore, although treatment programs share many characteristics, they vary significantly in their ability to retain participants in treatment. Research suggests that both patient attributes and program features have distinctive and complex influences on outcomes. Ideally, comprehensive assessments help to match individuals with the appropriate treatment plan; however, in reality, programs often have an established set of options to choose from. Moreover, the person's adherence to program requirements such as abstinence and attendance often affect the availability of options. For instance, if a person is unable to remain abstinent or to regularly attend an outpatient program, he or she may be offered a narrower range of services. On the other hand, this may demonstrate that a more intensive program, such as an inpatient one, would be more appropriate.

Finally, because length of treatment is such a key factor in AOD treatment success, whatever the individual or program can do to increase motivation and commitment to recovery, the better. A fairly new development in treatment practice is the use of systematic efforts to improve the individual's engagement in, and readiness for, treatment. These efforts are now recognized as being crucial to program effectiveness. In addition, improving the quality and structure of treatment services also raises participation levels and retention rates.

TREATMENT SETTINGS

There are a variety of settings available for the provision of substance abuse treatment. The type of setting chosen may depend on the client's physical, psychological, emotional, financial, and social needs and should be based on a thorough assessment and objective patient placement criteria. Each substance abuse treatment setting offers various programs and services designed to decrease substance misuse. In addition, the length of stay and the intensity of substance abuse treatment regimen can vary across treatment settings. The availability of various health care providers (e.g., certified drug abuse counselors, physicians, nurses, clinical psychologists, social workers, general practitioners) also differs across treatment settings. Treatment settings for substance use disorders typically include detoxification (pretreatment), long-term residential, short-term residential, intensive outpatient, outpatient, and support groups. This entry provides an overview of each treatment setting.

Detoxification Settings (Pretreatment)

Detoxification is the initial step toward obtaining sobriety. Although the client's psychological, social, and behavioral problems are not addressed in detoxification settings, detoxification is most successful when it includes assessment and referral components. Detoxification usually begins after a period in which the substance of choice is not consumed.

Detoxification can be based on either a medical or social model. In medical detoxification settings, the withdrawal process, or the cleansing of the body of alcohol or drugs, typically occurs under the care of a medical professional. Medical detoxification is designed for individuals with existing medical conditions or poor health and those who are anticipating severe withdrawal symptoms. The detoxification process can produce a wide variety of physiological and psychological symptoms, depending upon the substance or substances the person is dependent upon, and may include sweating, vomiting, stomach cramps, headaches, chills, restlessness, insomnia, depression, and anxiety. In the case of opioids, physiological symptoms are often comparable to a bad case of the influenza virus. The detoxification process is relatively safe for most drugs; however, detoxification from the

central nervous system depressants (e.g., alcohol, barbiturates, and benzodiazepines) should occur under medical supervision because untreated withdrawal can be medically dangerous. The severity of the symptoms and the length of the detoxification process vary by the type and duration of substance use.

Social detoxification is designed for individuals who do not have any urgent health problems. As such, social detoxification does not usually require medication or medical personnel. A social detoxification model emphasizes rest, social support, and alcohol or drug education. Depending on the extent of detoxification services needed, the social detoxification process can take anywhere from 3 to 10 days.

Long-Term Residential Settings

Long-term residential treatment can occur in a variety of settings. Therapeutic communities, also known as TCs, are the best-known form of long-term residential treatment and are usually associated with criminal offenders. Therapeutic communities have been around since the 1960s and are historically rooted in a therapeutic commune called Synanon. Charles Edwin Dederich was the charismatic leader of this nonfunded, self-directed community of criminally involved, alcohol- and drug-dependent individuals. Clients usually remain in a therapeutic community for 18 months to 3 years. The therapeutic community setting emphasizes the "community as treatment method," the need to "resocialize" clients, developing personal accountability, increasing social responsibility, and learning how to lead a socially productive life. These highly structured therapeutic communities can at times be confrontational, and behavior is reinforced with rewards and punishments. Activities in a typical therapeutic community would include clinical treatment groups, community and clinical management activities, educational training, and vocational training, as well as community or house meetings.

A therapeutic community is unique from other treatment settings because it is essentially staffed and managed by recovering alcohol- and drug-dependent individuals. The overall goal of a therapeutic community is for clients to remain completely abstinent from all alcohol and drugs. Treatment within a therapeutic community setting is usually structured in three phases. The first phase is an induction phase in which the individual is housed within the therapeutic community so there is minimal contact with individuals outside of the therapeutic community. In the second

phase, the individual resides in the therapeutic community but works outside. The third phase is the re-entry phase. In this phase, the individual lives and works outside the therapeutic community but returns for specific activities.

Short-Term Residential Settings

Short-term residential settings are the quintessential 28-day inpatient substance abuse treatment program. Oftentimes, the 28-day setting is the most recognized treatment setting among clients, medical professionals, and the general public. However, this length of stay was not based on research but rather on financial considerations.

The short-term residential setting is a popular treatment setting among individuals with alcohol or drug problems ranging from adolescents to business executives to celebrities. These settings were originally designed to provide treatment for alcohol-dependent clients; however, the majority of facilities now treat clients with alcohol and drug problems.

Clients in short-term residential settings reside in the inpatient program 24 hours a day for anywhere from 3 to 6 weeks. This means that clients eat all meals, shower, and sleep in the short-term residential facility. Within short-term residential substance abuse treatment settings, clients are immersed in the recovery process. The short-term residential setting usually incorporates the Twelve Steps of recovery from Alcoholics Anonymous (AA). The ultimate goal is abstinence from all alcohol and drugs. There are a variety of medications that are sometimes dispensed in short-term residential facilities for the treatment of alcohol or drug dependence. Examples of these medications include Antabuse and naltrexone for the treatment of alcohol dependence and buprenorphine for the treatment of opioid dependence. Oftentimes, clients in short-term residential facilities are diagnosed with both a substance abuse disorder and mental health problems. These clients, labeled with “co-occurring disorders” or as “dually diagnosed,” have issues that differ from clients with only substance use disorders. For example, clients with co-occurring disorders may require medications to treat their mental health problems. A clinically depressed client may receive a prescription for a selective serotonin reuptake inhibitor (SSRI).

Short-term residential treatment settings can be either hospital based or nonhospital based. These

nonhospital settings are generally based on the Minnesota Model (i.e., a disease concept, abstinence-based treatment that incorporates the Twelve Steps of recovery) and include such well-known facilities as the Betty Ford Clinic and Hazelden. During short-term residential treatment, clients engage in structured substance abuse treatment activities throughout the day. Interventions within short-term residential programs include individual counseling, group counseling, participation in support groups (e.g., AA or Narcotics Anonymous [NA]), and job skills training. These residential programs can also include more innovative treatment activities such as art therapy, music therapy, acupuncture, or yoga therapy. To illustrate, a typical client might eat breakfast and then engage in individual counseling. Afterward, the client might go to an employment seminar or job skills training for the remainder of the late morning. After lunch, the client may go to an AA meeting and then engage in art or music therapy.

Short-term residential substance abuse treatment facilities have been popularized by the media, but they are no longer the norm in substance abuse treatment. This is primarily the result of managed care. Over the past 20 years, managed care has generated intense scrutiny of substance abuse treatment practices in an effort to control costs, while hopefully increasing treatment efficacy. Both long- and short-term residential substance abuse treatment settings are expensive and oftentimes not covered by the client’s health insurance. Instead, clients are oftentimes referred by managed care organizations to an outpatient setting, such as an intensive outpatient program, because it is less expensive. These outpatient substance abuse treatment settings are now the most commonly used substance abuse treatment settings.

Intensive Outpatient Settings

The intensive outpatient setting falls between short-term residential treatment and outpatient treatment on the substance abuse treatment continuum. Intensive outpatient settings range in intensity and duration. For example, some intensive outpatient settings can provide “day” treatment in which the client comes to the substance abuse treatment facility for 8 hours per day, 5 days per week for several months. In essence, the day treatment approach is akin to full-time employment in that it is the client’s job to become

alcohol and drug free. Other programs can be less intensive and shorter in duration. Clients in this sort of intensive outpatient substance abuse treatment setting might attend treatment for 4 hours a day, 5 days a week for 28 days.

Most intensive outpatient substance abuse treatment settings are based on the Twelve-Step model. These programs aim for their clients to achieve a lifestyle free of alcohol and other drugs. Similar to the short-term residential substance abuse treatment settings, clients in intensive outpatient substance abuse treatment settings receive a variety of programming and services, including individual counseling, group therapy, Twelve-Step meetings, and job skills training.

Outpatient Settings

As alluded to earlier, outpatient substance abuse treatment settings are currently the most common settings for substance abuse treatment. Due to the rise of managed care organizations, the majority of alcohol- and drug-dependent clients will receive traditional outpatient care. Outpatient settings provide care to clients who come to the substance abuse treatment facility. Usually clients come in for treatment 1 to 2 hours per day, several days per week. These settings may be best suited for clients who are employed and have established non-drug-using social support networks. Clients receiving substance abuse treatment in an outpatient setting can still engage in everyday activities such as employment and child rearing. On the flip side, clients are also residing in their natural environment, which could provide greater exposure to the lures of substance use. Education is usually included in the treatment regimen in outpatient settings. In addition, due to the limited duration and frequency of the typical outpatient substance abuse treatment setting, individualized or group counseling is usually the only clinical service provided.

Another form of outpatient substance abuse treatment is methadone maintenance. Methadone maintenance is used only to treat clients who are addicted to heroin, morphine, or other opioid drugs. In a methadone maintenance setting, clients are prescribed a long-lasting synthetic opioid medication called methadone. In this agonist maintenance treatment, the client is orally administered a specified dose of methadone on a daily basis that will suppress opioid withdrawal for 24 to 36 hours. Methadone maintenance

is a minimal form of care that allows for the client to maintain his or her daily routine. Some clients receive treatment in a methadone maintenance clinic for years. In addition, the client will engage in individual or group counseling, and referrals will be provided to address other medical, psychological, and social needs.

Support Group Settings

Support group settings encompass all of the Twelve-Step programs, including AA, NA, and Cocaine Anonymous (CA). These support group settings are entrenched in the history of alcohol dependence treatment. (AA was cofounded by Bill W. and Dr. Bob in the mid-1930s.) These Twelve-Step programs are run by the individuals who attend the meetings and are guided by the Twelve Steps. There is no identifiable spokesperson or figurehead for any Twelve-Step program, because the programs are based on the principle of anonymity. Individuals who attend meetings are identified only by their first name. For example, the First Step of Alcoholics Anonymous (“We admitted we were powerless over alcohol—that our lives had become unmanageable”) is encompassed in meeting introductions (e.g., “Hi. My name is _____. I’m an alcoholic.”).

Twelve-Step meetings are held at different times across the day (i.e., morning, noon, and night) worldwide. These settings are guided by individuals who work their way through each of the Twelve Steps. This process is facilitated by attendance at meetings, the principle of sponsorship, and the Twelve-Step literature. Twelve-step settings eliminate economic barriers to participation in substance abuse treatment because meeting attendance is free. In addition, the anonymity reduces the stigma attached to alcohol and drug dependence. Spirituality, rather than religiosity, is a central feature of any Twelve-Step setting. Each individual in a Twelve-Step program is encouraged to select a sponsor who can provide fellowship and guide the individual through the Twelve Steps. The “Big Book” is also the centerpiece of Twelve-Step settings. It contains an outline of Alcoholics Anonymous and a collection of stories of people in recovery.

Twelve-Step meetings are usually divided into “closed” and “open” meetings. Closed meetings are attended only by members; closed meetings provide a forum for drug- or alcohol-dependent individuals to discuss topics with which they may feel

comfortable, talking only with other drug- or alcohol-dependent individuals. Open meetings are open to both alcohol- and drug-dependent individuals and non-substance-using individuals. Twelve-Step settings view recovery as a lifelong process. Therefore, individuals are described as “recovering” rather than “recovered.” The frequency of attendance at Twelve-Step meetings varies. Some individuals attend Twelve-Step meetings once a day for their entire lives; others attend meetings only when they feel the participation is needed.

Although some alcoholics and addicts recover through attending support groups as opposed to formal treatment, professionals regard support groups as an adjunct to treatment and a means to support ongoing recovery.

Conclusion

No one treatment setting is appropriate for all alcohol- and drug-dependent individuals, because addiction is a complex disorder. Although the choice of treatment setting should be determined after a comprehensive assessment and should be dependent on the needs of the client, financial considerations and availability are often determining factors. Substance abuse treatment settings offer a variety of behavioral and pharmacological approaches. Care should be taken in choosing an appropriate substance abuse treatment setting.

TUBERCULOSIS

Tuberculosis (TB) is among the oldest recorded diseases in human history. Infection with *Mycobacterium tuberculosis* occurs when the bacteria are expelled—along with moisture from a diseased person’s respiratory system while coughing, sneezing, speaking, singing, or exhaling—and are inhaled into another person’s lungs. Transmission of TB through close human contact is common; about one third of the world is infected with TB. Only a minority of those infected will develop active TB disease, which is deadly if untreated or improperly treated. Progression from infection to active disease is much more likely among people with compromised immune systems, such as the very young, the very old, and those with HIV infection. TB has long been linked in the popular imagination with alcoholism and drug addiction, and in fact heavy drinkers have an elevated risk of TB disease, as do injection and other drug users. Furthermore, substance users tend to come from the marginalized groups most vulnerable to TB, including the homeless, those living in poverty, and those without access to health care. Because in the United States the disease disproportionately affects substance users, they have been a particular target of public health efforts to control TB. Since the late 19th century, these efforts have been directed by state and local governments acting on their legal authority to protect the public’s health and safety. Modern TB control efforts consist essentially of a dual strategy of ensuring a cure for every case of TB disease, while at the same time confining active cases in some manner, in order to reduce contact with others and thus transmission of TB while the patient is infectious.

TB is often described as a “social disease.” Some use the term simply to recognize the influence of malnutrition, crowded or otherwise inadequate housing, and other aspects of poverty on progression from infection to active disease. Others go further to argue that the ultimate cure for TB must also be social and should ameliorate the social problems that give rise to the disease. Modern TB control efforts in

the United States, as well as globally, have largely recognized that it is essential to address the socio-economic context of TB disease in order to effect a cure, although the extent to which public health officials are committed to solving social ills has varied over time and place.

Public Health Responses

Early public health responses to TB called for removing its victims from their social environment, often to *sanatoria*, where bed rest, fresh air, and a nourishing diet were usually all that was offered toward a cure. The discovery in the late 19th century that TB was transmitted through close human contact did not dispel popular beliefs linking susceptibility to TB to poverty and sometimes to the immorality and depravity thought to flourish in poverty. Rather, the understanding of the disease as contagious gave new energy to campaigns to remove sick individuals from crowded urban communities, for the safety of the healthy as much as for the improvement of the sick. Those who resisted isolation were often characterized as recalcitrant, even “vicious,” and a danger to their communities. The unemployed, drifters, and alcoholics were particularly vulnerable to such characterization. Those who did agree to confinement within a public or private sanatorium were often offered some measures to facilitate their social “rehabilitation,” including vocational training, psychiatric evaluation, and treatment for alcoholism, in addition to medical care.

Antibiotic treatment for TB became available in the mid-20th century, and public health departments adopted effective antibiotic treatment of TB cases as the most direct means to prevent transmission of the disease. The combination of the drug isoniazid with streptomycin, para-aminosalicylic acid, and later, rifampin, offered a cure for patients who stayed on the therapy for a prolonged period, often as long as 2 years. Many patients who had been long-term residents at sanatoria were discharged and given outpatient antibiotic treatment.

Even as new anti-TB drugs were developed, the promise of pharmacotherapy was tempered by the corresponding new challenge of ensuring that outpatients completed the therapy and avoided the reactivation of their disease. Not only were patients with reactivated disease infectious, they presented the threat of drug-resistant strains of TB emerging from a partially completed course of antibiotics. Even though

reactivated cases could stem from improper prescribing of medications, noncompletion of therapy was widespread. Coincident with the use of antibiotics, a majority of U.S. states adopted procedures for forcibly detaining patients who had proved unwilling or unable to complete TB treatment. Detention was originally intended to shield the public from patients who were contagious, but it was also used for patients who repeatedly stopped treatment before it was finished. Such patients presented no immediate contagion threat, but their refusal to complete therapy created the potential for reactivation and thus future contagion, perhaps with a drug-resistant strain of TB. Several court decisions established patients’ right to due process in the course of detention, while upholding the right of public authorities to enforce completion of TB treatment. Detention procedures varied locally and were usually preceded by measures to convince patients to complete therapy, such as education and the provision of social services, including treatment for alcoholism.

Public support and public funding for TB control declined through the 1960s and 1970s, largely as a result of downward rates of TB. States and large cities reduced funding for TB control, closed TB programs, and reduced the number of hospital beds dedicated to TB. Many believed that new pharmacological therapies had subjugated the age-old disease and that TB would soon be nearly eradicated in developed countries.

Yet if the bacterial power of TB was debilitated, its social force was unchecked. In the early 1980s, large cities in the United States witnessed a dramatic resurgence of TB, with reversals of downward trends and rates of new cases doubling. New York City was particularly hard hit, with cases tripling from 1979 to 1992. The defunding of public TB control programs coincided with long-term, upward trends in urban poverty, increased immigration from countries where TB is endemic, and, in some cities, housing shortages. Rising homelessness was particularly acute in New York City, where families squeezed out of low-income housing joined newly de-institutionalized mental health patients in overcrowded shelters. Outbreaks of TB in shelters, hospitals, and prisons revealed that infection control systems for congregate living facilities were inadequate. The 1980s also saw a rise in substance use in major U.S. cities, and injection drug and crack cocaine users were disproportionately affected by the new surge in TB. Most important, the emergent epidemic of HIV/AIDS created a national pool of

immunocompromised individuals uniquely vulnerable to TB disease. In the midst of resurgence, there was a frightening subepidemic of multidrug-resistant TB, stemming largely from widespread noncompletion of treatment. Multidrug-resistant TB required a more complex, longer course of treatment and, in immunocompromised patients, led to extremely high fatality rates if not adequately treated. Many of these causative factors intersected. So, for instance, the population within an urban shelter system included high numbers of substance users who tended to be malnourished and spent time together, often engaging in behaviors that put them at high risk for HIV infection. In addition, these individuals had no regular access to health care or were reluctant to access services for fear that their drug use would be investigated. Such a group would be at high risk for TB infection and for progression to TB disease in the absence of appropriate treatment.

Directly Observed Therapy

In response, federal, state, county, and local resources were invested in rebuilding TB surveillance and treatment programs and in strategies to ensure completion of TB treatment while providing alternatives to mandatory detention. The most important of these strategies has been directly observed therapy (DOT) for outpatients, in which patients receive daily or twice-weekly doses of TB medications from a health care worker who witnesses that each dose is ingested. DOT may be done in a clinical setting, patient residences, schools, workplaces, or other agreed-upon settings. DOT is often combined with other outpatient services, including substance use treatment programs, and includes access to social service providers. The intensive resources required by DOT are invested in patients who have demonstrated that they are unwilling or unable to complete a prescribed course of TB treatment on time, and many programs go further and initiate DOT for patients believed to be at high risk for noncompletion, including active or former substance users. The routinization of DOT has led to a decline in incidence of detention of TB patients and much-improved rates of treatment completion. This improvement, along with increased funding and interagency collaboration, improved surveillance and diagnostic techniques, and changes in recommended drug regimes, enabled TB control programs to regain the ground lost in the 1980s and early 1990s, so that TB in the United States is now at historic lows.

Challenges

Despite these successes, TB poses stubborn challenges to its host societies. The majority of cases of TB disease in the United States are now among foreign-born individuals, and TB control programs often struggle to meet the medical and material needs of foreign-born patients in linguistically and culturally appropriate ways. Treatment of TB infection in individuals who do not have active disease but who are considered to be at high risk for progressing to active disease is considered an essential step toward elimination of TB in the United States. High-risk groups appropriate for treatment of TB infection include children; people with HIV or other immunosuppressive conditions; people in congregate settings such as prisons, shelters, and long-term care facilities; and alcohol and other drug abusers. Rates of treatment completion for TB infection are consistently low, weakening the effectiveness of this strategy and raising fears about the development of drug resistance among people with TB infection. The progression of multidrug-resistant TB into extensively drug resistant TB, for which treatment options are limited, is a reminder of the disease's undiminished threat.

