Despite the fact that there is utility in SNA for primatology, Sade and Dow (1994) argue that information is not passed from one individual to a second and to a third, the way information is passed through human groups. However, aggression can be passed down the hierarchy and SNA can identify what that chain will be. Previously, primatologists believed the strongest individuals would “win” these aggression displays. However, SNA has cast doubt on this assumption. Further analysis in the 1970s has shown that the dominance hierarchy plays a more important role in aggression displays than does physical strength (Chase, 1974).

Additionally, primatologists can study social networks not only to understand group structure, but also to appreciate brain research. The neocortex is the outer layer of the cerebral hemispheres that are part of the cerebral cortex. This region of the brain is associated with higher functions such as sensory perception, generation of motor commands, spatial reasoning, conscious thought, and, in humans, language. Neocortex size and group size are strongly correlated in primates because the information-processing capabilities of the neocortex constrain the number of individuals that can coexist (Kudo & Dunbar, 2001). In other words, some primates have a limited ability to store, understand, and process complex social relationships of the group members, resulting in smaller group sizes. Additionally, primates form coalitions, or alliances, that are particularly important and complex features of group dynamics.

Kudo and Dunbar (2001) studied the relationship between coalition size, group size, and neocortex size in 32 species of primates. Their sample included species of prosimians, monkeys, and apes, including humans. The authors used SNA methods and sociograms to identify primary relationships and the total number of relationships in groups. Relationships were defined as grooming partners because all nonhuman primate species engage in this activity to some degree and there is reliable, consistent data collected on grooming patterns for many primate species. Conversational groups were used for the human analysis.

Kudo and Dunbar found that for the majority of species sampled, the mean size of networks is around 75% of the total group size. This means that the majority of individuals are linked together in a single network by a continuous chain of relationships, with a small number of individuals on the periphery. Additionally, the authors state that neocortex size does correlate with the size of grooming cliques, as well as with total group size in many primate species (p. 719). Kudo and Dunbar assert that neocortex size appears to limit group size. The neocortex size may constrain the size of coalitions, or cliques, that animals can maintain for cohesive relationships. Group size seems to be mainly determined by the number of animals that can be incorporated into a single network.

Conclusion

The complex, and often symbolic, interactions between people are what make us distinctly human. As has been shown in the SNA case studies of primate social groups, the nonhuman primates do not even approach the information-sharing social support networks that humans possess. People place much importance on their social relationships, often seeking primary assistance and advice from their social support networks before seeking out professionals. Social scientists recognize the pivotal and central role social relationships play in our daily lives and have developed advanced methods to study these relationships.

Social network analysis is a research methodology developed by social scientists from such diverse fields as psychology, anthropology, and mathematics. The development of SNA took many twists and turns on its long journey to become the methodology that we recognize today. Historically, theoretical frameworks have been attached to SNA, but it is now largely recognized as a set of methods that many researchers and professionals can utilize. This chapter discussed the utility of studying social relationships through SNA, as well as the history and major current uses of SNA in anthropological research. Additional attention has been given to the unique problem of ethical and power issues of SNA research and respondent bias. Last, we concluded with a discussion of diverse anthropological case studies that utilized SNA methodology, such as for nonprofit organizations, childhood social development, medical anthropology, business anthropology, and even primatology.

Of course, there are many other ways in which anthropologists and researchers can utilize SNA. There are also many other methodologies with which to study social relationships. This chapter focused on SNA because of its growing popularity, broad range of utility, and opportunities for development in new directions by anthropologists and social scientists alike.

RANK, STATUS, AND ROLE

DEBRA M. LUCAS

D'Youville College

Human beings belong to a social species that has evolved to exist in dependence with other human beings. Accordingly, humans survive with others in society and cannot exist as lone individuals. In anthropology, a human society is a group of human beings who live together. Their interactions are patterned in regular and sometimes predictable manners. The society in which one lives is identified by its common language, customs, and geography. Anthropology and other social sciences assist in studying, understanding, and explaining the orderly interdependence of human society. Individual interactions with society are not independent because interactions occur among people who hold recognized positions in society. The concepts of rank, status, and role are indicators of recognized positions in social systems.

Principles of rank, status, and role can be examined within the context of individual social systems. *Rank* most commonly refers to a type of society in which people have varying degrees of access to resources, power, and status. These rank societies contain social groups with various degrees of prestige. In turn, this creates stratification. Rank can also represent one's position within a social scheme, system, or network.

A *status* is the social position a person occupies within a social network. For example, husband and wife are statuses. All individuals within a society may hold a range of statuses in their lifetime because they will partake in many different types of social interactions.

Each status is then accompanied by a corresponding *role*. A role is the set of expected behaviors specific to a status. When a role is not fulfilled effectively, the other members of society will show disapproval. People will behave in their individual roles according to this combined set of rights and obligations. It is the expected set of actions, for example, to be a loving and affectionate spouse. Kinship status is a good example of the relationships between status and role. The status of parents will include the right to discipline their children. It is also their role to feed and educate them. The relationships an individual has with family, friends, coworkers, neighbors, and other people who are in the groups to which the individual belongs form a social network. Recreation, politics, and religion are examples of social-networking groups.

Social stratification is the process by which the members of a society are arranged into a pattern of superior and inferior ranks. It is a structural hierarchy of social inequality. These hierarchies may contain ranks, statuses, and classes, to which certain role behaviors will be assigned. Anthropologists consider social stratification a recent historical development because archaeological evidence from about 7,500 years ago shows distinct equalities in housing and burial sites. Anthropologists believe that members of those societies had similar access to resources and privileges. Recent industrial and postindustrial societies are considered socially stratified. These societies have families, social classes, and ethnic groups that have unequal access

to economic resources, power, and prestige. Differences exist at more defined levels such as age, skill, gender, and education. For example, adults have greater status than children, and in many societies, men still have greater status than women. Those with special skills, technical training, or other advanced education may also have greater status and prestige.

Social stratification is related to the manner in which economic resources are divided. In separate studies anthropologists Gerhard Lenski (1966) and Marshall Sahlins (1958) found that the production of surplus stimulates the development of stratification. Lenski also felt that conflict arises over the control of the surplus and that the manner of distribution determines the basis of power. Inequalities in power create inequalities in access to economic resources and prestige.

Some theories state that social stratification is the result of production that creates surplus. Other theories stress that stratification exists in rank societies when there is pressure to consume, possess, and control available resources. If all people have the same access to economic resources or to society's division of labor in creating goods and services, then it would follow that there would be greater societal equality. However, social stratification is not merely a matter of economics.

Economic resources are items of value, including land, goods, money, tools, and technology. Power is the influence or ability to force others to do what they may not otherwise want to do. In societies with unequal access to resources, it naturally follows that those with more economic resources will have greater power or influence. Political affiliations, for example, can bring power or influence to the general group. Prestige connotes a sense of honor for individual or group members.

Types of Societies

Anthropologists introduced concepts to highlight distinctions in the ways societies are organized. A fourfold classification of societies based on political organizations includes bands, tribes, chiefdoms, and states. A *band* is a small group with a simple social structure. It has no complex differentiated political institutions or social institutions. A *tribe* is a pastoral or horticultural society that primarily relies on the land for all of its subsistence. A *chiefdom* has patterns of social stratification and an economic system of redistribution of goods. A *state* is the overall territory and social system that is ruled by a particular governing agency. An essential requirement for and consequence of a state society is that the society's economic surplus be centrally appropriated and that the society be socially stratified. Evolutionary anthropological experts in the United States say these systems developed organically. Chiefdoms developed from the tribal systems and existed before the state.

Classification systems based on subsistence strategies include hunter-gatherers (foragers), pastoralists, horticulturalists, and agriculturalists. A fourfold classification of societies based on economic conditions are forager, herder, and extensive and intensive agriculturalists. Foragers are also called food collectors or hunter-gatherers. These societies do not own individual land. Instead, hunter-gatherers value the wild game and the plant life that live upon the land. Individuals from food-collecting societies do not maintain exclusive rights to the land where they hunt. Everyone in the society can hunt, gather, and draw water.

If the food supplies run low because the game migrates or the plant life dries out, then the land loses value. In these cases, communal ownership of the land is more practical. Territoriality tends to develop in areas where the land resources and access to water and game are abundant. In this situation, a group may become more sedentary and reluctant to let members of other groups travel onto their land. Territoriality is minimal in areas where plant and animal resources are unpredictable.

Like food-collecting societies, horticulturalists do not individually or as a family own the land. However, plots of land may be allocated to families for their own use. After their herds graze an area low, horticulturalists move to new land, allowing the land they used to lie fallow and replenish. Horticulturalists are generally more self-sufficient than pastoralists. They make their own tools, but are obliged to communally share their tools and other weapons. For example, in the Truk society, if a canoe is needed for fishing, it may be taken from a close kinsman, without asking permission. If the canoe belongs to a distant kinsman, one must first ask permission, but the canoe owner is obliged to loan it.

In intensive agriculturalist societies, land is individually owned. Owners have the rights to use the resources and sell or give the land away as they choose. Occupying and cultivating the land increases its wealth and long-term usability. In industrial societies where intensive agriculturalists exist, individual landowners have absolute control of the land. In this absolute ownership, they are also subject to absolute loss due to natural disasters, national economic crisis, or catastrophic climate changes.

Lewis Henry Morgan (1877) was a pioneer in the study of human societies, concluding that cultural evolution was ranked on subsistence patterns and depended on technological complexity. His final scheme contained three ethnic periods: (1) savagery, (2) barbarism, and (3) civilization. He believed that every society would pass through these as they evolved to a higher form. Morgan ranked each group into lower, middle, and upper categories, based on the complexity of their tools. Savages may never have domesticated plants or animals for subsistence. Furthermore, an upper savage may have used fire and fished, but not used a bow or arrow. Barbarians may have domesticated animals and plants for subsistence. They also may have invented new tools and techniques. Morgan believed civilization

was the next ethnic period to evolve from savages and barbarians. Although anthropologists have stopped using such terms as savage and barbarian, they do recognize the value in his classifications. He studied a variety of societies, concluded that subsistence was systematic, and correlated technological developments with forms of social organizations.

Anthropologists have continued to further classify societies as either egalitarian or stratified. In egalitarian societies, members or member groups have primarily equal access to the same degree of wealth, power, and prestige. In stratified societies, members or member groups have different levels of access to these resources. Egalitarian societies are often seen in smaller and less technologically developed communities like bands and tribes. Stratified societies are seen in larger, more complex, bureaucratic, or advanced societies like chiefdoms and states. Rank societies may lie somewhere in between these two.

Egalitarian Society

Egalitarian societies believe in the importance of human equality in social, political, and economic affairs. Members in egalitarian societies communally share economic resources such as food, tools, and weapons. The practice of sharing maintains equal access to these resources.

In egalitarian societies, there are few or no formal methods to give authority or power to certain individuals or groups. There is no hereditary right or position to power or authority. In most cases, egalitarian means that every man has equal say in what affects the tribe or clan. In some societies, this equality extends to women. Egalitarianism performs well in small band societies like hunter-gather, horticultural, and pastoral cultures. Most of these food-gathering societies live in family units that manage subsistence activities by consensus.

Members of these societies have primarily similar access to all economic resources and advantages. No social groups within these societies have greater or lesser access to resources or advantages. Morgan Fried (1967) defined egalitarian society as a society containing as many positions of prestige as there are members. Valued statuses are adjusted to meet the number of persons who are skilled to fill the positions. Egalitarian societies cannot fix or limit the number of persons who are capable of exerting power.

Rank Society

Rank refers to the social positions within societies that recognize social hierarchies. A rank society is one with equal access to economic resources or power. Within smaller social groups in a rank society, there is unequal access to status and prestige. Ranking is often practiced in agricultural or herding groups. Rank may be ascribed or it may be achieved. For example, ascribed rank is assigned at birth. If a child who is born to a great hunter or artisan is

automatically assumed to be a great hunter or artisan, he has been given an ascribed rank and the accompanying status or prestige. However, people who possess different physical skills, levels of intelligence, and other abilities may achieve a rank through their actions or achievement.

A tribal chief is another example of an ascribed ranked position that is hereditary or genealogical. The rank of a tribal chief is given to the oldest son of a reigning tribal chief. The son succeeds his father in that rank. A chief will receive special honor and be shown greater respect by lower ranked citizens. People of lower rank must always keep their head bowed lower than the heads of those with higher rank. They will bow their heads lower than a chief who is sitting and bend low before a chief who is standing.

Fried describes rank societies as those that limit positions of status. Not all of the people qualified for such a rank position may occupy such a position. These rank societies exhibit varying degrees of stratification. In rank societies, individuals are placed in labor tasks or occupations that are suitable for their age, gender, and ability. However, Fried argues that in the rank societies, no political power derives from these specializations. Specializations in craftsmanship developed from a natural division of interest. The consensus among anthropologists is that fully stratified societies emerged from rank societies; the manner in which the transitions occurred is still debated.

Some controversy does exist in the belief that members of rank societies have equal access to economic resources and power. Material advantages exist for a chief, who maintains a storehouse and receives gifts from the commoners. Sahlins (1958) argues that although these benefits exist, the chief has no power to demand gifts and that the storehouses are only used to keep what will be consumed during feasts or later redistributed to the tribe.

Other studies show that food sharing and divisions of labor are not equal in rank societies. In collective meal preparations, for example, the chiefs are served first, and as tradition, the women bow in reverence. In tribes where the chiefs own the fishing areas, it was found that their households received twice as much fish per person as the rest of the tribal families. It was widely believed that principles of generosity would balance out the distribution of resources. However, recent studies by Laura Betzig (1988) show that gifts from all families to the chiefs did not equal the gifts from chiefs to other families. She found that in the small atoll of the western Carolines, even though all tribal households gave gifts to the Ifaluk chiefs, the chiefs most often only gave gifts to their own families.

Stratified Society

In stratified societies, members or member groups have greater and sometimes permanent access to wealth, power, and prestige. Anthropologists traditionally describe stratified societies as class systems or caste systems. These societies often exist in chiefdoms and states. The two forms

of stratified societies are internally divided into hierarchical groups. These societies, class or caste, are fully stratified and have unequal access to economic resources, power, and prestige.

Caste

Some stratified societies have a closed class system called a *caste* system. Although the first prototype of a caste system originated in India, anthropologists use the term to define other similarly arranged societies. A caste system is a ranked group system in which there is no social mobility. Many people believe that a caste is determined by one's occupation, but that is not entirely true. Membership within a caste rank is determined at birth, and caste systems practice endogamy. Marriage is legally restricted so that caste members must marry within their same caste group.

Castes can be identified by traditional occupation and are ranked on a scale of purity. In India, villagers have been stratified from the upper elite to the lowest caste members who perform street sweeping and other menial labor. Higher caste members, such as Brahmin priests, are obligated to hold strict dietary restrictions and are subject to other taboos to maintain their caste purity. On the other end of the spectrum are the outcastes or the untouchables whose occupations bring them into close and regular contact with animal skin, meat, and excrement. Between these two extremes are thousands of castes and subcastes.

Members of a lower caste can sometimes obtain a better wage-paying job and this can increase their social standing. In fact, the economic basis of the caste system has changed since World War II because many occupations have shifted from a barter or exchange system to a pay-for-service model. In this, a son born to the barber caste can become a wage-earning teacher during the week and cut hair on the weekends. Although the system allows him the benefits of having a teacher's salary, it does not change his caste. He is and always will be in the barber caste, as his father was.

In a caste system, membership is ascribed and set for life. One mechanism to maintain caste immobility is to legally restrict marriage within castes. Because one cannot marry into a higher caste, it is impossible to achieve social mobility. Because the caste system gives advantages to the higher castes, it has caused resentment and hostility that has led to some economic and practical uprisings.

Class

A social *class* system is comprised of ranked subgroups in a stratified society. Membership in a social class is determined by economic criteria, such as income, property ownership, or educational levels. A class is also a category or group of similar occupational types that has similar opportunities in terms of economic resources, power, and prestige. Not every class has the same access to land, livestock, money, food, and other significant resources. In

class societies, people can achieve different status or prestige through occupation, education, and achieved or inherited wealth. A class system is different from a caste system because the class system is open. Laws or other social norms do not strictly prohibit social mobility.

Class boundaries may have been formed by customs and traditions. According to the studies of Michael Argyle (1994), people identify with a social class very early in life. Differences in many different social indicators go beyond the basics of occupation, wealth, and prestige. People in different social classes relate to others of similar religious affiliation, family upbringing, child-rearing practices, activities of leisure, social manners, and social graces. People are comfortable with other people of the same class because they share many commonalities. People generally stay within and marry within the class to which they were born.

The class to which one belongs throughout one's lifetime is neither fully determined at birth nor fixed throughout an entire lifetime. The American society is generally an open class system. It is possible to move from one class to another through educational attainment, by marriage into a higher class, or by developing a highly valued skill that makes one marketable and well compensated. In addition to occupation, other class indicators include religion, family tradition, leisure, and quality or quantity of possessions. In an open class system, it is believed that dedication and a strong work ethic, along with great effort, can lead to greater social mobility.

Status

Status is the position one holds in a social system. As members of a status group, people have rights, duties, and lifestyle benefits or burdens. Statuses exist in societies that contain a hierarchy for power and prestige. Status has its own stratification. Those with higher status can influence, through the use of their power or prestige, the actions or conduct of other people. Status is related to role, or an expected social behavior. A person occupying a specific social position or status has various roles or behaviors, such as actions and qualities, to fill. In Western industrial societies, having a respected occupation, owning and/or consuming material goods, and even appearance, etiquette, manners, and morality have become more important than lineage as status indicators.

Occupations in these societies are stratified so that achieved occupational promotion can enhance the social status of individuals and their immediate families. Social scientists have defined two basic kinds of social status: ascribed and achieved. Either one is assigned to a status group at birth, or one achieves status through educational, occupational, or skill-level accomplishments. In ascribed status, one is either born into or grows into the status. When status is assigned at birth, little knowledge exists of the person's individual skills or predominant traits. It is

assigned based on birthrights, gender, family relations, ethnicity, and age. Membership in an ascribed status group is most often nonvoluntary, and ascribed status cannot be discarded. People qualifying for a status are expected to fulfill all role obligations assigned to that status by general society and those determined within the status group.

The kinship system can best illustrate ascribed status. Anthropologists say that when people are born, they automatically become a child, either a son or daughter, to the parent. When they grow older and have their own child, they automatically become a parent, either a mother or father, to the child. Individuals within a status group are not ranked of their own accord. It is the status group as a whole that is ranked.

Concomitantly, an achieved status is one that is earned after fulfilling certain criteria. An achieved status is based on efforts and it includes accomplishments. In open class societies with mobility, individuals may increase their social status by achieving a higher education or an advanced degree, working toward a professional occupation, or making significant accomplishments in their personal, professional, or community life. Graduating from college is one such example of achieved status. In addition to requiring dedication and effort, it oftentimes also requires the financial resources to pay school tuition and living expenses while one pursues a degree. In open societies, a higher status can also be achieved by marrying into a different social class.

Social stratification that is based only on status is a pre-modern societal structure, in which members of each status group interacted only with other members of their group. In other societies, clan or lineage are ranked as either aristocratic or common, with some clans being stigmatized.

Role

People take on a variety of social interactions based on the status they occupy at that moment. They know how to interact, or what behaviors to exhibit, because each status is associated with corresponding roles. A role is a collection of obligations and responsibilities for the occupants of a status. In sociological theory, a role is a behavior that is determined by what is expected of that position. Roles are socially defined attributes and are not related to individual characteristics or personalities.

Social relationships provide a structure for patterned or predictable social behaviors. Status and role are linked together in complementary pairs. Status is not independent of role and role is not independent of status. For example, parent and child are complementary roles because the parent has a role responsibility to discipline the child and the child is expected to obey the parent. When people within their status fail to act effectively in their role, other members of the society will show disapproval.

When a role is socially recognized, it helps people in a society create a strategy to deal with recurrent social situations, and to cope with the roles that others play. People create the expectations for the roles that they and others

will perform. Clusters of statuses and their complementary roles create the core of enduring social relationships. The existence of these clusters then provides regular and predictable patterns of behavior, or social structures, that can be reviewed for appropriateness and changed as needed.

Role confusion occurs when people experience difficulty knowing which role needs to be filled within their current status. Similarly, role strain and role conflict may develop. Role strain is the tension between the many roles one is expected to fill and pressure to choose a focus for one or more roles. For example, a parent may feel conflicted over her obligations to act as a parent who teaches manners, arithmetic, and moral behavior while also meeting the rigors of being a professor who lectures at a university. As such, she may also feel conflicted over being an adviser to students while also working as a tenured faculty member who is required to advocate for faculty rights on campus.

Contemporary Theories of Social Organization

Most societies create status sets particular to social groups. Religion, gender, family, clan, occupation, and political affiliations define these sets. Highly structured social groups sharing a common focus or mission are called institutions, and these social organizations consist of interlocking role relationships. These relationships become active when status positions are filled and social groups have members.

French sociologist Émile Durkheim (1858/1984), considered the founder of both modern sociology and anthropology, studied societal adherence, contrasting mechanical solidarity to organic solidarity. In mechanical solidarity, small-scale, kinship-based societies were held together by the efforts of their family members. The members of these small groups performed all survival tasks. These societies stayed together because they had a strong sense of commonality or likeness, which occurs when groups share the same language and customs. Because these groups are kinship based and can meet their own survival needs, smaller groups could break from the whole and the smaller groups would still survive. Organic solidarity exists in larger-scale societies like nation-states. In these societies, specialists in subgroups handle survival tasks, and the division of labor is complex. The occupational groups are dependent on other occupational groups and cannot exist if they break off into smaller groups. For example, tradesmen like metal workers and pot makers do not also produce their own clothing. In these larger societies, each occupational group depends on the work produced by other occupations.

Contemporary Theories of Social Class

Although the term *social class* most often refers to modern-day industrial societies, it has also described various groups from city-state, empire, caste, and feudal societies.

During the feudal, industrial, and political revolutions of the 18th and early 19th centuries, the terms *rank* and *order* were challenged. The term *social class* became the popular hierarchical determinant in society as feudal distinctions of rank became less important. New social groups emerged as a new commercial, industrial, and capitalistic society replaced the feudal societies. An urban class of factory workers subsequently developed, and a wage-labor economy with capitalistic property owners developed. Therefore, new economic conditions emerged.

Early scholars in the concepts of social class developed their theories in the social sciences. Political philosophers of the 14th to the 18th centuries, such as Jean-Jacques Rousseau, John Locke, and Thomas Hobbes, began writing about and discussing social stratification. When 19th-century French social theorist Henri de Saint-Simon argued that the type of governmental body was directly related to the mode of economic production, he opened the door for the development of our most predominant theoretical traditions of social class and class conflict.

While social status is directly related to achieved honor, occupational standing, cultural delineations, and birthrights, social class originally related directly to the economic interests of its membership. The theories of Karl Marx (1872/1988) and Max Weber (1968) defined class in economic terms, even though the determinants in their theories varied. Marx classified societies by their modes of production. He believed that capitalist societies had two social classes: those who owned property and those who did not. Property owners in his capitalistic society were called the bourgeoisie. The remainders were the proletariat. When class is determined by ownership of capital, one class has privileged access to necessary material resources and that creates a class system where one class controls the other. The more powerful class uses these privileges to dominate the less fortunate. While the dominant bourgeois class owned the capital, the proletariat was the exploited working class. Members of the proletariat provide the services or the manual labor required for the bourgeoisie to remain in business.

The relationship between the two would forever be in conflict, according to Marx, because they disagree over who shall control the means of production. They will continue to disagree until the powers of those controlling the economy are overthrown. In addition to controlling the material production, the work conditions, and the earning power of the proletariat, Marx also felt that the bourgeoisie controlled the production of ideas, cultural styles, and political doctrine. They established the governmental structure, political climate, and major structural changes in society. Although Marx recognized that postindustrial society contained social groups outside of the bourgeoisie and the proletariat, such as peasant farmers and small shop owners, he firmly believed that the industrial revolution would eventually eliminate such economic class nuances. These classes were the residual effect of precapitalist societies and would disappear as capitalist systems matured, he said.

Marx argued that an uprising was necessary and inevitable because of class antagonism and class conflict that drives critical social change. In *The Communist Manifesto*, Marx wrote that when private property disappeared, then the class system that originates in the division of labor would disappear. Marx also theorized that an increased ability to obtain an education would enable society's younger generations to quickly learn the whole system of production, freeing them from the present-day division of labor. Equality would eventually diminish the need for class separation. Furthermore, Marx said that communist society would be incompatible with the existence of class. The difference between this communist system and socialism is that in socialist societies, the means of production are publically owned and managed. Communist society would produce a sufficient mass of products to satisfy the needs of everyone.

Scholars and philosophers since Marx have dedicated their intellectual pursuits to provide alternative theories to communism. German sociologist Max Weber (1968) said that the development of a social class structure in a modern society was based on more than economics. Weber believed societal variables, such as capital, education, and workforce skills, also affected life chances in the social class system. Having a special trade, sought-after skills, or educational achievements would help those with less property achieve placement in a more desirable social class.

Unlike Marx, whose social structure contained only the bourgeoisie and the proletariat, Weber contended that four social classes existed. The highest class contained the upper ranked property owners. The next level consisted of intellectuals, scholars, managers, and skilled administrators. Additionally, Weber's system contained a traditional petit bourgeois class of smaller shop owners and businessmen. The lowest class in his four-class system contained the traditional working class. While he maintained property ownership as a class, he recognized that those with high-demand special skills formed another social class grouping. He believed that class conflict would exist, but only within those classes in direct opposition, such as the worker and the worker's manager.

Weber wrote that power is distributed according to status, classes, and parties. His insights expanded also upon theories of social stratification, where social honor and status impacted, but was different than, social class. He wrote that power is generally the chance that is taken against the will of the larger group. Although power is alluring in itself, the quest for power contains social honor. Achieving social honor or prestige is the foundation of political or economic power. He distinguished class from social status and the pure economic indicators used in the past. Social order is a manner in which social honor is distributed, Weber said. Economic order determines the distribution of goods and services and social order depends on economic order. However, class is not based on economics alone. It is also based on power and prestige. Class refers to any group of people with the same class situations.

Future Directions

Social Stratification: Class

Contemporary capitalistic societies have lost some of their class distinctions. Social and economic statuses are continually transformed, overstepping the traditional boundaries in which they were defined. Modern class theories, although reflective of Marx and Weber, have moved from these models, partly because modern theorists believe that individuals are ranked on a variety of indicators, often unrelated to economics. They took Weber's notions of status and created a more multidimensional approach to social status, including occupation, religion, gender, education, and ethnicity. In post-World War II America, prestige and social status challenged a traditionally and economically stratified class system. The post-World War II era brought—across the board—a raise in living standards, greater social mobility, and a redistribution of economic resources.

Recent research conducted by Marshall and Swift (1999) used an odds-ratio methodology to consider equality and inequality and chances for social mobility. Comparatively, and often argumentatively, sociologist Ottar Hellevik (1997) prefers to use the Lorenz curve and the Gini coefficient to measure the existence of societal inequalities. Prior to Hellevik's assertion of this stance, Gordon Marshall (1996) examined whether communism had in practice increased equality in East Germany. Marshall believed the German experience with communism offered an unusual research opportunity in social stratification. Following World War II, West Germany followed a capitalistic path to economic growth. East Germany chose communist structure in an attempt to increase social and economic equality. Marshall concluded that communism did little to help the citizens of East Germany achieve social equality.

Despite decades of disagreement over class structures and social status boundaries, social scientists have generally agreed that class is divided into three main categories: upper class, middle class, and lower or working class. The upper class in modern society exists through its largely inherited wealth. They are the owners of large properties from which their current income is derived. They enjoy many benefits in their membership in the upper class, including influence on the governing economic and political policies of their society. Through the privilege of membership in this class, they have access to better educational and economic opportunities that also enhance the wealth of their families, for generations to come.

The middle class is the socioeconomic class that includes those in professional, highly skilled labor, and middle- to lower-management occupations. It is a tiered middle class, with wealth professionals and managers at the top, and clerical, transportation, and distribution workers near the bottom.

In contrast, modern capital societies with a three-class system have a lower or working class. They are often in the

lowest-paid, lowest-skilled jobs in the economic structure. These workers are nonunionized and often work in the service or retail industries. Their living conditions have the lowest standards, with restricted access to education and almost nonexistent power to make policy decisions in the political and economic arenas.

Social Stratification: Caste

During the 20th century, relationships between and among castes in India have changed. Some similarly ranked castes have worked together to form political alliances. In the lower castes, members have been striving for a higher status and attempting to escape the permanent position in which they are placed at the bottom of the closed caste system. In other cases, the members of the same caste have worked together to implement increased national solidarity.

Since World War II, the caste system in India has changed due to the growing trends in a global economy and trends in earning cash payment for services. For example, in addition to working in one's caste profession, one may also improve his social standing by obtaining a better education or wage-paying job. However, marriage is still restricted to within one's caste. According to research done by Fuller and Narasimhan (2008), the rate of child marriages has significantly declined and the rules of endogamy have lessened. Individual qualifications and personal characteristics are now vital to marriage in India, and education is now a key rank indicator. In fact, having a college or university degree is sometimes considered more attractive than being a very successful farmer or landlord. Additionally, these preferences exist across genders. Fuller and Narasimhan found that educated husbands prefer educated wives, even if the wives plan to work within the home. However, despite these more lenient marriage practices, ancestral status is still considered a marital asset.

Rank and Status

Anthropologists have shown increased interest in status and rank research. Steffen Daisgaard (2008) found a current tendency for people using social-networking Web sites to post individual information on the Internet, publicly ranking themselves and their personal relationships. They also publicly display status information. With the use of current social-network sites, people may present their preferences in art, music, literature, and social events. They may also publically post photographs and videos of themselves, their significant others, and significant events. More important, social-network users can show lists of their "friends" or other recognized social relations. Similar processes of social identity formation, Daisgaard said, have been discussed since the early 1980s. People would dress in a particular style so that they would be identified with others who dressed in that manner.

Facebook and MySpace are the most commonly used social-network sites. In posting a "virtual self," people

become the center of their social universe. These social-networking sites, Daisgaard also pointed out, involve systems of ranking and hierarchical structures. MySpace has a “Top 8” feature in which the social self may rank their top eight friends. Other Internet rankings are seen daily in more nondescriptive manners. For example, Daisgaard said that Google search results are ranked according to relevance. One might think this means that Google results are ranked according to their relevance to the person who inquired, but it is not so. Relevance is ranked according to Google’s sponsors or according to popularity that is determined by hit counters (Daisgaard, 2008).

Other recent studies in ranking systems outlined the current practices used in colleges and universities in Canada and the United States. Research by M. Reza Nakhaie (2004) showed that preestablished universal and impersonal criteria are the determinants for employment rank and status. To maintain an atmosphere of progressive collegiality, personal and social attributes are not considered when a faculty member is reviewed for rank and status promotions. Rank promotion may also be based on seniority. Nakhaie noted that this universalistic approach relies on the belief that opportunity for social or professional mobility is the foundation of legitimate power. In this environment, rank is achieved.

Conclusion

Members of a human society are interdependent beings who behave in patterned and predictable ways because of their social positions. Rank, status, and role are indicators of these positions and the social structure in which one lives. Examining egalitarian societies, rank societies, and the variety of social stratification systems assists in understanding the ranks, statuses, and roles that people maintain. Simple societies practice egalitarianism, in which resources for subsistence are communally shared. Rank societies also communally share resources, but rank members may be privileged to power or prestige. More complex societies may be stratified, and often have unequal access to resources, power, and prestige. No matter which system, its members have rank, status, and role considerations to maintain. These criteria are understood and adhered to by its members. In addition, societal structures are impacted by changes in economic structures and technological advances. As such, corresponding systems of rank, status, and role continually evolve.

CEREMONIES

DEBIKA SAHA

University of North Bengal

Life is nothing but a process beginning with acts, rather than with thoughts. In the journey of life, every moment brings necessitation, which humans try to satisfy in their own way. Need was the first experience and efforts were there to satisfy the need. It is a general assumption that there are certain inherited tendencies—instincts—that humans acquired from their ancestors. When these inherited acts are repeated, they became customs in the same way; acted up individually, if repeated, they then became habits.

Customs are social habits forming the basis of an order of social behavior. There are various names for customs depending upon the situation. *Ceremonies* are customs signaling important events with the observance of some formal act or series of acts in the manner prescribed by custom. For example, there is a custom of giving the bride a ring at the wedding ceremony. Ceremonies, then, resemble the results of natural forces, unconsciously put into operation, or they can be equated to the instinctive behavior of animals, which is developed out of experience. These ceremonies are passed on by tradition and generally allow no exceptions. However, in the course of time, with new environmental conditions, the ceremonies become modified. So, it may be said that the life of human beings, in all ages and stages of culture, is primarily controlled by these forms of ceremonies. These ceremonies regulate the whole of human actions. From cradle to grave, human beings are the slaves of the various ceremonies.

Nature of Ceremony

Ceremony is a kind of social control that creates order for particular parts of life. It belongs to the structuring aspect of the cultural process. As a way of control, the ceremony has both subjective and objective aspects. As a social control, there is always explicit or implicit reference to other selves, be they real or imaginary. In ceremonial practices, attitudes, ideas, and emotions all reflect multitudinous form—and in the most diverse ways. According to Herbert Spencer (1974), social control is a modified form of action. Ceremonies are spontaneous responses of one individual to the presence of another. Later, these ceremonies are fixed and conventionalized. Ceremonies control behavior by defining social roles. These roles, assigned to individuals according to some principle of attribution, demand that the persons identify their personal identities to the social roles and encourage others to identify and treat the persons as constituted by the role.

Because they shape identity, ceremonies transform people. If they are successful, ceremonies produce not just a temporary emotion, but rather a permanent change in identity conforming to the society's expectations of right conduct. Because ceremony exercises a powerful influence over behavior, it is appropriately conceived as a form of social control. Ceremonies are repeatable events—people can perform them for the same purposes, in the same orderly manner, and sometimes also with the expectation

of the same result. They are expressions of shared feelings and attitudes through more or less formally ordered actions; these actions hold an essentially symbolic nature performed on appropriate occasions. A ceremony sometimes involves stereotyped bodily movements, often in relation to objects possessing symbolic meaning. For example, people bow, exchange greetings, and perform a myriad of other forms of action.

From the anthropological perspective, ceremonies express, perpetuate, and transmit elements of a culture's values, and aim to preserve such values, while inhibiting sentiments of doubt and opposition. Moreover, they intensify the solidarity of the participants. The study of ceremony from the anthropological point of view has been confined mainly to the analysis of religions and magical procedures. The works of Tylor (1871/1958), Weber (1922/1993), Durkheim (1912/2001), and Frazer (1890/1959), in particular, draw the association between the ritual ceremonies and their religious or magical purposes. The reason behind this association is that anthropologists have often dealt with societies in which everything has a religious wrapping, or in other words, all of daily dealings are imbued with the sacred.

But this is not to say that there are only religious or sacred ceremonies. On the contrary, there are secular ceremonies. Ceremony and rituals are also used in the secular affairs of modern life. Secular ceremony extends authority and legitimacy to the positions of particular persons, organizations, moral values, and the like. Here, ceremonies are employed to analyze particular interpretations of social reality in a way that bestows them legitimacy. Ceremony not only belongs to the structured part of social behaviors; it also can be construed as an attempt to structure the way people think about social life. Ceremonies mirror existing social relationships and existing modes of thought.

MacIver and Page (1988) noted sociologists bring out three main factors to reveal the importance of ceremony in human affairs. The first is the character of *impersonality*. Any formal event wears an impersonal look, though it is the individual who plays the lead role. This feature is noticeable in the field of military personnel when they bow toward the uniform or rank, not toward the individual. Here, this bowing-down ceremony clearly transforms the ritual to impersonal.

Myth, the second factor, plays a great role in shaping any stable life. Since social life moves continuously with some order, its movement requires a system of myths like the myth of law, power, freedom, and so forth. These myths are value-loaded terms where ritual plays an important role. With this, ritual and ceremony convey a feeling of broader realities of faith, and social establishment never fully comprehended by the individual. Certain concepts like "the church" and "the state," which are abstract in nature, find concrete expressions through the rites of the church or the inauguration of the president.

The third factor is *utility*. Clear from the earlier discussion, there are certain compulsive and emotional parts of ceremony, but along with this, there are certain everyday assignments that need to be worked out. In a society, there are various functions that must be performed in a right way—how to behave in a particular occasion, like when a soldier performs well in protecting his country, or what to do when one's daughter gets married. There are countless occasions like this when ceremony supplies the answer. As social beings, it is not possible to be aloof from such events, and these functions reflect the social life that one leads in a particular community.

Classification of Ceremonies

Let us first discuss some ritual ceremonies and their religious purposes. Herbert Spencer (1974) showed how, in the course of evolution, certain conduct first treated as daily ritual ceremonies converted into religious ones. For example, fasting as a functional rite gave origin to religious fasting and the prayers that were offered to the deceased grew into religious praises and prayers.

In almost every society, religious rites connect to the act of daily living. Through the prayer ceremony, divine grace is sought; this attitude reflects human beings' craving for the supernatural. Ceremonies sometimes play three kinds of control—political, religious, and social (Spencer, 1974). The accession ceremony of the Chinese emperor explains this point.

The emperor kneels thrice and bows nine times before the altar of his father, and repeats the same ceremony before the throne on which the empress dowager sits during the accession ceremony. Then, after he ascends the throne, the officers line to their ranks, kneel, and bow nine times. Not only the Chinese, the Japanese too follow the same line. Starting from the emperor, down to the lowest subject, there is a constant succession of prostrations. The emperor bows to the divine, showing his religious attitude. The officers bow toward the emperor, showing their political subordination, while also showing the common people their social subordination. So, they express the same form of behavior—religious, political, and social subordination.

Tylor (1871/1958), a noted anthropologist, showed that in the science of religion, the study of ceremony occupies a major role. There are certain ceremonies that show marvels of permanence and hold the same form and meaning throughout ages. From the anthropological point of view, the performance of certain sacred rites express these ceremonies. Tylor has shown that there are rites of prayer, sacrifice, fasting, and expressions of artificial ecstasy, orientation, and lustration; these all have their unique place in any ceremonial performances. Though these rites were in practice among the primitive culture, they are still in vogue now among the different cultures in some revised form or other.

What is a prayer? Prayer is a kind of desire, uttered or unexpressed, addressed to disembodied or deified human souls. In almost every culture, the harvesting ceremony, which is celebrated periodically, offers prayers to the earth. This ensures that the crops come out in full strength and the plantation may be saved from evil eyes. During the harvesting ceremony, sowing, plowing, and reaping special rites are performed to control the processes of vegetation. Prayers, then, are a type of request to appease the unforeseen situations.

In some parts of the world, this prayer is a kind of sacred utterance where repetition requires verbal accuracy. In the course of time, it works like traditional formula. In Buddhism, the chanting of *om mani padme hum* evokes a kind of sacredness, and creates a kind of devotional atmosphere. This line is written on the prayer mill and these prayer mills vary in size. It may be little wooden toys held in the hand or big drums tuned by wind power with the devotee repeating the sentences. The use of the rosary among the Mohammedan and Christian religions are the outcome of this Buddhist tradition. Therefore, prayer of any form is a means of strengthening emotion, courage, and hope. It also sometimes serves as a source of motive or power behind the action performed by the individual.

Like prayer, sacrifice is an offering toward the deity to receive a favor. Generally, food and valuables are offered and there is custom in some parts of India to sacrifice an animal. The blood of the animal is then offered for the deity and the devotee retains the meat. In the temples, incense sticks are offered before the images of the gods during the sacrificial ceremony. The sacrifice by fire is well-known to almost all the religious ceremonies of the world. These rites, connected historically with different ceremonies, remain more or less unchanged in this modern world. The devotee who bows before the deity seeks her favor in all spheres of her action. In fact, the primitive people offered food and valuables to the gods in a large scale, for they did not know much about the mysteries of nature. With these offerings, they aspired to appease the supernatural powers. Almost everywhere in the world, it is the priest who acts as guardian of the deities and has the maximum share of the offerings. The priest is supposed to intake the food as representative of divinity. In India, during the yearly Mother Goddess Durga festival, there are offerings in front of the deity, such as fruits, sweets, vegetables, and clothes. After the sacred ceremonies are over, the priest takes the offerings along with him.

Taylor (1871/1958), while discussing these rites of sacrifice, distinguished the ideas as the gift theory, the homage theory, and the abnegation theory. In all three aspects of sacrifice, the ritualistic change may be traced from practical reality to formal ceremony. As mentioned, the gifts consist of foods and valuables and generally the priest is in charge of the gifts. There is also a ceremonial

make-believe to feed the idol. In ancient times, it was a belief that the deity devoured the meals.

One of the most remarkable sacrificial rites of the world is that of offering by fire. This ranges from the classic Greek to the ancient Chinese, and it is a peasant custom still prevailing in Europe. But whatever may be the real intention of the sacrifice, afterwards, it becomes a feast. Public banquets are arranged in the name of the sacred deity and the whole event transforms into sacrificial feast.

Along with the gift theory and homage theory, there is another sacrificial rite, known as sacrificial abnegation. There is a sect of Buddhists who offer boiled rice, sweet meats, and coconut fried in oil to the temples; crows and dogs devour these offerings. The Muslims, on their return from Mecca, sacrifice sheep, oxen, and camels in the valley of Muna. They consider this a meritorious act and come back without eating anything of it. Similar customs exist in the Buddhist sect, and Buddhists explain this behavior as the sinful men coming back in the form of demons. These demons in turn may receive offerings of food and drink from their relatives who can further benefit them by good acts done in their name, such as offering food to priests. Even if it is held that this type of act does not benefit the spirits whom it is addressed to, it does benefit the person who performs it. Fasting as a rite is also part of many religious ceremonies. Through fasting, a kind of purification of the body results, which helps to feel good. It is a kind of penance coming from the abstinence from food.

There are also a group of ceremonies dealing with symbolism. Here "sun myth" plays an important role. While discussing the role of sun, Tylor (1871/1958) showed that from ancient times to this day, the east side associates with light and warmth, life, happiness and glory, while the west associates with darkness, death, and decay. This symbolism of east and west gives rise to a series of practices associated with the various ceremonies of the temples and the position of the dead in their graves. Sun always brings warmth and enjoyment in every aspect of our lives. It is common belief that the rising sun symbolizes new life, and setting sun symbolizes the concept of death. It is a well-known story that the body of the Christ was laid with the head toward the west, thus seeing toward the east. From that time onward, it is a custom among Christians to dig graves east and west.

Along with relating to the burial of the dead, this sun worship found a place in temple worship. The famous sun temple of Konark in Orissa, India was one of the remarkable places of sun worship. It is a remnant of an old solar rite. In other parts of the world, such as ancient Mexico, sun worship was one of the central parts of religious ceremonies, when people used to kneel in prayer toward the east and the doors of the sanctuaries viewed westward. In addition, in Peru, the villages were built on the slopes toward the east, so that people might view and receive the sun's first rays at its rising.

In Asia, especially in India, sun worship is a regular ceremony that the Brahmins must perform daily. In the temple, before any ceremony, the Brahmins still pay tribute by mantra (sacred word) to the sun. These solar rites are found in other countries as well. In the Jewish tradition, the front door of the Jewish temple is toward the east and the sanctuary is toward the west.

Tylor's (1871/1958) research allows for various and extended explanations for sun worship: On the one hand, there is Asiatic sun worship, which has its origin to the veneration of the rising sun in old Persian religion and, on the other hand, this orientation ceremony is recognized in classic Greek religion as a principle. Thus, in Athenian tradition, the temples have their entrances toward the east, looking out through which the divine image is welcoming the rising sun. It then became an accepted custom to turn toward the east during prayer, facing the region of the "light of the world" or "the sun of righteousness."

This orientation ceremony finds its full narration in the rite of baptism among Christians. In this ceremony, turning toward the west shows abhorrence to Satan while turning to the east shows reverence. These acts are common to both Latin and Greek ritual.

There is another ceremony, known as purification of lustration, that involves both the clearing of bodily impurity and also mental purification. In Peru, this lustration ceremony connects to childbirth. There is a ceremonial washing of the child, and through this act, it is believed that evil influences wash away. After the baptism, there is a custom to cut off a lock of the child's hair. The same ceremony was performed in old Mexico. In the name of the water goddess, the nurse washed the infant. This washing helped the child to discard the impurity of his birth, cleanse his heart, and also offer the child a good and perfect life. With the washing, there was a prayer toward the invisible deity to cleanse the child from sin and foulness, and to protect him from misfortune.

In other parts of Asia, like Japan and China, this lustration ceremony is well-known. In Japan, the sprinkling and naming of the child and other lustrations connected with worship are prevalent. In China too, sprinkling holy water over sacrifices is common, and after funerals, holy water is often dispersed throughout rooms and on the mourners.

This ceremony is even more famous in both Hindu and Muslim traditions, where bathing is a main part of daily worship. It may be said from the very first day of life until the last day, ceremonial purification by holy water is a must in every household. Even in this technologically advanced world, this cleaning and purification form a necessary part of life for the youth and the old. This sprinkling of holy water is always part of special ceremonies such as the naming of a newborn child, placement of the sacred cord over the neck, and the purification of the mother after childbirth. In the laws of Islam, it is necessary to wash

hands and feet before the prayer. For this reason, to remove the impurities, a person washes five times before uttering the holy prayer in the name of Allah. In Greek and Roman churches, holy water is also used. As one enters the church, the individual is blessed with the sprinkling of holy water. It may be said, then, that this concept of lustration is well-known in almost every culture of the world. It is a faith of the invisible.

Arnold Van Gennep (2004), one of the most well-known anthropologists, coined the term *rites of passage* while studying the significance of the ceremonies in connection to the transitional stages of human life. He, in opposition to Émile Durkheim (1912/2001), argued that society is composed of individuals, and so it is possible for individuals to change the whole. This is contrary to Durkheim's view that individuals cannot go against the collective will of the society. It is Van Gennep who noted first that the ritual ceremonies that accompany the transitional stages of human life may differ in detail from one culture to another, but they are, in essence, universal.

What, then, are rites of passage? From the anthropological point of view, a rite of passage is a ritual that marks a change in a person's social status. It is a universal phenomenon through which the social hierarchies, values, and beliefs of a specific culture are revealed. There are ceremonies surrounding events such as birth, initiation, puberty, adulthood, marriage, and death. These are the phases of life through which the individual passes from one defined position to another. Van Gennep (2004) considered these ceremonies sociocultural rather than biological. A. M. Hocart (1954), British anthropologist, viewed the transition from one stage to another as the result, rather than the cause, of ceremonies. These phases are composed of three parts: separation, transition, and incorporation.

In the first stage, separation, participants disassociate from their social state. This separation makes them unique, as they are the special persons for whom the ceremonies are organized. For example, the wedding ceremony is a special social ceremony. There are variations in different cultures, but the point is to prepare the couple for the auspicious wedding day.

The second stage is the vital transitional stage. During this stage, participants almost remodel the past social status. New values in the form of sacred rites and objects are calculated. The changed perspectives are the seedbeds of cultural creativity and give rise to new ideas and paradigms. This transition may be symbolized by the act of transformation, for example, through a change of clothing or a special incantation. In the wedding ceremony, the couple is granted some privileged rights within the community.

The third stage, incorporation, welcomes the participants back into the community. In marriage, the couple merges back into the culture with the rights and privileges of their new role.

These ceremonial enactments possess a primordial and vital role by appealing to the place within human beings where culture is created and recreated by human behavior. From the anthropological point of view, ceremonies are more than social glue holding society together. Ceremonies instead happen to mirror the spiritual, religious, and emotional nature of human beings. In other words, ceremonies reflect how people build, learn, and transform culture in ways that infuse meaning and give definition to their existence.

Life Ceremonies

Ceremonies to celebrate the life cycle are universal and are found in all societies, although the rites vary. The ritual part of these ceremonies includes various kinds of rites, such as celebrating childbirth, as exemplified by baptism in Christian society. In other societies, for example in Hindu society, there are certain elaborate ceremonies performed by mothers before the childbirth. After the birth of the child, the mother observes certain restrictions regarding her food and way of living to ensure the well-being of the child. The child and the mother are kept in seclusion for at least 21 days, and after performing certain rites, they both are included within the family. Both mother and child are often regarded as defenseless at this time, and ritual acts are performed in order to protect them from harmful supernatural forces.

In all societies, some ritual observances surround childbirth, marriage, and death, although the degree of elaboration of the rites varies from one culture to another. In Southeast Asia and Indonesia, a practice called mother roasting, requiring that the mother be placed for some days near the fire, appears once to have had the goal of protecting the mother from such evil influences. This practice survives even today in altered form in the rural Philippines, where it is regarded as having therapeutic value. From an anthropological perspective, all these ceremonies are ways to reinforce familial ties. In addition to serving as a means of bond between husband and wife, these practices promote familial and societal solidarity.

Functions

The rites performed in functional ceremonies bear positive values for the individual in relieving stress at times when certain life adjustments occur, such as puberty and marriage. The rites are also viewed as socially supporting, such as to prevent social disruption by relieving the psychological stress of the individual. This prevention comes in the form of instructing all members of societies to continue life in a normal way with the new social role. New social and moral values emerge with this new role as they become part of the ceremonies, and life moves on as usual.

Entertainment is one of the primary functions of social rites. Centering these events, pleasurable activities follow in the society and find expression through art, music, dance, song, and other ceremonies. Performance of various ceremonies protects the sociocultural unity of society. They are a means to gain livelihood and sometimes they also act as incentive to keep unity of the group.

In ancient times, most of the ceremonies were religious events; that is, they were performed in a religious framework and regarded as religious acts. But more recently, from the viewpoint of social science, these events are considered secular. The primary significance of most rites reflects a change in the sociological structure of society. Modern life is viewed as dominated by a rational culture in which human responses are governed by selective choices. In other words, it is a disenchanting, nonmagical rationalized world, as Max Weber (1922/1993) has noted. In fact, anthropologists differ regarding the issue of the similarities between the primitive and modern cultures. In primitive and tribal culture, objects like plants and animals were worshipped. Even wind, sun, and water were treated as sacred. The real end behind this ceremonial worship was to increase the food supply and receive protection from natural disaster. But, as the modern culture advanced, this ceremonial behavior changed. It may be said that instead of religious wrapping, the tendency of recent times views the events as secular.

In today's globalized world, most of the rites are viewed on the basis of their sociocultural context. The inventive and symbolic capabilities of human beings are treated as a constant factor, and attention is given to differences and similarities in the sociocultural traditions in which the ceremonies are performed. For instance, in attempting to understand why the marriage ceremony is an elaborate rite in one society and simple in another society, researchers have looked to the social order and manner of gaining a livelihood to judge the relative importance of the enduring union of the spouses. Since culture includes the social order, and composes a coherent inclusive system, scholars have interpreted the ceremonies in terms of their functional significance in the social system. In this way, scholars have broadened their investigations from observations of the symbolism of rites to include all the behavioral actions during the rites and their social contexts—uncovering the social identities of the performers and their relationships to other performers and the entire society.

Social Significance of the Rites of Passage

From ancient times to this technologically improved century, the rites of passage help to maintain society as a system of congruent parts. To operate any system coherently and effectively, it is necessary that the elements are mutually supportive or congruous. These rites

help to keep society in a state of equilibrium. Social systems include a fixed number of people with a fixed number of roles. Any change disrupts social equilibrium. For example, when a child is born, a new member is added to the society and accordingly, due to changes in the social behavior and statuses of the parents, other members of the society are affected. In fact, rites of passages help to foster the development of a new state of equilibrium in adjustment to the social changes upon which the rites focus. The rites act as threads through which the members of society are informed of the new social development and, at the same time, permit social approval. The ceremonial observances also offer psychological assurances to the members of the society. The members are instructed, by the ceremonial enactment, to return to normal behavior as the situation demands. This kind of reasoning is not only applicable to social ceremonies but also to religious ceremonies. Anthropologists interpret these social rites, and others, as rites of intensification. The social rites reinforce or intensify the existing habitual relations, and thus serve to maintain their conditioned response. In other words, the performance of these rites prevents the extinction of habits to which the person has been trained.

From the anthropological perspective, besides balancing social equilibrium, there are a group of additional functions—some of which apply first to the individual whose positions change and then to the behavior of the entire social group. Other functional effects directly apply to the whole society. Whenever the individual faces any anxiety or stress, the functional effects of the rites prevent social disruption. For example, with funerals, the anxiety and stress caused by death and the grief of the bereaved are held in check. Funeral rites and ceremonies are held in every society, but then, in order to keep social harmony, the bereaved still must regain normal behavior after a certain period.

There is another implicit way that the rites are socially supporting. The shared rites are dramatization, with supernatural sanction of the social order of society. Relatives have a special role to play and the entire social hierarchy may be on display during the ceremonial rites through the assignment of ritual roles. Thus, statuses of kinship, caste, social equality, and hierarchy are all reimplemented by their dramatic presentation.

Accepting the social significance of these rites of passage, anthropologists have also offered explanations for the variations in behavior among societies of the world. A fundamental assumption is the idea that the greater the importance of a social change, the greater the ritual attention will be. It is an accepted fact that the birth, marriage, and death of a ruler obviously is more important to the entire society than these events in the life of a common person. Rites of marriage ceremony, for example, may be very simple or very elaborate in different societies of the same economic base and comparable levels of cultural

development. The differences happen due to different structures of society. For example, marriage ceremonies in matrilineal societies—organized into subgroups primarily upon a principle of descent through female lines—only tend to be simple and divorce in these societies is also simple. Marriage ceremony in patrilineal societies, on the other hand, tends to be elaborate and divorce initiated by females is difficult. But whatever the case may be, in patrilineal societies, the role of the mother is vital for the birth and rearing of the children. In some societies (e.g., in some African societies), marriage ceremonies are elaborate and often involve the transfer of property, known as marriage suits. If the marriage fails, then the property must be returned.

Among almost all societies of the world, marriage ceremonies divide into three parts: premarriage ceremony, the main-day function, and postmarriage ceremonies. All three parts are performed for the well-being of the couple; the bride and the groom have undergone the whole series of rituals, from engagement parties to the religious ceremony, and may reasonably be seen as more firmly married than couples united by a simple civil ceremony. Anthropologists view marriage as one of the earliest social institutions. Marriage ceremonies have often included clearly visible signs of the new social status, in such forms as wedding rings, distinctive hair dress, new garments, and decorative ornaments. Traditionally, preliminary ceremonies have often provided instruction in the wifely role. Such instruction might be formal or conducted through mimicry, dancing, and other symbolic acts that dramatically depict the woman's role in society, expressing her economic and social obligations with reference to her husband and other members of the family. Overall, the prime significance of marriage ceremonies may be seen to especially stress the social bonds between husband and wife and their relatives.

Government Ceremonies

Besides the rites of passage, there are government ceremonies, or celebrations of events that also play an important role in society. Sometimes, a ceremony may only be performed by a person with certain authority, such as the presidential oath in the United States. Here also the three stages of separation, transition, and incorporation apply. The particular person is being separated from the mass and offered a unique place. The point is to honor the person in the new role.

In the second stage, the participant acquires a new social status with other values. For the U.S. presidency, the transition is symbolized by the act of taking sacred oath to stand by the country and protect from all odds. The final stage follows, where the community welcomes the participant as one of the members of the mass with a special position.

There are also certain ceremonies, such as British coronations, that show a symbol of moral values to unite the British people and provide a consensus underlying political differences. This type of ceremony promotes the authoritative, official, and public image of the society. There emerges a sense of individuality and of collective membership.

Dancing Ceremonies

Physical display, such as dancing in a procession or the laying of hands, is an outstanding feature in ceremonial observances often accompanied by singing and clapping. In fact, songs and dances are so closely interwoven that the one cannot be separated from the other in any performances. These ceremonies have occupied a rightful place in all the principle celebrations in the cycle of human life (initiation, puberty, marriage) and of the seasons (planting, sowing, and harvesting).

These dances promote solidarity and mutual goodwill among the people dancing. In the tribal sort, the mimic aspect comes to the forefront with the behavior of animals' fertility processes; natural phenomena are represented in a realistic manner in order to obtain control over the supernatural powers governing the objects and events portrayed. Dancing ceremonies are a way to appease the supernatural powers among tribal people, but among more sophisticated groups, communal dances afford an opportunity for social mingling, fringing people together for fun besides the ritual observances.

Religious Ceremonies

In all traditions and cultures, spiritual ceremonies and rituals play a central role. The very act of dancing, music, chanting, singing, and other ceremonial expressions bounds a community and also serves the purpose of connecting to the higher spiritual forces. The expressions in various communities are different, but the goal is the same—to stimulate the connectedness, communion, and spiritual experience of a group or an individual. In almost every religion, there is certain external ritual to help people unite with the divine. To develop this point, two types of ceremony are discussed: the Eucharist ceremony in Christianity, and the ritual of the Puja in Hinduism.

The Eucharist and Puja Ceremonies

The idea of unification with the divine is known as the *Eucharist ceremony*. These ceremonies fulfill the psychological need to find a place in this vast and ever-changing universe. The urge for divinity finds satisfaction through the observation of these types of ceremonies. Within this framework, the Eucharist ceremony

is the ritual observed by the Christians through which direct unity with God is invoked. *Eucharist* is a biblical term that also means communion with God. The ceremony is observed by the congregants who gather together in their church. After the pastor reads and recites a specific holy passage, the participants are presented with a small amount of wine and a little piece of bread, and they eat in unison or one by one. The actual ceremony varies within the different sects of Christianity, but the aim remains the same—to invoke communion with God. The Eucharist is a moral and spiritual union with Christ through the bond of love. The spiritual part of this ceremony is revealed in the reference of the “Lord’s supper.” There are mainly five parts of this ceremony: (1) thanksgiving, (2) memorial of Christ’s death and resurrection, (3) invocation of the spirit, (4) communion of the faithful, and (5) feast of the future fulfillment of God’s reign. Before highlighting the anthropological significance of this ceremony, let us also discuss the rituals that are associated with Puja ceremony of Hinduism.

In Hinduism, Puja is a comparable ceremony to the Eucharist, performed to establish communication with a deity. During the Puja, the deity is treated as a guest. Similar to the Eucharist, the priest welcomes the deity during Puja. There are 16 steps of this ceremony performed during the deity worship, normally occurring in a temple (though a devotee can also perform the ceremony in a simplified manner): (1) invocation of the deity; (2) offering of the seat; (3) offering of water for washing the feet of the deity; (4) offering of sacred water; (5) a process for rinsing the mouth; (6) bathing; (7) clothing ceremony; (8) offering of the upper clothing; (9) offering of fragrant materials, like (10) flowers and (11) incense; (12) offering of the lamp along with the fragrant materials; (13) offering of food; (14) performing the puja by going around the image of the deity clockwise; (15) salutation; and finally (16) offering of flowers with the recitation of *mantra* (sacred words). In the end, blessings are sought from the deity. In either case, the main purpose is to procure happiness and sometimes there is a specific request that the devotee wants to achieve.

From an anthropological perspective, both the Eucharist and the Puja fill a deep void. There is an attempt to justify the loneliness of human beings in the vast world. An act of unity with divinity results through the partaking of food and drink during the worship. As a large number of people are present both during the Puja or Eucharist, a sense of intimacy develops by eating and serving food to each other. By eating together, people regard themselves as identifiable groups, representing themselves to each other as such and expressing their connectedness. A sense of unity therefore develops among the groups. It is not that always after performing all these rituals participants will be able to get whatever they want, but this is a kind of self-purification through which they can feel refreshed and encouraged. It may be

said that there is an emotional effect, which helps people to start any work with more energy.

Celebration of Religious Events

Celebrated among different communities, there are certain annual, seasonal, or recurrent ceremonies like weekly Sabbath day or feasts held in honor of the saints. In some Asian cultures, tea ceremony plays an important role. Another important ceremony is the purification of the Virgin Mary, commonly known as Candlemas; it is of eastern origin, and symbolizes the meeting of the Christ with Simeon and Anna. However, in the West, it is the purification of Mary according to Jewish custom.

According to E. O. James (1961), the purification or Candlemas ceremony traces to the symbolism of the Feast of Lights and the ancient perambulations associated with the return of the goddess from the underworld and the rebirth of nature in the spring. Here, candles are emblems of the divine vitalizing power of the sun and work as a protection against plague, famine, and earthquake. Fire also symbolizes the emergence of the sun from the darkness of winter. In Christianity, Mary came into great prominence as the light bearer, since the sacred light became a symbol of the Holy Child who was declared to be the light to lighten the glory of human kind.

In Japanese, the Asian tea ceremony is called *Chanoyu*, which literally means “tea-hot-water.” It is a multipurpose traditional activity influenced by Zen Buddhism, in which powdered green tea is ceremonially prepared and served to others. Not only in Japan, the custom of drinking tea, first for medicinal and then for pleasurable reasons, is also widespread throughout China. This ceremony has its own aesthetic sense. Through the observation of this tea ceremony, a sense of harmony, respect, purity, and tranquility develop. In this framework, one of the essential constituents of society is ceremony. Ceremonies help to draw people’s attention to something that is extraordinary and worth mentioning in some way.

Another famous ceremony occurs in Rajasthan, India in the city of Puskar, where a fair is organized every year in November. Puskar is famous, as it is believed that Brahma, the creator of the world, resides here. The place is also known for its natural beauty with hills on three sides, with the 14th-century temple of Brahma in the center. Hindu mythology narrates that the gods created a swan with a lotus in its beak and let it fall on earth where Brahma would perform a *yagna*, that is, sacrificial fire. There is a sacred pond, known as *Brahma kund*, where people used to bathe. It is a belief that by the healing touch of this water, one may recover from all ills. So, bathing ceremonies are the top attraction and give people a new strength of life. It is also believed, even in this 21st century, that after bathing in this sacred water, it is possible to begin a new cycle of life.

There is a market around the temple of Brahma where local people sell handicraft works. In fact, this yearly Brahma ceremony allows the local people to earn their livelihood, and the fair also reflects the rural lifestyle. In addition, there is propagation of ecotourism through the village-type resorts. From an anthropological perspective, these types of ceremonies, which are abundant throughout India, help to foster not only earnings, they are also a way of knowing each other’s culture through the colorful lens of local handicrafts.

Conclusion

Ceremonies are reflections of culture. This may vary from country to country, but the focal point of the ceremony always remains the same—the reflection of culture. Culture is a blank sheet, an empty pigeonhole where forms of life are expressed through the actions and words of community members. Since every society is dynamic, complex, and ever changing, ceremonies play a central role in the cultural work of human activities.

Ceremonies work as a tapestry of patterns of culture and they create a backdrop against which individual behavior can be viewed in the context of past, present, and future activities. As such, the ceremonies serve as social glue that binds the whole community together.

From an anthropological perspective, it may be said that human beings, through agency and free choice, continuously make and remake their existence. This is possible because while culture provides the script for ceremonies, rituals, and other culture-building activities, humans are free to change that script according to their choices within the norms of the society. The result is complexity, and a dynamism that provides scope for cultural change and transformation.

FESTIVALS AND RITUALS

CYNTHIA J. W. SVOBODA

Bridgewater State College

Festivals and rituals have played an important role in developing an understanding of the social network of societies. They have existed since the dawn of humankind and remain vital to civilization today. Their role is recognized by anthropologists as central to the understanding of human culture, customs, and beliefs; as such, anthropologists have studied festivals and rituals ever since anthropology emerged and developed as a scientific field of study in the second half of the 19th century. There is an extensive body of literature and much anthropological debate on how festivals and rituals should best be defined, why they are important, and what kinds of events they may include. The study of the nature, origin, and purpose of festivals and rituals has closely followed the anthropology of religion and the history of the field of anthropology. Reviewing past practices and examining current trends in the study of festivals and rituals will help anticipate the next stage in anthropological research.

Anthropologists have approached the study of festivals and rituals from many and varying viewpoints. These perspectives have changed with time but can generally be broken down into five major categories including (1) evolutionary (origin), (2) functional (purpose), (3) structural (framework), (4) symbolic (symbols), and (5) modern (contemporary). Two broad classifications of ritual often studied within these various approaches are rites relating to the human life cycle and periodic events. These two classifications may be broken down further into a number of ritual types.

Although individuals create routine periodic behaviors, such as washing hands before and after each meal, it is the established, publicly organized rituals that generally interest anthropologists. Single social actions, such as greeting handshakes, have not traditionally been the basis for this examination either. It is the interplay between the individual and the larger society and with the greater powers of being, and the result of this series of actions, that is studied in this chapter. When people come together for festivals and voluntarily communicate through verbal and nonverbal actions, their participation exudes deeper meaning. Human responses to ritual stimuli remain a fascinating aspect of anthropological research to this day. The evolution of festivals and rituals and their existence in primal and modern society has been the focus of hundreds of research studies, but there remains much more to learn.

In this chapter, first the history of the anthropological study of festivals and rituals is reviewed and summarized. Second, common reoccurring descriptive terms used to express the definition of *festivals* and *rituals* as used in the field of anthropology are discussed. Third, significant theories in the history of the research on festivals and rituals, along with major contributors to the discipline, are reviewed. Fourth, a brief summary of the research methods applied by researchers in the field follows. This chapter then contains a brief overview of some of the major types of festivals and rituals. Recent application of festival and ritual studies in the study of arts and communication follows. In conclusion, the final section suggests future directions for

anthropological research on festivals and rituals. Over time, the study of festivals and rituals has changed from observation of religious rites of the sacred to now include embracement of secular and profane study.

Overview

Anthropologists study human origins, patterns and variations of human behavior, and physical and social development in different cultures. They then compare and contrast their findings to learn what values and beliefs have been established as vital components of human society as a whole and also as important elements within specific cultures. In this research, anthropologists have found religion to be an important lens through which to understand culture. The observation of a society's religious underpinnings provides anthropologists with information on the faiths, values, and beliefs of the society's members, and also on how members interact with one another and their cosmic forces.

The study of festivals and rituals was initially undertaken by anthropologists who saw them as keys to understanding their places in religion and their roots in tribal societies. In examining tribal societies, anthropologists realized that ancient peoples had basic needs that required humans to unite in order to obtain food, water, shelter, and clothing. As they observed these processes, anthropologists understood that satisfying and stabilizing immediate requirements allowed the participants to focus their attentions on acknowledging their fortunes and celebrating the mysteries of life. The animal that was sacrificed or the god that provided the sustenance was given thanks and appreciation. The divine powers and the spirit of the dead animal had to be appeased and blessed, not only to give thanks for the bounty but also in hopes of future good fortune. As these feasts emerged as regular practices, they developed into intricate festivals that became central to societies. As time passed, specific rituals became associated with these and other events. Festivals and rituals and their history, function, structure, performance, symbolism, and efficacy are inherent components of anthropological research.

Defining Festivals and Rituals

Anthropologists usually identify what festivals and rituals are and can describe their general characteristics; but they have not agreed to apply specific narrowly prescribed definitions for the terms.

Traditionally the term *festival* has been used as an adjective meaning "regarding a day of feasting" and as a noun denoting "a time for feasting." As an adjective, festival also came to be used to mean "joy, glee, or merriment." When anthropologists began describing festivals in the late 1800s, they were usually reporting accounts of religious events, seasonal celebrations, or other practices involving

major events in human life. Their reports generally referred to festivals as periodic celebrations or times set apart from the ordinary or everyday. At this time, anthropologists distinguished festivals as episodic events that were not commonplace routines. In other words, they were special. As per their observations, most of these festivals pertained to a holiday, a "holy day," or day of religious feasting. Most of these interpretations were based on statements gleaned from observations of what were believed to be religious events. Ethnographers, sociologists, and anthropologists documented intricate performances that took place within tribal communities. Feasting was a major component of these practices: In some cases, special foods were prepared following closely scrutinized customs, while in other situations, specific items were restricted from the diet.

During these formative years in the field of anthropology, the general public began using the word *festival* to include artistic performances also. This new definition became more prominent and had wide-ranging effects on future research. Numerous modern anthropologists now adopt a wider interpretation and identify political, national, sports, and mass communication events, art exhibits, and intense film series as festivals, too. The broader view of festivals allows some anthropologists to interpret festival as including nearly every cultural event. This leaves wide-ranging research opportunities for anthropologists who study festivals, but not everyone agrees on the broader view. Although clear-cut definitions and specific applications have not been determined, festivals, as explained by anthropologists, usually include feasting and rituals.

Like *festival*, the term *ritual* has also had many and varying definitions throughout history. The earliest and most basic dictionary entries refer to ritual as "relating to rites or ceremonies." Further depiction of rituals often described them as established or orderly actions or performances. Application of this secondary level of meaning may be limited to religious events, but it may also be applied broadly to pertain to nearly any living species. The migration of birds, the flight of bumblebees, and the feeding patterns of animals are all examples of actions that fall under the more general rubric. Another narrowly described, but still widely used, definition for ritual is formal, repetitive actions. Sequential, reenacted, redundant, repetitive, predictable, stereotypic, and reiterated are just a few variations that have been used to describe this phenomenon. Another variation of rituals as repetitive actions more specifically considers them beliefs in action. By adding beliefs to the explanation, the focus of the term becomes more expressly centered on human endeavors.

Since anthropologists study the science of humans, their definition of ritual has centered on actions of people, but this is not true for all social scientists. Traditionally, anthropologists have understood rituals as actions that are different from everyday events. This implies that they are

not used for ordinary events but for a unique purpose. Further elaboration for some anthropologists has included delineation of the more specific traits of formality and prescription. These added details imply a need for procedure, instruction, or some form of direction for participants to follow. This definition also implies that rituals are not arbitrary phenomena, but ones that require skill or previous training to perform.

Some anthropologists include symbolic objects or words as necessary components of a ritual. Adding symbolism as part of the definition leads anthropologists to further emphasize meaning and emotion. Thinking about the meaning behind ritual objects, words, and behaviors has led some researchers to consider questions that relate to their expression, interpretation, and efficacy. How do the activities transcend the actions themselves? It is this underlying meaning that many anthropologists have found to be the most valuable part of studying rituals. The actions within the performance of rituals are interesting, but the significance of the ritual for the participants, the shared experience for the community, and the connections they make to the divine are often the focal points for anthropologists. The effects of ritual on the participants and the community often surpass understanding. Anthropologists have used function, purpose, and meaning as methods for investigating these intriguing happenings.

The lack of specific definitions for festivals and rituals has, at times, led to ambiguity in determining what can be classified as ritual. This has also resulted in various interpretations as to what actually constitutes a festival or ritual. This vagueness leaves the field open to both broad and narrow interpretations of what should be included in the study. While there is now a vast array of literature on festivals and rituals in both primitive and contemporary societies, their study is still in its infancy.

In their research, anthropologists have observed that festivals and rituals often occur around the major events of the human life cycle. Fertility, childbirth, naming, healing, initiation, adulthood, marriage, death, and funeral rites are just a few examples of this phenomenon. Hunting, planting, gathering, and other agricultural and seasonal events are cyclic events that are also examined. In their observation of ritualistic activities, anthropologists have noticed that a sense of unity develops among the participants. The rest of this chapter will generally focus on the group dynamics and the interplay that occurs during festivals and rituals.

Theoretical Approaches to the Study of Festivals and Rituals

Evolutionary Approach

Many late 19th- and early 20th-century anthropologists studied festivals and rituals by seeking their roots in primitive

cultures. They recorded other people's accounts of witnessed events and also directly observed actions in tribal societies in order to gain insight on their existence in primal lives and in their own civilization. Numerous ethnographers, sociologists, and anthropologists of the day adhered to an evolutionary approach to understanding why feasts, festivals, ceremonies, holidays, rituals, and rites exist. These early anthropologists worked to explain ritual from a historical perspective. They saw a direct link between primitive rituals and the ones they celebrated in their own time and societies, and they often perceived present ceremonies as relics of the past. Sir Edward Burnett (E. B.) Tylor (1832–1917), Sir James Frazer (1854–1941), and William Robertson Smith (1846–1894) are three well-known researchers who studied rituals from an evolutionary approach.

In 1871, E. B. Tylor published *Primitive Culture* (1871/1958), which included a chapter on “Rites and Ceremonies.” In his work, Tylor discusses prayer, sacrifice, fasting, orientation, and other religious rites. His view of these ceremonies portrayed rituals as dramatic performances that allowed for communication with the deities. His discussion focused on the philosophy of *animism*, in which both animate and inanimate objects have souls. In his writings, Tylor used accounts of primitive rituals and ceremonies to attempt to explain the roots of modern culture. In his studies, he infers that modern religion and its rituals are relics of archaic practices.

A contemporary of Tylor, Scottish classicist Sir James Frazer, also believed that it was possible to trace the customs of modern society by studying primitive ancestry. Like Tylor, Frazer wanted to prove that many modern practices were holdovers from the past. In 1890, Frazer published the first edition of *The Golden Bough* (1890/1935). This massive work includes numerous rites from all over the world. Frazer's linguistic abilities, penchant to acquire evidence for comparative study, and writings have led scholars today to call him the father of anthropology.

During the 1880s, Scottish biblical scholar and *Encyclopedia Britannica* editor William Robertson Smith (1894/1969) hypothesized that ritual was an important component of religion, and that in primitive cultures rituals or practices preceded myths and beliefs (dogma). In his study of primitive religion, Smith observed that some clans were united by an affinity to a particular totem. He also determined that one of the oldest rituals, sacrifice, involved a ritual killing followed by a feast that was communally shared by the tribe and its god. Smith saw religion as a community unifier and ritual as a method of worshipping society. Smith's observations and perspective on primitive social cultures have led some researchers to the conclusion that Smith deserves to be called the father of social anthropology.

Toward the end of the 19th century, the evolutionary approach to the study of festivals and rituals lost its luster. Critics argued that data and analysis under this approach

were not scientific. They wished to conduct fieldwork and to implement more theoretical and methodological instruments.

Functional Approach

In the beginning of the 20th century, new functional approaches emerged among European and American sociologists and anthropologists. Functionalists studying festivals and rituals sought to explain their function or purpose. They observed festivals and rituals, but then went further by asking participants in the ceremony what this event meant to them. This form of methodology brought research forward by asking questions that required anthropologists to use more refined methods of comparison. This functional approach to studying festivals and rituals sought to understand how a particular ritual related to other customs within the society, why it was important to society, and how it might relate to similar occasions in other cultures. These functional anthropologists used firsthand observation and interviews with people participating in the ceremony. They attempted to explain festivals and rituals by appreciating the particular custom from the perspective of an individual within the society, and by understanding the social order as a whole.

French sociological theorist Émile Durkheim (1858–1917) promoted a basically functional theory of ritual. In *The Elementary Forms of Religious Life* (1912/1995), Durkheim's study of the Aborigines of Australia, he discussed the solemnity of religious ceremonies and the characteristics of rituals. Durkheim separates rituals into two categories: the sacred, which he dubbed "positive," and the nonsacred "negative." He describes the positive, religious ritual as a code of conduct that provides the proper behavior for religious comportment. He explains religious ritual as formal public enactments that include symbolic representation to provide meaning to the participants. According to Durkheim, positive rituals solidified the relationships between the individual, the society, and the spirit. He describes rituals as a means of gathering people together, motivating participants, and bringing about a new state of action. Durkheim views positive ritual as a method of reconstructing society and affirming its basic tenets, and he observes negative rituals as taboos.

Like Durkheim, Polish-born anthropologist Bronislaw Malinowski (1884–1942) viewed ritual as an important element in the function of society. After receiving training in mathematics, physics, and psychology, Malinowski traveled to the Trobriand Islands, north of New Guinea, where he conducted extensive fieldwork. Malinowski (1954) saw ritual as a means of aiding humans during their weakest hours. The presence of ritual, he suggested, provided guidance and an acceptable means of expressing emotion, especially during times of discord or distress. According to Malinowski, rituals helped to satisfy individuals' basic needs; satisfying these basic requirements was the function of society.

A third famous functionalist, British anthropologist Alfred Reginald (A. R.) Radcliffe-Brown (1881–1955), was obviously influenced by his predecessors' findings. Like Durkheim and Malinowski, Radcliffe-Brown (1952) included research on the function of ritual, in his studies, but he was more interested in the social framework of ritual. By providing a structure of analysis, Radcliffe-Brown created a better strategy for comparing different global societies. While he was not the first functionalist, anthropologists today consider Radcliffe-Brown a major contributor in the formulation of the methodology.

Many British and American anthropologists have pursued the study of ritual from the functionalist perspective. Among the major contributors who have followed this route are English social anthropologist Edward Evan (E. E.) Evans-Pritchard (1902–1973), American sociologist Talcott Parsons (1902–1979), and British anthropologist Edmund Leach (1910–1989). South African-born Meyer Fortes (1906–1983) was a functionalist who was heavily influenced by British scholars. Many functionalists have used the study of festivals and rituals as a way to explain religious activities and to understand the correlation between the participants' individual needs and the demands of the civilization. After World War II ended, many anthropologists sought a new paradigm for ritual explanation.

Protostructural Approach

In 1909, Flemish anthropologist Arnold Van Gennep (1873–1957) published *Les Rites de Passage (Rites of Passage)* (1909/1960). Van Gennep observed individuals' movement from one social status to another and concluded that there was a specific structure to the rites that surround major life crises. He examined birth, initiation, marriage, death, funeral, and other rites associated with transitioning from one stage of human life to another, and found that the events could be broken down into three steps. He labeled the crossing from one stage of life to another as the threshold or *liminal* phase. This liminal point, Van Gennep postulated, was preceded by a *preliminal* or separation period and followed by a *postliminal* or reintegration point. According to Van Gennep, rites of passage marked the stages in which an individual proceeded from one phase of life to another, allowing people a systematic method of coping with transition. The individual was removed from the former stage of life, went through a period of limbo, and then was incorporated back into society under a new standing. Van Gennep's research has been very influential in the study of festivals and rituals.

Structural Approach

Belgian classicist and anthropologist Claude Lévi-Strauss (1908–2009) examined myths and rituals from various cultures and concluded that there were similarities in the structure of myths that transcended cultural boundaries.

Having previously studied structural linguistics, he applied structural analysis to the study of myths. This afforded him the opportunity to show a logical, more scientific, method of understanding culture and relating the past to the present, and the present back to the past. He viewed ritual not only as a method of conveying myth, but also as a way of relating what society dictates. Lévi-Strauss was a major contributor in forming structuralism as a new method of studying society. This structural approach to myth and ritual has not proven to be the definitive answer that anthropologists hoped to find for the study of humankind, but it has added a new method for interpretation and analysis.

Symbolic and Interpretive Approach

Scottish writer Victor Turner (1920–1983) enhanced Van Gennep's ideas on the liminal or transitional stage of rites. He referred to this midpoint as being “betwixt and between” social stages of life. Turner believed that in this phase of liminality, when people are in a state of limbo, participants form a sense of unity and a spiritual bonding he called *communitas*. Turner's (1969) investigations of primitive societies led him to seek meaning in ritual rather than simply focusing on its function in society. He questioned the participants to gain knowledge of their interpretation of their rituals and found cognitive and emotional factors to be influential, and that symbolism was a basic element of ritual. Turner used his findings to create a method of analyzing symbols in terms of their level of meaning.

Symbolism and interpretation were key elements in American cultural anthropologist Clifford Geertz's (1926–2006) research on ritual. In the 1960s, Geertz advocated for a more philosophical explanation of culture. He studied rituals, myths, and symbols as valuable entities that provided meaning and order to life. In *The Interpretation of Cultures* (1973), Geertz describes ritual as “consecrated behavior” that makes people more committed to their beliefs. Geertz elaborates this basic definition by explaining the importance that symbolism has within these ceremonies and that they, too, serve to empower and enrich the experience. Geertz envisioned symbols and their meanings as units of religious rituals that, when understood in their original context, would explain the society's culture.

Modern Approaches

Ecological Approach

American anthropologist Roy Rappaport (1926–1997) focused his studies on culture, religion, rituals, and their environmental influences. In the early 1960s, he observed the Tsembaga clan of New Guinea and concluded that rituals

function to help control environmental relations. He perceived rituals he observed in New Guinea as a means of balancing the ecological system of the human beings and the pigs that resided in the area. In *Ritual and Religion in the Making of Humanity* (1999), Rappaport provides a lengthy explanation of his interpretation of ritual. He refutes some previous studies, supports a definition with a wider scope, and specifically denies that ritual is limited to religious occurrences. He also emphasizes the communication aspects of ritual and particularly accentuates that ritual is not just a succession of acts but includes *utterances* as well. Rappaport emphasizes that words and sounds are important in ritual. In his lengthy explanation, Rappaport also defines ritual as performance and highlights ritual as sequential and formal. With this, Rappaport and others were beginning to take a more secular, broader approach toward ritual.

Performative Approach

Sri Lankan social anthropologist Stanley Tambiah (1929–) began his studies examining kinship and ritual in Ceylon (Sri Lanka), transferred his research to Buddhist practices in Thailand, and later returned his focus to Sri Lanka. Tambiah worked to develop analytic modes that reflected the community he was examining. He rejected contemporary processes that superimposed Western thoughts on non-Western communities. In his research on rituals, Tambiah took what he called a *performative approach*. He related ritual to performance and saw connections between the actions and verbal expressions in rituals. Ritual language was an important part of Tambiah's research. His research also investigated politics, conflict, violence, ethnic identity, and social identity.

Neurotheology/Biogenetic Structuralism

Some anthropologists have recently begun examining festivals and rituals from a more biological viewpoint. These anthropologists have been applying psychological and neurological methodologies to determine how the human brain is wired and how it has evolved over time. American neurotheologist Eugene Guy D'Aquili (1940–1998) and Canadian neuroanthropologist Charles Laughlin Jr. (1938–) proposed a new school of thought—biogenetic structuralism. They theorize that the human body, particularly the brain, allows for human behavior characteristics that enable us to have the necessary skills for music, sex, linguistics, etc. They hypothesize that the brain provides for religious abilities, too. Based on this premise, neuroanthropologists use an interdisciplinary approach that combines neurosciences and physics with anthropology. Thus, they use physiological analysis to investigate the balance between the central nervous system and the environment. Since rituals are central components in all societies, these biogenetic structuralists apply their methodology to rituals.

Modern Applications

Modern anthropologists have continued to review their predecessors' research and to add their own insights to the body of literature on the topic. British anthropologist and functional structuralist Mary Douglas (1966) applies Durkheim's premises as she examines religion and symbolism in contemporary and tribal cultures. South African-born British Anthropologist Max Gluckman initially pursued Radcliffe-Brown's models, but later created his own school. Gluckman (1962) is noted for adapting Durkheim's and Van Gennep's theories to his own findings and enhancing them to apply to his fieldwork research on African legal systems and local conflict.

Since the 1960s, anthropologists have broadened their focal points of study. They have carried on with their interest in ritual in the context of religion, but have increased their investigation of formal procedures within secular events. This new, more cultural approach has triggered expansion of ritual inquiries into the arts, laws, customs, performance, and other areas as well. Recent anthropologists have delved into research areas that include academic traditions, military rites, parades, social clubs, oaths of office, habitual shopping sprees, health and folk festivals, and other public performances as falling into appropriate perimeters for ritual research.

Some of these anthropologists have also included major political events, national holidays, and national ceremonies in their studies. A review of the recent table of contents (1990–2008) of journals that focus on the study of rituals reveals articles with titles that include research on food, everyday life, art, gender, sports, athletes, professional wrestling, tooth-filing, well-being, snow days, television, and many that deal with performance or drama. These varying topics show the breadth of research today. Some anthropologists who study these events see similarities between the gathering of crowds for social events and for religious festivals and rituals. While religious rituals continue to be investigated in developing countries, there is clear indication that modern anthropologists are investigating broader aspects of civilization. Modern anthropologists have analyzed festivals and rituals from the traditional evolutionary and structural approaches but have tended to examine the functional, symbolic, and cognitive methods more often.

Research Methods

Descriptive Research

While observing and studying religious aspects of society, anthropologists realized that studies of festivals and rituals are essential for understanding religion and human origin. They are small building blocks that convey important aspects of religious life. Recognizing this value,

anthropologists began recording other people's accounts of festivals and rituals and then continued by documenting their own observations. In these accounts of festivals and rituals, anthropologists worked to provide descriptions of the people, details of the processes undergone in the ritual activity, and information regarding relationships among the group. Festivals and rituals were elements of religion in ancient times, and, as such, early ethnologists, sociologists, and anthropologists began providing empirical accounts of their existence in society.

Explanatory Research

Observation of tribal societies and their feasts, rituals, and festivals led anthropologists to follow their descriptive research with explanations as to why they exist in society. Attempting to understand their importance led anthropologists to exam their function, purpose, meaning, and symbolism for civilization. Endeavoring to clarify empirical studies with reasons for the survival of rituals has helped to broaden anthropologists' overall understanding of what they observed in these ceremonies, and it gave rise to new theories and interpretations. Explaining festivals and rituals from various theoretical points of view has been enlightening, but it has also fueled debates among social and cultural anthropologists.

Records of these observations and explanations have provided a wealth of information on festivals and rituals. These field research studies and analyses have also allowed social scientists to compare case studies with other historical accounts of festivals and rituals. Anthropologists continue to seek measurable standards that allow quantitative and qualitative data to be compared. Creating hypotheses, collecting and analyzing data, drawing conclusions, evaluating findings, and comparing and contrasting the information with information found from other rituals and cultures continues today. Recently, anthropologists have applied quantitative and qualitative research methods from other disciplines to provide further analytical information.

Types of Rituals

Imitative

As mentioned previously, most anthropological definitions of ritual include an aspect of repetitive or patterned behavior in their description. These behaviors may mimic or reenact actions from the past. These imitative actions can be ingrained traditions of religious ceremonial practices, repeat a story, or share a myth. The debate as to whether these actions stemmed from myths, or whether the myths came from actions, was a central point of contention between many anthropologists in the early 20th century. Later anthropologists appear to have agreed that some rituals stem from myths and some myths are

offshoots of ritual. Imitative rituals may include rites of passage, healing, purification, and more. They may be periodic or celebrate a particular occasion.

Periodic/Seasonal Rituals

Rituals that are celebrated at regularly spaced intervals are known as periodic rituals. Periodic rituals observe special days or seasonal events. They may occur on a specific date such as July 4th or at a more open-ended time such as during the first harvest moon or on the second Sunday in May. These rituals can be associated with seasonal celebrations, national events, community festivities, religious commemorations, and more. These holidays, or “holy days,” offer an opportunity for friends and family members to unite and celebrate a commonly held belief or practice. Most of these days are periodic, and many of them include symbolism. An American flag to mark the celebration of Independence Day, or an evergreen to celebrate Christmas, are just two such symbols.

While not necessarily holidays, similarly celebrated periodic occasions include birthdays, graduations, retirements, reunions, and anniversaries; these events are often honored with ritualistic activities. People gather together to honor someone or something, and to participate in prescribed actions that are not everyday activities for the honoree. The occasions are important to the individual, and the coming together of family and friends who participate in the attached activities enhances their value. These episodic revelries sometimes take on even greater significance at certain times in human life. Certain birthdays, for example, are more heavily revered than others. In some cultures, the first birthday is marked as a time of extra rejoicing because the baby has lived through a year that is often a tenuous year for children in those societies. In other cultures, this particular occasion is celebrated at a later point in life, but observed, nevertheless, for the same basic purpose, to mark the individual’s arrival at a safer plateau in life.

Healing Rituals

Among the many events commemorated during a human’s lifetime are those that are organized to assist people with healing processes. The loss of a loved one, major illness, or horrific violence can leave individuals in despair. A major life crisis, such as death, may leave family members and friends needing to bond with others in order to regain a sense of order in their lives. Ritual processes like the three phases discussed by Van Gennep (1909/1960) provide opportunities to express emotions and begin the healing process. Those people who are closely attached to the departed generally need to separate themselves from the lost member through mourning, transition through the phases of grief, and then rejoin society. Traditional ritual services that honor the lost person are celebrated throughout

the world. These ceremonies provide an opportunity to share the loss and provide mutual support during the darkest time periods. This need for therapeutic rituals occurs in times of illness, too. Special healers use time-honored practices to ward off evil and bring health to the ill.

Purification Rituals

Purification rituals may also serve a therapeutic purpose. Like healing ceremonies, they help people traverse through a series of cleansing processes: sanitization, solidarity, reflection, beseeching, and sacrifice. These rituals are practiced with all seriousness, for the ultimate goal is to show repentance in hopes of returning the sinner to society’s good graces. If a person has upset the divine order, restorative measures may be used to attempt to regain stability.

Ritual, Performance, Theater, Arts, Media, and Recreation

The challenge of defining festivals and rituals has resulted in no specific guidelines as to what they actually constitute. This lack of specificity has led to various interpretations as to the difference between rituals and theatrical performances. It has been argued that there are ritualistic festivals and ritualistic theatrical performances. Both include actions and incorporate the arts of singing, dancing, and music. The debate is whether or not theatrical performance is ritual, or ritualistic behavior. In this same vein, there has also been a disagreement over festivals and rituals and their place in parades, carnivals, beauty pageants, protests, and national ceremonies. Western anthropologists generally describe the entertainment aspects of theater, and the serious efficacy aspects of ritual, as methods of codifying what belongs within each of these categories; but festival, which has been affiliated with both ritual and theater, has a secondary definition of gaiety and merriment. While festivals may be merry, by most definitions rituals are not strictly fun, frolicking, and frivolous. In the past, anthropologists have contemplated ritual in theater and the other branches of the visual arts, but recent research has concentrated much more extensively on the secular arts and their relationship to festivals and rituals.

Ritual and Communication

When anthropologists began documenting rituals, they noted that the ceremonies appeared to include nonverbal messages. The participants seemed to be following a format in which they had been taught to share a series of actions with the community. In some instances, these activities appeared to provide the participant with some freedom of expression, and the anthropologists perceived that they were witnessing repetitive and imitative behaviors that communicate messages to society and the gods. Both the

solemn and highly charged rituals seemed to transform and empower the participants. Many of these rituals included verbal communication forms, too. Both verbal and nonverbal ritual communication, their meanings and their structures, have been of interest to modern anthropologists.

The process of analyzing and interpreting festivals and rituals includes three phases: (1) the messages conveyed within rituals and festivals, (2) the anthropologist's attempts to interpret and effectively express knowledge gleaned from these performances, and (3) the readers' or listeners' efforts to effectively receive this information. The communication that takes place within the ritual itself has been a regular component of the interpretation of festivals and rituals. Anthropologists recorded what they saw and later attempted to clarify their interpretations through participant interviews. Most of the anthropological studies of festivals and rituals that have been generated for English-speaking communities have been transmitted from a European-American perspective; but many of these festivals and rituals have been translated from non-English-speaking communities. Hence, there has been more effort to gain direct insight on festivals and rituals from within the culture.

Rituals and the Family

Social scientists' study of ritual may be viewed within the smallest social unit, the family. Families establish festivals and rituals that bind them as members of a large clan, as constituents of a religious unit, or as affiliates of political or social groups. Wedding services, holiday celebrations, and other family occasions provide people with shared experiences and develop and create new relationships. Rituals help meet humans' need for unity and stability. Family members thrive in households that provide unifying experiences that offer continuity with past generations, familiarity with periodic events, predictability in routine, and protection from the unknown. Rituals also provide significant coping techniques in a world that can often seem overwhelming.

Family rituals can be viewed as both emanating from society and providing protocol for the social order. Viewing the ebb and flow of festivals and rituals from all of the various interpretations has expanded research into many arenas. Today, even a family vacation holiday to a favorite getaway place may be seen as ritual.

Future Directions

The study of festivals and rituals has evolved parallel to the field of anthropology as a whole. Anthropology has been studied from both cultural and social traditions; but modern anthropology includes a host of subdivisions such as action or development, architectural, biological, business, ecological, economic, environmental, evolutionary, feminist, forensic, industrial, linguistic, political and legal,

psychological, and visual. These various divisions of anthropology offer even more study opportunities when a multitude of more specific categories are explored: aging, carnivals, education, race, social class, bioethics, ethics and justice, sexuality, and gender. Each of these research areas offers opportunities for further investigation of festivals, rituals, and ritualistic behaviors.

As the field of research has expanded, so, too, have the various approaches to the study of festivals and rituals. A review of the most recent literature appears to indicate that cognitive approaches, which involve thinking and reasoning, are likely to be in the forefront in the foreseeable future. New scientific emphasis on biology—also known as physical anthropology—and neurology are also providing anthropologists opportunities for unprecedented exploration. Current theoretical approaches to the study of festivals and rituals appear to be those that require thought, scientific methodology, and humanistic views. These methods are also ones that most easily lend themselves to cross-cultural interpretation. As communication methods and global transportation have seemingly shrunk the world, anthropologists have also become more inclined to utilize international and interdisciplinary approaches to investigate these basic elements of human existence. The study of festivals and rituals is inherent in the field of anthropology and will continue to be a valuable element in the science of human beings.

Conclusion

Festivals and rituals seem to have existed nearly as long as humans have walked the face of the earth. They are performed all over the world for a variety of purposes, including ritual compliance, recognition of respect, satisfaction of personal needs, improvement of cultural bonds, and social acceptance. Anthropologists have documented festivals and rituals as worship rites, rites of passage, celebrations of joy and sorrow, and components of everyday culture. They are integral parts of most societies that help shape culture and assist in establishing common connections between members of the culture. They provide a sense of commonality that facilitates participants' understanding of their heritage, eases transition from one stage of life to another, and provides legacies for the future. Although festivals and rituals are fundamental aspects of human culture, anthropologists have yet to truly understand their intrinsic values and their ubiquitous nature in society.

Anthropological studies of festivals and rituals have evolved from accounts of tribal religious practices to scientific methodology applied to both religious and secular events. Over time, some social and cultural theorists have described various aspects of festivals and rituals as being the most pertinent for their research in understanding humans. They have depicted festivals and rituals as ranging from prescribed, symbolically controlled sequences of

beliefs in actions with deep-rooted symbolism and meaning to simply being action that is separate or different. Various theorists and researchers have come to different conclusions regarding the function, meaning, and structure of rituals and the boundaries of festivals.

The abundance of literature on festivals and rituals has exploded into nearly every social and cultural arena. The broad and variant interpretations for festival and ritual have ranged from very solemn functional affairs to happy moments of social interaction. They have included periodic, life cycle, and performance events. When viewed in humanistic terms, the field of festival and ritual studies may have reached its preteens or adolescence, but there are still major growth prospects ahead.

MUSIC AND DANCE

SHAYNA SILVERSTEIN

University of Chicago

Ethnographic approaches to music and dance in the 21st century explore how modes of expression and performance practices are involved in the making of lifeworlds. Cultural production is situated in specific contexts that generate meaning as particular sonic and kinesthetic phenomena relate to discursive processes and social structures. Scholars of music and dance engage with cultural flow through dialogic encounters and interpretative analyses. These studies help illustrate how performance practices produce meanings, mediate socialities, and configure political relations.

Ethnomusicology, which generally encompasses anthropology, dance ethnology, folklore, musicology, and sociology, situates specific theoretical issues in comparative social and historical contexts. Up to the late 1960s, the discipline explored and indexed the musical phenomena of non-Western cultures in ways that resonated with concurrent anthropological trends in area studies. Critical analysis of these approaches led to a rethinking of music in which music became not the object of culture, but rather the product and expression of human experience. In his writings on the relations between music and society, anthropologist John Blacking (1995) proposed:

We need to know what sounds and what kinds of behavior different societies have chosen to call “musical;” and until we know more about this we cannot begin to answer the question, “How musical is man?” As “humanly organized sound,” music is a bearer of meanings insofar as it exhibits and necessarily demonstrates a set of values that the society that generates it would otherwise lack. (p. 5)

Relations between music, dance, and society are thus viewed as complex networks of interdependence through which a given act embodies temporal and emplaced experiences that structure social processes. Contemporary ethnomusicology pursues a rigorous analysis of how cultural production generates social significance by positioning the individual as the agent of social change through historical encounter.

Theoretical Approaches

The Meaning of Music and Dance

Musical and social structures mutually constitute each other through human interaction. This cultural-studies approach derives from the seminal work of Raymond Williams, who claimed that culture is not fixed as a bounded work or elite mode of production, but is instead embedded in everyday experience and activity. As a cultural materialist who challenged orthodox Marxist accounts of historical epochs or phases, Williams framed cultural practices as sites of political contestation through which groups reproduce and resist modes of domination, particularly those that critique industrial capitalism (Williams, 1977). Critical to his work are structures of feeling that configure the ways in which particular generations and social classes experience difference among social relations. These feelings beget a lived experience of a particular moment in society and history that brings meaning into the lives of individuals and the

lifeworlds that they constitute. The production of cultural meaning is a fluid and dynamic process that emerges as a necessary process in which “new meanings and values, new practices, new relationships, and kinds of relationship are continually being created” (Williams, 1977, pp. 122–23).

Musical meaning is not itself generated through aesthetic critique, nor by reference to something extramusical, such as an emotion, landscape, or harmonic figure. Rather, musical elements and structures discursively relate to lived experience by an act of representation that fixes musical experiences to metaphoric and metonymic structures, forms, and works. These bounded entities are placed in a network of complex relations that can be explained through systems of representation in which musical ontologies serve as interpretive frameworks for diverse musical systems, whether Western symphonic music, Hindustani classical music, or Japanese *gagaku* court theater, or for categorization of musical cultures as classical, folk, popular, and traditional. Categories, however, do not necessarily correlate to an intrinsic value, but more productively relate to “how they are used and embodied in community relations to become structuring forces in musical life” (Holt, 2007, p. 29).

Ethnomusicologists today explore the discursive production of musical meaning as a contemporary response to what comparative musicologist Charles Seeger (1977) problematized as the “musicological juncture” (p. 16), or the gap of representation that occurs when communicating about one system of human communication (music) through another (speech). To redress claims that music is “untranslatable and irreducible to the verbal mode” (Feld, 1982, p. 91), ethnomusicology suggests that musical practice is less a latent mode of (artistic) representation but rather a (socially) active and engaged mode of producing reality. If speech is the communication of “worldview as the intellection of reality,” then music is the communication of “worldview as the feeling of reality” (Seeger, 1977, p. 7). What we perceive as “feelingful” occurs through the “generality and multiplicity of possible messages and interpretations . . . that unite the material and mental dimensions of musical experience as fully embodied” (Seeger, 1977, p. 91). As suggested by interpretive approaches to cultural anthropology, ethnographers study not experience, per se, but the feelingful and discursive structures through which experience occurs.

Musical experience is constituted as meaningful when social structures conjoin with individual consciousness through structures of feeling. Whereas structures suggest fixed relationships that are rigid and determined, feeling inflects the intense and personal experience of what is “believed, felt, and acted upon” (Frith, 1996, p. 252). This becomes important with regard to the construction of cultural forms, whether musical genres and styles or social categories and spaces. How people behave with regard to sound relates to what they perceive and think about such behavior. Anthropologist Alan Merriam (1964) proposed a model of musical anthropology that triangulates these axes of sound, concept, and behavior. This tripartite structure has been redressed by an interpretive analysis of dialectical

processes that consist of historical construction, social maintenance, and individual adaptation and experience; in other words, an agency-centered inquiry into how people create, experience, and use music (Rice, 1987).

Reception

Feelingful experiences occur through culturally specific processes that produce and perceive sound. Recent directions in the phenomenology of acoustic phenomena argue that sound is not the property of a musical object separated from its origin, but rather, sonic significance lies in the encounter of sound as musical. Sensory dimensions of experience suggest that sonorities may be heard as affective, feelingful, and emotional when perceived as musical patterns in specific cultural contexts. Phenomenological studies suggest the ways in which people relate to each other through senses of hearing. A hearing culture may make it “possible to conceptualize new ways of knowing a culture and of gaining a deepened understanding of how the members of a society know each other” (Erlmann, 2004, p. 3). In turn, individual and social processes perceive musical encounter “not through layers of cognitive categories and symbolic associations, but with a trained and responsive body, through habits copied from others and strictly reinforced, by means of musical skills” (Downey, 2002, p. 490). Listeners’ acquired habits of assimilating sensory experience to musical systems affect them viscerally, and lived bodies are fashioned by patterns of acting in relation to music at the same time that they are responsive to sonic textures.

Performance

Performance emerges through the interaction of corporeal gestures, discursive tropes, and performative utterances in social settings that situate these actions as musical or extramusical, verbal or nonverbal, cognitive or affective, sacred or secular. These actions are held together by aesthetic principles that are represented in the social and material world, just as the social and material world is imbued with extraordinary value. Performance and listening are intersubjectively and physiologically experienced in a trained and socialized set of artistic bodily movements that reflect values and ideas (Meintjes, 2003, p. 176).

Embodied realms of experience situate cultural practices in the physiological and expressive body and the social forces that operate through those bodies. Performativity asserts the materiality of nonverbal communication and expression and the presence of the body as it is mediated by the production of sound. Whether sound is produced by a singer, a musician, or mediated by technology, the presence of the medium leaves a material trace that regulates its origin (Barthes, 1978). For example, analyses of timbre consider the grain of the voice in recording—in addition to elements of texture, attack, delay, and pitch—and interpret studio techniques as signifying practices that are deeply connected to the discursive production of style and genre (Théberge, 1997).

Embodiment

Embodied performance by a socialized musician or dancer suggests how bodies may be regulated or may resist forces of power (Comaroff, 1991). The discourse of bodies in motion at Greek weddings, for instance, produces the dialectical relationships and mutual dependencies that are also regulated and constrained by their repetitive power as a body politic, or collective unit. By introducing non-Greek Roma musicians at wedding parties as *daulia*, or drums (Cowan, 1990, p. 102), Greek townspeople exert power over the materiality of both resonant and outside bodies. As sites of reception and agency, bodies bear narratives of time and place that coalesce into corporeal memories. The ways individuals perform these narratives construct identity and differences that endow sound and movement with the capacity to represent lived experience.

As forms of social action and as meaningful activity, music and dance create and give expression to human and social experience. Epistemological concerns have critically responded to the ways in which a kinetic body and a sound dialogically compose form through performance events, structured practices, and representational strategies. Rather than treat music and dance as objects of discourse that possess meaning in and of themselves, or frame body movement techniques and sonic phenomena as abstract properties that may be reconfigured according to context, ethnographers seek to localize the very terms by which understanding and knowledge of these performative dynamics are produced.

Research Topics and Issues

Sacred Performance

Music plays a significant role in preserving and transmitting the world's religions in terms of history, culture, and practice. The study of music in religious practices considers the ways in which music transforms experience into sacred meanings, narrates religious myths, and structures religious ritual and communities. The performative conditions associated with religious practice consider sacred sound not as the taxonomy of a particular belief system, but rather as a sensory spectacle through which experiences become enchanted. The sacred nature mediates by sonic utterances that may induce a phantasmagoric state of being, encode sacred language, or embody affective experience. Sound indexes religious experience through the presence of sacred instruments and the act of listening to liturgical chant. Sound also marks sacred spaces through pilgrimages and festival rituals, among other religious practices (Beck, 2006; Berliner, 1993).

The efficacy of music in sacred spaces suggests the ways in which sound may be sacred and how this sacred nature may be mediated through sonic practices. How sound conveys sacred meaning and experience in specific contexts raises ontological distinctions in that what is often perceived as musical in European and North American contexts may be considered nonmusical and sacred in other sacred spaces.

Contexts may determine how sound is received and interpreted and in what ways sound may be ontologically separate from music. Interpretation of sound also structures power relations, in which religious authority is maintained by ideological boundaries of sound seeking to differentiate between sacred practices and secular forms of expression (Baily, 2003).

Ethnographies of sacred performance practices have tended to focus on the capacity of music, dance, and ritual drama to organize religious activity through modes of social interaction that produce webs of associative meaning (Reily, 2002). Performance has been conceptualized as a medium through which participants demonstrate religious conviction and commitment; as a means to structure time, narrative, and symbolic systems; and as a mode of interaction that codifies organizational patterns and the conditions of participation in religious activity. For example, the sacred voice is a medium that binds individuals communally in religious activity. How these experiences shape and are shaped by musical practice is determined by the theological ways in which individuals engage with music and music making. More recently, ethnographers have considered ways in which religious-ritual activity depends on the act of performance in order to be perceived as sacred and, in particular, how sound and movements are mediums that frame a ritual act as sacred. As individuals negotiate moral boundaries between the sacred and the profane in contemporary contexts, the act of producing sound and movement becomes a contested arena where religious authorities judge the ethics of cultural production. Performance through music and dance may allow departure from the profane and entrance into the sacred, mark the aesthetic boundaries of secular space, or itself articulate the boundaries between the sacred and the profane by which religious practices acquired enchanted and sacred meaning.

Several bodies of scholarship have addressed musical change, religious renewal, soteriological potential, musico-religious orthodoxy, and other related issues. These different forms of religious practice, or syncretism, may be marked through distinct genres and styles that expose moments of encounter and uneven relations of power. In colonial spaces, religious repertory may occupy cultural spaces in ways that reproduce a hegemonic religious order and erase subaltern religious practices (Comaroff, 1991). Folkloric ensembles typically relate to historical or contemporary religious practices through complex processes of aestheticization that problematically blur distinctions between sacred worship, cultural traditions, and popular culture. These distinctions are in part based on a collective memory of the sacred that is translated through aesthetic ideals. The embodiment of these ideals demonstrates how religious ideologies are manifested through bodily practices that themselves produce sacred sound, movement, and performance.

Chant and Recitation

The power of sound embodied in speech patterns, or chant, may preserve and transmit knowledge and religious authority as well as mark historical change. For example, the Rigvedic texts of the Harappan in Pakistan and northwestern India are

considered sacred when correctly rendered through transmission and pronunciation of Vedic hymns. Recitation of these hymns occurs through three types of spoken accent with a melodic contour dependent on the succession of accent in the sung syllables, as well as the duration of each relative pitch. The consideration of Vedic chant as the foundation of contemporary Hindustani music in South Asia is, in part, attributed to its preservation through Brahman recitation. Codification of early performance practices, such as Gregorian chant in southern Europe, began when clergy notated plainchant in order to correlate its liturgical function with the medieval Roman liturgical calendar. Compositional practices that developed from these notations are widely considered to be the conceptual and historical basis for Renaissance and late European courtly arts (Bergeron, 1998).

Some religious cultures regard practices of recitation, or the sounding of religious text, as the divine act that makes speech patterns sacred by mediating the transmission of sacred texts through the vocal performance. The significance of such performances is governed not only by the syntactic conditions such as pitch and duration, but also by audition, or the appropriate response, performed by the ethical listener (Hirschkind, 2006).

Instruments

Instruments embody religious experience when endowed with the capacity to produce sacred sound. In some ritual practices, performance on a particular instrument, such as batá percussion ensembles in Cuban Santería, realizes the divine potential of the ritual event and produces religious transformation. Instrumental-performance practice marks the shift from secular to sacred contexts; produces the appropriate performance conditions for trance, ecstasy, possession, and other states of heightened sacrality; symbolizes tropes of religious narrative and function; and transfers knowledge and participation among believers (Hagedorn, 2001; Rouget, 1985; Wong, 2001).

Narrative

Sacred musical practices are often narrative—telling stories and relating myths to generate a sense of historical and religious meaning. Narrative may be considered musical through, for example, the ways in which music marks the passage of time in ritual performance and in the narrative sequence of events, or through the juxtaposition of different musical genres that layer and texture religious stories. Instruments often play a significant role in narrating epic myths with sacred content, such as within bardic traditions or Sufi mysticism. One way in which narrative components of sacred music may shape a religious community is by mediating a sense of place. The act of recalling an original event, such as an act of martyrdom or a miracle, links the event to a specific site. When enacted through song and other musico-poetic genres, the act of recall layers subsequent events to that site in ways that parse history as locally meaningful in religious communities.

Critical Musicology

During the early 1990s, musicologists readjusted paradigms in which musical performance expresses a natural mode of human existence or formalizes a universal set of aesthetic ideals (Solie, 1993). The critical inquiry espoused by “new musicology” advocated for the deconstruction of ideologies into iconicities of style that are reproduced and transformed by acts of performance. Performance practices now produce social relations that are represented in different categories of gender and sexuality, race and ethnicity, generation, class and nation, and other forms of identity. Cultural meaning is discursively constructed by specific practices of signification, and links between signifier and signified are not fixed but arbitrary. These practices may construct meaningful experience in ways that depend on conventions of taste and class that are situated in a particular time and place.

Place

Studies of place tend to be located in everyday life and explore the tactics by which people interact and engage with their environment. Gatherings, such as rehearsals among English rock musicians, are not only mediated by these practices, but also produce affective relationships to the settings in which social activities take place. Yet, as conditions of modernity separate space from place in lived experience, the physical settings of social activities are “thoroughly penetrated by and shaped in terms of social influences quite distant from them” (Giddens, as cited in Stokes, 1994, p. 1). Therefore, approaches to place, music, and dance seek to relocate cultural geographies within specific social, economic, and political spaces by addressing how individuals produce sound and movement in order “to reestablish their presence, situate events in a fixed place and time, and reembed actions within social structures” (Stokes, 1994, p. 3). Place becomes meaningful through affective processes that recognize and enable different experiences, mediate emotional relations to an environment, or produce nostalgia through acts of memory that bestow music and dance “with an intensity, power and simplicity unmatched by any other social activity” (Stokes, 1994, p. 3).

As individuals perceive what takes shape around them, they participate in the construction of a *soundscape*, or an environment structured by the perception and reception of sound. Soundscapes are differentiated not only by dynamics of power, class, and difference, but also by sentimentality, or the emotional and affective relationships that constitute a sense of place (Feld & Basso, 1996). An acoustemology of sound analyzes the sentimental relations to place that are embodied by sound production and reception among, for instance, Kaluli people in Papua New Guinea. Through interlocking, overlapping, and alternating singing that mimics bird calls in the rainforests, Kaluli voices index the natural environment; mediate places as sites of memory; and express an ecological sense of self, place, and time (Feld, 1982). Acoustic environments have also been critical to the historical progression of musical form in bourgeois

European society and the displacement of instrumentalists to the role of musical interpreters. Early performance practices were comprised of extramusical, literary, or narrative material that was, in part, marked by a musician's individualized embellishment of musical material.

In the 19th century, the concert room emerged as a performance setting that aestheticized the impression of immediate contact with the music as a listening ideal. Musical practices shifted to uphold universalist aesthetic ideals not only through listening appreciation, but also in celebration of a composer's genius. Dramatic structures were communicated by composers such as Beethoven through "the abstract logic of pure form" and the formal properties of the music itself in ways that privileged structural-listening practices in European art music. Thus, the commodification of musical knowledge and musical emplacement fetishized sonata form in the historical development of instrumental Western art music (Leyshon, Matless, & Revill, 1998).

Globalization

The commodification of musical place in a globalized world has induced a certain anxiety among critical musicologists over the ways that disembedding music and dance practices stimulates desires for authenticity by late-capital consumers in a hegemonic economic order. While the capacity for music to travel has augmented an appreciation for place and dismantled cultural borders, the poetics and politics of this have problematically differentiated relations between self and other. World music, and related configurations of art music, ritual, folk and ethnic genres, and world beat and roots music (Aubert, 2007), are authenticated by conditions of place. By privileging the geographically local as authentic, the particular can be naturalized in ways that fetishize locality through terms of belonging. The act of splitting sound from its source and reproducing it depends on uneven processes of representation that contest cultural rights and negotiate various modes of ownership (Feld & Basso, 1996). Styles associated with world music then demarcate community by linking dispersed places and allegiances that, through subjective identity, allow the strategies by which individuals register difference (Erlmann, 1999).

The globalization of world music has also been critiqued as a *pastiche*, or a process of reconfiguring time and space that detemporalizes the encounter between self and ethnographic others into an event beyond history, or perhaps at the horizon of a certain historical moment. For instance, the production and consumption of alternative folk rock links different historical moments into one bounded cultural space, while world-dance music may layer disparate local styles into a repetitive, temporal sequence (Erlmann, 1999). Cultural interchange and interaction in popular music thus depends upon a concept of culture that binds territory to groups in ways that demand the political engagement of cultural critique. Whereas narratives of cultural interchange such as hybridity, creolism, and syncretism tend to privilege myths of origin, postcolonial analyses encourage new approaches that no

longer engender forms of being by binaries of self (self and ethnographic other), place (here and there), and time (then and now), but rather by a third space that is constituted by these boundaries. The circulatory relations of cultural flow have furthered understandings of how historical consciousness may undermine essentializing cultural strategies. Studies of the black Atlantic (Gilroy, 1993) address how black popular music and dance styles shape and are shaped by particular African retentions and situate the Atlantic as a site of crossings, mediations, and exchanges that continually reconsider the cultural flow of African and African American expressive forms.

In response to large-scale processes of migration, globalization, and transnationalism that destabilize structures of belonging, critical approaches to place have also emphasized the production of locality through cultural practices. Tropes of place may uneasily mark displacement from an imagined structure of belonging, for instance when tropes of the crowd and the machine in the South African vocal genre of *isicathamiya* signify a sense of nostalgia for rural agricultural economies among populations who migrated to cities in search of labor opportunities. Another example can be found in how the mapping of memory fragments onto musical events, instruments, and kinship narratives of a retired Jewish community in Liverpool, England, shapes collective relations that in turn construct an immigrant neighborhood whose identity is nurtured by newly mediated and localized imaginaries of home and community. Locality may also be produced by sound-engineering practices that index a particular place and authenticate a musical style through the technological reproduction of sound in specific performance conditions such as "live" Austin country music (Greene & Porcello, 2005).

Gender and Sexuality

Gender and sexuality analyses situate performers and their texts within specific musical worlds and examine how these worlds produce gendered ideologies through performance practice, singing style, repertory, performance events and occasions, lyrics and elaborations, and instrumental practice. Thus, gender and sexuality are mutually constitutive of cultural experiences, and also mutually construct processes of subjectivity and alterity in ways that have been binarily opposed to biological explanations of lived experience. As a method of cultural critique, gender and sexuality studies analyze the ways in which ideology is maintained and transformed through the performance of a gendered self. These studies also examine the ways that musical practices mediate social relations as variously gendered—masculine, feminine, and perhaps hyperreal. Because gender theorists have understood sexuality as constitutive of gendered norms, distinctions between gender and sexuality have been largely premised on identity construction as theorized in psychoanalytic discourse. Lacanian theory argues that linguistic signs triangulate the enlightened self from its other in ways that destabilize a sense of identity by the desire for an object that might represent such identity. By reading social and cultural texts for hidden and repressed desires, critical theorists reveal conditions of heteronormativity that

shape and are shaped by cultural practices. Ultimately, gender and sexuality studies suggest how social distinctions may be magnified rather than ameliorated by the performative act of music making and structured movement.

A substantial body of literature has been devoted to highlighting and documenting women's contribution and women's roles in musical performance. As professional entertainers, as dramatic personalities, and as audiences, women convey social values and transmit cultural meanings in ways that may be different from those performed by men. The expression of sentimentality by women through forms and repertoires, such as sung poetry among Bedouin women in upper Egypt, resist, maneuver, and maintain patriarchal norms of modesty, honor, and shame that have been typified in Mediterranean studies (Abu-Lughod, 1986), whereas songs sung by Berber women in northern Morocco strategically empower potentialities of marital life (Magrini, 2003). Performance events and contexts have been analyzed with discourses surrounding these practices through elements of lyrics, style, technology, and appropriate behavior. These suggest how identity may be encoded and performed as masculine, feminine, or ambiguously gendered. Postmodernist approaches to the paradigmatic relations between musical and social structures have produced seminal readings of the gendered hierarchies in composition, such as immanent relations between the masculine and the feminine in sonata form (McClary, 1991), formulations of the Western music canon, constructions of ontological difference through gender (Solie, 1993), and the potential of music itself—as a performance rather than as text, to disrupt the masculine musicological narratives within which it is often contained (Abbate, 1991).

The broad compass of vocal performance in different registers constructs gendered and sexualized identities by embracing some, and refusing other, conventions of style and genre. Voice may characterize a range of erotic and emotional relationships among women who sing and women who listen in ways that “resonate in sonic space as lesbian difference and desire” (Brett, Wood, & Thomas, 1994, p. 28). This *sapphonicvoice* is found in operatic practices by female singers who assume “pants” roles, or castrato male roles sung by women, as well as other singers and singing personalities (Brett et al., 1994). Koestenbaum (1994) argued that the *brea* between registers is a gendered split that emplaces a voice between male and female. The ways in which the *brea* is negotiated may be “fatal to the act of natural voice production” (p. 220) when gender and sexuality are transferred beyond normativity, such as the *sapphonicvoice*'s synthesis of register; this replaces its splitting, or the falsetto register's failure to disguise this break. The combination of different registers may refuse vocal categories and polarities of natural and unnatural, and may establish interpretations of female desire, male desire, and the relations of class, age, sexual status, and identity through vocal performance (Koestenbaum, 1994).

The performance of gender engages with the kinds of subjects that musical and dance performances engender, both onstage and among audiences, and the ways that such

performance relates to everyday life as lived, embodied, and theorized. For instance, a feminized atmosphere at a wedding in Morocco is not dependent on the presence of female dancers, but rather on the performance of femininity among communal relations that may differentiate between gender, sexuality, and class. Perceptions and representations of Asian American femininity have shifted due to North American *taiko* performance that represents social space through gesture, movement, and the presence of women in drumming practices. In post-Apartheid South Africa, Zulu *ngoma* song and dance is critical to the performance of masculinity and the anxieties of retaining the presence of individualized expression and stylized body movement in the midst of unemployment, an AIDS epidemic, and a history of violence in KwaZulu-Natal (Meintjes, 2003).

Race and Ethnicity

Critical race studies examine how constructions of difference on the basis of body type and color are perpetuated by the representation of essentialized metaphysical conditions. Concepts of race are linked to the emergence of modern scientific inquiry into the natural world and are largely considered a product of Enlightenment thought and observation. The late 18th century produced a world “observed, processed and remapped on the imagination of Europe” (Radano & Bohlman, 2000, p. 13) in which race and music constituted logics of difference that categorized the natural world and sought to make it understandable. Moreover, racial discourse contributed to the formation of musical difference as human difference was mapped onto musical difference, that is, to the object of music itself. The epistemic model that measured harmonic relations on a mathematically proportionate scale and unified differences in pitch influenced Enlightenment thought on the structure and substance of not only resonating, but also racialized bodies. How music participates in the construction of race and racial imaginaries ultimately raises ontological questions of whether music itself represents these qualities, or whether our understandings of music are shaped by and through racial relations.

Racial constructs are connected to music through structures of understandability, that is, the capacity of sound to signify and communicate meaning, and through materiality, or the technologies, objects, and bodies that represent music and musical histories through particular ideologies (Brown, 2007). For example, the 19th-century German composer Richard Wagner claimed that the language of European opera and vocal music was degraded through the inability of European Jewish composers to fully control the language of music, which Wagner instantiated in terms of 19th-century German universalism that was first and foremost predicated on language and an assumption that music instantiates comparative linguistic properties. Elsewhere, race interacts with other systemic hierarchies, such as the historic provision of wedding and court entertainment by Jewish musicians in predominantly Muslim worlds situated along the Silk Road, from Bukharan weddings in central Asia to the Abbasid and

Omayyad caliphates of the 11th century. Categories in which instruments function as a racial mapping of power relations may be critiqued by participants themselves, such as Karnatak and Hindustani musicians who negotiate caste systems in South Asia that distinguish between the permissibility of Brahmin performance on the Karnatic vinalute and the delegation of instrumental performance on untouchable leather-skinned drums to less privileged castes. Conditions of difference, shaped by cultural practices, help to better understand relations of power in systems based on class, caste, kinship, religion, and other forms of belonging and ownership.

Racial conventions of blackness, whiteness, and other morphologies play a critical role in ideological distinctions of music as rational and intellectual, or as orally transmitted, communal, and embodied. The naturalization of certain structures as African retentions, such as improvised movement, antiphonal oppositions, and repeated cycles of interlocking rhythmic patterns, reinforces the putative inseparability of music and dance in the African diaspora (Meintjes, 2003). This becomes problematic when what is musical and universal is defined against conceptions of blackness as physical and embodied. Yet, performance practice and histories may join as lived experience in ways that affirm how blues practices in African American working-class communities in the southern United States influenced the emergence of jazz, gospel, soul, R&B, rock, hip-hop, and other black vernacular music. The problem of race translates into a cultural critique in which creative strategies destabilize the tropes through which they emerge by means of intertextuality, subversion, and other signifying techniques (Radano & Bohlman, 2000).

Ethnicity, like other forms of difference that participate in processes of exclusion and inclusion, is constructed on the basis of shared beliefs in a “common ancestry, memories of a shared historical past, and elements in common, such as kinship patterns, physical continuity, religious affiliation, language, or some combination of these” (Shelemay, 2001, p. 249). Musical and dance practices instantiate ethnic relations by performing social boundaries that reproduce and subvert ideologies; these relations simultaneously also produce meanings, that is, “a patterned context in which other things happen” (Waterman, 1990, p. 214). Ethnic identity is often discussed in terms of minority relations and population movements that are themselves predicated on political difference. Often, ethnic boundaries “define and maintain social identities which can only exist in context of oppositions and relativities”; thus, ethnography can engage with how “actors use music in specific local situations to erect boundaries, maintain distinctions between us and them, and use terms such as ‘authentic’ to justify these boundaries” (Stokes, 1994, p. 6).

Nationalism

Cultural nationalism is a complex process by which institutions and actors integrate diverse populations into structures of national belonging. Ethnography investigates the ways in which music and dance practices—and the discursive spaces that are dialogically created and inhabited by

such practices—generate national imaginaries in local contexts. Early forms of nationalism celebrated the universal claim to a single shared language and a set of particular customs and traditions situated in an ethnonational framework. Scholars have since criticized collective national identity as a product of state apparatuses that seek to reify lived experience into internationally recognized forms. Thus, the invention of tradition has been linked with nation-building projects in which state power emerges through the performance of national imaginaries and the efficacy of imagined communities (Askew, 2002). The extent to which symbolic production produces and sustains state hegemony through particular genres suggests whether these processes might be “multivalent, multivocal, and polyphonic” (Askew, 2002, p. 273) and how agents and institutions are involved in negotiating, defining, and contesting that which constitutes the nation. Musical ethnographies reveal the strategic shifts that characterize nationalist projects, ask whether events coincide with or interrupt official ideologies, illustrate why specific forms are chosen to represent the nation, and address how issues of authenticity and preservation are managed in these endeavors. Though global capital flow, access to electronic media, and transnational migration of people have decentered and deterritorialized processes of nationalism, the mediating structure of the nation continues to relate how people cross lines of difference through local transactions and cultural production.

Representation of the nation through music depends on a belief in the representational potential of music, that is, music’s capacity to embody a cultural whole that exists prior to its mediation. The production of national symbols, therefore, depends upon a modern discourse that is represented by cultural mediation. This discourse emerged from Johann Gottfried Herder’s claim that based national identity on the common narratives and histories of a given people and, in particular, on the capacity of language and folksong to represent such shared experiences. Herder’s proto-nationalist theory is comprised of a geographic model where music marks a place, such as the landscape of the nation, an acoustic model whereby sound distinguishes the nation as a whole, and a narrative model in which music encodes stories that represent the history of the nation (see Bohlman, 2004). The quintessential image of the nation, or a “preexisting entity that is more indefinite than definite,” is reflected by national music, “for whom it becomes the task to bring out as much of the definition as possible” (Bohlman, 2004, p. 83).

Conversely, nationalistic music does not harbor relations among a nationalized people, but rather services competition between nation-states. Nationalistic music secures the geographic identity of the nation-state by marking borders and producing alterity through the production of national difference. Alterity may be differentiated on the basis of class, race, ethnicity, and gender dynamics that exclude those whose presence prescribes the need to regulate desires and who trigger ambivalence as a condition of modernity. The marking of borders is instantiated by a presentation of the nation that embeds power in performance, or through a means of communicative interaction in which the act itself

is privileged over that which it mediates. Thus, nonverbal performance may communicate messages whose meaning is located in elements of sound and movement and in dialogic interaction between performers and audiences, or between modes of modernity—contingent on the specifics of the temporal and spatial moment.

Migration

Early studies of population movement addressed patterns of assimilation and acculturation through theories of culture-contact that failed to engage with political disparities and the contradictions of multiculturalism in modern societies. More recent approaches redressed these patterns as a postmodern condition that negotiates instantiations of nationalism, transnationalism, and displacement through the appropriation of expressive culture and the making of political alliances among transnational populations (Garofalo, 1992). However, the rigidities and essentialisms of diasporic identity created by multiculturalism may articulate or contradict the politics of national, postcolonial, and minority identities even as they stress emergent forms of culture, uneven relations of cultural hybridity, and ambivalent relations to national homelands (Ramnarine, 2007). Contemporary diaspora studies thus emphasize the “newness” of the diasporic experience, and address political belongings and further substitutions as historically specific and shaped by a historical consciousness. Fragments of this consciousness are inscribed within an in-between space by which immigrants may register a sense of loss, exile, and rupture through cultural production. Diasporic music making may thus be a practice of everyday life in local communities by individuals making strategic choices through music festivals, individual biographies, song texts, musical instruments, and intellectual movements. Politically articulated readings of these social relations and creative processes reveal economies of desire in colonial encounters, performances that mourn and remember ancestors, intercultural borrowings in African-Peruvian theater, or state interventions in the creation of broader diasporic groups (Ramnarine, 2007).

Studies of popular culture and music have helped to differentiate between experiences of voluntary and forced migration. The actions and behavior of refugees affect how groups produce and give meaning to their music as they negotiate loss and trauma, and pursue a state of stability that is represented by resettlement. For instance, Vietnamese refugee communities in the United States tend to display a preference for love songs and Western-oriented popular music that convey anticommunist nostalgia for a pre-1975 period of French, U.S., and Japanese colonial influence in Vietnam (Reyes, 1999). Other histories of dispossession and violence have prompted ethnographers to consider the social construction of place, self, and other through aesthetic experience as a means for understanding the performative capacities of particular histories and repertoires of violence and “the ensuing meanings violent performances carry for victims, perpetrators, and witnesses alike” (McDonald, 2009, p. 59).

Future Directions

Medical Ethnomusicology

Medical ethnomusicology seeks to integrate disciplines of music; health sciences; integrative, complementary and alternative medicine (ICAM); the physical and social sciences; medical humanities; and the healing arts through integrative research and applied practice. Research in music, medicine, and culture recognizes the dynamic and diverse practices by which specialized music and sound phenomena function as therapeutic strategies and as a means to cure illness and disease. Ethnomusicological discourse has demonstrated the extent to which specialized music emerges from a spiritual or religious ontology and is practiced in ritual or ceremonial events. When music combines with or functions as prayer or meditation, it may constitute preventive and/or curative practices that can be situated among a set of local medical practices. Medical ethnomusicology focuses on the performance of healing and the culture of health in order to better understand disease and illness, health and healing, as well as the performative nature of diagnosis, treatment, and healing. Recent studies and interventions include locating sites of ritual healing in *ngoma* practice among disparate communities; correlating beliefs about spirit possession to the intricacies of indigenous health care systems in Tumbuka communities; advocating and critiquing how the decline of HIV infection rates in Uganda correspond to the use of local musical traditions that support medical initiatives; engaging with science and religion through a focus on music, prayer, meditation, and healing; and the ways that these processes intimately link with transformational cognitive states in Tajikistan (Koen, 2008).

Applied Ethnomusicology

Applied ethnomusicology refers to work in the public sector that encourages the advocacy, curation, documentation, education, and performance of music and dance. These efforts apply the perspectives, principles, theories, and methods of ethnomusicology to encourage public awareness and participation in broadly defined fields of cultural practice. Advocacy engages with public-policy issues, such as arts access and participation, artists' rights, censorship, intellectual property, and cultural heritage through institutional and noninstitutional efforts. The Society for Ethnomusicology debates and assumes positions on the ethics of music and fair use, music and torture, and the rights of human subjects in scholarly research. Cultural initiatives facilitate opportunities for performers and performance practices through festival and concert organization, recording and documentary film production, and museum exhibitions.

Efforts to document and archive materials are encouraged through the acquisition and digitalization of archives, collaboration between institutions, improved access, and the support of scholarship, publications, and public programs. Public education and outreach develop curriculum at the

primary and secondary levels; establish performance ensembles and programs to nurture skills; and foster audiences and public awareness through the promotion and distribution of related events, productions, and publications. Performance of music and dance by specialists is encouraged not only as a research method in observing participants, but also as a means to preserve, transmit, and produce communities based on knowledge production and creative expression.

CONFLICT AND AGGRESSION

CRIS CAMPBELL

University of Colorado at Boulder

Humans, it often seems, are creatures of conflict. Without doubt, the annals of history bear stark witness to the reality of human aggression. By most measures, human conflict and aggression have directly or indirectly resulted in hundreds of millions of deaths over time. If mute statistics had explanatory power, then the inevitable conclusion would be that humans are by their natures irredeemably aggressive. This aggression, in turn, is at the heart of perpetual conflict. Certainly, this view has long been dominant in the West, where the biblical story of human corruption in the Garden of Eden has been a powerful and enduring influence.

Anthropology's particular approach to the related topics of conflict and aggression is biological and cultural, or *biocultural*. Humans are, first and foremost, animals that have evolved over many millions of years. This evolutionary history has present consequences, not the least of which is that humans are in many ways determined and constrained by their biology. But that is not all. As humans evolved, they developed tools, technologies, language, and knowledge which, taken together, are called *culture*. These processes were not, of course, separate. Physical change led to cultural change and cultural change promoted physical change. This synthetic process of coevolution has produced the most cultural and potentially aggressive of all animals.

Background

During the millennia dominated by Christian and scholastic thought, no one contemplated prehistory. Indeed, there was no such thing because it was believed that everything began with Genesis. Human nature was a settled issue. Over time, however, an increasing awareness of antiquity caused some to question the received biblical account. These thinkers began wondering about human life and society before the appearance of the first civilizations in Mesopotamia, Egypt, and Greece. One such person was Thomas Hobbes, and another was Jean-Jacques Rousseau. Between them, Hobbes and Rousseau established two sharply conflicting—and long-persisting—views of what human life had been like in the prehistoric past. Contained within each view is an assessment of essential human nature.

In 1651, Hobbes published *Leviathan*, a foundational work of political philosophy in which he argued that strong and centralized governments are essential to human well-being. Hobbes's entire argument hinged on his belief that humans are aggressive and forever in conflict. Projecting this belief back in time, he envisioned a dark and misty prehistoric past in which humans were perpetually at war. Hobbes called this imaginary time and place the "state of nature." For Hobbes, life in a state of nature was bleak, brutal, and brief. Humans without

government were in constant conflict. The operative assumption for Hobbes is that humans are by nature aggressive, and in the absence of governing authorities, will engage in conflict.

In 1762, Rousseau published *The Social Contract*, another foundational work of political philosophy. While advocating for certain forms of government, Rousseau outlined his own vision of humans in a prehistoric state of nature. As Rousseau imagines things, resources are plentiful and humans peaceful. It is society itself—a movement away from a state of nature—that corrupts and causes conflict. From this, later writers conjured the idea of the “noble savage,” people who lived harmoniously in a time before society and government. For Rousseau, humans are not by nature aggressive and are drawn into conflict only by dysfunctional societies.

Although these competing visions were purely speculative, they proved exceptionally influential and remain so today. Most modern forms of government are founded, in theory if not in practice, on an allegiance to one of these two visions. Rousseau’s ideas continue to inspire all manner of utopian idealists, while Hobbes’s thinking continues to legitimate all forms of centralized authority. This continuing influence is remarkable, considering that neither Hobbes nor Rousseau knew anything about the prehistoric past or peoples. It was not until science began its slow assault on the unfettered imagination that others began to question these two visions of the past.

Evolutionary Foundations

In 1859, the publication of Charles Darwin’s *On the Origin of Species* forever changed the way humans viewed themselves. Besides discrediting the notion of a special creation, Darwin also undermined purely speculative assessments of human nature. Although the *Origin* and Darwin’s later work, *The Descent of Man* (1871), firmly placed humans in the animal kingdom, this placement was not without its own set of ideas about the humans living in a state of nature. Darwin came of age in a time of great intellectual ferment, and the classical economic works of Adam Smith and David Ricardo shaped many of the debates. Unsurprisingly, the topics of competition and conflict were prominently featured.

Despite being couched in the language of economy and markets, Victorian ideas about nature ultimately remained rooted in Hobbes, whose bleak assessment of prehistory was based on his belief that all resources were scarce in a state of nature. In the absence of governments, this scarcity results in “war of all against all.” Thomas Malthus, an English demographer and political economist, shared Hobbes’s assumption that prehistoric societies suffered from scarcity. Consequently, population sizes were limited.

Over time, advances in technology increased production of foodstuffs, which in turn caused population growth. This growth created additional subsistence demands, in effect creating a positive-feedback loop involving improved technology, increased population, and intensified production. It was this process that caused Adam Smith to theorize that competition was the driver of all progress.

Darwin was familiar with these ideas and it was upon reading Malthus that the theory of evolution through the process of natural selection crystallized in his mind. All organisms are driven to reproduce, and this imperative causes a constant increase in numbers. Because resources are limited, competition ensues. Only the most fit survive and reproduce. This competition and struggle occurs not only within species, but also across species. Those traits that enable an organism to survive are favored and passed along through reproduction. Natural selection described a harsh nature “red in tooth and claw.” Although Darwin might have found a certain grandeur in this view of life, others were less sanguine. On close examination, the “new” Darwinian perspective did not really seem all that different from older biblical or Hobbesian ones—humans were condemned to a life of struggle, filled with both conflict and aggression.

Early Anthropological Views

After centuries of speculation about prehistoric humanity, Darwin finally had provided a theoretical framework within which this issue could be considered scientifically. In the decades following publication of the *Origin*, anthropology was founded as a discipline. In Britain, Edward Tylor applied evolutionary principles to culture and began assessing archaeological evidence of the past. In America, Lewis Henry Morgan studied native cultures and became a pioneer in ethnographic methods. Not surprisingly, neither Tylor nor Morgan was able to shake free of past prejudices, including those holding that prehistoric humans lived in near perpetual conflict. Both used words like *primitive*, *savage*, and *barbaric* to describe such early humans. The aggressive connotations were unmistakable.

During the first half of the 20th century, anthropologists largely busied themselves traveling the globe in search of little-known or unknown societies. The societies they studied were variously characterized as native, primitive, indigenous, and almost without fail *warlike*. That early 20th-century ethnographers should find aggression and conflict in the peoples they studied is hardly surprising. These anthropologists, after all, came from state-level societies in which aggression was considered natural and conflict inevitable. These anthropologists may have been looking in a refracted mirror, with the horrors of two world wars serving as background. Though with some notable exceptions

(such as Margaret Mead's pacific account of Samoan society), early ethnographies emphasized the aggressive natures of traditional peoples and highlighted their conflicts.

On the human evolutionary front, things were not much different. Although enigmatic Neanderthal fossils had been turning up in Europe since the late 1800s, no one at that time understood how they related to human evolution. In 1924, Raymond Dart's description of the Taung child (*Australopithecus africanus*) was the first of many hominid fossil finds in Africa. As these fossils accumulated, a basic understanding of human evolution began to emerge. With the exposure of "Piltdown Man" as a forgery or hoax in 1953, anthropologists began to accept the fact that australopithecines were ancestral to *Homo*. Dart, who had earlier come to this view, had by this time developed his own detailed and speculative vision of australopithecine life.

Dart initially had hypothesized that australopithecines were savanna scavengers; however, his subsequent examination of all the fossils associated with australopithecines caused him to conclude they must have been hunters. But these were not ordinary hunters—they were bloodthirsty killers. Dart noted that not only were many of the australopithecine skulls dented and crushed, but also that surrounding fossil bones were broken and damaged. For him, these were certain signs of hunting and butchery. Australopithecines thus became, at least in Dart's mind, vicious predators who used bones as weapons and tools. He even coined a name for this behavior and activity, calling it *osteodontokeratic* culture. It apparently never crossed Dart's mind, as it did later examiners of the same fossils, that the bones had been gathered and processed by two of Africa's most common predators—leopards and hyenas.

Although Dart's hypothesis failed to make headway in the scientific community, it captured the imagination of Robert Ardrey, a popular playwright and unlikely figure in the history of anthropology. After spending some time with Dart, Ardrey became a believer. Not only did he accept Dart's ideas; he also decided that the story needed to be told. Human ancestors as killer apes certainly made for good copy, and was entirely in keeping with a long line of thinking regarding human nature and prehistory. In 1961, Ardrey published *African Genesis: A Personal Investigation Into the Animal Origins and Nature of Man*, a best-selling book that shaped both public and scientific opinions regarding human nature. Ardrey argued that human ancestors could be distinguished from other primates primarily by the increased amount of aggression that is required for predation and hunting, which he identified as the key characteristic and defining feature of hominids.

Dart and Ardrey's shared vision of human ancestors as killer apes corresponded well with a biblically rooted tradition that became secular with Hobbes and scientific with Darwin. This traditional view received further support from the influential papers and ideas emanating from the

1966 symposium titled *Man the Hunter*. The anthropologists and primatologists who attended were nearly unanimous in concluding that hunting—with its attendant aggressive impulses and territorial conflicts—was the key to prehumanity and prehistory. Because anthropologists had phylogenetically linked humans to other primates and considered humans to be apes, it was only natural to begin looking for clues to human behavior in other species, including nonprimates.

Coincident with the *Man the Hunter* conference in 1966, Konrad Lorenz published his famous book *On Aggression*. Although Lorenz was a zoologist and a founder of ethology (the study of animal behavior), his observations and conclusions substantially influenced scientists of all stripes, including anthropologists, primatologists, and psychologists. Over several decades, Lorenz had recorded animal behaviors across many species. He interpreted his observations through a distinctly evolutionary lens, one which construed animal behaviors as contributing to the twin imperatives of survival and reproduction. Of the several instinctive behaviors Lorenz identified, aggression was paramount. The more familiar form of aggression occurred across species, *interspecific*, and was nearly always associated with predation. Aggression within species, *intraspecific*, was less familiar but nearly always associated with access to essential evolutionary resources—food and mates. The latter was a particularly important source of aggression in males, who often had to fight for access to females. Animal territoriality implicated both types of aggression; space was taken and defended because it provided access to food (survival) and mates (reproduction).

Whether as a result of religious belief or philosophical dualism, humans have long been kept separate from animals. After Darwin, this separation became difficult to maintain, and as our knowledge of other species increased over time, the lines between human and animal became blurred, if not obliterated. As a result of Lorenz's pioneering work, human conflict and aggression could be viewed more dispassionately, and without the distorting cultural fog that afflicts the study of so many things human. With empirical observation at the forefront, behavior could now be assessed within a Darwinian framework relatively free from metaphysical, moral, or cultural biases.

Biological Aggression

Aggression is a biological behavior exhibited, in several forms and with differing degrees of intensity, by all animal species. Any animal entirely lacking the ability to become aggressive would neither survive nor reproduce. In a broad study of aggression across animal taxa, Moyer (1976) has identified seven types of aggression: (1) predatory, (2) intermale, (3) fear-induced, (4) irritable, (5) territorial, (6) maternal, and (7) instrumental. Although this typology is useful for identifying the circumstances under which

aggression often occurs, it should not be interpreted exclusively or categorically. Any given display of aggression, in other words, is a synthetic behavior that may combine several of these types into coordinated action. Predatory aggression is required for animals that prey on other animals. Intermale aggression is an essential aspect of competition for resources, including food, mates, and territory. Fear-induced aggression is required for defense against attack. Irritable aggression frequently is used to reinforce dominance and rank. Territorial aggression is displayed by both males and females and is directly linked to resource acquisition and defense. Maternal aggression is required for defense of offspring. Finally, instrumental aggression is goal oriented and forward looking—it has a future objective. Although several species display instrumental aggression, it is especially well developed in primates.

Great Ape Aggression

Because culture plays such a prominent role in human conflict and aggression, it can be difficult to ascertain the extent to which biological factors account for these behaviors. The confounding effects of human culture can, however, be controlled to a limited extent by examining conflict and aggression in nonhuman primates, and especially among the “great apes” who are most closely related to humans. Although the analogies are imperfect, the aggressive behaviors of our nearest phylogenetic relatives can provide important insights into the core of human conflict. Over the last few decades, primatological field studies have greatly increased our understanding of great ape behavior. A general conclusion arising from such research is that conflict and aggression among nonhuman primates is highly variable between species and heavily dependent on ecologies. Because human behavioral plasticity exceeds that of any other primate, it is reasonable to infer that intraspecific conflict and aggression is, for *Homo sapiens*, similarly variable and dependent.

Chimpanzees

(*Pan troglodytes* and *Pan paniscus*)

Of all the great apes, chimpanzees and humans are most closely related and last shared a common ancestor approximately 5 million years ago. Because chimpanzees are our nearest evolutionary relatives, scientific interest in their behavior has been intense, and chimpanzees have been intensively studied in both captive and natural environments. Although early studies of “common” chimpanzees (*Pan troglodytes*) failed to reveal exceptionally violent behavior, more recent research shows that chimpanzees are quite aggressive toward one another and engage in behaviors that, at least among humans, would be labeled “warlike.” Given their closeness to humans, violence among chimpanzees surprised no one, and it was commonly accepted that these two species were genetically

and behaviorally alike. In recent years, however, primatologists have discovered that another species of chimpanzee, the bonobo (*Pan paniscus*), has remarkably different behavioral patterns, and that these differences are most pronounced in terms of conflict and aggression. Unlike common chimpanzees, bonobos are rarely aggressive toward one another and mortal conflict between them has yet to be observed.