TWELVE-STEP FACILITATION

Twelve-Step Facilitation (TSF) is an evidence-based, manual-guided, 12-session outpatient treatment program for substance use disorders. TSF had its origins in Project MATCH, a national collaborative study of treatment for alcohol abuse and alcoholism funded by the National Institute on Alcohol Abuse and Alcoholism. Project MATCH sought to test a series of treatment matching hypotheses across three different treatments: TSF, Cognitive Behavioral Therapy (CBT), and Motivational Enhancement Therapy (MET). The hypotheses, based on earlier single-site studies, were based on the assumption that these different treatments would be differentially effective across different client demographics, problem severity, and personality dimensions. The initial outcome data from Project MATCH showed that TSF was effective in significantly reducing drinking behavior and that this improvement was sustained at the time of the 12-month follow-up assessment. Contrary to predictions, none of the matching hypotheses were confirmed. TSF proved to be equally effective with moderate problem drinkers as it was with severe drinkers, and it worked as well with men as it did with women.

In a 3-year follow-up study of Project MATCH, one of the original matching hypotheses was confirmed. Specifically, it was found that TSF was more effective for those clients whose social networks supported drinking—in other words, clients whose friends and family members drank. This finding, coming 2 years after the original outcome data were published, led the study authors to recommend that involvement in Alcoholics Anonymous (AA) should be given special consideration for those clients whose social networks are supportive of drinking, irrespective of the type of therapy they receive. Accordingly, TSF has adopted active participation in AA or other Twelve-Step fellowships as its primary treatment goal. TSF seeks to achieve this goal through a combination of education, coaching, role playing, and helping clients examine and work through resistance.

Theoretical Underpinnings

Twelve-Step recovery fellowships such as AA and Narcotics Anonymous (NA) evolved as social institutions organized by peers, as opposed to being professionally devised treatment programs. Accordingly, the program of recovery that is embodied in the Twelve Steps of AA, as well as the rituals and traditions that define Twelve-Step fellowships, are not constrained by any one theoretical framework. However, they do reflect certain core beliefs about the nature of addiction and recovery. These core beliefs include the following.

Powerlessness Over Addiction

AA, NA, and other Twelve-Step fellowships believe that addiction is a progressive illness. The compulsive behavior that addiction leads to (e.g., drinking, using drugs, gambling) eventually progresses to the point where individual willpower alone is not enough to contain it, hence Step 1: “We admitted we were powerless over alcohol, that our lives had become unmanageable.” In embracing this step, members of AA are not acknowledging either pervasive powerlessness or hopelessness; rather, they are acknowledging that they have become unable to contain their addiction through individual willpower and that the addiction has led to consequences that make their lives increasingly chaotic. Steps 2 and 3, meanwhile, instill hope and point the way to recovery.

Recovery Versus Cure

Twelve-Step fellowships are founded on the belief that addiction is an illness that cannot be cured but can be arrested through ongoing active involvement in a Twelve-Step fellowship, combined with a lifelong effort to “work” the Twelve Steps. Together these activities are often referred to, within the Twelve-Step community, as “walking the walk.”

Spirituality and Pragmatism

Twelve-Step fellowships have a long-standing tradition of balancing spirituality with pragmatism. The Twelve Steps of AA make several references to God, and they assert that the end result of following the steps is a “spiritual awakening.” At the same time, because they are essentially secular organizations,

Twelve-Step fellowships do not advocate for any particular view of God; rather, they encourage members to embrace any concept of a “power” greater than their own individual willpower that is acceptable to them, as a key to recovery. It is acceptable, for example, to embrace the power of the group itself (i.e., group support) as one’s “higher power.” Because AA and other Twelve-Step groups lack a religious dogma as well as a centralized controlling organizational structure, Twelve-Step meetings have proliferated with respect to format and content. Some meetings have a decidedly spiritual overtone; others are more pragmatic. In larger urban areas it is easy to find AA meetings for men, for women, for gay men or women, for particular cultural groups, for professionals, and so on. All qualify equally as AA groups. As for pragmatism, most AA slogans and aphorisms—“One Day at a Time,” “Easy Does It”—embody practical advice of a nonspiritual nature. In addition, official AA publications such as *Living Sober* consist exclusively of practical suggestions for staying sober, such as avoiding hunger and loneliness and coping with resentment and anger.

Desired Therapist Characteristics

Therapists need not necessarily be regular participants in a Twelve-Step fellowship, or be in recovery themselves, in order to effectively implement TSF. However, therapists do need to be familiar with the Twelve-Step culture if they hope to be maximally effective. Toward that end it is highly recommended that therapists who are not in recovery, or who are unfamiliar with Twelve-Step meetings, attend a number of different open meetings in order to become familiar with their tone, as well as their diversity.

In addition to familiarizing themselves with the Twelve-Step culture, therapists seeking to implement TSF most effectively are advised to reflect on their thoughts relative to the agent of change that is responsible for ongoing recovery. TSF takes the position, as supported by research, that active, ongoing participation in a Twelve-Step fellowship is what is ultimately responsible for sustaining recovery—as opposed, for example, to any particular skill the therapist might teach or insight the therapist might instill. With this in mind, the therapist is cognizant of the need to refer the client to the resources of the fellowship (e.g., going to meetings, getting a sponsor, using the telephone) as opposed to reinforcing reliance on the therapist.

Organization

TSF is organized into three parts: the core program, the elective program, and the conjoint program. Each of these programs consists of a number of manual-guided topics, as follows:

Core program: assessment; acceptance; surrender; getting active; termination

Elective program: genograms; enabling; people, places, and routines; emotions; moral inventories; relationships

Conjoint program: enabling; detaching

Therapists are advised to cover the entire core program and to selectively choose topics from the elective and conjoint programs in order to develop an individualized treatment plan for each client. The two-session conjoint program is strongly recommended for inclusion in a treatment plan for the client who has a significant other who is willing to participate.

Structure

The assessment and termination sessions of TSF each have a unique structure. For all other TSF sessions, therapists are guided in following a consistent format, as follows:

Review: The therapist discusses the client’s recovery activities since the last therapy session. Specific areas of inquiry include the following: all Twelve-Step meetings attended; Twelve-Step literature read by the client; days of sobriety; “slips” (including what seemed to cause the slips and what the client could do differently next time); and any entries made in the client’s recovery journal.

New material: In this part of the session the therapist uses a facilitator guide and session checklists to facilitate a discussion of a topic selected from one of the three TSF programs.

Recovery tasks: In this wrap-up to the TSF session, the therapist elicits from the client what he or she learned in that session. The therapist ends the session by engaging the client in a discussion of specific recovery tasks that the client agrees to engage in before the next session. Typical recovery tasks include specific AA or other Twelve-Step meeting to attend,

specific suggestions regarding ways to “get active” in meetings, handouts to be completed between sessions, and readings to be done.

Process Issues

Therapists wishing to implement TSF need to be cognizant of certain process issues, the first of which is to avoid therapist “drift” over time. Therapist drift refers to any inclination to allow therapy sessions to diverge, to any significant degree, from the content and structure of TSF. Examples of therapist drift include forgetting to begin the session with a review of recovery-related activities since the last session, allowing the client to take the conversation outside the bounds of TSF (and therefore leaving insufficient time to cover new material), or failing to assign recovery tasks at the end of the TSF session.

A second issue is called “maintaining therapeutic momentum,” and it relates to the issue of therapist drift. TSF considers it vital that the therapist get the client accustomed to following the therapeutic structure and format. For example, clients should become accustomed to being given recovery tasks and to being asked about their compliance with these tasks at the beginning of the next session. Therapeutic momentum is considered important to getting clients to “work” the TSF program, just as they are encouraged to “work” the steps of AA or NA.

Content

The following is a synopsis of the material that therapists cover when implementing TSF. Each topic includes specific therapist checklists that can be used both by therapists, to be sure they cover all the material, and by supervisors who may wish to monitor treatment fidelity. Many topics also include client handouts that may be used in-session or assigned as recovery tasks.

Core Topic 1: Assessment

As part of this initial session the therapist administers the Alcoholics Anonymous Affiliation Scale, which provides a pretreatment baseline measure of the client’s level of participation in AA or NA. The therapist also conducts a substance use history, catalogs consequences associated with substance use, assesses tolerance and loss of control, and shares a diagnosis

with the client. The client is given an overview of TSF and is assigned initial recovery tasks.

Core Topic 2: Acceptance

Following the review, the new material presented centers on Step 1 of AA and NA, the concepts of unmanageability, loss of control, and powerlessness as they are defined within the Twelve-Step culture. The concept of denial is also introduced and illustrated, and recovery tasks are assigned.

Core Topic 3: Surrender

New material in this topic involves a discussion of Steps 2 and 3 of AA and NA and the concepts of hope (for recovery) and willingness (to reach out to others for help). An optional DVD, titled *Introduction to Twelve-Step Groups*, may be shown to give clients an idea of what to expect when attending AA or NA meetings. Recovery tasks assigned include reading and attending one or more Twelve-Step meetings.

Core Topic 4: Getting Active in AA or NA

The focus of this topic is to promote active participation in a Twelve-Step fellowship through discussion, education, and role playing. Key aspects of getting active include participating in meetings, learning to utilize the telephone and e-mail to build a support network of recovering individuals, and obtaining a sponsor. Recovery tasks include specific recommendations for things to do to facilitate active involvement, such as volunteering for housekeeping duties, arriving early for meetings, and making a list of things to look for in a potential sponsor. The client handout used in this topic is the Recovery Journal.

Elective Topic 1: Genograms

The genogram technique originally developed for use in family therapy is adapted in TSF to help construct a visual “family tree” with a focus on substance abuse and addiction and the consequences for the individual and for families. The goal of this topic is to reinforce the concept of addiction as an illness, which is, in part, the result of a biological vulnerability, and also to motivate clients by pointing out the potentially devastating consequences of addiction.

Elective Topic 2: Enabling

This elective topic defines and illustrates the concept of enabling and the role enabling plays in allowing addiction to progress. Motivations for enabling are explored, forms of enabling are defined, and the client is asked to discuss why he or she might have promoted enabling either intentionally or accidentally. The client handout used in this topic is the Enabling Inventory.

Elective Topic 3: People, Places, and Routines

The goal of this elective topic is to help the client understand the significant role that people, places, and routines play in sustaining addiction. For example, research shows that a social network supporting of alcohol or drug use contributes to relapse. The therapist works with the client to develop an inventory of people, places, and routines that promote addiction versus a parallel inventory of people, places, and routines that would support recovery. The client handout used in this topic is the Lifestyle Contract.

Elective Topic 4: Emotions

The purpose of this topic is to help the client understand how emotional states can affect recovery and, specifically, how certain emotions can trigger an urge to drink or use drugs. The therapist helps the client identify his or her most dangerous trigger emotions and how the client might cope with them. The client handout used in this topic is the HALT Worksheet.

Elective Topic 5: Moral Inventories

In this elective topic the therapist explores with the client the nature of the damage that substance abuse or addiction may have done to self and others and the extent to which the client might be experiencing guilt or shame over this. Also, the therapist helps the client to construct a balanced “moral inventory” that includes not only faults, flaws, and errors but also personal assets and positive acts. The client handout used in this topic is the Moral Inventory.

Elective Topic 6: Relationships

In this elective topic the therapist helps the client focus on how addiction damages relationships,

including the client’s most important relationships. The therapist also guides the client in defining and establishing rules for healthy, effective communication and conflict management. Finally, the therapist explores with the client ways in which sexual victimization may have contributed to substance abuse, as well as how substance abuse may have made the client vulnerable to such victimization. The client handout used in this topic is the Relationship Inventory.

Conjoint Topic 1: Enabling

This topic is intended for use in the context of a conjoint session with the substance abuser and his or her significant other. As in Elective Topic 2, the therapist, working with the couple, defines and illustrates the concept of enabling and the role enabling plays in allowing addiction to progress. Motivations for enabling are explored, forms of enabling are defined, and the client is asked to discuss how and why he or she might have promoted enabling either intentionally or accidentally. The client handout used in this topic is the Enabling Inventory.

Conjoint Topic 2: Detaching

This is the second of two sessions that are recommended for use when a client has a significant other who is willing to participate. In this session the therapist defines and illustrates the concept of “detaching” and contrasts it to “enabling.” The therapist helps the significant other, in the presence of the client, identify specific ways in which he or she might detach from addiction, as opposed to enabling it, in the future. The client handout used in this topic is the Enabling/Detaching Worksheet.

Termination

The goal of the termination session is to allow the therapist and the client to jointly assess any progress the client has made both in staying clean and sober and in getting actively involved in a Twelve-Step fellowship. The Alcoholics Anonymous Affiliation Scale is administered, and its results are compared with the client’s pretreatment score. The client is asked to give the therapist feedback about the most useful aspects of the TSF treatment program, his or her experiences in AA or NA, his or her plans for recovery now that

treatment is over, and any suggestions for how the program might be improved.

Conclusion

TSF is a manual-guided, evidence-based outpatient treatment program that can be used with men and women across a range of substance abuse problem severity. TSF is particularly indicated for substance abusers whose social network tends to support drinking or drug use.

TWELVE-STEP RECOVERY PROGRAMS

Twelve-Step fellowships are commonly recognized and widely attended groups for recovery and support. Involvement in Twelve-Step groups such as Alcoholics Anonymous, Narcotics Anonymous, and Cocaine Anonymous is correlated positively with both retention in treatment and abstinence. Most Twelve-Step

groups introduce a spiritual focus toward life, espouse principles of conduct, and provide ongoing support for as long as an individual wishes to participate.

The Twelve Steps have been described as a way of life and are applied in a variety of recovery fellowships. Behavioral issues such as compulsion or addiction to sex, food, and gambling have been found to be resolved, or at least placed in remission, with the daily application of the Twelve Steps in such fellowships as Sexual Compulsives Anonymous, Overeaters Anonymous, Gamblers Anonymous, and Emotions Anonymous.

There are Twelve-Step groups that have been adapted to meet participants' needs, preferences, and level of comfort. Depending on the population and perhaps geographic location, there may be women's groups, groups for people who are hearing impaired, men's meetings, Spanish-language groups, meetings for agnostics, gay, lesbian, and bisexual groups, young people's meetings, and meetings for beginners.

Sponsorship Within the Twelve Steps

Frequently, Twelve-Step programs utilize a mentoring model wherein an experienced member known as a sponsor guides a less experienced member through the process of understanding and applying the steps as a personal program of recovery. A sponsor is frequently described as an individual who demonstrates a life in recovery that the new member finds attractive and may want to emulate. Many publications from Twelve-Step fellowships emphasize that sponsorship is a "one-on-one" relationship of shared experiences using the structure of the Twelve Steps as a foundation of the relationship. Spiritual growth as defined by the Twelve-Step process is often the focus of these relationships, and individuals may study together the literature specific to the obsession or addiction the two have in common. Fundamentally, the sponsor has the single purpose of helping the new member begin his or her recovery from the addiction that brought the individual into the Twelve-Step program.

A primary tenet of Twelve-Step recovery is a surrender of willful self-reliance and adoption of the practice of reliance on God or another "Higher Power" of the member's own understanding. Proponents of Twelve-Step programs allege that agnostics and even atheists can be helped by a Twelve-Step program with a spiritual focus. It is frequently stated in Twelve-Step

meetings that any power perceived as being greater than oneself will suffice, provided the power is not any other single individual or one's own unaided will.

Limited research has been conducted to examine the efficacy of Twelve-Step programs. This literature is not clear in terms of understanding the effectiveness of the Twelve Steps when held to rigorous scientific examination. In spite of this lack of scientific evidence, Twelve-Step programs inspire nearly universal acclaim and enthusiasm among addiction treatment personnel in the United States. The anecdotal evidence postulated by so many individuals participating in these groups offers hope to those still suffering from their addiction.

Groups Applying the Twelve Steps

Regardless of the lack of scientific evidence, there continue to be groups of individuals adopting the original Twelve Steps as their path to recovery from substance or other behavioral addictions. Perhaps it is the simplicity of the Twelve Steps and how they guide recovery efforts, or the power of a person's belief in the steps, that explains the expanding number of Twelve-Step groups. One common experience of Twelve-Step recovery programs is the availability of others who proclaim the steps as their personal guide to recovery and those individuals' willingness to share their experience, strength, and hope with newcomers.

Listed below are examples of the more common Twelve-Step programs in communities across the country. Although the following list is not comprehensive, it provides a well-rounded picture of the groups applying the Twelve-Step model.

Adult Children of Alcoholics is a Twelve-Step, Twelve-Tradition program of women and men who grew up in alcoholic or otherwise dysfunctional homes. They meet with each other in a mutually respectful, safe environment and acknowledge their common experiences. They take positive action, by practicing the Twelve Steps and accepting a loving Higher Power of their understanding. Their success is in finding freedom from the past and a way to improve their lives.

Al-Anon/Alateen has been offering hope and help to families and friends of alcoholics for over 50 years. No matter what relationship a person has with an alcoholic or whether he or she is still drinking, all who

have been affected by someone else's drinking can find solutions that lead to serenity in the Al-Anon/Alateen fellowships.

Alcoholics Anonymous is a fellowship with the only requirement for membership being a desire to stop drinking. Members' primary purpose is to stay sober and help other alcoholics achieve sobriety.

Chemically Dependent Anonymous does not make distinctions in the recovery process based on any particular substance, believing that the addictive-compulsive usage of chemicals is the core of their disease, and the use of any mood-changing chemical will result in relapse.

Cocaine Anonymous is a fellowship of men and women who have the primary purpose of staying free from cocaine and all other mind-altering substances and to help others achieve the same freedom. They use the Twelve-Step program because they believe it works.

Co-Dependents Anonymous (CoDA) is a program of recovery with the goal of achieving freedom where there has been bondage and peace where there has been turmoil in relationships with others and oneself. Application of the Twelve Steps and principles found in CoDA to daily life and all relationships reveals a new freedom from self-defeating lifestyles.

Debtors Anonymous is a fellowship of individuals with a goal to solve their common problem and help others to recovery from compulsive spending resulting in debt. Their primary purpose is to stop credit-based spending one day at a time and to help other compulsive debtors stop incurring unsecured debt.

Dual Recovery Anonymous is a fellowship of people who meet to support each other in their common recovery from both an emotional or psychiatric illness and chemical dependency. Dual Recovery Anonymous is a Twelve-Step, self-help program that is based on the principles of the original Twelve Steps and the experiences of men and women in recovery with a dual diagnosis.

Gamblers Anonymous is a fellowship of individuals attempting to solve their common problem and help others recover from their gambling problem. Their primary purpose is to stop gambling and to help other compulsive gamblers do the same.

Love Addicts Anonymous is a fellowship of men and women whose common purpose is to recover from unhealthy dependency on love as it plays out in their fantasies and relationships.

Marijuana Anonymous is a fellowship of men and women who share their experience, strength, and hope with each other that they may solve their common problem and help others recover from marijuana addiction.

Narcotics Anonymous is a nonprofit fellowship or society of men and women for whom drugs have become a major problem. When adapting Alcoholics Anonymous's first step, the word *addiction* was substituted for *alcohol*, thus removing drug-specific language and reflecting the disease concept of addiction.

Nicotine Anonymous is a nonprofit, Twelve-Step fellowship of men and women helping each other live nicotine-free lives. The primary purpose of Nicotine Anonymous is to help all those who would like to cease using tobacco and nicotine products in any form.

Overeaters Anonymous is a fellowship of individuals who, through shared experience, strength, and hope, are recovering from compulsive overeating. Their primary purpose is to abstain from compulsive overeating and to carry this message of recovery to those who still suffer.

Recovering Couples Anonymous (RCA) is a fellowship of recovering couples. They are committed to restoring healthy communication and caring, finding greater joy and intimacy. The only requirement for RCA membership is a desire to remain in a committed relationship.

Sexaholics Anonymous is a fellowship of men and women with a primary purpose of staying sexually sober and helping others achieve sexual sobriety. Sexaholics Anonymous is a recovery program based on the principles of Alcoholics Anonymous; it received permission from AA to use its Twelve Steps and Twelve Traditions in 1979.

Survivors of Incest Anonymous is a support group of women and men, 18 years or older, who are guided by a set of 12 suggested steps and 12 traditions. The only requirements for membership are a history of being a victim of child sexual abuse and no current involvement in the abuse of a child.

Conclusion

Twelve-Step programs appear to represent people's efforts to find relief from their emotional pain as a result of substance or behavioral addiction or compulsion. Each group has in common an effort to bond with others who experience the same life struggle and apply the Twelve-Step path to an emotional recovery and serenity. Most Twelve-Step groups stress that the only requirement for membership is the desire to stop

using the substance or stop demonstrating the behavior causing the emotional distress. The common bond of interpersonal relationships under the umbrella of shared struggles in life is the ultimate intention of Twelve-Step programs.

All Twelve-Step programs begin with an admission of an individual's powerlessness over his or her substance abuse or compulsive behavior (first step) and end with a spiritual awakening as a result of the individual's efforts and intention to share the message with others while applying the learned principles in every aspect of his or her life (twelfth step). Ultimately each Twelve-Step program offers the individual a way of life that is free from his or her substance or compulsive behavior while developing a life-long plan for recovery.