Pan troglodytes, or common chimpanzees, are scrupulously territorial animals that live in male-dominated troops. As females reach maturity, they transfer from their natal group into neighboring ones. Males, who typically remain in the same troop their entire lives, continuously form coalitions as they strive for alpha status. This coveted status confers upon males various evolutionary benefits, including access to prime feeding grounds and females. High rank, however, is often tenuous and temporary. Males jockeying for dominance continuously form new coalitions, and dominance hierarchies are fluid. The formation and dissolution of these coalitions is the focus of Frans de Waal’s (2000) book *Chimpanzee Politics: Power and Sex Among Apes*. Despite the nearly constant tension between them, males within a single troop readily set aside their differences to defend—and even extend—their troop’s territory. With surprising regularity, males form “raiding” parties to patrol territorial boundaries. During such patrols, males will sometimes cross boundaries to attack and kill chimpanzees from neighboring troops. This aggressive behavior has drawn inevitable comparisons with humans, and it is the subject of Richard Wrangham and Dale Peterson’s (1996) book, *Demonic Males: Apes and the Origins of Human Violence*. Regardless of how one characterizes these behaviors, it is difficult not to conclude that chimpanzee and human aggression are similar in kind and intensity.

Not all chimpanzees, however, act in such distressingly familiar ways. Conflict between bonobos (*Pan paniscus*) is relatively rare, and aggression limited. Unlike common chimpanzees, bonobos live in a society that is female dominated, and newly mature males transfer to neighboring troops. Dominance is established by relatively stable matrilineal lines. Males do not form coalitions for purposes of rank. Instead, males attempt to ingratiate themselves with high-status females. Male competition is minimal due to the fact that sex among bonobos is constant, open, and prolific. Bonobos routinely greet one another sexually, and use sex to defuse tension and maintain cohesion. Sex is not limited to male-female copulation (though this is certainly common), but also includes frequent female-female genital stimulation. When neighboring bonobo troops meet at territorial borders, there may be unease but there is little to no fighting. Indeed, the groups will occasionally and temporarily mix. Though conflict certainly exists among bonobos, it is modulated and rarely results in physical confrontations.

Although much research remains to be done regarding the extraordinary behavioral differences between common chimpanzees and bonobos, two factors appear to account

for them: resource availability and mating opportunities. Common chimpanzees live in a much broader range of habitats than bonobos, and many of these ranges are limited or seasonal in resources. Bonobos, for their part, are geographically isolated and live in a small range of rainforest that is rich and regular in food resources. These differences in resource availability seem to be driving two remarkably divergent types of behavior. When resources are limited, conflict inevitably ensues. When resources are abundant, conflict is minimal. Resource availability thus sets the stage for differences in mating behaviors that impact the evolutionary imperative of reproduction.

Because territory is critically important in resource-constrained settings, male common chimpanzees advance their interests by forming strong coalitions that are able to defend and extend home ranges. This, in turn, provides males with access to females and their young, who are dependent on an adequate resource base for survival. But when resources are abundant, the dynamic is considerably altered. With adequate resources, the importance of territories—and males—diminishes. Females become free to pursue their evolutionary interests, which do not generally include high levels of conflict and aggression. Under the relatively rare circumstance of resource abundance, males become essential only for sexual reproduction. The result, as we see with bonobos, is a female-dominated, tranquil society characterized by frequent and open sexual behavior.

Gorillas (*Gorilla*) and Orangutans (*Pongo*)

After chimpanzees, gorillas are the nearest evolutionary relatives to humans, having separated from the hominid lineage around 8 million years ago. Unlike humans, but like our ancestors the australopithecines, gorillas exhibit a high degree of sexual dimorphism, a trait associated with dominance by a single alpha male and haremlike social structures. Gorilla troops typically number between 5 and 30 members. A single dominant male, known as a silverback, leads the troop and is the only reproductive male. Conflict within the troop is rare, and aggression is kept to a minimum by the silverback. Many field researchers have been struck by the apparent peacefulness of gorillas. As young males within a troop near maturity, the dominant silverback will force them to leave. After dispersing, young males roam alone or in small groups for a period of 2 to 5 years. When they have reached full size and maturity, these males begin seeking troops of their own. The primary source of conflict among gorillas occurs when silverbacks challenge one another for troop supremacy. Although the rewards are great, in terms of reproductive opportunities, the risks are significant for participants and others. Aside from the grievous injuries males may inflict on one another during such contests, victorious challengers may promptly kill any infants sired by the deposed silverback. Such killings cause mature females to resume estrus, and allow

the new male to begin propagating his own genetic lineage in relatively short order.

Of all the great apes, orangutans—who last shared a common ancestor with humans approximately 14 million years ago—are the least social, a fact probably linked to habitat and feeding ecology. Though orangutans live in verdant rainforests on the islands of Borneo and Sumatra, food resources are often scarce. Orangutans are dietary specialists largely dependent on ripe fruits. Because such fruits are both sparse and seasonal, orangutan density is limited and sociality constrained. This fact alone may account for reduced conflict between them. Female orangutans and immature males do not establish territories, and they usually avoid one another as they forage across the territories of mature males. Mature males, for their part, are highly aggressive toward one another, and their territorial conflicts can be intense, even if infrequent. In a remarkable display of phenotypic plasticity, reproductively mature males who lack territories do not develop the large fatty deposits, or *flanges*, and long hair characteristic of territorial males. Because flanged males apparently fail to perceive nonflanged males as competitors, territorial males generally ignore them. This, in turn, allows ostensibly non-mature males to avoid conflict and roam across territorial boundaries in search of food and females. When non-flanged males encounter females, they are known to force copulation. This aggressive behavior finds its parallel in human rape. By nearly all accounts, female orangutans prefer copulation with flanged, territorial males who mate by invitation rather than force.

Although this brief survey of aggressive behavior and conflict among the great apes cannot possibly capture the full and subtle array of such behaviors, it provides basic insights into the wellsprings of that behavior. Evolutionary fitness ultimately is determined by differential survival and reproduction. Successful organisms are those that survive long enough to reproduce. Dominance and rank usually determine which individuals have access to the resources necessary for survival and the mates required for reproduction. Given these biological facts, it should come as no surprise that animals—humans prominently included—aggressively pursue these goals, and conflict is often the result.

Group Aggression

Like other animals, all humans are born with the behavioral capacity to be aggressive. This capacity, however, varies considerably depending on contexts and cultures. There also is variation in aggressive propensities between individuals. Certain people are more aggressive than others, and these differences may provide those individuals with a fitness advantage in some situations. In social settings, however, excess aggression can be costly, in terms of both energy and reciprocity. As is true of all adaptations, costs are weighted against benefits. Among highly intelligent

social animals, this calculus is not as simple as it might seem. The biggest, strongest, and most aggressive—those most prone to conflict with others—do not always prevail. Studies of chimpanzees and baboons—both of whom live in troops similar in size to those of most known hunter-gatherer groups—consistently show that high rank is the balanced result of many factors, including inheritance, cooperation, intelligence, and aggression. Within-group aggression is limited—though never absent—by this combination of factors. Without-group aggression, however, implicates a different kind of calculus.

Out-group aggression can be either interspecific (across species) or intraspecific (within species), and sometimes both. Interspecific group aggression is frequently observed between species that occupy similar ecological niches, with the most prominent example being that of lions and hyenas. These sympatric and social species routinely attack one another in coordinated groups, and the results are often fatal. Because lions and hyenas directly compete for the same limited resources, conflict between them is nearly constant. Although postagricultural humans do not have many direct competitors, a few species have been perceived as such, with wolves being a primary example. Throughout history, humans have waged war on wolves, with the result being the near extinction of that species in many areas. Nonetheless, interspecific aggression involving humans and other species is relatively rare. The same cannot be said of intraspecific aggression involving humans. Human-on-human aggression is most intense and prevalent when it involves opposing groups.

On a general level, group living is a behavioral adaptation that confers significant benefits on social species. Among these benefits are cooperative foraging, predator avoidance, collective defense, offspring assistance, food sharing, and reproductive opportunities. Given these advantages, maintaining group cohesion becomes an important and perhaps even paramount goal. When groups splinter or individuals are expelled, the costs may be high. Smaller groups are less able to compete with larger ones, and social solitaires often do not survive. These costs intrinsically limit the amount of competition and conflict within a social group. Because group solidarity is critical to survival, cohesive behaviors have been favored by natural selection. Essential to these behaviors is the ability to distinguish group members from nongroup members and to treat them differentially. Primates, in particular, have well-developed abilities for recognizing outsiders. When survival depends on group solidarity, the differential treatment of in- and out-group members is adaptive. But when survival no longer depends on strict maintenance of boundaries between groups, such behaviors may become maladaptive.

Cultural Conflict and Aggression

Although it is difficult to reconstruct the precise social structures of early humans, it seems probable that

Homo erectus lived in groups similar in size and nature to those of common chimpanzees. Whether characterized as a troop or a band, this type of social unit persisted for nearly 2 million years and played a key role in human evolution. At some point, these groups would become recognizable to us as band-sized hunter-gatherers. Despite this more modern characterization, these foraging bands continued to resemble common chimpanzee troops in overall size and structure.

While many bands were affiliated with one another through kinship or marriage and occasionally aggregated into something like tribes, these units eventually enlarged into chiefdoms, cities, and states. In all cases, this process involved a movement to centralized authority and social stratification. To consolidate power and govern, ruling elites began controlling cultural institutions and generating cultural products. These institutions and products were both material (public works, temples, palaces, art) and immaterial (knowledge, religion, ideology, nationalism). Regardless of form, many of these cultural forces played directly into the strong evolutionary behaviors associated with in- and out-groups. The creation of separate and distinct identities—setting one group apart from another—has long been the occupation of elites, who manipulate these identities to channel aggression and direct conflict. In the setting of cities, states, and empires, our ancestral hostility toward group outsiders—or the “other”—has proven costly, and it is in most modern contexts maladaptive. This emphasis on groups, however, does not imply that individuals are unimportant or that they passively imbibe something called “culture.”

Individual Acculturation and Aggression

At its core, *culture* is learning passed from generation to generation through social behaviors. By this definition, humans are not alone in having culture—many species teach their offspring behaviors essential for survival and reproduction. Despite this fact, human culture is qualitatively and quantitatively different from that of all other species. It has been said, with good reason, that the primary evolutionary adaptation for humans is culture. Culture does not, however, operate on a blank slate. In the absence of some defect, humans are born with certain capacities and limitations. These capacities and limitations are biological in nature and are sometimes explained by anthropologists using the biogram concept. The biogram represents a human at birth—an individual who has not yet been imprinted with learning or culture of any kind. Immediately after birth, cultural patterning begins and continues for the remainder of one’s life. This biocultural model is depicted in Figure 79.1.

Starting with an infant, the heuristic in Figure 79.1 tracks different phases of development and acculturation. Each outer circle represents a layer of social learning imprinted on the individual biogram. These acculturating

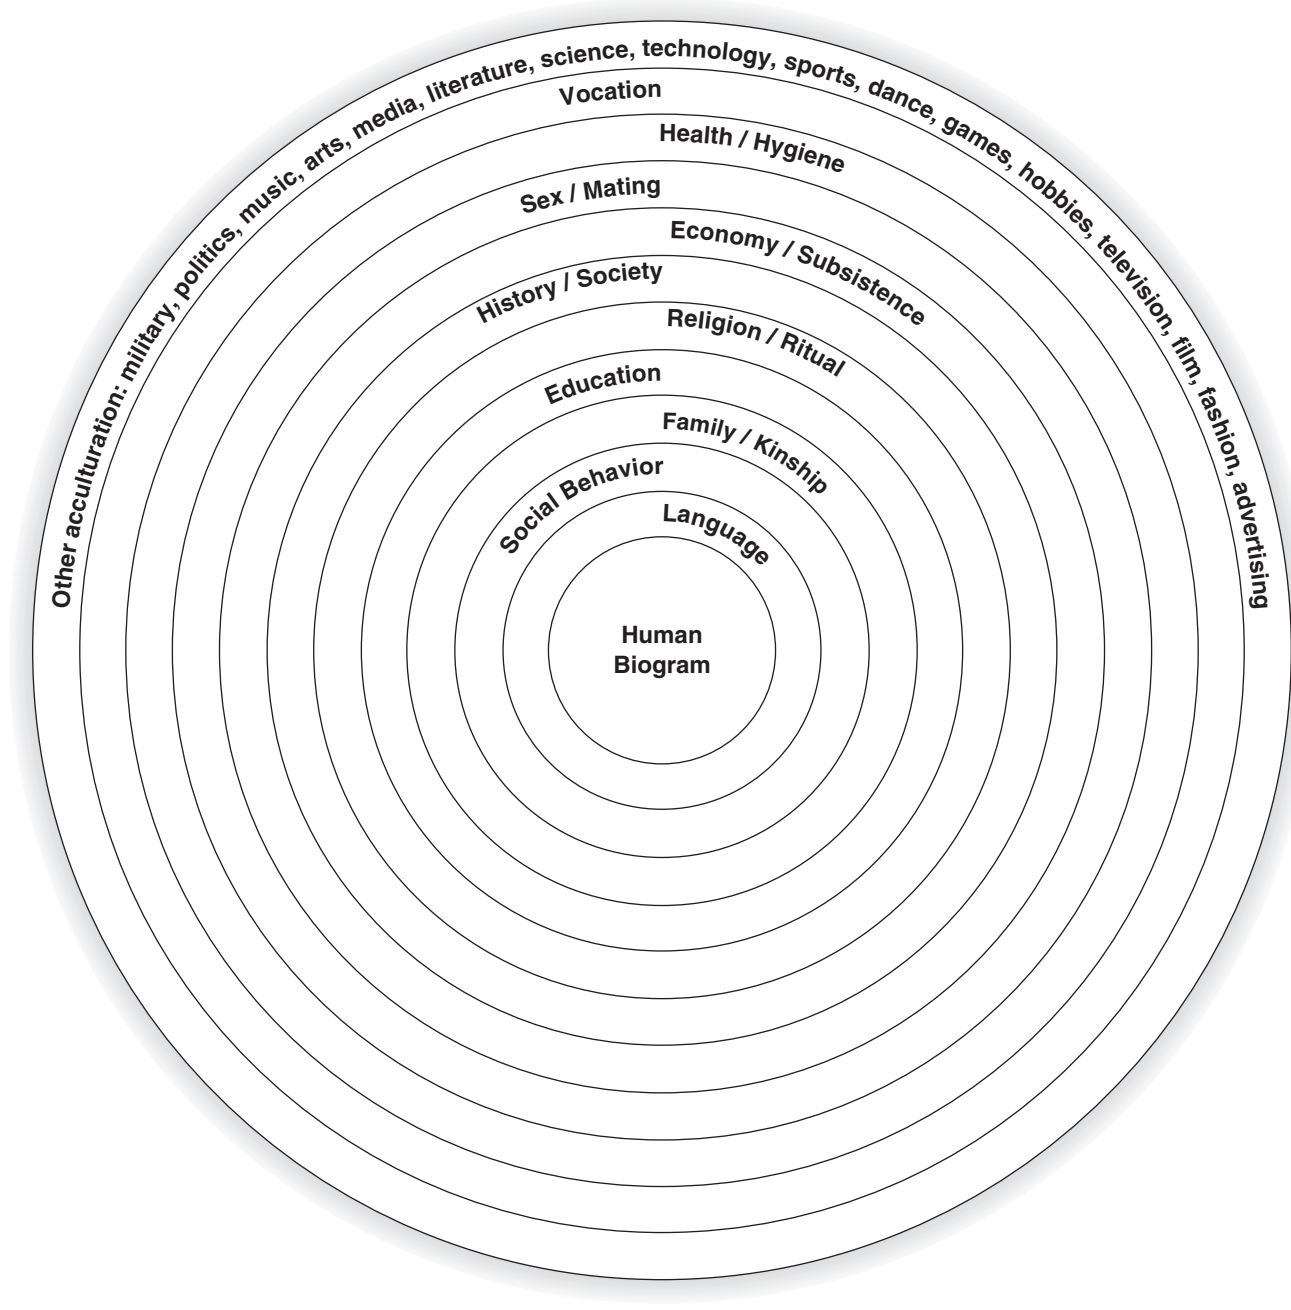

Figure 79.1 The Biocultural Model

SOURCE: Cris D. Campbell.

layers are not rigidly fixed, neatly separated, or always applicable. The innermost rings are, however, fairly consistent across space and time: The first things infants learn are socialization and language. From the moment of birth, a child is embedded in social and linguistic settings. By the time children are able to interact and speak in social settings, the patterning process is already far advanced.

This process is both formal and informal, active and passive. It occurs by instruction, example, observation, and interaction. In nearly all cultures, this formative period

also includes teaching and, in most societies, prominently features religion. A bit later, children begin absorbing cultural knowledge regarding society, history, vocation, and health. As children continue the long process of maturation, most receive additional instruction, with varying degrees of emphasis and intensity, in the following cultural topics: politics, economy, reproduction, sports, military, science, technology, literature, music, arts, dance, games, hobbies, and fashion. In developed countries, media play a key role in acculturation.

It is important to note that every individual participates differently and unevenly in culture and that the acculturating layers represented by this model are permeable, multi-directional, and variable. Layers can be added or deleted, depending on what is omitted, accepted, or rejected through the lifelong process of social learning. It is equally important to note that this process is never disinterested—someone or some group is always producing cultural knowledge and materials.

With these concepts in mind, it becomes easy to see that culture strongly patterns both aggression and conflict. Much of this patterning is a mere happenstance of birth at a particular time and in a particular place. Although these acculturating forces do not precisely determine how any given individual will act, they are powerful predictors of such action. When families, religions, societies, and governments take a keen interest in patterning individuals in a particular way, people usually think and act in accord with that acculturation. Through this process, essential evolutionary behaviors such as aggression and conflict can be either amplified or modulated. A good example of amplification is the militarist acculturation of children in ancient Sparta. A converse example of modulation is the pacifist acculturation of Semai children in Malaysia. In each case, interested adults and societies raise children in environments that place great emphasis on aggression (Sparta) or nonaggression (Semai), with fairly predictable results in terms of propensity for aggression and penchant for conflict. Most people are not, however, raised in cultural milieus so dedicated to these antipodal positions. For them, acculturating influences on aggression and conflict are less obvious, though no less influential.

Power, Population, and Resources

Though the drive for power is often obscured by the workings of culture, it is a fundamental, evolutionary impulse nearly always directed toward the acquisition of resources. In the late 1800s, Friedrich Nietzsche was the first to recognize this relationship and link power to evolutionary ideas regarding dominance. Nietzsche noted that all interactions between humans implicate power because, as social animals, we habitually order ourselves according to rank. This ordering creates hierarchies, and those on top have access to more resources than those on the bottom. As Michel Foucault later recognized, these relationships and imbalances do not involve only those of high and low rank—they envelop everyone in the social and cultural system. And as these systems become ever larger and more complex, power relationships become more subtle and pervasive.

This is a process that materialist thinkers have long understood, even if their analysis begins with economy rather than biology. For Karl Marx, all things cultural arise from and are tied to underlying material factors. Economic modes of production determine cultural forms, whether

political, religious, legal, or moral. Historical progressions are an important aspect of this understanding. By materialist reasoning, hunter-gatherers have a mode of economy that structures their cultural forms. Similarly, feudalism produces one type of culture, and capitalism another. Cultural forms may vary, but only within the constraints of economy. By making economy foundational to culture, materialists simply recognize that all economies are constrained by resources, and ultimately by populations.

For nearly 2 million years, humans foraged for a living. Because naturally occurring plants and animals are everywhere and always limited, population sizes remained relatively small. Hunter-gatherer groups that became too large eventually depleted their resources and were faced with a stark decision—leave or starve. As long as there were unoccupied territories with untapped resources, migration could occur without conflict. However, migration into already occupied areas most often came at the price of conflict. Groups living in those areas would not have welcomed outsiders and usually resisted incursions by groups not closely related by kinship. It is not surprising, therefore, that archaeologists have discovered evidence of conflict among most preagricultural societies, and that among historical hunter-gatherer groups, conflict was a fairly regular occurrence. In most instances, this conflict revolved around resources.

Approximately 12,000 years ago, humans began domesticating plants and animals. Other than evolution itself, no other event has so profoundly influenced human history and culture. The shift from food gathering to food production led to permanent settlements and population growth. When the process of domestication began around 10,000 BCE, there were perhaps no more than five million people worldwide. Ten thousand years later (1 CE) and as a direct result of agriculture, global population had increased to 300 million. This explosive growth had many consequences, not the least of which is that hunter-gatherers were pressed on all sides by expanding agricultural communities. In some cases, this expansion would have occurred through assimilation. In others, it would have been violent. Though foragers had a long history of fighting one another over fertile lands, the conflicts they now faced were different. With their ability to produce food surpluses, agricultural communities were populous and specialized. Some of these specialists devoted themselves solely to the arts of war. Foraging warriors were no match for agricultural armies. This inexorable accretion ultimately resulted in the formation of chiefdoms, cities, states, and empires.

Although this sequential description is overly simplified and there were important variations, it roughly describes the transition from band-size groups to empire-size states. In a mere 10,000 years, humans had gone from living in groups numbering not more than 150 to groups numbering in the hundreds of thousands and even millions. Marvin Harris (1977) describes this process as one of constant intensification; once it started, it could not be stopped.

Intensification has a logic and inertia of its own, and social groupings can only become larger and larger. Growing populations demand more resources. To meet these demands, production is improved and territories are expanded. Improvements in production and expansion of territories generate more resources, which are in turn consumed by growing populations. At this point, the cycle begins anew. Admittedly, this is a rather dry and mechanical description of postagricultural human history. It has the virtue, however, of identifying the resource-based cause of much conflict and aggression over the past 10,000 years.

None of this is to deny that aggression can be highly individualized, and that in isolated cases, those in power have pathological tendencies which may result in larger scale conflict. Only infrequently, however, do individual pathologies translate into war. When it comes to mass conflict, it is the people—those who produce and fight—who must be persuaded. Blatant appeals to conquest and spoils have not, except in rare cases (i.e., the Vikings and Mongols), proven effective in mobilizing entire populations for war. The material costs and mortal risks of conflict simply are too great. Knowing this, rulers and elites persuade and delude the masses with politics, ideology, religion, ethnicity, and nationalism. With depressing regularity, these identity-forging cultural forces have proven effective at tapping into ancestral and primatelike behaviors that favor, at all costs, one's own group over another. Maintaining group separation and solidarity is key to this persuasion. So long as others remain strange and outside the group, aggression toward them is encouraged and justified. It is only when others are familiar and inside the group that aggression is discouraged and prohibited.

Future Directions

Aggression is an essential animal behavior that has evolved through natural selection over millions of years. In evolutionary terms, success (or fitness) is a matter of survival and reproduction. An animal entirely lacking in the capacity for aggression would not long survive and almost certainly would not reproduce. Certain animals are naturally more aggressive than others, and these differences usually relate to feeding ecology. Predators are sensibly more aggressive than browsers. Like other primates, humans are born with the capacity for aggression. At a biological level, this capacity does not differ in degree, kind, or intensity from that of other primates. Any primate—including humans—can become aggressive under various conditions or circumstances. Limited resources of all kinds (food, water, territory, mates) guarantee competition, and where there is competition, there will be aggression.

Where humans differ from other primates, and indeed from all other species, is in their capacity for extreme aggression and continuous conflict. Humans also differ from other primates and species in the extreme development

of their cultural adaptations. It is this variable—culture—that accounts for hypertrophied human aggression and conflict. Culture can operate either to dampen aggressive impulses or to amplify them. For the better part of human history, culture has unfortunately been used to amplify those impulses, primarily through the promotion of distinct identities and separate groups. When culture co-opts naturally adaptive behaviors such as aggression, the results can be disastrous. Culture has the capacity to detach aggression from the pursuit of food, protection of offspring, and defense of territory. It also has the capacity to engender and redirect aggression toward others, with an intensity and scale unique in the animal kingdom. No other species cultivates aggression and encourages conflict with the same dedication or intensity as humans.

Because the capacity for aggression is neither mysterious nor deviant, and because conflict can nearly always be explained in terms of power and resources, there is not much to be gained from additional studies explaining what is already known. Although the proximate causes of conflict—such as people involved, issues invoked, and reasons provided—will continuously change with the progression of time, the ultimate evolutionary causes remain the same. So long as these causes are obscured and distorted by acculturating forces—whether in the form of nationalism, religion, ethnicity, or ideology—prospects for change are minimal. As is true of any behavior or description of behavior, aggression and conflict have their opposites. To understand aggression and what provokes it, future research should be directed at converse behaviors such as cooperation. The same is true for conflict. Without a thorough understanding of the conditions and circumstances under which aggression is minimal and conflict absent, our understanding of these subjects will remain incomplete.

SOCIAL PROBLEMS

ROBERT M. WORLEY

Penn State Altoona

Social problems are relevant to all of us, and it is no coincidence that scholars from many different disciplines—including anthropology, sociology, psychology, and criminology—have systematically studied this area. Unlike natural scientists, social scientists often employ moral judgments during the course of their research. If, for example, an anthropologist wanted to study the effects of Hurricane Katrina, then he would face different obstacles than if a meteorologist were to study the same phenomenon. Most people would agree that it would be unethical for an anthropologist to passively sit by and take notes, rather than offer assistance to victims while conducting fieldwork in the aftermath of a devastating storm. A natural scientist, on the other hand, would probably not experience the moral dilemmas that would be faced by social scientists. Because anthropologists often are in the unique position of studying other human beings, the potential for bias is not surprising, and they may often face difficulties in remaining neutral and objective during the course of a particular study (Newman, 1999).

Because there is no broad consensus as to which type of social problems are the most worthy of our attention, social scientists may show their biases merely by the topics that they choose to study (Mooney, Knox, & Schacht, 2009). By choosing which issues are the most worthy of investigation, anthropologists are employing their own personal discretion. This makes the systematic study of social problems somewhat subjective. For example, one researcher may identify

racism as the most important social problem plaguing society, whereas another researcher may avoid this issue altogether. Because anthropologists are humans studying other human beings, anthropology will never be as scientific as disciplines in the natural sciences. Nevertheless, in spite of this caveat, anthropologists can add much to the discussion of social problems. They employ a unique set of methodologies, such as ethnography, which provide valuable insights into various problems (Newman, 1999; Malinowski, 1941). Additionally, an anthropological perspective is important to our understanding of social problems because it examines factors, such as culture and power dynamics (Bodley, 2008). As it will later be shown, powerful institutions, including the media, have largely shaped and defined society's conception of what is and is not a social problem.

Problems of Natural Disasters and Erosion of the Earth

There is no question that the 21st century has seen its share of natural disasters, especially when one considers that we have not been in this new millennium for even a decade. Perhaps, at least for Americans, the most recognizable instance of a recent natural disaster occurred in 2005 when Hurricane Katrina devastated the city of New Orleans. Hurricane Katrina is considered to be one of the deadliest and costliest natural disasters in American history. It may

have been responsible for taking the lives of as many as 1,836 people and causing upwards of \$81.2 billion worth of damage (Mooney et al., 2009). Hurricane Katrina shall be referred to periodically throughout this chapter because it represents numerous types of social problems in addition to being a problem associated with the environment. For example, Hurricane Katrina illustrates problems related to inequality, racism, and sexism. African Americans, Latinos, women, and children tended to be disproportionately affected by this natural disaster and were the most likely to be among the dead in the aftermath of the storm (Kornblum & Julian, 2009).

According to anthropologists, ethnocentrism is when an individual believes that her culture is superior to other cultures (Malinowski, 1941). When discussing these and other social problems, social scientists strive to adopt a global perspective, rather than to engage in ethnocentric thinking. It is particularly important, then, not to focus solely on natural disasters that have occurred in the United States. In addition to Hurricane Katrina, there have been other natural disasters that have occurred throughout other parts of the world during the 21st century. While there is no question that Hurricane Katrina may be one of the most frequently cited natural disasters, it pales in comparison with the destruction caused by the Asian tsunami of 2004. It is likely that this disaster claimed the lives of more than 150,000 people (Mooney et al., 2009). As in the case of Hurricane Katrina, most of the victims of the Asian tsunami were poor. These individuals had substandard homes that could not withstand any type of resistance force, and most did not have insurance policies or savings accounts to help them get on their feet in the aftermath of the disaster. It is safe to speculate that the poor are usually more vulnerable to natural disasters than other members of society.

It is a cruel irony that while the poorest segments of society often suffer the worst from natural disasters, in many ways it is wealthy and privileged individuals who bear the most responsibility in destroying the earth. Corporate greed and consumption have led to global warming and climate change, which may contribute to an increase in natural disasters of a magnitude similar to that of Hurricane Katrina and the Asian tsunami in the future. Relative to its population, the United States emits the highest amount of carbons. For example, in 2005, less than 5% of the world's population lived in the United States, yet it still produced 21% of the world's carbon emissions from burning fossil fuels (Energy Information Administration, 2007). These gas pollutants from automobiles and factories produce a "greenhouse effect," which could have catastrophic consequences if this goes unchecked (Heiner, 2006). As the temperature increases, some areas of the world may experience heavier rains, and at the same time others may become drier (Bodley, 2008). A temperature increase of only a few degrees has the potential to drastically change life on this planet. In

addition to emitting the highest carbons, citizens in the United States also generate a disproportionate amount of solid waste relative to other countries. For example, according to Cheeseman (2007), more than 380 billion plastic shopping bags are used in the United States every year. These bags are particularly bad for the environment and may take up to 1,000 years to decompose. Countries such as Taiwan, Singapore, South Africa, and Bangladesh have restricted or outright banned these harmful products, yet the United States refuses to follow this example (Cheeseman, 2007). In addition to this, a recent study conducted by the Environmental Protection Agency (2009) found that Americans dispose of approximately 4.54 pounds of garbage every day. Also, citizens in the United States and other industrialized countries are likely to dispose of large amounts of electronic equipment. This phenomenon, which has been referred to as "e-waste," is very devastating to the environment (Mooney et al., 2009). When disposed of in a careless manner, electronic equipment has the potential to contaminate our water supply and soil.

Anthropologist Richard H. Robbins (1999) contends that capitalistic societies, such as the United States, are responsible for elevating human consumption levels which in turn leads to the depletion of natural resources and the destruction of the environment. He argues that our culture encourages laborers to accumulate wages, capitalists to accumulate profits, and consumers to hoard goods. Robbins also suggests that a handful of powerful elitists reap the benefits from being involved in a culture dedicated to consumption. In fact, these individuals often are responsible for using the media to create consumerism in order to advance their own interests. It is a well-known fact that capitalists in the United States rely heavily on advertising in order to sell commodities. Even when a commodity is frivolous, clever advertising often has the ability to present the product as a necessity and make consumers feel compelled to rush out to the stores. This has devastating consequences for the environment and often results in pollution, resource depletion, and waste.

Generally speaking, capitalists and corporations have been highly resistant to the idea of allowing the government to regulate businesses in order to preserve the environment. In fact, beginning in the late 1970s, U.S. businesses began spending billions of dollars a year to convince the American public that there was too much environmental regulation (Beder, 1997). This intense lobbying proved to be very effective because many environmental regulations that were passed in the seventies were either repealed or simply unenforced during the 1980s (Bodley, 2008). The fact that corporations have been so resistant to environmental regulation illustrates how a small number of powerful people are benefiting from the destruction and pillaging of the earth's resources. The forces of capitalism not only have depleted valuable natural resources but also have produced a highly stratified and nonequalitarian social system. Social problems related to poverty and

inequality are of considerable concern to anthropologists and shall be discussed in the following section.

Problems of Poverty, Inequality, and Racism

In addition to exemplifying a recent and horrific natural disaster, Hurricane Katrina also represents social problems related to poverty and inequality. It is very plausible, for example, that before the storm hit New Orleans, wealthy residents and visitors were given priority over poorer residents and bused out first. In fact, one account suggests that 700 guests and employees of a Hyatt Hotel were given the first opportunity to leave, while lower-class individuals were relegated to the end of the evacuation line (Dowd, 2005). It is true that low-income African Americans were the most likely to remain in the city during Hurricane Katrina (Dyson, 2006; Elliot & Pais, 2006). It also may come as no surprise that during the Asian tsunami of 2004, foreign tourists also received substantially more aid during the storm than the thousands of impoverished villagers who were more or less left to fend for themselves (Mooney et al., 2009).

Almost without exception, whenever a natural disaster strikes, those who are poor or are considered to be on the fringes of society tend to be victimized the most. It may be no coincidence that in the aftermath of Hurricane Katrina, women, children, and racial minorities were very likely to be among the dead that were found scattered throughout the streets of New Orleans. Dyson (2006) argues these groups were unable to evacuate the city prior to the storm due to financial constraints. Many low-income New Orleanians may have simply not had access to reliable transportation. Even if some of these individuals were fortunate enough to have personal vehicles, evacuating may have been seen as a considerable expense. Some residents may have opted instead to take their chances, only to realize later that they had made a monumental mistake.

While racial minorities were disproportionately the victims of Hurricane Katrina, the media also victimized them throughout this natural disaster (Brezina & Kaufman, 2008). During the storm, for example, there were media reports that grossly exaggerated the levels of violence among New Orleanians. According to Brezina (2008), many of these stories stereotyped the urban poor as prone to violence and extreme forms of criminal behavior. Other scholars suggest that a few of the media depictions were outright racist. For example, Tierney and colleagues (2006) contend that the news media coverage following Hurricane Katrina portrayed New Orleans as a “snake pit of anarchy, a violent place where armed gangs of black men took advantage of the disaster not only to loot but also to commit capital crimes” (p. 68). Stories were also published with alleged incidents of child rape and mass murder among evacuees who were in the New Orleans Superdome.

It is astonishing that major news outlets published the bogus stories described here without any meaningful attempt to check for accuracy. It is even more disconcerting that most of the general public seemed willing to accept these stories without question. Perhaps for a few individuals, these horrific tales even confirmed a few privately held beliefs regarding the poor and people of color. Even in spite of overwhelming evidence to the contrary, some white Americans still regard racial minorities as being culturally or intellectually inferior to themselves. It does not help that the media often exacerbate these misperceptions by frequently publishing stories that depict racial minorities, particularly members of the African American community, in a negative light. One does not have to look very hard to find stories that portray African Americans as either welfare recipients or criminals.

Fortunately, many anthropologists have dedicated their careers to speaking out against racial stereotypes. One relatively recent example is illustrated in the work of the late Eugenia Shanklin. In perhaps her best-known work, *Anthropology and Race*, Shanklin (1993) advances the notion that race is socially constructed. She also argues against the notion that race is a valid scientific concept. In many respects, Shanklin’s argument builds upon the classic work of renowned anthropologist Franz Boas. Boas wrote extensively about race during the beginning of the 20th century, and he too concluded that this was a social, rather than a biological, concept (as cited in Williams, 1996). In retrospect, his writings against the evils of racism were quite ahead of their time. This is especially true when one considers that these were written during a period when social Darwinism and eugenics were at the height of their popularity (Williams, 1996).

In addition to writing about race, other scholars have also examined the processes by which members of racial minorities become disenfranchised. For example, in his classic article, “The Culture of Poverty,” anthropologist Oscar Lewis (1966) argues that for some people poverty is a way of life. Often this may be due largely to structural barriers, such as a lack of jobs and inadequate educational systems. Lewis contends that at an early age, children living in urban slums begin to subscribe to a set of values and beliefs that are conducive to poverty. It is not uncommon for many of these children to be racial minorities. Children who are assimilated into this culture have problems deferring gratification and avoid participating in society’s major institutions (Lewis, 1966). This culture is also characterized by a high concentration of single-parent households that are usually headed by females. Over time, children who are socialized in these environments begin to adopt self-defeating attitudes that can make them less competitive in the marketplace when they enter adulthood. Even today, more than 40 years since it was published, Lewis’s study still has relevance. African Americans and Hispanics are among the poorest people in the nation. In fact, year after year, the rates of poverty among these minority groups are 2 to 3 times higher than

the poverty found among Caucasians. Sadly, many of those who are impoverished in this country are children. For example, Conley (1999) writes that “over half of African American children under the age of 6 are living in poverty” (p. 10).

It can often be very challenging for individuals who are raised in poverty to overcome obstacles in order to obtain even the most menial types of employment. According to Princeton anthropologist Katherine S. Newman (1999), even minimum-wage jobs at fast-food restaurants are extremely competitive, and there are usually more applications than there are positions. She contends that often African Americans are excluded from these jobs, even if the restaurant is in a predominantly African American neighborhood. Individuals who are fortunate enough to obtain jobs as “burger flippers” must still compete with other employees for hours and often suffer incivilities from supervisors and customers. During the course of her research, Newman (1999) conducted countless interviews with low-income fast-food workers and observed them in their natural environment. She argues that many of America’s poor are working in dead-end jobs, such as the fast-food industry, with little hope of advancement.

While the United States certainly has problems of inequality and poverty, it is currently the richest and most powerful nation and does not suffer from the same level of poverty as many third-world and developing countries. As mentioned previously, it is important for anthropologists to adopt a global perspective when studying various problems. Regardless of where someone lives, we are all members of the human race, and therefore a problem experienced by one culture inevitably affects us all. Consider that throughout the world more than one fourth of the earth’s population (roughly 2.5 billion people) subsist on less than \$2 a day, and approximately 1 billion people (or 1 in 6 individuals) live on less than \$1 a day (World Bank, 2007). The planet has more than enough resources, yet millions of people throughout the world currently lack access to food, durable shelter, and clean drinking water.

Anthropologists such as Bodley (2008) argue that these are the consequences of living in the contemporary commercial world. Unlike small tribal societies that were prevalent thousands of years ago, the contemporary commercial world prevents some individuals from obtaining basic necessities. Today, levels of global inequality are at an all-time high. As power elites race toward accumulating capital, this has produced enormous wealth and power differentials. Bodley (2008) writes:

The daily lives and future prospects of virtually all of the world’s 6 billion people are shaped by the political and economic decisions made by a relative handful of people who command trillions of dollars in financial capital and overwhelmingly powerful armed forces. (p. 17)

Given this statement, it may come as no surprise that currently the wealthiest 10% of adults own 85% of the world’s

total wealth, while the poorest half of the adult global population holds slightly more than 1% of the world’s wealth (Davies, Sandstrom, Shorrocks, & Wolff, 2006).

Clearly inequality, poverty, and racism are problems not only in this country but also throughout the world. Bodley (2008) contends that many of these problems stem from global competition. In the name of competition, corporate executives in the United States hold back wages from their employees and deny benefits that are standard in other industrialized countries (Gray, 2000). There is no question that workers in European nations enjoy far more rights than workers in America. In Western European countries, for example, it is much more difficult to fire an employee, and it is virtually unheard of for companies to “downsize” merely to add to the overall profit margin. Also, workers in France enjoy a shorter workweek and more paid time off compared with their United States counterparts (Heiner, 2006).

While it seems as though European nations have the most humane system, there is at least some indication that a few of these countries are beginning to imitate the U.S. model in order to gain a competitive edge (Heiner, 2006). Currently, the United States is considered to be the most capitalistic society in the world because it has the least amount of governmental regulations. This lack of regulations has resulted in gross disparities and outright discrimination (Bodley, 2008; Kornblum & Julian, 2009; Mooney et al., 2009). Global competition has also led to the exploitation of third-world countries. According to Heiner (2006), this has been going on for several hundred years. He contends that there is a long history of powerful nations establishing colonies throughout the third world in order to plunder and export valuable natural resources such as gold, silver, silks, and other items. Also, even though some corporations have recently relocated from the first world to the third world, Heiner (2006) suggests that poverty has actually been on the rise in underdeveloped countries since the arrival of these new companies. Standards of living have also been on the decline in the third world and are likely to continue (Mooney et al., 2009). It seems that extreme forms of capitalism exacerbate inequalities in poor countries just as they do in wealthy ones, such as the United States.

While it may seem obvious to many of us that unbridled economic pursuits have created enormous inequalities throughout the world, the media have done much to shape the way we think about capitalism. By and large, in the United States, capitalism is held as one of the highest virtues. This is in great part due to the media-constructed image of the “American Dream,” where anyone can achieve wealth and success with enough hard work (Messner & Rosenfeld, 2007). Even though extreme forms of capitalism have resulted in gross inequalities, Americans are socialized to believe that it is the best system. Ironically, this also applies to poor people. Newman (1999) suggests that even the poor tend to embrace the notion of the

American Dream, in the hope that they may one day achieve success and accumulate wealth.

The media, owned in the United States by the power elite, bears a large responsibility in generating the idea that anyone can be successful in a capitalistic society (Heiner, 2006). This has dire consequences. When individuals in the United States fail to move from rags to riches, they often blame themselves. In this country, perhaps more than anywhere else in the world, there is a tendency to blame the poor whenever they fail to be successful or provide for their families. It is no surprise that in this country, in order to be considered successful and good providers, many workers are spending more time at the office and less time with their families. While some individuals have been able to accumulate more possessions and increase their purchasing power by working longer hours, sadly this has come at a considerable expense to their families (Mooney et al., 2009). In fact, one of the greatest social problems facing Americans today involves problems related to the family. This deserves a considerable amount of attention and shall be discussed in depth in the following section.

Problems Related to the Family

In the United States and elsewhere throughout the world, there are many different varieties and types of families. The U.S. Census defines a family as a group of two or more people who are bonded by marriage, adoption, or blood. Mooney and colleagues (2009) contend that the above definition is somewhat restrictive because it does not take into account foster families and unmarried same-sex and opposite-sex couples. The official definition of a family also fails to consider those relationships that function and feel like a family. For example, college students living together and sharing expenses and household chores might be considered a family in the broadest sense of the word. As we begin to examine the various social problems that plague the family, it is necessary to understand that today's family knows virtually no bounds. In fact, the traditional conception of the family, with a father who is the breadwinner and a mother who stays at home with the children, is probably one of the least typical types of families in the United States.

According to Skolnick (1991), throughout history people have warned that the family was on the verge of becoming extinct. During political campaigns, social conservatives tend to be the most vocal about the decay of the traditional family unit. For instance, it is not uncommon for conservative candidates to attack liberals for their tolerance of gay marriage and single parenthood (Kornblum & Julian, 2009). It is also not unusual for some traditionalists to blame problems of the family on working mothers. Many social conservatives argue that in order to solve many of society's problems, families should return to the breadwinner-housewife model that was

popular in the United States during the 1950s (Heiner, 2006; Hewlett & West, 1998). Some scholars claim, however, that these are merely tactics to divert attention from the low levels of government funding given to families that are struggling financially.

Conservatives, who ardently favor independence and self-sufficiency, often fail to remember that their idealized conception of the 1950s family was possible only because of unprecedented amounts of governmental assistance, such as low-interest housing loans and educational subsidies (Hewlett & West, 1998). During the 1950s, the federal government spent billions of dollars on public transportation, sewage systems, parks, and other projects designed to help families (Hewlett & West, 1998; Kornblum & Julian, 2009). From past experience, it would seem that a similar use of public subsidies would be an effective way to help facilitate families in the new millennium. It is ironic, however, that many traditionalists tend to be against this idea. Of all the industrialized countries in the world, the United States has the fewest governmental policies and programs designed to support the family. Given this, perhaps it should come as no surprise that the United States also has one of the highest divorce rates and is willing to tolerate levels of child poverty that would be unconscionable in other countries. These are current issues that plague the family and will be discussed later in more detail.

In his classic ethnographic study of familial relations among natives of the Trobriand Islands, anthropologist Bronislaw Malinowski (1941) argues that even in the most primitive societies, there is an expectation that "every family must have a father," and "a woman must marry before she may have children" (p. 202). Currently, while it is true that premarital pregnancy in the United States is frowned upon, unmarried mothers are generally not as stigmatized as they have been in past history (Kornblum & Julian, 2009). In fact, today approximately one out of three children in the United States is born out of wedlock (Mooney et al., 2009). While this may seem high to some people, it is important to note that countries such as Norway, Sweden, Iceland, Denmark, the United Kingdom, and France have even higher rates of nonmarital births than the United States. In Iceland, as many as 2 out of 3 children are born out of wedlock, and in approximately half of the births in Norway and Sweden, the mother and father are not legally married (Money et al., 2009).

In addition to the above countries, there are also parts of West Africa where unmarried women may have children without being ostracized or punished. This is especially true if the mother is not considered to be promiscuous. According to Kornblum and Julian (2009), as long as the identity of the child's father is known, an unwed mother will experience very little, if any, stigmatization. While some social conservatives have expressed moral outrage at the rise in the rate of nonmarital births, many children both in this country and in other cultures throughout the world have been able to find love and acceptance in

family structures that may not be considered traditional by American standards. It is also important to mention that children who are raised in nontraditional families may be provided with a higher level of care and nurturing than those whose father is present but struggling with a problem such as substance abuse or unemployment (Kornblum & Julian, 2009).

The family is very important to our understanding of social problems because it is often identified as being either the solution to or the source of societal ills, such as alcoholism, crime, and poverty (Heiner, 2006). If children come from a “good” family, for example, then it is commonly believed that they will avoid engaging in deviant or pathological behavior. Most traditionalists assume that children who are adequately socialized will ultimately receive a good education, raise families of their own, pay taxes, and more or less be productive citizens. On the other hand, if a child is delinquent, turns to drugs, or has problems in school, the family is often singled out as being the source of the problem. Given the importance that we place on the family, it is no surprise that this has been an important research topic for many social scientists.

Recently, there have been numerous studies examining whether or not—and to what extent—financial problems plague the family. Most of the current literature indicates that a tough U.S. economy has led women to largely abandon the role of solely being a homemaker (Jacobs & Gerson, 2004). Today, approximately 71% of women with children under the age of 18 are employed outside the home (U.S. Department of Labor, Bureau of Labor Statistics, 2007). Also, ever since the 1970s, both men and women have consistently been working longer hours. In the United States, it is not unusual for many individuals to work more than 50 hours a week (Jacobs & Gerson, 2004). In fact, a recent study conducted by the Economic Policy Institute (as cited in Bernstein, Mishel, & Schmitt, 2000) found that, on average, married working couples with children spent 256 more hours at their jobs in 1997 than they did in 1989. This is roughly the equivalent of an extra month and a half of time spent at the office rather than at home.

Not surprisingly, family members today are more stressed out than ever before as they try to juggle domestic and work responsibilities. Sadly, children often have the most difficulty in adjusting to the pressures of living in a dual-income family. Occasionally, some may even become “latchkey children,” who are largely responsible for their own care, since both of their parents are working. If this is true in two-parent households, then it is especially the case for children who live in families with only one parent. In this country, 49% of non-Hispanic white single-mother households are due to divorce, in contrast to 62% of African American single-mother families, where the mother never married (Fields, 2004).

Currently, the United States has the highest rate of divorce among Western nations. According to Kimmel (2004), 40% of marriages in this country end in divorce.

The rate of divorce rate is even higher when one looks at couples who have already been married at least once. Also, children are involved in 60% of divorce cases. In other words, when a marriage dissolves, more often than not, children will be affected by this decision.

Divorce represents perhaps one of the most serious problems plaguing the family because it has the potential to result in many devastating consequences. First, divorce is likely to create significant economic hardships for mothers and their children. Many women, who might have been unpaid homemakers or part-time employees during their marriage, are not fully prepared to enter the workplace in the aftermath of a divorce (Amato, 2003). Usually, following a divorce, they must go back to school and at the same time find a way to increase their income. Often, this entails getting a job (or a second job), putting in more overtime, and finding other means to make money. At the same time, they often have to take on new financial responsibilities, such as balancing the family budget. On top of this, women are disproportionately likely to assume many (if not all) of the child-rearing duties following a divorce (Amato, 2003). To make matters worse, it is not uncommon for fathers to offer little or no economic support.

In addition to the adverse economic impact that it has on families, divorce also places children at a higher risk of developing psychological and emotional problems. Some children with divorced parents may become extremely sensitive or overly aggressive and develop serious self-esteem issues. If this behavior goes unchecked, it can lower a child’s performance in school and have serious long-term effects on his or her future. Amato and Cheadle (2005) contend that the repercussions of divorce are so powerful that even future children, who have not even been born, have the potential to be affected. For example, a divorce that occurs in the first generation of a family may be associated with lower education, more divorce, and greater familial tensions in the second generation, which then may in turn contribute to similar problems in the third generation. While there are some situations where divorce may be the only option, there is no question that it can result in many negative consequences for a family’s well-being.

Finally, there is some relatively new literature indicating that natural disasters can affect a family’s well-being. While these events can result in the loss of lives and financial ruin, it appears that events such as floods, hurricanes, and tornadoes can also impact families. In one recent study, for example, it was estimated that approximately 1 in 4 (22%) of New Orleanians indicated that they had experienced marital discord as a result of Hurricane Katrina (Kaiser Family Foundation, 2007). In this study, 10% of the subjects even admitted to throwing things at their partner, yelling, and losing control. Other studies have confirmed the above finding that natural disasters, such as Katrina, can lead to domestic violence and various other forms of familial abuse (Brezina & Kaufman, 2008; Enarson, 1999). While domestic violence clearly is an issue that is related to the

family, it is also one of many social problems that are related to crime. Problems related to crime shall be discussed in more detail in the following section.

Problems Related to Crime

Of all the various social problems, perhaps those related to crime tend to receive the most attention. According to Mooney and colleagues (2009), a crime is considered to be an act or omission of an act that is punishable by either federal, state, or local law. In other words, in order for there to be a crime, the state must be able to impose a punishment. Also, someone who commits a crime must be acting willfully and voluntarily. An action is also likely to be seen as a crime if there is no legitimate excuse as to why the actor engaged in a particular proscribed act (Mooney et al., 2009). Interestingly, in spite of clear-cut legal definitions of crime, the popular media have influenced our conception of crime and criminals. Television shows such as *CSI*, *COPS*, and *Law & Order*, for example, have provided distortions about the criminal justice system. The media, then, often take an active role in shaping and defining the types of acts that we as a society should consider to be crimes, as well as the types of people who are likely to be perceived as criminals.

In order to illustrate the above point, one only needs to tune in to an episode of *COPS*, a reality television show that enables viewers to follow police officers during the course of their 8-hour shifts. The viewer, from the comfort of home, sees life from the inside of a patrol car. One of the more controversial aspects of this program is that it features a distorted view of criminals. For example, usually, but not always, the perpetrator on the show is a minority male. The suspect is often intoxicated and portrayed as a burden to society. The officers, on the other hand, are seen as the heroes who quell the disturbance and dispense justice within the confines of the law. Almost always, the officers are depicted as being fair, calm, and highly professional. They are very seldom, if ever, shown to be aggressive, hostile, or downright abusive. While some television viewers may find crime shows such as *COPS* to be extremely entertaining, these programs nevertheless have the potential to be very misleading and can even generate negative stereotypes about racial minorities. As Heiner (2006) argues, much of the reality of crime is edited out of “reality-based” crime shows. In writing about these shows, he contends that they “depend upon the cooperation of the authorities, and their producers must keep in mind that if the police are not presented in a positive light, then they will not get their cooperation for future broadcasts” (Heiner, 2006, p. 115).

As a result of being exposed to a heavy regimen of cop and reality crime shows, some members of the public may be left with an impression that most racial minorities use drugs and are an overall menace to society (Heiner, 2006).

These shows rarely, if ever, portray offenses that are committed by law enforcement agents, though certainly these do exist. Also, they say very little about white-collar offenses, though these have the potential to be much more costly to society than traditional street crimes (Messner & Rosenfeld, 2007).

The images of crime that are perpetuated by the media also have a high likelihood to create a sense of fear and anxiety. Every year, Americans spend billions of dollars on safes and home-security devices. One can only wonder how many of these expenditures are related to the distorted images that are routinely shown on reality cop shows and the nightly news (Beirne & Messerschmidt, 2000). Many television programs are notorious for portraying criminals as disproportionately likely to be members of racial minorities who offend against Caucasians. Sadly, this does little to further race relations in this country.

Even though there is absolutely no evidence that members of racial minorities are more likely to be criminal by nature, African American and Hispanic males are disproportionately overrepresented at virtually every stage in the criminal justice system (Bureau of Justice Statistics, 2006; Steffensmeier & Demuth, 2000). This may be due in large part to an institutional bias against minorities. Police officers, for example, may engage in racial profiling where they target suspects solely based on their race. This practice amounts to little more than outright discrimination and may be just one example of the racial bias that is inherent in the criminal justice system. African American males are particularly likely to be the recipients of institutional racism. According to the Bureau of Justice Statistics (2006), it is estimated that 12% of all African American males in their late 20s are in some type of correctional facility compared with only 1.7% of white males in this same age range. African American males are also more than 8 times as likely as Caucasians to be sent to prison for drug offenses (Mooney et al., 2009). In fact, 1 out of every 8 African American males can be found serving time in some type of correctional facility on any given day (Kornblum & Julian, 2009). It would be naive to think that members of racial minorities are not discriminated against at every checkpoint on the criminal justice assembly line.

Perhaps one of the greatest problems plaguing the criminal justice system today is the current incarceration binge in the United States. As of this writing, the United States has one of the highest rates of incarceration in the world, with approximately 702 out of every 100,000 of its citizens incarcerated (International Centre for Prison Studies, 2005). Also, Americans are more likely to be incarcerated than individuals living in less democratic countries, such as Russia or South Africa. The United States, without question, has the highest incarceration rate of all other industrialized democracies. Yet many Americans tend to believe that we are “soft” on crime (Mooney et al., 2009). This is in spite of the fact that between 1975 and 2002, the prison population increased from 204,593 to 2,033,331 (Heiner,

2006). In other words, in slightly over 25 years, it increased almost tenfold.

The costs of America's obsession with punishment should be enough to scare any fiscal conservative, yet often these are the very individuals who are lobbying to build more prisons. Perhaps the most frightening fact of all is that this recent preoccupation with imprisonment has not corresponded with an increase in crime. In other words, even as the crime rate in the United States has decreased, the incarceration rate has nevertheless continued to increase (Kornblum & Julian, 2009). Again, it cannot be understated that the current incarceration binge is extremely expensive. Today, American taxpayers spend approximately \$60 billion a year to maintain the prison system. This is quite astounding when one considers that the cost was \$9 billion only two decades ago (News Highlights, 2007). Perhaps if the United States was not so preoccupied with punishment, this money could be utilized for education, health care, and public transportation. Society's response to crime has in and of itself become an enormous social problem and is currently depleting valuable tax dollars.

Conclusion

One does not need to look very far to see that there are numerous social problems currently plaguing the world. Though this chapter has discussed a variety of different types of problems, this in no way implies that the list is exhaustive. In addition to the social problems mentioned in this chapter, anthropologists also study problems related to health and the health care system, population and immigration, alcohol and drug use, gender and sexuality, mental illness, and terrorism. Unfortunately, there are a variety of problems that the world is currently facing. It would be beyond the scope of this chapter and quite impossible to discuss them all.

One major theme of this chapter is that the media play a vital role in defining and constructing various types of problems. Often, the information that the media present has the potential to be biased. Contrary to popular opinion, most news organizations are a far cry from being radical, left-wing institutions. Instead, many tend to be tainted by corporate influences and sponsors who buy advertisements (Heiner, 2006). This inevitably affects the way we as a society view social problems. To make matters worse, many citizens in the United States seldom go to the polls to cast their votes. If policymakers perceive the public as being largely apathetic and uninformed, then there is a high likelihood that little action will be taken to alleviate social problems. Therefore, it is crucial for Americans not only to vote but also to stay informed.

Admittedly, it can be difficult to keep abreast of the latest news, given that many media outlets have been co-opted by powerful corporations. Nevertheless, there are at least a few Web sites that provide insights into different social

problems throughout the world. Heiner (2006), for example, points to the following sites: factcheck.org, truthout.org, alternet.org, corpwatch.org, and projectcensored.org (a site that is maintained by students). Perhaps through open communication and the dissemination of information, individuals can work together and begin to find ways to solve today's problems. Anthropologists and other social scientists have a special responsibility to educate and empower the people of the world. Though there is undoubtedly a great deal of work to be done, this is not an undertaking that is altogether impossible. In order to be successful, everyone must do their part to make the world a better place. This can start on a small, individual level and can include activities such as volunteering and recycling. If everyone is willing to contribute, there is great hope.

GANGS

PATRICIA E. ERICKSON

Canisius College

Gangs today are a worldwide phenomenon and, moreover, not unique to contemporary societies. Youth gangs have existed in Western and Eastern societies for centuries, and in the United States, gangs in urban centers existed before the 19th century. More recently, researchers have studied gangs in Amsterdam, Australia, Brazil, Germany, Hong Kong, Ireland, Italy, Kenya, Mexico, the Netherlands, Norway, the People's Republic of China, Peru, Russia, South Africa, South Korea, Taiwan, and Tanzania. In many instances, gangs use the symbols, style of dress, and behavior of American gangs because these features are transmitted through movies, books, videos, and magazines. Indeed, today's urbanized and globalized world is producing gangs faster than ever before in a variety of shapes and forms, and contemporary gangs play a significant role in many kinds of violence.

Curry and Decker (2003) indicate that gangs in the United States developed during four distinct periods. The first stage occurred as a consequence of immigration and industrialization in the latter part of the 19th century, when groups of recent immigrants—primarily Irish and Italian—engaged in petty property crimes. In the 1920s, a second wave of gangs emerged in cities, again composed of recent immigrants, but they had symbols of membership and were more actively involved in crime than the gangs of the first period. In the 1960s, another generation of gangs developed that contained a significant number of

racial minorities. The availability of automobiles and guns gave these gangs the ability to fight other gangs in neighborhoods across a city. As a consequence, more gang members served time in prison and the prison itself became a source for the perpetuation of gangs. Once released, these individuals brought gang ideology and practices with them and recruited young new members. This creation of intergenerational gangs in the 1990s is the fourth generation of gangs.

This chapter examines the phenomenon of gangs from several vantage points. First, it describes how gangs are defined and the social conditions for their emergence and persistence. Second, it considers how social scientists study gangs by describing some of the classic and contemporary studies of gangs. Third, the chapter will analyze some of the contemporary issues associated with gang activity: female gangs, prison gangs, and drug trafficking. A fourth focus is to examine gangs in a global context, especially in terms of the reasons for the proliferation and growth of gangs in the world today. A fifth focus examines future directions for social science research. Finally, while the word *gang* can refer to many different kinds of groups, such as organized crime groups (gangsters) and hate groups (the Klan), most social scientists use the word to refer to youth gangs, also called street gangs. These gangs are comprised of adolescents and young adults. Therefore, this chapter will primarily focus on youth/street gangs.

Theory

A discussion of gangs is replete with a variety of theoretical issues that are of importance to social scientists. Three issues of special significance are (1) the definition of a gang, (2) the conceptualization of what constitutes gang membership, and (3) theoretical explanations concerning the social conditions that stimulate the development and persistence of gangs.

Definition

Social scientists have not formulated an agreed-upon definition of what constitutes a gang. Generally, there are two distinct conceptualizations that dominate theory and research. The first conceptualization emphasizes that gangs are unsupervised peer groups of adolescents who may or may not engage in criminal activity. Early definitions of gangs emphasized this conceptualization and described the gang's social-support function. For example, Thrasher (1927) argued that the gang is not initially organized to commit delinquent acts; rather, it is spontaneous and unplanned in origin. It serves to give members a sense of community or belonging that is lacking in their lives. Therefore, from this perspective, gangs function as a residual social institution when other institutions fail. Contemporary researchers who subscribe to this meaning of gang argue that gangs are unsupervised peer groups who are socialized by the streets rather than by conventional institutions. They emphasize that members identify themselves with a gang or some similar term.

The second conceptualization requires engagement in criminal activity as part of the meaning of what constitutes a youth gang. For example, Malcolm Klein and colleagues (1971) argue that a gang is a group of youngsters who are perceived as a distinct group by others, recognize themselves as a distinct group, and have been involved in a sufficient number of delinquent acts that call forth a negative response from law enforcement or neighborhood residents. Usually, this conceptualization views gangs as groups with an identifiable leadership and internal organization that claim control over territory in a community, and whose members engage in violent activity or other forms of criminal activity. Often, researchers using this second formulation emphasize the changed character of gangs in contemporary societies because of their increased involvement in violence and other illegal behavior, especially narcotics trafficking. From this perspective, contemporary gangs pose a greater danger to public safety and call for an increased response from law enforcement.

Sharing the second conceptualization but with an attempt to further isolate the characteristics of contemporary gangs, Curry and Decker (2003) posit that there are a number of elements typically included in the definition of a gang. The first element is that a gang must include a group: Seldom does a gang have as few as two members.

A second element is the use of symbols that represent membership. Clothes and hand signs are examples of such symbols and serve to give gang members a sense of belonging and identification. While most gang symbols only have meaning within the gang, sometimes symbols become widely known throughout a community or society. Third, gangs use a variety of words and nonverbal forms of communication, including graffiti and hand signs, to communicate messages. Often gangs also use graffiti to mark the external boundaries of their territory. The fourth element is permanence: Gangs must be in existence for a period of time. This element can be highly variable. For example, some gangs in Los Angeles have been around for nearly 60 years while other gangs have a very short life span. Hagedorn (2008) notes that major gangs in Chicago, Cape Town, and Rio de Janeiro have been around for more than 40 years and have spread outside their original neighborhoods. In these cases, the gangs have become institutionalized. A final element included in the definition of a gang is involvement in crime. Curry and Decker (2003) claim this characteristic is the factor that distinguishes gangs from other youth groups.

Gang Membership and Organization

Closely related to the problem of defining what constitutes a gang is the issue of deciding the criteria for gang membership. In part, the difficulty stems from the fact that researchers use different methods to obtain measures of gang membership. The clearest measure of gang membership is self-nomination; that is, individuals identifying themselves to researchers as belonging to a gang. Yet, this kind of estimate relies on individuals sufficiently trusting researchers to acknowledge gang membership. In addition to self-nomination, symbols and behaviors can be used to distinguish gang members from nonmembers. For example, a gang tattoo or clothing that displays gang symbols indicates gang membership. Researchers can also ask neighborhood residents about their knowledge of gang activity, and researchers can observe the company that an individual keeps to establish whether that person is a gang member. Finally, law enforcement and police agencies keep records of the names of gang members. Generally, their figures are based on arrests or a focus on "high-profile" gangs. Law enforcement data, therefore, may not capture the true extent of gang membership in a community.

Similarly, while much juvenile crime is committed by groups of young people, most researchers do not count membership in a delinquent youth group as necessarily indicating membership in a gang. Spergel (1990) indicates that while research in the 1950s and 1960s tended to view delinquent youth groups and gangs as equivalent, contemporary researchers attempt to provide definitions of gang membership that differentiate delinquent youth groups from gangs. From this perspective, gang delinquency is law-violating behavior committed in groups that are complexly organized

with established leadership and rules. This view also holds that gangs display more violence than a delinquent youth group and, furthermore, share communal values; have conflict with other gangs; and have a tradition of turf, colors, signs, and symbols.

Social Conditions and Gangs

Anthropologists and sociologists who were members of the Chicago school of sociology conducted some of the first studies on gangs in the 1920s. These social scientists used observation and intensive interviewing to study the urban communities of Chicago, emphasizing the study of the relationship of social phenomena to their environment (human ecology). Much of the explanation for the emergence and persistence of gangs is derived from research by these social scientists. This research emphasizes the social conditions (social structure) that generally stimulate and perpetuate gangs and juvenile delinquency. From this perspective, delinquent youth are a product of their environment and gangs develop in response to environmental conditions. This section will review the major social-structural explanations used to explain gangs and gang membership, including social disorganization theory and subculture theory. These theoretical perspectives are not exhaustive of all theories that place emphasis on social conditions to explain gangs, but they serve to highlight some of the most significant classical theoretical developments in this area.

Social Disorganization Theory

Social disorganization theory was one of the most important theories developed by the Chicago school of sociology in the 1920s and 1930s. *Social disorganization* refers to the confusion of norms, values, and relationships at a community level. In this kind of community, there are weak personal ties between residents and, consequently, it is argued that there is weak social control over the individual. In his studies of Chicago gang youth, Thrasher (1927) first utilized social disorganization theory to understand the development of gangs. Thrasher posited that gangs were “interstitial,” meaning that they filled the gaps created by deteriorating neighborhoods, shifting populations, and the disorganization of slums. Thrasher argued that these neighborhoods were to a large extent isolated from the wider community and its culture. Those who resided in socially disorganized neighborhoods were the losers in the processes of competition and conflict within the larger society. Weak families and schools that were not effective in socializing youth characterized these neighborhoods. Their weakness left an opening for the development of gangs. Therefore, social disorganization theory advanced the view that gangs would not develop in strong communities.

Thrasher and those who followed him, especially Shaw and McKay (1943), argued that different degrees of social disorganization might exist in low-income neighborhoods. Those neighborhoods that suffer from extreme disorganization are characterized by extensive deterioration, social disorder, and greater violence. In these neighborhoods, gangs exert greater control because social institutions fail to function as agencies of social control. Moreover, it was the growth and development of cities that created the conditions for social disorganization because there was a succession of different racial, ethnic, and income groups in urban areas, often undergoing a very rapid transition, thereby creating a culture of conflict and a corresponding succession of gangs. Using social disorganization theory, Miller (1975) explained that an exodus of whites from central city areas occurred in the 1960s and 1970s and gave rise to the development of the segregated ghetto and an increased population from which to draw gang members. Social disorganization theory became a key theory in developing gang policy in the 1960s and 1970s. Creating strong communities became the approach to preventing the development of gangs.

In the 1990s, Robert Bursik and Harold Grasmick (1993) further developed social disorganization theory by arguing that there were three levels of community social control in urban areas. The first level was the personal level of social control based on the interpersonal ties among community residents. This was the level that Thrasher and his followers had identified. The two additional levels of community social control identified by Bursik and Grasmick were the parochial and the public. The parochial level consisted of ties between community residents and institutions such as schools and businesses. Ties such as these can create, for example, employment opportunities for residents or after-school activities for young people. The public level of social control concerns the control of residents over community resources such as law enforcement. Involvement in community policing is an example of the public level of social control. Bursik and Grasmick argued that even when personal control is high, low levels of parochial and public social control can result in gang activity. Their modifications to social disorganization theory remain an important contribution to explaining the development and persistence of gang activity in a community.

Subculture Theory

Closely connected and derived from social disorganization theory is subculture theory. A subculture is an identifiable group within a society that has patterns of behavior and norms that set that group apart from other groups within the society. Researchers who initially formulated a social disorganization explanation for the emergence of gangs later often extended their analysis to include subculture theory. For example, Thrasher's book *The Gang* (1927) contains conceptions about subculture as applied to gangs.

Thrasher argued that urbanization, along with the miseries of poverty, created classic conditions in poor communities for the growth of what he called gangland. Similarly, while Shaw and McKay initially focused on social disorganization theory to explain juvenile delinquency and gang behavior, the criticisms of the weaknesses of social disorganization theory led them to develop subcultural explanations. They argued that the subculture of gangs could serve as a social mechanism for transferring deviant normative values and behaviors from older to younger members.

Since these early writings on subcultures, several subculture theories were developed, each with its own set of important concepts and theoretical formulations. Four of the most influential subculture theories are Albert Cohen's (1955) subcultural theory of delinquency, Walter B. Miller's (1958) focal concerns, Gresham Sykes (1957/1990) and David Matza's (1964) techniques of neutralization and delinquency and drift, and Marvin Wolfgang and Franco Ferracuti's (1967) subculture of violence. More recently, James Diego Vigil's (2002) multiple marginality theory has drawn upon the ideas contained in subculture theory. Each of these theories will be briefly reviewed.

In 1955, Albert Cohen developed one of the most influential subculture theories of delinquent gang behavior. He focused on young males who live in economically disadvantaged neighborhoods. Cohen asserted that lower-class boys are judged by middle-class standards in school. However, lower-class boys fail to succeed in meeting these middle-class standards. Cohen maintained that lower-class boys do not have the prior socialization of middle-class youth and therefore are not prepared for achieving middle-class goals. As a reaction, lower-class boys develop a set of negative values that, when collectively shared, lead them to become a gang. Cohen argued that when lower-class boys are not able to achieve middle-class achievement goals taught in schools, they experience status frustration and react by inverting middle-class values. These middle-class values emphasize independence, success, delayed gratification, control of aggression, and respect for property. Instead, the values that lower-class boys adopt are nonutilitarian (gang members steal items for no reason), malicious (gang members enjoy the discomfort they cause others), negative (norms are opposite those of society), and versatile (gang members steal a variety of things) and include short-run hedonism (gang members emphasize momentary feelings) and include and group autonomy (gang members resist outside pressures for conformity).

In 1958, Walter B. Miller proposed a refinement of subculture theory in which he asserted that lower-class culture contains systematically related attitudes, practices, behaviors, and value characteristics designed to support and maintain the basic features of the lower-class way of life. He developed what he termed the *focal concerns* or key values of delinquent subcultures. Such concerns include trouble, toughness, smartness, excitement, fate, and autonomy. He claimed that subcultural crime is not the direct

consequence of poverty and lack of opportunity, but rather derives from specific values that are characteristic of a subculture. More specifically, Miller claimed that trouble is a dominant feature of lower-class culture. Getting into trouble, dealing with trouble, and staying out of trouble become focal points in the lives of many members of lower-class culture. Miller believed that the lower class's concern with male toughness was an outgrowth of the fact that many men were raised in female-headed families and consequently, lower-class boys lack a consistently present male role model. He described smartness as a capacity to outsmart, outfox, con, or dupe another person in order to achieve some valued end, such as material goods or personal status. He described excitement contained in such activities as fights, gambling, and picking up women as a search for thrills, which he saw as often necessary to overcome the boredom of lower-class life.

A concern of subcultural theorists was to explain why subcultural participants choose behaviors that negate the norms or values of the larger society when they, at the same time, to a certain degree, are participants in the larger society. More simply stated, how can a person be committed to two different sets of values—those of the subculture and those of the larger society? Gresham Sykes (1957/1990) answered this question by claiming that offenders can overcome feelings of responsibility when involved in criminal activities by using types of justifications for their actions which he called techniques of neutralization. Five types of justifications were identified: (1) denial of responsibility, by pointing to one's background of poverty and the lack of opportunity as the reasons for criminal behavior; (2) denial of injury, by claiming, for example, that "everyone does it" or that the specific victim could "afford it"; (3) denial of the victim, by asserting that the victim deserved the victimization; (4) condemning the condemners, by claiming that authorities are corrupt or responsible for their own victimization; and (5) an appeal to higher loyalties, such as in defense of one's family, gang, or neighborhood as the rationale for the criminal behavior.

A few years later, David Matza (1964) argued that youth tended to drift between criminal and conventional activities and used techniques of neutralization as justifications for deviant behavior. Matza used the term *soft determinism* to explain that youth were neither forced to make delinquent choices, nor were they entirely free to make choices unencumbered by their life situation.

In 1967, Marvin Wolfgang and Franco Ferracuti published *The Subculture of Violence: Towards an Integrated Theory in Criminology*. They claimed that violence is a learned form of adaptation to certain life circumstances, and that learning to be violent takes place within the context of a subculture that emphasizes the advantages of violence over other forms of behavior. Certain features characterize these subcultures, such as songs and stories that glorify violence, gun ownership, and quick response to

insults in order to preserve one's prestige within the group. Wolfgang and Ferracuti maintained that subcultures of violence both expect violence from their members and legitimize it when it occurs. In other words, they claimed that for participants in violent subcultures, violence can be a way of life. Wolfgang and Ferracuti also developed the idea of the "wholesale" and "retail" costs for homicide. They asserted that killings that are perceived to occur within a violent subculture generally result in a less harsh punishment than do killings that occur outside of the violent subculture. Punishments, they argued, relate to the seriousness of the offense; if the members of a subculture accept the violence, then members of the wider culture that impose the official sanctions on the perpetrators will also.