A common criticism of Twelve-Step programs is the spiritual foundation and how this may be religious in nature. The ongoing debate of spiritual versus religious appears to be a rationalized effort to avoid the suggested step asking the individual to turn over his or her will and life to "God" as god is understood by that person (third step). The presence of God or a Higher Power in the Twelve Steps is simply an effort to realize that each individual is not in control of all life issues and that acceptance of powerlessness is the answer to all his or her problems. The steps are a journey of surrender to a higher power, confession of life harms to self and others, and asking for removal of the character defects that were learned in the process of self-examination.

Development of a spiritual foundation in life is the common denominator among Twelve-Step programs. Admitting powerlessness, surrendering to a higher power, and living life on life's terms are common expressions from members of any of the aforementioned Twelve-Step programs. When members achieve abstinence from their substance or behavior, confidence grows in knowing they can and will do the next right thing while continuing to develop a spiritual way of living through the lessons within the Twelve Steps.

TWELVE STEPS

In 1939 the basic text for Alcoholics Anonymous was published, and in its fifth chapter, 12 steps were suggested as a program for recovery from alcoholism. Since then, “The Twelve Steps” have become synonymous with the term *self-help* or *support group program*, and their concepts have been applied to a variety of addictive maladies, including gambling, narcotics, overeating, and sex. What are the steps and the ideas behind them? How do they address addictive problems? This entry reviews the steps individually and collectively and sees how they are applied to various problems.

The Twelve Steps of Recovery

Alcoholics Anonymous allows the reprinting of the Twelve Steps of recovery with written permission from Alcoholics Anonymous World Services that includes a statement that AA has neither reviewed nor approved the content of the publication. This statement is included at the end of this entry.

1. We admitted we were powerless over alcohol—that our lives had become unmanageable.
2. Came to believe that a Power greater than ourselves could restore us to sanity.
3. Made a decision to turn our will and our lives over to the care of God *as we understood Him*.
4. Made a searching and fearless moral inventory of ourselves.

5. Admitted to God, to ourselves, and to another human being the exact nature of our wrongs.
6. Were entirely ready to have God remove all these defects of character.
7. Humbly asked Him to remove our shortcomings.
8. Made a list of all persons we had harmed, and became willing to make amends to them all.
9. Made direct amends to such people whenever possible, except when to do so would injure them or others.
10. Continued to take personal inventory and when were wrong promptly admitted it.
11. Sought through prayer and meditation to improve our conscious contact with God *as we understood Him*, praying only for knowledge of His will for us and the power to carry that out.
12. Having had a spiritual awakening as a result of these steps, we tried to carry this message to alcoholics, and to practice these principles in all our affairs.

Analysis of the Twelve Steps

The initial driving concept of the steps—and to many people the most objectionable—is personal powerlessness. Persons seeking to practice the steps first admit they are powerless over their malady and that their life has become unmanageable. This is counterintuitive for many people who have been socialized to value and believe that self-control and willpower will solve most problems. With the first step, admission of one’s own essential limitations is seen as key to overcoming difficulties. People using the steps will let go of the idea that they will personally and willfully be in control of their addictive behavior. Evidence for the truth of this conclusion will be drawn from the previously out-of-control addictive behavior—usually marked by repeated failed attempts at self-control. The acceptance of personal powerlessness, that the addiction is in fact beyond self-control, is often liberating for individuals. For others, it is just too bitter a pill to swallow.

When the basic text for Alcoholics Anonymous first advanced this concept as part of a larger program of recovery, many saw it as radical, particularly with regard to alcoholism. The idea had, however, been around in various forms for a long time, perhaps having its base in diverse religions that suggested all overwhelming human foibles were best addressed by powers greater than those of humans themselves.

Coming to believe that a power greater than oneself could restore sanity of mind is, in fact, the second step. Participants in this suggested program of recovery are invited to consider the idea of a “higher power” (a phrase frequently used in support group meetings) that will do for them what they cannot do for themselves, namely, overcome the seemingly insane obsessive and compulsive nature of addiction. Although the word *sanity* often draws the most attention and controversy in this step, leading to arguments about whether or not addiction is a form of *insanity*, the more important operative term here is *believe*. Step One encourages an often dismaying admission of personal powerlessness, but Step Two softens the blow by indicating that recovery, while contingent upon belief in a higher power, is possible. This affords hope—something many addicted individuals have not experienced in a long time.

Step Three: “Made a decision to turn our lives and wills over to the care of God as we understood him” introduces the term *God*, and throughout most of the original Twelve-Step writings, the term is used almost interchangeably with *Higher Power*. For this reason many consider the Twelve Steps a form of religion. A subtle difference is that various religious doctrines define the nature of God *for* an individual, but this step leaves that definition *up to the individual*. Moreover, religious injunctions, like the Ten Commandments, tell readers what they shall and shall not do, whereas the steps are all worded in terms of reporting the successful experiences of the authors and simply suggest that if the reader chooses to do what they did, the reader may have the same results. Note the use of the terms *we*, not *you*, and *our*, not *your*. By accepting the invitation to do as others have done, individuals are “joining” the program (i.e., joining with those who went before them and learning from their experience). It is not only the addictive problem that one “turns over” to a higher power, it is the entire life and will. This indicates that addiction is seen not in terms of a condition that one has, but as an existential state. Addiction encompasses the entire being, and sanity may result from surrender to the will of a self-defined God.

Steps Four and Five take a different turn, encouraging a process of moral introspection—an inventory, admission, and reconciliation with a higher power of past wrongs relative to self-defined moral standards. *Alcoholics Anonymous*, the “Big Book,” outlines some fairly detailed suggestions of how this may be accomplished. A plethora of popular press self-help

books offer further suggestions, usually based on the experiences of the authors. Directly examining, facing, and reconciling the “wreckage of the past” in collaboration with God, self, and another human beings are crucial steps in recovery.

The next steps of the program are remarkable for their lack of specific reference to addiction, as they concern themselves with the rehabilitation and development of moral character and an increasingly intimate relationship with God as understood and defined by the step-taker. Idiosyncrasies, defects, and personal shortcomings are scrutinized and examined with a goal of making progress toward soundness of character and a spiritual way of life. God is relied on to remove defects and shortcomings. Instincts for sex, economic security, social status, and other needs are perceived as having often run amok in the addicted individual’s life, and these steps encourage a rebalancing of wants, desires, and needs. Persistently undesirable impulses and behaviors are surrendered to the same higher power that the step-taker’s life and will were turned over to in Step Three. The work involved in these steps is often seen as extraneous by newer adherents to the steps, but the original authors of *Alcoholics Anonymous* found them absolutely essential to the achievement of long-term recovery from addiction.

The importance of the eighth and ninth steps is often more readily grasped by members of various self-help programs. Still using nondictatorial and inclusive terms like *we*, persons taking Step Eight make a list of all people they think they have harmed and, at the same time, work to become willing to make amends to them all. It is often easier to construct the list than it is to become willing to let go of old relational hurts. Interestingly, the term *apology* is not used in the language of the step. Perhaps because to apologize is to excuse, justify, or rationalize; whereas to amend is to improve, make better, remedy, or ameliorate. The difference is more than semantic, given that circumstantial apologies on the fly for past wrongs in relationships may have been previously issued and not followed by a sincere change in behavior or life perspective. By taking time to become willing to make amends, the whole process of reconciliation is slowed down—it is bigger than a hastily issued “I’m sorry” and follows the moral inventory and examination of character engaged in during previous steps. Primed with this new knowledge of self, a list of past relational harms, and a humble, willing heart, step-takers then make direct amends, except when doing so would further hurt people. Having achieved a

degree of healing themselves, recovering addicted persons now begin the process of helping others heal.

Step Ten reiterates the earlier work, as adherents continue to take personal inventory and promptly admit when they are wrong. The parallels to Steps Four and Nine are clear, and Step Ten amplifies their importance, suggesting that examination of self and humility in relationships are ongoing processes.

Support group participants taking Step Eleven are again redoubling their earlier efforts, as the turning over to God of one's life and will (as decided in Step Three) advances even further here. Prayer, meditation, improved awareness, and conscious contact with a self-defined higher power are desirable, with the focus being on seeking both the will of God and the power to carry that out; the step indicates that these are the *only* things sought. This leaves aside all specific concerns about particular situations regarding life, death, work, and family and yet includes them as a lump sum package, described in Step Three as "life" and "will." The original descriptions of the steps by Alcoholics Anonymous are very specific that there is no piecemeal process here, no halfway measures, when it comes to this surrendering of self-will. The care and protection of a loving, self-defined higher power is to be sought with complete abandon, and Step Eleven is clearly designed to further this spiritual process.

Step Twelve indicates that a spiritual awakening was the result of previous steps and that adherents tried to bring the message of it to still-suffering addicts and to practice the principles of the steps in all their affairs. It was actually this practice—of trying to reach out and help another addict achieve and maintain abstinence—that Bill Wilson, the cofounder of Alcoholics Anonymous, credits with repeatedly ensuring his own sobriety and the sobriety of many other alcoholics. "Twelfth stepping," or reaching out to the addict who still suffers, is a long-standing tradition of support group programs, most of which maintain a phone line and telephone listing specifically for this purpose. But it is mostly by word of mouth that addicts in recovery who are seeking to help others are able to connect with them.

Application to Other Addictive Behaviors

Although the original Twelve Steps specifically addressed alcohol, their simple yet seemingly powerful

message was soon applied to other maladies. Persons addicted to gambling and to narcotics centralized their Twelve-Step program efforts, with many early self-helpers being recovering alcoholics who found the steps effective in dealing with their other problems. Over time, people with overeating problems, sexual compulsivity, and other compulsive behaviors successfully applied the principles.

Conclusion

Although widely popular, the Twelve Steps are not for everyone. The initial driving concepts of the steps—personal powerlessness, the rejection of self-control and willpower, reliance on a higher power or self-defined God—are not beliefs that all are willing to subscribe to. Agnostics and atheists may find the invitation to a God-centered spiritual life unappealing, and this is addressed in a specific chapter in the original text of *Alcoholics Anonymous*, the "Big Book." But for many, living the Twelve Steps is a remarkable healing and living process, freeing them from the misery of diverse addictions.

Timothy B. Conley

Note: The Twelve Steps are reprinted with permission of Alcoholics Anonymous World Services, Inc. ("AAWS"). Permission to reprint the Twelve Steps does not mean that AAWS has reviewed or approved the contents of this publication, or that AAWS necessarily agrees with the views expressed herein. A.A. is a program of recovery from alcoholism *only*—use of the Twelve Steps in connection with programs and activities which are patterned after A.A., but which address other problems, or in any other non-A.A. context, does not imply otherwise. Additionally, while A.A. is a spiritual program, A.A. is not a religious program. Thus, A.A. is not affiliated or allied with any sect, denomination, or specific religious belief.

U

UNDERAGE DRINKING

Alcohol use by children, adolescents, and young adults under the age of 21 years is one of the top public health concerns in the United States. In fact, research has shown that nearly half of all eighth grade students in this country have had at least one drink, while nearly 30% of all 12th graders report drinking at least three times per month. According to the 2007 Monitoring the Future Survey, approximately 10% of eighth graders and 26% of 12th graders reported drinking five or more drinks consecutively in the previous 2 weeks. Moreover, the National Institute on Alcohol Abuse and Alcoholism reported that the average age adolescents started to drink alcohol was 17½ years in 1965 compared with an alarming 14 years in 2003. Currently, approximately 3 million U.S. teenagers are alcohol dependent, and at least 1 million more abuse alcohol. College-age students between the ages of 18 and 24 are even more likely to drink and to drink haz- ardously, with 31% of college students meeting criteria for alcohol abuse and 6% meeting criteria for alcohol dependence. This demographic also accounts for the majority of drinking-related negative conse- quences, with nearly 600,000 college students suffer- ing unintentional injuries each year as a result of their alcohol use, while many more are involved in assaults, drunk driving, sexual abuse, unsafe sex, property dam- age, legal problems, and academic problems stem- ming from their alcohol consumption. Furthermore, over 1,700 college students die each year from alcohol- related incidents. Unfortunately, for each message sent to U.S. youth about the dangers of alcohol use, other

messages are sent through the popular media glorify- ing excessive drinking. Further complicating the issue is that alcohol is the most widely available mind-altering substance and has quickly become the drug of choice among U.S. youth.

Consequences of Underage Drinking

The consequences of underage drinking can be devas- tating. Drinking-related incidents such as motor- vehicle accidents, homicides, suicides, drownings, falls, and burns kill and injure thousands of adolescents each year. Those under 21 who drink and drive are twice as likely as their adult counterparts to be involved in a fatal drunk driving accident. Moreover, alcohol is commonly a factor in sexual assaults, and in fact, rape and aggression are far more likely to occur when either the perpetrator or victim has been drinking. Teens who drink are also far more likely to engage in high-risk sexual activity such as unprotected sex and sex with multiple partners than those who do not use alcohol.

Acute intoxication is not only directly involved in the injury and death of thousands of young people each year; drinking habits formed in adolescence and young adulthood often develop into alcohol abuse and depen- dence later in life. For example, a teen who begins drinking at age 15 is 4 times more likely to develop alcohol dependence at some point in his or her life than is an individual who begins drinking at age 20 or later. In addition, research suggests that the earlier children begin drinking, the more likely they are to use other illicit substances. According to the National Survey on Drug Use and Health, among youth who drank

heavily, two thirds also reported using other illicit substances in the past 4 weeks. Similarly, the Center on Addiction and Substance Abuse reported that, compared with young people who abstained from drinking, youth who reported some degree of alcohol use were 50 times more likely to use cocaine.

Drinking at a young age damages the developing brain and liver and can also disrupt the normal hormonal process that assists with proper organ, bone, and muscle growth. As a result of the rapid neurological changes that occur during adolescence, teens that drink heavily also run the risk of suffering cognitive impairment. Many teenagers experience alcohol-induced learning difficulties such as short-term memory deficits that have the potential to impact long-term academic and occupational achievement.

Factors Related to Underage Drinking

Although all young people are potentially at risk for hazardous drinking, certain demographic characteristics are related to an increase in problematic drinking behaviors. For instance, boys are more likely than girls to use alcohol and to develop alcohol problems. Similarly, White and Native American youth are the most at-risk ethnic groups for hazardous drinking, followed by Hispanic, African American, and Asian adolescents.

The adolescent and young adult years are filled with crucial developmental tasks. It is a time during which the human body and brain experience vast and rapid changes, including neural, hormonal, and cognitive processes that science has yet to fully understand. The human brain continues to develop into the mid-20s, so an individual's ability to communicate, plan, and make decisions is not at its optimal capacity until after the typical young adult is well on his or her way to being fully independent. In addition, research has shown that because of the neurological growth occurring at this time, the maturing adolescent brain affords young people a much greater tolerance for alcohol, making them less susceptible to some of the negative effects of alcohol use such as drowsiness, hangovers, and diminished coordination compared with adults. Accordingly, drinking and drinking excessively may be far more appealing to adolescents.

As a result of the physical, social, and environmental turmoil surrounding adolescence, teens often feel the need to try forbidden and even dangerous behaviors in order to gain a sense of independence

through risk taking and rebellion, and even to gain a better understanding of which lifestyle characteristics best suit them. Toward that end, experimentation with substances such as alcohol is often one way in which young people push boundaries set by their caretakers. Alcohol is perceived by adolescents to be less risky than harder drugs, and given its widespread availability, alcohol may be particularly attractive to use for experimentation.

Other individual personality factors may also contribute to an adolescent's choice to use alcohol. Some adolescents are inherently predisposed to risk-taking behavior because they are hyperactive, aggressive, or prone to conduct disorders or even antisocial behavior. Others, however, choose alcohol as a means to self-medicate emotional troubles such as overwhelming anxiety, depression, and social withdrawal; these emotional difficulties can be compounded by alcohol use and abuse, creating a very serious downward spiral. Considering that adolescent males are the demographic at the highest risk for suicide, they may be the population that is most vulnerable to alcohol-related self-harm as well as the most difficult to identify and treat. Heredity is also known to play a role in alcohol use and abuse. Not only are children of alcoholics more likely to begin drinking early, but they are also far more likely to struggle with dependence and other alcohol-related problems later in life.

Prevention and Treatment of Underage Drinking

As a result of the multiple factors that contribute to a child's developmental trajectory, it is difficult to predict the best way to shape a child's environment so as to equip him or her to make responsible choices and avoid dangerous drinking behaviors. Today, the most widely accepted perspective toward prevention is a biopsychosocial view that includes each individual's genetic, biological, personality, social, and environmental characteristics that may contribute to or buffer against risk-taking behavior generally and alcohol use specifically.

Despite all that is known about this issue, the question of how to prevent and treat underage drinking and its consequent physical, social, legal, and academic problems remains. The treatment needs of this population remain largely unmet with only 227,000 of the 1.4 million adolescents currently struggling with an alcohol use disorder receiving treatment for their problem. In addition, the vast majority of available treatment

modalities are not designed to address the unique needs of an adolescent or young adult. Research has shown that traditional methods of intervention such as residential treatment, outpatient care, and Alcoholics Anonymous are less effective in this population than brief interventions that are tailored to the adolescent's specific problems and concerns and the severity of the teen's alcohol use and resulting problems. Ideally, these brief interventions occur in primary care settings such as a doctor's office or emergency room, or even in school at the first sign of alcohol use in an attempt to prevent the development of an alcohol use disorder.

One extensive line of research has examined the role of alcohol expectancies in people's quantity and frequency of use, as well as techniques for altering alcohol expectancies so as to make drinking less appealing. In other words, an adolescent who perceives or experiences drinking in a positive light is more likely to drink. Accordingly, some family- and school-based prevention programs have been designed to target alcohol expectancies so as to better enable students to avoid drinking. For example, school-based programs address the dangers of drinking and the social pressures that young people face, as well as teach resistance techniques in the hope that this information will create a negative view of alcohol use and thus promote abstinence. Research has shown that one of the most effective prevention interventions to date, Project Northland, integrates all aspects of a child's life by incorporating community task forces, school curricula, peer leadership, and parental involvement programs. Although this project has been shown to be extremely successful initially, it is currently being evaluated in more ethnically diverse and urban populations.

Of course, open and honest communication between an adolescent and his or her caregivers is an important component to preventing any risky behavior. Considering that approximately one third of both sixth and ninth graders report that the alcohol they consume comes from their own home and that children often report drinking in their friends' homes, family-based approaches are integral to targeting and reducing underage drinking. Some of these approaches include setting clear boundaries regarding alcohol use including strict antidrinking rules and the consistent enforcement of those rules. As acceptance of drinking and alcohol use by peers are also strongly correlated with adolescent drinking behaviors, closely monitoring children's friends and whereabouts may help limit their access to alcohol and the temptation to drink. Each of these approaches has empirical support but relies on

the availability of public financial and personnel resources and collective initiative-taking in order to be successful. On the other hand, approaches that are known to be ineffective or even to exacerbate the issue are harsh, inconsistent discipline, hostility, and rejection.

Other methods for addressing the problem of underage drinking remain a topic of debate in the U.S. culture and government. For example, some avenues to preventing underage drinking include policy changes such as raising the price of alcohol to make it less accessible, increasing the minimum drinking age, enacting zero-tolerance laws for drinking and driving, and increasing the stringency with which the existing underage drinking and drunk driving penalties are enforced. These community-based approaches aim to decrease the prevalence of underage drinking by increasing the effort required to obtain and use alcohol nationwide and by imposing harsh consequences that may serve as a deterrent. Public policies that limit the availability of alcohol to minors have demonstrated encouraging results in abating underage drinking, as measured by decreases in motor vehicle fatalities, crime, sexually transmitted diseases, tobacco use, and the consumption of other illicit substances.

Conclusion

Drinking among U.S. youth is a major public health concern that requires immediate and prolonged attention from social scientists, caregivers, teachers, and the children and adolescents who will continue to be confronted with this issue. By exploring and implementing community-, family-, and school-based interventions, the prevalence of underage drinking and drinking-related consequences suffered by so many children and adolescents may be significantly reduced.

URINE TOXICOLOGY TESTING

Urine toxicology testing (i.e., urinalysis) includes chemical analysis of an individual's urine to assist in determining the presence of mind-altering substances. In most cases, the urine sample is sent to a testing agency for analysis. However, panel dip tests are also available that permit the person who obtains the urine sample to conduct immediate on-site analysis, leading to immediate feedback of urine toxicology results. Although the results of many of the older dip tests were open to interpretation, most of these tests now permit a positive or negative reading for each drug tested (i.e., positive indicates the drug-produced metabolite was present). When objective substantiation is important (e.g., legal proceedings), the urine specimen can be sent to a testing agency for analysis through thin layer chromatography (TLC) or enzyme multiplied immunoassay (EMIT). Depending on the number of drugs in the tested panel, these tests are usually available for less than \$25.00. Immunoassays determine if an antigen (in this case, the respective drug tested) binds to its specific antibody, indicating a positive result. Thin layer chromatography separates chemical compounds to assist in determining what drugs are present in the sample. Positive test results

are usually validated with gas chromatography/mass spectrometry (GC/MS), which is relatively more accurate than TLC and EMIT. GC separates the chemical into components that may be analyzed, and MS separates drug molecules according to their mass. GC/MS is more expensive and accurate than TLC and EMIT. Although urinalysis has proven to be a relatively reliable and valid measure of substance use, false positives (i.e., indicating drug use when no drug use occurred) and false negatives (i.e., indicating no drug use, when drug use did occur) may occur due to various factors mentioned below.

Uses of Urine Toxicology Screening

Although costly, urine toxicology procedures were first implemented on a large scale during the 1980s as a result of President Reagan's War on Drugs initiative. It was during this time that many federal agencies in the United States adopted drug testing programs, with many private corporations soon following suit. The initial intent was to create a safe and drug-free workplace environment. The subsequent development of sophisticated and inexpensive urinalysis technologies, as well as continued governmental support, made it easier for smaller businesses to adopt similar programs. Although employers and school officials are legally permitted to implement urinalysis testing procedures in certain situations (e.g., in the hiring process, when sufficient cause exists to suspect a drug abuse problem in someone involved in school-based activities), a number of controversial issues have limited the adoption of drug testing procedures in work and school settings. Some of these issues include costs due to litigation (e.g., being sued for inappropriate sampling and testing procedures, inaccurate results), expenses due to testing, reports of violating privacy and civil liberties, and evidence suggesting the implementation of drug testing is not associated with job performance. In any event, employers often administer urine toxicology tests as a preemployment method in determining staff members who may evidence problems with substance use that may interfere with their job performance or increase their risk of injury on the job site. Toxicology screens are also administered to employees on a random or probable cause basis. Similarly, within substance abuse treatment centers, urine toxicology procedures are often initially utilized to screen for the presence of various substances, with continued urinalysis on a random or

regular basis depending on the amount of funding available, results of the initial toxicology testing, and the extent of risk for substance use that is assessed (e.g., staying out late, going on a weekend pass if in a residential facility). Ongoing testing is often implemented to monitor therapeutic progress of clients in clinical programs or to measure outcomes of participants in clinical trials.

Adulteration

Urine toxicology screening is usually a reliable and valid method if precautions are implemented to prevent specimen adulteration, and the length of time between ingestion of the substance and administration of testing is within the specified detection period (see “Information Relevant to Detection” below). However, adulteration of a urine sample is a threat to the validity of urine toxicology testing. This may occur when the donor attempts to alter the urine sample by adding water (e.g., dipping the urine cup in the toilet), bleach (e.g., touching urine with bleach that is on the donor’s finger), or some other chemical to the urine sample. Other strategies to obtain false negative results in urinalysis testing include substituting someone else’s “clean” urine (e.g., spraying urine into the cup through a water-gun that is concealed in pants) or ingesting commercially available drinking solutions into the body prior to testing. There is some support to suggest certain adulterants may lead to negative results on the EMIT but not in GC/MS. Urine creatinine levels can be a useful indicator of sample alteration—that is, because creatinine is produced by muscle protein metabolism and is secreted in urine, creatinine levels are typically stable in accordance with normal liquid consumption. However, low levels of creatinine may indicate water loading, which is an attempt to alter a urine sample by consuming large quantities of water to drop drug levels below testing cutoff levels. Urine creatinine levels below 20 milligrams per deciliter (mg per dL) may indicate water loading. Creatinine levels less than 5 mg per dL may indicate that the sample is not normal human urine and may have had water added to it.

Collection Protocol

Urine sample collection procedures may vary depending on the context of analysis. However, there are basic procedures that can be followed to assist in ensuring the

sample will be reliably obtained. First, the donor’s identification should be confirmed, as it is possible the person scheduled for testing may have sent a proxy to provide the urine sample. Prior to testing, the individual should empty all pockets to assure there are no concealed adulterants, and the donor should at least be casually observed while providing the urine sample. Indeed, the collection site must be secure from adulterants, and the collector must be trained regarding how to eliminate the possibility of adulteration. Observed collection should be utilized at collection sites where adulterant access cannot be eliminated or monitored closely. If the donor reports it is difficult to urinate, the tester should run water in a sink, flush toilets, or run water over the respondent’s hand. If problems with urination persist, the individual should be instructed to initiate the consumption of diuretic fluids (e.g., fruit juice, coffee) in copious amounts prior to attempting urination. There is a condition known as paruresis, which is a type of social anxiety disorder in which the individual is unable to urinate in the presence of others (e.g., in public restrooms). In these situations, anxiety management skills training procedures may be employed, and if the donor is male, it is advisable to permit the donor to attempt urination in a stall rather than a public urinal. If the latter strategy is employed, the stall should be thoroughly checked to assure there is no access to adulterants, the toilet should be flushed before the individual is permitted to enter the stall, and upon urination, the temperature of the urine sample must be measured immediately to rule out substitution of water. A normal, unadulterated sample will have a temperature between 90 and 100 degrees Fahrenheit (32–38 degrees Celsius). If the sample is being sent to an off-site testing agency, the donor identification must be recorded on the sample, and the sample must be sealed. Proper collection is a key element in obtaining an accurate sample.

Information Relevant to Detection

Urinalysis can be used to detect a wide array of drugs from several classes. Commonly tested drug classes include stimulants, semisynthetic analgesics, synthetic analgesics, hallucinogens, cannabinoids, and depressants. Stimulants are drugs that cause mental and physical processes to speed up. They are used for recreational purposes, but some types also have therapeutic value. Some examples of stimulants include amphetamines,

methamphetamines, and cocaine. Stimulants can be detected through urine analysis for approximately 24 to 72 hours after use. Analyses for amphetamines include enzyme immunoassay, radioimmunoassay, and fluorescent polarization immunoassay. Some over-the-counter cold and diet medications will cause a positive test result for amphetamines. If the client reports use of such medications, further testing should be done to confirm results. The most widely used methods for detecting cocaine are immunoassays, which are used to detect metabolites of cocaine.

Some semisynthetic analgesics are referred to as *painkillers*, and are partially derived from natural sources. The analgesics are typically prescribed by health care providers for pain management but tend to be highly addictive. Semisynthetic analgesics include codeine, morphine, and heroin, Vicodin, Dilaudid, OxyContin, Percodan, and Percocet. Semisynthetic analgesics can be detected in urine for 24 to 72 hours after use. Immunoassays may be readily used to detect opioid use. Cutoff levels vary for different opioids. Synthetic analgesics are highly addictive drugs that are generally prescribed for pain management. Some synthetic analgesics include Demerol, methadone, and Darvon. Detection time for synthetic analgesics varies. Methadone can be detected up to 72 hours after use. Darvon's detection time varies from 6 to 48 hours after use.

Hallucinogens are drugs that change the user's thought processes, perceptions, and feelings. They often cause people to believe they are seeing or hearing things that are not actually present. These drugs are generally used for recreational purposes. Examples of hallucinogens include lysergic acid diethylamide (LSD), phencyclidine (PCP), methylenedioxyamphetamine (MDA), and methylenedioxymethamphetamine (MDMA). Urine test detection time for MDMA is between 1 and 4 days, PCP between 14 and 30 days, and LSD between 1.5 and 5 days.

Detection of cannabinoids (marijuana) varies greatly depending on the amount of usage. Light marijuana smoking by a novice user is detectable for only 1 to 3 days after use, whereas moderate usage is detectable for 3 to 5 days after use, and chronic use is detectable for 10 to 21 days or more after use. When ingested orally, marijuana can be detected for 1 to 5 days after ingestion. The most common methods for detection of marijuana are immunoassays and gas chromatography. Results are reported as "total cannabinoids" due to cross reactivity between THC and other cannabinoids excreted in urine.

Depressants are drugs that reduce anxiety and generally slow down physiological processes. Although these drugs have therapeutic value, they are used for recreational purposes as well. Types of depressants include barbiturates, benzodiazepines, Quaalude, tricyclic antidepressants, and alcohol.

Alcohol detection in urine involves testing for alcohol dehydrogenase, a metabolite of alcohol. This form of testing is suitable for clinical use, but more extensive testing should be done for forensic purposes. Immunoassays detect barbiturates as a drug class. Individual types of barbiturates can be detected through use of more extensive confirmatory testing. Immunoassays also detect benzodiazepines as a class. Types of benzodiazepines can be detected through use of more extensive confirmatory testing if warranted.

Conclusion

Urine toxicology testing can be a useful tool in detecting and monitoring drug use. Many different types of drugs can be detected through urine testing. When preventative measures are in place to reduce the possibility of adulteration, and self- and significant other reports of substance use are obtained, urine analysis is particularly reliable and valid. Indeed, urine analysis testing can meet the needs of many facilities and purposes because the collection methods can be altered to meet various situational needs. Urine toxicology testing is also practical since samples can be tested on site for immediate results as well as sent to labs for comprehensive testing, and these procedures are cost-effective. Certainly, urine toxicology testing in schools and in the workplace should be conducted in accordance with federal and state laws governing these practices.

V

VETERANS, SUBSTANCE ABUSE AND TREATMENT

A veteran is considered any person who served in the United States Armed Forces (i.e., Army, Navy, Marines, Air Force, Coast Guard) and those retired from the Public Health Service Commissioned Corps. Due to their military experience, research suggests that some veterans have issues that are not as commonly found among nonveterans, including substance abuse problems. For example, according to the National Survey on Drug Use and Health, veterans were overrepresented proportionally in regard to recent marijuana use, heavy alcohol use, and alcohol and drug abuse treatment.

To better understand veterans with substance abuse problems, it is helpful to examine their experiences while serving in the military. Veterans who abuse alcohol or other drugs may have problems stemming from multiple and often overlapping causal factors, such as cultural reassignment, stress, combat-related post-traumatic stress disorder (PTSD), and homelessness. The role of each of these factors in the etiology of substance abuse problems among veterans is presented.

Cultural Reassignment

Cultural reassignment refers to the process in which new members of the military are thrust into a situation in which they must learn a new vernacular, a new way to dress, and new everyday rituals. When joining the military, new members are displaced from their homes of origin and family environments. For many young

recruits, this is their first experience away from home. Basic training strips the new recruits of their civilian cultures and reassigns them to the military environment. This process is achieved by redressing them in uniforms and providing extensive training in policies and norms, many of which are quite foreign relative to their past experiences. New recruits are often psychologically dispirited and then retrained for toughness, survival, and uniformity during basic training. After all of the arduous training, new recruits feel a tremendous sense of pride and patriotism. This process culturally reassigns them to the military environment.

Once personnel complete training and are stationed at their new base, they may be introduced to new social norms of alcohol and drug use. These new soldiers may abuse alcohol because they are reinforced to do so by social recognition and acceptance in the new environment. Although illegal drug use is not tolerated in the military, drinking is often an acculturated norm. This pattern of alcohol use far too often carries over into the veteran's civilian world—that is, due to experiences in the military where consumption of alcohol in large quantities may have been the norm, veterans may continue this behavior when they leave the military. Therefore, potential alcohol and drug addictions may have developed in veterans well before release from duty, and these addictions are carried into the civilian world.

Stress

Stress is one of the most commonly cited reason for substance use and abuse in the general population. The same holds true for military personnel, where the chronic nature of stress can take a remarkable toll.

There are unique stress factors within the military, such as deployments, death of service personnel, frequent moves, and retirement from service. To cope with these multiple stressors, personnel may use alcohol and other drugs to mitigate these feelings. This phenomenon is commonly known as self-medication in that people may abuse drugs and alcohol to relieve stress and anxiety. Though self-medication is not necessarily a universal coping mechanism within the military, data do suggest that both active military and veterans engage in substance abuse behavior more often than their nonmilitary counterparts. Indeed, multiple stressors related to past military experience and combat in particular are most often cited by veterans in treatment for substance-related disorders.

Deployments

World travel is an incentive to join the military for many new recruits, but there may be an emotional cost to the frequent moves required in the military. According to a study conducted before the Iraq War, soldiers deploy about 14 times in a 21-year career. There was a correlation between deployment length and frequency and stress symptoms. Continued deployments can also strain family relationships. Members who are deployed for long periods of time lose the sense of security that a consistent family environment establishes. Divorce rates, spousal abuse, and infidelity are also correlated with deployments.

The stress of deployments and the problems associated with deployments may lead a soldier to the use of alcohol and other drugs to cope, at which point a substance abuse problem develops. This poor coping mechanism may continue into civilian life, where a veteran continues to face stressors and may never have developed an appropriate or supportive family system due to continued deployments. More troubling, however, is that many veterans who had been deployed into combat may not get the help they need to adapt to the civilian world, potentially destroying what family system of support they may have had. Loss of a supportive family environment, though not unique to veteran alcohol or drug users, can exacerbate current substance abuse problems and delay treatment for this group.

Retirement

Retirement certainly is not unique to the military, but it does have an intrinsically different meaning to

its members. Displacement from the military environment after retirement can be an enormous stress and requires relearning civilian roles, rules, and obligations. Successful reintegration into the civilian world requires cultural reassignment, as discussed above. Those veterans who can successfully make this adjustment are less likely to turn to negative coping strategies than are to those who do not successfully reintegrate.

PTSD

It is estimated that 35% to 75% of veterans with PTSD abuse alcohol or other drugs. PTSD was formerly called *combat fatigue* since it was often seen in those returning from combat situations. In this disorder, exposure to an extreme traumatic stressor (e.g., combat) can cause a variety of problematic symptoms. There are three main groups of symptoms that are associated with PTSD: (1) reliving an event—for example, nightmares and flashbacks related to a combat situation; (2) avoiding reminders of the event—for example, isolating oneself from veteran peers; and (3) being on guard or hyperaroused—for example, being on edge or restless due to the combat exposure.

Many turn to alcohol and drug abuse in an attempt to cope with memories and other psychological and physical symptoms. Research with veterans supports a self-medication theory, as it has been reported that an extremely high percentage of veterans with alcohol dependence also had other psychiatric disorders, such as depression, mood disorders, or PTSD.

Homelessness

The Department of Veterans Affairs reports that 30% of the adult homeless population is believed to be veterans, with approximately 50% of these being veterans of the Vietnam War. It is also estimated that at least 60% of the homeless population have mental health problems. The factors that influence these significant rates within the veteran population are a lack of social support, holding many short-term jobs, mental health issues, and alcohol and other drug abuse. Josef Ruzek, associate director for education at the National Center for Post-Traumatic Stress Disorder, believes that greater levels of alienation from civilian society, trauma-related guilt, and problems maintaining employment have all contributed to the relatively greater social isolation seen in veterans of Vietnam.

The homeless veteran suffering from PTSD and alcohol and other drugs (AOD) addiction can be one of the most challenging clients to help.

Veteran Alcohol and Drug Treatment Statistics

Summary data reports from the Office of Applied Statistics in the Substance Abuse and Mental Health Services Administration indicate some interesting characteristics of veteran admissions into non-Veterans Administration (VA) treatment facilities. In 1999, slightly more than 65,000 veterans were admitted into substance abuse treatment. Of these, 68% of admissions were for alcohol, 13% for cocaine, 8% for opioids, 6% for marijuana, 2% for stimulants, and 3% for other drugs. In 2003, the next year that data were calculated for this specific population, just over 61,000 veterans were admitted into substance abuse treatment. Of these, 62% of admissions were for alcohol, 15% for cocaine, 10% for opioids, 6% for marijuana, 3% for stimulants, and 4% for other drugs. By 2004, nearly 60,000 veterans were admitted into substance abuse treatment. Of these, 61% of admissions were for alcohol, 15% for cocaine, 10% for opioids, 7% for marijuana, 4% for stimulants, and 3% for other drugs.

Clearly, alcohol abuse and dependence stands out as the primary drug of choice among veterans. Interestingly, cocaine-related admissions and opioid-related admissions have increased over time. Given recent wartime events and the large number of personnel returning from active combat duty, data on substance-use admissions into treatment facilities will provide much-needed data to inform the treatment community.

Treatment Issues and Considerations

Overall alcohol and drug abuse problems may go untreated for longer periods of time in veterans due to stigmas held about seeking mental health care in the military (in this case, mental health care includes substance abuse treatment). Military members in all services are given yearly ratings on their performance based on testing scores, physical fitness, personal responsibility, and education. The past procedures of including negative references to mental health care on performance ratings may have been the bedrock of this stigma. Today's practices no longer allow including

references to mental health care or treatment on personal records. Mental health privacy issues are also hindered by the practice of informing the member's chain of command. This means that the supervisor and each person above the supervisor must be informed of the member's personal appointments. This practice causes members to avoid reaching out for mental health care that is available due to the stigma.

The military refers to its counseling clinics as the Life Skills or Mental Health Office. Military clinical psychologists and social workers use the Alcohol and Drug Abuse Prevention and Treatment (ADAPT) Program to treat alcohol and drug abuse problems. The ADAPT program is defined as the identification, treatment, and management of personnel with AOD problems. Enrollment in the ADAPT program can be either voluntary or involuntary. If a serviceman has an alcohol-related incident, he or she will be required to complete ADAPT. Another aspect of this program is the identification of drug use. This identification is conducted through mandatory, frequent, and unpredictable urine testing. The ADAPT program also implements a prevention element through advertising campaigns and briefings. The focus of ADAPT is to enhance personal reliability and accountability. The ADAPT model closely follows the disease model of addiction, although other treatment elements can be integrated.

Unfortunately, many veterans suffering from substance-use disorders may not have the ability to receive treatment from federal military or VA programs. Veterans may be isolated geographically from such programs or may not seek treatment owing to the continued stigma of receiving treatment. Private-practice counselors with an interest in (and knowledge of) working with this group are greatly needed.

Conclusion

A life of military service can be a highly rewarding experience. It does carry inherent risks such as cultural reassignment, PTSD, and homelessness. Steps are being taken to reduce alcohol abuse, such as consistent prevention briefings and fewer events incorporating drinking. In the area of deployments and PTSD, the military is implementing rigorous awareness and assessment procedures pre- and postdeployment. One interesting awareness project is the Veterans Affairs self-assessment for PTSD. This allows service members to go online and learn about PTSD and take a short assessment tool. This education campaign helps not

only the service member but also the families. There are more family support organizations that educate families about better communication practices and also warning signs for substance abuse. Stigma is also being reduced by no longer recording diagnosis and treatment in personal records. The dedication to duty that veterans gave to the United States should be matched by the community to support them with treatment.

VIOLENCE, INTIMATE PARTNER AND SUBSTANCE ABUSE TREATMENT

There is an abundance of empirical and theoretical evidence linking substance abuse to intimate partner violence perpetration and victimization. Substance abuse is overrepresented in samples seeking treatment

for intimate partner violence, and intimate partner violence is overrepresented in samples seeking substance abuse treatment. Moreover, recent research has shown that there is a temporal connection between substance use and episodes of intimate partner violence. This research has documented that the likelihood of intimate partner violence perpetration and victimization is significantly increased on days in which individuals use alcohol or drugs relative to days in which they are abstinent from substances.

Given the high prevalence of intimate partner violence in substance abusers, it is critical to find means of reducing the incidence, frequency, and severity of intimate partner violence in individuals seeking substance abuse treatment. For example, across a variety of male inpatient and outpatient samples, the prevalence of male-to-female intimate partner violence in the past year ranged from 54% to 84%. Timothy O'Farrell and colleagues reported that intimate partner violence was five to six times more prevalent in their male alcoholic treatment sample than in a demographically matched nationally representative sample. Across studies of women substance abusers seeking treatment, research has shown that 50% to 68% perpetrated violence against a partner in the past year, with 25% to 50% reporting severe violence perpetration. Several studies have reported on the victimization of alcoholic women seeking treatment, and consistent with findings from male patients, the prevalence of male-to-female partner violence ranged from 47% to 87%.

Researchers have begun to examine the potential impact of substance abuse treatment on intimate partner violence. To date, this research has taken two primary forms. First, researchers have examined the influence of general substance abuse treatment on violence perpetration and victimization in which there is no particular emphasis on relationships or intimate partner violence in the treatment. Second, researchers have examined the impact of behavioral couples therapy on substance use and intimate partner violence.

Substance Abuse Treatment and Reductions in Violence

Several studies have documented an association between individual substance abuse treatment and reductions in intimate partner violence. Gregory Stuart and colleagues evaluated the impact of an individually based intensive partial hospitalization treatment for alcohol dependence on alcohol use,

intimate partner violence, and psychological aggression among a small sample of heterosexual male patients and their partners. Male patients received 5 to 6 days of substance abuse treatment in which there was no direct focus on the intimate relationship. Patient and partner assessments were conducted at baseline, 6-month follow-up, and 1-year follow-up. Results revealed a decrease in alcohol use in male patients as well as significant reductions in the frequency of male-to-female physical violence and psychological aggression from baseline to 6-month and 1-year follow-up. Furthermore, results showed significant decreases in the frequency of female-to-male intimate partner violence from baseline through 1-year follow-up.