A more recent extension of subculture theory is contained in the work of anthropologist James Diego Vigil (2002). He maintains that embedded within the subculture of violence framework are the issues of "street realities" and the "state of mind" of the individual. Street realities include such factors as neighborhood, poverty, culture conflict, and sociocultural marginalization. Street realities ensure that a street subculture emerges among children who do not receive social control from families, schools, and law enforcement. Street socialization occurs when individuals who have traumatic family and personal backgrounds have to spend most of their lives in the streets from a very early age. During adolescence, group-oriented preteen activities coalesce and merge into that of the street gang. The streets become the place to learn how to gain recognition and approval. The culmination of all street experiences is the shaping of a mind-set that Vigil calls *locura*. He describes *locura* as a kind of quasicontrolled insanity, of moving in and out of wild events and adventures, showing fearlessness and toughness, and exhibiting daring and especially unpredictable forms of destructive behavior. This mind-set, Vigil argues, becomes a necessity for street survival and a standard for identification and emulation. He claims gang violence is a complex problem and social scientists need to include many factors or levels of analyses, referring to his complex research approach as multiple marginality theory.

Limitations

Social disorganization and subculture explanations of gang behavior are macrolevel explanations; they do not attempt to focus on specific individuals or examine the specific social or psychological reasons why an individual joins and stays in a gang. That kind of research is important, but historically it is not a primary interest of research conducted by anthropologists or sociologists who explore and examine the relationship between social conditions and the presence of gangs. The focus for understanding the formation and persistence of gangs, for these researchers, is at the societal and community level of analysis.

Methods

Researchers have used both qualitative and quantitative approaches to study youth gangs. Early studies primarily used qualitative approaches. These studies of gangs relied upon ethnographic fieldwork and interviews with gang members. Beginning in the 1970s, the early emphasis on qualitative research gave way to more emphasis on quantitative research, especially because of the availability of data gathered by police, the courts, and corrections. For the most part, this shift occurred because of increased government funding in the United States for criminal justice research that could assist law enforcement in controlling gang activity.

The Qualitative Approach

The qualitative approach generally focuses on the non-delinquent and noncriminal aspects of gang behavior, as well as law-violating behavior. This approach frequently examines the everyday realities of gang life. Often these studies indicate that crime and violence are only a small part of gang life. Instead, gang members spend much of their time "doing nothing" or drinking and partying. These descriptions portray gangs as loosely structured groups that lack clear and stable leadership. For example, Frederic Thrasher's (1927) pioneering work on Chicago gangs examined how members are motivated by typical youthful concerns, such as thrills and excitement. Fighting was the predominant activity and stealing was the most serious crime. Also of note is William Foote Whyte's (1943) study of an older group of corner boys in Boston during the Great Depression that he identified as the Nortons. While the main activity of the Nortons was gambling, Whyte focused on giving detailed descriptions of personal interaction among group members. Other field studies include but are not limited to Yablonsky's study of New York City gangs (1962), Spergel's (1964) research on New York City gangs, Short and Strodbeck's (1974) Chicago field research, Klein's (1971) research on Los Angeles gangs, Moore's (1978) research on Los Angeles gangs, Hagedorn's (1988) research on Milwaukee gangs, Padilla's (1992) study of a Chicago drug-selling gang, Decker's (1996) research on Saint Louis gangs, and Fleisher's (1998) ethnography of a Kansas City gang.

Although qualitative studies provide rich descriptions of gang life, they have several limitations. Qualitative research does not provide general information about the extent of gangs or sociodemographic characteristics. Moreover, Hughes (2005) notes that qualitative research is subject to methodological biases. Researchers tend to study the gangs to which they are able to gain access because the research requires a great investment of time and may entail both significant risks and the cooperation of the research participants. Therefore, using qualitative methods, the representativeness of the gangs studied is

questionable. In addition, observational data may be biased because of the presence of the observer and observer-participant relationships. Also, field researchers often assume that the members they interview are representative of other gang members. However, interview samples may consist of gang members selected because of certain considerations, such as their willingness to be interviewed or because they are currently under investigation for violent crimes. Finally, gang members' accounts of their criminal and violent activity may be exaggerated and may be contradicted by other evidence.

The Quantitative Approach

Quantitative research on gangs includes surveys of law enforcement officials, analyses of data compiled by law enforcement agencies or the courts, and self-reports of samples of youth or young adults. Walter Miller (1975), a Harvard anthropologist, published the first study of the nation's gang problem. Miller studied gangs in 12 cities by interviewing police and asking them whether they thought there was a gang problem in their city. He classified 6 of his 12 cities as "gang problem" cities. In 1982, Miller conducted a second study that included interviews with 173 agencies in 26 intensive study sites. He concluded that there were 9 cities with gang problems. Miller's research, as well as more recent surveys of law enforcement officials (e.g., Curry, Ball, Fox, & Stone, 1992; Klein, 1995; Needle & Stapleton, 1983; Spergel & Curry, 1989), indicates that gangs are disproportionately involved in delinquent and violent activities. Research methods expanded further in 1994, when the Office of Juvenile Justice and Delinquency Prevention established the National Youth Gang Center in Tallahassee, Florida. In its first national survey in 1995, 1,492 municipal police departments reported gang problems in their jurisdictions. Since 1996, the National Youth Gang Center has annually conducted a survey of a representative sample of city and county law enforcement agencies concerning the scope of the gang problem. In 2007, for example, the National Youth Gang Center reported that, following a marked decline from the mid-1990s to the early 2000s, a steady resurgence of gang problems has occurred (Egley & O'Donnell, 2007).

Although quantitative studies provide important general information about gangs, like qualitative research, they have limitations. Hughes (2005) notes quantitative studies do not explain the dynamics of gangs, such as how youth become involved in gang crime and gang violence. In addition, it is difficult to compare research that utilizes different definitions of gangs and different sampling strategies (e.g., official records, surveys of law enforcement, incarcerated youth); official records may also be incomplete, inaccurate, and confusing. Moreover, interviews of gang members may be problematic because gang members may feel pressure to hide delinquent and violent activities, or to exaggerate them to corroborate gang images. However, quantitative research

appears to be the only method to assess general patterns of gang prevalence. Indeed, quantitative research that relies on surveys of law enforcement officials, or data compiled by agencies or the courts, generally focuses on the control of gangs, and therefore their research serves the purpose of responding to the gang problem in society. On the other hand, research based on self-report samples of youth or young adults tends to have crime prevention as its focus—achieved through using results to further understand the youth who become involved in gangs. In this respect, it is similar to qualitative research in that both focus primarily on understanding the nature of gangs.

Applications

Early research on gangs focused on adolescent males involved in street gangs who were generally involved in such delinquent activities as petty property crimes. More recent research examines other gang-related issues. Three such topics will be reviewed: female gangs, prison gangs, and drug trafficking.

Female Gangs

It was often assumed that females did not become gang members, and therefore early studies of gangs concentrated on males. While it is true that, at that time, most gang members were male and mainly males commit gang related crimes, Chesney-Lind and Hagedorn (1999) describe how previous researchers ignored the study of female gangs or saw their study as unimportant. Moore and Hagedorn (2001) note that most early research focused on whether female gangs were "real" gangs or merely satellites of male groups. Female gang members were portrayed in terms of their sexual activity or as weapon carriers for male gang members. Being a gang member, for girls, meant being a bad girl. These early studies reflected the widespread notion that gang membership for females was more shocking than for males because it violated gender-role norms.

In the United States, both male and female gangs proliferated in the 1980s and 1990s. Campbell's (1984) research documents both the neglect of research on female gangs and the growth of female gangs. Moore and Hagedorn (2001) maintain that the proliferation of both female and male gangs stems from the economic decline in the 1980s and 1990s with the resulting growth of an informal economy, especially drug dealing. They indicate that female gang members were also affected by recent changes in the welfare system that have reduced or eliminated welfare payments and therefore created pressures to participate in the informal economy. As a result, many female gang members are involved in some type of delinquency or criminality, with drug offenses as among the most common offenses committed by female gang members. Available

research also consistently indicates that the gang is a refuge for women who have been sexually abused at home. Joining a gang can be an assertion of independence from family, as well as from cultural and class constraints. However, in spite of recent research, further research on female gang members' lives is needed.

Prison Gangs

A prison gang is a close-knit and disruptive group of inmates organized around a common affiliation. Prison gangs exist for the purpose of mutual care taking, solidarity, and profit-making criminal activity (Camp & Camp, 1985). The Gypsy Jokers, a gang formed in the 1950s in Washington state prisons, was the first documented American prison gang. The Mexican Mafia, which emerged in 1957 in the California state prison system, was the first prison gang to have nationwide ties. In the United States, the Crips, the Mexican Mafia (also known as *La Emet*), *La Nuestra Familia*, the Texas Syndicate, the Mexicanami (also known as the Texas Mexican Mafia), the Gangster Disciples, the Bloods, Latin Kings, and the Vice Lords are among the largest prison gangs.

Criminal activities of incarcerated gang members have a distinctive character. Tattoos, special attire, macho images, and official titles reflect the sense of ganghood. In contemporary societies, prisons and street gangs are interrelated. Sometimes gangs are created in prison and these gangs move into the streets after inmates are released. However, usually prison gangs are a consequence of street gangs (i.e., incarcerated gang members continue gang activities in prison after incarceration). In addition, older gang members in prison are often leaders in their gangs, and from prison they regulate the activities of other incarcerated gang members and continue to provide leadership to gang members on the street. Activities of prison gangs include extortion, intimidation, drug trafficking, gambling, and homosexual prostitution. Gangs often bribe weak correctional officers, infiltrate job assignments, and abuse privileges to gain privileges, money, and drugs (Camp & Camp, 1985).

Discipline matters are far more serious among gang members than nongang members. Most prison-gang hostilities are not directed at prison officials but are directed at other prison gangs or inmates. To identify gang crime or gang violence, the term *security threat groups* (STGs) is used within the prison system in the United States (Knox, 2000). With this, prison officials have implemented a number of strategies to control gangs, such as segregation units for prison gang members, isolating gang leaders, and monitoring the internal and external communication of gang members.

Drug Trafficking

The relationship between gangs and drug trafficking is not clear and is the subject of debate by researchers. Curry

and Decker (2003) state that there are two different views about the role of gangs and gang members in drug sales. The first view claims that street gangs are well-organized sellers of illegal drugs. Researchers who share this view see gangs as directly and substantially involved in drug transactions. An alternative view rejects this claim and argues, instead, that drug sales by gangs are rarely well organized. Furthermore, when drug sales occur, it is because gang members act independently of their gangs in selling drugs. Proponents of the first view often argue that many gangs are organized solely for the purpose of selling drugs. These gangs are entrepreneurial gangs and not the traditionally territorial gangs usually associated with street gangs. Entrepreneurial gangs are well-organized groups with clear goals. However, this view of gangs as well-organized groups with a common purpose is contradicted by other research that claims that gangs are often disorganized and lack shared goals. Therefore, gang membership adds little of a distinctive character to street-drug sales.

Some researchers propose an evolutionary framework to understand the relationship between gangs and drug trafficking. Hagedorn (2008) makes a distinction between the periods before and since the 1970s. He maintains that there has been more gang violence since the 1970s because of the adoption of economic functions (especially drug trafficking) by some gangs, the use of violence to regulate illicit commerce, the proliferation of firearms, the effect of prisons on neighborhood gangs, and the effect of mainstream cultural values regarding money on gang youth with limited opportunities. The National Drug Intelligence Center (2006) reports that some gangs have evolved from turf-oriented gangs to organized, profit-driven criminal enterprises whose activities include not only retail drug distribution but also other aspects of the trade such as smuggling and wholesale distribution. Some of the most highly organized gangs, such as the Latin Kings, Gangster Disciples, and Vice Lords, have centralized leadership cores that can conspire to transport and distribute drugs throughout the country.

Global and Topical Comparison of Gangs

As indicated at the beginning of this chapter, gangs are not confined to American society. They are present throughout the world, and in many cases gangs outside of the United States use the symbols, style of dress, behavior, and language of American gangs, with adaptations to their host culture. Social scientists are involved in research that seeks to understand formation, growth, and persistence. For example, the Eurogang Program (Decker & Weerman, 2005) examines street gangs in Europe utilizing both qualitative and quantitative research. Unlike contemporary American research that is government funded for the purpose of gang control and suppression, the Eurogang program is not based on such an ideology. On the contrary, many countries researched by social

scientists in the Eurogang Program contain a wide variety of social service and justice models.

In *A World of Gangs: Armed Young Men and Gangsta Culture*, John Hagedorn (2008) argues that the recent proliferation of gangs is a consequence of globalization (i.e., conditions associated with contemporary globalization such as urbanization, poverty, and immigration create the marginalization and isolation of groups, leading to the formation of gangs). Moreover, he maintains that many urban areas are transforming into megacities of more than 20 million people, and while the populations of cities are growing, so are their youth populations. Hagedorn claims that in today's world, the government has retreated from providing social welfare, cutting back on the safety net for the urban poor. Moreover, in the third world, the government cannot provide adequate employment, services, or security for the vastly expanding, poor-urban neighborhoods. Hagedorn asserts that when there is no regulation and control by legitimate forces of the government, there is ruthless control by the illegitimate forces of violent, private groups. Young men, particularly armed young men, he claims, are filling the void left by weak, repressive, racist, or illegitimate rulers. In some cities, gangs have exercised ruthless control of areas for decades. They have become institutionalized, like the Colombian drug cartels. Moreover, the gang "subculture" is no longer located in a neighborhood but rather is present in hip-hop culture and gangsta rap. Hagedorn argues that gangsta rap has become popular because it expresses the rage of the gang members in the ghetto.

Future Directions

Future research on gangs is important for many reasons. First, gangs provide us with information about a society and its values. Second, studying gangs informs us about the lives of young people and how social structure and social institutions influence them. Third, researching gangs is essential because gangs contribute to crime and delinquency and, as such, it is important to understand the social factors that give rise to gangs. Finally, some gangs have become institutionalized, or persisted for generations, and show no signs of disappearing. Youth growing up in cities where gangs have been institutionalized have an ever-present role model in local gangs. The gang may be the only chance many youth have to get a job, given the lack of legitimate economic opportunity in the slums of many cities. However, gangs not only give youth an economic opportunity but also have rituals, ceremonies, and a distinctive outlook. Young people searching for an identity can find one in gangs that are deeply rooted in inner cities. Future research needs to examine the relationship between globalization, urbanization, poverty, marginalization, and the development of gangs and their institutionalization. As inequality increases in

many parts of the world, racial and ethnic groups are often the most neglected populations economically and politically. Therefore, the youth in those populations will continue to find meaning and identity in gangs.

Conclusion

Gangs are one of many kinds of groups that are socialized in the streets and not by conventional institutions. The vast majority of gangs are adolescent peer groups that have been socialized to the streets. In other words, gangs are mainly made up of youth who are displaying delinquent behavior. However, in the wake of a vast increase in urbanization and social and economic marginalization, gangs are being spontaneously created in cities all over the world. Gangs as a social problem become a more complicated issue for study when we understand that many of today's gangs contain young men and women who exercise power not only over neighborhoods, but also sometimes even in larger spheres in cities of all sizes. The globalization of gangs and their institutionalization is one of the most significant developments of the 21st century.

DEVIANT BEHAVIOR

ROBERT M. WORLEY AND VIDISHA BARUA WORLEY

Penn State Altoona

Many anthropologists have studied deviant behavior throughout the course of their careers, yet deviant behavior has always been somewhat difficult to define since it can vary from situation to situation and across cultures. It would not be necessarily deviant, for example, to cry at a funeral. In fact, it might even be expected to some degree. On the other hand, if a student was to begin crying hysterically during one of his classes, this could certainly be seen as deviant.

While the term *deviance* often has negative connotations, it is important to remember that deviant behavior can also include attributes or characteristics that are highly valued (Heckert & Heckert, 2002). For example, in the once popular television show *Doogie Howser*, the title character was a 16-year-old doctor. If such a doctor actually existed, he would certainly be considered deviant, even though being a genius or academically gifted is not at all a bad thing. In the show, the character Doogie faced problems that were directly associated with his unique situation. He was, after all, different than his peers, and his status as a teenage doctor affected his interpersonal and social relationships.

While one can certainly find examples of modern-day deviance by turning on the television set, anthropologists often choose to study this phenomenon by examining behaviors in other cultures. Interestingly, what is considered to be deviant in one area of the world may be a perfectly acceptable practice elsewhere. In this sense, deviant

behavior can be a difficult concept to define. Howard Becker (1963), in his classic examination of deviance, contends that the term is somewhat relativistic. In other words, it can be in the eye of the beholder. This may complicate matters immensely for even the brightest students of anthropology. According to Goode (2008), deviance involves the violation of a norm. Norms are informal rules that govern what we should and should not do. Usually, they are held by a wide segment of society. Of course, they can vary from culture to culture. For example, in America, it is generally considered rude to belch, especially at the dinner table. In other parts of the world, however, this may actually be seen as being polite.

It is important to remember that in order for an individual to be labeled as “deviant,” at least one other person must witness an offending behavior and judge it as breaking a norm. If the behavior is especially egregious, this is likely to result in stigmatization. In some cases, if the norm violates a law, this could even result in an individual’s loss of freedom. If an individual commits murder, then he is very likely to be sent to prison or perhaps even executed. This, of course is an extreme case. The vast majority of norms are not laws. For example, while many people might find it repugnant to see someone picking his or her nose in public, one would be hard-pressed to find a law that forbids this activity. Deviant behaviors such as this tend to be sanctioned informally. From an early age, members of society are socialized as to what is and is not acceptable

behavior. Small children are usually permitted to break social norms with impunity, since it is assumed that they have not become fully socialized. If a child was picking her nose in public, then this might go virtually unnoticed. If, on the other hand, an adult was doing the same act, then he might receive angry glances or other forms of disapproval. This illustrates that some deviant behavior can vary from person to person, depending on a variety of different variables.

Virtually all of us, at one time or another, have engaged in some type of deviant behavior. As Goode (2008) contends, human beings are after all “evaluative creatures” (p. 3). By this he is inferring that it is not uncommon for people to cast judgments and disapprove of one another’s behavior. Of course, some forms of deviant behavior are more likely to be tolerated than others. A behavior such as nose picking, for example, is much more likely to be forgiven than a violent criminal offense. One of the challenges for anthropologists is to examine various behaviors without imposing their own moral judgments. It is important to remember that different cultures have different social mores. What may be acceptable in one area of the world might not be tolerated elsewhere. Nevertheless, all societies have members who do not conform. In this respect, deviant behavior is a phenomenon that is central to the human race. This chapter will provide a discussion of the various types of deviant behaviors. First, we shall examine deviant behavior in culturally pluralistic societies, such as the United States.

Deviant Behavior in Culturally Pluralistic Societies

Belgian anthropologist Marie-Claire Foblets (1998) contends that the greater the number of cultures that come in close contact, the greater will be the number of ways available to deal with a situation, making it less likely that any set of norms will be followed, oftentimes leading to more deviant actions as defined by the penal law of the host country. This is a problem when migrant populations are poorly acculturated into the host society. The legal system of a society, usually of a postcolonial society, is influenced by several legal systems whether overtly or covertly. This has resulted in a significant increase in cultural conflicts (Foblets, 1998). According to Foblets (1998), culture conflicts are an “outgrowth of the process of social differentiation” (p. 190), where several small social groups are created within the host society and each group tries to compete and exert the importance of its own rules and regulations, leading to a legally or culturally pluralistic society (Demian, 2008; Foblets, 1998; Leach, 1977). At this point, it is very likely that the action of an individual based on one set of rules could easily violate other sets of rules. The issue of an honor killing or vendetta is a case in point, where families are obligated

to avenge the death of their family members by killing members of the family that killed their own relative to protect the honor of their family (Foblets, 1998).

This leads to the other extreme issue in a pluralistic society where conflict arises between parents who still uphold the values of their own cultures and the children who have adopted the values of the country they reside in. This has been the subject of innumerable movies where parents resent the adaptation of the new culture of the host country by the children. Despite several attempts on their part to keep the old traditions alive, the environment plays a major role, and simple actions, like making friends in school with members of the opposite sex, which are acceptable in the country they reside in, might be looked upon as deviant behavior by the parents and grandparents. Foblets (1998), drawing from ethnography, notes that even when the various social groups within a society might agree as to the deviant nature of an act, the ways to deal with this criminality may be almost infinite. While some reject the crime rather than the offender, others focus on retribution and the responsibility of the offender in the commission of the crime. Yet others focus on ways of healing and treating the deviant behavior.

Culture-Related Alcohol and Substance Abuse

The Navajo, the largest Native American tribe in North America, are currently faced with high rates of alcohol and substance abuse. According to Garrity (2000), the abuse of substances such as marijuana, cocaine, and amphetamine is highly prevalent among the Navajo people, with the younger population starting out by abusing inhalants such as glue, paint thinner, and gasoline. Alcohol abuse in particular has contributed greatly to the higher rates of morbidity and mortality among the Native American population (Garrity, 2000; Mail & Johnson, 1993). The crisis of alcohol and substance abuse has affected the Navajos both at the individual level and as a people (Garrity, 2000). One Pentecostal minister, coming from a family of medicine men, could not become a medicine man because his father, who learned about the trade from his father, was always too drunk to pass on the family trade to the next generation (Garrity, 2000). While the Native American Church and the Pentecostal Church are actively involved in the process of healing and treating Native Americans suffering from alcohol and substance abuse, the traditional healing practices are geared toward altering the mind to its former good and driving away the evil spirit that leads to tobacco smoking and other deviant behavior in general.

This traditional healing among the Navajos has never developed a way to treat alcohol abuse in particular even though it is a serious problem (Garrity, 2000). The reason lies in the findings of anthropologists Stephen Kunitz and

Jerrold Levy (1994), who point out that alcohol had a positive connotation and was associated with wealth, prestige, and status from the 1800s to the 1960s. Navajos blame the Anglo population for introducing alcohol to them and hold them responsible for the misfortunes alcohol has brought. Traditional chanters also blame the erosion of traditional values among the Navajo youth as another cause for alcohol and substance abuse as well as their lack of willpower to change their deviant behavior (Garrity, 2000).

Jessor, Graves, Hanson, and Jessor (1968) carried out an anthropological study on deviant behavior in a tri-ethnic community consisting of Anglo, Hispanic, and Native American populations. While the Anglo population comprised the elite, the Hispanic and Native American populations held subservient positions in society. In their study of this small town in southwest Colorado, the authors found that the Native American and the Hispanic people were more prone to drinking alcohol than the Anglos. As opposed to 3% of Anglos, 38% of Native Americans reported having been drunk at least three times in the past year. In addition, 74% of Native Americans, as opposed to 34% of Anglos, reported that they drank heavily. In fact, the Native Americans exceeded both the Hispanics and the Anglos in their level and frequency of deviant behavior. The authors found that while 59% of Native Americans had court records, only 1% of Anglos had court records. Moreover, 60% of the Native Americans as opposed to 25% of the Anglos admitted to serious deviance such as child neglect.

The authors ascribed such deviance to sociopsychological factors resulting from a feeling of alienation and a high degree of anomie, or social instability, suffered by the Native Americans and the Hispanics due to personal and external forces. Citing Merton (1949), anthropologist Theodore Graves (1967), in another article drawn from the same study of the tri-ethnic community in southwestern Colorado, held that retreatist behavior as categorized by Merton is often characterized by excessive drinking. Retreatism, according to Merton (1949), manifests when there is a lack of socially approved means to achieve the socially approved goals of society, which usually includes monetary success in an American society. Thus the Native Americans who were in a socially and financially disadvantaged position in society did not have access to socially approved means for monetary success and thus suffered from anomie.

These new goals of monetary success among Native Americans can be explained by the concept of *acculturation* in anthropology, which can, for instance, come about with Native children attending high school and thereby adopting Anglo American values and being exposed to middle-class goals (Graves, 1967). Graves (1967) found that those Native Americans who were acculturated and had jobs, thus providing them an access to their new goals, showed lower levels of drinking and other deviant behavior. Besides sociopsychological explanations, culture itself

plays a role in behavior that is defined as deviant by a dominant group within any given pluralistic society.

Cultural Defense of Deviant Behavior

The United States is a melting pot of extremely diverse cultural entities. While following a common situational bond, these cultures often conflict for the lack of understanding of one another's cultures. The law depicts the norms of the cultural majority in a nation, but the norms of the other ethnic groups may be defined as criminal behavior. Sellin (1938) focused on the cultural diversity in a modern industrial society where people have come together from various parts of the world. For instance, Sellin cited the case of a Sicilian father who killed his daughter's 16-year-old lover to protect the honor of his family, and as such was quite surprised when he was arrested for it. In another instance, a Turkish father forced his 16-year-old daughter to marry her polygamous distant cousin to honor a previously arranged contract between the two men that also involved a stipulated bride price. At times, host authorities have shown deference to cultural norms of the migrant populations that would otherwise be considered deviant. For instance, authorities often left Chinese gamblers alone, as gambling, being deeply entrenched in the customs of the Cantonese population, was viewed as an internal matter for the Chinese to deal with (Smith, 1937).

The concept of cultural defense in criminal law relates to the presentation of cultural dictates as a justification for criminal behavior (Demian, 2008). Wikan (2002) expressed frustration at anthropologists being called in by lawyers to be expert witnesses in cases where they feel a cultural defense is the only way out of a difficult situation. According to Demian (2008), the concept of cultural defense has found its appeal in the last 20 years or so as a result of multiculturalism and its politicization. To elucidate the point of cultural defense, it can be said that when a cultural defense is invoked in a lawsuit, the intention of the actor while engaging in the criminal behavior can be found in the dictates of the person's culture where the act in question is the norm (Demian, 2008).

An instance of cultural defense in the United States can be found in California. Lawyers successfully defended the case of a Japanese woman who tried to kill her children to protect her family's honor, following the norms of her culture, as her husband was involved in an adulterous relationship (Demian, 2008; Renteln, 1987/1988). In this case, *People v. Kumira* (1985), on hearing about her husband's adulterous relationship, Kumira tried to drown herself and her children in a parent-child suicide ritual. The children died, but she survived. Kumira was initially charged with first-degree murder, but later the charges were dropped to voluntary manslaughter because a team of psychologists testified that she was insane. A petition

signed by 25,000 Japanese was sent to the district attorney's office explaining that the parent-child suicide, called the *oyaku shinju*, although illegal in Japan, was a cultural concept, and that Kumira's actions were dictated by it (Demian, 2008). Although the insanity defense was the one that succeeded in this case, Demian believes that the cultural defense definitely played a role in apprising the court of Kumira's intentions. Even where the culture is the same, the dominant class within it has the potential to define deviant behavior and ostracize the minority as outcasts. Such behavior is seen in northwestern California, where the Maidu people, discussed in the next section, are still residing.

Deviance in the Maidu Culture

In northwestern California—the home of the Maidu people, who reside in the Sierra foothills and the Sacramento River valley—the society is divided into small tribes that follow their own norms and have their own definitions of deviance (Brightman, 1999; Dixon, 1905). Anthropologist Robert Brightman (1999) studied the ritual clown performances that occurred during the late 1800s and early 1900s among the northwestern Maidus as they parodied deviant behavior by outrageously defying the authority of the priests. While this practice was performed in jest, it nevertheless was an important form of social conditioning. According to Brightman, the Maidus, in both the foothills and the valley, comprised several triblets with their own autonomous social structures. They had a hierarchical structure, with the village headman (foothills: *huku*; valley: *yeponi*) and the priest (*yukbe*) being at the top of the ladder. At the lower extreme were the deviant population called *suku*, comprising indigents, vagabonds, immoral women, and cross-gender people of both sexes (Brightman, 1999; Loeb, 1933).

Brightman (1999) contends that Maidu males were formally initiated into a secret society called the Kuksu cult, which sponsored various kinds of dances featuring spirit and animal impersonations. The elite occupied a high status in these societies. Those who were not members were socially ostracized, and these were usually the *sukas*, who were viewed as social deviants (Loeb, 1933). It is likely that a similar society was there for females (Brightman, 1999). During the ceremonies of the societies, clowns played a major role, often mimicking women dancers, and taking pleasure in feasting, smoking, and gambling. Disobeying the commands of the priest, the clown often indulged in several socially disapproved deviant actions like lying, begging, pilfering, excessive eating, and malingering (Brightman, 1999). Brightman (1999) comprehends the clown as one in the garb of comic relief, pointing out through license and ridicule the social constraints as being artificial and not necessarily consensual—ones that restrain rather than emancipate the individual in society. Interestingly, what makes it even more ironic is that the clown, according to Brightman,

is actually a *yeponi* who trained young boys in the society after their formal initiation.

Deviance Based on Physical Characteristics

Brightman's (1999) examination of the Maidus illustrates that individuals can be labeled as deviant for being indigents, vagabonds, or sexually permissive. It is important to note, however, that an actor can also be viewed as abnormal due to a deformity or unusual physical characteristic. In other words, even if an individual follows all of society's social norms, a physical defect has the potential to render the actor as deviant. For example, if a person is considered too tall, plus-sized, or simply too ugly to look at, there is a high likelihood that she will be stigmatized. Sadly, if a person is physically handicapped, it is also likely that he will be treated differently. Members of racial minorities may also be seen as deviant. All of the above examples involve what are known as "ascribed statuses" (Adler & Adler, 2006, p. 11).

According to Goode (2008), ascribed statuses are usually thrust on individuals from the time they are born. For example, in the classic play *Cyrano de Bergerac*, the title character has an unusually long nose. Although he is a talented poet and swordsman, Cyrano is subjected to ridicule and is painfully aware of his deviant physical appearance. He attempts to manage this stigma by helping another man woo the woman of his dreams. Like Cyrano de Bergerac, many people are born with physical imperfections. If they have the financial means and perceive that the imperfection is extreme enough, then some individuals may even opt to engage in plastic surgery. Of course, there are also those individuals who are addicted to plastic surgery and have operation after operation, even when it is completely unnecessary. This is another interesting form of deviance in and of itself. While today plastic surgery is certainly a viable alternative for some, this was unfortunately not an option for Cyrano de Bergerac. He lived in the mid-17th century, an era when cosmetic surgery was by and large unavailable.

In his classic book *Stigma*, Erving Goffman (1963) writes extensively about the stigmatization of individuals who have unusual physical characteristics. He refers to these people as having "abominations of the body" (p. 4). These can include features such as being deaf, mute, or handicapped. He contends that individuals with deviant physical characteristics are unable to have conventional interactions with other people (whom he refers to as *normals*). When someone with an abomination of the body has any kind of a contact with one of the normals, it tends to be awkward, superficial, and strained. Goffman contends that normals may attempt to conceal their feelings of repulsion. However, they are never fully able to look past the deviant traits. He contends that actors who possess these deviant physical characteristics are often acutely aware that other people find them to be repugnant. Understandably, they

may be very self-conscious and in some cases seek refuge in the arms of fellow deviants.

Although Goffman (1963) did not specifically discuss obesity as being a type of “abomination of the body,” many scholars have written that individuals who are overweight tend to be viewed as socially deviant. Interestingly, some studies have suggested that even children perceive this to be true. There are even a few well-documented cases of young children who attempt to diet. Even today, in spite of the fact that obesity presents serious health issues, it is still considered somewhat acceptable to poke fun at people who are overweight. One only needs to turn on a sitcom to find numerous examples of fat jokes. It would be much more difficult, on the other hand, to find television shows that ridicule other abominations, such as being an amputee, blind, or confined to a wheelchair. For whatever reason, social mores have afforded obesity less protection than other ailments. Perhaps it is because there is a misperception that individuals who are overweight are gluttonous and lazy. As Clinard and Meier (2008) suggest, many people assume that obese people could have avoided this label had they exercised basic self-discipline. Some “normals” may even believe that by taunting overweight people, they may actually help them become motivated to diet and exercise. This attitude, however, does little to help and is more likely to be counterproductive. Obese people may become overwhelmed by cruel jokes and simply decide to quit trying to lose weight.

While it is likely that anyone who is overweight is likely to be stigmatized, females may be especially vulnerable to being criticized. In the Western world especially, women are led to believe from an early age that they must be thin and petite. One need only look at the latest fashion magazines to see images of tiny (perhaps even slightly emaciated) models. Often, unbeknownst to many people, these images have been airbrushed and manipulated by computer technology. In other words, imperfections, such as a model’s little “potbelly,” go completely unnoticed. This gives men completely unrealistic expectations and often forces some women to attempt to achieve this ideal by whatever means necessary. Sadly, women who are perfectly healthy may even develop eating disorders in their attempt to mimic the images in magazines. Women who are excessively overweight are especially vulnerable, and they may be the most likely to be regarded as deviant. Goode and Preissler (1983) argue that overweight women may even be exploited in the dating arena. According to the authors, average-sized men will enter into relationships with these women with the implicit understanding that they will have a high level of sexual access while offering a low level of sexual exclusivity. Clearly, being overweight is seen as deviant and sanctioned by society.

Culture and Mental Illness

Mental illness may be a stigma and seen as deviant or may be viewed sympathetically depending on the dispositions

of cultures. While human behavior can be observed, the mental process that leads up to that behavior is often implicit or hidden. Anthropologists Lorand Szalay and Bela Maday (1983) defined *implicit culture* as “psychological dispositions, perceptions, and motivations which are shared by people with similar backgrounds and experiences and which lend organization and direction to overt behavior” (p. 110). In their study on the measurement of psychocultural distance between groups, they looked into the theme of mental illness as perceived by two cultural groups, Hispanics and Anglo-Americans, and found that Hispanics considered mental illness as an extreme form of incurable madness. It was highly stigmatized, considered a matter of shame—a deviance that brought disrepute in society. An analysis of related themes like mental health and psychiatry showed they were similarly stigmatized by the Hispanics: Mental health has little positive connotation, and psychiatrists are to be visited only when all hope is lost. Anglo-Americans, on the other hand, consider the possibility of treatment and cure of mental illness, look at a psychiatrist as a friend and helper, and view mental health positively, something that gives a proper understanding of the mind and the environment and so is necessary for happy and wholesome living (Szalay & Maday, 1983).

Interestingly, a common source of mental disorders such as anxiety and depression can be economic. Anthropologists Craig Hadley and Crystal Patil (2008) identified the source of anxiety and depression as insecurities in various societies—poverty and low educational level in urban societies and food insecurities in rural societies. Hadley and Patil conducted a study of two groups of people in rural western Tanzania, the *Sukuma*, who were the agropastoralists, and the *Pimbwe*, the horticulturalists, living in areas with seasonal agriculture, subsistence economies, and limited health care. While the Sukumas, who raise cattle and grow rice and corn, enjoy higher household production, the Pimbwes are poorer, have smaller households, have no cattle, and have smaller plots of land (Hadley & Patil, 2008).

During the insecure food months (December through March), people struggled for food, went to bed hungry, or sold their labor for food, with the Pimbwes suffering more as a group than the Sukumas, thus experiencing greater food insecurity (Hadley & Patil, 2008). The researchers randomly selected women from both the Pimbwe and the Sukuma communities and found that increased levels of food insecurity in households caused higher levels of anxiety and depression among women as opposed to men, who were concerned with owning material assets. The researchers also found that Pimbwe women experienced higher levels of anxiety and depression as they faced higher levels of food insecurity. According to Quisumbing, Brown, Feldstein, Haddad, and Pena (1995), women play a major role in the production and preparation of food for the family throughout sub-Saharan Africa, and thus are more sensitive than men to issues like access to food. Clearly,

deviant behavior that is related to mental illness has the potential to vary from culture to culture.

Sexual Deviance in the United States and Across Cultures

While virtually all societies believe that certain sexual practices are deviant, there is at least some variation across cultures. In the United States, as in virtually every other society, there are strong taboos against rape and incest. Still, however, some exceptions do exist even for this norm. For example, cultural anthropologist Gilbert Herdt (1987) contends that the Sambia of Papua New Guinea force young boys to orally ingest the semen of older boys and men. While this behavior would be considered extremely deviant and illegal in most areas, it is not condemned in this society. According to Herdt, the Sambia engage in this behavior because they believe that ingesting semen is the only way that a young boy can grow into manhood. If a child refuses to engage in this activity, he is beaten into submission. This activity may go on for many years until the boy develops muscles and is considered to be masculine by other members of the tribe (Herdt, 1987). At this point, he will then force younger boys to engage in this activity.

Clearly, the above case of the Sambia tribe illustrates that what is considered to be sexually deviant has the potential to vary across cultures. Prostitution is another sexual behavior that can vary from culture to culture. While most areas throughout the world stigmatize prostitution, some societies are nevertheless more accepting of it than others. In her analysis of the sex-trade business in Southeast Asia, for example, medical anthropologist Marjorie Muecke (1992) contends that prostitutes are usually able to avoid stigmatization. According to Muecke, if a prostitute supports her family and contributes money to the Buddhist temple, she will usually be seen as a “good Buddhist.” Rather than being labeled as a social deviant, she may even be revered through her good deeds. Muecke even argues that some prostitutes in Southeast Asia, particularly in areas such as Thailand, are able to bring prestige to their families. Muecke views sex work as a strategy that women employ in order to pay for their siblings’ educations and help take their families out of poverty.

Unlike in parts of Southeast Asia, Americans generally disapprove of prostitution, and it is perceived as deviant. Currently, Nevada is the only U.S. state where prostitution is legal, with certain counties that do not criminalize it. Still, this act is regulated and heavily taxed by the state. Women are required to work in brothels, which are typically large trailer complexes on the outskirts of town (Brents & Haasbeck, 2001). Many of the women who work in these brothels pay as much as 50% to 60% of their income to the brothel. While this form of prostitution is permissible in parts of Nevada, it is important to note that it is

not allowed everywhere throughout the state. In the city of Las Vegas, for example, prostitution is actually illegal.

Also, *streetwalkers* are not allowed to operate anywhere in the United States, including Nevada. According to Clinard and Meier (2008), streetwalkers are the most visible types of prostitutes. They tend to solicit clients in public and may even perform their sexual acts in places such as alleys, parks, or cars. In most cases, they are modestly paid and may often exchange sexual favors for drugs. While most streetwalkers in the United States are women, there are also men as well as those who are transgendered. In virtually all cases, they sell their services to men.

In addition to streetwalkers, *call girls* are another type of prostitute in the United States. Call girls tend to have the highest status of the various types of prostitutes. Generally, they make the most money and are less likely than streetwalkers to be stigmatized by society. In fact, they are usually able to operate with a great deal of autonomy and privacy. Many call girls have a select clientele, and some may even perform background checks on their clients. It is not uncommon for some call girls to have college degrees, and some may opt not to have sex with their clients. They are also much less likely than streetwalkers to be arrested by the police (Clinard & Meier, 2008). Shuger (2000) suggests that many call girls use the Internet to meet customers. He explains that they may pay a monthly fee to advertise on an escort Web site. By advertising on the Web, some call girls are able to find customers who are willing to pay as much as \$4,500 a day.

Sexual Paraphilias in the United States

According to criminologist Eric Hickey (2006), a *paraphilia* is defined as “sexual arousal through deviant or bizarre images or activities” (p. 26). Paraphilias can range from behaviors that are seemingly harmless to those that are sadistic and violent. In order for a behavior to be considered a paraphilia, there is typically a fantasy that fuels a particular behavior. An actor will experience extreme frustration if not able to fulfill this fantasy. Hickey argues that males are far more likely than females to engage in paraphiliac behavior. He also contends that according to the current *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*, an individual must engage in a behavior for at least a 6-month period in order for it to be considered a paraphilia. In the United States, an actor may engage in a variety of different sexual paraphilias.

Perhaps one of the most common paraphilias in the United States involves the usage of pornographic and obscene materials. It is no surprise that computers have played a large role in disseminating pornographic material, including illegal “kiddie porn.” Individuals who are obsessed with pornography may also surf Internet chat rooms in hopes of having *cybersex*. Cybersex is an activity where participants flirt and exchange romantic messages

via the World Wide Web. Cybersex can be completely anonymous, or participants can use a webcam in order to see and hear one another. Some chat rooms cater to individuals with fetishes. According to Hickey (2006), one who obtains sexual gratification from objects has a fetish. Some individuals, for example, have foot or shoe fetishes. Someone with this paraphilia may actually spend hours fantasizing about inanimate objects.

Another sexual paraphilia in the United States is known as erotic asphyxiation. This activity occurs whenever an individual deliberately cuts off his or her oxygen supply as a means of achieving sexual gratification (Hickey, 2006). It is important to note that this behavior has the potential to be extremely dangerous. Every year, hundreds of people die from engaging in this deviant activity. Another type of sexual paraphilia is known as sado-masochism. This occurs whenever someone receives sexual pleasure from either receiving pain (masochism) or inflicting it on other people (sadism). The pain may be of either a mental or physical nature. Typically, at least two participants engage in this behavior. It is always consensual. Often, individuals who engage in this behavior will have a *safe word* that is used whenever one of the actors feels that the activity is getting out of hand.

While most people with paraphilias tend to be men, there is at least one condition that tends to be more common in females. This phenomenon, known as hybristophilia, refers to individuals who are attracted to prisoners and criminals (Money, 1989). According to Linedecker (1993), many hybristophiles have been victims of domestic abuse and a few may even wind up being murdered by their criminal boyfriend or husband. This is consistent with Worley and Cheeseman (2006), who assert that some females who have romantic relationships with inmates are likely to have been involved in abusive or promiscuous relationships at some point in their lives. Often these women harbor tremendous feelings of guilt and inadequacy (Linedecker, 1993). Some hybristophiles are also socially isolated and decide to become romantically involved with an inmate in order to achieve a sense of belongingness (Worley & Cheeseman, 2006). This deviant paraphilia has the potential to be very harmful for the hybristophile and her family. Individuals who are sexually attracted to criminals are also highly likely to be exploited by criminals and prisoners.

Conclusion

As this chapter has shown, there are a variety of different types of deviant behaviors. Anthropologists have conducted numerous studies in researching this phenomenon. When many people think of the term *deviant*, they may tend to conjure up images of criminals or perverts. Hopefully, we have demonstrated that deviant behavior is a much broader term. It is likely that all of us, at one time or another, have been labeled as deviant. Humans, after all, tend to be very

judgmental beings. Certainly, it would be atypical for an individual to go an entire lifetime without violating at least one social norm. Whenever someone breaks a social norm, no matter how small, this individual runs the risk of being considered deviant. Also, as shown earlier, if an individual possesses certain physical attributes, this can also result in the actor being labeled as deviant.

It is important to note that deviant behaviors vary across cultures. For example, as discussed earlier, young boys in the Sambia tribe of Papua New Guinea are treated very differently than are boys in other parts of the world. In most societies, the activities that the Sambia engage in would be considered highly illegal, or at the very least, repugnant. The fact that the Sambia encourage a practice that is not tolerated in other places illustrates that deviant behavior may be influenced by a society's religious, ethnic, and "tribal" characteristics (Goode, 2008). Also, whenever someone violates a norm, it is likely that the actor's social position may play a role in whether the individual is regarded as deviant. If an individual is poor and a racial minority, for example, he may be more likely to be sanctioned than someone who is a wealthy member of the racial majority. It is also likely that a deviant behavior that is committed in private will be much less likely to result in a sanction than behavior committed in public places. Given this, Americans understandably may be leery of being captured on camera. In today's society of phone cameras and YouTube, virtually anyone has the potential to have a deviant behavior recorded and displayed before a large audience. This is a topic that in and of itself warrants further academic study. It would behoove anthropologists to examine this area in the future.

Finally, as this chapter has shown, deviant behavior is seldom criminal. In other words, it usually does not violate laws. While crimes are certainly deviant, most deviance does not rise to the level of being a crime. Criminologists and legal scholars may be the best equipped to study behaviors that violate formal norms. For the purposes of this discussion, we are most curious about the softer forms of deviance, such as the examples that have been presented throughout this chapter. Clearly, deviant behavior is an area worthy of our attention. It has been the focus of numerous anthropological studies for several decades, and it is likely to be a topic that will continue to interest other social science scholars in the years to come.

DELINQUENCY

MELISSA A. MENASCO

Canisius College

What is juvenile delinquency? In common parlance, there is an understanding of juvenile delinquency as meaning adolescents breaking the law or participating in mischievous behavior. Defining juveniles as being under the age of 18 years is the general rule of thumb because, in the current legal system, upon reaching this age individuals can be tried as adults, serve in the military, and, in some states, consume alcohol.

One may ask why juvenile delinquency is viewed as a separate construct from adult deviant behavior. The answer to this legitimate question is derived historically from societal attitudes about children (Aries, 1962). Only after the Victorian Age were children seen as emotionally and intellectually developing human beings. During the Victorian Age, children were simply viewed as little adults. They were not regarded as having a world of their own. Their reality was that of their elders. With the industrial revolution and the social reforms that followed (child labor laws, mandatory educational requirements, etc.), children were viewed as a group to be protected. From this attitude concerning the welfare of children sprang the juvenile justice system. The role of the juvenile justice system was to rehabilitate wayward youth. The idea of *parens patriae*, the court acting as the parent, became the foundation for the juvenile justice system. Unlike the adult criminal justice system, which was a penal system demanding restitution and levying penalties for breaking the law, the juvenile justice system was seen as a means to reform adolescents

who, through no fault of their own, had fallen victim to deviant ways, through either bad friends or lack of parental guidance. Driving the juvenile justice system was the philosophy that the young could be rehabilitated.

It is this view of adolescence that persists to this day, at least to a limited degree. While there is the inevitable ebb and flow of societal reaction to juvenile crime, the underlying attitudes about society's perceptions of childhood emotional and psychological development affect how society assesses juvenile crime.

Historical Perspective

Upon birth, it was customary for children during the Middle Ages to be presented to their fathers, who either accepted them into the family or rejected them. If they were not accepted into the family, then they would be left to churches or orphanages. Reasons for not being accepted could be deformity or disease (Aries, 1962).

As soon as they were physically capable, children were expected to take on adult occupations. Society did not acknowledge the existence of childhood as we know it today. As soon as they were old enough to train or apprentice, children would, depending upon their economic class, prepare for their given occupation.

Social status would determine whether schooling was in a young man's future. For boys of landholding families, a

monastery school might be called for with eventual knight-hood. Girls from landholding families might be taught rudimentary household finances in order to run their future husband's homes. For boys of poorer families, education would entail farming or learning their father's trade such as masonry, and for the girls, these occupations would include housekeeping and domestic trades such as needlework.

From today's perspective, children were treated severely. Instead of the warm and nurturing family that we cherish as the hallmark of the environment for a child, friendly, safe place to raise children, children were raised by wet nurses. Children were typically separated from their parents from their earliest years.

In terms of discipline, infractions were treated with physical beatings. To the parent of the Middle Ages, the idea of giving a child a period of "time-out" would be a concept difficult to comprehend. An infraction would be handled with immediacy and swiftness, as well as blunt force. This perspective developed for a number of reasons. First, parents saw corporal punishment as a means of preparing their offspring to survive the inevitable harshness of adulthood. Second, with the emphasis on the oldest male child in terms of inheritance, there left little room for the other children in terms of their parents' attention. Finally, the high mortality rates of children led to a more detached and impersonal relationship between parent and child, although this commonly held belief has been questioned in recent years (Hanawalt, 1993).

This is not to say that children did not commit criminal activity during the Middle Ages, but rather that the concept of juvenile delinquent was not part of the vocabulary during this period of time. If a transgression occurred, then punishment was meted out regardless of child or adult status.

With the passage of the Middle Ages came the dawn of the Enlightenment. The Enlightenment produced the writings of Voltaire, Jean-Jacques Rousseau, and John Locke, as well as a change in the family. Schools were established in many of the larger cities and children had the opportunity to learn some of the basic academic subjects. The status of children improved considerably during the Enlightenment as alternative forms of punishment replaced corporal punishment.

In England, chancery courts were founded primarily to protect property rights; however, these courts also were charged with looking after orphans. The Latin phrase *parens patriae* originated with these courts; that is, children were under the protection of the king and it was the right of the king to take care of his people, especially the children. This term became the basis for the court's intervention in the lives of the families under the crown's authority and, in time, came to mean the right of the state to act in the best interest of the child.

In early American life, children's lot was not so different from that of their peers in Europe. If they worked as apprentices, then they had to deal with abusive masters. If

they worked in factories, as many did during the turn of the 19th century, then they were working alongside their parents. Furthermore, while discipline may have been considered harsh by today's standards, few cases of child abuse were reported to the courts.

Children who were accused of crimes were sentenced in court alongside adult criminals. And their punishment was commensurate with their crime. Youthful status would not necessarily be taken into account when administering sentences.

By the turn of the 20th century, there was an air of reform in America. This reform movement was the basis for the idea that children had a special place in society. This movement promoted the realization that children, who were working alongside adults in factories and were being punished as adults, should not be treated with the same harshness as their laboring adult counterparts. The leaders of this movement, or child savers as they were known, argued that children should be sent to school, should not be working long hours in factories, and should not be subjected to the sentences of adult criminals (Salerno, 1991). With this, the child savers pushed for a separate juvenile justice system. It is from the efforts of these reformers that our modern-day juvenile justice system was born (Fox, 1970). The idea of *parens patriae*, or the government stepping in to care for wayward youth, was again called into action. The juvenile justice system, unlike the criminal justice system that was one of punishment, was one designed to focus on the best interests of the child.

The inherent philosophy of the juvenile justice system, as originally envisioned by its founders, is one of rehabilitation and treatment, not of retribution. It is from this understanding of the juvenile justice system that the term *juvenile delinquency* comes. Juvenile delinquents were those youths who had committed crimes and were now under the jurisdiction of the state. Under the juvenile justice system and *parens patriae*, the state was charged with rehabilitating. Juvenile delinquency is thus a fairly modern concept, as it is closely tied to the concept of childhood and adolescence in the 20th century.

Reflection of Societal Values

Delinquency as portrayed in the cinema is another interesting means of assessing our society's views of adolescent misbehavior. Beginning with Marlon Brando's portrayal of the rebel teen in the 1950s movie *The Wild One* (1953), there followed a host of movies showing teenagers suffering the angst of preadulthood. The Hollywood version of these movies is especially interesting because it depicts the times, the breaking away of these youths from their familial ties, and the struggles that they faced in doing so.

According to Daniel Biltereyst (as cited in Shary & Seibel, 2007), movies such as *The Wild One* (1953), *Blackboard Jungle* (1955), and *Rebel Without a Cause* (1955), so-called juvenile delinquency movies, caused a great deal of public

debate because they brought the topics of drugs, sex, and crime to the forefront of the public square. The discussion centered upon whether the viewing of these movies promotes delinquent attitudes and therefore delinquency. In essence, the debate that arose around these movies was based on an argument regarding the social values of the era. These movies were created in the post–World War II era. The 1950s was a period of rebirth of sorts for America. The GIs had returned victorious and were assuming their roles both in the family and in the corporate world. This was the period when the baby boomers were born. Social roles were well-defined. Rosy the Riveter, who had worked tirelessly during the war years, now put down her tools to stay home and take care of her family so that her GI Joe husband would have a job. A good wife was someone who stayed home and took care of her family, and a good husband was someone who went to work every day and provided for his family. Children were to obey their parents by going to school and avoiding trouble.

What these movies signified was an undercurrent of discontent to the façade of happiness that was the American dream. For some who opposed the showing of these movies, these movies challenged the social norms that they had come to accept as fundamental to their way of life. For others who were necessarily afraid of the challenge, this was a negative reinforcement for impressionable adolescents at the time.

Theory

Male Theories

Many theories have been proposed to explain delinquent behavior. Since males commit the majority of crimes (Federal Bureau of Investigation, 2008), most of the theories are directed toward explaining male delinquency. For the most part, it was assumed that theories applied to both males and females in spite of the fact that research studies focused primarily on males due to their higher delinquency rates. However, with the increase in female delinquency (U.S. Department of Justice, 2008), there has been an acknowledgment that the causes of female delinquency may be different than the causes for male delinquency. This is reflected in the Office of Juvenile Justice research-supported agenda. A research team known as the Girls Study Group has been given the task of looking into female delinquency.

In addition to the differences between male and female delinquency theories, the question of whether delinquents are born or created—that is, a nature versus nurture perspective—is one that continues to be debated. Some theories propose that there is a biological basis for delinquent behavior, while other theories propose that delinquent behavior is learned, while still others propose that delinquent behavior is a psychological problem.

Suggestions of biological causality have their earliest roots with the work of Cesare Lombroso (Lombroso & Ferrero, 1895/1980). Lombroso studied the physical makeup of convicted criminals and noted their physical characteristics. Greatly influenced by the work of Charles Darwin, Lombroso concluded that some men were “born criminals” and is credited with use of the term *atavism*. Criminals were evolutionary throwbacks, according to Lombroso, and hence atavistic in nature. Some of the traits that Lombroso reported were low foreheads, broad noses, enormous jaws, acute sight, and tattoos. The criminals had an inordinate number of tattoos, he reasoned, because they were insensitive to the pain associated with administering them.

While his theories of criminality are, for the most part, no longer accepted, it is important to note that those scientists who now study biological criminology trace their scientific lineage to his line of research.

The major theories of juvenile delinquency for males fall under three major categories: social structure, social process, and social conflict. Suffice it to say that this is not meant to be an exhaustive list of theories, but rather an introduction to the highlights in these areas.

Social Structure Theories

Social structure theories are so named because they attribute the causes for delinquent behavior to the structure of society (i.e., place, identity, and socioeconomic factors). Social structuralists suggest that environmental factors influence delinquent behaviors. These theories do not necessarily say that individuals lack choice as to their delinquent behaviors, but, instead, propose that the choices that are offered to them are in many ways limited due to race, class, or gender. While there are a plethora of researchers who deserve credit for their contributions to this line of theoretical reasoning, some factors deserve mention in particular: social disorganization, strain, and cultural deviance.

One of the earliest theories of delinquency is that of social disorganization. The idea of social disorganization theory has its introduction in the work of W. I. Thomas and Florian Znaniecki (1927). These early sociologists studied the immigrant Polish population in Chicago in the early 1900s. They noticed that the crime rates of this immigrant population were higher than rates for those who lived in the surrounding areas of Chicago and proposed that the cultural transmission of values was somehow disrupted by the immigration process. They referred to this disruption as social disorganization. Their proposal was an important first step toward understanding criminal behavior in terms of place.

Robert K. Merton proposed strain theory in his 1967 book, *Social Theory and Social Structure*. In his work, he proposed that dysfunctional behavior (i.e., criminality) was due to societal pressure—or the strains of society on the individual. Merton explained that American

society was particularly susceptible to societal strains because of the cultural norms to attain economic success. American society stresses attainment of the American dream—a large home, expensive car, designer clothes, and, in general, acquisition of material wealth. He further explained that individuals respond to the pursuit of the American dream in different ways, and he classified them into typologies.

Cultural deviance theories (Miller, 1958; Sellin, 1938; Thrasher, 1927) propose that criminal behavior is caused by different cultural norms of various groups in society. It is the differences among group definitions of behavior that generate delinquent behaviors.

Social Process Theories

Social process theories, also known as interactionist theories, support the notion that delinquency occurs as a result of behaviors learned through the individual's interactions with society. The nature of the individual's interactions delineates the perspective of each of these theories. The theorists who support the social learning model of delinquency believe that delinquent behavior is a learned behavior. Unlike the structuralists who believe that societal influences promote and, indeed, incite criminal behavior, social process theorists attribute behavior to association with others who influence and teach values. Primary theories that promote this perspective are differential association, social bond theory, labeling, and dramaturgy.

Edwin Sutherland and Donald Cressey (1978) first proposed the theory of differential association. The crux of this theory is based on the premise that criminal acts are learned. Sutherland and Cressey proposed a list of nine propositions to describe the nature of criminal behavior. At the heart of this theoretical perspective is the idea that all human behavior is learned and criminal behavior is simply another learned behavior. In spite of societal messages regarding acceptable behavior, they believed that crime occurred because individuals learned or were more strongly influenced toward these negative behaviors.

Social control theory, as originally proposed by Travis Hirschi in 1969, claimed that the reason for juvenile delinquency was the weak social bond that the individual formed with society. Rather than ask the question of why delinquency occurred, Hirschi asked why most individuals conformed to the rules of society. He answered this question by stating that it was the individual's bond to society that prevented deviant behavior. This social bond was comprised of four elements: (1) attachment, (2) commitment, (3) involvement, and (4) belief.

Attachment as defined by Hirschi referred to the direct and indirect control that parents and teachers exercised over adolescents. Indirect control is the influence that parents or authority figures have over the decisions of the adolescent when not physically present. Within this context, the adolescent reflects upon the opinion of the parental figure and

refrains from participating in deviant activity. The stronger the indirect control, the less likely the adolescent will transgress societal norms. The weaker the indirect control, the more likely the individual will commit the act. Commitment, according to Hirschi, refers to future goals. He believed that individuals striving to attain college degrees, obtain good jobs, and marry would be less likely to participate in activities jeopardizing their success. Hence, commitment toward personal goals would decrease the likelihood of delinquency. Hirschi also thought that involvement in extracurricular activities would decrease the likelihood of delinquency, as this would minimize the opportunity to commit crimes.

Belief, for Hirschi, refers to the acceptance and support of social norms. Adolescents who agree with societal standards of right and wrong are less likely to commit delinquent acts. Conversely, if they reject the norms, then they are more likely to become involved in delinquent activity. Each of these four elements contributed to building the social bond and, according to Hirschi, if any single element was not present, then it would weaken the individual's bond to society, thus increasing the likelihood of engaging in delinquent activities.

In its earliest formation and presentation, labeling theory is associated with Frank Tannenbaum (1938); it is identification that occurs once an individual has passed through the criminal justice system. Rather than identifying the act as evil, society identifies the individual as evil until there is little or no differentiation between the act and the individual. Tannenbaum referred to this process as the "dramatization of evil." The idea of tagging individuals as criminals is, then, the introduction of the idea that individuals identify with and become the criminal that society has defined.

Labeling theory is most closely identified with Howard Becker, who, in his 1963 book *Outsiders: Studies in the Sociology of Deviance*, described how the process of identification as a deviant occurs. From his perspective, deviants are defined by the dominant culture and are considered outsiders. They are outsiders because they do not conform to group rules. These rules are defined by the group, and therefore, according to Becker, the social group has defined deviancy. From this perspective, acts are not deviant in and of themselves; acts are defined as deviant by the social group. In his work, Becker attempted to describe the transformative process of being identified as deviant.

The social process theory proposed by Erving Goffman was of the dramaturgical perspective. In his 1958 book *The Presentation of Self in Everyday Life*, Goffman suggests that all individuals play multiple social roles. Similar to an actor in a play, a man might possibly have a role of husband, father, son, construction worker, and volunteer. All of these roles must be kept in balance with respect to other players; for the individual, this means proper impression management. Impression management, as defined by Goffman, serves to define the stage

for the players and, ultimately, to decide whose issues become the dominant ones.

Social Conflict Theories

The final group of theoretical perspectives is that of social conflict. These theories challenge the perspectives of the social process and structuralist positions. They claim that, in fact, the very definitions of these sociological approaches are problematic to defining delinquency. These theories trace their heritage to Karl Marx (Tucker, 1978) and propose that those in power made the laws and it is from this position that deviant behavior is defined. While each theory looks at the idea of the power structure differently, at the crux of their commonality is the premise that those who make the laws decide who is deviant. Radical (Chambliss & Seidman, 1971; Quinney, 1974), feminist (Adler, 1975; Simon, 1975b), and social constructionist (Henry & Milovanovic, 1995) models are examples of this belief system.

Female Theories

Since males commit the majority of delinquent acts, delinquency research has traditionally been focused on males, with the assumption being that delinquency theories applied to both males and females. Yet, researchers understood that the focus of concern was male offenders. In addition, the paucity of female delinquents was found to be an obstacle to the collection of meaningful research data. Females were simply not committing as many crimes as males and the official statistics reflected their lower numbers. Yet, within the last 30 years, with the overall rates of delinquency in decline, there has been an increase in the rate of female delinquency. Males still commit a majority of the crimes as listed in the Federal Bureau of Investigation's Uniform Crime Reports (Federal Bureau of Investigation, 2008), but it is noticeable that female delinquency has been increasing.

A number of issues arise with regard to these observations. First, there are more delinquent males than females. This subject alone has been the focus of debate and ongoing discussion. One of the ongoing debates in various theoretical frameworks is whether delinquents are born or socialized to behave as delinquents. This section will provide an overview of the research attempting to explain the differences between male and female delinquency. Second, males and females engage in different types of delinquent behavior. Girls, for example, run away from home at a rate far greater than boys, while boys commit the majority of violent crimes. This section then discusses the differences between the delinquent behavior of males and females, as well as the trends in delinquency based on current official statistics.

Theories of delinquency have discussed societal-norm violation in terms of male deviancy because of the evidence

that juvenile crime is overwhelmingly male dominated. One of the questions that arise is whether the theoretical framework for any theory of deviancy is applicable to female delinquency. The unspoken assumption of researchers is that a general theory of deviancy applies to both males and females with the emphasis on males. Since female delinquency has always been very low in comparison to male delinquency, females were simply ignored in the theoretical framework. Their numbers were just too small to test the validity of a theoretical approach. With the increasing delinquency rate of girls during the last 30 years, there has been an accompanying interest in explanations for female delinquency. The following section is a historical review of the theoretical paradigms proposed for female delinquency.

Masculinity Theory

In his 1895 book *The Female Offender*, Cesare Lombroso proposed that female criminals were biologically and psychologically similar to males. Unlike non-criminal females, Lombroso argued, the female criminal had excessive body hair, wrinkles, and an abnormal cranium. He argued that girls committed fewer delinquent acts than boys for a variety of reasons: their maternal nature, their sexual frigidity, and their low intelligence (Lombroso & Ferrero, 1895/1980). Noting that males were more delinquent than females, Lombroso attributed this fact to the uniformity among females. The female criminal was an anomaly among females.

Lombroso's work influenced subsequent explanations of the biological nature of female criminality. Cyril Burt, in 1925, wrote that female delinquency was linked with menstruation. In his 1950 work, *The Criminality of Women*, Otto Pollak continued Burt's work by discussing pregnancy and menopause in addition to menstruation as links with female criminal behavior.

Chivalry Theory

In addition to offering a biological link to female criminality, Pollak (1950) claimed that female deviancy occurs more often than reported. According to Pollak, women were naturally more inclined toward deceit and concealment. His argument was based on the biological differences in the sexes. Since men are unable to hide their sexual arousal but, by their physiology, women can, he deduced that by their very nature women were capable of deceitful behavior. He further reasoned that culturally, women were encouraged to behave in a socially proscribed manner. These socially proscribed manners included feigning behaviors that made it easier for them to commit crimes.

In addition to cultural expectations, the inequality of the sexes also affects the underreporting of female crime. By their nature, he reasoned, males wish to protect females. This desire to protect females, or chivalry, is consequential

to the treatment of females when they are adjudicated in the criminal justice system. With men dominating law enforcement, it is of no surprise that police are reluctant to arrest females, lawyers are reluctant to prosecute females, and judges are reluctant to sentence females. Pollak (1950) attributed this reluctance to chivalry. Females did not actually commit fewer crimes, he reasoned, they simply were treated less harshly than their male counterparts. Furthermore, the types of crimes that females committed were directly related to the roles that society proscribed. These roles made it easier for women to commit and conceal their crimes. As substantiation for his theory, Pollak noted that in their primary role as homemakers, women had easy access to victims of violent crime (i.e., their family members). Child abuse was given as an obvious example of a crime that might escape detection by law enforcement officials. Another crime Pollak identified was stealing. Since the typical shopper is a woman, he reasoned that the store displays were designed to entice women. These displays created desires to attain material goods. If women were unable to satisfy these needs, then they would be induced to commit crimes.

While a good deal of Pollak's original argument has been discarded, the central premise of the chivalry theory—the differential treatment of females in the criminal justice system due to inequalities between the sexes—remains a topic of debate among researchers. Proponents of the chivalry theory argue that law enforcement agencies are more lenient toward female offenders. As an example, when comparing similar crimes, female sentencing has been found to be less severe than for males (Reckless, 1955). The idea that females are central to the nuclear family and their removal from that environment threatens to disrupt not only the family, but also society by leaving children without their mothers, is a key concept underlying the chivalry theory.

As a direct test of the chivalry theory, Corley, Cernkovich, and Giordano (1989) conducted a sociological study to determine if a difference exists between the treatment of delinquent males and females within the family, at school, and in the judicial system. If the chivalry theory is true, they reasoned, penalties for delinquent behavior should be unequal with boys receiving more serious penalties. They found that within the family, both boys and girls were similarly disciplined, primarily through grounding. However, girls indicated parents would be more likely to react negatively to certain behaviors. Within the school setting, they found that males were suspended more often than the females because their offenses were more serious than the females'. Furthermore, when males and females committed similar crimes, it appeared that school officials were reluctant to suspend females. Within the criminal justice system, they found that males were more likely to have contact with the system than females. Males committed more serious crimes than the females as well. However, they did not find support of the chivalry theory within the court system. The factor that was most

relevant to imposed sentences was severity of the crime. They could not find support for sex, race, or age influencing the imposition of sanctions by the courts. While finding limited support for the chivalry theory with respect to the family and school, Corley et al. (1989) found no support for it in the judicial system.

Psychological Theory

From a biosocial and psychological perspective, the reasons for female delinquency are attributed to physical and emotional traits. Theorists in this tradition believe that biology, psychological factors, and the social environment are all factors influencing delinquency. Some of the more prominent ideas promoted by these theorists are precocious sexuality, hormonal differences between males and females, premenstrual syndrome, and aggression.

Precocious sexuality as explained by Glueck and Glueck (1934) linked the early onset of physical maturity with female delinquent behavior. Delinquent girls were viewed as more sexually promiscuous, and their sexual activity was an indicator of their inability to follow societal norms. In a supporting view, Buchanan, Eccles, and Becker (1992) found an association with early onset of puberty and female delinquency. It has also been proposed that girls who mature at a younger age may attract older, adolescent boys who are influential factors in the behavior of these girls. In another sociological study, Caspi, Lyman, Moffitt, and Silva (1993) found that as girls matured, the delinquency gap between the early and late bloomers declined. The importance of the precocious sexuality approach is the recognition that female delinquency is not easily traced to a single biological explanation. If there is a biological basis for nonnormative behavior, then these theorists recognize that it operates within the context of the social and psychological spheres.

Theorists who advocate the hormonal differences between males and females believe that male hormones, or androgens, are responsible for more aggressive male behavior. Walter Gove (1985) found that androgens reduced the effects of environmental stimuli on the brain, which in turn explained the need for males to seek increased levels of stimulation such as that acquired from committing crimes. According to this theoretical approach, lower androgen levels in females explain the lower rates of female criminal behavior. Those females who have higher androgen levels, according to these theorists, will exhibit more male traits, such as aggression, and thus will be more likely to engage in criminal activity.

While relatively rare, female violence has been associated with the premenstrual syndrome (Fishbein, 1971). Fishbein's study of incarcerated females found that a significant number of crimes were committed in the premenstrual phase. In addition, a small number of women appear to be more susceptible to hostility and anxiety due to hormonal fluctuations during the menstrual cycle. However,

Fishbein points out that most of these women who are susceptible to hormonal fluctuations do not engage in criminal activity. While her study remains significant, there has been conflicting evidence regarding premenstrual syndrome and criminal activity (Harry & Balcer, 1987; Horney, 1978), primarily due to methodological considerations. These researchers question the causal ordering of premenstrual syndrome and criminal activity. From their perspective, it is unclear whether criminal activity and the stress of such activity induces the onset of menstruation.

Another theoretical approach with biosocial origins is the idea that males are inherently more aggressive than females (Ellis, 1988). This aggression, according to some psychologists, exists before socialization occurs; that is, it is innate. As evidence, they cite male aggression across all societies (Maccoby & Jacklin, 1974). One explanation given for the difference between male and female aggression is the difference between the male and female reproductive systems. According to this reasoning, males pursue multiple sex partners as a means of increasing their progeny, while females focus on the selection of a partner who will provide the resources necessary to protect and care for their young (Ellis, 1988). Critics point out that aggressive behavior is not exclusively limited to males, and under certain circumstances, females exhibit aggressive behavior (Frodi, Maccauley, & Thome, 1977).

Socialization Theory

From the socialization perspective of female delinquency, sex matters. By studying the differing lifestyles of males and females, socialization theorists hope to find the relationship between females and delinquency. Under this theoretical framework, girls are monitored more closely than boys. Girls' parents are more mindful of girls' misbehaviors than those of boys. Adults treat boys with greater leniency because of expectations that boys are brash and greater risk takers than girls (Farrington, 1992b). Since the primary adult figures in children's lives are their parents, this perspective places a good deal of emphasis on the quality of children's home life. Children from troubled families, including broken homes, or those who lack supervision are at greater risk for delinquency.

As early as 1927, W. I. Thomas noted that female delinquency was linked with the desire for material wealth and excitement. According to Thomas, girls from lower socioeconomic classes had not been schooled with appropriate middle-class values and, in their desire for wealth and thrills, were forced to engage in sexual activity as a means of acquiring material possessions. A reflection of its times, Thomas's assessment of female delinquency was based on an economic, moral, and social differential between the classes.

In *The Adolescent Girl in Conflict* (1966), Gisela Konopka pointed out that love deprivation and isolation were the basis for female delinquency. According to Konopka, an important

aspect of the maturation process for adolescent girls is the need for acceptance by males. If the adolescent girl is unable to develop these relationships with family and friends, then she may turn to sexual relationships as a means of satisfying her need for male approval. Pursuing sexual relationships with males would then lead to disapproval of her behavior by both family and community. This disapproval, in turn, would serve to increase her feelings of isolation from family and friends. Konopka posited that girls who lived in fatherless homes were especially disadvantaged because they had no means to develop the basis of a healthy relationship with a male figure.

Vedder and Somerville (1970) attributed female delinquency to family pressures. They found that 75% of institutionalized females had family problems. In their work *The Delinquent Girl*, they note the impact of unfair social practices on girls, as well as the effects of living in a male-dominated culture. Vedder and Somerville's work proposes that female delinquency originates in the family and, more specifically, with regard to gender role definitions.

Subsequent work of socialization theorists continues to link female delinquency with a troubled home life. In their study of incarcerated girls, Belknap, Holsinger, and Dunn (1997) report that delinquent girls spoke about physical and sexual abuse, as well as degrading and embarrassing social situations. Citing an association with abuse within the home and female delinquency, Chesney-Lind (1987) notes that many of these girls end up running away from home only to become victims of the system that set out to protect them.