Similarly, in a small sample of heterosexual female alcohol patients and their partners, Stuart and colleagues examined the potential impact of an intensive outpatient treatment for alcohol dependence on alcohol use, intimate partner violence, and psychological abuse. Patients received the same intensive individual partial hospitalization program described above. Results showed a decrease in alcohol use in female patients as well as declines in the prevalence and frequency of male-to-female partner violence over time. Results also showed decreases in the prevalence and frequency of female-to-male partner violence and psychological aggression.

The aforementioned studies suggest that intimate partner violence is reduced subsequent to individually based alcohol treatment. Other studies of individual substance abuse treatment have reached similar conclusions. For example, O'Farrell, William Fals-Stewart, and colleagues have shown that, in a sample of 301 individuals seeking alcohol treatment, the prevalence of male-to-female partner violence decreased significantly, from 56% in the year before treatment to 25% in the year following individual treatment. Similarly, in a sample of 147 male drug abusers seeking individual treatment, the prevalence of male-to-female intimate partner violence decreased from 60% in the year prior to treatment to 30% in the year following treatment. In both of these studies, the prevalence of intimate partner violence was substantially higher among relapsed substance abusers relative to substance abusers who were remitted. In addition, in both studies, the prevalence of intimate partner violence among remitted substance abusers was comparable to the prevalence of intimate partner violence among a non-substance-abusing control group.

Overall, these studies suggest that intimate partner violence perpetration and victimization by male and female patients, as well as the patients' partners, is reduced subsequent to substance abuse treatment. Studies have shown an association between relapse to substance use and continued relationship aggression.

Behavioral Couples Therapy

Rationale

Although the use of couples therapy with violent couples is somewhat controversial, there are compelling reasons for initiating behavioral couples therapy for substance abuse and intimate partner violence. First, by addressing both relationship discord and substance use, behavioral couples therapy may reduce the substance use and relationship problems that are general risk factors for aggression, thereby decreasing intimate partner violence. Second, behavioral couples therapy teaches specific skills to prevent violence. For example, behavioral couples therapy teaches communication and negotiation skills to reduce hostile conflicts that may escalate to violence, as well as problem-solving skills to address relationship issues. Importantly, in this therapy both partners are called upon to firmly commit to non-violence. Continuous monitoring of relationship aggression by the therapist takes place at each session. Moreover, an action plan to stay safe is also developed in the event that substance relapse occurs. Finally, behavioral couples therapy also directly focuses on sobriety by including elements such as a daily sobriety contract, encouraging the use of support groups, monitoring urges to drink or use drugs, crisis intervention for substance use, and relapse prevention.

Inclusion and Exclusion Criteria

Offering couples therapy to substance abusers with a history of domestic violence is somewhat controversial, as critics argue that couples approaches may increase the risk of violence in both partners. Since couples must speak freely about relationship conflict in therapy, the concern is that either partner (particularly the female partner) may fear that disclosure and addressing relationship problems may escalate the likelihood of violence. However, it should be noted that severe intimate partner violence that carries a high risk of injury is rare in substance abusers (i.e., less than 2% of couples seeking therapy) as is endorsement of one partner fearing the other. In general, behavioral couples

therapy is only considered if there is a history of low or moderate levels of violence, if both partners independently agree to participate and do not express fear of negative consequences for discussing the relationship and violence, and if both partners commit to avoiding future additional physical aggression. In addition, most research conducted on the impact of behavioral couples therapy has involved couples in which only one partner, but not both, have a substance abuse problem. To date, research has not addressed the potential benefits of couples approaches when both partners have an addiction.

Results From Studies

O'Farrell and colleagues examined intimate partner violence before and after behavioral couples therapy for 303 married or cohabiting male alcoholic patients and compared their findings to a demographically matched nonalcoholic sample. In two studies, male-to-female partner violence was significantly reduced in the 2 years subsequent to behavioral couples therapy. Moreover, intimate partner violence was nearly eliminated for male patients who achieved abstinence from alcohol. In the year prior to behavioral couples therapy, 60% of male alcoholic patients and 64% of their female partners had perpetrated intimate partner physical violence. In the year after behavioral couples therapy, violence decreased significantly among male patients to 24% of the alcoholic sample but remained higher than the comparison group (12%). The prevalence of male-to-female intimate partner violence in the year following couples therapy was 12% among male patients whose alcohol problem was in remission, compared with 30% among male patients who relapsed to alcohol. The 12% prevalence of intimate partner violence in remitted male alcohol patients was identical to the matched comparison sample. Similar results were found during the second year of follow-up after behavioral couples therapy; specifically, the prevalence of intimate partner violence was reduced, with remitted alcoholics evidencing less violence than relapsed alcoholics. Thus, partner violence decreased after behavioral couples therapy, and clinically significant violence reductions occurred for patients who ceased drinking after treatment. An earlier study of 88 male alcoholics found comparable results.

In four methodologically rigorous studies conducted by Fals-Stewart and colleagues, behavioral couples therapy reduced intimate partner violence more than individual substance abuse counseling. In each study,

differing primarily by the patient population examined, all patients were assigned the same number of outpatient therapy sessions. Patients were randomized to receive either all individual counseling sessions or half couples therapy and half individual sessions. Although participants across all four studies demonstrated a high prevalence of male-to-female physical violence in the year prior to treatment, participants demonstrated a substantial reduction in violence in the year subsequent to receiving treatment. In addition, participants receiving behavioral couples therapy exhibited greater reductions in intimate partner violence, demonstrated more abstinence from alcohol, and reported greater relationship satisfaction than participants who received individual counseling. These nearly identical results occurred in four studies of 80 male drug-abusing patients mostly with cocaine and heroin problems, 195 male alcoholic patients, 105 female alcoholic patients, and 215 cocaine-dependent patients.

Conclusion

Although substance use and abuse are not an excuse for perpetrating intimate partner violence, the association between intimate partner violence and substance use is extremely strong. In both male and female substance abusers, individual substance abuse treatment is associated with considerable reductions in intimate partner violence perpetration and victimization, with relapsed substance users having worse partner violence outcomes than remitted substance users. Behavioral couples therapy is a well-studied approach to treating substance abuse and intimate partner violence. Randomized studies comparing behavioral couples therapy with individual-based treatment show a consistent pattern of more abstinence and fewer substance-related problems, happier relationships, lower risk of relationship separation, and lower risk of intimate partner violence for substance abusers who received behavioral couples therapy. Additional research with behavioral couples therapy should be conducted in an effort to examine whether couples therapy may be offered in shorter duration, in group rather than individual format, and for couples in which both partners misuse substances.

VIOLENCE PREVENTION

Violence and substance abuse are serious public health concerns. Violence refers to high levels of aggression, that is, behavior intended to harm another person. Violence is a pervasive and universal social phenomenon that elicits substantial societal, economic, and health costs. The relationship between substance use and violence is exceedingly complex. Indeed, most alcohol and drug use does not result in violent behavior, and some psychoactive substances have no link to violence at all. However, evidence of

alcohol and drug use is often found in both perpetrators and victims of violence. Violence and substance use are multiply determined by a variety of factors including social, economic, and cultural forces. Substance use interacts with personality and situational variables in determining whether violence will occur in a particular situation. This entry first explores the types of violence associated with substance use, followed by an examination of which substances are associated with aggressive behavior. Next there will be a discussion of the situational and personality factors that moderate the relationship between substance use and violence, as well as the risk factors common to substance abuse and violence. Strategies for preventing substance-induced violence are discussed.

Violence Associated With Substance Abuse

Numerous types of violence are associated with some forms of substance abuse. Although admittedly an oversimplification, for the purposes of this discussion, these types can be dichotomized into violence that is related to the pharmacological effects of the substance and violence that does not meet this criterion. The first category refers to violence occurring after ingesting alcohol or drugs or during withdrawal, or violence resulting from long-term use. Examples include violence as a result of intoxication or agitation resulting from withdrawal symptoms. The second category refers to instrumental aggression that occurs due to the expense associated with purchasing substances or the result of the illegal status of the substance. Examples include assault and robbery to support one's addiction, gang warfare over territory, and retribution (e.g., for a drug deal gone bad). Because the prevention of such types of violence typically requires resources that are unavailable to most mental health professionals, this entry primarily focuses on violence associated with the pharmacological effects of alcohol and drugs.

Substances Associated With Aggression

Because most of the research on aggression and substance use is correlational, one must be careful about assuming causal relationships. Controlled experimental studies are helpful for inferring causal associations between manipulated situational variables, measured personality variables, and pharmacological effects on

aggressive behavior. However, with the exception of alcohol, experimental studies are either uncommon or nonexistent in this literature. In the United States, two of the most frequently used substances are alcohol and marijuana. The empirical evidence for the pharmacological effects of alcohol in increasing aggression is overwhelming. In contrast, the evidence for marijuana suggests no causal relationship between its pharmacological effects and violence.

Among all the substances of abuse, alcohol has the most consistent relation with violence in the research literature. Alcohol is the most common substance found among victims of violence and perpetrators, although this result is confounded with its widespread availability and abuse. A 1998 U.S. Department of Justice report found that approximately 3 million alcohol-related violent crimes occur each year and that about two thirds of these crimes were characterized as assault. Acute alcohol use by the perpetrator is especially likely in intimate partner violence (about two thirds of cases) relative to violence by strangers (about one third of cases). Alcohol is also involved in a large number of homicides and suicides. Estimates of alcohol use by offenders prior to committing homicide are typically quite high (up to 86%). A 2005 Australian government report found that 47% of homicide perpetrators had consumed alcohol at the time of the murder and 32% had consumed illegal drugs. Perhaps the strongest evidence for a causal role of alcohol is found in several meta-analyses of laboratory experiments. These data have revealed consistent relationships between alcohol and aggression, most often in the presence of provocation (see below).

A commonly proposed mechanism underlying alcohol-induced aggression is the lowering of anxiety and inhibitions against violence. Alcohol reduces the fear of retaliation normally associated with aggressive behavior. This reduced fear lowers restraints against violence. Thus, when provoked, intoxicated individuals may be more likely to behave aggressively than sober individuals. Sedative-hypnotics have been similarly implicated for identical theoretical reasons; however, experimental research indicates that the degree of violence associated with this class of drug is minor compared with alcohol-induced aggression.

Claude Steele and colleagues have focused on a cognitive explanation for alcohol-induced aggression, known as alcohol myopia theory. According to this theory, alcohol impairs cognitive processing capacity, thereby narrowing attention, and ultimately restricting

the focus of attention to those cues that possess the most salience. These highly salient cues could include acts easily interpreted as aggressive (e.g., an innocuous “bump” in a bar). Cues that might inhibit aggression are potentially more distal and therefore less salient, especially for intoxicated individuals.

In a 2003 qualitative review of the experimental and nonexperimental literature on alcohol, drugs, and aggression in humans, alcohol and stimulants (i.e., amphetamines and cocaine) appeared to increase aggression. However, another 2003 review concluded that the experimental literature on stimulants and aggression was inconclusive. Thus, the role of stimulants and aggression remains debated. Initial responses to alcohol can include increased arousal and approach motivation—reactions also common to stimulants. Increased arousal leading to violence is consistent with social psychological research on Dolf Zillman’s excitation transfer theory. According to this theory, when an individual is aroused (perhaps via intoxication) and provoked, the physiological arousal is misattributed to the provocation and thereby amplifies aggression. Provoked individuals who are also experiencing drug-induced arousal might misattribute the arousal to anger and subsequently lash out.

A qualitative review also concluded that nicotine, marijuana, and hallucinogens are not associated with violence. This same review suggested that links between the opioids and aggression stemmed from withdrawal or instrumental acts of aggression perpetrated to obtain money for drugs. Only limited case study evidence supports a link between PCP and violence. Although there is limited empirical evidence, sedative-hypnotics (i.e., barbiturates) may increase aggression due to agitation during intoxication and withdrawal. A 2003 review concluded that there was too little research on MDMA (ecstasy) to suggest a link between the drug and violence. There is also too little research on inhalant use to suggest a causal association.

Risk Factors Common to Substance Abuse and Violence

Because the majority of research on substance use and violence is correlational, caution must be exerted when inferring causal associations. Numerous factors tend to covary with both substance use and violence. Perhaps the most obvious is gender. Men tend to be more aggressive than women. A 2006 report by the Centers for Disease Control (CDC) found that men

had a homicide rate three times higher than women. Men tend to drink more and use some drugs more often than women, although not universally. Young people also engage in more substance use and violent acts than older people. The recent CDC report found the highest rates of homicide among 15- to 24-year-olds. Perhaps not surprisingly, certain problem youth tend to engage in multiple deviant behaviors simultaneously (e.g., alcohol and drug use, violence, risky sexual behaviors). For example, a recent study of American middle and high school students reported that both substance abuse and other nonviolent deviant behaviors accounted for violent behavior equally well. Among adolescents, even marijuana use, a drug with no direct causal effects on violence, is sometimes correlated with violence among adolescents, likely due to the deviant nature of illegal drug use. In addition, childhood maltreatment or being a victim of violence and other trauma may also covary with alcohol and drug use.

Personality and Situational Contributors

Both person and situation variables contribute to the effects of substance abuse on violence. The vast majority of this research has examined alcohol. For instance, individuals who tend to behave aggressively (e.g., those high in trait aggression or individuals with antisocial personality disorder) behave even more so when given alcohol. Moreover, those who tend to ruminate about interpersonal transgressions are also more likely to behave aggressively when given alcohol. Another individual difference variable that may increase aggression is the expectancies that people hold regarding alcohol and aggression. Although most research suggests that expectancies do not directly increase aggression, there is evidence that heavy drinkers who expect alcohol to increase aggression tend to behave in a manner consistent with their beliefs. This tendency appears to be especially true when there are aggressive cues in the environment. Social-cognitive models of personality posit that some individuals possess aggression-related knowledge structures that are easily accessible when triggered by situational cues (e.g., alcohol consumption, provocation). Thus, these situational features may trigger aggressive behavior among those high in trait aggression, ruminators, those who endorse aggressive alcohol-related expectancies, and people with antisocial personality disorder.

Quantitative reviews of the experimental literature consistently show that alcohol increases aggression and that this effect is moderated by a number of situational variables. Alcohol consumption is particularly likely to increase aggression after provocation in locations where aggression is more normative. Thus, the primary situational variable responsible for increasing aggression is provocation. In laboratory experiments that orthogonally manipulate intoxication and provocation, intoxicated individuals who are provoked are usually the most aggressive. These provocations are often relatively minor or ambiguous and can be verbal or physical in nature.

Another important situational variable that may increase aggression among intoxicated individuals is the set of social norms associated with certain places or events. For instance, some bars are characterized by norms that tolerate violent behavior. Sporting events and some sports bars make team social identities salient (e.g., team banners, wearing specific clothing). The salience of this group membership can trigger norms of in-group protection and outgroup derogation, especially among those who tend to identify strongly with their in-group. Such events, when combined with alcohol, can lead to violence between groups such as that exhibited during some soccer matches. Alcohol and some types of drug intoxication in conjunction with large group settings may also increase deindividuation (a loosening of normal moral constraints in groups), which can increase violent behavior.

Strategies for Prevention

Although many interventions have specifically addressed either violence or substance abuse, relatively few studies have investigated interventions for both. Given the causal effects of alcohol and some other drugs on violence, violence intervention programs should contain some component to address alcohol and substance abuse. Violence interventions have typically been directed at the individual level (e.g., intimate partner violence, child maltreatment), the community level (e.g., youth and gang violence), or both. Although not commonly investigated, changing situational features of the environment where drinking and drug use occurs is likely to prove beneficial as well.

At the individual level, couples therapy and therapy designed to reduce substance abuse reduces intimate partner violence. At the community level, violence

prevention programs that address multiple factors have proven most effective. Indeed, reducing alcohol consumption without addressing other factors among at-risk youth is unlikely to decrease aggression, especially if these individuals are involved in violent gangs or other risky, delinquent behaviors. In addition, alcohol and drug availability remains important. Neighborhoods with more bars and liquor stores per capita are more violent. Because violence associated with substance use disproportionately affects young men and women of color from disadvantaged economic backgrounds, most research at the community intervention level has focused on these groups. Such violence prevention and substance abuse programs should be culturally sensitive with input and assistance from community members whenever possible.

At the situational level, a number of inexpensive and simple changes could decrease aggression markedly. Given alcohol's strong impact on violence and its availability, preventing alcohol-induced violence is a challenge. Perhaps the most obvious situational intervention would require decreasing the probability of provocation in locations where alcohol is consumed. Security staff at bars can reduce aggression by reducing provocation. Some bars are characterized by acceptance of violent behavior, rowdiness, and high levels of intoxication. Norms of interpersonal tolerance and moderate drinking should be promoted at such bars and events involving alcohol. When such norms are salient, aggression is likely to decrease. Sports bars could display team memorabilia from multiple teams and focus on creating a welcoming environment for fans of all teams, thereby reducing the salience of one social identity over another. A meta-analysis revealed that increased self-focused attention (e.g., having a mirror in the room) reduced alcohol-induced aggression. Self-focused attention increases the accessibility of one's personal norms and ideal self, which usually involves being a good, moral person. Thus, mirrors, cameras, and bright lighting in bars and in homes may prove effective in reducing violence associated with alcohol and drugs.

Conclusion

Due to limited conclusive evidence and sometimes inconsistent findings, more experimental research is needed on drugs other than alcohol to tease apart the

complex interactions among numerous factors that contribute to violence. Ultimately, such research will increase the effectiveness of substance-related violence prevention strategies. Also, because not all individuals behave aggressively after consuming alcohol or drugs, more research and better identification instruments are necessary to determine who is at risk for substance-induced violence. More research and funding is needed for intervention programs that simultaneously address numerous risk factors for alcohol- and drug-induced violence. Such research may lead to marked improvement in these serious public health problems.

W

WAR ON DRUGS

The War on Drugs may best be described as a long-standing effort ranging from limitation to eradication of the production, distribution, sales, and use of primarily illicit psychoactive substances. In addition, some proponents of the War on Drugs have expanded the mission to address the continuing production, distribution, sales, and use of legal psychoactive substances. This war is unique in that it has historical significance, presents administrative and policy challenges, has evolved in a sociopolitical context, and continues to advance in scope and meaning today.

During the late 1960s, President Richard M. Nixon refueled the national campaign against illicit drug use by referring to drugs as “Public Enemy Number One.” During the Nixon administration, the 1970 Controlled Substances Act was passed. This key legislation produced many changes in terms of drug regulation and penalties for possession and sales. This act was responsible for the following:

1. It established protocols for drug education and prevention activities, and it identified practice models for addictions treatment.
2. It moved control of drug regulation from the Department of the Treasury to the Bureau of Narcotics and Dangerous Drugs, later to the Drug Enforcement Administration (DEA).
3. It established drug schedules for regulation of controlled substances.

4. It identified penalties for drug possession.
5. It identified penalties for drug sales.

Nixon’s War on Drugs (coined in 1971) emphasized the importance of treatment and prevention as primary strategies in combating drug use. A public health approach was utilized to offer available services to addicted persons and their families. This was one of the few periods in history when the War on Drugs emphasized pathology and treatment instead of deviance and criminal justice interventions. Although treatment provided a practical strategy, it was merely one tactic that was used to address an enormous problem. Alongside treatment, one must consider the importance of additional war initiatives such as domestic law enforcement, interdiction efforts, and international efforts aimed at targeting illicit drug use. These components evolved in their own right and set the course for the direction of the contemporary War on Drugs.

In 1972, the Nixon administration established the Office of Drug Abuse Law Enforcement (ODALE), and in 1973, the DEA. The DEA was created as a centralized organization composed of members of ODALE, Customs, the CIA, and smaller factions. Its primary purpose was to merge all facets of legal and administrative controls in targeting illicit drug abuse. Abroad, the United States worked with allied nations such as Canada, France, and Mexico to diminish the threat posed by cocaine, heroin, and marijuana.

Following Nixon’s resignation in 1974, the Ford administration is less recognized for any significant contributions to the War on Drugs. In 1978, the Carter administration supported the decriminalization of

marijuana and the ending of federal penalties for possession of small amounts of marijuana. Further, asset forfeiture was introduced as part of a revision to the Controlled Substances Act.

During the Reagan era, the drug war continued to gain momentum while grounded in rigid philosophies and backed by militaristic interventions. Reagan's drug policies supported a trend toward domestic and international law enforcement as a primary strategy in the War on Drugs. The Reagan administration advocated for mandatory federal sentencing for drug-related offenses, supported insurgent groups affiliated with drug trafficking for political strategy, and instituted a federal death penalty for drug lords. Some feel that the U.S. economic and military support provided to many of these factions may have facilitated the materialization of present-day terrorist groups. In the spirit of a militant atmosphere, a zero tolerance policy (a criminal justice approach to drug control) was adopted. Zero tolerance refers to a federal prohibition against the import or export of illicit drugs in the United States and to significant penalties for possession or sales. Consistent with this philosophy, First Lady Nancy Reagan was celebrated for promoting the "Just Say No" campaign. Called simplistic and impractical by critics, the message was directed toward youth as a strategy for dealing with drug pushers or the peer pressure often associated with drug abuse.