Liberal Feminist Theory

The liberal feminist perspective of female criminality argues that economics and sex-role differences are stronger predictors of delinquency than socialization. Liberal feminists such as Rita Simon and Freda Adler argue that socialization alone cannot account for the differences in criminal behavior between the sexes. In her book *Sisters in Crime* (1975), Freda Adler stated that females commit fewer crimes than males because of their limited access to opportunities. By their nature, sex roles are restrictive for women, but as women enter the ranks of male-dominated professions, she predicted, the crime rate for females would begin to increase to match that of males. From the liberal feminist perspective, there is no difference between the sexes in terms of causality of criminal behavior. Rates of criminal behavior would begin to converge as more women gained access to traditionally male-dominated positions.

Rita Simon asserted that as women gained more economic and social power, they would be more likely to engage in male-dominated crimes (Simon, 1975a). Her prediction is supported by the increase in the female crime rate over the past 25 years. In fact, while male delinquency rates still far exceed those of females, the patterns of

crimes between the sexes are more similar than different. Critics of the liberal feminist position argue that the increase of female delinquency may be attributed to the attitudes of law enforcement agencies toward the female offender. Perhaps the arrest rates are rising, they argue, due to a change in police attitudes toward female offenders.

Radical Feminist Theory

Similar to the liberal feminist tradition, the radical feminist position argues that female delinquency is structural in nature. Drawing from a Marxist perspective, it sees the capitalist society as creating an unequal distribution of power with males dominating females. James Messerschmidt (1993) has developed a theoretical model that explains inequities between the sexes as a consequence of power in the patriarchal capitalist system. Female delinquency is created by male exploitation of females, whether through abuse, harassment, or undue influence.

In his power-control theory, John Hagan proposes that differences between the sexes are generated by class differences (Hagan, Gillis, & Simpson, 1985; Hagan, Simpson, & Gillis, 1987). These class differences influence family life. Hagan et al. (1985; 1987) therefore propose that the traits associated with positions within organizations—such as executive, middle management, or staff—are reflected in the family structure. Defining families as paternalistic (i.e., father as breadwinner with stay-at-home mother) or egalitarian (i.e., father and mother have similar positions in the workplace), Hagan et al. argue that the type of family structure influences the family management style. Paternalistic parents give their sons more freedom while limiting their daughters' freedom, thus explaining fewer female delinquents in these types of families. Egalitarian families, while giving their sons and daughters greater freedom, experience similar delinquency rates between brothers and sisters. Egalitarian families are more likely to be found among the upper class, since the parents are by definition managers in the workplace. Paternalistic families are more likely to be found in the lower classes, again due to the definitions that Hagan et al. have developed; that is, there is a single wage earner in the family, usually the father. While Hagan et al. have found support for their theory, critics argue that differences in delinquent behavior in terms of social class are problematic to delinquency theory. As an example, they propose that upper-class youths are greater risk takers and are more likely to engage in petty delinquency than lower-class youths.

Types of Male and Female Delinquency

While girls have traditionally engaged in delinquent acts less frequently than boys, there has been a steady increase in the delinquency rates of girls over the last 30 years. Boys still engage in criminal activity at a far greater rate than

girls, but girls are closing the gap between the sexes. The Uniform Crime Reports (UCR; Federal Bureau of Investigation, 2008), a compilation of crime statistics from over 10,000 law enforcement agencies as reported to the Federal Bureau of Investigation (FBI), confirms that, overall, boys are arrested more than twice as often as girls (U.S. Department of Justice, 2008). The statistics reported by the UCR show that the arrests for girls in 1967 constituted 13% of all juvenile index-crime arrests, and they now constitute approximately 29% (U.S. Department of Justice, 2008). Of particular note are the increased arrest rates of female over male delinquency for aggravated assault (99% vs. 14%), simple assault (258% vs. 99%), and weapons law violations (125% vs. 7%) over the period of 1980 through 2002. Drug abuse violations increased at a comparable rate (42% vs. 47%) for both sexes.

Regarding types of offenses, boys are far more likely to be arrested for violent crimes and serious property offenses. Boys are 5 times more likely to commit violent crimes, including homicide, forcible rape, robbery, and aggravated assault, than are girls. For serious index property crimes, including burglary, motor vehicle theft, and arson, boys are more than twice as likely to be arrested as are girls. Overwhelmingly, boys are arrested more often than girls for drug-law violations. Other offenses, such as stolen property, vandalism, weapons offenses, and "other assaults," are also typically associated with higher arrest rates for boys (Chesney-Lind & Shelden, 2004).

Types of offenses for which girls are typically arrested include running away from home and prostitution (Chesney-Lind & Shelden, 2004). Over half (60%) of the arrests for running away from home are girls. Girls are far more likely to be arrested for status offenses, which in addition to running away from home include truancy, curfew violation, incorrigibility, and loitering. The 2002 UCR reports that running away from home and curfew/loitering account for 18.2% of all girls' arrests and only 6.5% of boys' arrests.

The 2002 UCR reports that 71% of all juvenile property crime-index arrests were larceny-theft, with the most common violation being shoplifting. Girls accounted for 39% of larceny-theft. Overall, the juvenile arrest rate for property crime-index offenses was the lowest since the 1960s with an increase in the arrest rates of girls over the same period of time (U.S. Department of Justice, 2008).

The UCR is not a perfect mechanism for tracking the commission of crimes because it is dependent upon crimes reported to law enforcement agencies. It is a means of gauging general trends in criminal activity, and, if anything, the UCR statistics reflect an underreporting of criminal activity. Nonetheless, the UCR provides valuable information regarding the categorization of crimes that are committed in the United States. Furthermore, it can be argued that the accuracy of the UCR increases with the seriousness of the crime. More serious violations, such as murder and rape, are more likely to be reported to law enforcement agencies than less serious infractions, such as vagrancy.

Furthermore, the information gleaned from the UCR describes several key factors regarding male and female delinquency. First, male delinquents continue to overwhelmingly commit the greatest number of juvenile offenses, with more than twice as many arrests (U.S. Department of Justice, 2008). Males commit most of the violent crimes and females commit the most status offenses (running away and curfew violation). Second, as mentioned, there has been a steady increase in the rates of female delinquency over the past 30 years. Third, when ranking the most common delinquent behaviors, male and female delinquents exhibit similar patterns of criminal behavior. The leading offenses for both male and female delinquency are the categories of larceny-theft, forgery and counterfeiting, and other assaults not included in the violent crime index.

Smith and Visher (1980) conducted an empirical review of studies comparing sex and involvement in crime from 1940 through 1975. In their review, they gathered information such as self-report questionnaires and official reports of arrest, class, age, race, offense type, level of family intactness, and level of urbanization. Their review of 44 studies found the gap narrowing between male and female deviancy in general, and delinquency in particular, depending upon type of offense. In terms of minor offenses, males and females exhibited similar propensity levels while the more serious criminal behaviors continued to be dominated by males. Of particular interest was their finding that African American male and female involvement in criminal activity appears to be converging, while European Americans do not exhibit a similar convergence. They posit that this result is consistent with stratification research; for example, African American females have experienced advancements in educational and occupational attainment relative to African American males at a faster pace than their European American female counterparts in relation to European American males. In other words, African American women have advanced faster than European American women, thus lessening the gap between the sexes and creating a similar propensity toward crime. Finally, they note a convergence of self-report with official data samples in reporting less serious deviant behavior and acknowledge that attitudes of official law enforcement agencies toward more serious offenses may impact agency responses.

Although this study was conducted 25 years ago, the trends of female and male delinquency have continued to the present. Boys continue to participate in the most serious offenses, but girls, by their increasing rates of participation in delinquent acts, have narrowed the gap that existed between the less serious forms of delinquent behavior.

Cross-Cultural Delinquency

One of the most interesting aspects of studying delinquency is that of cross-cultural comparisons. Up until this

point, the discussion has focused on American delinquency, which is unique in its development. But, as has been previously discussed, social structure is fundamental to the perspectives of adolescence and, consequently, to the idea of delinquency within that culture.

Does delinquency exist across all cultures? And, most important, if not, why not? This examination cannot possibly hope to cover all cultural groups, but, instead, it will attempt to provide a brief description of a culture that had witnessed virtually no delinquency but, over time, has seen a metamorphosis of its youth toward deviant behaviors.

In order to answer the question as to whether delinquency exists in all cultures, it is important to recall the original premise of this discussion. Delinquency exists in societies where there are concepts of adolescence. If there are no concepts of adolescence, then the concept of delinquency has no point of reference. If the social structure embraces childhood with an initiation into immediate adulthood, then an adolescence is not conceivable. Children move immediately into their adult roles, meaning that they take on the responsibilities and tasks that their elders have prepared them for. Delinquency, and the attitudes associated with it, is an extension of childhood roles that are eliminated in a culture that initiates children into adult roles. This is not to infer that deviant activity does not occur upon initiation into adulthood, but, rather, that any deviant activity is treated as a social infraction at an adult level. In these contexts, there is no concept of special treatment for adolescents. Upon initiation into adulthood, there is an acceptance of the rights and responsibilities associated with this newly attained status.

How to compare delinquency between different societies becomes problematic for a number of reasons. First, there is a necessary agreement as to the definition of delinquency. Delinquent behavior in one society may not be considered delinquent behavior for another social group. The idea of delinquent behavior assumes a stage within human development that may be a foreign concept in another social setting. Second, criminal behavior in one society may be acceptable behavior in another society. An example of this would be some of the tribes of India who have taught their young to steal as a matter of survival (Cavan & Cavan, 1968).

There are enough variations in differing societies that this piece will attempt a brief comparison of two social groups. In order to contrast the differences between these two groups, a preindustrial society compared with an industrial society will provide an illustration of how delinquency differs in each society. There are, of course, differing cultural norms that will affect attitudes toward delinquency. In addition, while examining the preindustrial society and its transition into an industrial state, there will be the opportunity to describe changing societal patterns of behavior and their effect on the behavior of youth within that culture.

Cavan and Cavan (1968) studied the closed society of the Eskimos as an example of a social group that, at one

time, had virtually no delinquency but has now witnessed the introduction of delinquency to their culture. Eskimos are differing ethnic groups of nomadic peoples who live in the regions of Alaska, Siberia, Greenland, and northern Canada. The idea of delinquency was virtually unknown to the Eskimos until the introduction of European explorers and settlers.

By looking at Eskimos as an example before the arrival of the Europeans, there is a marked difference in the family and its approach to delinquency (Cavan & Cavan, 1968). Prior to the arrival of the Europeans, the Eskimos lived in tightly knit family groups wandering in hunting groups in search of food. Their travels roughly followed their search for food: caribou, seal, and walrus. Their culture had little or no delinquency. Families shared single-room huts in the winter and, in the summer, they would spread out in other dwellings within a general area. To live in one room during the course of the winter months, with no control over an unruly adolescent, could be a problem not only for the family, but also for the entire community. Hence, keeping a tight rein over troublesome youth in such tight household circumstances was essential.

Furthermore, the Eskimos lived in a patriarchal society and the father immediately attended to any transgression. In this society, women were subservient to men and wife lending was customary, relating to lack of children and sexual tension. In addition, according to Cavan and Cavan (1968), these arrangements were agreed to without any problem by the women. Children were kept in close proximity to their mothers and, in fact, were watched by the extended family. In addition, the Eskimos had no social classes. Everything in their society was geared toward survival, and cooperation was essential in order to meet that end.

The greatest problem would appear to be living in close quarters for many months of the year. Yet, this was handled by the separation of each nuclear family unit, during the summer months, from the main group in order to go its separate ways. According to Cavan and Cavan (1968), the simple need to survive, the care of mothers for their children, the authority of the father, and cooperativeness of the family unit as a whole met their overall goals: All contributed to the lack of delinquent attitudes. It is interesting to note that upon the introduction of the European settlers, delinquent attitudes and problems began to creep into the Eskimo culture. As long as the culture remained closed to the outside world, it appeared to be able to keep delinquency at bay. It was when Eskimos came into contact with the outside world that issues of delinquency, such as alcohol consumption and sexual promiscuity, became problematic.

With the introduction of the European immigrants came missionaries and ideas outside of the Eskimo culture. The Christian missionaries discouraged the practice of wife lending, which had been common practice among the Eskimos. Coincidental with the changes that the Europeans brought to the Eskimos came changes to the Eskimo way of

life. The missionaries sought to establish a moral system of beliefs, which the Eskimos absorbed into their system. While accepting the beliefs of the missionaries in addition to their own belief system, the Eskimos found that their way of life was slowly changing.

This transition brought with it a myriad host of difficulties—another culture in which the young were curious and by which they were easily influenced, as well as the realization that there were goods beyond the necessities for survival that could be acquired. In the past, the Eskimo family had been concerned with survival, and now there was the opportunity to obtain supplies to make life easier. While it is easy to place blame for the appearance of deviant behaviors in the Eskimo culture on the European settlers and their introduction of material goods, a few cautionary reminders are appropriate: Nonconformity in the Eskimo culture was not tolerated because of the close living conditions; dealing with those who deviated from societal norms was immediate, and children were initiated into adulthood, meaning that no juvenile culture existed, thus eliminating delinquency.

Future Directions

The development of preventive strategies will necessarily follow from an understanding of delinquency's root causes. If social structure is a key factor in the development of juvenile delinquency, then prevention will entail addressing issues regarding place, identity, or socioeconomic status. For example, if poverty is considered a significant causative factor, then taking steps such as providing jobs, job training, and perhaps additional welfare benefits becomes an important social concern. By eliminating poverty, society will thus work toward eliminating the deviant behaviors that exist as a result of socioeconomic status. If, on the other hand, gender is viewed as contributing to the majority of delinquent behaviors, then a closer look at the roles that are encouraged in society becomes an important factor.

Since males commit more delinquent acts than females, a preventive measure would entail focusing upon males. As an example of ethnicity- and gender-based solutions, mid-night basketball was promoted in the 1990s as a means of decreasing incidents of delinquency (Hartmann, 2001). Its primary intent was to keep adolescents off the streets at night by keeping them occupied, and its target group was inner-city, African American males. Initially seen as a means of addressing crime in the inner city, this program came under intense criticism by its opponents for being racist, as it was directed toward a single ethnic group, and ineffective, as there was a lack of supporting evidence for minimizing delinquency.

From its inception, our juvenile justice system has viewed juvenile delinquency as a problem that, at its heart, is one of redemption and restoration. Our society views the young as easily influenced, adaptable, and with many years

of productive life ahead of them. Unlike the criminal justice system with its primary purpose as retribution, there is a separate juvenile justice system with an entirely different purpose of rehabilitation, although arguably this has changed over recent years toward a more retributive system. As society has witnessed many horrific crimes, such as the school shootings of Columbine and Virginia Tech, there has come to be a growing concern that perhaps youth should be treated as adults. By moving these youth to adult courts, society has, in effect, made a decision to move away from the rehabilitation model and into that of retribution. This movement toward a retributive model is illustrated by the changes in the laws that have lowered the age under which juveniles can be transferred to adult courts, the addition of crimes for which underage youth can be charged, and the modification of prior-record provisions (DeFrances & Strom, 1997). Under these circumstances, society has determined that the seriousness of the crime demands that justice be served regardless of the age of the perpetrator. There are those in the juvenile justice system who would argue that although juveniles may understand the serious nature of their act, they do not have full and clear comprehension as to the meaning of their criminal act.

There is a real need for anthropologists to pursue cross-cultural research in delinquency. There are two primary reasons to pursue this line of research: (1) to provide a better understanding of the transmission of cultural norms including delinquency from one culture to another, and (2) to study delinquency as defined by differing social groups. The benefits would include lowering delinquency rates through an understanding of its causes, increasing the understanding of cultural definitions related to norm violation, and finally providing credible research to influence social policy.

VIOLENCE AND WARFARE

VIDISHA BARUA WORLEY

Penn State Altoona

Warfare is an organized, socially sanctioned armed conflict that takes place between two independent political units, groups, or communities using military force (Malinowski, 1941; Mead, 1940, 1968; Otterbein, 1994). Otterbein (1994) has categorized warfare into three types: (1) internal war and two types of external war, (2) offensive war and (3) defensive war. While internal warfare is between political groups within the same cultural unit or larger aggregates within society, external war is between culturally different units or between the society under study and other societies (Ember & Ember, 1997; Otterbein, 1994). Of the two types of external war, offensive is attacking and defensive is being attacked (Otterbein, 1994).

Violence, a ubiquitous aspect of warfare, is a part of everyday life in modern times. At present, the war on terror that is being waged in Iraq by the U.S. government was a major issue in the 2008 presidential elections as violence continues to take center stage with the rising number of casualties of American soldiers. Terrorist attacks are also at an all-time high. While the September 11, 2001, attacks in New York City and Washington, D.C., were still fresh in the minds of the people, the terrorists attacked Mumbai, India, in November 2008 for 4 days, leaving the financial capital of the country debilitated. Violence, however, is not unique to the world of today. It can be traced back to prehistoric times. Osteological and archaeological data about

ancient groups from the Americas and Europe point toward this fact. Archaeological data and skeletal remains also show evidence of domestic violence, homicide, ritualized combat, warfare, cannibalism, and human sacrifice (Martin & Frayer, 1997).

Violence in Prehistoric Warfare

Despite lack of concrete evidence, prehistorians believe that violent clashes between different groups were likely since Paleolithic times (Guilaine & Zammit, 2001/2005). According to Leroi-Gourhan (1965), aggression, an integral part of hunting, was essential in prehistoric times as a technique for obtaining food and warfare. Thus, violence, an extension of hunting, was a natural means for survival. Among the few remains that exist of Neanderthal man in the cave of Shanidar in northern Iraq, there appears to have been a high frequency of trauma-related deaths that show a likelihood of aggression (Cunliffe, 2006). Remains found in the Upper Paleolithic cemetery of Gebel Sahaba in Nubia, Egypt, show that at least 50% of those buried died from violence (Cunliffe, 2006). Looking at the aggression shown by the hunting populations of American Indians today, Guilaine and Zammit (2001/2005) surmise that hunting societies of the Upper Paleolithic Age were warring societies.

Burials of the Mesolithic man in Europe show signs of deaths by traumatic injuries, and those found in Bavaria show that heads were severed from the bodies, which could be indicative of either ritual sacrifice or widespread warfare among the hunter-gatherers. Among early farmers of the Neolithic Age from about 6000 BCE, violence and warfare in the form of raids and routs using bows and arrows, along with spears and axes, seem to have intensified as people started competing for resources (Cunliffe, 2006). The reason that warfare was so rampant among the hunter-gatherers and the early farmers is because they enjoyed war and it formed an integral part of their social existence (Clastres, 1997). However, unlike modern warfare, prehistoric warfare had few participants. Adult males, who had no training or strategic war plans, took part in disorganized confrontations with no one leading the warring factions (Guilaine & Zammit, 2001/2005). According to Thomas Hobbes (1588–1679), this lack of leadership—an authority to establish social organization—led to constant warfare.

Hobbes, in his famous work *Leviathan* (1651), noted that human beings adopt means for self-preservation when they perceive danger. As such, Hobbes argued that men have the natural capacity for violence and that war is a social condition that can be averted only when society gives up certain rights to a sovereign who takes over decision making for a long-term good (Cunliffe, 2006). According to Hobbes's theory, in the absence of discipline, human beings are in a state of animosity where a constant mistrust of others leads to rebellion and conflict (Clastres, 1997; Guilaine & Zammit, 2001/2005). Clastres (1997) perceived this constant need for war as a way for primitive societies to retain their individualism and independence and not bow before a powerful authority figure where power would be centralized. Spencer (1896) contended that military efficiency came before the development of centralized political power.

Jean-Jacques Rousseau (1712–1778) believed in the idea of the “noble savage,” asserting that man is gentle in his natural state. He argued that man is led to violence when restrained by social mores (Cunliffe, 2006). The theory of the noble savage is that primitive life was conflict-free and that the peaceful character of man and nature were in harmony with each other (Guilaine & Zammit, 2001/2005). The scientific view believed that primitive life was easy because there was scant population and nature was bounteous. Thomas Malthus (1766–1834) hypothesized that population increases faster than the means of subsistence, and warfare was a means to check population growth, which was later referred to by Julian Steward in the late 20th century as “cultural ecology” (Cunliffe, 2006). Malthus's theory had a major impact on Charles Darwin (1809–1882) in propounding his theory of natural selection, which was the nucleus of both his *On the Origin of Species* (1859) and *The Descent of Man* (1871). Thus, Malthus and Darwin looked at violence and

warfare as natural and positive when it led to the survival of the fittest (Cunliffe, 2006).

Evolution of Violence and Warfare

War as an institution was created at some point of time in social evolution even though less complex collective violence did exist prior to that (Mead, 1964; Meyer, 1990). Wilson (1978), in his book *On Human Nature*, opined that aggression arose in defense of territories where intruders were attacked. Territories defined the control over resources like fruit and water; game and warfare were also an important mechanism to maintain this control (Meyer, 1990). Adding to this, Otterbein (1994) identified 16 theoretical approaches to the anthropology of warfare. The theories currently being advocated were grouped under three components—material causes, efficient causes, and consequences. Material causes included physical environment and social structure; efficient causes included goals of war and military preparation; and consequences comprised effects on social organization, survival value, and origin of state. Theories that are no longer advocated strongly were divided into causes and effects. Causes included innate aggression, frustration-aggression, diffusion, and cultural evolution. Effects included effect on species, ethnocentrism, acculturation, ecological adaptation, and patterns and themes.

Vayda (1961) argued that a community that becomes overpopulated will move into unoccupied areas or take over land of communities that are militarily weak. A major proponent of ecological theories of warfare, Vayda initially looked at warfare as an adaptive mechanism leading to equitable distribution of resources, thus focusing on material causes of war. Later, he looked at purposeful human behavior in its context, which is classified under theories on efficient causes of war. Otterbein (1994) contended that causes of rape, feuding, and internal war were to be found in social structure, and this is a material cause. He pointed out that the efficient causes of war were to be found in the goals of war, and these were usually economic, for example land to obtain land and plunder. Otterbein also examined the third component of the theories of war, consequences or outcomes of war. This included different types of wars, casualties, and changes in territorial demarcations. Later, he came up with a unified theory of feuding and warfare that combined the various theoretical approaches to warfare.

The unified theory tries to bring together the structural and ecological approaches to the causes of war. According to this theory, groups in a region compete for the same resources. This becomes their goal of war. In the case of natural disasters or population growth, people from the areas that have a shortage of resources will attack those with greater resources. Smaller groups that are defeated can form political alliances to become stronger. Thus, social structures merge as a mode of ecological adaptation.

On the other hand, groups that have achieved a high level of military sophistication will try to conquer the weaker groups—both within their region and outside. This therefore reduces competition, expands their territories, and increases their population (Otterbein, 1994).

Examining the evolution of warfare and violence in the northwestern coastal region, including areas between the Pacific Ocean and the coastal ranges of the mountain systems of northwest North America, Maschner (1997) noted that the people of the area had one of the most aggressive forms of organized conflict among hunter-gatherer societies. According to Maschner, the first evidence of conflict in the region dates from at least 3000 BCE, and the injuries were found to be mainly nonlethal. By 200 to 500 CE, a shift in violence and warfare was evidenced by the construction of defensive areas, conglomerations of villages, and a decline in population. By 900 CE, a great increase in the construction of defensive sites was evidenced. Maschner also pointed out that despite a decline in population, the early 19th century saw a rise in conflicts in the area that brought into question the material explanation of warfare and demonstrated that the region had a long history of war.

Views of Ancient Greek and Roman Philosophers

The first Western writer to address the issue of morality in warfare was Thucydides (460–400 BCE) in *The Peloponnesian War*, which contained the historical account of the war fought between Sparta and Athens in 431 BCE (Reichberg, Syse, & Begby, 2006). In *The Peloponnesian War*, the Athenians said to the Melians, a colony of Sparta that refused to submit to Athenian rule, that right was an issue only between those who were equals in power, not between the strong and the weak; the strong could do what they wanted while the weak had to suffer (Strassler, 1998). When the Melians questioned how it would be good for them to serve while the Athenians ruled, the Athenians replied that it would save them from worse sufferings, and the Athenians would gain without having to destroy the Melians. The Peloponnesian war finally ended with the defeat of Athens and the establishment of Sparta as the leading military power in Greece (Strassler, 1998).

Plato (427–347 BCE) wrote little about war, but he believed that to have peace, it was important to be prepared for war. He emphasized that the right kind of education must be imparted to the soldiers so that decisions about when to wage war could be prudent and well guided (Reichberg et al., 2006). Subsequently, Aristotle (384–322 BCE) was critical of the organization of Sparta's political life being geared toward war. According to Aristotle, military power should not be an end in itself but must be a defensive tool to maintain peace. Aristotle berated tyrannies for being more predisposed to violent conflicts than other forms of

government and suggested that leaders must be properly trained in statecraft (Barnes, 1984).

In ancient Rome (7th century BCE–1st century CE), decisions to wage wars were taken by priests or *fetiales* who were essentially responsible for maintaining peace, and a war was considered just if it was carried out in accordance with the religious laws; these were usually in the form of lawsuits (Watson, 1993). Roman statesman Marcus Tullius Cicero (106–43 BCE) was one of the first thinkers to voice the need for developing a legal and normative structure for war and insisted that war should be undertaken only with the objective of peace (Reichberg et al., 2006).

Crusades and Just Wars

Crusades are holy wars fought for the defense of religion. Reichberg and his colleagues (2006) identify at least seven crusades—or Christian holy wars or medieval wars—that were fought against the Muslims between 1095/1096 and 1274 for the liberation of Jerusalem and the holy sepulcher, which is Christ's grave. They contend that the crusades failed to uphold Christian virtues and remained at best a mixture of religious ideals and experiences of brutal violence suffered by the people. Similarly, Muslim holy wars are fought under the concept of *jihad*. Innocent IV, who was the Pope from 1243 to 1254, wrote commentaries on the contemporary papal legislation known as Decretals, which highly influenced Thomas Aquinas (1225–1274) in his development of the concept of the just war (Reichberg et al., 2006). In his Decretals, Innocent IV wrote that the Pope could legitimately take steps to recover and defend the holy land that had been taken over by the Muslims, while also protecting all the faithful inhabitants, but mentioned that the property rights of infidels in other jurisdictions must be respected (Innocent IV, 1535/2006). He argued that the holy land was won in a just war by the Roman emperor after Christ's death, and so it was legitimate for the Pope to take it back from the infidels (Innocent IV, 1535/2006).

Thomas Aquinas wrote that holy wars are to be waged against unbelievers not to convert them to Christianity but to prevent them from obstructing the Christian faith. As for those who had once accepted Christianity and do not believe any more, they should be compelled to keep the faith as they are obligated to do so once they have accepted it by exercising their free will (Aquinas, 1268–1271/1920). The key criteria—princely authority, just cause, and right intention—identified by Aquinas for resorting to armed force in a just war are followed even in today's world (Reichberg et al., 2006). On warfare and violence, Niccolò Machiavelli (1469–1527) wrote in his book *The Prince* (1532/1985) that war was just if it was necessary, that arms were pious if there was no hope in anything else, and that the end justified the means.

Global Conflicts and the World Wars

New patterns of violence and warfare around the world can be attributed to European contact with indigenous peoples and Europeans' territorial expansion as they built their empire across the world and formed colonies (Ferguson & Whitehead, 1992; Rosman & Rubel, 1999). Ferguson and Whitehead (1992) identified three types of responses by the indigenous peoples in the form of warfare as a result of the changes around them: (1) wars of resistance against the state, (2) indigenous peoples enrolled in the armed forces of the states, and (3) war among different factions of the indigenous population as they responded to the changes around them. Before European invasion of the world, the balance of power was maintained among the various groups that took to war. However, since Europeans focused on expanding their rule, power was concentrated in their hands. They also introduced more advanced weapons like guns and had more resources (Rosman & Rubel, 1999).

The island of New Ireland, a part of Papua New Guinea, had its first European contact in the 1880s. This was marked by violent conflicts and intense fighting, which was then accelerated by the introduction of guns and iron axes. In 1884, New Ireland became a German colony as part of German New Guinea. Although it started out as a commercial enterprise, the German government soon took administrative control of the region (Rosman & Rubel, 1999). Although weapons were a major factor in the dramatic escalation of violence and warfare in New Ireland from 1880 onward, Rosman and Rubel (1999) suggest the main factor was the imbalance that was caused by the interference of Europeans in the hostility equation between traditional enemies in the area. Prior to European contact, the indigenous communities around the world had traditional enemies and allies maintaining a balance of power in the region, and so no single group was able to seize power or be in an advantageous position for a long period of time. With European contact, the goal of warfare also changed to control of strategic resources in the region (Rosman & Rubel, 1999).

A similar situation can be seen in Somalia, where the population is divided into several small clans. European contact (colonized by Britain, Italy, and France) gave more powers to some clans recognized by the colonial governments and given stipends (Lewis, 1965). This led to the disruption of the balance of power in the region. After Somalia achieved independence in 1960, these clans emerged as political parties, and the balance of power continued to be disturbed with those in high political positions favoring their clansmen while harassing those from other clans (Rosman & Rubel, 1999). Later, during the Cold War, both the United States and the USSR gave large amounts of weaponry to Somalia, further upsetting the stability in the country. Colonialism unleashed long periods of impoverishment, violence, and conflict in diverse places like India, South Africa, Algeria, and Ireland, and at the present time in Rwanda, Bosnia, and Palestine (Sáenz, 1999).

World War I (1914–1918) was a global war that began in July 1914 with Austria-Hungary declaring war on Serbia. Soon, Britain, France, Belgium, Russia, Serbia, Japan, Italy, and the United States were fighting against Austria-Hungary, Germany, the Ottoman Empire, and Bulgaria. The Great War utilized the powerful weapons that had been invented in the 19th century with heavy gunpowder, artillery, and machine guns; all products of a machine age, these transformed the war into one never seen before—of mass slaughter, death, and carnage, with the dominant cultural image being one of collective ravage and plunder rather than celebration of individual heroism. As the war progressed, aircraft were used strategically to bomb the enemy and destroy vital areas where war arrangements were being made. Aerial bombing had a momentous impact on industrial societies, which were particularly vulnerable (Lawrence, 1997).

By the end of the World War I, the French had lost 1,700,000 men, Germany had lost 2,000,000 men, and the British had lost 1,000,000 (Keegan, 1993). The United States lost 48,000 men in battle and 56,000 from disease (Leuchtenburg, 1958). The war brought about a strong sense of gloom in modern times as thinkers began reflecting on the meaninglessness of modern life and the futility of war, while questioning the possibility of progress that was brought about by the Industrial Revolution. With severe slaughter by machines going out of control and a strong sense of human alienation, World War I turned Europe into a “real charnel-house” (Lawrence, 1997, p. 58). The war ended with the signing of the Treaty of Versailles in June 1919. The League of Nations was created as an international organization to prevent future wars. However, it proved to be a failure as World War II began in 1939.

The Treaty of Versailles resulted in Germany losing parts of its territory. In 1935, Germany under the leadership of Adolf Hitler repudiated the Treaty of Versailles and in 1938 annexed Austria. In 1939, Germany and Hungary occupied Czechoslovakia. While Germany began raiding British cities in 1940, Britain retaliated with aerial attacks that lasted for the next 5 years even though these bombings lacked precision (Lawrence, 1997). Massive raids were carried out in German cities, affecting civilians beginning in 1942. In December 1941, the Japanese Navy attacked the U.S. naval base at Pearl Harbor, Hawai'i. There were two waves of aerial attacks launched by Japan that led to severe destruction of U.S. naval battleships and loss of personnel. This led to the United States joining World War II in 1941. World War II, which began in 1939 and ended in 1945, was divided into two military factions, the Allies and the Axis. The Allied countries were the British Empire, the Union of Soviet Socialist Republics, the United States of America, China, Poland, and France. The Axis countries were Germany, Italy, and Japan.

World War II ended in the defeat of the Axis powers. The Western countries mercilessly used air power and technology to their benefit, killing hundreds of thousands

of civilians by strategic bombing (Lawrence, 1997). The United States dropped atomic bombs developed by their scientists on two Japanese cities, Nagasaki and Hiroshima, in early August 1945 causing complete destruction of the cities and crushing Japan. Surrender by Japan on August 15, 1945, finally ended World War II. After World War II, the United States and the USSR emerged as the two superpowers and the Cold War continued between them until the early 1990s when the USSR was dismantled. The United Nations, an international organization, was established in 1945 to maintain world peace and security.

Genocides

Traditionally, anthropologists were neutral and dispassionate observers of the human condition, not influenced by politics, and therefore kept away from issues like genocide and state-perpetrated terrorism (Scheper-Hughes, 1995). However, recently, genocide has been of interest to certain forensic anthropologists who have made important contributions to the field (Jones, 2006). Anthropologists are now studying areas that were under siege or affected by violence and insurgency rather than just looking at small, stable communities (Hinton, 2002). While studying genocides, anthropologists examine local and cultural dynamics and try to understand factors that lead to such terroristic actions (Jones, 2006).

The term *genocide* was coined by Raphael Lemkin (1900–1959), a Polish-Jewish jurist and refugee from Nazi-occupied Europe. Genocide involves the deliberate destruction of an ethnic group or nation based on their collective identity (Jones, 2006). The United Nations defines genocide as any act including killing members of a group, causing serious bodily or mental harm to members of a group, taking measures to bring about the destruction of a group, or preventing births within a group or forcibly transferring children to another group, done with an intent to destroy a national, ethnic, racial, or religious group.

Rome's siege of Carthage toward the end of the Third Punic War (149–46 BCE), where 150,000 Carthaginians out of a population of 200,000 to 400,000 were wiped out, has been regarded as the first genocide (Kiernan, 2004). Later in the 13th century, Mongolian horsemen under the leadership of Genghis Khan invaded vast territories, exterminating entire populations in search of wealth. In France, following the execution of King Louis XVI in 1789, the new revolutionary government in Paris was faced with opposition and revolt in the Vendée with a rise against the government. As a result, all inhabitants of Vendée, including children, were slaughtered by the government; the death toll was estimated to be 150,000 by 1796 when the genocide waned. Another instance of genocide was the one perpetrated by the Zulu kingdom in Africa. Under the leadership of Shaka Zulu, between 1810 and 1828, large-scale annihilation of populations was carried out in an

attempt at expansion. While Shaka took all the men to increase the strength of his army, he destroyed women, children, and old people, as they were useless to him (Jones, 2006).

Europeans, for over five centuries, have taken genocidal measures in the Americas against the native indigenous population. Jones (2006) describes this as the "most extensive and destructive genocide of all time" (p. 70). The Spanish invasion and occupation of large parts of Latin America in the late 15th century led to the extermination of tens of thousands of native Indians, as the invaders slaughtered men, women, and children alike. Those not killed this way were worked to death in gold mines, reducing the population of a Caribbean island (present-day Dominican Republic and Haiti) from 8 million to 20,000 in 30 years. Soon the Spanish invaders massacred native populations in Mexico, Peru, Bolivia, and Ecuador; a vast majority died as a result of poor working conditions in mines where they were forced to work (Jones, 2006). Besides bringing in diseases that caused a demise in the native Indian population in North America, Europeans began the first genocidal war (the Pequot War, 1636–1637) in present-day Connecticut as an overreaction to a Native American raid, exterminating hundreds of Indians. Several more such wars were to follow in the coming years. The Yuki Indians of California were reduced from an original population of 20,000 to 168 by 1880 (Jones, 2006). In Guatemala, a military coup overthrew the reformist president in 1954 and started military rule. In the 1970s, a guerrilla army rose in revolt against the military regime to which the military reacted with a holocaust that befell the Mayan highlands. Within a span of 6 years, 440 Indian villages were razed and 200,000 Indians tortured and killed. Forensic anthropologists in Guatemala studying exhumed victims in recent years have given significant input in determining that the mass slaughter carried out by the military in Guatemala against the Mayan Indians was indeed genocide (Jones, 2006).

Both the Aborigines of Australia and the inhabitants of Namibia, at the hands of Britain and Germany, respectively, suffered fates similar to that of the Native Americans. The Aboriginal population in Australia was 750,000 when the British colonists first arrived in 1788, and was reduced to 31,000 in 1911 (Jones, 2006). In addition, German colonists almost exterminated the Herero nation in Namibia. German colonists arrived in 1903 and began pushing the native people out of their territories. In 1904, the Hereros rose in revolt against the Germans, killing 120 Germans (Jones, 2006). Another tribal nation, the Namas, also revolted against the Germans. The Germans crushed both the Hereros and the Namas, killing almost half their population. In 2004, 100 years later, the Germans formally acknowledged the genocide and apologized to the people of Namibia, offering development aid after the Hereros filed a suit in the United States for \$4 billion in compensation from the German government and German companies who profited from those lands (Jones, 2006).

The first truly modern genocide was the Armenian holocaust, where over a million Armenians were killed in Turkey between 1915 and 1923. In April 1915, the Turkish army assaulted Armenians, who were Christians, as opposed to the Turkish, who were Muslims, and who were thus seen as supporters of Russia, Turkey's enemy in World War I. On April 24, 1915, hundreds of Armenians were imprisoned and later killed, or tortured to death (Jones, 2006). Some Armenians were stripped of their arms and made to work until they died; others were shot in cold blood; 200,000 Armenians were exterminated in this way by July 1915 (Jones, 2006; Mann, 2005).

In Russia, during the Russian Revolution, Lenin's Bolshevik party, which followed the Marxist socialist ideology, seized power, overthrowing the tsarist regime in 1917, and founded the Soviet Union. Stalin was appointed the general secretary of the Communist party. After Lenin died in 1924, a struggle for power ensued and Stalin successfully became the Soviet leader in 1928. The Bolsheviks hated a class of peasants called the kulaks, as they were seen as slightly better off than the others (a peasant who owned just a cow or hired a helper would be labeled a kulak) (Jones, 2006). The Soviet regime forced the kulaks onto collective farms. Thousands of heads of families were shot and killed; over a million were sent to concentration camps with most of them dying on the way (Jones, 2006). The number of inmates in the concentration camps rose from 212,000 in 1931 to almost a million by 1935; about 2 million kulaks were sent on internal exile to distant corners of Russia (Applebaum, 2004; Werth, 1999). After destroying the kulaks, the regime next started the practice of forced collectivization and grain seizures, resulting in widespread famines in Ukraine, the Volga region, Kazakhstan, and other territories (Jones, 2006). Between 1930 and 1933, 5.7 million people are estimated to have died from famine in the USSR (Jones, 2006). According to Werth (1999), 4 million of these victims were Ukrainians.

The Jewish Holocaust, the most well-known genocide, took place between 1941 and 1945; in it, 5 to 6 million Jews were systematically exterminated by the Nazi regime in Germany (Shermer & Grobman, 2002). The Nazi Party was founded by Adolf Hitler and his colleagues, and Hitler, a decorated veteran of the First World War, envisioned German domination over all of Europe. Hitler also had an extreme hatred for Jews, who had allegedly rejected and killed Jesus Christ. Hitler became the chancellor of Germany in January 1933. Once in power, he began a systematic boycott of the Jews in Germany, forcing large numbers of Jews to flee the country. In November 1938, several Jews were killed, and about 30,000 male Jews were rounded up and put in concentration camps, while hundreds of thousands of Jews were confined in ghettos with the intent of genocide (Jones, 2006). In 1941, following the German invasion of the Soviet Union, 1.2 million Jews were rounded up and killed by point-blank rifle fire (Rhodes, 2002). The Germans then came up with the idea

of the death camps, in which the victims were killed in gas chambers, thus allowing a distance between the killers and the victims. In Auschwitz, 1.25 million Jews were killed this way (Jones, 2006).

Other known genocides were carried out in Cambodia by the Khmer Rouge (1975–1979), in Bosnia and Kosovo (1998–1999), and in Rwanda (1994). In Cambodia, between 1975 and 1978, the ruling party at the time, the Khmer Rouge—composed of communist revolutionaries—carried out a spree of killing all those who were perceived as their enemies in Cambodia. Approximately 1.9 million people, constituting about 24% of the Cambodian population, died during this period (Jones, 2006). The Khmer Rouge imposed forced labor and conducted mass executions and internal purges similar to those in Stalin's Russia. In 1989, the Serbs, under the leadership of Slobodan Milosevic, started repressive measures in the Albanian-dominated province of Kosovo, throwing thousands of Albanians out of jobs. Kosovo's Albanians revolted with guerrilla warfare from 1998 through 1999, leading to the killing of about 10,000 ethnic Albanians by Serbs and the mass deportation of about 800,000 Kosovar Albanians to Albania and Macedonia. In February 1992, when Bosnia-Herzegovina declared independence from Yugoslavia, Bosnian Serbs broke free. Wars ensued, with the Bosnian Serbs persecuting the Bosnian Muslims. Muslim men and some women were detained in Serb concentration camps where thousands died in conditions similar to the Nazi concentration camps. In Rwanda, about 1 million Tutsis were killed in 1994 by the Hutu regime within a span of 12 weeks (Jones, 2006).

Internal Conflicts and Terrorism

Internal conflicts are violent, armed clashes that are a result of domestic political disputes including power struggles, ethnic conflicts, secessionist movements, and revolutions; they range from guerrilla warfare and terrorist attacks to civil wars and genocide (Brown, 1996). Brown (1996) identified five reasons internal conflicts are important: (1) They are widespread, (2) they cause extreme suffering, (3) they usually involve neighboring countries, (4) they weaken the stability of the region, and (5) they might draw the attention of international organizations and countries farther away as their nationals might be in the affected regions. The international community is now taking an increasing interest, and efforts are on to handle these issues as they take on international dimensions. Reviewing the scholarly literature on internal conflicts, Brown identified four different clusters of factors that were responsible for causing internal conflicts: structural, political, economic/social, and cultural/perceptual. Structural factors include weak states, intrastate security concerns, and ethnic geography; political factors include discriminatory political institutions, exclusionary national ideologies, intergroup politics, and elite politics; economic/social factors include

economic problems, discriminatory economic systems, and modernization; and cultural/perceptual factors include patterns of cultural discrimination and problematic group histories.

An example of the political factors can be seen in India, a political entity that was artificially created as a result of British colonialism, and as such, the different parts of India are constantly trying to secede. This has been accentuated by the perception that while the interests of some groups of the population are catered to by the central government, certain ethnic groups and states that are further away from the center resent the neglect shown to them over the years, resulting in the mushrooming of armed insurgent groups (Barua, 2006). Spear (1996) has suggested that availability of weapons has not only been a proximate and permissive factor in armed internal conflicts, but also a way to maintain and intensify these revolts. Around the world, internal conflicts have also begun between the government and insurgent or rebel groups (see Barua, 2006; Brown, 1996).

Terrorism drew the world's attention on September 11, 2001, when Al Qaeda attacked the twin towers in New York City and the Pentagon in Washington, D.C. On November 26, 2008, terrorism raised its ugly head once again, drawing the world's attention when Mumbai, the financial capital of India, was in the grip of terrorists for 4 days, resulting in the deaths of 188 people, including 22 foreigners. This technique of inflicting mass killing both in the United States and in other countries poses an urgent need for the international community to quell this threat.

Conclusion

Ancient Greek and Roman philosophers professed that being prepared for war is the way to ensure peace. However, with Al Qaeda carrying out its holy war in terror attacks around the world, the war is already on. The United States, under the presidency of George W. Bush, started the "war on terror," attacking Iraq and Afghanistan in an attempt to wipe out terrorists (although terrorists generally do not indulge in "conventional" war on the battlefield, making it extremely difficult to contest them). After two world wars, the United States was engaged in a Cold War with the USSR until the Soviet Union was dismantled in the early 1990s. In this millennium, the United States is invested in a war against terrorism.

An examination of the anthropology of warfare suggests that the current violence and warfare in the form of internal conflicts and global terrorism can be classified under all three clusters of theories as categorized by Otterbein (1994): material causes, efficient causes, and consequences. Material causes include physical environment and social structure. In this case, the rebel groups and terrorists are attacking the physical environment in an attempt to dismantle the current social structure against which they have grievances. Efficient causes include goals of war and military

preparation. Here, the rebel groups and terrorists are trained militarily in the use of firearms and sophisticated bombs, with their goals of war being to have their demands met; draw attention to their issues; and, in the case of *jihad*, convert people into believing in their religious ideals. Consequences include effects on social organization, survival value, and origin of state. Dissatisfied with the current social organization and afraid of losing their ethnic identities, several secessionist groups around the world are demanding their own separate states or countries.

Otterbein's (1994) unified theory of war, where structural and ecological approaches reconcile, suggests that it is time for a new kind of ecological adaptation, in which the established social structures that are present in the form of nations combine and achieve the highest possible level of military sophistication and make the defeat of terrorism a universal goal. The United States is already showing support to India and talking with Pakistan to end the reign of terror. The day may not be far off when the forces that are creating havoc around the world will be quelled as a result of the ecological adaptation of the affected nations.

PART XIV

ANTHROPOLOGY TODAY

FOLK CONCEPTS

JAY H. BERNSTEIN

Kingsborough Community College, City University of New York

Anthropology is strongly concerned with conceptual analysis in that a large part of its purpose is to penetrate and interpret cultural meanings. Unlike philosophy and psychology, both of which devote considerable attention to theories and techniques for studying concepts (which may be defined as “units of thought”), anthropology’s approach to concepts stresses cultural particularities or contingencies rather than universals. Anthropology’s distinct contribution to conceptual analysis lies in its method of eliciting concepts and meanings from people through participant-observation, which ideally involves extended and fully committed absorption into their community, during which the anthropologist not only conducts formal interviews but also aims to learn a culture at a personal level by observing and participating in community life.

This methodology, along with anthropology’s intellectual heritage in studying traditional, often nonliterate societies, makes the anthropological approach highly suited to the study of folk concepts. A folk concept is a notion that has a general, popularly understood meaning particular to a sociocultural grouping, but which has not been formally defined or standardized. Folk concepts are encoded in discourse, nonverbal behavior, and social practices rather than in published texts (such as newspapers, magazines, or books) or other media. They could, however, arise from folk interpretations of texts or other media. Folk concepts and other kinds of concepts penetrate each other in many

ways. For example, the practice of saying grace before meals may combine culturally specific folk practices with textually based religious teachings. The important point is that ethnographers discover and interpret folk concepts based on the study of human behavior rather than on texts. Once folk concepts are recorded in writing or other media, they are no longer undocumented; but unless such documentation causes a change in meaning and affects the way people know the concept, they remain folk concepts.

The folklorist Alan Dundes uses the term *folk ideas* and defines such ideas as “traditional notions that a group of people have about the nature of humanity, the world, and life in general,” “unstated premises which underlie the thought and action of a given group of people” (Dundes, 2007, p. 185). They are “part of the unconscious or un-self conscious culture of a people” (Dundes, 2007, p. 189). Such folk ideas are the building blocks of a worldview. Since people are not fully conscious of them, they must be “extrapolated” from folkloric data. Dundes overlooks the fact that many unstated traditional notions underlying thought and action do not directly concern the nature of humanity, the world, or life in general, but are significant only in some more limited sphere of life.

Folk concepts may be embedded in oral tradition or spoken discourse, but it is important to realize that many concepts are not verbalized, for example, knowledge about making craft items or tying knots, or the practice of saluting the flag as a sign of respect for the country. Since interviews

are carried out in language, nonverbal concepts are more difficult to interrogate than verbal concepts, and thus, they present a special challenge for ethnographers.

Emic Versus Etic and Related Distinctions

The emic/etic distinction refers to the distinction between the subjective or internal viewpoint on the one hand and the objective or external viewpoint on the other hand. This distinction, which can be most simply glossed as “insider” (emic) as compared to “outsider” (etic) outlooks, has been pondered by many anthropologists, most notably Kenneth L. Pike (who coined the terms) and Marvin Harris, and it underlies much anthropological work (Headland, Pike, & Harris, 1990). It is useful in locating the position of folk concepts in anthropological inquiry. Folk concepts are *emic*, meaning that they represent the insider’s viewpoint. The concepts anthropologists use to ground their inquiries come from an external perspective. The external perspective is called *etic*. Etic concepts are also objective, scientific, and operational, and they may yield measurable and falsifiable data. The etic perspective concerns behavior rather than folk concepts. But the etic approach is usually the starting point for the effort to elicit and explicate emic folk concepts. The emic/etic distinction underscores the need to differentiate between observed realities and informants’ statements. This does not mean that etic data are more important than emic data. Both approaches are needed in field studies, and they provide complementary data. Emic analysis of concepts is the linking of concepts to other concepts in a domain. Etic analysis is the linking of concepts to behavior and to outcomes.

Emic concepts emerge from data that are obtained initially through etic inquiries. For example, an anthropologist studying folk concepts concerning property will begin with anthropological notions about the characteristics and associations of property, such as those defined in detail in *Outline of Cultural Materials*, published by the Human Relations Area Files (Murdock, 2004). The starting definition of property must be shared by other researchers and based on objective characteristics. By asking questions about property in a vernacular language, it is possible to work up folk concepts about property in vernacular terms. These notions and definitions may express ideals, such as norms for the inheritance of real property. By observing transactions, the ethnographer may see how much these concepts guide behavior and whether actual behavior diverges from definitions and concepts. Descriptions of actual behavior pertaining to property (as locally defined) use etic terms. Emic data concerning unstated assumptions about property are treated to both emic and etic analysis.

Emic and etic knowledge are parts of different models of reality. Rappaport’s distinction between the cognized model and the operational model of reality is identical to the emic/etic split. The operational model includes

elements of which the actors are unaware (such as microorganisms and trace elements) but which affect them in important ways. The cognized model, on the other hand, may well include components, such as supernaturals, whose existence cannot be demonstrated by empirical procedures, but whose putative existence moves the actors to behave in the ways they do. (Rappaport, 1979, p. 98)

Related, too, is the distinction made between beliefs and knowledge, since knowledge is that set of beliefs that are objectively true, universally applicable, and can be verified empirically. In the context of health, for example, *knowledge* might refer to concepts such as the role of the mosquito in causing malaria, while *belief* might refer to ideas about malaria being spread by “bad air” or “miasma.” In environmental anthropology, too, there is a movement to document indigenous knowledge, which refers to factual, empirical knowledge of the environment and means of managing resources and to a differentiation between belief and knowledge.

Calling something a belief rather than an instance of knowledge suggests an etic perspective and implies that the phenomenon or statement represents something that is untrue or does not exist. The term *folk belief* suggests that something is erroneous and a potential obstacle to development. For example, thinking that a child’s illness is caused by a spirit attack may induce parents to seek help from a spiritual healer rather than a clinic. Pelto and Pelto (1977) pointed out that differentiating between knowledge and belief based on truth value puts the ethnographer in the uncomfortable position of having to judge whether a belief is true or not, whereas the ethnographer’s focus should be on the relationship between belief/knowledge and practice. For this reason, Pelto and Pelto think it may be useful for ethnographers to lump belief and knowledge into a single notion, belief/knowledge. To the extent that one wishes to emphasize that a folk belief is false, one might call such a belief a *folk fallacy*, as Dundes (2007) did. Other anthropologists, like Ellen, Parkes, and Bicker (2000), want to emphasize the content of folk concepts as practical knowledge.

Yet another important distinction of interest to anthropologists studying concepts is between cognition and affect. Belief and knowledge refer to the cognitive side. Affect refers to the emotional charge and associations that may involve the five senses. The affective side includes opinions, attitudes, and levels of emotional commitment to or rejection of something. To the extent that a folk concept has any affective dimension, part of conceptual analysis is to uncover that aspect.

The Ethnographic Method

Ethnography, the chief methodology of cultural anthropology, combines interviewing with observation and participation. The ethnographer is usually an outsider, and in many cases ethnography proceeds without an exact plan;

or, if there is a plan, then it is revised or even scratched as one discovers salient topics. Ethnographic research is often undirected (at least at first), because it may be impossible to know in advance which areas will come into focus. The informal, ad hoc quality of ethnographic research permits flexibility to focus on problems of which the ethnographer was initially unaware and to constantly revise and adapt techniques of inquiry. Through the discovery of salient concepts, the ethnographic project of explaining these concepts in depth emerges.

The ethnographic method generally aims for total cultural immersion, participation, and observation in addition to interviews and any other measures or tests. To the extent possible, and depending on the topic, the ethnographer lives in the community under investigation and thus can observe or join in activities whenever they occur, rather than going by the ethnographer's schedule. The practically unattainable ideal of total immersion underscores the goal in anthropology of accounting for the total culture.

The ethnographer begins with conversations and the informal asking of questions, and only later moves on to more formal methods. One of the first considerations is to establish relationships with interview subjects (informants) who will be sources of information throughout the study. Depending on the needs of the study, a sample representing different constituents of the community needs to be recruited. In any case, it is important to have good demographic data (age, sex, marital status, etc.) and to link all interview data to informants. Typically, a few informants will stand out as persons who can help explain data obtained from other informants. Some informants may stand out as "experts" in a given domain (hunting, for example). In such cases, it is useful to know by what standard the person is an expert and whether many others in the community agree with such an assessment. The variation in knowledge among individual persons, for example between experts and laymen, can be tested by using structured interviews. Garro used illness terms she had previously elicited and sentence frames ("Does ____ come from eating lots of 'hot' foods?") to examine consensus and variation in knowledge (or belief) between curers and non-curers in a Tarascan village.

Choice of informants is an important part of ethnography and needs to be analyzed rather than taken for granted, since informants are rarely selected randomly in a community study. One should check how representative of the community an individual is. One way to do this is to work with a broad variety of persons along with one's key informants.

Concept Elicitation

The goal of ethnography, as far as the study of folk concepts is concerned, is to explain how these concepts are understood and used by participants in their context of action and in relation to other concepts. Before they can be analyzed, concepts first must be identified. In a naturalistic

setting, concepts may come to the ethnographer's attention without direct interrogation. Once these concepts have been discovered and identified, the ethnographer can develop hypotheses about them that can be tested through interviews or conversations with informants.

For topics that rarely come up in normal conversations, it is possible to start with interviews only if one already knows which concept one wants to study. Naomi Quinn (2005), who studied American folk concepts concerning marriage and commitment, used such an approach. As an American woman, she already knew a great deal about her chosen topic. But her interviews were open-ended and undirected, with the only directive being that interviewees talked about their marriages. From these interviews, a small number of themes emerged that Quinn analyzed as metaphors.

Quinn used interviews to elicit information that would come out in ordinary talk but where regular participant-observation was not feasible, since marriage is not a subject that ordinarily comes up in public discourse. Interviewers took note of keywords and phrases used by interviewees along with paralinguistic and kinesthetic cues. They let interviewees talk with a minimum of interruptions or questions, with the hope of getting people to open up about their reasoning processes as shown in notions about cause and effect. Afterward, they guided each subject through a checklist of questions about all aspects of marriage in general, and their own marriages in particular, that had come up in the previous interviews.

In such an approach, concepts emerge through conversation and the informal asking of questions. The informal approach moves to a more formal method when terms or expressions are compiled that encapsulate what the ethnographer thinks are concepts, and interview subjects (informants) are asked questions about each term. In taking notes on the interview, the ethnographer records observations about nonverbal behavior as well as verbal answers. In many cases, it is useful to obtain information on affect and personal experiences relating to a concept.

Part of elicitation, beyond casual interviewing, is to get at those aspects of concepts that are below the surface of consciousness. Complex concepts are not explained just through words; one is informed about them through observation, practice, and sometimes participation. Anthropologists must strive to maintain objectivity in documenting not only their informants' subjectivity but also their own in this learning process, accounting for the effects of their presence in the mix.

The ethnographic method is chiefly descriptive and observational rather than experimental. However, certain experiments can be done with informants by having them perform a certain task or respond to a list of questions. The more formalized an ethnographic approach is, the closer it approximates experimental science procedures. An example of a semiexperimental approach is to have an informant name every plant he knows, while counting the number of

plants he cannot name within a circumscribed plot of land (Bernstein, Antaran, & Ellen, 1997).

A methodological problem is that a vocabulary is needed to elaborate a concept, even though the concept may not be a verbal one. For example, concepts about food involve the five senses as well as actions and behaviors involving food preparation, storage, eating, and so forth. The terminology of food may not reflect the full richness of the concepts. Yet, this vocabulary is an opening-up point for interrogation about food concepts.

Holy and Stuchlik (1983) maintained that the study of folk concepts (“notions”) is rather straightforward in terms of data collection but that the interpretation of these notions poses problems in terms of relating them to actions. People use and know about many concepts that they cannot define. The concepts’ meanings are obscure and inscrutable, even though they are used in actual practice. These complex concepts may be “fundamental notions.” Boyer (1990) gave as an example in the Fang concept of *evur*, which is generally glossed as “witchcraft substance” or “witchcraft organ” but which he says is far more complex, since “people have extremely vague views on what *evur* actually consists of and the mechanism of the action” (p. 26), even though they are clear about the effects of *evur* and the social relations revolving around *evur*-related actions. Boyer finds that these vague kinds of concepts, which he considers “vacuous,” tend to be the focus of traditional symbolism and practices. He notes that there are three kinds of discourse in which such concepts occur: common discourse, gossip, and expert discourse; only the last is both definite and reliable. Most people use such a concept and its verbal label without knowing what it really means. The same can be said about technical knowledge that is not mystified: For example, people use notions of electricity and telephony without knowing or understanding the science and technology underlying them. The “anthropology of experience” (Turner & Bruner, 1986) takes into account the processes by which concepts are learned and the feelings associated with learning and transmitting them.

When starting research, the ethnographer knows neither the criteria nor the limits of a domain. The “free listing” approach can be used to elicit terms that can provide information on the domain. By asking different kinds of informants to list all the kinds of X they know, it is possible to determine the salience of certain items and how knowledge of them is distributed within the society. This may help the ethnographer map the concept. More formal analysis can be used to determine the perceived similarities and differences between terms within a conceptual domain using sorting. Through successive sorts, it is possible to discern the clustering of data into taxonomies (Weller & Romney, 1988).

Informal interviews can be used to ask about the extent of a concept. In asking about spirits, for example, one might ask the informant to name every spirit known to him or her, along with the spirits’ attributes and locations and any other information about them. If the ethnographer can

obtain a comprehensive list using this technique, then the process is reversed by asking informants about each item (in this case a spirit entity) on the list. Such a method, when given to a range of informants, will provide a sense of the extent of a concept in its domain.

Symbolic and Cognitive Anthropology

A focus on cultural meanings spawned movements in cognitive and symbolic anthropology, both of which led theoretical developments and ethnographic practices in the 1960s and 1970s. Present approaches to the anthropology of folk concepts and meanings are descended from these earlier schools of thought. (Indeed, certain anthropology departments were closely identified with either cognitive or symbolic anthropology.) Cognitive anthropologists zeroed in on language usage, but their aim was to uncover the classificatory principles such as taxonomies and paradigms underlying identifiable domains such as property, kinship, or the spirit world. While the terms just used are etic, cognitive anthropologists sought to lay bare emic domains using linguistic models. Cognitive anthropologists viewed ethnographic description as specifying what one needs to know in order to function appropriately within a given role in a society as well as what is appropriate knowledge for behavior.

Agar (1966), a cognitive anthropologist, advised that to obtain information on folk concepts, one should get informants to contrast terms or sort them into categories or give them values (e.g., numbers on a scale, rank order based on a given criterion). The field of meanings of concepts is based on relations between terms. For example, A is a kind of B, A is used for B, A is part of B, A is a process of B. Questions are asked in the form of a frame, a sentence with a blank word to be filled in, for example, “A _____ is a kind of car,” or “A father’s sister’s husband is called _____.”

The symbolic anthropologists had a somewhat different agenda. The field of symbolic anthropology emphasized salient concepts that were thought to symbolize other things and have pervasive meanings relating to core values and ultimate realities. A classic example is the *mudyi* (“milk”) tree, which has a variety of emotionally compelling but contradictory significations in Ndembu culture, as analyzed by Turner (1967). Pointing out that the *mudyi* tree combines two polar aspects of meaning (natural/biological and sociomoral), he identifies the *mudyi* tree as a dominant symbol. Similarly, Ortner looks for focal, master, or “key” symbols in a society. As for how we would know that a symbol is salient, Ortner provides some helpful guidelines: (1) The natives tell us X is important, (2) the natives seem positively or negatively aroused by X rather than indifferent to it, (3) X comes up in many different contexts, (4) X is culturally elaborated through vocabulary, folklore, and so on, and (5) numerous cultural restrictions surround X. The symbols of interest to symbolic

anthropologists sum up and condense pervasive cultural themes and may metaphorically extend to views about life and the world.

Early cognitive anthropology was heavily linguistic, with language categories assumed to be equivalent to conceptual categories. Subsequent anthropologists in the cognitivist tradition, such as Maurice Bloch (1998), warn against a view of cognition that relies mainly on language, and they recommend the theory of connectionism, in which thought is seen to occur in clumps with multiple interconnections working simultaneously rather than sequentially. Bloch uses such an approach to explicate Zafimaniry concepts of the person, gender, and the natural environment, arguing that this knowledge, which “goes without saying” in Zafimaniry society, is best learned through ordinary participant observation rather than interrogation. Cultural knowledge is only partly lexical and is also tactile, visual, aural, gustatory, and olfactory. This view is shared by William Merrill (1988) in his study of Rarámuri (Tarahumara) religion, particularly concepts of the soul. Merrill found that folk concepts were tacit rather than explicit and were transmitted mainly through nonverbal practices such as community events, drinking parties, and healing. Depth psychology techniques akin to psychoanalysis may also be used to elicit folk concepts that are not verbalized. Ultimately, even these techniques rely on verbal statements. As a result, some ethnographers have attempted to learn techniques themselves through apprenticeship. Such an approach seems appropriate in gaining access to knowledge about arts such as weaving, sculpting, or dance.

The nonverbalizable concept is perhaps a material object, either crafted, like the Hopi *kachina*, or occurring in nature, such as the aforementioned mudyi tree in Ndembu culture. The ideology surrounding such objects can be complex. Among the Taman, the stones used by shamans in curing patients are supposed to be neither natural nor manmade but to have been transformed from pathogenic spirits during initiation ceremonies. These stones are central to healing practices in Taman society; their individual identities are revealed to practitioners in dreams (Bernstein, 1997).

Symbolic anthropology, previously concerned with abstract and disembodied meanings, has evolved into interpretive anthropology, with an eye open to practices, embodiment, and power relations. But the notions of symbolic and cognitive anthropology have both come to seem outdated, as succeeding generations of anthropologists search for fresh approaches to cultural meanings that will avoid the shortcomings of those fields: for cognitive anthropology, an exposition of trivial domains; and for symbolic anthropology, a sense of self-indulgence and unclear demarcations between folk concepts and the ethnographer’s own ideas and interpretations. Symbolic and cognitive anthropology have at times joined forces, and both fields can be revitalized by expanding their horizons

(Colby, Fernandez, & Kronenfeld, 1981), but future research on folk concepts will probably draw on theories of meaning and knowledge originating outside anthropology.

The Breadth of Topics

Anthropology’s involvement with folk concepts has spanned the gamut from “exotic” to “mundane” topics. Many scholars have observed and complained about anthropology’s stress on peculiar, exotic phenomena in the cultures they study and particularly on the conceptual systems underlying behavior. Keesing (1985) maintained that the tendency in anthropology to translate folk concepts as nouns rather than verbs gives them a mystical aura they would not otherwise have. This has the result of attributing to people’s belief systems invisible beings and mysterious substances. Folk concepts can get reified as well, because they are considered “traditional,” which implies that they do not change over time. Ethnographic studies carried over a given stretch of time cannot show whether or not a concept ever changes.

The more exotic areas of inquiry have involved concepts of illness in which folk terms for illnesses do not correspond to a single illness as defined in scientific medicine. This is often because the principles by which illness is defined are different from those used in scientific medicine. A classic study by Frake (1961) on Subanun concepts and vocabulary about skin ailments reflected classificatory principles of diagnostic criteria and levels of specificity. Through interrogation, Frake was able to reveal the structure of Subanun concepts about these illnesses. Even more exotic are culture-bound syndromes, which are specific to certain ethnic groups. These include *amok* in the Philippines (“running amuck”), *susto* (“magical fright”) in Hispanic America, *latah* in Malaysia, and *windigo* psychosis among North American Indian tribes. Although these may be said to be psychiatric disorders, they do not translate into any standard psychiatric categories and have culturally specific, often paradoxical, symptomatologies. An illness like windigo psychosis, which involves humans who are transformed into monsters who have cannibalistic urges, can only be understood in terms of folk concepts. Other culture-bound syndromes also have bizarre characteristics: *Koro* is characterized by a fear that the genitals or breasts will retract into the body, resulting in death, and *latah* is characterized by the blurring out of obscenities upon being startled (Simons & Hughes, 1985). These illnesses raise questions not only for anthropology (in the interplay and entanglement between emic and etic) but also in psychology and psychiatry about the ability to generalize cross-culturally about psychological processes and mental illnesses.

Another classic field for the study of folk concepts is the explanation of misfortune, including illness and death, in terms of magical human causation. This is obviously

connected to the work on folk medical concepts. Many have wondered whether a belief in witches and sorcerers is rational or whether it expresses an alternative rationality. The study of the rationality of beliefs in witches led to the question of whether foreign cultures can be understood at all. E. E. Evans-Pritchard's 1937 study of witch beliefs among the Azande people of the Sudan set off a long-standing debate among philosophers about the rationality of such beliefs and the comprehensibility of foreign cultural belief systems (Horton & Finnegan, 1973; Wilson, 1970). In addition to concepts about magical causation through witchcraft and sorcery, folk concepts about time have received considerable attention (Munn, 1992). These investigations reveal folk metaphysics.

A more mundane area for investigation of folk concepts has been the area of kinship studies, with anthropologists studying the principles whereby people were reckoned to be related to one another, and the meaning of vernacular kinship terms in both theory and practice. Here, too, anthropologists have sought to define dimensions of contrast and components of meaning. Much of the main research in the "ethnoscience" tradition of cognitive anthropology used componential analysis to account for levels of contrast used to define kinship terms. Any given language's list of kinship terms is small enough that an entire vocabulary can be identified, and one can study the dimensions of contrast between terms. The study of kinship concepts extends outward toward research on concepts concerning gender, age, and interpersonal relations, and inward toward concepts of the person or self.

As with conceptual analysis itself, the concept of the person or self is most frequently approached from the angles of philosophy and psychology. Anthropologists have challenged the supposition that the concept of the self is universal, noting that it is culturally shaped in many ways. Anthropology's role in studying the concept of the person is to reveal cultural patterns in these notions. One of the first such studies was A. Irving Hallowell's (1967) work on the Ojibwa Indians. More recent work has paid attention to notions about emotions, intentionality, action, hierarchy (as in race or caste), thought, and consciousness. Some, like Howell (1989), have linked concepts of the nature of the human being to larger cosmological systems and notions about life in traditional societies.

Biographical interviews, as well as folklore and origin myths, can yield data about culturally specific senses of the self. In some theories, the self is a social construct rather than a psychological one, and in some ways, the self is culturally constituted. According to Hallowell, culture provides multiple orientations through language: self-orientation, object-orientation, spatiotemporal orientation, motivation, and norms. Concepts can also relate to interpersonal relations, as with jealousy and commitment.

Another area for investigation of folk concepts has been the understanding of the natural environment, including concepts about plants and animals—how they are perceived,

categorized, and classified. While ethnobiology includes some exotic topics, such as supernatural characteristics associated with plants and animals, it is more frequently concerned with utilitarian issues, such as the usability of trees in construction or firewood. Most significant in ethnobiology has been the study of the hierarchical ordering of concepts and vocabulary about plants and animals from the most general to the most specific levels (Berlin, 1992). The study of ethnobiology also encompasses empirical knowledge about the natural environment and traditional means of managing resources (Ellen et al., 2000).

Mention should also be made of studies of sociopolitical folk concepts: value systems and notions about race, ethnicity, and other social groupings. A classic groundbreaking ethnographic study of sociopolitical concepts in a nonstate society is Edmund Leach's *Political Systems of Highland Burma* (1954), which looked at contrasting ideologies and theories of rival groupings about themselves and their enemies within a single larger society, the Kachin.

Folklore is an obvious source of data on folk concepts. Besides stories, legends, folktales, myths, proverbs, and axioms, data also come from jokes, riddles, songs, superstitions, and other genres. In addition to verbal and narrative arts, there are games, charms, handicrafts, and other nonverbal genres that come under the larger category of folklore. All of these involve conceptual systems.

Schema Theory

In understanding a cultural concept, it is not enough to know only what it identifies; one must also know the expectations, feelings, and motivations regarding it. In other words, part of the meaning of a cultural concept concerns associations causing happiness, anxiety, and other emotions. The full meaning of a concept is situated in a larger semantic field. In studying folk concepts, one also wants to know how much what it means or represents is valued, how much it is shared, whether it is considered true (e.g., Santa Claus is a ubiquitous and well-defined folkloric person representing many things, but he is not believed to be a real person), whether it is thought to represent the whole society, and whether it is associated with any restrictions or prohibitions.

The contemporary anthropological view of the meaning of concepts concerns schemas (or schemata), or cultural models. Schemas are the way people understand whole scenes. They are the unspoken meanings embedded in cultural models, and they include not only what a concept identifies but also the expectations, feelings, and motivations surrounding it. A schema is a simplified scenario; it may be well theorized, inarticulate, or somewhere in between. To understand the notion of schemas, one can imagine observing a high school setting and seeing students dressed in various ways, wearing different kinds of

accoutrements and accessories, and having different styles of behavior and speech. A knowledgeable informant might identify numerous subcultures among the students, each associated with certain television shows, kinds of music, preferences in food, automobiles, and many other things. These associations are the schemas. Schemas enable us to make sense of artistic works, such as paintings and photography, since they provide narrative stories implicit in a scene. The association of ideas in schemas works automatically in members of a culture (or subculture) but must be explained to outsiders and those who, like ethnographers, visitors, or journalists, are learning the culture. To master a kinesthetic procedure (such as weaving), it is necessary to practice it rather than just have it explained.

From interviews, it is possible to develop schemas. Agar and Hobbs (1985) gave an example of how such analysis might proceed in the case of a person telling the story of how he became a burglar. Their analysis shows causation and action in terms of behavior and identifies elements of the schema: hustling, fencing stolen goods, being ratted out, getting busted, and so forth. Quinn (2005), as noted above, also discovered and formulated schemas that she found embedded in narratives. She found the work to be highly laborious, since it required the collection of extended interviews, all of which needed to be transcribed. Only when she pored over multiple transcripts did the schemas emerge. In her analysis of schemas, Quinn reconstructed implicit, culturally shared assumptions from statements.

Psychological and anthropological approaches to schemas are complementary. Unlike the psychological study of mental models, the anthropological approach used by Strauss and Quinn (1997) among others (Casson, 1983) looks for shared cultural models that underlie and affect an individual's constructs. Psychologists, unlike anthropologists, examine the concept-formation process at an individual level.

In Shore's (1996) complex taxonomy of *cultural models* (his term for what others have called schemas), conceptual models, which he combined with expressive models, are but one of several functional forms of models, the others being orientational, spatial, and task-oriented. Conceptual/expressive models he divided into classificatory models, ludic models, ritual and dramatic models, and theories. For Shore, the most important cultural model is the foundational schema, which organizes and links other schemas together.