The Anti-Drug Abuse Act of 1988 was instrumental in establishing the Office of National Drug Control Policy (ONDCP). Its mission was to create policies and priorities to reduce illicit drug trafficking, manufacturing, and sales. In addition, it is charged with targeting drug-related crimes and violence, and in addressing public health concerns relating to illicit drug use. Further, the Anti-Drug Abuse Act of 1988 (amended in 1996) created a cabinet-level position of the Executive Office of the President known as the *drug czar*. The drug czar is the director of the ONDCP.

The Clinton administration surpassed the legacy of its predecessors by using the criminal justice system and the military as primary interventions in the drug war. During the Clinton era, incarcerations for nonviolent drug offenses escalated and appeared to be a major tactic in the War on Drugs. The U.S. military broadened its operations to target regions abroad that were most associated with illicit drug production and export. In the United States, concerns over marijuana use (reminiscent of the 1930s) resurfaced. Medicinal use of

cannabis and advocacy for legalization of the drug triggered considerable government backlash. Some analysts argue that communities and families were those most affected by the drug policies of the 1990s. Again, a considerable amount of resources were invested in strategies that were less than optimal for reducing the evident threats of drug use in the United States.

The Reauthorization Act of 1998 expanded the authority and functions of the ONDCP. It prioritized a national drug control strategy, committed funding for a 5-year national drug control program, granted authority to high-density drug trafficking areas (particularly border areas), and reorganized the ONDCP and other national drug control agencies.

The George W. Bush administration persisted in utilizing economic and military resources to eradicate illicit drug use. Unfortunately, the reality of terrorism shifted national priorities, but it did not dismiss them. It is evident that the War on Terror has depleted existing resources that may have been previously allocated for drug control. Although parallels may exist between the two campaigns, caution should be utilized when deriving causal inferences. President Bush was instrumental in supporting the expansion of drug abuse education and treatment programs in the United States. However, the Bush agenda was laden with religious ideologies as paths to recovery and evidenced by considerable financial support for faith-based addiction and recovery programs. Although some revere the utility of faith-based programs, many others view them as problematic and ineffective. Bush advocated for and committed federal support to the high-density drug trafficking areas in the United States. Bush promoted aggressive community and family education programs and supported the allocation of funding for drug testing in schools.

Consequences of the Drug War

Economic Costs

According to the ONDCP budget summaries, the United States is spending approximately \$13 billion per year on the War on Drugs. When factoring in additional rising costs for drug-related incarcerations and state and federal corrections, these figures may be inaccurately low. Of these dollars, approximately two thirds is spent on supply reduction activities, while approximately one third is spent on treatment, prevention, education, and research. Figures relating to the War on Drugs vary significantly across sources and are often contextually

determined. The majority of resources spent on controlling illicit drug use in the United States primarily supports drug-related law enforcement activities and the incarceration of drug offenders.

Personal Costs

Approximately 29,000 people die of drug-induced causes in the United States each year. These figures do not include drug-related homicides, suicides, or accidents.

Communities and families have experienced innumerable hardships and losses due to continuing drug use and the current War on Drugs. The development of the drug trade within economically disadvantaged communities has created a breeding ground for illicit activity including violence and crime. Sadly, funding to these communities for necessary resources is often limited by allocations for public safety and corrections.

Racism

The War on Drugs has been notorious for its association with racism. Beginning with the Opium Wars, concerns over Chinese immigrants stirred panic in the United States and led to restrictions that directly affected the Chinese (particularly restrictions over opium use). Mexicans and African Americans were also targeted as marijuana “fiends” during the early 1900s. Mexicans were seen as threatening because they used marijuana and brought it into the United States. In addition, Mexican workers competed for employment with American workers. African Americans were characterized as hypersexual and violent under the influence of marijuana. Disproportionate numbers of minorities (particularly African Americans) in the criminal justice system demonstrate compelling evidence for racist practices in the disposition of drug offenders. Evidence from varying sources substantiates the premises that Caucasians are more likely to receive probation for similar offenses than African Americans or Hispanic Americans and are less likely to receive state or federal incarceration as compared with minorities.

Crime and Criminal Behavior

Some argue that the U.S. War on Drugs has been a futile attempt at restricting individual rights and has

actually increased criminal behavior. Alcohol prohibition and the expansion of organized crime is an example of this point. Other problems seem to emerge when drug controls are enforced, for example, an increase in drug trafficking, in underage use of illicit substances, in the use of illegal paraphernalia, and in crimes committed while under the influence. However, caution should be utilized with making assumptions about drug use and crime and violence because drugs have variable effects and may or may not be associated with these behaviors. The War on Drugs was intended to reduce illicit substance use, an identifiable social problem. While attempting to reduce crime and related problems, it may inadvertently be contributing to them.

Conclusion

The War on Drugs is both a national and an international effort to reduce the sales, distribution, and use of illicit psychoactive substances. In the United States, the War on Drugs is controversial. It has shifted emphases over time, and has both favorable (i.e., research efforts, treatment options) and unfavorable consequences (i.e., elevated incarceration rates, human rights violations). Abroad, the War on Drugs has encountered similar obstacles. Historically, efforts to reduce or eliminate illicit drug use have been unsuccessful in accomplishing their aims and have contributed to larger problems both at home and abroad. The inclusion of the military and state and national law enforcement has altered the course of Nixon’s War on Drugs. For some, it is considered necessary and consistent with ideologies established for public safety. For others, it is seen as a violation of individual rights and a form of unconstitutional government control. Today, the War on Drugs is characterized as an ineffective campaign, one with a compromised integrity due to economic and political variables. The economic costs of a sustained war are escalating, while strategies to resolve illicit drug trafficking and related activities are unattainable. Although the current War on Drugs is well intended, it may require some fine-tuning to achieve optimal goals.

WELFARE REFORM AND SUBSTANCE ABUSE

In 1996, federal legislation known as the Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) was passed. This legislation represented a sea change in welfare policy. Key changes made by PRWORA legislation include shifting funding for welfare benefits from a federal entitlement to a state block-grant program and incorporating time-limited benefits and the addition of work requirements for receipt of benefits. The state block-grant program resulting from PRWORA legislation is known as the Temporary Aid to Needy Families (TANF) program. Since the passage of PRWORA, research to date has focused on identifying barriers to employment among recipients of welfare that include mental health, substance abuse, human capital deficits, and domestic violence. The current entry (a) presents a brief history of welfare legislation, culminating in TANF legislation; (b) discusses barriers to employment among welfare recipients of which substance abuse may be one; and (c) presents an outline of one state's welfare program developed in response to federal legislation: California's Work Opportunities and Responsibility to Kids (CalWORKs) program.

Brief History of Welfare Legislation

Established in 1935 under the Social Security Act, Aid to Families with Dependent Children, commonly

known as welfare, was originally conceptualized as a means to provide support to women with children without a male wage earner. In 1957, with the passage of the Work Incentives Program, recipients with children over 6 were required to seek employment or face losing their benefits. A training component was added in 1988 with the passage of the Family Support Act, which created the Job Opportunities and Basic Skills Training Program. With the passage of PRWORA in 1996, a major change occurred in the welfare program. This legislation changed funding for welfare from a federal entitlement to one funded by block grants to states. Work requirements were formalized and required increasing percentages of welfare recipients over a number of years, and benefits were limited to 60 months lifetime, with the stipulation that states could exempt up to 20% of their welfare caseloads from this time limit. In addition, a portion of funds under the new legislation can be used to address client needs that may interfere with meeting work requirements, such as mental health problems and substance abuse problems. Failure to meet work requirements can result in sanctions (i.e., reduction in aid).

Between 1997 and 1999, a 38% reduction in welfare caseloads occurred, which some have attributed to the 1996 welfare reform package. However, during this time period economic conditions in the United States improved and possibly resulted in increased employment among former welfare recipients. Some studies suggest that nearly three fourths of former welfare recipients report at least half-time employment 1 year after leaving the welfare rolls; however, just over 50% report employment at the time of discontinuation of benefits. In addition to problems such as educational or job skill deficits, childcare needs, substance abuse, and mental illness may be barriers to finding and maintaining employment among TANF recipients.

Substance Use Among Welfare Recipients

Most estimates of substance involvement among welfare populations indicate that approximately 20% of welfare recipients report recent drug use, and approximately 10% report use of hard drugs such as methamphetamine or opioids, which have a high risk for dependence. These numbers suggest that a relatively small percentage but numerically large subgroup of

welfare recipients may be in need of referral for assessment of and treatment for a substance-related disorder. Women receiving welfare benefits who also have a substance disorder are generally older, have more children, are less likely to be employed, and have lower levels of education or job skills than their non-substance involved counterparts. In addition, they may have unstable or temporary housing or be homeless. With regard to welfare tenure, women with substance problems are more likely to leave welfare as a result of state-imposed sanctions than women without substance disorders. It is unlikely that a single barrier impedes employment among welfare recipients. It is more likely that multiple barriers exist, and a large-scale study of barriers to employment done by Sheldon Danziger and colleagues suggests that 37% of women with children on welfare rolls in the Michigan Family Independence Agency had two or three barriers to work, 24% had four to six barriers to work, and 3% had seven or more barriers to work. Thus, nearly two thirds of women sampled from welfare rolls may have complex service needs that impede employment opportunities.

The co-occurrence of other psychiatric disorders and substance use is well documented, and the prevalence of psychiatric disorders is higher among long-term welfare recipients than among the general public. For example, estimates of the prevalence of various psychiatric disorders among long-term welfare recipients range from 28% to 40% as compared with rates of approximately 12% to 15% among general welfare recipients. Frequent diagnoses among welfare recipients include depression, anxiety disorders, post-traumatic stress disorder (PTSD), and substance abuse disorders. It may be that long-term welfare recipients are unable to find and maintain employment due to the symptoms of their mental illness, or it may be that individuals experiencing economic problems requiring public assistance are more likely to manifest psychiatric symptoms as a result of the strain and stress of these difficulties. Regardless of cause, psychiatric disorders such as depression, PTSD, anxiety disorders, and the like may be associated with an increased likelihood for substance use and abuse among welfare recipients as it is in the general public. The co-occurrence of a psychiatric disorder and a substance use disorder is common among women in substance abuse treatment, and some data suggest that the more severe employment problems seen among women in drug treatment are mediated by psychiatric problems.

Studies suggest that (a) women on welfare report higher rates of experiencing intimate partner violence, which may result in trauma; (b) have more health-related problems; (c) are more likely to have children with serious health problems; and (d) often live with partners who have mental health problems or substance problems. Thus, the types of barriers to employment faced by women on welfare are multifaceted and include more than substance use and mental illness. Such problems require comprehensive intervention if the policy goal is to facilitate the transition to work.

With the increased emphasis on transition to employment now embodied in statutes that place time limits on the receipt of welfare benefits and the data that show that some percentage of welfare recipients face health barriers including mental illness and substance abuse, assessment and referral for interventions designed to improve functioning among welfare recipients has become necessary. Some have argued that what has occurred is a *clinicalization* of welfare services in which welfare recipients are required to reveal sensitive information that had not heretofore been necessary for the application for and receipt of benefits. This clinicalization may result in the viewing of unemployment as a disease rather than as a temporary condition that can be remedied through increased job skills training, education, and intervention to reduce barriers to employment. In addition, the vagaries of the nation's economic conditions may result in as much or more transition from welfare to work or from work to welfare than do the factors reported here that affect a subgroup of the welfare population.

CalWORKS

California has some of the most liberal welfare policies and one of the highest benefit rates of any state in the nation. California's welfare rolls represent a significant portion of the national caseload. California's response to PRWORA legislation was the Welfare to Work Act (AB 1542), which created the CalWORKS program that was initiated in 1998. Key eligibility requirements for CalWORKS include being a U.S. citizen or legal immigrant, having children or being pregnant, and working 32 to 35 hours per week. Researchers have examined various aspects of the CalWORKS program, including barriers to employment, sanctioning patterns, and domestic violence.

A report on the San Joaquin County CalWORKs program provides an outline of the process of application and entry into the CalWORKs program. Initial application for CalWORKs benefits is handled by an eligibility worker who accepts the application for benefits and determines eligibility and whether the applicant should be subject to work requirements. If no exemption from work requirements is warranted, an accepted applicant is referred to an employment specialist who, in conjunction with the client, formulates a welfare-to-work plan. This individual also serves as the participant's case manager. If barriers such as mental health and substance abuse are determined to be issues, behavioral health activities can be incorporated in the welfare-to-work plan; however, in San Joaquin County, this resource was rarely put into practice and may speak to a "work first" approach to welfare. Most recipients begin job readiness and search activities, which they can engage in for up to 4 weeks, after which they are assigned a case manager who monitors compliance with work requirements. Participants who are already working part-time at the time of application must continue to meet work requirements and must participate in activities to move them toward full-time employment. Students who meet application requirements can continue with schooling if it is determined that education will lead to employment.

Findings regarding CalWORKs populations and substance use have mirrored national findings. Key reports have examined substance use among CalWORKs populations. Consistent with national estimates, the rate of substance use among a CalWORKs sample has been estimated to be approximately 20%, with about half of those using substances reporting use of methamphetamine or opioids. Among those individuals reporting substance use, multiple problems were the norm. For example, mental health problems and involvement with child protective services were more common among substance-using CalWORKs applicants or recipients. For those reporting specific types of barriers to employment in a sample of CalWORKs recipients studied using a longitudinal design, the stability of health-related barriers and human capital deficits was notable. However, over time physical health problems declined and work skills increased. Childcare and transportation needs remained high over time, and the majority of individuals in this sample reported not owning a car. A corollary of transitioning to work from welfare is the maintenance of health benefits. Individuals applying for CalWORKs may be eligible for public health benefits as

well. It is important that health benefits be maintained after transition to employment, particularly among those CalWORKs recipients with physical or mental health barriers to employment.

Conclusion

Since its inception in 1935, welfare has undergone a number of reforms culminating in TANF legislation in 1996, which shifted welfare funding from a federal entitlement to a state block-grant program, instituted work requirements, and introduced time-limited benefits. The policy goal for welfare is now transitioning welfare recipients from TANF benefits to employment. Welfare beneficiaries face multiple barriers to employment, and for a subgroup of welfare recipients, mental illness and substance abuse may be issues. As in the general public, psychiatric disorders and substance use problems are related in the welfare population. Among long-term welfare recipients, mental health and substance abuse treatment needs may be particularly pronounced. Women with substance-related problems and mental illness who are receiving welfare benefits may be more likely to lose benefits due to sanctions and may be unable to maintain stable employment. Thus, they may experience severe economic stressors resulting in homelessness. Some have argued that the increased attention to barriers such as mental illness and substance abuse among welfare recipients has led to a clinicalization of welfare services that requires welfare recipients to reveal sensitive personal information that has previously been unneeded for benefits application or receipt. Service needs among welfare recipients may be complex and multifaceted, and given the implementation of work requirements and time limits on benefits, it appears that addressing these service needs is of great importance. California's response to TANF legislation (the CalWORKs program) is an example of one state's current welfare policies, and analysis of this program has indicated that behavioral health activities to reduce barriers to employment such as mental health and substance abuse may not be emphasized enough among program participants.

WILLPOWER

Willpower is typically defined as an individual's ability and determination to control his or her own behavior. Historically, there has been much debate about whether insufficient or weak willpower is a cause of addiction or relapse. The current consensus among experts is that addiction is a biopsychosocial disease, meaning that a combination of biological, psychological, and social factors influence its occurrence.

The extent to which addiction is viewed as a problem of willpower has implications for whether individuals with addictions are viewed as responsible or blameworthy for their substance use. The viewpoint that addiction is a willpower, moral, or misconduct problem results in prejudice against individuals with addictions and promotes the myth that individuals who abuse substances do so entirely by choice. In contrast, the viewpoint that addiction is a disease encourages sympathy and de-emphasizes individuals' personal responsibility for their condition. Currently,

the most widely held perspective on addiction among substance abuse researchers occupies a middle ground that acknowledges the roles of both personal choice and biological dependence. It is generally agreed that substance misuse begins as a voluntary behavior; however, neurological changes can occur as a result of repeated substance use whereby an individual's capacity to choose to discontinue using the substance is significantly diminished.

Twelve-Step Programs' View

Twelve-Step programs (e.g., Alcoholics Anonymous, Narcotics Anonymous) hold the view that addiction is a lifelong disease and that attaining and maintaining sobriety are not matters of willpower or personal choice. The first of the Twelve Steps entails admitting that one is powerless over substance use. Subsequent steps underscore the idea that personal control over substance use is not attainable for individuals with addictions. Instead, members of Twelve-Step programs are encouraged to identify and trust in a higher power that will help them refrain from using alcohol or drugs. In the jargon of Twelve-Step programs, the use of personal willpower to overcome addiction in the absence of a Twelve-Step program is called *white knuckling*. Program members are discouraged from relying on personal willpower to maintain sobriety because it is seen as an empty strategy almost certain to fail in the long term. Critics of the Twelve-Step perspective have argued that fostering the belief that people with addictions have no control over their substance use discourages the development of self-control and self-efficacy and may cause individuals who resume substance use in a minor way to assume that a severe relapse is inescapable.

Health Care Professionals' View

Despite empirical evidence that chronic substance use alters neurobiology, some experts claim that many physicians and other health care professionals have been slow to embrace physiological explanations for addiction and that they persist in attributing addictive behavior to patients' inappropriate values, poor motivation, or inadequate willpower. This perspective may impede health care providers' abilities to screen, identify, and refer substance dependent individuals to effective treatment. Educating health care providers that addiction affects neurobiology and that it has both

social and genetic determinants may reduce the erroneous belief among some health care professionals that addiction primarily results from a lack of willpower.

Relapse

Although addiction causes changes in neurochemistry that may compel affected individuals to seek out and use the substance upon which they are dependent, many people with addictions view willpower as essential to their own recovery. In other words, many people who are dependent on drugs or alcohol believe that the strength of their own character and commitment to sobriety is an important determinant of whether they will relapse. For this reason, the concept of willpower has salience in many forms of individual and group treatment for drug and alcohol addiction.

Measurement of Willpower

Recent empirical studies of alcohol and drug-related behavior use the terms *self-control* or *restraint* rather than *willpower* to describe and to study individuals' abilities to override undesired behavioral tendencies. Both behavioral and emotional self-control have been studied in relation to substance use. Behavioral self-control includes the ability to persist despite frustration, regulate inappropriate behavior, and delay gratification. Emotional self-control includes the ability to restrain disruptive emotions and impulses. Both are thought to be influenced by the prefrontal cortex of the brain, which is responsible for executive cognitive functions, such as planning, abstract reasoning, and self-directed behavior.

Evidence suggests that people with substance use disorders tend to have lower self-control than other people; they are less likely to approach decisions with a plan, monitor their course of action, and stay focused on a long-term goal. Several studies have also found that self-control may be a resource that is subject to depletion; individuals who exert self-control in a given situation may temporarily deplete that internal resource and thus be more vulnerable to temptation.

Research on self-control has led to the development of a treatment approach called behavior self-control training (BSCT). BSCT is a strategy for reducing problem drinking, often by focusing on decreasing the amount and frequency of alcohol intake rather than on abstinence. This controlled

drinking (harm reduction) treatment approach remains somewhat controversial despite considerable evidence demonstrating its efficacy because many treatment programs have been influenced by the Twelve-Step approach, which promotes the complete cessation of alcohol and drug use.

Numerous measures of self-control and drinking restraint exist. These generally assess participants' abilities to act assertively and decisively to try to govern their own behavior. Germinal work by William R. Miller and Ricardo F. Munoz on alcohol-related behavioral self-control strategies may be of particular interest.

WITHDRAWAL

Withdrawal is defined as both the act of ceasing to use an addictive substance and the physiological and mental changes that accompany such discontinuation. These changes are often referred to as a physical or psychological addiction. Most drugs result in some sort of physical addiction that may produce discomfort, pain, and illness and can, in rare cases, result in death during the withdrawal process. A few drugs result only in a psychological addiction, where the cravings or desire to use the drug have no biological basis.

There are many drugs that one can become addicted to and therefore, suffer the consequences of withdrawal. This section will focus on the most commonly reported drugs of abuse and will include illicit and legal drugs, beginning with alcohol.

Alcohol

Withdrawal from alcohol may occur when one ceases to drink or when there is a substantial decrease in drinking. The reduction required to initiate withdrawal symptoms varies greatly from person to person, and symptoms can be physical or psychological, or include characteristics of both. When withdrawal symptoms do commence, they can begin as soon as a few hours after the cessation of drinking.

Alcohol is one of the more dangerous substances from which to experience withdrawal. Hallucinations—visual (e.g., pink elephants), auditory (e.g., voices), or tactile (e.g., bugs under the skin)—are common but tend to be transitory, beginning about 12 to 24 hours after drinking ceases. Other symptoms include anxiety, sweating, hand tremors, nausea, vomiting, insomnia, rapid pulse, anxiety, and the most dangerous, grand mal seizures.

Grand mal seizures, when they occur, can last 2 to 3 days; however, not everyone who stops drinking, even if they previously drank excessively, experiences seizures.

Delirium tremens (DTs) refers to specific indicators of withdrawal and usually indicates a physical illness. Characteristics of DTs include memory disturbances and other symptoms of withdrawal, the most common being tremors. DTs may last several days. Note that the term *delirium tremens* is no longer the preferred term, and when referring to physical and psychological symptoms, *alcohol withdrawal* should be used, as it is more inclusive of all symptoms.

At many times, those experiencing withdrawal realize that the tremors, hallucinations, and agitation are all a result of the decision not to drink, but this realization is not always the case and care should be taken when confronting someone with these symptoms. If seizures, tremors, or hallucinations occur, hospitalization is recommended.

Benzodiazepine and Other Sedatives

Withdrawal from many sedatives (and certain hypnotics may also be included in this category) depends on a number of factors that include whether the drug is a short-active or a long-active medication. Individuals taking a short-active medication may begin to experience symptoms within 12 to 24 hours after the last time the drug was taken, whereas individuals taking long-active medications will not experience withdrawal for

24 to 48 hours. In addition, the age and health of the person experiencing the withdrawal may also affect the intensity and duration of the withdrawal, with older individuals or those with poor liver functions experiencing symptoms gradually.

Regardless of the timing of the onset of symptoms, the specific signs are similar and include tremors, anxiety, sleeping problems (insomnia, nightmares), seizures, nausea, and vomiting. As with alcohol, the withdrawal from sedative drugs can be dangerous and should be medically monitored.

The duration and intensity of the withdrawal will depend on the extent of use or addiction. Of note is that many individuals who take low-dose sedatives for medical reasons may not experience any withdrawal symptoms, but the problems for which the drugs were originally prescribed sometimes reoccur, prompting a cycle of drug use that may lead to addiction.

Cannabis (Marijuana)

Cannabis is one of the longer lasting drugs from which many individuals experience withdrawal symptoms. Withdrawal can include feelings of anxiety, tension, decreased appetite, depressed mood, and irritability. In addition, strong cravings are often reported and can result in problems when trying to reduce or cease use. These experiences may appear within the first day after prolonged, chronic use and may continue for up to a month.

Although most will argue that withdrawal from marijuana is purely psychological, a growing number of researchers are beginning to find anecdotal evidence of physical withdrawal symptoms.

Cocaine and Crack

Both cocaine and crack cocaine are stimulants. The extra processing used to produce crack cocaine results in a stronger drug. Nevertheless, both drugs result in similar withdrawal symptoms in the users that consist of depression, anxiety, fatigue, agitation, lack of motivation, problematic sleep patterns, irritability, aches and pains, and angry outbursts. Strong cravings for both versions of cocaine are also reported.

The differences in withdrawal between cocaine and crack cocaine appear to be related to the strength of the cravings, the level of physical and psychological dependence, the intensity of the “crash” and resulting

depressive symptoms, and the speed of onset of withdrawal symptoms since the first time the individual used the drug. All that being said, crack cocaine results in worse symptoms in all of the aforementioned areas. Some would argue that this is due to the nature of the manufacturing of crack cocaine that results in a faster and more intense high. This initial high is something encountered only during the first few times crack cocaine is used (similar experiences are reported with other drugs—see heroin withdrawal), and the high is so enjoyable that many would go to extensive lengths in an attempt to regain that intense high, which unfortunately is always just out of reach. Others argue that because crack cocaine is smoked, this method of administration contributes to the intense high. Regardless, addiction to crack cocaine can occur after only a few encounters with the drug. As a result of the quick onset of tolerance, many individuals report that more and more crack cocaine must be used to get close to that initial high.

Finally, those addicted to cocaine and crack cocaine may use other drugs (alcohol or marijuana) to ease the crash that follows the high. Withdrawal symptoms from these additional substances should be considered as well.

Heroin

Unlike alcohol and other sedatives, where there is a chance of death if the person is not supervised carefully during the withdrawal period, heroin withdrawal rarely results in death, although those experiencing the withdrawal may feel as if death is upon them. Heroin is an opioid. Opioids include a wide range of drugs used for their analgesic effects such as morphine, Vicodin, and opium. Many of the withdrawal symptoms for opioids are similar, and the severity of the symptoms may depend on the dosage, years of use, and the specific drug (opium is probably the least potent of the opioids). In other words, someone who is experiencing withdrawal from 6 months of opium use will not experience the same severity of symptoms as someone who has ceased heroin use after daily injections for the past 10 years.

Due to its widespread use and popular depictions in popular media, withdrawal from heroin is familiar to most people. The list of symptoms is rather long and at times may read like a description of a particularly bad case of the flu. The symptoms include goose bumps, runny nose, loss of appetite, tremors, chills,

nausea, cramping of the muscles and stomach, diarrhea, vomiting, sweats, irritability, jitters, dilated pupils, and watery eyes. At times, panic and sleep disturbances such as insomnia are also reported.

As with alcohol, withdrawal symptoms may commence when someone ceases to use or when there is a reduction in the usual amount of drug that is ingested. Onset of withdrawal symptoms can begin less than 12 hours after the last dose was administered and are at their worst 2 to 3 days into the withdrawal period. This period is the time when many will abandon their effort to quit using heroin cold turkey and will resort to use simply to ease the extreme malaise. Symptoms dissipate within about a week. Also, because most will inject heroin, usually there are additional health consequences of use that may exacerbate the withdrawal (e.g., abscesses, infections, bloodborne diseases).

Due to the strong cravings for heroin, the many triggers (events, people, or elements in the environment that result in cravings) that remind the person of how he or she felt while using, and the length and intensity of the withdrawal period, many who try to quit using heroin may require some pharmacological assistance such as methadone or buprenorphine.

Methamphetamine

Methamphetamine is a stimulant that is comparable in chemical structure to amphetamine, but its effects on the central nervous system are greater. Withdrawal symptoms of both drugs are similar.

Some begin use of methamphetamine as a way to deal with depression. Depression may also be a symptom of withdrawal, even in those who did not experience depression prior to methamphetamine use. In addition to depression, irritability, anxiety, and intense hunger are also reported. Sleep disturbances and fatigue are common. Many individuals who binge on methamphetamine report sleeping for extensive periods of time, upwards of 16 to 24 hours, as they come down off of the high.

As a result of the deficits in the neurotransmitters serotonin and dopamine, many individuals experiencing withdrawal from methamphetamine report depression. Whether this depression is solely a symptom of the drug use, a symptom that predated the drug use (e.g., the individual was already depressed prior to taking methamphetamine and used the drug to self-medicate), a result of the realization of the damage that was done, or some combination is still under

debate. Regardless, informing the person experiencing withdrawal that there may be cognitive deficits and that the mental confusion and other effects are normal and should improve with time can go a long way toward helping the individual understand his or her experiences.

Conclusion

Excessive use of alcohol and simple use of many of the drugs described here can result in withdrawal symptoms when the individual who previously used the substance ceases its use or simply reduces the consumption of the drug or alcohol. Withdrawal is a varied experience depending on the substance and the amount used, frequency of use, health of the user, and administration procedure. For some drugs, care must be taken when assisting someone who is experiencing withdrawal, and if the symptoms are severe or life threatening (e.g., seizures), hospitalization may be necessary.

Overall, withdrawal can be unpleasant and dangerous; however, withdrawal symptoms are rarely as bad as the consequences of continued excessive use of alcohol or drugs.

WOMEN FOR SOBRIETY

Women for Sobriety (WFS), a nonprofit self-help network for women in recovery, was developed by Jean Kirkpatrick, a Ph.D. in sociology. This program espouses the belief that there is no reason for any woman to die from alcoholism. After years of drinking and attempts at recovery through participation in Alcoholics Anonymous (AA), Kirkpatrick realized that the program did not address the things that were important to her as a woman. She realized that by changing her thinking she could make the changes in her life that she had been pursuing. Major emotional problems for alcoholic women, from her experience, include an excessive feeling of guilt, poor self-esteem, depression, and loneliness. Kirkpatrick was keenly aware that alcoholism is harder on women both physically and emotionally than it is on men. Physically, alcohol is metabolized by women more slowly, is more destructive to the system of the body, and leads to earlier dependence among women as compared with men. She drew upon her own experiences, her work with other women alcoholics in AA, and her extensive reading to create WFS in 1975 as the first self-help group designed specifically for women. She devoted her life to helping women alcoholics until her death in 2000. Important influences on her efforts include the feminist movement begun by Betty Friedan in the 1960s and the strong emphasis, made popular by the widely read book *Our Bodies, Ourselves*, placed on women to take charge of themselves.

In 1978, Kirkpatrick published her first book, *Turnabout: New Help for the Woman Alcoholic*, which offers guidelines for recovery for women through WFS. WFS can be used as either an alternative or concurrent self-help system with AA. Kirkpatrick developed a set of 13 affirmations that are the core of WFS. In addition to absolute sobriety, the affirmations emphasize positive thinking in line with the best interests of the person, an important emphasis on self-acceptance, and a belief in personal competence and a commitment to emotional and spiritual growth. This emphasis on self-efficacy and assertiveness and an active pursuit of life goals is in contrast to AA's emphasis on humility. WFS provided a program and a self-help organization for alcoholic women in recovery to replace sources of drinking—including emotional pain, depression, boredom, and lack of self-esteem—with self-efficacy and activities that provide satisfaction and purpose in life. WFS believes that many

women are able to maintain basic functioning and manage their alcoholism for many years. These coping skills also cause women to increase their dependence on alcohol and to reduce their ability to achieve recovery without the assistance of others.

WFS also suggests that women in recovery begin the day with 15 minutes of contemplation on the 13 affirmations and plan to implement these throughout the day. It is suggested that 15 minutes before bed also be spent to review the efforts to operationalize the affirmations. A record or diary of use of program affirmations during the day is used in the program. In addition to individual efforts to achieve and maintain sober living, WFS meetings provide an important resource to support ongoing sobriety. As in AA, confidentiality related to issues discussed in WFS meetings is a major rule. The ideal size of a group is seen as 6 to 10 participants, and groups are led by an individual who has a history of maintaining sobriety and is familiar with the WFS program and process. Groups generally meet once a week and follow a structured format. Rather than starting the meeting as in AA with "I am Jane, and I am an alcoholic," WFS groups begin with participants introducing themselves with the statement "I am a competent woman," followed by a brief statement of a positive personal characteristic. WFS emphasizes peer assistance outside of groups, and the organization has audiovisual materials, books, pamphlets, and workbooks on the program of WFS and common problems such as guilty feelings, depression, and self-image.

Some initial research, based on a survey of 600 members of WFS in 1991, provided information on the reasons women initially turned to WFS for help and on the benefits that women feel they have received from participation in WFS. Respondents identified the following problems as turning points for participation in WFS: physical problems (30%), emotional problems (29%), life problems (20%), loss of control of drinking (19%), driving related (8%), and encouragement from significant others (15%). Major benefits of WFS participation were seen as support and nurturance (54%), safe environment for discussing concerns (26%), emphasis on women's issues (42%), and focus on self-esteem (39%).

Currently there are approximately 5,000 members of WFS in the United States with 300 to 400 meetings posted per day. The Internet now provides a greater resource for WFS message boards and chat rooms that allow women the opportunity to interact even when they live in areas with no opportunity for face-to-face

meetings. Approximately 5,800 women worldwide participate in a public message board and also in online real-time chat services where certified leaders moderate the private online meetings.

Inspired by the pioneering work of Jean Kirkpatrick and other feminists, Charlotte Davis Kasl identified 16 steps for empowerment in drug and alcohol dependence recovery. Her broader understanding of recovery, which includes personal and social awareness, is an important complement to the work of WFS.

WOMEN'S ISSUES IN PREVENTION AND TREATMENT

See GENDER ISSUES

WORKPLACE DRUG POLICIES

Workplace drug policies can be categorized into two types: those that address drug abuse as a health issue, leading to limited opportunities provided by the employer to conserve individual employment,

and those that view any association with illegal drugs by an employee or a prospective employee as a violation, leading to punitive or exclusionary actions. Many workplaces have combinations of these two types of policies. In some instances their coexistence describes progressive steps toward exclusion, while in other instances their basic principles appear contradictory.

Several approaches address drug abuse as a health issue. These are employee assistance programs (EAPs) and peer intervention or union-based member assistance programs (MAPs). A third approach, health promotion, is oriented toward prevention, but does not address employer policy when events of drug dependence occur. Workplace prohibition and drug testing are policies oriented toward punishment and exclusion, although in some instances they can be coupled with EAPs.

Definitions of Substance Abuse in the Work Setting

At the outset, it is important to address the issue of ambiguous definition. What constitutes substance abuse in the work setting? This answer is somewhat clearer with the legal drug, alcohol, than with illicit drugs. As is well known, alcohol use is forbidden in most workplaces, and those who use alcohol while on the job or in some relatively immediate timeframe before coming to work are rule-breakers. On occasion, alcohol use before or during work leads to serious accidents in the workplace, and there can be no argument that preventing any injurious accident should be a workplace goal.

Alcohol dependence develops over a period of time, and while extensive data on the matter are rare, many anecdotes suggest that on-the-job drinking or intoxication among alcohol-dependent employees is relatively rare, usually occurring after a long period of visibly deteriorating job performance. Thus, the alcohol-using rule-breaking employees and the alcohol-dependent employees are different groups of employees and are the subjects of different policies. There is some overlap between the two groups in some circumstances, and this generalization about the independence of deviant drinkers and alcohol-dependent persons is but a frame within which to understand policies.

This alcohol-linked ambiguity is modest compared with that associated with illicit drugs. Because of their illegality, psychoactive substances such as marijuana,

cocaine, heroin, and methamphetamine cannot be used, only abused. Although there is a generalized societal belief that many people use marijuana without serious life consequences, there is no legally or medically acceptable definition of legitimate marijuana use. Indeed, great social controversy roils around whether anyone should be permitted to use marijuana for its very narrow medical applications. In at least one instance, a court has ruled that an employer has the right to fire an employee who has used medically prescribed marijuana.

Beliefs that are more diffuse and vague are associated with drugs such as powdered cocaine and ecstasy, but again, any use is legally abuse. There is even greater ambiguity as to when abuse becomes dependence. This ambiguity increases as one moves into the more marginalized drugs such as heroin, crack, and methamphetamine. Of significance is the fact that the response in the workplace has been to define any evidence of use on a yes-no criterion and regardless of the drug in evidence, to treat drug-positives in an equivalent manner, at least in principle.

Health-Oriented Workplace Policies

Looking first at the policies that define substance abuse within a health paradigm, we see that EAPs are widely prevalent and usually embed clear policies about employee substance abuse. EAPs are discussed in a separate entry in this encyclopedia.

Peer intervention and member assistance programs have many features in common with EAPs, but are also distinctively different. Instead of being operated by workplace management, these programs are based in professional associations and labor unions. In many ways, their principles exemplify the guild traditions wherein artisans and craftsmen first joined together in the Middle Ages to enhance the social status and value of a particular craft as well as to provide mutual fellowship and protection.

Since the 1970s, in the fields of medicine, law, dentistry, psychology, clinical psychology, nursing, and other professions, programs and policies have been developed that are oriented toward resolving problems of alcohol abuse and alcoholism through peer intervention. These programs are not widely publicized and have in fact elicited concern by the mass media when they have been discovered. These programs are, however, vigorous and involve substantial investments of resources.

Two intertwined concepts underlie such programs. First, professionals have autonomy in determining work hours and many aspects of their work styles. Indeed, independence of performance is often the primary defining characteristic of the professional. Second, there exists a strong sense of community in these professions, with members of a professional group tending to protect one another from external confrontations, interventions, or criticism. Such mutual protection is in turn supportive of autonomy and also ensures that members of the profession do not lose their jobs or their careers. To the extent that supervision of professionals occurs at all, it typically involves one member of a profession supervising other members, usually with a gentle hand.

With these characteristics of work, organizationally based interventions directed toward substance abuse problems would have a low likelihood of utilization. Few professionals are subject to the kind of supervisory scrutiny that is assumed in the design of EAPs. Likely, professional practice is designed to occur with a great deal of privacy. Thus, it would be expected that professionals' problematic performance would be minimally visible, that professionals would readily cover up for one another, and that because of their power and autonomy, professionals would be highly resistant to any form of confrontation, particularly by a functionary who is not a member of the profession.

Further, professionals have what can be called shared fate. The deviance or misbehavior of one professional undermines the trust that society accedes to professionals and may put at risk the reputation and status of professional peers, to a degree bringing disgrace on them all. Finally, because most professions are certified or licensed through boards of professional peers, the professions have to a large extent been assigned to police themselves. Thus, professions have a mandate to discipline or threaten sanctions against members with substance use problems.

Given the nature of professional work and its sometimes mysterious nature to outsiders, those who would be aware of a professional's drinking or drug problem are fellow professionals. Peer intervention programs are typically based within the local or state-level association of a particular professional group, such as a medical society or a bar association. These programs are operated and governed by members of the profession, frequently by members who have recovered from their own substance abuse problems.

Although private surveys of some impaired professionals programs have been conducted, detailed evidence about how these programs work is almost nonexistent. There is, however, strong inferential data that they are useful and effective by the facts of their widespread growth and diffusion and of the low visibility of impaired professionals in everyday life. Recently, data reported by the professionals who operate state-level programs for impaired physicians has been analyzed by an outside research team. The results indicate that the programs entail a substantial investment of resources, but yield strongly positive results that are not paralleled by substance abuse treatment programs that are typically available to the general public.

MAPs serve a different component of the workforce, those in labor unions, but they have much in common with programs for professionals and also utilize peer intervention. The first study of a MAP focused on a small, independent union with an intense drinking culture that included on-the-job drinking. The gradual and nonthreatening introduction of an informal program staffed by a union member who was a recovering alcoholic created a recovery culture alongside the heavy drinking culture and gradually moderated the latter. Recovery and abstinence became accepted as chosen lifestyles, and near-universal pressure to drink with work peers both on and off the job diminished. The key to success was that the members handled the pressure themselves with trusted professional assistance where needed. External imposition of rules was not part of the picture. Later studies focused on the success of more formal MAPs in the transportation industry.

The U.S. workplace is said to be moving away from hierarchical management and toward a model of peer organization, one involving participative management and collective responsibility. Should these predictions prove correct, peer intervention and member assistance programs might turn out to be particularly appropriate means for managing employee substance abuse. Perhaps the most attractive feature of these programs is their lack of association with authority, power, and accompanying opportunities for coercion and threat.

On the other hand, whether among professionals or within unions, peer intervention raises potential problems. Defining and implementing actions toward deviant behavior within an informal and undocumented framework may lead to abuses that are greater

than in a bureaucratic hierarchy. A bureaucratic system, governed by rules and administered by supposedly objective outsiders, offers opportunities for obtaining equitable treatment and for lodging grievances when authority, procedure, and rules are breached. A series of suicides among patients in an impaired physician program in Georgia some years ago highlighted these possibilities.

Approaches that address prevention within a health framework often have wide attraction, particularly on the basis of their eminent practicality. Many employers have introduced policies that encourage and reward employees for engaging in healthy behaviors. Recent research suggests that workplace-based health promotion and wellness programs may be effective in preventing substance abuse problems, with educational programs having a measurable impact on self-reported drinking behavior.

As of yet, there is no evidence of widespread impact of health risk appraisals on employee drinking. It is possible, but undocumented, that employees participating in exercise programs or other health-oriented leisure activities may change their drinking or drug-using behavior because such behaviors do not fit in with their new healthy regimen, and keep them away from environments that facilitate substance abuse.

Likewise, although stress management is a widely used intervention in the workplace, its effect on employee substance abuse has not been studied. A recently reported study combined several of these concepts and embedded alcohol use reduction education into a cardiovascular wellness program and demonstrated significant reductions in participants' drinking.

Punitive Workplace Policies

Turning to workplace drug policies that are built around a punitive framework, prohibition is a widely diffused passive primary prevention strategy. Unlike an exercise or stress management program, employers do not mandate that their employees actively do anything; rather, employers require that their employees not perform certain acts that in themselves are not directly linked to work. In nearly all cases, these rules proscribe the use of alcohol or drugs during work hours and prior to coming to work.