D'Andrade (1984) presented a readily accessible example of a cultural construct: the concept of "success" in American culture. D'Andrade asserted that success can be understood as a domain that can be elucidated through an explication of related terms that are components of success: accomplishment, recognition, hard work, prestige, self-satisfaction, and others. The model of success is used in many schemas, in that we can think of things that lead to success in a given domain of life. Within the domain of success itself, we can find putative causal relationships among terms. For example, hard work leads to recognition and is accompanied by self-satisfaction.

Future Directions

As an older, established academic field, anthropology is being swept up in a movement of new interdisciplinary formations and is being absorbed by other disciplines more than it absorbs other disciplines. As such, the future of anthropology is in its contributions to emerging fields of knowledge. The ethnographic approach to concepts fills a gap in a broad multidisciplinary science of cognition by focusing on culturally shared meanings and models. Possible contributions lie in science and technology studies, environmental science, and health studies, along with more traditional applied fields such as management and education. The ethnographic approach to folk concepts also has applications in consumer research and in settings such as offices, hospitals, and libraries, and in city and regional planning.

The emerging field of knowledge organization, which grew out of library and information science, is in a position to take advantage of the anthropological approach to concepts. Knowledge organization research not only tends to focus on documented knowledge but also recognizes undocumented modes of knowledge. Hjørland's (2009) survey of concept theory, in connection with frameworks for the theory of knowledge (empiricism, rationalism, historicism, and pragmatism), illustrates how the documentation and study of folk concepts fit into broader intellectual movements.

The growth of social networking over the Internet presents new opportunities and challenges for the ethnographic study of folk concepts in cyberspace. Sites such as Second Life create virtual worlds in which users interact through the use of avatars. These sites provide opportunities for persons to communicate, collaborate, and present themselves in ways never before possible (Turkle, 1995). In doing ethnography in such a space, anthropologists might choose to create their own avatars and interact with users in the virtual environment rather than try to meet informants in the flesh. Such an unorthodox approach can be justified by reasoning that the entire user community exists online rather than in "real life" and may never meet face to face.

In addition, many Web sites allow users to tag objects and ideas and to relate to others interested in the same domain (Weinberger, 2007). Web 2.0 technology has spawned social networking sites, such as Delicious and Flickr, that encourage users to label content with their own tags. Such tags have evolved into *folksonomies*, user-driven classification systems that bring out nonhierarchical relationships between individual tags. The concepts emerging from such environments are part of new cultural formations that transcend fixed locations. Such environments lend themselves to ethnographic research strategies, even though the particular techniques are vastly different from those of traditional ethnography. In a remarkable study, Jenkins (2001) was able to observe the underground culture of pedophiles entirely by gaining access to online child pornography bulletin board systems and reading messages posted by participants without downloading illegal images. Of course, the study of

cyberculture can also be integrated in to, or added on to, more traditional research methods. Ethnographers can also participate in emerging forms of interaction based on new information technologies, such as text messaging, instant messaging, and the exchange of digital audio, image, and audiovisual files.

MIGRATION AND GLOBALIZATION

MARCIA B. DINNEEN

Bridgewater State College

Throughout the history of humankind, people have migrated. From ancient peoples crossing oceans in wooden or even reed boats to entrepreneurs traversing the globe on jet planes, migration is part of human existence. People have migrated to find food, safety, or shelter. They have migrated to flee enemies, to find work, or to practice their faith. Some migrations are local; others are within a country, across national borders, or from one continent to another. Once viewed as a sign of crisis, migration is now viewed as a normal element of human society. In a 1959 paper delivered at the 11th International Congress of Historical Sciences in Stockholm in 1959, Frank Thistlethwaite wrote that migration is central to the general human pattern, essential for the functioning of families, and crucial to the operation of the labor market. He went on to state that migration streams are as much a part of the history of the American people as Frederick Turner's frontier policy. To study history is to take into account the causes and effects of migration. Continually, humans have looked to improve their lives by taking the often dangerous but always wrenching step of leaving their homes and seeking a new place to live. Some people experience several migrations in their lifetimes; others never leave their homes.

Migration and Anthropology

Just as migration is not a new human activity, the study of migration is not a recent concern for scholars. Social

scientists have long recognized the importance of migration as a factor in social change. Geographers, historians, political scientists, sociologists, economists, and others have studied the causes and effects of migration for years. In 1885, E. G. Ravenstein published his laws of migration; this is the earliest systematic study of migration. These "laws" are generalizations on the characteristics of migrants as well as on their origins and destinations. Migration streams (flows) and counter-streams (return migration) are also included within Ravenstein's laws.

These laws have stimulated researchers over the years. Since the mid-1960s, the focus has been on migration as a system, examining migration streams and counter-streams as well as the effects of migration on sending and receiving societies. What is comparatively recent in the study of migration is the interest expressed by anthropologists. As a discipline, anthropology was a latecomer to the study of migration as a social and cultural process. Caroline Brettell (2003) stated that anthropologists did not write about what was happening in front of them, since the social and cultural aspects of migration did not appear to fit their modes of study. However, by the late 1950s and early 1960s, many anthropologists felt that migration should receive more attention as a source for research. Thereafter, studies of people moving from rural villages into cities as well as other migration streams began to populate the literature of anthropology.

Some Theories

In addition to developing an interest in migration, anthropologists worked toward developing a theoretical approach that would suit their discipline. Part of developing a theory was answering key questions as to why people move, who these people are, and what happens to them after they move. Political scientists and economists are generally interested in the migration flows that exist between countries and how they are shaped by policy or by labor markets. They and others have used the *push-pull* theory, showing how overpopulation and environmental deterioration in rural areas is the “push” toward migration, and the allure or attraction of the city is the “pull” aspect. Push can explain migration for income betterment. The pull may be job opportunities in addition to a desire to see a new place or try one’s wings. Sociologists tend to look at broader issues, the macro approach, concerned with the integration of migrating people into the existing population of a place. They focus on general studies of population, using categories such as race, sex, and occupation as the units of analysis. The microapproach looks at individuals and the reasons they choose to migrate. Anthropologists look at both the causes and effects of migration for sending and receiving societies and the effects of migration on the individual.

A recent viewpoint on migration that is appealing to anthropologists is the *meso* (societal) approach, looking at household and social networks as units of analysis. Rather than being strictly an economic decision, the decision to migrate is often shaped by social and cultural contexts, as was pointed out by Brian Du Toit (Du Toit & Safa, 1975). Individuals do not act on their own; families and households often shape decision making. This mesolevel, detailed by Thomas Faist (1997), encompasses social relations between individuals, families, neighborhoods, and friendship circles. These relationships form networks central to social relations. Many anthropologists see the network approach to migration as preferable to the economic, labor-needs approach. Migration is seen as embedded in social relations. The choice to migrate is determined by the experience of others, and the decision is made within a family. The move is assisted by relatives and friends. Douglas Massey and others suggest that networks promote migration, as each migration creates the social structure necessary to sustain it (Brettell, 2003). Over the years, different theories to explain migration have been used, amended, and sometimes rejected by anthropologists. Some of these are described below.

Modernization Theory

Much of the early work on migration within anthropology, up to about the mid-1970s, was influenced by the modernization theory. Originally developed around the turn of the 20th century, it was focused on development, as people flowed into the cities. An anthropological approach, developed by Robert Redfield in 1941, included a model

that opposed city and country and contrasted two distinct ways of life: traditional and modern. Within this theory is a focus on migrants making rational and progressive economic decisions with respect to leaving where they are and choosing where to live. Migrants were viewed as progressives who would bring new ideas to their communities. The main unit of analysis was the individual migrant. Modernization theory splits causes of migration into the push factors associated with a traditional society and the pull factors of developed areas. It encompasses a model of development in which the forces of resources and population pressure are equal, relying on the push-pull concept. However, research by M. P. Todaro found that migration was not entirely progressive and that high urban unemployment was an unlooked-for result of rural to city migration (Kearney, 1986).

Dependency Theory

Dependency theory relates economic relationships and processes at national and international levels. The focus is on a single world capitalist system and is not seen as progressive in that it results in the impoverishment of less-developed countries. Since this theory does not focus on distinctive local communities but is instead broad (macro) in scope, it has not been useful for anthropologists for specific fieldwork projects. Dependency theory is concerned more with the extraction of surplus and less with the flow of cash and goods in the opposite direction. It has generally been incorporated into the world systems theory, a global system, based on an international division of labor, producing commodities traded worldwide.

Historical-Structural Theory

Another theory to explain why people migrate is the historical-structural approach, framing migration in the context of global economy. With its intellectual roots in Marxist political economy, this approach stresses the unequal distribution of economic and political power in the world economy, and migration is seen mainly as a way of mobilizing cheap labor for capital. The unit of analysis in this theory is not the individual migrant but the global market, and the theory explicates how national and international economic and political policies have disrupted, displaced, and even attracted local populations, developing different migration streams. Within this theory, the individual is not an active agent but is manipulated by the world capitalistic system. This theory does not take into account cultural factors.

Articulation Theory

Originally formulated by Marxist anthropologists in the early 1980s, this theory rejects the world system to focus on the community and household. This theory is more useful to the anthropologist doing fieldwork, as it identifies

and isolates the domestic community. It theorizes how such communities are inserted historically and economically into the global world and narrows its focus to households. Concern with culture is central to this theory.

Transnationalism

A new theory is based in the concept of transnationalism, a social process whereby migrants operate in social fields that transcend geographic, political, and cultural borders. From this perspective, migrants are no longer uprooted by crises and forced to move; rather, they move freely back and forth across international borders and between different cultures and social systems. These migrants bring both social and economic changes to local communities. Nina Glick Schiller, Linda Basch, and Christina Blanc-Szanton (1992) described transnationalism as a way to view globalization.

Types of Migrants

A basic way to study a discipline is to look at the types within that discipline. Since its beginnings as a comparative and cross-cultural science, anthropology has relied on typologies to develop theories on similarities and differences. There are numerous types of migration: national and international, voluntary and involuntary, legal and illegal, return migration and transmigration, seasonal and nonseasonal, and that represented by sojourners and settlers. In 1961, Nancy Gonzalez described six types of migration by laborers: seasonal, temporary, nonseasonal, recurrent, continuous, and permanent (Gonzalez, 1961). Different types continue to be differentiated. In 1989, Gonzalez added another type to her 1961 list: conflict migration, describing migration prompted by violent conflict at home (Gonzalez & McCommon, 1989). Economic conditions, political situations, environmental issues, and even gender determine the different types of migrants.

Voluntary

Types of migrations can be broadly classified as voluntary and involuntary. This type generally encompasses those who migrate for financial reasons, such as for jobs.

Seasonal

The most common migrant is the seasonal worker who travels, both nationally and internationally, to work, mostly in agricultural industries. Generally, the migration is temporary and driven by crops to be harvested. Such seasonal migrations have continued over the centuries. For example, through much of the 19th century, northern Italians migrated to nearby countries in the spring and returned home in the fall. This type of migration can be viewed as voluntary despite

the fact that the migration is dictated by environmental and/or economic reasons. Seasonal migrants may also be described as recurrent, reflecting the generations of families who have traveled to pick crops.

Temporary

Brian M. Du Toit discusses three types of temporary migrants, including the weekly commuter, the seasonal migrant who returns home, and the sojourner whose point of reference is back home in his village despite years spent in a city (Du Toit & Safa, 1975). Temporary migrants aspire to return home. A type of temporary worker is the guest worker, also called the *gastarbeiter*. In the post-World War II economic boom, almost all northern European countries actively recruited contract labor migrants, mostly men—Portuguese, Italian, Spaniards, Turks, and Yugoslavs—who traveled to northern European cities. These blue-collar migrants worked mainly in manufacturing and construction. The host countries expected that these workers would remain for a short period of time and then go home.

In the 1960s, to assuage a labor shortage, Turkish guest workers were recruited by the Foreign Labor Office on behalf of industries in West Germany. The program, which resulted in one of the largest migrant populations in western Europe, was supposed to be a temporary fix. Migrant workers were regarded as temporary labor units, which could be recruited, used, and sent away again once they were not needed by employers. In reality, many did not return home, and although the practice was discouraged by the West German government, their families joined them. Their presence caused a major problem as the “guests” began to establish ethnic communities. What started as a temporary migration resulted in a permanent residence. However, the social costs for providing housing, education, and health care for the migrant families became burdensome on the host communities. By 1974, such contract worker migrations to western Europe had ceased.

Permanent Migrants

Although originally these migrants plan to return home, they do not. If they are not successful in their new community, they may be ashamed to return home. Some marry local residents, and others may prefer the host society to home. Permanent migration might involve never returning to the home country or returning often and maintaining strong family and friendship networks. Some permanent migrants hold dual citizenship. These temporary-turned-permanent residents may be essential to social networks, providing support to newcomers. As these networks are established, so are communities of ethnic minorities, fueled by new arrivals and stabilized by permanent migrants.

Sojourners

These migrants plan to return to their home, but frequently this is postponed. Unlike those who migrate for a season, usually for agricultural work, those working in commerce or industry generally have no need to coordinate their length of stay with the seasons and may stay abroad for a number of years, depending on their purposes. In her study of Brazilians in New York City, Maxine Margolis (1995) noted that they see themselves as sojourners, temporarily in the United States to save money to fill a specific need back home, whether to buy an apartment, start a business, or return to school. Sojourners include technicians, engineers, and businessmen. Others are small retailers and middlemen who follow the migrants from their countries to supply them with goods and services. Many sojourners spend their working years abroad and return home to retire. Others do not return home, because they have made permanent homes abroad or because they fear oppression and violence in their home countries. Sojourners may have a major economic impact on their countries of origin by sending money home.

Returnees

In 1977, the “new” topic of return migration was proposed for the annual meeting of the American Anthropological Association, to develop a conversation on Donald Bogue’s statement that for every migration stream there is a corresponding counterstream flowing in the opposite direction. The proposal was rejected, but a few years later the topic had become important in the discipline. George Gmelch, in 1980, defined *return migration* as the “movements of emigrants back to their homelands to resettle” (Gmelch, 1980, p. 136). Others, such as Nina Glick Schiller, discussed the relationship between return migration and the transnationalism of a global economy (Schiller, 1997). Return migrants do go back to live in their sending communities. Most studies show that strong family ties, rather than financial factors, determine the desire to return. Bad times at home can both push the migrants away and bring them back home. Sometimes the decision to return is influenced by negative or push factors in the host country. For example, Jamaican migrants in Britain encountered extreme racial prejudice and discrimination. Others decide to return due to an inability to adjust to a new climate. Those used to warm climates may be unable to adjust to the cold North American winters. When the economic prospects do not materialize and the migrant finds the streets are not paved with gold, he or she may be forced to return home.

On the positive side, returnees not only bring back money but may also bring back new skills, ideas, and lifestyles. Some settle with other returnees, being unable or unwilling to resume their place in their home country. Other returnees who were not financially successful in the

host country return home to resume the life they had led before. Those who worked lower-level jobs abroad had no higher skills upon returning and generally will not migrate again. Returnees who move frequently between two or more places, such as in seasonal labor migration, may be referred to as circular migrants.

Involuntary

Involuntary migration, also called forced migration, is caused by human-made or natural disasters. National disasters may be crop failures, such as the one that resulted in the 19th-century potato famine in Ireland, earthquakes, floods, or volcanic eruptions. Human-made causes include war and the persecution of racial, ethnic, and religious groups, as well as political dissenters. In previous centuries, both indenture and slavery were types of forced migration. Even though those migrating as indentured servants or laborers may have been given the carrot of freedom after a number of years or signed a contract to receive a sum of money, often their lives were more like those of slaves. Slavery was forced migration; after the abolition of the slave trade in the early 19th century, this type of forced migration generally ended. Unfortunately, it still exists in the sex trade “industry.” By the time of World War II, the indenture system had basically ceased.

Refugees

A continuing type of forced migrant is the refugee. Although most refugees decide to leave their countries of birth because of oppression, unlike slaves, they can choose where to go. Often that choice is linked with labor opportunities and/or existing social networks. In 2002, Ted Lewellen described the 20th century as the Age of Refugees, estimating that 100 million people have been uprooted by war and the threat of political violence during this time. Since the mid-1980s, the number of refugees has dramatically increased. According to the 1951 United Nations Convention Relating to the Status of Refugees, a refugee is a person living outside of his or her country who either is unable or unwilling to return to the home country due to fear of persecution principally because of race, religion, or nationality. Once these types of migrants are officially recognized by the United Nations as refugees, they have a legal status and are protected by the United Nations High Commissioner for Refugees, making them better off than other forced migrants.

In some instances, mass migrations of refugees may present a military threat to the host country. They certainly create a demand on the resources of host countries. The strain on a country’s social services and physical infrastructure as well as the impact on local economic conditions may destabilize developing countries. Gil Loescher, in 1995, noted that the great majority of refugees seek safety in the world’s poorest states (Cohen, 1995). There is also a concern that

mass migration will alter the ethnic, cultural, religious, and linguistic composition of the host country.

The study of refugees by anthropologists is relatively recent. In 1988, the Committee on Refugees and Immigrants was established within the General Anthropology Division of the American Anthropological Association. Some scholars equate refugees with politics and others with environment, making the study of refugees complex.

Legal and Illegal (Undocumented)

Most migrant streams are “legal.” Migrants have permission to leave their regions and/or countries and to relocate to a new region and/or country. Yet there is a group that may be regarded as either legal or illegal. Between the early 1970s and the late 1990s, the numbers of people seeking political asylum increased greatly. Although many seeking asylum are rejected, a large share of those who apply for asylum are able to remain in the countries where they had applied for legal status. Some say the asylum seekers are “economic” migrants, looking for work rather than political asylum and abusing the asylum systems. Others argue that asylum seekers are genuine refugees. Appeals for legal status as a refugee may take years, leaving the seekers in a type of limbo. In some countries, they are not allowed to work. Illegal (undocumented) migrants are a growing concern, particularly for host countries. The potential for illegal flows is greatest in the areas where poor countries are near or share a common border with rich countries, such as between the United States and Mexico. Illegal workers tend to be low skilled and tend not to bring their families with them, for fear of increasing the probability of their illegal status being detected. With globalization, there has been an increase in illegal movements and people smuggling.

Chain Migration

Of increasing interest to anthropologists is chain migration, particularly the resultant social networks. Chain migration involves social arrangements that aid people moving from one place to another. It is the process by which prospective migrants learn of opportunities in a new place, are provided with transportation, and have initial accommodations and employment arranged by previous migrants. Complex networks provide information and support all along the line and are self-perpetuating as new networks form and expand through marriage and friendships. Some equate the network to a spider web rather than a chain, and many of these networks are extensive. One study of migrants in a single pueblo in Mexico found no less than 110 destinations in the United States. The linking of people from specific places of origin in one country to specific destinations in another can be viewed in the development of ethnic clusters in various neighborhoods. Studies have shown, for example, that Jewish immigrants from Poland settled in streets on the

lower east side of New York different from the streets occupied by Jews from Russia, Hungary, and Romania. More than 90% of the immigrants to Australia during the first half of the 20th century came via the chain migration process. As labor markets expand beyond the boundaries of a particular nation, both companies and governments may look abroad for employees, skilled and unskilled. The migration policies of industrial democracies have given priorities to close family ties in selecting migrants for admission. Therefore, chain migration has become a dominant pattern in long-term migration.

Globalization and Transnationalism

Migration is part of the human story. It can be seen in stories of ancient peoples crossing the sea and in the 20th-century research of Thor Heyerdahl detailing the voyages of those traveling from South America westward on the *Kon Tiki* and those traveling eastward from Africa on the *Ra*. Within countries, people migrated from rural lands into developing cities. After 1870 and the development of the steamship and steam railroad networks, migration increased dramatically. This era of mass migration ended in 1914 with World War I. Following that war, there was a decline in migration, but after World War II, due to rapid and sustained economic growth, a new age of migration began. By the end of the 20th century and into the 21st, migration flows became more global in scope as well as more complex and diverse. The word *globalization*, as defined by Michael Kearney in 1995, refers to “social, economic, cultural, and demographic processes that take place within nations but also transcend them” (p. 548). Globalization relates to behaviors and to institutions that affect more than one state. It describes an intensification of worldwide social relations, linking distant places, with the result that local happenings are shaped by events occurring many miles away and vice versa. One of the central aspects of globalization is the growth of cross-border flows of people and the proliferation of social networks connecting migrants to their home communities.

National (Rural to City)

Some of the earliest waves of human migration in modern history were from the countryside into the developing cities or from one rural area to another. Past migrations have nearly depleted the countryside in industrialized countries. Some years ago, two thirds of the population in Latin America, Asia, and Africa lived in rural areas. A little more than a generation later, two thirds would be urban residents.

International (Global)

Modern international migration differs from that of previous centuries; in the 19th century, for example, migration

was usually a one-way movement, with major streams of migrants leaving Europe and Asia for North America. Since the end of the Cold War, migration has taken on a more global aspect, partly due to the ease and speed of transportation as well as global communication. With the global explosion in mass communications since the late 1980s, particularly satellite television, many people in third world countries have become aware of the supposed affluent lifestyles of rich countries. Many are attracted to the consumer culture that appears available to them, and the costs of long-distance moves are within the reach of poor families, which was not the case 150 years ago.

Stephen Castles, in the book *The Age of Migration*, commented that international migration is “part of a transnational revolution that is reshaping societies and politics around the globe” (Castles & Miller, 1998, p. 5). International migration is also seen as a consequence of global inequalities in the distribution of wealth and power, and international migration flows are almost always from poor to richer countries. Types of migrants include not only permanent migrants, seasonal workers, and refugees but also students, military personnel, businessmen, and even tourists, since such short-term movements may lead to subsequent long-term ones. Unlike earlier waves of migration, current migrants are reflecting the worldwide shift from a rural agrarian base to an urban-industrial base in the economies of most third world countries. With the growth of multinational companies and international capital transfers, international movement of labor within firms and their foreign associates has become possible and basic to globalization.

Transnationalism

In the 1960s, the word *transnational* referred to corporations with established bases in more than one state. The word evolved to also represent ideas and political institutions that went beyond national boundaries. Now, the meaning of the word *transnational* overlaps that of *globalization* but with a more limited scope. In the 1990s, the study of transnationalism as a system of migration became a focus of a group of anthropologists. In anthropology, transnationalism describes the flows of culture and population across national borders. It not only explores how immigrant populations adapt in new cities but also how they maintain connections with their societies of origin. Previous generations of migrants generally attempted to make a clean break from their home societies, but transnational migrants continue to maintain ties with the communities they left. With the rapid improvement in the technologies of transport and communication, it has become relatively easy for migrants to stay in touch with those back home. These developments also facilitate the growth of circular or repeated migrations, in which people migrate regularly between different places where they have economic, social, or cultural ties. Transnationalism also involves questions relating to ethnicity and ethnic identity.

Basically, it updates the older assimilation model in which newcomers worked to become part of the existing culture. But it also addresses the potentially serious consequences for national identity, as some migrants are not willing to let go of their own ethnic identities and merge into or adopt into those of the receiving society.

Schiller, Basch, and Blanc, in their 1995 study of transnationalism, have detailed forces in the global economy that lead people to live transnational lives while migrating to countries that are centers of global capitalism. One such force is deteriorating social and economic conditions in both labor-sending and labor-receiving countries; another is racism in the host countries. A third force is nation building in both home and host societies, where political loyalties are encouraged in each nation-state where a migrant maintains social ties. Sometimes migrants become “long distance nationalists” in their devotion and connectedness to their “home” country.

Globalization and the New Migrants

Within a global world, migration is similar to the streams of the past, yet different. The former waves of mass migration were more a continual stream of people, traveling usually from underdeveloped third world countries to countries in which they could improve their economic and sometimes social status. Globalization has created a new migration market, organized by labor recruiters and migration agents who can make a profit from migration, whether legal or not. With globalization, new types of migrants have emerged.

Transmigrants

Studies of globalization look at the connections that migrants maintain and build across international borders. As defined by Schiller, Basch, and Blanc, transmigrants are those whose “daily lives depend on multiple and constant interconnections across international borders and whose public identities are configured in relationship to more than one nation-state” (Schiller, Basch, & Blanc, 1995, p. 48). Transmigrants may hold dual citizenship in two or more countries. They maintain ties with their home countries and become involved with the economic, social, religious, and political spheres of both their sending communities and their host societies. Some home countries, such as Portugal, actively encourage the loyalty of their citizens abroad because of the benefits these migrants bring to the home country. Benefits include not only money sent to those back home but also the investments of citizens abroad in businesses and real estate in their home countries.

Brain Drain

Characteristic of globalization, migrant types include more skilled labor. These are the professionals, executives,

technicians, and other highly skilled personnel who travel around the globe, sometimes on their own, marketing their skills for lucrative returns. Large international companies transfer skilled employees to different locations. Because some large employers have shifted production to places where production is possible at lower wage levels, usually in third world countries, they transfer managerial and technical staff to supervise operations. These migrants are usually university-trained people who move from less-developed to highly developed countries, and their leaving may lead to shortages of skilled personnel at home. Being a student is often a precursor to migration of skilled workers. Those students who leave their home countries for educational opportunities in developed countries stay on following graduation. Many students in developed countries are from Asia and have concentrations in business or information technology. Sometimes educated people migrate because they cannot find work in their home countries. Employers in receiving countries are eager to welcome skilled migrants; the reverse is generally true for the unskilled.

Middlemen

Although middleman minorities have been following migrant streams for decades, this type of migrant is particularly significant in a globalized world. These migrants include small retailers and international merchants. They are small-time money lenders, loan sharks, and international financiers. Middlemen facilitate the movement of goods between the producer and a specific set of consumers within a community in which others are the majority of the population.

There is a cultural difference between the middlemen and those they serve. Middleman minorities do not represent a particular race or culture. Some are Middle Eastern; some are Asians. Many live in cities, and their high levels of concentration in one or a few cities in each country suggest a social need for contact with their fellow middlemen. With the passage of time and acculturation of later generations to the world of the host society, these concentrations lessen.

Some believe middlemen are parasites, preying on those ignorant to the ways of their new communities. Many feel that making money by simply transferring a product to the consumer without changing the product but charging more for it is morally wrong. For example, money lenders who demand to be repaid more money than they lent have been condemned through the ages.

Diaspora

Diaspora is a term used to describe practically any population that is considered “deterritorialized” or transnational. This word often implies a forced dispersal of people, as well as an emotional relation to the homeland. These populations have originated in lands other than those in which they currently reside, and their social, economic, and political networks cross the borders of nation-states and

may even span the globe. At one time the term *The Diaspora* referred almost exclusively to the experiences over the ages of the Jewish people, exiled from their homeland and dispersed throughout the world, with always the dream of return. More recently, the term has been applied to other populations, such as the Armenians and even the Palestinians. Although globally dispersed, diaspora populations are self-identified ethnic groups. In some cases, the sense of commonality on a worldwide scale provides a key to their success in the new global economy as they pool resources, transfer credit, and invest capital within the organizations they create and within families and extended family. However, the people maintain a collective memory or a dream of their ancestral home to which they long to return. If the homeland no longer exists, they are committed to restore it. They are generally not accepted within the countries where they have settled.

Further Directions

Because of the rising significance of migration in political, economic, and security concerns, interest in migration theory and research has increased. Current research is less focused on migration flows and more on how people react to a global society and how globalization has impacted adaptation and cultural changes. Such research in the field of anthropology has focused on questions of identity and ethnicity as well as community and social networks, kinship structure and family migration strategies, and gender as it relates to migration.

Networks

Networks are a relatively new topic of study for migration scholars and are important in that they play critical roles in a person’s decision to migrate and his or her success in the host country. Not simply groups of family and friends who provide information, resources, and assistance to migrants, networks are more far reaching. Migration networks can consist of institutions as well as individuals and be national as well as transnational in scope. Networks can include multinational corporations, recruitment and travel agencies, government institutions, and financial institutions. The networks help with expenses, they aid the migrant in adaptation into the new society, and they maintain links to the original society. Douglas Gurak and Fe Caces (1992) have studied the various functions of migrant networks, including linking communities of origin and destination, serving as channels for information, and insulating migrants from the negative aspects of living in the host society as well as aiding in their adaptation to it.

Migration has become an industry due to these developing social networks and transnational links. Many people make their living organizing both legal and illegal movements of people. Travel agents, labor recruiters, brokers, and lawyers specializing in immigration law focus on

legal migrants. Others who smuggle humans across borders focus on the illegals. Some institutions, such as banks that set up special transfer facilities, help migrants to send earnings (remittances) back home. Shopkeepers, priests, teachers, and other community leaders work to facilitate the well-being of the migrant.

Yet there are those who prey on migrants. Part of the migration industry is organizations devoted to smuggling and trafficking migrants. The difference is that smuggling is illegal and for profit, yet the migrants are knowing partners in a commercial transaction: paying exorbitant fees to be secretly moved across borders or landed on foreign shores. Human trafficking implies sale of a person's sexual services or labor in the country of destination. The trafficking of women and children for the sex industry is a global enterprise.

Gender

In the 1960s, feminists declared that women were hidden from history. This is also true with the study of migration, and a major new focus in anthropology relates to gender, specifically the migration of women. Historically the study of migration related to the movement of men. It was assumed that women migrated as wives or daughters or as the second of a two-step male-female process: The man migrated first, established himself, and then sent funds enabling his wife and family to join him. Some women waited at home for husbands or fiancés working somewhere else, trying to improve their finances.

The reality is that some women migrated alone, as adults, seeking jobs or land. Some, once established in a new place, refused to return home because of personal gains they had made in the new country. Such is the case with Christian nurses from the state of Kerala in India. There, traditionally, the profession of nursing for women was considered "dirty" because it was forbidden to speak with unrelated men. Yet nursing has become a path of upward mobility and independence for women. Rather than remain in India, subject to low status, low pay, and dismal working conditions in Indian hospitals, nurses have migrated to the United States. Such a migration is a reversal of gender roles, because the woman moves first to become the breadwinner. Husbands and families follow.

Brettell (2003) noted that in the late 20th and early 21st centuries, migration patterns have changed. Often women are the first to migrate, and in some international migration streams, they outnumber the men. She cites studies of Caribbean women migrating to the United States to illustrate her point and mentions that the increasing numbers of women involved in both internal and international migration flows have led some scholars to write extensively on the feminization of migration. Women who migrate may become domestic workers, may work on assembly lines for multinational industries, or may labor as garment workers, and young women may become prostitutes as part of the growing global sex industry.

Another aspect of gender and migration has to do with those women who remain at home and become the heads of households in the absence of their men. They are empowered by having to deal with issues of daily life as well as crises, and they have a break from childbearing. When the husband is sending back money, their economic situation improves.

Conclusion

For thousands of years, migration has been a major social phenomenon. Although modern migrations are not as dramatic as the earlier migrations when people took often terrifying journeys, forced and by choice, migration during the 21st century is vital to the globalization of the world. Yet moving continues to have many and often heavy costs that are not just financial. To go to a new place searching for work or a new home involves severing ties to family and familiar places. Dangers today are not those encountered in previous centuries as people were crammed into wooden ships that were at the mercy of storms and rough seas. Today's migrants are subjected to increasingly stringent immigration policies, and they are scrutinized and often feared by residents of the host country.

Migrants, in addition to their varied aptitudes for labor, bring their culture from their countries of origin. Yet over the years, migration has continued to be from poorer countries to more prosperous ones. Few American engineers and doctors migrate to poor countries. India sends engineers and physicians to the United States, but lower-skilled contract labor goes to the Middle East. The political and economic impact of migration on both sending and host countries is substantial. As some countries lose a vital, skilled labor force, other countries are impacted by unskilled labor forces in need of jobs. Politically, migration policies have been developed and rewritten because of changes in the types of migrants.

Migration is no longer limited to shifts of families from country to city but now involves wholesale population movements across national boundaries and into different cultures and economies. By the end of the 20th century, worldwide, there were about 100 million people residing outside their countries of citizenship. The causes and consequences of migration have changed since before World War I. And unlike in the past, migration flows now go mainly between countries in the global South. Flows toward the global North face increasing restrictive immigration controls from governments.

The 21st century has been called the Age of Migration. Migration has changed the world and many of its societies. Both developed and less-developed countries have become more culturally diverse. Ethnic diversity, prompted by migration, has been welcomed in some areas and seen as a threat in others. The extreme example is ethnic cleansing. Although many saw the emergence of international migration as a force for social change, others saw it as a source of conflict. Problems of diverse ethnic groups living together and

increasing difficulties with immigration policies and security are also characteristic of this age. One aspect of this problem is that modern migrants reject assimilation as a mode of adaptation. They do not want to be part of a melting pot, like those of previous centuries; they wish to maintain their own ethnic identity within a new multicultural world.

GLOBALIZATION

CHRISTOPHER MORRIS

University of Colorado at Boulder

Globalization is an inconsistent concept, and definitions of it abound. However, most anthropologists agree that, experientially, globalization refers to a reorganization of time and space in which many movements of peoples, things, and ideas throughout much of the world have become increasingly faster and effortless. Spatially and temporally, cities and towns, individuals and groups, institutions and governments have become linked in ways that are fundamentally new in many regards, especially in terms of the potential speed of interactions among them. Examples of these interactions are myriad: The click of a mouse button on a Wall Street computer can have immediate financial effects thousands of miles away on another continent, and events like the fall of the Berlin Wall in 1989 or footage of the 2005 tsunami in southern Asia can be televised internationally, whereby millions of viewers interpret the same images concurrently.

Beyond these shared perspectives on and approaches to globalization, anthropologists disagree with one another in important regards. The first concerns the “what”: Does globalization name a more-or-less singular and radical transformation that encompasses the globe, in which technoeconomic advancements have fundamentally reorganized time-space, bringing people, places, things, and ideas from all corners of the world into closer contact with one another? Or, is globalization a misnomer, even a fad, a term too general to describe a vast array of situated processes and projects that are inconsistent and never entirely “global”?

A second discussion concerns the “when”: Is globalization new—do we currently live in the “global era”? Or, has the world long been shaped by human interaction spanning great distances?

These debates are not limited to two opposing sides. Some scholars feel that these very questions blunt meaningful analysis of the contemporary world and all of its nuances. By focusing largely on absolutes—that is, what is entirely singular versus wholly chaotic, what is radically new versus something predicated largely on the past—important questions are passed over. For example, what are the specific mechanisms of human interconnection and the particular histories in which they are embedded?

Anthropologists do agree, however, on how to best go about investigating globalization: through long-term, intensive fieldwork, either in a single locality or in several linked analytically together. This fieldwork is ethnographic; that is, it seeks an intimate understanding of the social and cultural dynamics of specific communities, as well as the broader social and political systems they negotiate. In a world of intensifying social relations, ethnography requires engagement in both empirical research and critical theory.

Anthropological attention to ethnographic detail is an important rejoinder to a vast globalization literature centered on macro phenomena, such as the relations between large-scale political and economic bodies like nation-states, political unions, trade organizations, and transnational corporations. Undoubtedly, these “translocal” entities

are of great anthropological interest as well. Yet the discipline has taken as its goal the understanding of how specific subjects respond to and act within these large-scale processes, institutions, and discourses through culturally specific lenses. Thus, anthropology's contribution to this literature lies in its assertion that social change, viewed in both distance-defying connections and inequitable disconnections within the world, can be compellingly grasped in the daily practices of individuals and the groups, institutions, and belief systems they inhabit.

It bears emphasis that a researcher cannot simply board a plane to "the global." The empirical aspects of human social interaction—while facilitated by the "placelessness" of systems and structures like international finance networks, religious chat rooms, or television broadcasts—are produced, interpreted, and negotiated by people in particular places. It is for this reason that the ethnographic method has continued to define anthropological research, even as it pertains to globalization. The ethnographic emphasis has long been to follow the question, the person, the commodity, or the idea—all things that are continually mobilized or constrained by human activity. As will be argued in further detail below, anthropologists have tended to warn against the erasure of human agency in depictions of such interaction, and the discipline's commitment to research continues to inform this warning. Some anthropologists have gone so far as to argue that empirically thin accounts of globalization, especially those that embrace it as a natural and ultimately unavoidable force in the world, actually obscure the means by which unequal relations of power are forged. The argument is significant, as anthropologists generally agree that the ability to define globalization and steer discussions pertaining to it greatly informs the decisions of wealthy and influential policymakers.

Earlier Attempts to Grasp Translocal Phenomena

While often understated in current anthropological scholarship on globalization, early anthropological attempts to grasp translocal phenomena greatly influenced the discipline's development. Indeed, anthropology has a history of engagement with translocal phenomena and has long argued that exchange across sometimes vast distances has been and is common to human social interaction. Arguably the first incarnation of such a notion is seen in the works of late 19th- and early 20th-century diffusionists, who held that cultural change was a product of initially distinct cultural traits being appropriated and dispersed among individuals and groups over great geographic distances. Franz Boas, often called the father of American anthropology, saw diffusionism as a corrective to unilineal evolutionary conceptions of culture change, which articulated the development of cultural traits as a product of independent and isolated trial and error rather

than as a product of permeable social worlds facilitating cultural exchange. Boas argued as follows:

It would be an error to assume that a cultural trait had its original home in the area in which it is now most strongly developed. Christianity did not originate in Europe or America. The manufacture of iron did not originate in America or northern Europe. It was the same in early times. (Boas, 1932, p. 609)

A fellow critic of cultural evolution perspectives during Boas's time, Bronislaw Malinowski spent over two years in the Trobriand Islands examining the kula ring, a regional system of exchange that Malinowski (1922) claimed functioned to maintain social solidarity and enhance status among males bestowing necklaces and armbands upon one another. Malinowski is most widely renowned as an early practitioner of participant observation, but Malinowski's study also required him to practice multi-sited research, which is now seen as a sometimes necessary mode of fieldwork to "follow" translocal phenomena.

Two other anthropologists informed by functionalism and influenced by Malinowski's study of nonmonetary exchange were Mauss and Ortiz, both of whom produced works that challenged readers to think beyond the local. Mauss's *The Gift* (first published in 1923) explored the historical beginnings of translocal systems of exchange that often brought about social cohesion through gift giving and reciprocity. Mauss cited examples of this exchange among groups in the South Pacific region, as well as in North America. Originally published in 1940, Ortiz's *Cuban Counterpoint* developed the concept of "transculturation" to describe the different phases of cultural hybridization between ethnically diverse groups (many of whom were arriving from foreign lands) in Cuba under colonialism. Ortiz further argued that the production and export of Cuban commodities like sugar and tobacco came to be deeply entangled with European and U.S. interests.

While the above works demonstrate early insights into the relationships between relatively small populations and an outside world, it is common to read of early 20th-century anthropology's insular emphasis on closed, internally coherent cultural systems. Leach's *Political Systems of Highland Burma*, first published in 1954, was a powerful response to the "bounded" conceptions of cultural change, as he took a regional scale as his point of entry into the indeterminate dynamics of identity formation in Burma. Leach also emphasized the power and creativity of individual actors to shape culture beyond local contexts.

The 1960s and the two decades that followed were formative in the history of anthropology's engagement with large-scale processes. The political turmoil of the "liberty," anticolonial wars, and rising nationalism in the global South during the 1960s are commonly cited as the greatest impetuses of this engagement. In addition, a principled dissatisfaction with the trajectory of anthropology and social science disciplines in general informed the

reanimation of the Marxist approach known as political economy. Much of this dissatisfaction stemmed from a lack of engagement with political economy's most central concerns: the nature of material production, class, and power.

Broadly conceived, the political economic approach within anthropology was utilized to understand the relations between large-scale processes of economic and political change and specific (usually subaltern) communities. The anthropological approach was heavily influenced by the "world-systems" theory of sociologist Immanuel Wallerstein and "underdevelopment" perspective of economist Andre Gunder Frank. Both of these thinkers emphasized the imposing gravity of the European- and American-dominated world economy. Concisely, this world economy provided a framework by which Western, or "core," economies could systematically exploit the non-Western, or "peripheral" nations of the world through the appropriation of their economic surpluses and labor. This perspective laid out a significant critique of economic modernization theory, for both Wallerstein and Frank stressed the causal relationship between worldwide capitalist expansion and subaltern subjugation, or development and underdevelopment.

A common perception among anthropologists sympathetic to political economy was that the "periphery" category was too generalized and unnuanced. Anthropologists believed that their disciplinary proclivities could bring the diverse reactions of "micropopulations" to capitalist penetration into clearer focus and thus provide a more detailed, if not more realistic, explanation of unequal relations of power. Eric Wolf and Sydney Mintz were exemplary in their efforts to conjoin the broad focus of world systems theory with anthropology's long-established object of study, the social dynamics of the subaltern.

Wolf demonstrated his materialist approach in his influential and ironically titled *Europe and the People Without History* (1982). The book sought ambitiously to trace the history of capitalism's expansion and eventual penetration into precapitalist societies, and thus account for the means by which particular non-Western localities were transformed into production sites of primary goods—gold and diamonds in South Africa, coffee in Mexico, and rubber in the Amazon, to name only a few of Wolf's examples—for Western consumption and profiteering. Wolf's analytic brush was decidedly broad, as he sought to outline patterns of this expansion and penetration on a massive geographic scale.

Mintz's *Sweetness and Power: The Place of Sugar in Modern History* (1985), while geographically narrower in its focus, was nevertheless an ambitious anthropological investigation of the politics of production and consumption between a metropole and colony during the 17th through 19th centuries. Mintz argued that slave labor in the Caribbean was a means for sugar to become a highly valued and common commodity in England. His work is important because it demonstrated that the Caribbean producers of

sugar were crucial actors in the shaping of the lifeworlds of metropolitan centers of global capitalism.

Contemporary Anthropological Approaches to Globalization

Methodology

Much the same as intellectual forebears like Boas, Malinowski, and Mintz, anthropologists today are apt to favor specificity and variation over generalization and central tendency. Anthropology has, subsequently, tended to shy away from grand theories that can essentialize peoples and characterize histories as predetermined. Indeed, a continued interest of anthropologists is to investigate how individuals and groups negotiate their social worlds in creative and unexpected ways. However, this has not prevented anthropologists from using macro theories as frameworks for inquiry nor from intimating how ethnographic detail is indicative of broader social configurations. The main point is that empirically supported arguments are paramount. This is where long-term, immersed fieldwork has been and remains a central element of anthropological contributions to the scholarship on globalization.

Yet the disciplinary interest in globalization has sparked debate about the future of fieldwork methodology. Indeed, while the ethos of anthropology continues to privilege single-sited fieldwork (as this has long been considered the best means to become versed in the social processes of a given community), many argue that a world of intensifying human relations has left traditional fieldwork approaches outmoded. In an effort to address this challenge, George Marcus (1995) outlined two strategies. The first argues for the use of archival data, as well as macro theory, to situate specific communities or individuals in larger socioeconomic processes. Ann Stoler's *Carnal Knowledge and Imperial Power: Race and the Intimate in Colonial Rule* (2002), as well as Fernando Coronil's *The Magical State: Nature, Money, and Modernity in Venezuela* (1997) are prominent examples of this approach.

The second method involves moving out from single sites to conduct "multisited" ethnography in order to examine movements of ideas, peoples, and things. Carolyn Nordstrom's *Shadows of War: Violence, Power, and International Profiteering in the Twenty-First Century* (2004) takes this as its task, using ethnographic methods to track the mobility of goods and money throughout large-scale extralegal exchange systems fueling conflict, marginalization, and profiteering.

The Global Political Economy

While definitions of globalization abound, the greatest differences in such definitions are typically a matter of

emphasis. Modern-day political economic anthropologists, for example, clearly emphasize political and economic processes that structure and are structured by landscapes of human interaction. Like Wolf and Mintz, these anthropologists view the political economic approach as a necessary corrective to scholarship that historically turned interconnected people and places into distinctive and disconnected phenomena. A great number of medical anthropologists, for example, call for anthropologists to cast light on the historical and contemporary connections and disconnections within the capitalist world system that bring about human affliction. Both Paul Farmer and Nancy Scheper-Hughes are archetypes of this contemporary political economy of health approach. Paul Farmer's "An Anthropology of Structural Violence" (2004) outlines the historically deep and geographically broad exploitive relations between Haiti and the United States that have predestined the deaths of Haiti's impoverished to AIDS and tuberculosis. Nancy Scheper-Hughes's "The Global Traffic in Human Organs" (2000) argues that economic globalization has facilitated the creation of an extensive market for the illicit harvest and trade of human body parts. Within this market, impoverished populations are targeted by brokers who, with the help of surgeons, turn high profits by selling these human organs and tissues to wealthier consumers in the global North.

Phenomena like these, political economists assert, are associated with the advent of late-modern capitalism—now commonly called "neoliberal globalization." Neoliberal globalization refers to the predominate theory of free market capitalism, which these analysts argue continues to be the primary engine of globalization. The term *neoliberalism* itself underscores an important element of the political economic argument—that globalization is a human-made and ideologically driven set of processes.

The focus on neoliberalism is also one manner in which scholars have come to conceptualize how the contemporary moment is fundamentally different from the past. The most clearly articulated and influential starting point for many scholars of this school of thought is David Harvey, a Marxist geographer who in his significant work *The Condition of Postmodernity* (1989) argued that economic restructuring and associated social and political changes in Western economies in the early 1970s sparked a fundamental reorganization of global commerce that sped up the turnover times of capital. These changes were characterized, according to Harvey, by an increasing sense of spatial attenuation and temporal acceleration in human economic and social relations. Harvey referred to this sensation as *time-space compression*, which was brought on by the collapse of significant geographic and temporal barriers to commerce. This collapse was a byproduct of an economic experiment promoted during a crisis of capital accumulation and subsequent recession that existing Keynesian fiscal and monetary policies could do little to stop. The experiment involved the transition from the Fordist model of standardized

commodity production and its related system of political and social regulation (the dominant mode of capitalism since the end of World War II) to the post-Fordist model of flexible accumulation. The increased velocity and reach of market transactions this new regime of accumulation prompted were realized through substantial innovations in transport and information technologies. Harvey's 2005 book, *A Brief History of Neoliberalism*, traces the neoliberal influence behind this shift, arguing that the transition was a political project intended to reinvigorate elite class power and capital accumulation mechanisms.

Perhaps the most recent and representative anthropological effort to further develop this perspective is Jean and John Comaroff's "Millennial Capitalism: First Thoughts on a Second Coming" (2000). The Comaroffs argue that neoliberal globalization at the turn of the millennium is a process that alienates capital from labor and marshals consumption as the primary shaper of social and economic phenomena like popular civil society discourses, occult economies and religious movements, and global youth cultures.

Much of the anthropological literature on neoliberalism thus far has focused less on the logic and mechanisms of its production and administration (though this is increasingly a field of study, as some anthropologists turn their eyes to understanding the inner workings of institutions like the WTO, IMF, and World Bank), and more on the impact of, and resistances to, neoliberal globalization. June Nash's *Mayan Visions: The Quest for Autonomy in an Age of Globalization* (2001) is a representative ethnography of this focus, as is Jeffrey Juris's *Networking Futures: The Movements Against Corporate Globalization* (2008).

The Global Cultural Economy

A second approach to globalization, coming to prominence in the early 1990s, places greater emphasis on anthropology's most common focus of attention: culture. (See Kearney, 1995, for an excellent summary of perspectives during the early 1990s.) Many proponents of this cultural approach, while acknowledging the world's deep history of social interaction, tend to stress the fundamental newness of the present, going so far as to describe a new global era. One of these proponents, Arjun Appadurai, writes a radical reply to center-periphery models of political economy and proposes that any framework emphasizing order in the present globalizing world is deluded. Appadurai's *Modernity at Large* (1996) understands the new global era as having been brought about by a complex and rapidly changing global cultural economy of exchange. The birth of this new era was facilitated by phenomena like media and migration, and both of these have served to reorganize nation-states and mobility on a global scale. Appadurai proposes that this chaotic world be grasped through five dimensions he calls *scapes*, or the landscapes across which cultural flows travel: ethnoscares, mediascares, technoscares,

financescapes, and ideoscapes. These scapes overlap to constitute the particular lifeworlds of individuals across the world—each lifeworld being wholly individualized. In short, Appadurai posits a disorganized, centerless world in which no single view yields any grasp of larger processes—the ubiquitous flows of ideas, technologies, objects, and images constituting the global cultural economy are nonisomorphic and indeterminate.

A perspective similar to Appadurai's, and borrowing from Ernesto Laclau, is that of Inda and Rosaldo (2008), who describe the contemporary world as "dislocated." The use of this term is intended to emphasize that a plurality of centers serve as the hubs of cultural traffic across the globe. This perspective, as well as Appadurai's, draws on ethnographic examinations of movements of commodities, people, and images and how these movements are perceived, translated, or appropriated by specific groups with whom they come into contact. At first glance, such movements suggest a significant imbalance in international exchange between the global North and South. Indeed, many Western, and indeed American, products like Coca-Cola, McDonald's, and films are promptly visible in a variety of contexts far from Europe and North America. It is from these and other observations that analysts have often come to consider cultural imperialism as a force of homogenization that levels cultural difference throughout the world (see Tomlinson, 1991).

Yet cultural homogenization assumes that the essential meaning of a commodity or idea is consistent and universally legible—meaning that, for example, a Sri Lankan teenager will interpret an *Indiana Jones* film the same way a German teenager might. Subsequently, it could be inferred that the circulation of Western commodities or ideas will have predictable local effects. Anthropologists argue that there is little inevitability in such exchanges. Rather, a consumer applies her or his own cultural perspectives to the interpretation of objects and ideas, culturally tailoring them in the process. Laura Bohannan (1966) discovered as much in the 1960s when she observed a West African production, and subsequent interpretation, of Shakespeare's *Hamlet*. Liebes and Katz's *The Export of Meaning: Cross-Cultural Readings of Dallas* (1990) is a modern retelling of Bohannan's experience, demonstrating how the popular American television program *Dallas* was quite variously received among Moroccan Jews, Russian Jews, and Arabs.

The cultural tailoring described above has, in many instances, become a rather common element of cultural interaction across the world, especially in light of myriad technological advances and their ability to radically compress time and space (see Harvey, 1989). Due to this, many researchers have come to see culture as less stabilized and more diffuse, going so far as to claim that globalization has "deterritorialized" culture.

As argued earlier, many anthropologists have historically mapped culture onto territorially demarcated places,

understanding distinctiveness as a product of social structures within supposedly locally bounded spheres. Said differently, place was the container of culture. (For example, the nation-state of China contained "Chinese culture.") Gupta and Ferguson rebuke these analyses and call for anthropologists to examine how such conceptions produce difference and reinforce unequal relations of power. They further argue that cultural forms cannot be conceptualized as being fastened to specific geographic locations. Rather, the contemporary world is characterized by the freeing of culture from specific localities, and the notion of deterritorialization captures this process.

Deterritorialization also stresses the tension central to the commonly articulated local/global dichotomy. Indeed, as individuals and groups engage with and are shaped by processes that connect their local worlds with others, cultural forms can come to have an impact regardless of whether they originate in the global North or South. Thus, the significance of non-Western cultural forms circulating in contexts outside of their origins should not be underestimated. Examples of this are everywhere visible, from the ethnic cuisine consumed in the global North, to popularly imported and exported religious beliefs like Buddhism, to non-Western modes of dress like headscarves that have engendered much debate in some European countries. This is due to the fact that while cultural forms become unfastened from one locality, they simultaneously fasten themselves to new contexts and can become highly relevant. Anthropologists cite examples like these to suggest that cultural and even political-economic exchange between the North and South can be mutually significant, or "relational" in its character. Hannerz (1996), borrowing from linguistics, referred to this relationality as the "creolization" of the core and periphery.

Further examples of this exchange are human migration and trafficking, which have left many culturally uprooted peoples "reterritorialized" in foreign lands where they navigate new ways of living with aspects of their cultural identity they have carried with them. Analysts often refer to such individuals and groups as *transnational*, as they move across and between national boundaries. At times, the connections between these "old" and "new" communities are so strong that anthropologists have argued they should be understood as single communities scattered in multiple localities.

Ultimately, the arguments and examples outlined above suggest that the world be viewed as a complex global society composed of interweaving cultural, political, and economic processes and forms. This is not to suggest that globalization engenders a homogenous global population, but rather to recognize the untethered nature and intensified potential of interactions between populations. Anthropologists argue that only continued heterogeneity within this global society can be assumed.

Of course, the discipline has been careful not to assume that movements are experienced by all peoples, things, and ideas or that all experience movements in the same way.

Indeed, many have argued that such processes have left areas and peoples excluded and marginalized. David Graeber (2002) made the point that processes of economic globalization like the North American Free Trade Agreement (NAFTA) have in fact tightened many national borders, and he cited numbers suggesting that since NAFTA's inception in 1992, the number of guards along the border between the United States and Mexico has more than tripled. Moreover, anthropologists like Escobar (2001) have argued that too great a focus on the deterritorialization of culture can obscure processes of place making, as well as the fact that people continue to imagine and build cultural forms that are situated in specific localities.

Questioning "Globalization"

As intimated earlier, the anthropological commitment to fieldwork has led many researchers to avoid nonempirical assumptions as to what globalization might be or what effects it might engender. Subsequently, the concept of globalization has been disputed by some anthropologists frustrated with its imprecise and assumptive nature. This view is summarized by Cooper (2005), who separates "global" from its affix "ization" to call attention to the term's problematic insinuations.

The first of these pertains to the scale of globalization—namely, that it is singular and worldwide, that it is something that encompasses the earth. Cooper argues that empirical truths about the world do not reflect the notion of global interconnection. Indeed, vast stretches of the planet, most notably in sub-Saharan Africa, remain largely disconnected from the wider world. As Ferguson (2006) has noted, movements of commodities, images, and ideas tend to hop over these geographic expanses, rather than smoothly envelop them. Equally problematic, according to Cooper, is the fact that a process that is global is everywhere and immeasurable, and therefore of little analytic value.

Second, the affix suggests the "when" of globalization—that it is currently happening, that this is the "global era." Cooper contends that one must be cautious in asserting that such mobilizations and exchanges are historically novel—or an original product of a contemporary global framework. Such an assertion ignores the fact that massive labor migrations (forced or otherwise) in the past engendered the diverse cultures with which we currently identify. In fact, Cooper has argued that movements of laborers in the 19th century were in fact more substantial than those of the present day. It is therefore more accurately stated that human mobility and interaction have been processes long defining cultures across the globe, though contemporary movements of people continue to create novel cultural dynamics and milieus. Similarly, Tsing (2000) has asserted that theories contending the absolute newness of a global era tend to obscure historical happenings that offer insight into both the past and present.

These analysts call attention to the fact that, due to its magnitude, globalization is a concept that must be imagined rather than directly experienced. Yet this is not to suggest that a singular system is out there—that it is simply a matter of lacking the proper tools to see it in its entirety. A metaphor commonly invoked to describe globalization imagines several blind men examining the extremities of an elephant. One man touches the trunk, another a tusk. Several stroke the elephant's legs. Each man will argue that he knows what the elephant is, or how the elephant in its entirety appears. Yet due to the size of the elephant and the sensory limitations of the men, none has the ability to know it fully. The problem with this metaphor is that it assumes a singular entity—the elephant—or a coherent framework that one claims to know is there but cannot fully experience. The consensus among critical anthropologists like Cooper and Tsing disputes this, arguing that globalization is an analytic construct, not a coherent world-making system. Moreover, they argue that collecting the variety of exchanges shaping relationships in the world under a single moniker makes for an inadequate analytic category, for it fails to capture the specific mechanisms of interconnection and the histories in which they are embedded. This is a view that rejects a singular world-making system in favor of a pluralization and inconsistency of agendas, projects, and processes. These international projects may be grand in scale, but they are not uniformly consistent or all encompassing. They vary according to the terms of their creation as well as their sites of origin.

These anthropologists call for examining globalization from a critical distance, paying attention to the arguments and mechanisms by which theories of globalization are mobilized. One example of this would be to challenge the exclusively celebratory espousals of globalization—what is often referred to as the "globalist" perspective—that, through popular media information, attempt to influence ideas of wealth and mobility. The power in this information lies in its ability to reproduce a specific logic that many globalist pundits advance—that of globalization's huge potentiality. This can be misleading, however, as the life of a farmer or laborer in the global South may be so socially and economically constrained as to prevent her from traveling to the closest major city, much less jet-set about the world.

Moreover, the critical distance approach is especially important in light of the fact that influential discourses defining globalization inform the decisions of the world's powerbrokers, especially transnational governing bodies like the World Bank, IMF, and WTO, as well as powerful nations whose leaders read popular political pundits. It is important to emphasize here that talk about difference can move quickly about the world, mobilizing individuals and institutions to act upon it for the purposes of security, economic profit, stability, and other aspirations. In this sense, talk about globalization, when wielded by actors embedded in complex relations of power, can have very real effects in people's everyday lives.

By way of example, a number of recent dialogues in North American academic and public circles have focused less on the homogenization of culture (or cultural imperialism) and more on cultural difference, while maintaining that a more or less singular global framework brings about foreseeable effects. This talk articulates a gray zone between globalization's positive and negative consequences, sketching a context in which cultural heterogeneity and increasing global mobility create both opportunity and threat. These claims to know a singular global system can have powerful effects. On the one hand, recent national best sellers by popular political pundits hail globalization as a force that flattens the world, creating an even playing field for those "willing" to participate. They inform international policy at the World Economic Forum and chastise governments resisting privatization and deregulation of large industries. On the other hand, these works instill a sense of fear in the post-9/11 world, as many nations and groups are depicted as foils to global connection—their own development complicated by dated cultural beliefs and traditions that ultimately threaten to violently derail the future. Thus, while globalization has brought us closer to allies, it has also compressed the world in such a way as to make it more vulnerable to conflict and resistance. Ultimately, these are fears of difference in which cultural heterogeneity, rather than the worldwide "McDonaldization" of societies, is emphasized.

A number of anthropologists have felt compelled to respond to these conceptions of globalization. Besteman and Gusterson's *Why America's Top Pundits Are Wrong: Anthropologists Talk Back* (2005), for example, takes its inspiration from public anthropologists like Boas and Mead and wields an anthropological sensibility with ethnographic evidence to challenge the destructive myths of America's most popular pundits writing about globalization. The volume's chapters are written in clear and compelling language, and are thus geared toward a general audience.

Finally, some anthropologists have cast a critical eye on the theoretical underpinnings of anthropological approaches to globalization, calling attention to the problematic gendering of epistemologies attempting to capture large-scale social change. Freeman's "Is Local: Global as Feminine: Masculine?" (2001) provocatively examines the implications of the partition of masculine macro theories of globalization (which largely ignore gender) and ethnographic approaches to globalization emphasizing locality and gender.

Development

Globalization is a term that has, in many instances, come to replace the older and no less complex notion of "development." In fact, Edelman and Haugerud (2005) have argued that *globalization* has replaced the term *development* as the new action word of contemporary international governance discourse. Not simply a term that describes an

inevitable process that is shaping the modern world, globalization, when conflated with development, is a metapolicy guiding the way to social and economic well-being in the global South.

The replacement of development by globalization is also evident in South American contexts like Venezuela and Bolivia, where supposed antiglobalization social movements and nationalization policies have been viewed by many Northern countries and transnational organizations as detrimental to international peace and global economic stability. In contrast, these Northern governing bodies espouse state-led implementation of globalization-friendly principles for the sake of individual nations' prosperity, as well as prosperity for the world. Thus, it is by ultimately opening up borders and financially connecting to the wider world that nations soar themselves out of poverty and into the global marketplace, developing in the process.

The two most influential anthropological works on development, Ferguson's *The Anti-Politics Machine* (1994) and Escobar's *Encountering Development* (1994), challenge this widespread thinking. Ferguson argued that in fact such development schemes usually fail and in the process further embed countries in the exploitative systems that were intended to help them. Ferguson also faulted these schemes for overlooking the social and historical specificities of countries and favoring techomanagerial solutions that are generally applicable to all "developing" countries.

In his influential book, Escobar attempted to denaturalize "development" by situating it in the political aftermath of World War II, when, in 1949, President Harry Truman argued for "developed" nations of the world to systematically restructure the global South, reconfiguring the world in the image of "advanced" nations. Following Walt Whitman Rostow and his work *The Stages of Economic Growth* (1960), many policymakers and social scientists in the years following Truman's speech came to view development as the establishment of preconditions for the "take off" from traditionality to modernity. Escobar examined how this language and categorization of development problems becomes the official knowledge of international development experts and how this expertise subsequently becomes unanchored to any political, cultural, or historical context. He ultimately argued that this categorization, or naming, of peoples and places as objects of development interventions has devastating material effects: Targeted "underdeveloped" communities are often left worse off than they were prior to the intervention, and in addition, increasingly reliant of foreign aid.

Governance, Sovereignty, and Citizenship

To what extent can it be said that recent transformations have changed how states govern and with what efficacy? Globalist claims have often declared the demise of the state with the

dissolving of national borders and the rise of international governing institutions like the WTO, World Bank, and IMF. Yet, as Tsing (2000) noted, this idea assumes that nation-states have been historically consistent and omnipresent.

There is little doubt that the development of international law and institutions upholding it have changed the means by which many states govern their populations. However, proclamations of the global dissolving of nation-states are exaggerated, according to anthropologists. This does not mean that states have not changed at all. Indeed, contrary to the traditional doctrine of sovereignty, many states are now held accountable by international authorities and in many instances are forced to comply with their policies. The degree to which such states are actually constrained and reshaped by international institutions varies, of course, from context to context. (Merry's 2006 overview of anthropology's engagement with international law is instructive on the above points.) Thus, one could argue that the sovereignty of states in the present has been to a large degree reorganized, if not in many instances greatly circumscribed. Sharma and Gupta (2005), in their important volume *The Anthropology of the State*, argued that "sovereignty can no longer be seen as the sole purview or 'right' of the modern state but is, instead, partially disentangled from the nation-state and mapped onto supra-national and non-governmental organizations" (p. 7).

The shifting nature of governance and states at present comes to heavily bear on conceptions of citizenship within countries. Many anthropologists argue that globalization has reformulated many notions of and policies pertaining to citizenship. Ong (1999), for example, used the term *flexible citizenship* to grasp how individuals and groups deploy various strategies to evade, as well as profit from, various national regimes of citizenship. Ong argues that the elite, flexible Chinese citizens have discarded traditional notions of nationalism in favor of a "postnational ethos" that transcends national boundaries for the sake of participation in the global capitalist market.

Conclusion and Future Directions

When considering the various viewpoints outlined above, it is important to remember that anthropologists' commitment to fieldwork and the empirical evidence it produces significantly informs their perception of the global. Said succinctly, where anthropologists work shapes their perspective on globalization. It is not surprising to find, then, that the most influential anthropologists working in sub-Saharan Africa talk of global disconnection, while many working in the metropolitan cities of India stress the interconnection brought about by a global cultural economy. Due to this, it should equally be stressed that every view of the global is always a view from somewhere. There is no perch from which an analyst can ascertain the world from an objective, comprehensive position.

Yet the contrasts in the above perspectives are highly positive in that they produce a creative tension that thwarts stagnation in favor of fresh approaches and directions for the study of globalization. One product of this tension has been an active emphasis on "studying up," or turning a critical eye to national and international institutions and actors whose projects aim to influence social and economic change. The recent anthropological concentration on the predominate economic philosophy of the present—neoliberalism—is laudable in this regard. Important recent works—like Ong and Collier's *Global Assemblages* (2005); Petryna, Lakoff, and Kleinman's *Global Pharmaceuticals* (2006); and Fisher and Downey's *Frontiers of Capital* (2006)—take states, transnational governing bodies like the World Bank and WTO, human rights NGOs, corporations, and even powerful individuals like the U.S. chairman of the Federal Reserve as objects of ethnographic analysis.

Furthermore, the means by which anthropologists go about examining these objects, as well as the way they write about them, is changing. The fact that anthropologists are increasingly turning their focus to the world's powerbrokers means that they take the discourses and policies of these powerbrokers very seriously. This is all the more important because anthropologists tend to disagree with these discourses and policies and subsequently wish to dispute them. Yet in order to successfully dispute them, anthropologists must write for audiences outside of the discipline. Two works already mentioned, *Why America's Top Pundits Are Wrong* and *Global Shadows: Africa in the Neoliberal World Order*, are prominent examples of this endeavor.

All told, the above discussion signals a much more general development in which anthropologists are increasingly seeking to bring their disciplinary perspective to bear on public discussions of globalization. Anthropology is one among many disciplines that can greatly contribute to this ongoing discussion.

EDUCATION AND ANTHROPOLOGY

SUZANNE E. D'AMATO

Medaille College

In the 1970s, education became an academic subfield of applied anthropology as it applies to different communities and cultures existing within education systems. From that perspective, students, parents, faculties, and school administrators represent different communities, and, by using anthropological theories, these groups can understand current conditions of education and conceive applications for the future. The importance of applied anthropology to education is spotlighted as we gain understanding of classroom dynamics with respect to increases in student diversity, in numbers of special needs students, and in the use of technology in the classroom. Concepts of race, gender, ethnicity, and nationality are especially relevant as students develop their sense of identity as members of groups. More than ever, these concepts are critical, as schools look to deal with conflict and promote positive intergroup relations.

As Charles Darwin cut across disciplinary boundaries and questioned conventional wisdom, teachers also cut across curricular boundaries to make cogent connections that enable students to achieve an understanding of and an appreciation for the human experience. One goal of today's teacher is to both understand and influence individuals so that they may become whole, rational, and productive citizens. An overall goal of education is to assist learners to construct meaning. Negotiating meaning requires an understanding of the prevailing culture, whether the subject is literature, music, social studies, science, or religion.

Effective education is based upon positive social interaction among all those involved in the school community. Teachers who build their practice on anthropological understandings and methodologies will leverage knowledge to improve student attitude and achievement.

Using this perspective, education and anthropology will work together to alleviate behavioral difficulties, drop-out rates, violence, and other negative influences that have the potential to impact the school and, ultimately, the individual. With Darwin-like insight, teachers assist learners to recognize the "internal logic" of classroom society. They foster a cooperative environment where students' similarities and differences are accepted and their interdependence is recognized. They encourage the sharing of ideas, experiences, theories, discoveries, and expertise. Teachers arm students with global information and thinking skills critical to following various career paths to success in 21st-century business, research, government, agriculture, advocacy, and public service.

While reflecting on the influence of Darwin on education, key skills that originated with Darwin are apparent. These include seeking multiple perspectives, rational speculation, observation, dialogue, analytical reading, data collection, comparing and contrasting information, testing hypotheses, drawing conclusions, and applying theories. Other pedagogies derived from Darwin include research methodology, logic and reasoning, detailed record keeping, clear thinking, and scientific inquiry.

The complexity of humanity directs anthropologists and educators to work in concert. Equipped with a satchel of scientific armaments initiated by Darwin, professionals are prepared to crack the smallest kernel of misinformation. Together, anthropologists and enlightened educators deploy such devices as scientific inquiry and logic to go about “solving” the problems that we face in our lives, studies, and classrooms. A huge mutual goal is to determine how we can consistently and successfully manipulate such tools, challenging America’s youth and changing how American youth process their inherent positions and perceptions. A typical U.S. public school classroom houses many nationalities. It is of utmost importance to educate all students to understand differences: cultural, socioeconomic, psychographic, and demographic. By expanding the horizons of our students, we are likely to invest in the notion that we are all similar despite being different in appearance, ability, or wealth.

Prejudice and ethnocentrism are the products of fear caused by a historic lack of both knowledge and understanding of differences. These conditions have shaped society. Throughout the ages, an attitude of “banish or perish” has launched attacks of humanity upon humanity. In the middle of the 20th century, the development of third world countries was seen as hopeful, a precursor to positive interethnic relations. Melting pot theorists predicted that as poor nations advanced in their development, ethnicity would become less important and peace would follow. This view was challenged by the conflictual modernization theory, and development was seen for a time as a cause of conflict. However, as the world approached the 21st century, development was more strongly considered to be a precondition for peace. To this day, bias, prejudice, bigotry, conflict, marginalization, and ethnocentrism continue to contaminate society, and these hazards trickle down into the schools.

The teaching of scientific inquiry, therefore, is significant when students learn to question circumstances and problems as they arise. Students need to be taught to question and respond profoundly—beyond transactional or procedural questions or the typical short answers to teachers’ questions. It is suggested that a learner’s questions can identify whether the learner’s thinking is naive or whether it is complex, depending on whether the questions focus on conceptualizations or minutiae and detail. Helping children to question situations may help a student achieve, but bringing students to understand that different people think of different ways to question is the greater lesson. This lesson brings with it an appreciation that people of other ethnicities and cultures may bring drastically different questions to bear on a given situation. Situations of small or large consequence may be solved collaboratively and skillfully when teachers accept and appreciate the contributions of others.

Why is there so strong a resemblance between anthropological methodology and educational methodology?

Was it coincidental that educational practice underwent a revolution after the publication of Darwin’s *On the Origin of Species* in 1859? Is it probable that Darwin’s evolutionary framework had an intense and powerful impact upon scholars throughout time—scholars who influenced their protégés who, in turn, influenced others?

It is possible to put forth the premise that Darwin was the originator, indeed, the true father of educational pedagogy and methodology throughout the world in the late 1800s and throughout the 1900s. Furthermore, one may contend that his effect upon education has been extended well into the 21st century. An evidentiary trail may be blazed from Darwin directly to John Dewey, and from Dewey to Tao Xingzhi from China, Maria Montessori from Italy, Lev Semenovich Vygotsky from Russia, and Howard Gardner, who is presently teaching at Harvard University in the United States. Each of these giants in the field of education and psychology has made his or her theories felt by others. For example, Vygotsky impressed the world-famous Jean Piaget, his contemporary from Switzerland, as well as Arthur Appleby, born in 1946 in the United States. Gardner brought his influence to bear on Spencer Kagan, who in turn influenced David Johnson and Roger Johnson (all from the United States, and all of whom we credit with extensive research into cooperative learning). The line does not, of course, ever end. All of these people have gone on to shape the thinking of scores of others worldwide who define education as a profession. Several will be discussed in this chapter, and it all began with Darwin!

In the Beginning

To understand the impact of Darwin upon the global educational community, it is necessary to understand the man. Known today as England’s greatest naturalist, Darwin—geologist, biologist, anthropologist—had a unique and replicable approach to learning. His joy in discovery and attention to observation, notation, comparison, and evaluation underlie his greatest discoveries and serve as an overarching model for educational pedagogy and methodology. With Darwin in mind, the connections between anthropological and educational procedures become apparent, and the fields of anthropology and education reflect more in common than might be realized at first glance. Key skills and dispositions that were used and refined by Darwin have been integrated into what is termed educational *best practice*. Darwin himself was open to change; the analytical categories and processes that he employed are useful in understanding the culture of today’s school children, for example, how teachers teach and how students learn.

The application of anthropology to education dates back more than a century, to when Hewitt published his thoughts on education in the *American Anthropologist*. However, it is here theorized that the connection between education and anthropology preceded Hewitt, originated

with Darwin, and moved in succession to Dewey, Vygotsky, and others down through the years. To some degree, historically, the education profession revised old programs and practices, renewed and renamed them, and implemented them in what was hoped to be a better way. A more Darwin-like approach to change is to study the old programs and practices in light of their relative success, break old molds, design innovations, and implement new and revolutionary practices, all based on research. Clearly, this approach indicates that it is the responsibility of the educator to teach social skills and to interact with cultural and ethnic groups other than their own. In turn, this allows students to study in collaborative situations leading to social acceptance, self-discovery, and the ability to take risks within the learning environment. Through the example of Darwin, education and anthropology aspire to similar goals and to utilize similar methods of research and discovery.

Charles Darwin

Charles Darwin (1809–1882) recalled his father once telling him, “You care for nothing but shooting dogs and rat-catching, and you will be a disgrace to yourself and all your family” (Barlow, 1958, p. 28). It was an inauspicious indictment of one of history’s greatest thinkers. Born in Shrewsbury, England, Darwin did poorly in traditional school settings and preferred to collect specimens of animals, plants, and minerals that he would experiment upon in his brother’s chemistry laboratory. He was, by today’s definition, a hands-on, tactile-kinesthetic learner. At age 16, with urging from his father, Darwin entered the School of Medicine at Edinburgh University, where he found lectures boring, cadaver dissections horrible, and surgeries, without the benefit of anesthesia, gruesome. After graduation, Darwin reluctantly enrolled in the University of Cambridge with the idea of becoming a clergyman. While at Cambridge, Darwin was inspired by the *Personal Narrative* of Alexander von Humboldt, the German naturalist, who wrote about his travels in South America and his discoveries in geology, geography, and mineralogy.

Having been invited to set sail on the HMS *Beagle*, a frigate designed for scientific research, Darwin embarked on a five-year expedition to chart the coastlines of South America. On board ship, he read intently and was influenced greatly by the geological ideas and perspectives presented by Charles Lyell. The *Beagle* reached Brazil in February 1832, and Darwin began to answer destiny’s call. He spent months observing and collecting plants, animals, minerals, and fossils and keeping careful and detailed records of his discoveries. He was astounded to find marine fossils high in the Andes Mountains and hypothesized that the land had once been covered by water. Darwin satisfied his belief that the earth’s topography is always changing when he lived through earthquakes in Chile.

Arriving in the Galapagos Islands, he discovered many life forms that were not found anywhere else in the world. Darwin was intrigued by the numerous species of birds found there and noticed how various species of finch had developed specialized beaks that aided them in gathering and consuming food. He further noted that organisms on the island seemed similar to, yet different from, those organisms on the mainland.

From his experiences on HMS *Beagle*, Darwin began to question the idea of creationism and the belief that a supreme god created immutable organisms to populate an unchanging world. He used the now-very-popular comparative method to challenge concepts and to introduce new facts and values. His constructivist methodology resulted in a most extraordinary evolutionary framework. To brief: All living things compete for space and sustenance while being constantly challenged by threats from their changing environment. Later, in *On the Origin of Species* (1859), Darwin explained his theory of natural selection as “grounded in the belief that each new variety, and ultimately each new species is produced and maintained by having some advantage over those with which it comes into competition; and the consequent extinction of the less-favored forms almost inevitably follows” (p. 93). Essentially, he implied that all life on earth, including the human species, is the result of evolution over millions of years of adaptations to changing environments. Darwin concluded as follows:

Having been originally breathed by the Creator into a few forms or into one, and that, whilst this planet has gone cycling on according to the fixed laws of gravity, from a simple beginning endless forms most beautiful and most wonderful have been, and are being evolved. (1859, p. 114)

As Darwin looked with awe upon Creation, the convergence of his evolutionary framework pointed ominously to the precarious position of our species and the essential need for mutual respect, global understanding, and planetary interdependence. As a species, humans are constantly competing for space and support. Opposing forces such as insurrection, disease, poverty, ethnocentrism, and racism threaten us. Shifts in the environment, climatic changes, depletion of natural resources, and pollution challenge us. For these reasons, educators have been influenced profoundly by Darwin, his research, his methods, and his theory of evolution. Far from being the disgrace his father predicted, in the 200 years since his birth, Darwin has become a model of optimism, unification, and hope for the future. He saw the magnificence of all living things, including humankind, and his theory of evolution impels us to respect one another despite any or all differences. For these reasons, we must come together as one diversified but unified species, evolved from a common ancestor, and aware of the interconnectiveness of our global society. Darwin told us the following:

It is a world of wonderful similarity and change among all living things; where the tiniest flea is directly, organically related to the most massive elephant; where struggle and even death make for progressive evolution in which good useful characteristics develop to benefit every species. (1859, p. 115)

Thanks to Darwin, present-day educators respect both the similarities and differences among their students and view them as an “evolving species,” which will grow and develop into productive adults. Teachers also consider themselves to be an “evolving species,” capable of adapting teaching styles and strategies to meet the diverse needs and wants of their students. Through the intersection of education and anthropology, humanity has its greatest hope of survival as we advance scientifically, morally, philosophically, technologically, and academically.

John Dewey

Education is a social process; education is growth; education is not a preparation for life, but is life itself.

—John Dewey (Boydston, 1972, p. 50)

In the same year that Darwin published his seminal work, *On the Origin of Species* (1859), John Dewey was born into a Burlington, Vermont, family. Son of a Civil War veteran and an evangelical Congregationalist mother, Dewey grew to become the most influential philosopher of modern times. His influence is most viable in political and educational forums. The founder and renowned “father of progressive education,” Dewey built his philosophy around his own life experiences as well as the emerging philosophy and scientific thought of the times.

Upon graduation from the University of Vermont in 1879, and unsure of his future, Dewey was tutored in philosophy for three years while he earned his living as a high school teacher. He then applied to and matriculated at Johns Hopkins University for graduate work. Studying under George Sylvester Morris, who followed Hegelian philosophy, Dewey wrote his dissertation on Hegelian idealism and earned his doctoral degree in 1884. In time, Dewey rejected absolute idealism, which suggested that fact and thought are connected in that facts develop from thoughts. However, he evolved a more naturalistic and pragmatic philosophy that was refined and supremely influenced by the works of Darwin. His theory of natural selection provided form for Dewey’s naturalistic approach to the theory of knowledge. *On the Origin of Species* (1859) introduced Dewey to a mode of thinking that would ultimately transform the logic of knowledge and hence his treatment of morals, politics, religion, and education. Rejecting supernatural explanations for the origin of species, Dewey adopted Darwin’s naturalistic account and then considered the development of knowledge as an adaptive response, that

is, as the product of the interaction between humankind and its environment. Dewey saw knowledge as having a practical instrumentality in the dominion and administration of that interaction. He termed his new philosophical approach *instrumentalism*. Clearly stated, if problems are constantly changing, then the instruments for dealing with problems must change. It follows, then, that if truth is evolutionary in nature, it does not have an eternal reality. In a collection of essays by Dewey (1910), the longest essay is titled “The Influence of Darwin on Philosophy”; it is an in-depth discussion of the impact that Darwin had on modern thought.

The influence of Darwin on Dewey’s philosophy of education was immeasurable. In his own practice, Dewey taught at the University of Minnesota and then at the University of Michigan. He achieved greatness as chairman of the Department of Philosophy, Psychology, and Pedagogy at the University of Chicago. He became president of the American Psychological Association in 1889, and he was the president of the Philosophical Association at Columbia University from 1905 until his retirement in 1930.

Dewey’s Darwinian philosophy of education has had far-reaching effects on other philosophers, on teaching, and on learning. He maintained a pragmatist stance that schools should prepare individuals for participation in community life and overcome barriers between school and community in order to provide education that satisfies the needs of a truly participatory democracy. Dewey favored practice over theory, based on his belief that learning best occurs when students are free to generate their own experiments, experiences, questions, and creations. He believed that under the direction and guidance of a good teacher, children could learn ways to cope with situations and conditions that may occur in the unfathomable future. Dewey believed strongly that schools should take on societal responsibilities. He was convinced that the acculturation of immigrants was the responsibility of the schools. Therefore, like Darwin, Dewey showed respect for diversity and saw individuals as valuable contributors to society.

In 1896, Dewey established laboratory schools where he highlighted the scientific method for problem solving and where students, in workshop settings, took ownership of their own learning. The role of the teacher was that of a facilitator, not director or instructor. An advocate of “the child-centered school and the school that gave full emphasis to real interests and to learning through doing” (Dewey, 1956, p. viii), Dewey believed that teachers were the designers of educational experiences. His pedagogy contrasted sharply with traditional teacher-centered methods of isolation, study, and recitation.

Dewey’s theories became very popular. However, progressive education began to take on tangential forms. Dewey’s Laboratory School in Chicago and Manhattan’s The Lincoln School both closed, primarily because progressive education was misinterpreted and secondarily

because the Cold War advanced conservatism and the rigorous and rote study of math and science. Today, applications of the progressive movement are flourishing in many American schools, as well as international schools, and action research, open classrooms, schools without walls, multiage groupings, looping, block scheduling, and cooperative learning are integrated forms of this movement. Emphases on multiculturalism, hands-on learning, and participation in authentic learning experiences with real-world audiences reflect the pedagogical contributions of Dewey. Notably, as Darwin inspired Dewey, so have Dewey's contributions inspired other movements of import to education, for example, contextualism, empiricism, humanism, and naturalism. A study of Darwinian methodology is especially relevant in the postmodern age, as we come to terms with immigration, globalization, and extensive cultural diversity. Clearly, Dewey stands with Darwin as one of the greatest intellects of our time. It is not surprising, then, that they had direct and intense impact on Xingzhi, Montessori, Vygotsky, and Gardner.

Tao Xingzhi

Primary education is the base of a nation's education, and so the quality of primary teachers can decide a nation's future.

—Tao Xingzhi

In 1914, at the age of 23, Tao Xingzhi, then known as Tao Wen Tsing, left the family farm in Anhui, China, to study political science at the University of Illinois. Upon earning his master's degree, he enrolled in Teachers College, Columbia University. There, he studied under the auspices of William Kilpatrick and Paul Monroe. However, the professor with the greatest influence on the young scholar was none other than John Dewey, a strong proponent of Darwinian methodology and pedagogy.

Armed with a substantial Western education, Xingzhi returned to his homeland to reform and restructure the educational and social systems in China. Like Dewey, Xingzhi saw education as an agent of change. Having achieved a teaching position at the prestigious Nanjing Teachers College, he taught his students that school must be intrinsically connected to society in order to play a meaningful role in social reform. He encouraged students to be constructivists and activists, and he related his instruction to prior knowledge and hands-on, real-world experiences. Unfortunately, when Xingzhi applied his principles in the traditional Chinese university, he was limited by what little the school had to offer his students in terms of reinforcement. Disillusioned, Xingzhi alternatively rejected his Westernized perspective, resigned his post, and retreated to the countryside to live the simple life.

It is noteworthy that at the very time Dewey visited China in 1919 on his world lecture tour, Tao Xingzhi

simultaneously became more acutely aware of the poverty and illiteracy that plagued China. Over 80% of the Chinese population was poor; 77% was illiterate. What followed for Xingzhi was a great deal of experimentation integrating Dewey's theories with then-modern Chinese history, specifically issues of importance in the 1920s. After much thought, Xingzhi reversed Dewey's notion of "school as society" to "society as school." The thought of "education as life" became "life as education." Xingzhi's "unity of teaching, learning and reflective acting" was directly precipitated by Dewey's theory about "learning by doing" (Dewey, 1956).

The outcome of this experimentation was the founding of the Morning Village Normal School. Basic elementary education was taught at the school, but the doors were open to adults as well as children. Rural teachers were trained in Xingzhi's philosophies, and school became the hub for all social, political, economic, and educational activity within the community. Self-defense classes and health care services were provided. Educational opportunities were made available to the masses. At last, the school and the community were interconnected.

As successful as this first "experiment" was in improving education, economic production, and living standards, the school was forced to close by the Chinese Nationalist Army. Nonetheless, "the school had gained national recognition as a significant force in teacher education and rural education reform and this was a great beginning to China's modern and contemporary history of education" (Anhui Provincial Society for the Study of Tao Xingzhi, 1993, p. 4). The Morning Village Normal School was reopened in 1949 upon the formation of the People's Republic of China. Its founder did not live to celebrate the occasion. But the man originally named Tao Wen Tsing, meaning "the hopes and dreams of his parents," renamed himself to reflect changes in his philosophy over time. Tao Wen Tsing became Tao Zhixing, "knowing by doing," and finally, Tao Xingzhi, "doing, then knowing." A true disciple of Dewey, Xingzhi will be remembered as the man who introduced both progressive, child-centered, experiential pedagogy and a democratic educational system into Chinese schools.

Maria Montessori

Scientific observation has established that education is not what the teacher gives; education is a natural process spontaneously carried out by the human individual, and is acquired not only by listening to words but by experiences upon the environment. The task of the teacher becomes that of preparing a series of motives of cultural activity, spread over a specially prepared environment, and then refraining from obtrusive interference. Human teachers can only help the great work that is being done, as servants help the master. Doing so, they will be witness to the unfolding of the

human soul and to the rising of a New Man who will not be a victim of events, but will have the clarity of vision to direct and shape the future of human society.

—Maria Montessori (1946, pp. 3–4)

If John Dewey was the father of progressive education, Dottressa Maria Montessori was the mother. Montessori was born on August 31, 1870, in Chiaravalle, Italy, to well-educated and prosperous parents. A precocious child, at age 13 she began a seven-year study of science and engineering at Regia Scuola Tecnica Michelangelo Buonarroti. Uninspired by the curriculum or the instruction there, Montessori determined to study medicine at the University of Rome. Initially she was denied entrance because she was a woman, but eventually she was allowed to enroll, and finally, in 1896, she received her degree and became the first female physician in Italy. After postdoctoral study of psychology and philosophy, Montessori went on to become a professor of anthropology at the University of Rome in 1904.

In 1906, Montessori began to study and teach mentally and emotionally retarded students in Rome. Her interest in what we now term *special education* lured her from higher education. She said, “I felt that mental deficiency presented chiefly a pedagogical problem rather than a medical one” (1946, p. 4). As director of the state-run Scuola Ortofrenica (School of the Disabled), Montessori’s effectiveness with special needs children was termed the “Montessori Miracle.” Montessori soon founded Casa de Bambini (Children’s House) in Rome, where the Montessori method developed (Shepard, 1996). Simplified, the method is progressive: The teacher pays attention to the child, not the child to the teacher; imaginative and authentic teaching materials and student-sized furniture are used; activities are generated to develop children’s social skills, emotional growth, physical coordination, and cognitive acuity; and baric, chromatic, motor, and other sensory exercises promote the “self-creating” process. Moreover, the child proceeds at his own pace in this controlled environment, and materials are self-correcting, so that students check and revise their own work.

Montessori’s popularity brought her to the Netherlands, where she founded the AMI—Association Montessori Internationale in Amsterdam, and to England, where she met Mahatma Gandhi, who asked her to “Indianize” her method of “controlled chaos!” It is interesting that Montessori was invited to share her methods with over 1,000 teachers in Madras, Ahmedabad, Karachi, and Bombay, all in India, during World War II. Montessori Schools multiplied, and Montessori’s lecture tours found her in Europe, South America, and Africa. Early on, she brought her vision to the United States, where she was awarded celebrity status. Montessori lectured twice at Carnegie Hall in New York City. None other than John Dewey made the introductions to standing-room-only audiences.

Montessori was a disciple of Dewey. They both believed that learning is best achieved by doing, and growth is achieved through purposeful interaction with the environment. Montessori wrote, “We especially need imagination in science. It is not all mathematics, nor all logic, but is somewhat beauty and poetry” (Mitchell, 1896, p. 205). In the same vein, Dewey wrote, “Every great advance in science has issued from a new audacity of Imagination” (Dewey, 1929, p. 310).

Yet, despite their similarities, Dewey and Montessori had differences that put a cloud over her theories. He criticized her methods as being too rigorous and urged that children not be taught to read before age eight. He was concerned that homework was not regularly assigned in Montessori Schools and that, if it were given, it would be hard to design, as students’ homes might not have the apparatuses available at their schools. Arguments on either side may be drawn, but today Montessori Schools exist all over the world. She retired to Noordwijk Aan Zee in Holland and died in her garden, at age 82, from a vascular incident. It is ironic that Montessori and Dewey both died in 1952.

Lev Semenovich Vygotsky

Learning awakens a variety of internal developmental processes that are able to operate only when the child is interacting with people in his environment and in cooperation with his peers.

— Lev Semenovich Vygotsky
(1978, p. 90)

In 1896, when Dewey was opening the laboratory schools where group work was fostered as a meaningful way to learn, another teacher was born in present-day Belarus, a place that would later become part of the USSR. A Russian educational psychologist, Lev Semenovich Vygotsky was recognized early on to be a brilliant and original thinker, and his novel ideas about teaching and learning were respected by the intelligentsia within the Soviet Union. At that time, progressive educators were attempting to reform education in prerevolutionary Russia. *School and Society*, Dewey’s masterpiece, had been translated into Russian and was widely read by progressives, who drew on him for inspiration. This, in itself, provides a foundation for a Dewey-Vygotsky connection. Further, in 1928, Dewey visited Second Moscow University, where Vygotsky was a highly respected young psychologist. Prawatt (2004) made a strong circumstantial case that both Vygotsky and his compatriot, Blonsky, actually met with Dewey at the university. To strengthen the connection, we may take into consideration that Dewey posited that humans are only human through their social interconnectedness, and Vygotsky and Dewey concur that the human condition is based in social interactions. Moreover, their combined major works are Darwinian in research methodology and pedagogy.

Vygotsky spent his short life in Marxist Russia, but his theories did not conform to the Communist ideology. The Soviet government banned the publication of Vygotsky's work after his untimely death from tuberculosis in 1934. Unfortunately, Vygotsky's work remained in obscurity until his books were discovered at Harvard University and printed in the West during the 1960s.

Vygotsky's views on teaching and learning are founded on the Darwinian premise that human intelligence is not a fixed characteristic but, instead, a dynamic entity that can be enhanced by social interaction and collaborative work. Central to Vygotsky's views on learning is the belief that knowledge is not directly transferable from teacher to learner. Rather, through social interaction, the learner constructs his own meaning. This constitutes the theoretical basis for cooperative learning, a method that has now found favor throughout the United States, Canada, and many other countries around the world.

To comprehend Vygotsky's views as they relate to cooperative learning, it is necessary to understand his concept of the zone of proximal development (ZPD) (Lee & Smagorinsky, 2000). The ZPD may be described as the dynamic range of intelligence that characterizes any individual. If we were to envision two concentric circles, or double rings, then the large space in the center of the inner ring would represent an individual's current developmental ability to solve a problem while working alone. This area or zone may be likened to what would be measured by an intelligence test. The space between the first and second rings represents where an individual solves a problem when being guided or coached by a more capable peer or a teacher. This, according to Vygotsky, represents the ZPD. As individuals solve problems with assistance, this zone is expanded, and another ring encircles and defines a new ZPD. What did lie within the original ZPD has been subsumed into the center, and now the expanded, current developmental level of abilities (the widened center of the circle) is encircled by a new and enlarged ZPD. Naturally, there are problems that cannot be solved despite the best help from others, and some tasks lie outside of the individual's current zone of development. However, those tasks remain proximal and may or may not be completed with more assistance.

Howard Gardner

My mind was really opened when I went to Harvard College and had the opportunity to study under individuals . . . who were creating knowledge about human beings.

—Howard Gardner
(Schaerer, 1999, p. 6)

A prominent leader in the field of education and brain research, Howard Gardner has investigated extensively

and documented cross-cultural studies on human intelligence. Gardner employs anthropological methods, and his research reflects a respect for scientific inquiry, the value of experience, and an acceptance of change that was intrinsic in the work of Darwin and Dewey. Considered to be a “new” progressive, Gardner has revealed, “My universe was framed by Dewey” (1991, p. 314). Currently a psychologist and professor at Harvard University's Graduate School of Education, Gardner developed the theory of multiple intelligences. In *Frames of Mind*, published in 1983, Gardner theorized that there were seven equally important components of intelligence. In 1999, an additional component of intelligence was introduced, and recently Gardner revealed a ninth intelligence.

Traditionally, intelligence has been seen as cognitive capacity, established at birth, fixed and uniform across a lifetime. Like Darwin, Dewey, Vygotsky, and others, Gardner disputes that intelligence is fixed, and his research illustrates that individuals exhibit unique variations of intelligence. If we were asked who is most intelligent—William Shakespeare, Albert Einstein, Salvador Dali, Barack Obama, Jesse Owens, Igor Stravinsky, or H. James Bix—we would be prone to name Shakespeare or Einstein. Our own thinking, however, tells us that all of the individuals listed are gifted in their respective fields, and they exhibit superior mental abilities in the areas of language, mathematics, art, leadership, athletics, music, and philosophical anthropology. Inappropriately, intelligence was and continues to be measured in terms of verbal-linguistic and logical-mathematical concepts. Most schools test students' competencies through the administration of short-answer standardized tests. Often, students qualify or fail to qualify for gifted programs on the basis of these largely verbal and mathematical scores. However, Gardner suggests that educators broaden their traditional and narrow conception of giftedness.

Gardner conducted his research through intensive interviews and in-depth analyses of the brain function of hundreds of subjects, including stroke victims, prodigies, autistic individuals, and individuals who are classified under the heading of “autistic savant.” While involved in Harvard University's Project Zero, Gardner studied the cognitive development of average, gifted, and brain-damaged children. As a result, Gardner views intelligence as consisting of three specific components: (1) ability to invent a useful product or offer a service that is valued within a culture, (2) skill to solve real-life problems, and (3) potential to find or postulate new problems for consideration in the light of new knowledge.

Gardner delineates his theory of pluralistic intelligence into ways of knowing. Criteria for identifying the existence of intelligence are grounded in neuroanatomy, developmental psychology, cognitive psychology, anthropology, and education. An intelligence, therefore, has a developmental pattern and a base in the physiology of the brain; it

is ignited by stimuli native to the particular intelligence, and it depicts ideas in a universally symbolic manner, as with music, words, or formulas. To date, Gardner has revealed nine intelligences, of which two, intrapersonal intelligence and interpersonal intelligence, are person-related. Four others—mathematical-logical, visual-spatial, naturalist, and bodily-kinesthetic intelligences—are object-related in that they are activated by objects in the environment. Three others, verbal-linguistic, musical-rhythmic, and existentialist intelligences are not connected to objects or persons.

Gardner hypothesized that individuals are born with and possess a unique compilation of all nine intelligences that may be enhanced through experience and effort. Realistically, students learn more readily when instruction is geared to their strongest intelligences. Gardner's understandings have had an immediate and dramatic effect on how curriculum is designed and delivered. Educators are internalizing a more flexible and progressive perception of intellectual development, and they are striving to incorporate some of the intelligences into each of their lessons as entry points to facilitate learning. Teachers who construct brain-compatible classrooms anticipate making future contributions resulting from the research of Gardner, who theorized that intelligence is definitely not fixed at birth.

According to Gardner (1983) himself, "Much of what I write about can be identified with the educational tradition of John Dewey—with what has been called progressive or neo-progressive tradition" (p. 3). Simply stated, where Dewey argued that problem solving is the essential of thought, Gardner frames intelligence around solving real-world problems and creative production.

A believer in cooperative learning as a mechanism for understanding, Gardner would agree that, when assigning problems for cooperative learning groups to solve, it is essential that they be at the outermost area of Vygotsky's ZPD for the most capable students in the group, thus allowing everyone on the team to be challenged to devise a solution. The newly discovered knowledge is shared within the group by a process that is often termed *scaffolding*. Scaffolding involves reaching out and sometimes down to assist another member of the group. Cooperative learning groups are progressive, and students are encouraged to share experiences and participate in their own learning. In effective cooperative learning settings, thought is continually being expressed through language, and students are engaged in a social-constructivist process, creating concepts through conversation. Teachers fill the role of facilitator, circulating among the learners to provide assistance as needed. Cooperative learning classes minimize the time that students spend sitting passively and taking notes while their teacher solves problems for them. Conversely, cooperative learning classes maximize the time that students spend interacting to solve problems for themselves. Gardner would concur that a sense of

optimism, hope, and power is infused in us when we realize that what children can do with assistance today, they can do independently tomorrow.

Conclusion

We might ask again, why is there so strong a resemblance between anthropological methodology and educational methodology? Was it coincidental that educational practice underwent a revolution after the publication of Charles Darwin's *On the Origin of Species* in 1859? No, it was not a coincidence. It is evident that Darwin's evolutionary framework had intense and powerful impact upon scholars throughout time, scholars who influenced their protégés who, in turn, influenced others. "The influence of Darwin upon philosophy resides in his having conquered the phenomena of life for the principle of transition, and thereby freed the new logic for application to mind and morals and life" (Dewey, 1910, pp. 8–9). The new logic inspired John Dewey to invest in schools as centers for social responsibility and interaction, thus providing the intersection of education and anthropology. Darwin's understanding of the earth and its populations as ever evolving and never fixed in nature underlie the philosophies of Dewey, Xingzhi, Montessori, Vygotsky, and Gardner. Darwin's philosophies are found at the heart of anthropological and educational thought and practice. Both anthropologists and educators enthusiastically welcome change. Instead of debating the legitimacy of their theories, they progress. As researchers, they are task specific, and they anticipate the further evolution of science and technology, as well as psychology and neuropsychology. Educators are cognizant of the impact that Darwin has had upon their methodology and pedagogy down through the generations.

It stands to reason that if humankind evolves, then its intelligence will evolve and expand through experience. Anthropology is both a mirror and a window for education. The mirror reflects our common humanity: our wants, our needs, our desires, our conflicts, and our resolutions. As such, anthropology reflects the human condition and offers the tools to ensure our survival as a species. The window opens to the future. *And it all began with Darwin!*

HISTORY AND LITERATURE IN ANTHROPOLOGY

FRANK A. SALAMONE

Iona College

This is a review of the works that have influenced and reflected anthropological thought from its earliest day to the present—and perhaps into the future. Of course, any substantial review of anthropological literature will include coverage of basic trends in the field, as well as references to major social and cultural currents in society. Anthropology did not develop in a vacuum. For better or worse, it is always a product of its times, reflecting those times as well as entering into dialogue and debate with them. In addition, anthropology is not a monolithic entity. It is better viewed as a many-headed hydra. Moreover, its development has not been in a straight line. It has not only gone in many directions but also often circles back to earlier ideas, rediscovering almost forgotten or neglected concepts and scholars. Nevertheless, there have been some basic concepts that help unify the field. This review attempts to express the unity in diversity, which marks the field and makes it among the most exciting intellectual fields in academic life.

Early Literature in Anthropology

Some scholars trace anthropology back to the ancient writings of Herodotus, Aristotle, and others. Certainly, the Greeks and Romans influenced anthropology as they did other later fields of study. There can be no doubt that the 19th-century founders of anthropology drew inspiration

from classic authors. Nor can there be any doubt that they were at least equally influenced by the great thinkers of the Enlightenment, such as Voltaire, Montesquieu, and Jefferson, among others. Moreover, the spread of the European Empire and exploration to the far reaches of the world, leading to contact with peoples whose appearance, customs, and traditions differed so greatly from European ways, sparked attempts to understand them in a systematic way.

People in the United States regularly encountered what people now term “the other.” American Indians were there to greet Europeans when they landed on the continent and began to establish what became the “American way of life”. Relations between them ranged from intermarriage to bitter hostility. Whatever a particular settlement’s current relationship was with Native Americans, the fact of Native American existence and otherness was never far from the American consciousness. Even those who had little to do with American Indians in the 19th century encountered Indians, in popular cultural representations and historic stories. Indeed, their presence inspired early American anthropologists like Lewis Henry Morgan. Morgan and others who were interested in understanding and chronicling earlier societies and their cultures found themselves adapting a framework from biology, namely, Darwinian evolution.

Although he was a biologist, Charles Darwin’s influence went well beyond that he had on biology. He was not

the first person to posit a theory of evolution. The ancients had people who advocated the idea, including Democritus and St. Augustine among them. Indeed, as Darwin noted in his *On the Origin of Species* (1859), his own grandfather Erasmus Darwin had put forth a theory of evolution as had many other scholars. Darwin even mentioned others who had anticipated his own contribution, natural selection, and notes the role of Russel Wallace in coming up with the idea of natural selection, or “descent with modification.”

Darwin was a shy individual who resisted controversy. Thus, he allowed others to carry on the struggle to establish acceptance for his ideas. Therefore, Thomas Henry Huxley (1825–1895) became “Darwin’s bulldog.” Huxley loved to argue and took on clergy who believed that Darwin’s ideas were antithetical to religion and the creation story in Genesis. In the social sciences, the concept of social or cultural evolution had made progress before Darwin published his works. Herbert Spencer (1820–1903), for example, had put forth his theory of “survival of the fittest” for societies, justifying colonialism and imperialism. He, and others, ranked societies on various ladders, with Victorian England always being on the highest rung. Not every social or cultural evolutionist regarded the evolutionary system as being a value judgment. Indeed, there was often more than a hint of the “noble savage” nostalgia in their writings, in which they felt something had been lost in the movement toward technological complexity. That something was always something moral, something natural. The artificiality of modern life left much behind in human social life that was precious and natural. This dichotomy between the “rational” and “romantic” is still very much a part of American anthropology.

This dichotomous characteristic is part and parcel of the manner in which modern anthropology developed and of its origins in the colonial context mentioned above. Field anthropologists found themselves in the midst of the colonial world of the imperialist powers. At one and the same time, they were able to conduct their work because of imperialism, but they tended to side with those people subjected to colonial rule. Stanley Diamond (1974) commented that anthropology was “the study of people in crisis by people in crisis” (p. 1). There has been a steady reflection on this dilemma in the discipline, a process that has accelerated in recent years, reflected in the studies of Kathleen Gough (1968a, 1968b), Dell Hymes (1969), Talal Asad (1973), and Stanley Diamond (1969, 1974) among others who recognized that there was a strong connection between repression in the United States and abroad, the spread of trade, and the development of anthropology.

Early Writings in Physical Anthropology

Certainly, Darwin had an enormous influence on physical anthropology as well as in cultural anthropology. The primary theoretical orientation for physical anthropology, in particular,

is Darwinian evolution through natural selection, just as it is for biological science in general. Of course, there were antecedents to Darwinian evolution, as Darwin noted in *On the Origin of Species* (1859). Indeed, the antecedents go back to the eras of classical learning, early Christian and Islamic periods, the Renaissance, and the Age of Reason.

Although the institution of slavery and Greek condemnation toward manual labor hindered the advance of empirical science, there were exceptions to the generally abstract nature of Socratic and Platonic thought, which reached its peak in the fifth century BCE. Aristotle (384–322 BCE) combined the talents of a theorist with the curiosity of an empirical observer. He conceptualized a ladder of nature, on which all living things were related to one another but also differed in degree from each other. The degrees were miniscule from one step to the next and yet were significant. Some scholars argue that Aristotle’s belief in a divine final cause hindered the full development of his evolutionary ideas. Other Greek scholars advanced his work, and it spread during the period of the Roman Empire. With the fall of Rome, the general task of preserving and building on Greek ideas fell to Islamic scholars.

The major advances in scientific thought, even though antievolutionary in nature, helped build the foundation upon which Darwin built. Thus, the work of the Reverend John Ray (1628–1705) in taxonomy led to the classificatory system of Carl Linnaeus (1707–1777). Ray’s system was built upon his interpretation of the biblical account of creation, holding that all current living things are fixed after the sixth day of creation. He further stated that species are fixed forever and that all individuals belong to the same species if they descend from the same parents. In sum, species are indivisible. His work became the primary source on taxonomy.

Linnaeus built on it. His system used binomial nomenclature, designating both genus and species. He discussed his system in *The System of Nature* (1735); its 10th edition (1758) is the standard for scientific naming based on anatomical characteristics. Linnaeus moved from the idea of the fixity of species to the development of new ones through observing the effects of hybridization and the viability of the offspring of hybrids to reproduce. However, so firmly established was the concept of the fixity of species that even his posthumous 13th edition, in which he embraces the idea of the fluidity of species, could not change scientific opinion. Indeed, the 18th-century notion of the great chain of being coming down from God through man to woman and all other lesser forms of being seemed to establish the fixity of creation for all time.

The field of geology offered material to challenge the notion of the fixity of the great chain of being and species. So troubling were the data of geology that the clergyman John Ray had to take them into account in his work. He had to try to find an explanation for fossils, for example, that fit with his notion of creation. He termed this *catastrophism*,

using the Bible to map the catastrophes that led to the creation of fossils buried deep in the earth.

However, legitimate scientists began to offer other explanations. The French botanist Jean-Etienne Guettard (1713–1786) was interested in the distribution of plants and discovered that certain plants were always found with particular minerals and rocks. This interest led him to map out the distribution, and he concluded that rocks were always found in bands, and these bands followed an orderly and predictable pattern from one area to another. His 1751 map of the distribution of rocks in France and England is taken as the beginning of scientific geology.

James Hutton (1726–1797) took the next few steps in the development of geology. Hutton not only promoted the idea of uniformitarianism, the notion that past geological processes have the same agencies as contemporary ones, but also held that the world is more than just a few thousand years old. He argued that geological time is vast and that the rocks prove it.

William Smith (1769–1839), a surveyor, developed the technique of stratigraphy. Stratigraphy identifies the layers of earth according to their fossil contents. Others adopted the technique, which became essential to the development of geology as well as archaeology. This principal of superposition provided a dating technique with the assumption that fossils in any particular stratum are older than those above them and younger than those beneath them.

During the same period, George Louis Buffon (1707–1788) produced a 44-volume work, *Natural History*, the first amalgamation of European biological information. Unfortunately, the Catholic Church was very influential in France and saw it that Buffon's work was heavily censored. At times, his work and innate humor got him into trouble. Nevertheless, Buffon made significant use of Linnaean taxonomy.

Buffon also provided material pointing to the age of the earth. He indicated that some sort of major cataclysm, perhaps a collision of a comet and the sun, led to the formation of the earth. He also concluded that other planets resulted from this collision. Buffon conducted a number of experiments, seeking to provide proof of his ideas. These strengthened his support of uniformitarianism. His attacks on the various biblical flood theories led to strong opposition from the theological faculty at the University of Paris. These attacks forced him to offer a public recantation.

Not the least of Buffon's contributions was his support of the work of Jean-Baptiste Pierre de Monet Lamarck (1744–1829). Buffon hired this ex-soldier to teach his son. Lamarck impressed Buffon with his system for naming botanical specimens. Lamarck used a system of giving each specimen a genus and species name. Buffon sponsored Lamarck's admission to the French Academy and subsequent position as a professor in Paris. Lamarck made significant changes in the Linnaean classificatory system.

Alas, all of the major scientists affiliated with Buffon except Lamarck died during the French Revolution, at the

end of the 18th century. Lamarck, however, carried on their work, arguing openly for evolution. He argued for the antiquity of the earth while proposing animal evolution. He arranged a ladder of animal evolution in steps from the simplest to the most complex. His major works were *Philosophie Zoologique* (1809) and *Natural History of the Invertebrates* (1815). Although Lamarck's various laws are no longer held to be true, they did provide an impetus for other biologists, including Darwin, to develop a more comprehensive system of evolution.

One of Lamarck's protégés, Georges Leopold Cuvier (1769–1832), became the most brilliant comparative anatomist of his day. Unfortunately, he reverted to the older notion of the fixity of species and opposed evolutionary thought. His work in comparative anatomy, nonetheless, proved essential to the development of evolutionary thought.

Charles Lyell (1797–1875) was a geologist who had a major impact on Darwin. Lyell's work on the effect of water, waves, and wind on the landscape led him to oppose the notion of catastrophism and embrace the notion of a long geological time period. Moreover, he applied the law of uniformitarianism to support his stand. His major work was *The Principles of Geology or the Modern Changes of the Earth and Its Inhabitants* (1831–1833), which overturned the previous accepted wisdom and provided the foundation for Darwinian evolution through establishing the millions of years needed for the slow process of organic change.

Edward Lartet (1901–1871), a French lawyer, disputed the notion that humans and apes developed in the present epoch. The discovery of mastodon teeth in his village led to an interest in fossils. Soon he became a collector of fossils. In 1837, he discovered a fossil ape from the tertiary period resembling a modern gibbon. He named it *Pliopithecus*. Later, in 1856, he found another fossil ape, which he named *Dryopithecus*. These discoveries were but a few of the challenges to the theory of catastrophism, and they paved the way to modern evolutionary theory.

In the same year that Darwin published *On the Origin of Species* (1859), Paul Broca founded the Anthropological Society of Paris, the first anthropological society in the world. Broca was quite interested in physical anthropology, attempting to make it a scientific discipline. Toward that end, he set up an anthropological laboratory in 1858. This became a training center for anthropologists. Broca was a pioneer in craniology, using the measurement of heads for the purpose of racial classification. The use of anthropometry, the measurement of human physical characteristics, spread rapidly and added to the debate between those who felt there were many origins for human races (polygenists) and those who saw a single origin (monogenists).

The connection between primates and humans became a matter for serious concern. Ernst Haeckel (1834–1919), for example, wrote an encyclopedia of primate anatomy. He drew for it the first scientific tree demonstrating the connection between primates and humans. The continuing

debate over the origin of races and their connection pervaded the late-19th- and early-20th-century development of physical anthropology. Not surprisingly, the debate traveled to America, where Frank Russell (1868–1903) became the first American to receive a PhD in physical anthropology. He was honored with the degree in 1898 from Harvard. His dissertation was predictably on a measurement of Eskimo crania.

A Bohemian medical student, Ales Hrdlicka (1860–1943), became a major American physical anthropologist. New York State hired him to work in anthropology and pathology. In 1903, the U.S. National Museum hired him, and he remained there. In 1918 he founded the *American Journal of Physical Anthropology*. Hrdlicka was a key figure in establishing that American Indians had migrated across the Bering Strait. He was also a major opponent of the idea of racial superiority. In 1930, he founded the American Association of Physical Anthropology.

In addition to his work on primates, Ernst Haeckel (1834–1919) contributed a number of other essential ideas to physical anthropology. He coined the phrase “ontogeny recapitulates phylogeny.” Moreover, he popularized Darwin in Germany and drew a genealogical chart connecting all known life forms. Haeckel was a noted artist who produced many illustrations of animals for his *Artforms of Nature*. His *Freedom in Science and Teaching* was written to defend the teaching of evolution.

Thus, by the end of the 19th century, physical anthropology was established as a discipline. It was mainly concerned with anthropometric measurements, the issue of race, and the relationship of human to nonhuman primates. There were many arguments over racial superiority of the “white race” over other races, but there were many who opposed that view and argued for the unity of humankind.

Early Writings in Archaeology and Linguistics

It is probably true that all people have some interest in the past. Archaeology grew out of such an interest, an interest that has roots in both the sacred and secular. Both religion and looting have contributed to what has become known as archaeology. Egypt, for example, looked for roots of its religion in the past, and the government of ancient Egypt may have sponsored the first excavations of the past. Search for biblical roots and areas mentioned in the Bible still inspire archaeological digs today. The hunt for treasure needs little comment, since popular culture is filled with such tales.

Most archaeologists agree that the beginnings of scientific archaeology are found in the 18th century with the second excavations at Herculaneum. These digs went beyond previous treasure hunts. Unlike the first hunts, which destroyed intact remains, these excavations were rigorously conducted. However, things changed when Charles of Bourbon, King of the Two Sicilies, decided to hire Marcello

Venuti to supervise the process. Venuti reopened the former shafts and was able to translate the inscriptions, certifying the authenticity of the site. With this careful process, archaeology became a science.

Or it was at least on its way toward becoming a science. Although the 18th century was termed *the Enlightenment*, the next truly archaeological excavation was not until 1784, when Thomas Jefferson made excavations in Virginia. However, the interest in abstract theory in the period did provide interest in cultural evolution, the progress from one stage of development to another. Some scholars and amateurs became interested in finding proof for this idea.

The idea of cultural evolution, unfortunately, quickly moved away from the notion of equality toward one of European triumphalism. Moreover it provided a rationale for imperialism and colonialism in which the “civilized” Europeans had an obligation to bring their superior culture to undeveloped “primitives.” Scientists developed various systems ranking societies on their development and progress toward the level of civilized European society. These systems not only aided the production of a great deal of information on individual societies but also were used to shore up the notion of the natural superiority of European civilization.

Some gifted amateurs have aided the progress of archaeology. Jacques Boucher de Perthes, for example, was a French customs officer. De Perthes had an interest in artifacts. Over a period of time, from the 1830s to the 1850s, he discovered a good deal of fossil material along with hand axes and other artifacts at Abbeville. In 1847, de Perthes argued that this Ice Age site proved that humans had been on earth for more than the 6,000 years many religious scholars stated. However, it was not until 1859, when two British archaeologists examined the site and supported de Perthes, that other archaeologists took notice.

The romance of archaeology, reflected in recent times in the “Indiana Jones” saga in cinema, was carried on at the end of the 19th century in the work of Heinrich Schliemann, Paul Emile Botta, and Austen Henry Layard, among others. Schliemann went looking for ancient Troy and found it but did not know he had found it. Botta thought he had found Nineveh of Biblical fame, but he had not. Layard, however, did find the site of the biblical Nineveh. These expeditions kept up popular interest in archaeology and were the inspiration for many popular works of fiction.

More scientifically, Christian J. Thomsen and Jens Jacob Asmussen Worsaae, both of whom were curators at the National Museum of Denmark, found evidence for the three-age system of tools—Stone Age, Bronze Age, and Iron Age. They discarded the mistaken notion that the poor used iron and the wealthy used bronze in prehistoric times.

This early period in archaeology left a number of issues with which archaeologists must still deal. The question of the equality of humans was one that the Enlightenment embraced and many early archaeologists abandoned in their search for stages of human social and cultural development.

The idea that European culture was the crown of cultural evolution may appear ludicrous today, but there are still people who believe this to be true. Moreover, archaeology still has to cope with religious and nationalistic leaders who hold fast to their beliefs and fight any evidence that puts these beliefs into question. There is also the issue of the return of all those artifacts taken from ancient sites to the countries from which they were so blithely taken.

Linguistics underwent similar developments in its history. It, too, had deep roots in ancient civilizations but did not become a science until the 19th century. There have been many in the field who believe that the best hope for linguistic advance lies in attention to the evidence, and therefore leads, that archaeology offers. There have been many examples demonstrating this proposal. The advance of linguistics in delineating American Indian languages has been aided through the evidence provided by both archaeology and physical anthropology on the northeastern origins of Native Americans. The search for the “origins” of the Bantu language family, now seen to be part of the Niger-Congo family, profited from the work of archaeologists as did earlier work on the Indo-European language group.

There were 18th-century developments in linguistic studies that aided its movement toward becoming a scientific field, for example, the work of James Burnett and Lord Momboddo in discerning logical elements in the evolution of human language. Sir William Jones’s *The Sanscrit Language* (1786) argues that there is a connection between Sanskrit, Persian, Greek, Latin, Gothic, and Celtic languages, taking a step toward developing the notion of the Indo-European language family and the fields of comparative and historical linguistics.

There is such a natural connection between language and culture that a deep relationship between archaeology, physical anthropology, and linguistics appears integral. Indeed, both Franz Boas and Bronislaw Malinowski deemed it a natural one. Both men were committed to fieldwork, and the learning of the language of the people among whom one works is important to successful fieldwork. Moreover, the language a person speaks offers significant clues about the culture of that person.

By the end of the 19th century, anthropological linguistics had developed into a modern science and, in the eyes of Boas, an equal part of the overall anthropological picture. It had developed its basic scientific concepts, demonstrated the rule-bound nature of language, made significant advances in comparative and historical linguistics, and was moving toward other major areas of the field, such as structural and descriptive linguistics.

One of Boas’s students, Edward Sapir (1884–1939), advanced the field of linguistic anthropology greatly, mapping out many areas later developed in its history. In addition to his work in linguistics, Sapir also worked in other areas of anthropology. His work included studies of personality and cultural behavioralism. Sapir held that

language shapes the way in which we perceive the world. Different languages condition people to see the world differently. Sapir viewed language as a symbol system and a royal road to understanding culture and personality. Sapir was a brilliant theorist and looked for the connections among language, culture, and personality. In fact, a number of his students compiled a book of his writings in his honor; it was titled *Language, Culture, and Personality* (Sapir, 1949).

Sapir anticipated many of the later developments in the field. His concept of language drift focused on the changing nature of language, but Sapir also emphasized the fact that important elements of language are slow to change. Moreover, he noted the role of body language in communication as well as its unconscious nature.

Certainly, the most famous aspect of his work was the Sapir-Whorf hypothesis. Benjamin Lee Whorf (1897–1941) was a successful businessman working as an inspector for the Hartford Fire Insurance Company. He pursued studies in linguistics and ethnology as a hobby. His work as an inspector brought many instances to his attention of the manner in which language influenced behavior. He noticed that people were careless around containers and trucks labeled “flammable,” believing that such containers were not able to break into flames. People would throw lighted cigarette butts into empty containers of fuel, not realizing that empty containers are the most dangerous because of residual fumes. Whorf contributed a number of ideas to linguistic anthropology. He developed the concept of linguistic relativity, helped further the area of sociolinguistics, and made substantial contributions to the study of American Indian languages.

Early-20th-Century Anthropology, 1900–1930

By the end of the 19th century, anthropology had become a professional field. Not only were there professional associations, but the discipline began to be offered in universities. By the beginning and early years of the 20th century, anthropology had become more of a professional or academic discipline, and power moved from the federal government (the Bureau of Ethnology and the National Museum) to major centers of learning—universities such as Columbia, Harvard, and the University of California at Berkeley. Franz Boas was a major force in this shift of power.

Boas and his students struggled against those who offered eugenic explanations of cultural differences. American anthropology became strongly empirically and culturally oriented, moving away from those racist stands that supported discrimination and colonialism. Many anthropologists were members of one minority group or another—Jews, women, American Indians, or others. They were hardly liable to support the dominance of a White Anglo-Saxon male establishment. That does not mean that

Boas and his students were able to eliminate bias in the profession or won easy victories. Many of these battles are still being waged today. Nevertheless, the influence of the antiracist, antibiological determinism position has remained strong in the profession.

Adding to the drive for cultural understanding was the move to ethnography. The detailed study of a given society or group requires a long period, ideally a year or two, of living with the group and intensive study of the group. This participant-observation provides more than an intellectual understanding of the group. It is sometimes referred to as learning through the skin. Most anthropologists view this fieldwork experience as a necessary rite of passage, and anyone who has undergone it finds it difficult to forget. It provides a means for deeper understanding of the meaning of otherwise “foreign” behavior and thinking.

Malinowski is generally given credit for developing the method in his Trobriand Island fieldwork, and he passed the method on to his students in England. Boas endorsed the technique as well and passed it to his students, along with his idea of culture and cultural relativism—understanding a culture on its own terms and in its own setting. Boas focused on symbols and values in his work on culture rather than on institutions and groups, which were the emphasis of British social anthropology. Fieldwork helped clarify many problems that had been inherited from 19th-century arguments in anthropology.

Ethnographers, for example, reached a general agreement that both *diffusion*, the spread of cultural traits from one group to another, and *independent invention*, the development of an idea or tool without outside influence, occur in cultures at the same time. However, they also emphasized the fact the even borrowed traits may have vastly different meanings in different cultural situations. The focus was on understanding each culture on its own terms, rather than comparing them cross-culturally in whole or in part. This view, termed *cultural relativism*, was a strong factor in American anthropology. This emphasis on meaning led to a great deal of interest in expressive forms—art and myth, for example. There was a great concern with meaning and self-definition as well.

The presence of so many American Indian nations in the United States aided the practice of ethnographic fieldwork. Although a number of Boas’s students conducted fieldwork outside the United States, as did Margaret Mead and Melville Herskovits, for example, most did at least some work among American Indians. The ready availability of American Indians encouraged repeated trips and long-term fieldwork over time. It also enabled American anthropologists to build on a body of earlier work, dating to the 19th century.

Boas was involved in political issues and skeptical of government-sponsored research, as well as that supported financially by the wealthy. Moreover, Boas demanded rigorous empirical work from himself and his students. He shied away from putting forth universal laws and over-

generalizations. He emphasized nature over nurture and directed research demonstrating that fact with immigrant children. In addition, Boas took a strong stand in favor of equality and against all types of discrimination, leading the FBI to keep a file, mainly inaccurate, of his activities. Boas stressed that the uniqueness of cultures did not evolve. Each culture had to be studied in itself.

Boas also underscored the need for the four-field approach in anthropology: physical (biological) anthropology, cultural anthropology, linguistic anthropology, and archaeology. Boas noted that these interrelated areas aided one in understanding culture. Boas emphasized his approach through his work at Columbia University and the American Museum of Natural History. Boas’s students included Alfred Kroeber, Robert Lowie, Ruth Benedict, and Edward Sapir, as well as Margaret Mead. Their work attacked the idea of a general line of cultural evolutionary development and emphasized what came to be termed a *cultural history* method.

Although they were opposed to overgeneralization, anthropologists who followed Boas did feel that there was some sort of need to go beyond mere statements of specifics. Kroeber wrote a textbook, *Anthropology*, outlining the general ideas of the field. “Culture and personality” studies were in conformity with many of Boas’s ideas. Mead’s *Coming of Age in Samoa* (1928) and Benedict’s *The Chrysanthemum and the Sword* (1946) highlighted this trend. Mead chose to stay away from a permanent anthropological appointment, noting the bias, despite Boas’s efforts, against women in the profession. Boas wanted Benedict to succeed him as chair of the anthropology department at Columbia, but Ralph Linton worked against her appointment, proving the wisdom of the always astute Mead’s stand on the issue.

Ruth Benedict (1887–1948) studied with Boas at Columbia and received her PhD in 1923. She joined the faculty in the same year. Two of her outstanding students were Marvin Opler and Margaret Mead. Benedict held that each culture chooses from the vast possibilities but a small number of traits. These traits form a gestalt that shapes personalities within the culture. Her *Patterns of Culture* (1934) remains influential, though criticized as too general, and it is still remarkably readable and interesting. Benedict was among the few who applied anthropology to complex cultures in its early days. Like Boas, she was strongly drawn to social causes, and she opposed racism and the bigotry of some so-called religious people, using anthropological data to combat these biases.

Following in the footsteps of Benedict and Boas, Mead became a major public figure who combated bias and ignorance in her work. More than either, however, she became the voice of anthropology to the public. From the publication of *Coming of Age in Samoa* to her death, she represented anthropology in the public forum. Her books sold well, and her column in *Redbook* had numerous readers. Mead wrote about situations in the United States and was

among the first, with her third husband, Gregory Bateson, to use photography and filming in fieldwork. She was as much at home in New York as in Bali. *Time* magazine named her Mother of the World in the mid-1960s.

The Turn to Modern Anthropology

One of the all-around anthropologists, a master of the four fields, was Ashley Montagu, whose birth name was Israel Ehrenberg (1905–1999). Montagu changed his name in an attempt to avoid the vicious anti-Semitism of his day. Although he was born in England, he migrated to the United States as a young man and became an American citizen. He was a brilliant anatomist, and this skill aided in his attacks on race and gender bias and discrimination. Montagu studied with a number of distinguished scholars in England, none more important than Malinowski at the London School of Economics. Shortly after, he attended Columbia University and studied with both Boas and Benedict, writing his dissertation under their direction; it was titled *Coming Into Being Among the Australian Aborigines: A Study of the Procreative Beliefs of the Native Tribes of Australia* (1938). Before becoming a professor of anthropology at Rutgers, he taught anatomy in a number of universities. After leaving Rutgers, Montagu became an independent scholar and a great popularizer of anthropology, explaining its importance to the general public on many television programs.

Although always opposed to racism, he became a great proponent in the 1950s for eliminating the concept of race from biology. He wrote a number of works; the most famous of his writings on race are the UNESCO *Statement on Race* and *Man's Most Dangerous Myth: The Fallacy of Race* (1942). Montagu was deeply opposed to the work of the anthropologist Carleton S. Coon.

Coon was interested in the manner in which infants bonded to their mothers. He was among the first scholars to emphasize the significance of touch and the effects of a lack of affection for infants on later adult criminal behavior. His work influenced a number of experiments with monkeys in isolation. It was but a small step to opposing genital mutilation of children.

Montagu's attacks on the concept of race, dating at least from the 1930s, challenged the beliefs of most anthropologists. We would say that Montagu argued that race was but a social construct with no foundation in biological reality. Instead, he looked to gene-frequency analysis to unravel the mysteries of human evolution. Montagu put his ideas in an article coauthored with Theodosius Dobzhansky (1947). They argued that early humans everywhere were hunters and gatherers, facing similar problems. These early humans adapted in similar ways to similar changes. The conclusion, going back to the law of uniformitarianism, is that there are no mental differences between populations. The overwhelming majority of anthropologists accept this fact.

It was about this time that modern primatology (ethology) began to develop. The study of animals in their natural settings, like so much else in anthropology, has a long history. However, modern scientific observation dates from the early 1950s and the publication of Niko Tinbergen's *The Study of Instinct* (1951) and Konrad Lorenz's *King Solomon's Ring* (1952) and *On Aggression* (1966). Many primatologists began extensive studies in the wild, the most famous being Dian Fossey and Jane Goodall.

These studies led to the gathering of significant data leading to better understanding of human evolution. In addition to fruitful models of possible human evolution, there was the inevitable sensational popularizing of this work in volumes such as Robert Ardrey's *The Territorial Imperative* (1966) and *The Hunting Hypothesis* (1970) as well as Desmond Morris's *The Naked Ape* (1967). Interestingly, most of the material to disprove and discredit these works came from further field studies in primatology. Among the leaders in this area was Jane Goodall, a protégée of Louis S. B. Leakey, a famous paleoanthropologist. He encouraged Goodall to study chimpanzees, hypothesizing that these studies held hope of offering material enabling us to understand better our ideas of human nature.

These studies did add to our understanding of evolution and human nature. When Goodall, for example, found that chimps at the Gombe Reserve made tools as well as used them (Goodall, 1983), many preconceived notions of Man the Toolmaker were discredited. Since the 1960s and 1970s, further work has shown more similarities between the great apes and humans. There has been work on human sexuality, aggression, politics, and almost any other topic one can imagine, including language acquisition, stemming from ethological studies.

The discovery of DNA (deoxyribonucleic acid) has also led to amazing strides in many areas, including anthropology. DNA contains basic genetic instruction for the development of living organisms; it is the code of life. It stores information in coded form. In 1951, James Watson, Francis Crick, and Rosalind Franklin were working on the problem of the structure of DNA. Linus Pauling was also involved in the search for the structure of DNA. Others were also involved in the search. The full story is murky at best and a mystery in itself. However, there is no mystery about the significance of the discovery of the structure of the DNA molecule and its coding.

The discovery of the DNA molecule and its structure fed into the growing importance of genetics in understanding human evolution. Just as Gregor Mendel (1822–1884) provided support for the process of evolution with his discovery and experiments on genetic processes, so, too, did an understanding of DNA provide a better understanding of genes. Mendel provided a statistical overview of genetics. He noted the stability of his genetic ratios; thus, the results were not chance ones. He then distinguished between genetic factors (genotype) and appearance (phenotype).

What you see is not always what you get. This factor led Mendel to conclude that there were two genes (alleles) for each characteristic, leading to an understanding of the existence of dominant and recessive traits. DNA allows us to understand how genes work and how mutations occur; they are best understood as changes in the code or message of the DNA.

Other developments aiding the study of evolution came in absolute dating. The Carbon-14 method was among the first. It permits the direct dating of any material containing organic material. There is a known rate at which Carbon-14 disintegrates. Larger samples are better than small ones. Obviously, great care must be taken to avoid contamination of the sample. Moreover, recent samples are difficult to date, as are those over 50,000 years old. Finally, the ratio of ^{14}C to ^{12}C is not constant in time or place for various reasons. It is best to obtain more than one sample for dating and to cross-check samples using other dating techniques.

Finally, these various advances have strengthened the movement, supported by anthropology, known as antiracism. Anthropologists such as Boas, Benedict, Mead, and Montagu argued for worldwide equality and attacked the so-called scientific basis for inequality. Anthropology provided theoretical and empirical support for the antiracist movement. The U.S. Supreme Court decision in *Brown v. Board of Education, Topeka, Kansas* (1954) drew heavily on the works of anthropologists in its decision. Robert Redfield, a lawyer as well as an anthropologist, filed an amicus curiae brief opposed to segregation. Modern anthropology, by and large, has attacked the alleged biological foundations for the concept of race itself.

The Emergence of Applied Anthropology

Some anthropologists add applied anthropology—the application of anthropological theories, concepts, or approaches to the solution of practical problems—as a fifth field of anthropology. Any of the other four areas or a combination of them may be termed “applied anthropology.” The first use of the term was in 1906 at Oxford University for a diploma program. An even earlier term for essentially the same ideas was used in the 1860s, when James Hunt used it. Hunt was the founder of the Anthropological Society of London.

The British early considered anthropology useful for their colonial administration. E. B. Tylor called anthropology a “policy science,” and he urged its use to solve problems of human life. Northcote Thomas used anthropology in 1908 to implement indirect rule in Nigeria, the policy of Frederick Lord Lugard. It took some time for the U.S. government to begin to use anthropology in its administrative services. In 1934, the Bureau of Indian Affairs used anthropologists to implement the Indian Reorganization Act. John Collier, head of the Bureau of Indian Affairs, used anthropologists in a number of capacities. They were able to “translate” between the American Indian

groups and the bureau, study the culture and society of tribal groups, aid in writing charters and constitutions for tribes, and in many other ways aid the implementation of programs of benefit to Native Americans. Archaeology also proved its usefulness to public policy during the 1920s, when archaeologists aided the establishment and execution of public works programs.

The U.S. government found many uses for anthropologists during World War II. Anthropologists worked for the War Relocation Authority, for example, working with resettled Japanese Americans. There were also other government projects, such as the Study of Culture at a Distance program that was used to help the United States understand its enemies. In 1941, a number of anthropologists founded the Society for Applied Anthropology (SfAA).

Applied anthropology continued to grow in the post-war world to help international aid and foreign policy programs. Archaeologists continued to work in cultural resource management programs after the passage of the 1969 National Environmental Policy Act. This came at a time when many cultural anthropologists refused government employment because of the Vietnam War. As a result of that war, students demanded more involvement of anthropologists to aid in meeting human needs. As academic jobs decreased, private and government sectors recruited more anthropologists.

There have been a number of famous examples of applied anthropology projects over the years. Some were successful, other not. Some had mixed results. A case often cited as a successful example of intervention is a project among the Fox Indians in Iowa, headed by Sol Tax and conducted by his students. Students initially went to the Meskwaki (Fox) settlement for a summer of fieldwork in 1948, and 35 students went to the area over the decade of summers that followed. Over that period, students wanted to do more than simply collect traditional anthropological data. They wanted to help the Meskwaki solve their problems. They desired to provide an answer to a frequently heard question: What did the Meskwaki get out of the project?

With Tax's blessing, the students attempted to help the Meskwaki. Tax was the students' director. Tax held that an anthropologist had an obligation to the people themselves, not to governments. This “action anthropology” challenged some basic ideas of anthropology as a pure science, suggesting that research is only justifiable if it aids the people being studied.

Eventually, students went from basic help, such as driving people to appointments, to more profound intervention. Fred Gearing, author of *The Face of the Fox* (1970), aided in the establishment of cooperative farming. Others worked for different improvements. Some of the projects were more successful than others. Gearing's book provides more detailed discussion of the project and an evaluation of its overall impact.

Another long-term project was the Cornell University Vicos project. Vicos was part of the Cornell-Peru project.

The project discovered that the 2,250 Vicosinos were starving and were afflicted with gastrointestinal problems. Moreover, they were obligated to work for the patrons of a hacienda; these patrons controlled the best land. Cornell had a lease on the hacienda that expired in 1957. The project made a recommendation to the Peruvian government, which the government followed. Basically, it called for control of the land to be taken from the elite patrons and given to the Vicosinos. A long struggle ensued contesting that decision. Cornell eventually became the new patron. Evaluation of its role has provoked much controversy in anthropology.

The infamous Project Camelot, a 1964 U.S. Army project, is often cited as a model of what anthropologists should avoid. The basic goal was to find ways to help established governments fight insurgents. Chile was the primary test case. Social scientists, whom Norwegian Johann Galtung alerted, forced the cancellation of the project. This position was a step away from the position of anthropologists during World War II. However, many have pointed out that World War II presented a very different situation from meddling in local governments or in Vietnam.

At Michigan State University (MSU), an advisory group existed from 1955 to 1962 that was a front for the CIA to promote covert action in Vietnam. MSU faculty and staff aided the Ngo Dinh Diem regime in South Vietnam. The advisory group helped write the constitution of South Vietnam and entered into training programs for Vietnamese personnel. The United States ended the program as CIA involvement became better known. This and other actions of the FBI and CIA led many, if not most, anthropologists to be wary of government programs, aside from programs like the Peace Corps.

The recent Human Terrain project in Afghanistan echoes the program in Vietnam and has stirred up controversy once again. The deaths of at least three of the anthropologists employed in advising the American military on the customs and traditions of Afghans have added greater heat to the controversy. The poor employment opportunities for anthropologists may have added to the temptation to engage in the controversial activities. However, the range of opportunities for working in applied anthropology is great, including medical anthropology, public anthropology, salvage archaeology, employment by indigenous peoples, and a whole range of programs, including studying and documenting endangered cultures.

Forensic and Medical Anthropology

Forensic anthropology is an applied area of anthropology in which physical anthropology is used in a legal endeavor. Frequently, osteology is combined with physical anthropology when criminal cases involve skeletons that have become difficult to identify. Forensic anthropologists use their skills to help solve criminal cases, judging age, sex,

size, background, and cause of death. As with so many other areas of physical anthropology, forensic anthropologists are often part of a team working toward a goal, in this case solving a crime. In addition, forensic anthropologists may be found using archaeological tools, identifying footprints, reproducing faces of victims, and using a whole host of other skills. A forensic anthropologist also works on identifying the “race” and gender of a crime victim, the manner of death, the weapon that may have been used, and other facts of the crime.

In common with forensic anthropology, medical anthropology spans a number of other areas of the field, including social, cultural, biological, and linguistic anthropology. It employs a holistic approach to examine all possible influences on health and disease in a human population. The factors include, but are not limited to, environment, beliefs about illness stemming from culture and social class, political systems, and other biological, cultural, and social factors. It seeks to understand how people experience illness, its epidemiological distribution, how disease may be prevented, social and cultural factors of the health system, and the existence of folk practices and practitioners in the health system.

Medical anthropologists are acutely aware of popular beliefs and practices related to medicine and of broader social and cultural factors of the health system. They seek to account for human and nonhuman interrelationships in the environment and their influence on health issues. The impact of globalization on local health systems is of increasing importance to an understanding of health. A complete list of globalization’s ramifications would include a range of factors such as those on the list below, found on the official Web site of the Society for Medical Anthropology (2009):

- Health ramifications of ecological “adaptation and maladaptation”
- Popular health culture and domestic health care practices
- Local interpretations of bodily processes
- Changing body projects and valued bodily attributes
- Perceptions of risk, vulnerability and responsibility for illness and health care
- Risk and protective dimensions of human behavior, cultural norms and social institutions
- Preventative health and harm reduction practices
- The experience of illness and the social relations of sickness
- The range of factors driving health, nutrition and health care transitions
- Ethnomedicine, pluralistic healing modalities, and healing processes
- The social organization of clinical interactions
- The cultural and historical conditions shaping medical practices and policies
- Medical practices in the context of modernity, colonial, and postcolonial social formations

- The use and interpretation of pharmaceuticals and forms of biotechnology
- The commercialization and commodification of health and medicine
- Disease distribution and health disparity
- Differential use and availability of government and private health care resources
- The political economy of health care provision
- The political ecology of infectious and vector borne diseases, chronic diseases and states of malnutrition, and violence
- The possibilities for a critically engaged yet clinically relevant application of anthropology

This list provides an excellent overview of the field while demonstrating its need for a number of anthropological specialties.

Present Developments

There are a number of developments under the heading of current anthropology, depending on where one draws the line. The major areas have been in symbolic anthropology, all the “post-” movements (poststructuralism, postmodernism, etc.), humanistic anthropology, and various areas of biological determinism, such as sociobiology. Each of these areas is far from monolithic, and there are internal arguments within them at times more bitter than between the various schools of thought.

Symbolic anthropology is interested in examining and understanding how people in a given sociocultural system make sense of their surroundings and the speech and behavior of other people. More simply put, symbolic anthropology interprets symbols and the way in which people assign meaning to these symbols. Because people share in a common cultural system of meaning, symbolic anthropologists, like Clifford Geertz (1963), believe these symbols address basic issues of human sociocultural life. These symbols, according to Victor Turner (1967, 1980), can initiate social action.

Symbolic anthropologists see culture, then, as a system of meaning. The interpretation of its symbols and rituals provides a key to the meaning and purpose of that system. In its attempts to make sense of sometimes unintelligible beliefs and practices, symbolic anthropologists have turned to interpretive devices to examine ideal as well as material cultural dimensions. In a sense, symbolic anthropology is part of the “post” world. It is a reaction to rigid structuralism, such as that Lévi-Strauss (1955/1973) promoted. Geertz’s *The Cerebral Savage: On the Work of Claude Lévi-Strauss* (1973) is an example of this position. On the other hand, symbolic anthropology is anti-Marxist and against materialism of all types. It refuses to reduce culture to simply visible behavioral patterns with culture as an epiphenomenon.

Postmodernism and its related fields are opposed to positivism, the reduction of science to that which is known

by the senses. On a more affirmative note, it is in favor of using personal experience as a guide. There is great skepticism about knowing anything for certain. A method that postmodernists employ is deconstruction, in which the text—and almost anything can be a text—is broken down to find what it hides and assumes so that inconsistencies can be revealed.

The postmodernists are also committed to interpretation. However, it is a type of intuitive interpretation based on an individual’s own understating. It results in a narrative rather than an observation. Indeed, Michel Foucault (1972) holds that there is never a final meaning for any symbol or anything else. All is interpretation.

The postmodernists have inspired a turn to reflexivity and an investigation of and sensitivity toward ethnography. This investigation has led anthropologists to examine hidden premises in their own and past work, examining power relationships and deeper meanings. The process is termed *demystification*. However, a number of anthropologists have argued that postmodernism results in purely subjective criteria, or standards. Roy D’Andrade’s *Moral Models in Anthropology* (1995), for example, argued that these purely subjective models defeat any attempt to discover how the world works.

Humanistic anthropology is concerned with what it means to be human. During the first half of the 20th century, most anthropologists were humanists and unselfconsciously so. However, with the growth of other areas of anthropology, it became necessary to stress a humanistic approach to the study of being human, taking a holistic approach that looks at the entire human experience. Humanistic anthropology in common with symbolic anthropology focuses on the importance of symbols and interpretive approaches. In common with postmodernism, it rejects positivism.

There is a strong emphasis on viewing the self as something that changes and that the individual negotiates and reinvents. There remains a belief that knowledge is the goal of anthropology. Thus, truth can be discovered. Moreover, there is a belief in the importance of writing well and clearly. In addition, storytelling, including fiction, is promoted in relating ethnographies and field experiences. The importance of symbolic anthropologists such as Geertz and Turner are clearly evidenced here. A fine summary of the position is found in *Writing Culture* (1986), edited by George Marcus and James Clifford and including chapters by Renato Rosaldo, Stephen A. Tyler, and Vincent Crapanzano. There are many other influences on humanistic anthropology. Pierre Bourdieu, for example is certainly a major influence

In contrast with these approaches is the field of sociobiology. E. O. Wilson introduced the term in *Sociobiology: The New Synthesis* (1975). He viewed it as a Darwinian or evolutionary approach to society. A good deal of effort was expended by sociobiologists to explain human altruistic behavior in which people put the needs, even the lives and survival of others, before their own. Their explanation was

that such behavior aided in evolution through ensuring the survival of one's genes into the next generation. Similarly, they looked for genes promoting survival in warfare through ferocity. Much of the dispute over Napoleon Chagnon's study of the Yanomamo was a result of his use of sociobiology to study these "fierce" people. Many anthropologists resist sociobiology as a means for bringing biological determinism back into anthropology.

Future Directions

It is difficult to predict the future direction of anthropology, and any predictions will prove wrong to some extent. However, at this moment there are some areas that have come to the fore. There is what can be termed neoclassical anthropology for want of a better term. It is a return to some previous areas of the field and to the history of anthropology. Thus, there is a return to the roots of the field. There is an interest, for example, in the meaning of cultural relativity, of the origins of anthropology, its influence, and its and overall history. There is not so much iconoclasm in the field as in the past; now there is a search for continuity between more recent and earlier trends.

There is also a greater attention to the problems and conditions of globalization. Tied in with this trend is the importance of power and human agency. There is general agreement that the only constant is change. Anthropologists from the beginning have studied cultures in change and societies affected by world events. This fact must be recognized and addressed in one's research. Eric Wolf (1982), for example, led the way in calling for explicit concern with how current societies, which anthropologists study, got to be the way they are. Historical factors, in other words, need to be taken into account.

Wolf took an explicitly Marxist stance in his work. He called for an investigation of economic, political, and social power relationships. These included multinational corporations, labor policies, and information control. He called for attention to the position of people in society and their perspectives on events.

Michel Foucault and Antonio Gramsci (1971) added a local perspective to the picture. They looked more closely at symbols in interpreting meaning for individuals. In sum, they wished to discern the relationship between power and ideas. They noted that there is no single truth. There is a truth for capitalists, for instance, and a truth for laboring people. There are peasant truths and the truths of landlords.

Bourdieu (1977) carried the argument even further. Bourdieu speaks of different types of *habitus*, a concept roughly equivalent to the collective conscience of Émile Durkheim (1933). Others have adapted it to speak of various scapes or scenes, positions in society that have unconscious shared perspectives with others who also occupy them. In addition to economic capital, Bourdieu speaks of cultural, political, social, and other forms of capital,

including symbolic capital. People strive to make the most of their lives through manipulating this capital through various scapes or positions.

Globalization theory, like so much emerging in anthropology, is a synthesis of a number of approaches. It is a merger of neo-Marxism, neofunctionalism, symbolic anthropology, and humanism. It is an attempt to put a number of approaches, including postmodernism, together to address the problems of the 21st century.

The Anthropologist in Popular Culture

Anthropologists pop up in popular culture from time to time. Indeed, there are some anthropologists who write about anthropologists, such as Stanley Elkins (2000) and Kathy Reichs (2009). The movie *Krippendorf's Tribe* resonates with a number of anthropologists in its depiction of fieldwork and its problems. One could write a long paper on the topics.

Perhaps most people get their views of forensic anthropologists through television and the movies. *CSI* and similar programs often bring in forensic anthropologists, usually women, to help the forensic team. *Bones*, featuring an earlier incarnation of Reichs's heroine, Temperance Brennan, a thinly disguised Smithsonian Institution anthropologist, focuses on the female forensic anthropologist and places her in improbable but exciting situations with her FBI colleague. Indeed, the anthropologist as hero had a life before Susan Sontag's (1966/2001) famous essay on Claude Lévi-Strauss. Mr. Spock of *Star Trek* was an anthropologist, and some of Jules Verne's characters were anthropologists as well.