Prohibition of alcohol and drug use is found in nearly all workplaces, and prohibition rules regarding alcohol predate by many decades the enactment of

national Prohibition. Employers were major supporters of the temperance and anti-saloon movements because of their concerns about lost productivity and general irresponsibility among employees due to drinking. With the emergence of attention to illicit drugs, these substances were included in the general list of intoxicating substances and were recognized and addressed in prohibition policy statements in most workplaces beginning about 35 years ago.

With workplace alcohol prohibition so deeply institutionalized, one might easily conclude that it is impossible to successfully integrate drinking and work. Alcohol and work have not always been segregated. Drinking breaks and on-the-job drinking were historically part of many occupational settings. Drinking was believed to make one strong and able to endure heavy labor. Such behavior was, however, far short of drunkenness. As perhaps a throwback to these old beliefs, President Harry S. Truman began most workdays with vigorous exercise followed by a shot of bourbon before breakfast. Changes to industrialized and routinized workplaces, together with the influx of many immigrants who were seen as needing discipline and control, led to industrialists' successfully breaking the historical links between alcohol and work.

Workplace prohibition cannot be easily evaluated since there are no comparison groups; that is, settings without prohibition are essentially nonexistent. Even without data, however, it is reasonable to conclude that many accidents and injuries would occur if alcohol and drugs were intermingled with the work technologies of today.

Workplace drug testing has been the subject of much debate, as it has rapidly diffused over the past 2 decades. At issue are whether preemployment screening identifies persons with drug problems and whether it is an accurate predictor of job performance. It has been found that drug use does not necessarily mean a drug problem exists and that evidence of drug use does not necessarily mean that persons cannot perform a job, and it is possible that preemployment drug testing facilitates discrimination in hiring. Further, there is no evidence that preemployment drug screening reduces the rate of drug problems that are subsequently identified in workplaces.

Nonetheless, it appears that preemployment drug testing has become the norm in the U.S. workplace. Its promoters do not argue that the positive tests (the vast majority indicating marijuana use) are predictors of

job performance but that they are indicators of criminal behavior. Thus, preemployment screening could be simply defined as criminal screening that goes beyond what is available in police records. In any event, and perhaps in large part for its symbolic value demonstrating managerial authority and workplaces' support for the War on Drugs, drug screening is attractive to U.S. managers.

Parallel tests for alcohol are considerably less feasible because of the rapid excretion of alcohol from the blood, but such testing is being adopted in safety-sensitive industries. This concept is not new; as part of their rules of conduct or fitness-for-duty regulations, many workplaces have reserved the right to test employees for the presence of alcohol either on suspicion of intoxication or after an accident or other disruptive incident.

Random drug screening of current employees might be seen as a follow-up to preemployment screening or possibly as a means of screening those employees who were hired before the practice of preemployment screening was instituted. Random drug screening is associated with the same problems as preemployment screening in terms of identification of drug abuse and prediction of job performance.

For-cause screening (i.e., screening after an accident or other serious workplace incident) fits more closely with traditional workplace intervention approaches and, like random screening, is sometimes accompanied by referral to an EAP for assistance—but often with the condition that such an offer of help will not be repeated if another incident of evidence of drug use occurs. Because for-cause screening is linked to a performance problem, which may involve accidents or injury, this form of screening appears well within employers' rights to require that employees be fit for duty.

In some instances, random drug screening protocols are developed for individuals who have undergone treatment for drug problems under EAP or peer intervention program auspices. Here also there may be only a single opportunity for an observed slip, although EAP and peer intervention program policies vary in the extent to which they regard relapse as one of the expected features of recovery from substance dependence. There is anecdotal evidence that the use of random testing can be a strong motivator for treated employees who desire to keep their jobs, and thus, this form of testing can be an important complement to EAPs, peer intervention programs, or individualized situations where a person's continued employment is made conditional on continuing negative drug screens.

Drug testing policies, particularly preemployment screening, are likely here to stay, at least in the United States. Although there are no available data, anecdotes are accumulating that prospective employees are increasingly required to pay the cost of their drug screen, with some settings skipping this charge for those found positive and denied employment but deducting the cost from the first paychecks of the drug-negatives who are hired.

Although not immediately evident, a major driver behind the use of tests for screening for the use of illicit drugs is the drug testing industry itself. This industry is in the multibillion-dollar category and, curiously, did not exist at all prior to 1970. Related is another industry that operates on the edges of the law, but is allowed to function. This industry is the drug detoxification industry, which provides a wide range of devices and formulae that allow job applicants who are illicit drug users to produce clean urine samples. It may be observed that the testing industry's reports of steady declines in positive urine tests over the past 2 decades are a direct reflection of the success of the detoxification industry. Like the testing industry itself, this shadow industry has a strong interest in maintaining mandatory drug testing in the workplace.

WORKPLACE DRUG USE

According to the 2006 National Survey on Drug Use and Health (NSDUH), 17.9 million adult Americans acknowledged illicit drug use, and 13.4 million of these individuals were employed either full- or part-time. Thus, the majority of people (74.9%) who use drugs were concurrently employed. Workplace drug use can be broadly defined as the use of a psychoactive substance in such a way that it negatively affects safety at work or work productivity. Harmful substance use impacts the workplace directly through employee intoxication and indirectly through resulting social and health problems, both causing a financial strain on the economy. To better understand the scope of workplace drug use, it is necessary to identify common substances used, specify the demographics of prevalent users, and understand the impact of workplace drug use on the economy. Finally, it is crucial to recognize the need for education, prevention, and policy to reduce workplace drug use.

The substances used that contribute to the problems created by workplace drug use include illicit drugs, prescription medication, and alcohol. The illicit drugs identified as most prevalent are cannabinoids (marijuana, hashish), followed by cocaine, methamphetamine, and other amphetamines. The types of prescription medications acknowledged as misused and abused are opioids (e.g., codeine, hydrocodone, oxycodone) prescribed as analgesics, central nervous system (CNS) depressants (e.g., barbiturates and benzodiazepines) generally used for the treatment of anxiety and sleep disorders, and CNS stimulants (e.g., phenethylamine, Benzedrine, methylphenidate), which may be prescribed for attention deficit disorder or appetite suppression. Opioids, CNS depressants, and CNS stimulants all have a high propensity for the development of dependence among individuals who inappropriately use a prescription or take these psychotherapeutic drugs without a medical prescription. In addition to the latter mentioned drugs, alcohol has also been identified as a substance that contributes to the adverse effects of employee drug use.

According to the 2002 NSDUH, 61.8% of full-time employed adults currently use alcohol. Consuming alcohol in the workplace can compromise the safety and efficiency of workers. It also increases the probability of errors, accidents, and injuries on the job. The aftereffects of drinking (i.e., hangovers) can also affect attendance and job performance. Over time, individuals engaged in persistent heavy drinking may develop significant social, psychological, and medical problems that add to health care utilization. Workers with a history of alcohol misuse are likely to change jobs more often and spend more time unemployed. Overall, although alcohol is a legal substance, its misuse in the workplace has many detrimental effects.

The demographics of the predominant drug users in the workplace have been identified by gender, age, and occupation. Based on the 2005 NSDUH, full-time employees disclosing current illicit drug use tended to be males between the ages of 18 and 25. These young men were typically White, less educated, and single. Workplace drug use was greatest among individuals employed as food preparation workers, waitstaff, bartenders, and other service-oriented workers. Higher rates of problems resulting from drug and alcohol use also occurred among construction workers, individuals working in the transportation field, and those working with the moving and transport of materials. Jobs in the arts, entertainment, sports, and media were also identified as occupations with high rates of negative substance use.

The impact of drug use in the workplace has been substantial. According to the National Institute on Drug Abuse, workplace drug use has resulted in more than \$110 billion in annual costs to the U.S. economy. This cost was attributed to decreased employee productivity, increased employee absenteeism and turnover, workplace injury, and increased health care costs brought on by illicit drug use and improper use of prescription medications and alcohol. In the 2005 NSDUH report, employees that used illicit drugs were more than twice as likely to have switched employers 3 or more times in a year as were nondrug users. Drug-using workers were 3 times more likely to be late to work and use 3 times as many sick days than their peers. They were also 5 times more likely to file a workers' compensation claim. The NSDUH also reported that up to 40% of industrial casualties and nearly 50% of injuries were linked to alcohol use and alcoholism. Drug use and alcohol misuse can lead to

deterioration of physical and mental health, which results in greater utilization of the health care benefits provided at the cost of the employer.

The financial cost due to decreased productivity, increased absenteeism, and increased utilization of health care benefits has created the need for comprehensive drug and alcohol use policies in the workplace. General guidelines for an effective policy include promotion of drug awareness education, enhanced preventative measures, and efficiently executed, fair, and just procedures against workplace drug use. The Federal Drug-Free Workplace Act of 1988 is a federal law that identifies minimum requirements to help sustain a drug-free workplace. All organizations and individuals receiving \$100,000 or more from a federal contract or grant must comply with the minimum requirements of this law. First, employers must have a written policy that explains prohibited use (including possession, manufacture, and distribution) of controlled substances and the penalties for violation. To implement the policy, employees must read and consent to the policy as a stipulation of employment. As an additional preventative measure, employers must establish a comprehensive awareness program to inform employees about alcohol and illicit substance use and also offer education for employees on available services for drug and alcohol problems. These awareness programs should also assist employees in understanding the employer's policy. If an employee is convicted for any drug-related offense, he or she must disclose this information to the employer within 5 days of the conviction. In turn, the employer must then notify the contracting agency of such a conviction and impose the appropriate sanctions according to the policy. Finally, employers must make a good-faith effort to establish and preserve a drug-free workplace. In addition to these requirements, many employers have incorporated the use of drug testing as a component of drug-free workplace programs.

Drug testing in the workplace has been used to prevent and reduce workplace drug use. Drug testing may be part of the hiring process (preemployment test) or utilized at random (randomly selecting and testing an employee arbitrarily) by the employing organization. Drug testing may also occur when reasonable suspicion arises (e.g., employer or coworker observes behavior indicative of illicit substance use). This suspicion is typically followed with postaccident testing (test administered after incident or accident on the

job) and a return-to-duty test or follow-up test (a specimen tested after the employee returns to work from leave of absence due to drug use). The most common drug test, urinalysis, screens for cannabinoids, cocaine, amphetamines (i.e., methamphetamine), opioids (morphine, heroin, opium), and phencyclidine (i.e., PCP). Prior to submitting to a drug test in the workplace, an individual must be informed of the organization's policy on substance use and the consequences of a positive test.

The consequences of a positive test vary according to the organization's policy on workplace drug use. Positive testing during the hiring process or after established employment can result in a range of outcomes such as failure to obtain a position with the company, immediate termination of employment, or a referral to an Employee Assistance Program (EAP).

An EAP is a company- or union-sponsored program that provides services for prevention and early intervention in employee matters. A well-designed EAP is available at no cost to the employee and provides access to assessment, counseling, and outside referrals for help with substance use problems. An EAP aids the organization in addressing issues of productivity among workers by identifying and resolving personal issues. Many EAPs do not limit assistance to employees with substance use and alcohol use problems but also offer support in many other areas including health, marriage and family relationships, legal issues, and finances. Although implementing an EAP may be costly for the employer, it will ultimately reduce the financial deficit created by workplace drug use and other personal problems by addressing the issue early and offering intervention and treatment to workers.

To summarize, problematic psychoactive substance use has resulted in substantial economic costs due to employee performance outcomes (i.e., productivity, absenteeism), employee attendance rates (i.e., absenteeism and tardiness), and health care costs. Although many awareness and prevention practices implemented within the workplace (e.g., Drug-Free Work Place Act, drug testing, and EAPs) are intended to reduce the prevalence of workplace drug use, there is not a definitive solution to completely eradicate the problem. The consequences of drug and alcohol use will radiate into the workplace as long as use remains a problem within the general population.

WORKPLACE PREVENTION

Substance abuse is a major public health concern in the United States. In fact, the National Institute on Alcohol Abuse and Alcoholism estimates that 10% of the population has a problem with alcohol. In addition, 17.9 million adult Americans are current illicit drug users. Although historically, drug and alcohol abuse has not been seen as an issue that needed to be addressed in the workplace, more recently, this line of thinking has changed because of the negative effects on both the individual and the workplace. The National Institute on Drug Abuse reports approximately 75% of illegal drug users are working. In addition to their own struggles, workers who use alcohol or other drugs may have a deleterious impact on other employees and affect employee health, safety, productivity, and health care costs. Alarming, Mary Bernstein and John Mahoney report, 40% of industrial fatalities and 47% of industrial injuries can be connected to alcohol use and alcoholism. Moreover, according to data from the Substance Abuse and Mental Health Services Administration (SAMHSA),

marijuana and cocaine are the two drugs most commonly abused in the U.S. workforce. Consequently, more and more businesses are developing programs to address employee issues, especially as they relate to drug and alcohol abuse. Unless otherwise noted, the information contained below has been modified and adapted from the U.S. Department of Labor and SAMHSA.

Scope of the Problem

Compared with non-substance-abusing workers, substance abusers tend to be less productive, take more days off, be more likely to injure themselves or someone else, and file more workers' compensation claims. More specifically, SAMHSA reports the following statistics:

1. Problems related to substance abuse (i.e., drugs and alcohol) cost businesses over \$80 billion in lost productivity a year,
2. substance-abusing workers only function at 67% of their total capacity,
3. nearly 40% of work-related fatalities and 47% of work-related injuries can be attributed to alcohol use and alcoholism,
4. employees who use drugs are more than three times more likely to be involved in a workplace accident and five times more likely to file a workers' compensation claim,
5. approximately 500 million workdays are lost each year as a result of alcoholism,
6. employees who use drugs are twice as likely to request early dismissal or time off or have absences in excess of 8 days and three times as likely to be late for work, and
7. employees who use drugs cost their employers almost twice as much in medical claims.

Furthermore, data from the National Survey on Drug Use and Health revealed that full-time workers, ages 18 to 49, with current illicit drug use lacked job stability. As staggering as these figures are, it is even more difficult to quantify the impact on employee morale and impaired judgment and decision making at work caused by substance abuse. Given the prevalence of substance abuse, coupled with the amount of time spent at work, the workplace presents a tremendous

opportunity to educate employees about substances and assist substance abusers in seeking help.

Prevention

In response to the growing concern over drug and alcohol abuse and the effect on workplace safety and productivity, the federal government established the Drug-Free Workplace Act of 1986, which requires all federal grantees and some recipients of federal contracts to provide a drug-free workplace as a condition of receiving federal funds. More specifically, all employees must adhere to policies and procedures designed to provide a safe workplace, discourage substance abuse, and encourage treatment and return to work for those employees with abuse problems. Substance abuse prevention and early intervention strategies and activities may include a drug-free workplace program, an employee assistance program (EAP), a health promotion or wellness program, an occupational health and safety program, and drug testing. Regardless of the type of program offered, SAMHSA recommends, at minimum, that workplace intervention programs should include the following:

1. a written policy describing the employer's expectations about substance use and the consequences of policy violation;
2. employee education to describe the program and the signs and symptoms of substance abuse and their effects on performance;
3. supervisor training to orient supervisors to the substance abuse policy, to clearly define the supervisor's responsibility to refer employees when job performance issues are encountered, and to recognize and assist employees with problems;
4. an EAP to provide confidential services; and
5. carefully controlled and monitored drug testing.

Substance Abuse Policy

The creation of a clear substance abuse policy is critical and management support is vital to the success of the program. More specifically, the purpose of the policy is to inform all employees that the company is serious and committed to providing a drug- and alcohol-free work environment. Ultimately, employees and management share a common goal: a safe,

secure, and healthy workplace. In addition, the substance abuse policy should be tailored to the workplace in which it is being implemented. For example, in the process of developing the substance abuse policy, it may be necessary to modify the existing rules regarding alcohol consumption at company-related events (e.g., holiday parties and company gatherings). Developing and publishing a clear and comprehensive substance abuse policy is essential. A written policy lets employees and job applicants know that the commitment to a drug- and alcohol-free workplace is strong and serious. Moreover, employees, from all levels of the organization, must be included and support the program if it is to be successful.

Employee Education

All employees, including top management, must be knowledgeable about substance abuse and how to develop effective programming that meets the needs of employees. The U.S. Department of Labor recommends that, at a minimum, employee education programs should contain the following:

1. information on the manner in which substances (i.e., drugs or alcohol) impact the company's productivity, absentee rates, health care costs, or accident rates;
2. information about the company substance abuse policy and the consequences of using alcohol or drugs, both on and off the job;
3. information about the health effects of substances (e.g., illegal, prescription);
4. information about how to seek help for alcohol- or drug-related problems, including a description of resources available to assist employees; and
5. a comprehensive description and explanation of any drug or alcohol testing procedures, if these are part of the program.

In addition to providing information to the person abusing substances, these programs can also offer information and assistance to non-substance-abusing workers who may be impacted, either directly or indirectly, by a substance-abusing colleague. In order to be effective, these programs must be offered on a continuous basis, rather than as a onetime orientation training component.

Supervisor Training

Supervisors play a critical role in the implementation and enforcement of workplace substance-abuse programming. Consequently, employees in supervisory and top management positions must be familiar with and understand the policy, and, by extension, respond when the policy is broken. Supervisor training programs may be delivered in many formats (e.g., seminars, lecture series, videotapes, printed materials) by knowledgeable top management or an outside consultant. Key ingredients of successful supervisor training programs include the following:

1. prevention and education strategies;
2. information on specific drugs;
3. background drug-testing issues and procedures, if appropriate;
4. effects (biological and psychological) of substance use;
5. methods for detecting substance use; and
6. review of the laws pertaining to substance abuse.

Typically, constructive confrontation (i.e., taking a caring, but firm approach) can be an effective supervisor strategy to engage an employee to seek help. However, it is very important to establish clear boundaries about the supervisor's role and expertise in this process. To be clear, a supervisor's role is to monitor employee job performance, not diagnose and resolve an employee's personal problems. These types of issues are better handled with a referral to a professional.

Access to Assistance

One way to assist employees who have problems that are affecting their job performance is to develop an EAP. EAPs are typically cost-effective, job-based programs designed to assist employees with a number of issues (e.g., alcohol or other drug problems, family issues, financial or legal entanglements, mental health difficulties). In general, an EAP is based on three fundamental assumptions: (1) Employees are an important part of business and valuable members of the team, (2) it is better to offer assistance to employees experiencing personal problems than to discipline or fire them, and (3) recovering employees will again become productive members of the workforce. From

an economic perspective, EAPs may result in reductions in absenteeism, work-related accidents and injuries, use of medical and insurance benefits, employee grievances and arbitrations, and employee replacement costs, which, in turn, all translate into tremendous savings for the company. To create an EAP, management should consult with an EAP expert for programmatic and procedural guidance. In general, setting up and implementing an EAP requires a significant amount of time, and the success of the program will depend on the quality of the staff, as well as the commitment and dedication of those responsible for program oversight. Thus, establishing a diverse team of personnel, consisting of employees, supervisors, employee representatives, and top management, can aid in the dissemination and implementation of the EAP program within the organization.

Drug Testing

Given the serious consequences and implications (both direct and indirect) associated with employee substance abuse, many companies have started to drug test their employees as a condition of employment. The purpose of drug testing is not only to deter and detect drug use, but perhaps more important, to facilitate engagement in substance abuse treatment. Given the sensitivity around drug testing, these programs must be developed in strict accordance with the law, which may vary by state. Consequently, upper management may wish to consult with the corporate attorney, or for smaller businesses, a lawyer with expertise in corporate law and knowledge and experience in the case law relevant to the development of these types of programs.

In addition to the legal considerations, some of the other logistical and procedural issues upper management will also need to consider include (a) who will be tested, (b) how often, (c) what drugs will be tested for, (d) what will be the company response if an employee tests positive, (e) how will employees' privacy be protected, and (f) where will employees be tested? Ultimately, management has a responsibility to ensure the drug testing program is fair and accurate and protects the rights of all employees. For more information, the Department of Health and Human Services has developed standards and guidelines for these types of programs (i.e., Mandatory Guidelines for Federal Workplace Drug Testing Programs). As a cautionary note, drug-testing programs should only

be implemented as part of an overall drug-free workplace program. Although testing is one of several useful tools that can assist in the deterrence and detection of substances, it should not be used as a stand-alone program. More specifically, drug-testing programs should only be used in conjunction with the components of a larger, more comprehensive workplace prevention program (e.g., written policy, EAP, supervisor training).

Conclusion

Substance abuse in the workplace is a complicated and multifaceted issue that has tremendous implications on employees and the company as a whole. As noted by the U.S. Department of Labor, there are no simplistic solutions to the complex problem of alcohol and other drugs in the workplace, and no single approach to workplace substance abuse will meet the needs of every organization. Every person in the workplace can take an active part in fighting workplace substance abuse. Drug-free workplace programs may be a useful approach to substance abuse prevention.