There is a long tradition of anthropologists writing fiction about their fieldwork. Laura Bohannon's *Return to Laughter* is the most famous, but there have been others. Issues of *Humanistic Anthropology* offer poetry and fiction celebrating the fieldwork experience. Of course, Indiana Jones in his four movies and TV program is the embodiment of the anthropologist as hero. Indy not only teaches at what appears to be Columbia University but also is a man of action into his 70s. Archaeology can be fun as well as enlightening.

WOMEN AND ANTHROPOLOGY

ANNE BENNETT

California State University, San Bernardino

Many a retrospective take on the history of anthropology has characterized the discipline's formative decades as deeply rooted in the narrative of male quest. That is not to say, however, that women were never an object of study or that there were not important and influential women anthropologists helping to shape the discipline in its early decades. For the most part, however, women in anthropology (whether observed or observer) through the first half of the 20th century were relegated to a supporting role in the family of man. Theory often reified this notion as did anthropological practice.

One such example is illustrated by the public-private analytical approach to circum-Mediterranean societies that was influential for several decades in the mid-20th century. This approach applied a theory of social structure across a broad region believed to share key cultural traits. Representative of this approach is an influential volume published in 1965, *Honour and Shame: The Values of Mediterranean Society*, edited by John George Peristiany, which was cited for decades in the anthropology of southern Europe and the Middle East. This volume's attempt to move beyond ethnographic particularism to vigorous theory making was dominated by a perspective positing that politics and power were located in men's public worlds, while domesticity, reproduction, and child rearing (and the then-implied corollary, powerlessness) were consigned to the private world of women and the household.

The public sphere was considered more consequential and more prestigious—socially, politically, and culturally—than the private sphere and, as such, occupied a more central place in anthropological research generally. A critical follow-up to this volume was published in 1992, *Honor and Grace in Anthropology*, coedited by J. G. Peristiany and Julian Pitt-Rivers, in which detractors and apologists collided in a universalism-particularism debate but came to agreement that the honor-shame concept, associated as it was with the public-private dichotomy, was too weak analytically to be a powerful theoretical tool. Although a circum-Mediterranean anthropology is now out of fashion, favoring as it did a de facto anthropology of men, honor, and an exclusionary public sphere, it generated vigorous discussion for several decades on many topics.

Another example of the treatment of women in early anthropology is offered by some incidental research conducted by Alfred Louis Kroeber on women's fashion. Kroeber had been Franz Boas's first doctoral student; in 1901 he both received his PhD from Columbia and became the first professor in anthropology at the University of California, Berkeley. In this example, he studied three centuries' worth of women's fashion in an effort to offer a case that supported his "superorganic" conception of culture. He found interesting patterns in the variations of styles that, in his view, supported the notion that fashion is purely cultural and beyond the influence of individual choice. Although this is an example of an influential anthropologist's focus

on women's worlds, it is not necessarily a significant contribution to understanding women's lives.

In general, the treatment of women in anthropology, before the sea change that came about after the 1960s, was peripheral and in the service of theory building. Drawing from the earlier example of circum-Mediterranean societies, although there are many forms of sex segregation related to public and private space and tied up with notions of honor in these societies, to rely on a starkly dichotomous explanatory framework is to lose sight of much deeper complexities and ambiguities. Or, similarly, Kroeber's study of women's fashion was productive in terms of theory building but says nothing about women's experience, for example, with pressures to conform to changing standards of beauty, or with any number of possible topics that were taken up in earnest after the 1960s, after women as a more central focus of analysis and theory building seeped into the discipline.

Iconic Women in Early Anthropology

The German-born "father of American anthropology," Franz Boas, established the first doctoral degree-granting anthropology program in the United States at Columbia University and, among other achievements, mentored many prominent female anthropologists. This list includes Ruth Fulton Benedict (1887–1948), Ruth Leah Bunzel (1898–1990), Frederica de Laguna (1906–2004), Ella Cara Deloria (1888–1971), Viola Edmundson Garfield (1899–1983), Erna Gunther (1896–1982), Zora Neale Hurston (1891–1960), Margaret Mead (1901–1978), Elsie Clews Parsons (1875–1941), and Gladys Amanda Reichard (1893–1955). All of these women made significant contributions to the discipline. Four among them were eventually elected presidents of the American Anthropological Association (AAA), starting with Elsie Clews Parsons in 1941. Parsons came to anthropology from sociology and is noted, among other things, for her feminism and textual innovations. Ruth Benedict, who along with Boas mentored a generation of students at Columbia, was the next woman elected AAA president, in 1948. Margaret Mead, who enjoyed widespread popularity among the general public, became AAA president in 1960. Frederica de Laguna, who founded the anthropology department at Bryn Mawr College and conducted research among the Pima, Salish, Makah, and Tlingit, was elected president in 1967.

Mead and Benedict achieved particularly wide renown among the general public with their best-selling books: Mead's *Coming of Age in Samoa: A Psychological Study of Primitive Youth for Western Civilization* (1928) and Benedict's *Patterns of Culture* (1934), both of which have gone through numerous editions, translations, and reprints. These two books were immensely successful in popularizing cultural anthropology and making the case for cultural

relativism, a hallmark of American anthropology as established by Boas. Mead's audience was voyeuristically fascinated by her depiction of a worry-free, sexually uninhibited Samoan adolescence and by extension the notion that adolescence is not a universally fraught experience as Americans might have assumed. Benedict's cross-cultural comparison of Dobu (New Guinea), Kwakiutl, and Zuni societies in *Patterns of Culture* was an argument against judging negatively the values and practices of peoples from different cultures. "Good," Benedict persuaded, is not absolute and universal but relative to a particular culture. Both of these best-selling books reached a public that was receptive to Benedict's and Mead's often idealizing and didactic lessons.

Although both of these women had high-profile careers and made important theoretical contributions, they both faced forms of gender discrimination in their professional lives. As progressive and encouraging as Boas was with his female students and colleagues, he also was ineluctably of his time in hiring practices in assuming that married women did not need employment. Mead, for example, never held a full-time academic appointment. For most of her career, starting in 1926 and during her first marriage, she held a curatorial position at the American Museum of Natural History in New York. Mead defended her position at the museum proudly, saying that it was far more advantageous for her than a professorship would have been. Her museum job gave her ample time to focus on writing, traveling, and research, enabling her to be the most productive scholar possible. Benedict, meanwhile, was considered ineligible for a salaried academic position while she was married. Boas essentially gave his position at Barnard to the unmarried Gladys Reichard in 1923, the year that Benedict received her PhD. It was not until after her divorce in 1931 that Benedict was able to secure a full-time academic position. When she did so, she was not only the first woman to receive a full-time academic appointment at Columbia University (in 1931), but also the only other full-time anthropology professor at Columbia besides Franz Boas for several years.

"Papa Franz," as many of his Columbia students referred to him, served as patriarch-mentor and father figure at Columbia's anthropology department. He firmly guided the trajectories of most of his female students' careers, deciding where most of them were to conduct research and on what topic. For example, he directed many of his female students to conduct fieldwork at Zuni Pueblo in the American Southwest, because it was considered safer than other more far-flung and less well-known field sites. As a result, most of his female students and colleagues developed active research programs focused on Native American groups among whom Boas had already established ties in the course of his career, including the Inuit, Kwakiutl, Tlingit, Tsimshian, and Zuni. Some of his female students focused on other locales, typically with his approval and support. Boas encouraged Zora Neale Hurston to collect folklore in contexts familiar to her, the

African American South and Caribbean, just as he encouraged Ella Deloria to focus within her own context on the language and oral traditions of the Sioux. Mead, however, defied Boas in choosing to conduct her dissertation fieldwork in American Samoa rather than at Zuni Pueblo, although she did adhere to Papa Franz's insistence that she focus on adolescence and the nature-nurture debate, when she would have preferred to investigate culture change. Mead's assent to Boas on her Samoan research topic greatly influenced the trajectory of the rest of her career.

Among these women anthropologists trained by Boas, and after 1931 by Benedict, Mead was the one who focused most specifically and extensively on women and their lives. After the success of her first book, *Coming of Age in Samoa* (1928), she went on to conduct field research among Native Americans (Omaha), and different groups in Papua New Guinea (Arapesh, Biwar, and Chambri) that resulted in pioneering works on gender consciousness, *Sex and Temperament in Primitive Societies* (1935) and *Male and Female* (1949). In these books, she was groundbreaking in separating biologically based sex from socially constructed gender as she continued her inquiry into nature-nurture questions by asking whether temperamental differences between the sexes were culturally determined or innate. Her popular audience continued to be fascinated with the many cross-cultural examples she described that contrasted so sharply with gender role expectations in the United States at the time. Mead's popular voice was enhanced through her frequent lecturing and the regular column she contributed to *Redbook*, a popular magazine oriented toward married women, in which she responded to questions from readers.

Kinship Studies and the Sexual Division of Labor

Kinship Studies

Since kinship is one of the primary ways that humans determine relatedness to one another and from there extrapolate patterns of obligation, reciprocity, and status, it has been a staple in both American and European anthropology since the inception of the discipline. Studying kinship bespeaks an interest in the family, marriage, and the management of female reproduction. But mere presence in an anthropological discussion does not itself generate a nuanced understanding or representation of women's lives. Moreover, and as some of the previous examples show, there was a tendency in earlier anthropology to view women as objects of interest only insofar as they helped illustrate a particular theory or dutifully played a part in the larger social structure.

In anthropology, most pre-1970s scholarship on both kinship theory and the sexual division of labor ignored or naturalized sexual difference and assumed universal

“natural” male dominance. The earlier treatments of kinship took a rather fixed view of kinship structure, which extended as well to discussions of “preferred” marriage patterns. By contrast, post-1970s revisions of kinship tend to stress the inherent flexibility of kinship designations and categories. More recent understandings of kin-based relatedness and preferred marriages stress that they are not necessarily the product of fixed rules. One classic example comes from the Middle East, where it has long been assumed and commented upon that paternal first cousin marriage was a preferred marriage pattern. Although not untrue, there is nonetheless considerable flexibility regarding, for example, who exactly is considered a *bint 'amm* (paternal uncle's daughter) or *ibn 'amm* (paternal uncle's son). The designation “paternal first cousin” seems specific, but its application can in fact be quite fluid, just as marriage matches that are considered preferable can be so for many contextually specific reasons besides the location of potential spouses in a kinship diagram. Revised approaches to kinship studies emphasize that classificatory kinship terminologies, kinship categories, and preferred marriage patterns can all look quite different on the ground than the normative view might claim and thus need to be understood on a case-by-case basis. What is valued, desired, or considered normative shifts from generation to generation with changing social, political, and economic constraints and, even more immediately, can change from interview to interview in a single context depending upon who is interviewing whom, who else might be present at the time, and so on.

Sexual Division of Labor

Along with kinship studies, the sexual division of labor has long been a bedrock concept in anthropology's cultural inventory. The classic and long-held understanding of the sexual division of labor model maintained that men and women had universally distinctive work routines and differential access to labor resources. This stance thus posits stark dichotomies among men and women and, further, implies universal inequality and male dominance. In the mid-1990s, M. Priscilla Stone, Glenn Davis Stone, and Robert M. Netting effectively countered the major assumptions underlying the conventional anthropological understandings of the sexual division of labor in an agricultural context with their year-long labor analysis of Nigerian Kofyar intensive agriculture. They took issue with the consensus that “there is a nearly universal difference in the agricultural work routines of men and women [and that] women have more limited means than men for mobilizing labor” (Stone, Stone, & Netting, 1995, p. 166). Instead, they found that “in contrast to others who emphasize processes that cut across and through households . . . we stress the degree of cooperation and overlapping interests that characterizes the Kofyar household” (Stone et al., 1995, p. 166).

Their contribution was one important example of the broad and sweeping revision of received wisdom that took place in the last quarter of the 20th century in anthropology. What had heretofore been the proverbial nuts and bolts of anthropology's analytical toolkit, from kinship to the sexual division of labor and beyond, was re-tooled—reassessed, revised, and reframed. This new perspective on an old topic was in no small part the result of anthropologists looking more closely and critically at what actually was going on in women's worlds. Stone et al. argued against universalizing about the sexual division of labor in agriculture, and they made the case for looking closely at context; in this case, they looked at both women's and men's contributions to the household in painstaking detail. This meant accounting for every hour spent laboring by both men and women over one year, including differentiating by crop and by task such as field clearing, beer brewing, harvesting, planting, ridging, weeding, and so on.

The sexual division of labor has also been important in archaeological reconstructions of the past and in anthropological studies conducted among living hunter-gatherers/foragers. A "man the hunter" model dominated Richard B. Lee and Irven DeVore's edited volume of the same name, (1968) tellingly subtitled *The First Intensive Survey of a Single Crucial Stage of Human Development—Man's Once Universal Hunting Way of Life*. This collection brought together papers from a 1966 symposium on small-scale, nonagricultural, "living fossil" hunter-gatherer societies and included case studies from Africa, Australia, India, and South America. DeVore and Lee had, in 1963, helped establish the Harvard Kalahari Project in Botswana, a long-term research program that, to date, has produced over 20 books and over 200 articles, as well as a veritable industry of controversy on many topics. In the 1970s, Lee would change the terminology he used to refer to the !Kung San from *hunter-gatherers* to *foragers* based upon evidence that the greater proportion of the !Kung San diet came from collected food, not hunted meat. A "man the hunter" model had asserted that men procured most of the food—and most of the prestige in the process—and that women were categorically not involved in hunting, neither of which is necessarily the case, at least not universally. Lee and DeVore's *Man the Hunter* is a good example of what has subsequently been criticized as an exclusionary, proscriptive take on the sexual division of labor, whereby women's roles were understood more by what they were not doing or not permitted to do rather than what they were doing.

Late-20th-Century Trends and Future Directions

Many upheavals—both external and internal, as well as practical and theoretical—have marked anthropology and social science as a whole in the last third of the 20th century. Nothing remained quite the same after the major shifts in

social consciousness that took place in the 1960s. The civil rights, Native American, antiwar, and women's movements all effected sweeping changes in American society and in the ways that social scientists conceived of their research. Within this ferment, the anthropological treatment of women was at first very specifically focused on the question of women's status relative to men's status from prehistory to the present.

Michelle Zimbalist Rosaldo and Louise Lamphere's coedited volume *Women, Culture, and Society* (1974) reflects this moment well. This collection, firmly anchored in a feminist anthropology sensibility, brought a programmatic new set of questions to anthropology, proposed new theoretical directions, and did so with a sense of urgency and purpose. Contributors to Rosaldo and Lamphere's volume mostly agreed that universal asymmetry defined sex roles in most societies, but they took an entirely different view of the nature of that asymmetry than had been dominant in previous generations: "The secondary status of woman in society is one of the true universals, a pan-cultural fact. Yet within that universal fact, the specific cultural conceptions and symbolizations of woman are extraordinarily diverse and even mutually contradictory" (Ortner in Rosaldo & Lamphere, 1974, p. 67). For her part, Rosaldo focused on the structural opposition between the public and domestic orientations of men and women in society, while firmly rejecting conventional understandings associated with that split, especially regarding power relations:

In those societies where domestic and public spheres are firmly differentiated, women may win power and value by stressing their differences from men. . . . The very symbolic and social conceptions that appear to set women apart and to circumscribe their activities may be used by women as a basis for female solidarity and worth. . . . Extra-domestic ties with other women are, then, an important source of power and value for women in societies that create a firm division between public and domestic, or male and female roles. (Rosaldo & Lamphere, 1974, pp. 37–39)

By the 1980s, however, before her untimely death, Rosaldo had shifted away from a dichotomizing public-domestic analysis to an approach that emphasized gender and the interdependence between women and men. This shift is reflected across the discipline generally and in feminist anthropologically specifically.

The contributors to *Women, Culture, and Society* were hoping to effect change beyond revised analyses and theory making in anthropology:

My interest in the problem is of course more than academic: I wish to see genuine change come about, the emergence of a social and cultural order in which as much of the range of human potential is open to women as is open to men. (Ortner in Rosaldo & Lamphere, 1974, p. 67)

Indeed, many of the volume's contributors went on not only to have productive and influential careers in anthropology

but to remain active advocates for gender equity. Louise Lamphere, for example, who became AAA president (1999–2001), received the Squeaky Wheel Award in 1998 from the Committee on the Status of Women in Anthropology “for her lifelong work for the equality of women in anthropology.” In her 2001 presidential address at the 100th annual meeting of the AAA, Lamphere referred to Rosaldo as “one of the pioneering young feminist anthropologists who helped revive the discipline’s interest in women,” adding that Rosaldo’s contribution to their coedited book “developed out of her participation in the early 1970s women’s movement” and was motivated by the notion that “theory had a critical role to play in political change” (Lamphere, 2004, p. 135).

Rosaldo and Lamphere’s volume helped establish a framework for a veritable explosion of anthropological research on women and gender. What started out as an investigation focused somewhat narrowly on “where women are and how we got here” has expanded dramatically in subsequent decades. Anthropological treatments of women have come to pay close attention to the myriad ways that women negotiate, resist, and/or accommodate power and moreover how they do so within overlapping contexts of class, race, ethnicity, gender, and so on. A number of subspecialties developed over the late 20th and early 21st centuries continue to produce fascinating and trenchant analyses of women and, for example, their experiences with and roles in colonial and postcolonial history, labor markets, and increasingly intrusive medical technologies. An interest in the dynamics of gender and identity itself has proliferated as well and considers everything from early child socialization (for which linguistic anthropology makes important contributions) to hybrid sexualities.

Ann Laura Stoler and Partha Chatterjee are just two of many noteworthy anthropologists whose theoretically rigorous research examines, among other things, the roles women have played within larger imperial and governmental contexts, such as colonialism, postcolonialism, nation building, and state formation. Their analyses typically give a nuanced accounting of class, gender, power, and race extant in these relationships. For example, one important, often-cited article of Stoler’s makes the argument that in the later colonial period, European wives of colonial administrators were encouraged to set up house in the colonies in an effort to maintain sex segregation between European men and local women. To do so was to preserve an all-important sense of racial superiority that was undermined, or at least severely challenged, by the existence of mixed race offspring (Stoler, 1989). These European women were strictly trained in how to establish a happy home in order to keep their husbands focused on family. These women, she concludes, were both oppressed and oppressors. The onus put on them to maintain racial and class superiority created an oppressive situation for them, and they, in turn, oppressed indigenous women and men whom they employed or otherwise dealt with in

country. A complementary example is offered by Indian scholar Chatterjee (1989), who discusses the effects of Britain’s “civilizing mission” on India. One Indian response was to promote an image of a new Indian woman, an exemplar and embodiment of a distinctively modern Indian national culture. This new female icon was considered superior to both Western women and “traditional” or lower-class Indian women. Better than the West also meant better than the rest of Indian women from lower status groups.

Labor studies offer another rich line of inquiry into women’s lives in recent anthropology. Anthropologists have always been interested in what people do to make a living, as the long life of the sexual division of labor model attests. The difference in post-1960s anthropology is reflected in the proliferation of ethnographies that look in depth at women’s economic lives, accounting for everything else related to that from intimate kin relations to global markets. One notable example, keeping in mind that there are many noteworthy examples from which to choose, is Gracia Clark’s *Onions Are My Husband* (1994), an expansive, detailed ethnography of Western Ghana’s Kumasi central market, where the “market queens” shrewdly negotiate with other queens, customers, vendors, police, market associations, and so forth as they make their livings. This ethnography, exhaustive in its detail, accounts not only for the dynamics of the local markets but also for how they are affected by regional, national, and global markets. In the Middle East context, Jenny White has made important contributions to the understanding of women’s labor in an urban Turkish context (2004). She focuses on rural immigrants to Istanbul and how their outside wage work, which is culturally valued but poorly compensated, affects kinship relations and social identity. White locates women’s paid work in larger contexts of global capitalism, Islam, gender, and Turkish family life.

In addition to labor studies, another important area of inquiry in recent decades of anthropology concerns “the body,” embodiment, and reproduction (both theoretical and literal reproduction). One important example is Emily Martin’s highly influential *The Woman in the Body*, which appeared in 1989 and is currently in its third edition. In it, she compares the way women speak about their own reproductive processes with the mechanistic model that informs the way their bodies are viewed and treated in medical settings. For example, Martin claims that medical science views menstruation as an instance of failed reproduction. Some women accept this model, but some do not. Among Martin’s informants, middle-class women tended to accept the failed reproduction model and were described as “mystified” by the physical process, whereas working-class women, both black and white, resist that conception and speak about menstruation in more explicit, immediate, and straightforward ways than middle-class women.

The next generation of “woman and the body” research reflects a biomedical landscape that is increasingly complex and ethically fraught. Amniocentesis, in vitro

fertilization, DNA testing, and surrogacy are but a few of the (often painful and invasive) treatments that raise complex personal and societal questions about reproduction—such as how reproduction can be manipulated, why, and with what results. This type of anthropological inquiry takes on the nexus between women's bodies and biomedical technology and considers the often confusing morass of ethically ambiguous options and technologies that are available to individuals, both women and men, dealing with infertility all over the world. For example, Rayna Rapp (2000) examined the social and personal challenges that fetal testing and prenatal diagnosis bring to women across a spectrum of racial, cultural, religious, educational, and financial backgrounds. In a more cross-cultural vein, Marcia Inhorn has done a great deal of important work, across the Middle East, on fertility and infertility issues that affect both women and men (Inhorn, 2006). Also from the anthropology of the Middle East, there are two ethnographies (Kahn, 2000; Kanaaneh, 2000) that lend themselves well to comparison in that they focus on two different groups of women in the State of Israel—Palestinian Arabs in the Galilee region and Israeli Jews—and their experiences related to reproduction, including fertility issues and reproductive technologies, sexuality, beauty, and political demography. These ethnographies describe the reproducing female body as a site of complex meddling and identity formation at the individual, communal, and national level.

These trends and ethnographic cases exemplify several exciting and productive directions that the anthropological treatment of women has taken in recent decades.

Women and Linguistic Anthropology

Linguistic anthropology formally emerged in the late 19th and early 20th centuries as part of the holistic, four-field approach championed by Boas. He insisted, for both practical and theoretical purposes, that language was a necessary lens through which to gain insight into culture. But he left it to his students to develop the language and culture connection further. Edward Sapir and Benjamin Lee Whorf's so-called Sapir-Whorf hypothesis fueled decades of productive, yet ultimately unresolved, debate across disciplines regarding the "linguistic relativity principle" and the degree to which language influences or even determines a worldview. This principle holds that language is more than just a means of communication; it actually shapes perception and exemplifies each society's unique model of the world. Gender and language studies would later invoke this principle across a range of language and culture issues. In the 1970s and 1980s, for example, an extended argument raged regarding the common use of gender-neutral "he," which feminist detractors insisted projects a diminishment of the female across language and penetrates into individual and social consciousness, influencing the worldview as per the Sapir-Whorf hypothesis. Calls for gender-based

language reform of sexist language came from many quarters, including linguistic anthropology. Gender-based language reform has been remarkably successful over the past 40-year period. Popular use of terminology that feminists had labeled sexist has in many cases shifted to significantly more neutral options that are widely used, including the use of a singular "they" for "he" and "she" (or an alternation among "he," "she," and "they"), "Ms." (as an alternative for "Miss" or "Mrs.," both of which identify a female based upon her marital status, contrary to the nonparallel example of "Mr."), and gender-neutral vocabulary related to work, such as "flight attendant" and "salesperson."

From "Women's Language" to "Gender and Language"

For linguistic anthropologists, a sustained focus on women's language is typically traced back to Robin Tolmach Lakoff's *Language and Woman's Place* (1975). Lakoff, a linguist and not an anthropologist, was not the first to write about women's speech, gender differences in language, sexist language, or gender-linked variation. But her book is widely regarded as having inaugurated gender and language studies. Lakoff proposed that a female speech style exists; it is characterized by the use of hesitations, qualifiers, "tag questions," excessive politeness, and "empty" adjectives that together work to weaken or mitigate the force of an utterance. She claimed, for example, that women ask tag questions more often than men, because women feel compelled to soften what they say, rather than be forceful and direct. She believed that the uncertainty expressed by tag questions reflected women's relative weakness in society. The actual findings on tag questions reveals significantly more complexity while at the same time supporting the notion that power is delicately negotiated in speech events that include tag questions. In claiming that women's language was a powerless language and further that it contributed to perpetuating male dominance and inequality between the sexes, Lakoff also emphasized women's own complicity in perpetuating inequality, by both using women's language and socializing their children into its use as well.

Over a quarter century later, some of Lakoff's insights may sound dated, and some of her claims have been disproven, or at least more succinctly problematized (especially regarding tag questions), but the overall impact of her book remains significant for having started the conversation on gender and language in a productive way. Lakoff argued for a notion of women's language as a social act, an act with real consequences, that is, the reproduction of power inequities. This aspect of her approach resonated deeply with linguistic anthropologists, for whom "language as a social act" is a central tenet.

Overall, linguistic anthropology came to reject the essentializing aspects of Lakoff's approach, such as the

notion implied in her analysis that women's language was part of a separate women's culture, when in practice there is much more cross-referencing, ambiguity, and shifting of contexts taking place:

If we understand women's everyday talk and linguistic genres as forms of resistance, we hear, in any culture, not so much a clear and heretofore neglected "woman's voice," or separate culture, but rather linguistic practices that are more ambiguous, often contradictory, differing among women of different classes and ethnic groups. (Gal, 1989, p. 178)

In critiquing Lakoff and other feminists writing on "women's language," Susan Gal emphasized the necessity of attending not only to words, but also to ethnographic context—the interactions in which these words are found and the larger political and economic contexts of communication. A research program that focuses on gender, speech, and power, as Gal described her own "theme," must determine what power and powerful language look like cross-culturally, something of which Lakoff and many other feminist commentators on language were woefully neglectful. In direct contrast to the type of argument explicated by Lakoff—grounded as it was in the white, middle-class experience—Gal describes an example from Madagascar in which Malagasy men's speech is characteristically indirect and deferential, avoiding confrontation, while women's speech is more direct, prone to angry outburst, and seen as conflictual. Among the Malagasy, it is universally agreed that men's speech is considered superior to women's speech.

The Malagasy example notwithstanding, it is interesting to note that the ethnographic literature shows that many of the features that Lakoff identified as characteristic of women's language—silence, indirectness, politeness—are in fact often associated cross-culturally with women's ways of communicating. Still that fact in isolation does not reveal much about the rest of the picture, such as how power is defined and differentiated in a particular culture or society or what other dynamics, such as class, race, gender, and ethnicity, are affecting social relations in general or in a particular speech event. Silence, to take one important example, is an inherently ambiguous communicative resource that does not always indicate the deference and passivity that Lakoff claimed it did. Sometimes, Gal emphasizes, silence is an effective way to enact opposition or resistance.

Language Socialization, Variationist Studies, and the Japanese Case

Language socialization studies is an important subfield of linguistic anthropology that sheds light on how girls and boys learn the gender norms of their society. Since the late 1970s, a great deal of research has been conducted on how

children and other novice language learners become both communicatively and culturally competent across the various speech communities they inhabit throughout their lives. To learn language is to learn culture, echoing the important link that Boas insisted upon in the early 20th century. Ideologies, identities, stances, values, practices—including those associated with gender norms and identities—are all learned in the process of language socialization.

In addition, language variationist studies have a great deal to offer in analyses of language, culture, and gender. Language variationist studies look at the different ways that members of the same "communities of practice" speak. Everything from phonological variation (pronunciation differences) through grammar to vocabulary is important in "self-constitution," that is, in showing who you are and what your affiliations are. Penelope Eckert spent three years conducting participant-observations at "Belten High" (Eckert, 2000). She found that over the course of their high school years, girls' speech tends to become increasingly standard, while boys' speech becomes increasingly non-standard. She claims that this reflects several things, including different senses of maturity, that nonstandard grammar is associated with autonomy (versus girls' conformity), and that boys are expected to curse more (reflecting gender norms that hold girls should be more conformist than boys, and boys have license to curse and speak more sloppily than girls). She also found telling symbolic significance associated with phonological variation that showed an interesting cross-cutting of gender and class categories. Different styles of pronunciation were shown to be inextricably linked with the construction of identity. Moreover, she emphasized how gender is not only a matter of male and female but also is embedded in other parts of our social lives, along with other socially significant categories, such as class, race, and ethnicity.

It is relevant to note here that language variationist studies typically come out of a sociolinguistics tradition (linguistics). There is, however, extensive overlapping and cross-referencing among sociolinguistics, anthropological linguistics, and linguistic anthropology in the area of gender and language studies. There is also some active disagreement regarding these subdisciplines' genealogies and disciplinary homes. For the purposes of this chapter, however, these disciplinary arguments are omitted in favor of maintaining the extended general focus on the anthropological treatment of women's arguments. Scores of syllabi across many universities attest to the fact that Eckert's "Belten High" case study is used extensively in linguistic anthropology classes across the country.

Finally, a productive case study that has been revisited often by linguistic anthropologists interested in women's language is that of Japan. In Japan, there are not only distinct female and male speech registers, but also other distinctive *isoo* ("sections"), styles of speech that reflect age, generation, social background, class, gender, regional background, and profession. Language is thus very tied up

with Japanese self-presentation and identity construction. Japanese women's language itself is characterized by the use of certain sentence-final particles (-*wa*), superpolite forms of speech (including honorifics), slow tempo, high pitch, and other features. It is seen as a highly valued cultural ideal—beautiful, elegant, and sophisticated—and important as a symbol of Japan itself. In the popular media, anxiety is expressed by some over the belief that women's language is disappearing—that the speech styles of *all* Japanese women are changing from less feminine to more masculine, and that young girls' speech in particular is becoming rough. At the same time, the use of honorifics is weakening in general in Japan, across all of society. Comparatively speaking, however, there is considerably less anxiety associated with declining use of honorifics than with changes related to women's language.

The Kogal phenomenon, a predominantly teenage girls' subculture, has provided one interesting site through which to examine ideologies related to women's language. Being Kogal is enacted through language and behavior. The language used when girls perform as Kogals includes non-standard forms, novel coinages, and explicit references to sexual or taboo topics. They use terms considered to be demeaning ("bitch" or "girl") "owning" the terms as endearing and playful forms of address. The dominant ideology holds that teenage girls' demeanor and speech should reflect qualities of innocence, modesty, docility, and deference. Japanese media have accused them of destroying their language.

Women in the Middle East

As with the rest of anthropology, the treatment of women in the anthropology of the Middle East was, until the 1970s, largely unidimensional and focused on formal roles. To complicate matters, however, there is a long history of mutual antagonism, suspicion, and misrepresentation between the Middle East and the West that goes back even further than the medieval Crusades and is alive and well in the early 21st century. It is certainly something that has thrived in both scholarship and the arts, as has been so famously documented by Edward Said (1978, 1993). Central to the perpetuation of this long-standing unease has been the "Middle Eastern woman," repeatedly stereotyped as passive, oppressed, and veiled. In addition, this stereotypically oppressed woman has sometimes played an inadvertent role in justifying outside intervention—to "save" her—from the colonial period to the 2001 invasion of Afghanistan. Lila Abu-Lughod, a major figure in Middle East anthropology, addresses the latter example in a trenchant piece presented shortly after 9/11 (Abu-Lughod, 2002).

An important exception to the prevailing pre-1970s unidimensionality with respect to women was Elizabeth Warnock Fernea's *Guests of the Sheik: An Ethnography of*

an Iraqi Village (1965), written while accompanying her husband, Robert Fernea, during his dissertation fieldwork on changing relations of political authority in a rural, southern village. *Guests of the Sheik* was the first in a very long line of contributions that Fernea made over her lifetime to an anthropology of Middle Eastern women (and their families and lives), both in print and in a number of documentaries. *Guests of the Sheik* is still in print and continues to be used frequently in university courses on the peoples of the Middle East. It offers a view "behind the veil" into women's lives and is effective in helping dismantle the stereotypes that students typically bring with them to the topic of women in the Middle East.

A relative absence of women in the scholarship of the Middle East, especially through the first two-thirds of the 20th century, perpetuated various assumptions: Women play little or no significant role in society, the world of men is much more interesting and significant than that of women, gender relations are not an issue, and there is little if any crossing of the boundaries between men's and women's worlds. Certainly this parallels what went on in other corners of anthropology at the same time, as discussed earlier. This kind of message reifies certain notions of power and associated notions of a public-private split in which the world is divided into neat binaries. It also has contributed to an implicit devaluing of theory in anthropology that comes out of women's experience, which is explicitly referred to in Abu-Lughod's 1989 *Annual Review of Anthropology* article on "zones of theory" in the Arab world. In this piece, Abu-Lughod identifies three gate-keeping concepts in the anthropology of the Middle East: segmentary lineage, the harem, and Islam. Segmentary lineage, she points out, has contributed the most in terms of theory, and thus prestige, to anthropology. The other two gate-keeping concepts she identifies as those of Islam and the harem (or, women). In referring to the harem, Abu-Lughod is clearly hearkening to the legacy that sensationalized focus on out-of-context phenomena, such as veiling and female circumcision, has created in both popular and academic views of the region. Veiling itself is a nonspecific gloss for any number of practices that are informed by often-competing ideologies. Also, veiling itself is not a frozen practice; it changes over time and means different things to different people at different times in their lives. An anthropology of Middle Eastern women in the past four decades has made this dynamism increasingly apparent.

It should go without saying that ideological conventions concerning women and gender vary considerably across the Middle East. There is not only no single Islamic view on women, but also, of course, no single Arab, Jewish, Christian, or Turkish view. The anthropology of Middle Eastern women has become increasingly effective at making this variety and contestation clear.

A generation of solid ethnographic work on women appeared in the 1970s and 1980s that focused on women in their familial, domestic, and village contexts. This work

was very successful in presenting humanized portraits of very unfamiliar (to Western readers) and mystifying lives long considered exotic. These valuable contributions gave detailed accounts of women's lives in very dense local contexts, accounting for processes of change in family patterns, livelihoods, household production patterns, and so on. A short list of contributions to this output includes Lila Abu-Lughod (1986) on Egyptian Bedouin women's lives, Christine Eickelman (1984) on women and community in Oman, Suad Joseph (1977, 1978, 1983, 1988) on women and the family in Lebanon, Andrea Rugh (1984, 1997) on family in Egypt and Syria, and Nancy Tapper on marriage, kinship, and politics in Afghan society (1978, 1991). They tended to present more "traditional" anthropological settings, that is, villages and tribal peoples. A more recent trend in anthropology has been to account for urban lives, such as Farha Ghannam's (2002) work in Cairo on the topic of "modernizing" entire neighborhoods by relocation and Christa Salamandra's Damascus ethnography (2004), which is also a departure not only for its focus on an urban context but also for its focus on the elite classes, which anthropology in general has by and large avoided.

Future Directions (Middle East)

As the late 1980s and 1990s progressed, ethnographic treatments of women's lives began to reflect a more fragmented, globalized, and disruptive world. Smadar Lavie's work on the Mzeina Bedouin of the Sinai Peninsula (1990) discussed the effects of Egyptian occupation, Israeli occupation, drug smuggling, and prison stays, as well as shifting gender norms in villages that are tourist sites and where men are away most of the year earning money.

One of the richest lines of inquiry in Middle East ethnography currently involves those works that consider the links between modernity, Islam, and women. The issue of how to balance modernity and tradition has long been a difficult one in Middle Eastern society. A neologism, *gharbzadegi*, or "Westoxication," was coined in the mid-20th century that describes being addicted to and intoxicated by the West, which also is believed to reflect Iranian self-hatred and self-doubt about themselves. On the one hand, there have been robust "modernization" movements—in Atatürk's Turkey, Nasser's Egypt, and the shah's Iran—that brought many irrevocable social changes, many of which have been viewed as betrayals of indigenous principles and local heritage. This complicated dynamic, tied up with notions of modernity, is part of an ongoing tug-of-war in a Middle East that is now very "wired" and very young. Future directions in the anthropology of Middle East women will necessarily deal with this dynamic as well as with the corresponding "mediatization" of women's (and others') lives.

Lara Deeb's ethnography of Shi'ite women in southern Beirut, for example, focuses on how a modern "authenticated" Islam is created through women's activism,

especially volunteering at local community centers, and women's active engagement with religious discourse. The Shi'ite women in this ethnography, for example, acknowledge that theirs is a patriarchal society, but they stress that an authenticated Islam, one based on engagement with the Koran, offers gender parity. Women can interpret religious texts *and* debate them with men, which they do with great frequency. The theme of men's misinterpretation of texts is a common one in everyday conversation. These women not only embrace models of strong women in Islamic history, especially Zaynab, but also Aisha and Khadija (all were wives of Muhammed). In short, this is one of several recent ethnographies problematizing the link between women's roles in defining both modernity and tradition, religious or otherwise. Deeb's work is nicely paralleled by both Saba Mahmood's important work on the women's mosque movement in Egypt (2005) and Azam Torab's research in south Tehran among Shi'ite women (2007), with its focus on women's increasing influence and participation in mosques.

There has also been a great deal of productive anthropological work done on issues related to women's health, public health, and demographic issues in the Middle East. A recent summarizing article by Marcia Inhorn is especially valuable in laying out what this body of anthropological literature, over 150 volumes, has brought over the past 25 years to the study of women's health, public health, reproductive politics, and gender roles in the Middle East, including, importantly, changing notions of masculinity and partnership in marriage (Inhorn, 2006). One important point concerns how a

specifically ethnographic approach [offering up deeply qualitative, women's voices] to women's health leads to a particular set of insights that are important, timely, and quite different from the women's health research agenda currently being promoted within biomedical and public health circles. (p. 346)

Anthropology's tendency to focus in these ethnographies on women's and men's voices, Inhorn claims, could be a valuable source of information for public health officials in understanding many of the health-demoting aspects of biomedicine that exist.

In short, the future trend of the anthropology of Middle Eastern women will continue to humanize and demystify their lives. Major topics will include reproductive politics and practices, changing notions of family, accommodating modernity on their own terms, effects of large-scale rural-to-urban movement, and mediatization.

Conclusion

The state of the art in the anthropological treatment of women is impressive in both its depth and breadth. Anthropology has gone from studying women in a largely essentialized and somewhat marginalizing fashion in its

earlier decades to a more contemporary concern, not only with women per se, but also with gender relations as they interact and are mutually informed by a number of interpenetrating axes of power, class, technology, ethnicity, and so forth. To have gotten from one end of this arc to the other has taken a little over a century.

Lamphere, in her 2001 presidential address at the 100th annual American Anthropological Association meeting, emphasized the structural marginality of some of the iconic women anthropologists of Boas's era. The most influential female anthropologists were of their time, in that their access to professional academic and research opportunities was mediated through the support of their benevolent patriarch, Boas, who was admittedly very ahead of his time in actively encouraging these opportunities for his female students. All of the early women anthropologists, however, laid a fundamental groundwork that enabled later generations to take off running when the opportunity arose. Lamphere, for example, claimed that Elsie Clews Parsons was structurally marginal in the discipline until elected AAA president in 1941, despite having joined Boas and Benedict on the Columbia faculty—exerting her own influence as an advisor, mentor, and patron.

Future directions in anthropology that concern women's lives will continue to reflect the challenging ambiguities people face navigating the many technologically mediated aspects of our lives, as well as the challenges and opportunities of living in a globalized, transnational, and information-saturated world. For anthropological treatments of women specifically, this will include continued research on issues related to reproductive technologies. There are some interesting parallels between future directions and old concerns to the degree that kinship and labor studies are still prominent concerns, but with the important caveat that these bedrock topics are now looked at in radically different ways than they were 100 years ago. This reflects a number of dynamics at work over the past century.

VISUAL ANTHROPOLOGY

LISA M. VAUGHN

University of Cincinnati College of Medicine/Cincinnati Children's Hospital Medical Center

KATIE E. ENGLERT

Northern Kentucky University

Visual anthropology is typically considered a sub-field of cultural anthropology that developed out of the study and production of ethnographic photography and film. However, there are some anthropologists who disagree and instead place it “squarely within the discipline of anthropology” (El Guindi, 2004, p. 19). Visual anthropology is useful for ethnographic research, media analysis, and studies of material culture. Visual anthropology also encompasses the anthropological study of representation, including areas such as performance, museums, art, and the production and reception of mass media. However, to date, photography and film have been the primary concerns of visual anthropologists and will be the main focus of this chapter.

Visual anthropology emphasizes the cultural meanings of visual expressions and visually recording cultural practices within an ethnographic context. This encompasses the idea that “culture is manifested through visible symbols embedded in gestures, ceremonies, rituals and artifacts situated in constructed and natural environments” (Ruby, 1996, p. 1345). Visual anthropology utilizes visual media to practice anthropology and to investigate the social realm. The discipline of visual anthropology has unclear boundaries ranging from the narrow to the broad and complex. It has been defined in a variety of ways: as audiovisual aids to supplement the teaching of cultural anthropology; as another descriptor for ethnographic films; as the anthropological study and production of media (Ginsberg, 1994); as

pictorial and visual communication, which consists of anything “made to be seen” (Ruby, 1996); and as “anthropology of visual systems or, more broadly, visible cultural forms” (Morphy & Banks, 1997, p. 5).

History of Visual Anthropology

Before visual anthropology was considered an academic discipline, early ethnologists were using photography as a research tool (Ruby, 1996). Many of these photographs, like those of Native Americans made by Edward S. Curtis, were made in an effort to preserve societies and their way of life (Prins, 2004). Historically, anthropological filmmaking was associated with documentary filmmaking; Barnouw suggests that a person who made such a film was a “documentarist as travel lecturer” (1993, p. 29), for instance, some of the first ethnographic films (e.g., *Promenades des Éléphants à Phnom Penh* [Elephant Processions at Phnom Penh], 1901) with the intent of exposing “pristine” cultures. This same pattern persisted in later ethnographic films, such as Robert Flaherty’s *Nanook of the North*, in 1922, about the lives of Arctic peoples and Robert Gardner’s *Dead Birds*, in 1965, about the Dani people of New Guinea (Barnouw, 1993).

In the history of visual anthropology within the scientific realm, early pioneers and their accomplishments included the following:

- Félix-Louis Regnault, chronophotographic film of a Wolof woman making pots and later a study of body movement and behavior, 1888–1896
- Alfred Haddon, photography of Torres Strait, 1898
- Baldwin Spencer, photographs, films, and recordings of aboriginal society in central Australia, 1899
- Franz Boas, 16-mm films of the Kwakiutl, 1930
- Marcel Griaule, 35-mm films *Au Pays des Dogon* and *Sous les Masques Noirs*, 1935–1938

Some credit Regnault, a physician interested in anthropology, as the first ethnographic filmmaker (El Guindi, 2004). All of these early research projects were marked by difficulty in transporting heavy, rudimentary equipment to the field (El Guindi, 2004). In the ethnographic arena, the work of John Marshall (Bushmen series), Tim Asch (Yanomamo series), Ian Dunlop (Yirkala project), David MacDougall (Wedding Camels), and John Bishop (Himalayan Herders) served as a bridge between anthropology and indigenous practice (El Guindi, 2004; Morphy & Banks, 1997). By the 1940s, anthropologists such as Hortense Powdermaker, Gregory Bateson, and Margaret Mead were incorporating anthropological perspectives into mass media and visual representation. Powdermaker is best remembered for her anthropological studies of an African American community in Mississippi (Powdermaker, 1939/1993) and one of the few substantial examinations of the American film industry (Powdermaker, 1950). Mead, a student of Boas, worked with Bateson to use visuals and film throughout their collaborative work in Bali and beyond (see, e.g., Bateson & Mead, 1942). Much has been written about Mead and Bateson's approaches to using the visual within the anthropological scope, especially their breakthroughs in incorporating film and photography. In the history of American visual anthropology, Mead and Bateson's work is unparalleled with respect to the sheer volume of footage they produced.

Karl G. Heider noted in his revised edition of *Ethnographic Film* (2006) that after Bateson and Mead, the history of visual anthropology is defined by

the seminal works of four men who were active for most of the second half of the twentieth century: Jean Rouch, John Marshall, Robert Gardner, and Tim Asch. By focusing on these four we can see the shape of American ethnographic film. (p. 15)

In addition, the depth of the work of leading ethnographic filmmakers David and Judith MacDougall, in both their observational approach to filmmaking and the extensive writing by David MacDougall over the past 20 years, has shaped ethnographic film outside the United States. Collaboratively, the MacDougalls have documented groups of people in Uganda, Kenya, Sardinia, Italy, Australia, and more recently, India, where David filmed a series of films about the prestigious all-boys boarding school called The Doon School (*Doon School Chronicles*, 2000).

The term *visual anthropology* was coined after World War II and slowly grew to include visual records about culture and the study of social systems ethnographically using description and comparison (El Guindi, 2004). Mainstreaming of visual tools in anthropology began in the 1980s. In 1984, the Society for Visual Anthropology (SVA) was formed as a section of the American Anthropological Association. The SVA publishes a regular newsletter now known as the *Visual Anthropology Review*. The SVA described itself as promoting

the use of images for the description, analysis, communication and interpretation of human (and sometimes nonhuman) behavior. Members have interests in all visual aspects of culture, including art, architecture and material artifacts, as well as kinesics, proxemics and related forms of body motion communication (e.g. gesture, emotion, dance, sign language). The Society encourages the use of media, including still photography, film, video and non-camera generated images, in the recording of ethnographic, archaeological and other anthropological genres. Members examine how aspects of culture can be pictorially/visually interpreted and expressed, and how images can be understood as artifacts of culture. Historical photographs, in particular, are seen as a source of ethnographic data, expanding our horizons beyond the reach of memory culture. The society also supports the study of indigenous media and their grounding in personal, social, cultural and ideological contexts, and how anthropological productions can be exhibited and used more effectively in classrooms, museums and television. (SVA, n.d.)

Several things are important about the SVA's statement: It includes diverse forms of media, including public media; it includes different domains of culture (including material manifestations of a culture), and it covers multiple approaches to the study of visual anthropology.

The first attempt at an academic home for visual anthropology was made in 1958 with the creation of the Film Study Center at Harvard's Peabody Museum of Archaeology and Ethnology. In 1994, the review section in the journal *American Anthropologist* formerly called "Ethnographic Film" was renamed "Visual Anthropology." At present, the SVA represents the subfield in the United States as a section of the American Anthropological Association. Ethnographic films are shown each year at the Margaret Mead Film Festival, and the yearly American Anthropological Association conference features a coinciding visual anthropology conference at which many emerging ethnographic films are viewed and screened. Films are also shown at other international annual festivals and conferences.

Early Ethnographic Photography

Much of early ethnographic photography cannot be separated from the popular scientific paradigms and cultural biases of the time. For instance, anthropometrics and race were central to early ethnographic photography, with the assumption that

visual depictions provided insight into the intellectual and moral characteristics of their subjects (i.e., indicating a hierarchy, with the more “civilized” at the top and the more barbaric further down). The next theme in early ethnographic photography challenged evolutionary origins of polygenesis (multiple races with differing origins) versus monogenesis (single origins, same evolutionary path). Next was a demonstration of cultural tools, dress, traits, and practices. Finally, early ethnographic photography was characterized by salvage ethnography with the goal of preserving cultures thought to be dying out (Morphy & Banks, 1997; Ruby, 1996). Overall, early ethnographic photography can be characterized by one of two themes: (1) romantic primitivism—a cultivated, artistic approach such as that seen in the photographs of Edward S. Curtis, who made images of American Indians and their cultural practices, rituals, and customs; or (2) salvage ethnography, best exemplified in the fieldwork of Franz Boas, a cultural relativist who intended to preserve aspects of American Indian life before they disappeared.

Taking photographs in anthropology was not new. Even as early as 1912, in *Notes and Queries on Anthropology*, there was a discussion of how to take photographs in the field. One of the first to use photography and film for research was French ethnographer Marcel Griaule. During the Mission Dakar-Djibouti, an expedition in Africa from 1931 to 1933, Griaule used aerial photography not only to analyze the spatial organization of societies but also as a stimulus to evoke responses in interviewing individuals to acquire knowledge about their religion (what is now typically referred to as *photo elicitation*).

Visual Media as a Research Tool

Margaret Mead and others in the field advocated the use of visual tools in research for the purpose of recording and discovering knowledge. In a classic article, Mead (1975/2003) criticized other anthropologists for being overly reliant on words in anthropology when they should be using visual media. Photography can be used in qualitative and ethnographic research for investigative purposes. In ethnographic research, photographs offer striking, rich data that can transcend the photograph’s visual content (Collier & Collier, 1986). With photos, researchers can examine aspects of people and life not easily studied with other methodologies. Because visual images can often reveal more than words, researchers may gain a deeper understanding beyond the objective content of data (Asch & Asch, 2003). Photographs can also help researchers to “push their analysis” when the data do not fit previously conceptualized theories and ideas.

Researchers use photos in interviews with participants to understand how participants define their world and to reveal what they take for granted or what they assume is unquestionable. Visual data can strengthen research through the use of multiple data sources (this is also known as *triangulation*) and can offer a deep authenticity to an otherwise singular dimension of data. Adding a visual

means of data collection like photography can enhance fieldwork, since no one method of data collection can adequately record and explain all aspects of a phenomenon (Asch & Asch, 2003). In addition, photographs provide an opportunity for researchers to take the photos back to the participants and review them to get feedback, explanation, and interpretation. This strengthens the study and gives voice to the participants in the research process and results (Collier, 2003). Photographs can prompt participants’ memories and help researchers discover information that may not be as easily exposed with traditional interview methods (Beloff, 1984).

There are several notable examples of this kind of work. In a study of the immigration experiences of Latino adolescents living in rural North Carolina, photographs were utilized as a basis for interview discussions (Streng et al., 2004). Kruse (2004) asked elderly women to take photographs about their perceptions of a recently deceased loved one. Gaskins and Forte (1995) combined photos and interviews in order to enhance the richness of their data. Four participants in their study were provided with single-use, automatic cameras and asked to take images they felt were suggestive of hope. The researchers used the resulting photographs to guide in-depth interviews with the participants in order to further explore the meaning and experience of hope.

In another research study using photos, Radley, Hodgetts, and Cullen (2005) interviewed homeless people about their experience with homelessness. After taking photos of a typical day, the homeless participants were asked to describe the story and focus of each of their photos and their response to the person, place, or object in the photographs. All photographs were then spread out, and each participant was asked to identify the ones that best captured their experience of homelessness. Participants were also asked about their experience of taking the photographs and the feelings that accompanied the pictures they had taken. Interviews were audio-recorded and later transcribed for analysis.

In addition to photos taken as part of studies, there is an enormous amount of extant photographic material available to researchers, such as yearbooks, family photo albums, historical images of indigenous people, and historical society collections. The historical activities associated with people or places in these photos supply nonverbal, historical data and offer perspectives on the changes between the past and present. Researchers can gain a considerable amount of data from a photograph alone, but the combination of archival photos with interviews allows for identification of the individuals and events in the photos (Collier & Collier, 1986). Another benefit of using archival photos alongside interviews is that researchers can access feelings that are connected with the moment depicted in the photograph. Photos viewed during an interview that occurs at some point after the photos were taken can invoke the same feelings and emotions as those of the moment the photos were taken (Akeret, 2000). This is of great value to the researcher, because the information from the interviews is enhanced, and the data

associated with the photos come alive (Collier & Collier, 1986). The use of visual images “inject(s) the emotional context that is such a crucial component of all social problems” (Huff, 1998, p. 577).

Photo elicitation is a research methodology used primarily in anthropology and sociology as a way to explore social class, community history, individual and community identity, and cultural studies (Harper, 2002). Through symbolic meanings assigned to photographs, the social world of individuals, families, and communities can be revealed and connected to the larger society, culture, and history (Harper, 2002). Photographs may also elicit visions of what is possible for the future.

Ethnographic Film

Visual anthropology is probably best known for producing ethnographic films. With the invention of photography in 1839, early pictures of the “other” accompanied the written word, when anthropology was still an armchair science. In 1895, the silent movie was invented, and sound was first added in 1930. With the establishment of sync sound in 1960, doors opened to produce films that allowed the moving image and sound to work together simultaneously. In 1990, digital technology opened up even more opportunities, and with the rise in technology, the viewing and seeing experience has changed significantly over the past 20 years.

Currently, the ethnographic filmmaker often films in situations that allow for an in-depth understanding; this requires long-term participant observation with the camera, whether it occurs in another culture or in the visual anthropologist’s own backyard. Filmmakers are concerned with making a contribution to anthropological knowledge and are always critical of the films they produce. Filmmakers such as Robert Flaherty, Robert Gardner, John Marshall, and Dennis O’Rourke have contributed greatly to the emerging field of visual anthropology. These filmmakers, often educated in cinema or documentary filmmaking, typically have worked collaboratively with anthropologists or have had backgrounds in anthropology themselves. They helped set what today is considered the standard in ethnographic filmmaking in that they spent long periods of time with the people they filmed.

Modes of Documentary Film

In the 1960s, observational and interactive styles of filmmaking blossomed, with sync-sound making it easier to record the words of the individuals in the film. These methods imitated television and radio journalism styles, which included heavy interviewing techniques. Bill Nichols, professor of cinema and director of the Graduate Program in Cinema Studies at San Francisco State University, has written extensively on documentary and ethnographic film. By looking at key features within documentary film, Nichols

(1991) developed four modes of representation, comparable to those used to classify written texts, which allow for a system of classification for the ethnographic film: expository, observational, interactive, and reflexive. Each mode addresses the issue of how people and issues can be represented appropriately. Further, each of the four modes has been emphasized in a particular time period or in certain regions or countries (Nichols, 1991). It is important to note that most films will have elements of various modes with one dominant form of content.

Expository

The expository mode in ethnographic film might be considered “classic documentary.” This mode contains much description, as it usually sets up an argument, often from the anthropologist’s point of view. It then provides visuals and film footage as evidence to support the argument. Voice-over dominates throughout the expository film and controls and leads the argument. The expository film can be viewed as the visual equivalent to a written essay, and as Nichols (1991) suggested, the visuals in the film illustrate and support for the viewer what is being commented on throughout the film. The editing is subordinated to the “voice of god,” with the use of words providing the logic. In the absence of sync-sound, subtitles may act as voice over, as evidenced in the 1922 film, *Nanook of the North*, by Robert Flaherty.

The editing process in the expository mode is usually not done in a chronological way where events unfold; rather, it is organized so that the visuals support the underlining argument, which is articulated through the spoken word or subtitles. Other classic visual anthropological examples of the expository mode include Basil Wright’s *Songs of Ceylon* (1934), John Grierson’s *Coalface* (1935), Jean Rouch’s *Les Maitres Fous* (1955), and Melissa Llwelyn-Davies *Maasai Women* (1974). In Grierson’s *Coalface*, heavy voice-over tells viewers what they should know about the coal industry, making this a film about the process of the coal industry. In *Maasai Women*, the voice-over, that of the anthropologist herself, powers and controls the argument set out within the film. Here, viewers listen as the anthropologist tells them what to think and what is happening while the film footage shows what is being described, all of which support the anthropologist’s words.

For this last example, it is noteworthy that the target audience was a television audience. This may have affected the type of mode used, thus illustrating further the importance of keeping the audience in mind when choosing whose story is being told and what type of film an anthropologist or filmmaker will set out to produce. Within the expository mode generally, there may be elements of interviews, but they are used to support the main argument of the film or provide evidence (Nichols, 1991). The viewer finds these films to be logical, with cause and effect—similar to the evening news. The viewer expects a problem to be solved in the film, making it solution-oriented.

Observational

The observational mode is also known as *direct cinema* according to Erik Barnouw (1993), or *cinema vérité* according to Stephen Mamber (see Barnouw, 1993, for more information on direct cinema and cinema vérité). This mode of ethnographic film is usually a favorite among ethnographer filmmakers who utilize long periods of time in participant observation. Here, the focus of the film is usually on the details of everyday life, often in intimate settings. It can be thought of as the “fly on the wall” type of approach. The final version of the film is not dominated by voice-over, and the point of view is that of the characters in the film; there is no script. The viewer is looking in on and overhearing the people’s lived experiences. Sync-sound, long takes, and everyday life activities and events are what make the content in the observational film. As Nichols (1991) suggested, the observational mode is missing commentary and generalized images, which encourages filmmakers to focus on specific social formations of the family, the local community, or an institution.

Classis ethnographic films that use the observational approach include David and Judith MacDougall’s films, most notably *To Live With Herds* (1974), John Marshall’s *Bitter Melons* (1971), and Gary Kildea’s *Celso and Cora* (1983). Another example of an observational film that also has expository elements is anthropologist Jerry Leach and Australian filmmaker Gary Kildea’s *Trobriand Cricket* (1976). Here, although the anthropologist’s voice dominates that of the Papua New Guinean’s chief throughout the film, the visuals illustrate a game of cricket played the Trobriand Islander way. This film is from the native point of view, and while it does have expository attributes, it is one of the most recognized ethnographic observational films. It is expected that the viewer of an observational film will have to do some work to understand it, and it is the skill of the filmmaker to capture viewer interest. There is typically some type of tension or movement that is created throughout an observational film. (See Kildea’s *Celso and Cora*, for example.)

Interactive

Interactive films are often based on interviews within the film. The filmmaker here is trying to get many points of view across, and typically the film becomes a film with words as the central subject. According to Nichols (1991), interactive documentary often includes testimony, verbal exchanges, and demonstration. One of the most famous examples of the interactive mode is Jean Rouch and Edgar Morin’s *Chronicle of a Summer* (1960), even though it does have elements of an observational film as well.

The interactive form raises ethical questions of its own, in that interviews are a form of hierarchical discourse deriving from the unequal distribution of power, as in the confessional and the interrogation (Nichols, 1991). A comparison of the interview technique used in the expository mode versus that used in the interactive mode reveals that

interviews in the former are used as evidence to promote the anthropologist’s or filmmaker’s argument, whereas in the latter, the interaction itself between filmmaker and subject is part of the evidence to support the film’s argument. The viewer of the interactive mode expects to be informed, to come to an understanding of something through listening to the words and viewing the interactions of the individuals in the film (Nichols, 1991).

Reflexive

The reflexive mode is based on the filmmaker’s reflections on the content and form of the film itself as well as on the filmmaking process. The reflexive ethnographic film is about the actual encounter between the filmmaker and the people being filmed, and it “addresses the question of *how we talk about the historical world*” (Nichols, 1991, p. 57). Examples include *Man With the Movie Camera* (Vertov), *Lorang’s Way* (MacDougall), and Tim Asch’s *Ax Fight* (1975). In Asch’s *Ax Fight*, the viewer’s assumptions about reality are challenged, not only by the content of the film itself, but also by how the film was made, including the chronology depicted in the film.

Asch, who was never educated in filmmaking, viewed film as a method for teaching anthropology (Ruby, 1995). He began working with Napoleon Chagnon in 1968, and over the course of 10 years made 39 films among the Yanomami of Venezuela. According to Ruby (1995), along with the !Kung Bushmen in Africa, the Yanomami have become one of the most filmed non-Western groups of people. Two of Asch’s best-known films, *The Feast* and *Ax Fight*, came from this time period. In *Ax Fight*, Asch produced four versions of the same footage, resulting in a four-part film. Unedited raw footage is shown first. Next, a voice-over narration is added (using the voice of Napoleon Chagnon, the anthropologist Asch was working with), along with slow freeze frames, including on-screen arrows that point out the particulars that are being discussed. Next come kinship diagrams describing the people being filmed and who is related to whom. Finally, there is an edited version of the film without voice-over that almost appears to be a somewhat observational finished product.

One of the main differences between this type of film and observational films, like MacDougall’s, is the filmmaker’s approach and reason for making films in the first place. Asch has always been concerned with making films for teaching anthropology, while MacDougall was more concerned with using film as a way of producing knowledge.

Challenges Within Visual Anthropology

One major critique of visual anthropology is the degree of “ethnographicness” of the visual medium. To address this concern, several anthropologists have defined what makes a film truly ethnographic. For instance, Ruby (1975) proposed that ethnographic films should focus on

entire cultures or specific portions of cultures, be informed by theories of culture, include an explanation of the research and film methodologies, and use an anthropological lexicon. Others believe that ethnographic film is suitable for use in undergraduate teaching, archiving of cultural material, design and presentation of research studies, fieldwork, and publicizing anthropology.

Many anthropologists are uncertain about the parameters of visual anthropology. They might have little to no background in critiquing the photographs or films as opposed to the written word most often used in anthropological research. Visual media do not have the same attributes, methodologies, and theories as the written word. While most ethnographic films are made today by anthropologists trained in the academy, many films in the past were made by professional filmmakers working collaboratively with anthropologists (Ruby, 2000). These filmmakers often did not have a strong anthropological understanding and, according to Ruby, depicted their subjects as exotic “others” and were “actively hostile to anthropology and [knew] next to nothing about issues of reflexivity, giving the subjects a voice or any other post-modern issues that have dominated anthropology for decades” (2008, p. 3). Deficient in theory and analysis, ethnographic film still lacks clear and rigorous principles to make a significant contribution to cultural anthropology (Ruby, 2008).

Other questions that concern visual anthropologists about ethnographic film include (Ruby, 1996): (1) Who is doing the filming? (2) Is he or she an anthropologist or a filmmaker? and (3) If the film is made by a nonethnographer, then was an anthropologist involved in the project and in what capacity? Ruby is clear that if the film is to be considered “ethnographic,” then the filmmaker must have the intention of doing ethnography, must use ethnographic field methods, and must seek validation among those competent to judge the work as ethnography using the standards of evaluation from anthropology (2000).

Another issue with ethnographic films is their degree of reflexivity. Filmmakers have addressed reflexivity in three main ways: (1) including comments about the filming process by the subjects, (2) identifying themselves as filmmakers (normally in a visual way) early in the film, and (3) leaving traces of material that demonstrate the workings of filming (Morphy & Banks, 1997). Without the conscious effort of reflexivity, visual anthropology runs the risk of objectifying and exoticizing others, which may connect the discipline with colonialism and the ethnocentric view of indigenous peoples (Smith, 2003).

A major issue for ethnographic filmmakers is deciding whose story is to be told—the filmmakers’ story or that of the subjects in the film. “Filming selves” connotes visual anthropology projects in which members of a population under study participate in the filming of themselves or actually film themselves directly (El Guindi, 2004). The indigenous population can serve as “local assistants, culture bearers, collaborators, native ethnographers, filmmakers or filmed” and can offer views of culture to

anthropologists (p. 121). Within the “filming selves” genre, films can be (1) procedural, to demonstrate the traditional culture; (2) investigational, to analyze assertions in anthropological theories; and (3) made for the purpose of self-empowerment, advocacy, and self-representation of marginalized populations (El Guindi, 2004).

Harald Prins (1997) described himself as an action anthropologist who uses video technology to give indigenous people a way to oppose political oppression and resist cultural assimilation. Through his work, Prins offers an alternative to the typical discrimination, incarceration, exile, abuse, torture, and even murder that indigenous people have experienced. He provides a way for these populations to highlight their homelands, distinctive sociocultural practices, language, and spiritual belief systems.

Future Directions

While historically ethnographic filmmaking might have been the predominant method used within visual anthropology, there is much room within the field for other techniques covering the visual sphere of analysis. The future of visual anthropology is concerned, according to Pink (2006), with thinking about and exploring visual research methods across disciplines, anthropology of the senses, and media anthropology, including digital and hypermedia technology. She believes that developing innovative visual technologies and new ways to work within the field will result in creative and novel research projects within visual anthropology. In the future of visual anthropology, Pink foresees more applied projects, greater recognition in the public sphere, and more theoretically and methodologically informed research projects (2006).

Multimedia Forms

Today, images are ubiquitous and ever present on cell phones, the Internet, family photos, and billboards. These images highlight the importance of understanding the sociocultural significance of images. Although the importance of societal images has long been acknowledged by anthropologists, the burgeoning of the visual media has resulted in a visual emphasis in the analysis of people and culture. The consequence of this change has been a transition from the very limited use of imagery by anthropologists to its use as mainstream technique that continues to increase with advances in new visual technologies. Contemporary traditions of visual anthropology include self-representation, culture reconstruction, research film/photography/video, digital/multimedia presentations, and visual ethnography (El Guindi, 2004).

Jay Ruby’s innovative work short films, various photographs, and stories on a Web site is one direction in which the field of visual anthropology seems to be headed in the United States. This new approach to conducting visual ethnographic fieldwork follows from Biella (1993),

who proposed that interactive multimedia blending text, photographs, and film offered a viable alternative to traditional methods. Ruby's *Some Oak Park Stories* project includes four interactive digital CD-ROMs containing ethnographic portraits of three diverse families and one portrait of The Oak Park Regional Housing Center (Ruby, n.d.). This innovative project includes text, photographs, video clips, and other media showing Oak Park, Illinois, a middle-class suburb outside of Chicago that consciously constructed itself to be ethnically diverse.

Ruby was interested in the suburb's idealism and the everyday impact of this idealism on the residents. In addition, Ruby was interested in notions of reflexivity, since the suburb was his hometown. In addition to CD-ROM portraits, Ruby utilizes the Internet, the Web, and other digital technologies as fieldwork devices and for output. His Web site includes his academic biography, a preliminary description of the project, copies of funding proposals, his professional lecture material from American Anthropology Association meetings, newspaper interviews, and quarterly progress reports. He created a listserv with 100 subscribers, mostly Oak Park residents, and obtained regular feedback through this outlet. An interesting aspect to this project is that viewers and readers of the Web site can start anywhere, since it is nonlinear—each portrait section includes a slide show with family snapshots and their corresponding comments. Video clips are less than 10 minutes in length and serve as a way of producing life histories on each of the adults involved.

Pink (2004) discussed the use of hypermedia as a mechanism to share research and as a vehicle for teaching and learning. Her Web project, *Visualising Ethnography* (Pink, 2002), exemplifies this modality and is both a resource in and of itself and an access point to other resources in visual anthropology. *Visualising Ethnography* offers instruction on using the visual during the ethnographic process. Pink's Web project includes interviews with and written works by visual researchers, exhibitions, introductions to different media, and useful Web links.

Participatory Forms of Photography

Photovoice is a participatory form of research where participants take photographs to document their lives, concerns, and communities. Participants then share and discuss the photos in order to identify personal and community/group issues. Photovoice has been used with numerous diverse populations, including rural Chinese women; neighborhood groups; people with mental illness in New Haven, Connecticut; homeless men and women in Michigan; youth peer educators in South Africa; American Latina girls; and many more (e.g., Vaughn, Rojas-Guyler, & Howell, 2008; Wang, Yi, Tao, & Carovano, 1999). Worth and Adair (1997) initiated *autophotography*, a method similar to photovoice. Worth and Adair gave movie cameras to Navajo Indians so they could describe themselves from their own perspective. Ziller and colleagues extended this approach to instamatic

cameras and asked various groups to take pictures within their environment. They believed that taking photos allowed one's true self to be expressed (Ziller & Lewis, 1981).

Community photography is a photographic methodology in which participants take photos of their daily lives in order to increase knowledge about issues in a community. It gives community members a way to inform policymakers and other people who control resources about community issues that are both strengths and challenges. Photography has been implemented as a methodology for studying social issues and for understanding people's lives in various communities. For example, participatory forms of photography have been instrumental in work with homeless children, children living in the Guatemala City garbage dump, children of Appalachia and India, children of poverty and affluence in Mexico, women in rural China, and the Kayapo in Brazil. Community members are given permission to tell their own story from their own perspective simply because they have cameras in their own hands. Thus, understanding of these communities is enriched because the data are being produced directly by the community participants. It is important that the photos and the corresponding stories offer a focal point for discussions of change and involve directly the people who will be affected by the changes.

Participant forms of photography permit people to explore and articulate their lived experience. Participatory photography gives participants freedom to depict their actual surroundings, to choose the people and places that are important, to reflect on priorities and belief systems, and to decide what issues are most salient in their lives.

Interdisciplinary Projects

Another way in which new approaches may be applied to visual anthropology is by looking to disciplines outside the field of anthropology. Other disciplines incorporating visual analysis include cultural studies, psychology, semiotics, media studies, sociology, and cultural geography. Incorporating visual research methods and visual applications used in cultural studies, cultural geography, and sociology as well as other social sciences allows room for innovative research and new knowledge within visual anthropology. According to Pink (2006), the following criteria should be considered in visual research regardless of discipline: "the context in which the image is produced; the content of the image; the contexts in and subjectivities through which images are viewed; and the materiality and agency of images" (p. 31). Pink (2006) proposed three sets of questions to ask while conducting social research on images: (1) What is the image of, what is its content? (2) Who took it or made it, when, and why? (3) How do other people come to have it, how do they read it, what do they do with it?

Quantitative Research in Visual Anthropology

Anthropological visual analysis is emerging in a cross-disciplinary way. Katie E. Englert's anthropology master's

thesis, *Pictures Worth Thousands of Words: Youth, Ethnicity and Photography* (2005), used content analysis following Philip Bell's (2001) methodology. Here, as a methodology for quantitative analysis, Englert devised a visual content analysis while researching the visual representation of Lebanese-Australian Muslim youth in two Sydney newspapers during a series of rape trials in 2001–2002. Initially, Englert utilized the four steps of content analysis, which, according to Bell (2001), include image selection, coding, analysis, and results. While such quantitative analysis may have ignored issues surrounding reflexivity and the audience view, she turned to a semiotic approach method after the visual content analysis in an attempt to investigate possible meanings produced once the images in question were viewed and consumed.

During the fourth step in visual content analysis (analyzing the quantitative results), Englert chose images and newspaper editions for the semiotic analysis. While Rose (2001) suggested developing graphs and tables with numbers of results from the coding process, Englert produced a finer semiotic analysis of the visuals she analyzed, which provided a deeper analytical view of how images were used within a wider set of components. These components included the images, captions, and headlines as well as the structure of the whole newspaper page in question and the entire newspaper edition, all of which allowed for broader interpretations from the large quantitative visual content analysis.

By looking at semiotic concepts of denotative and connotative meanings developed by Roland Barthes (1975) and his notion of mythologies, while also keeping the viewer in mind, Englert developed several attributes residing in the visuals analyzed that denoted wider anthropological themes. Salient themes included generational differences between Muslim immigrant parents and their children and issues surrounding multiculturalism and tolerance of the “ethnic other” in a Christian dominated society. The widespread Anglo-Australian idea of “mateship,” media use of language, and notions of honor and gender were also investigated. Finally, the nature of the Muslim immigrant friendship group, as opposed to that of organized ethnic gangs, was considered, as were issues around sexual assault (Englert, 2005). Englert was able to carry out original anthropological visual analysis while reaching across disciplines, incorporating both visual content analysis (often found in other social science fields like cultural studies, sociology, and psychology) and semiotics.

Visual Anthropology in Academia

Most universities with anthropology departments offer a range of courses in anthropology, but few offer courses in visual anthropology specifically. Many undergraduate courses, especially introductory cultural anthropology courses, utilize visual anthropology only in the viewing some of the well-known classic anthropology films. Even within this sphere, the films viewed are often more than 20 years

old. For example, most professors show films known to be classics within anthropology, like *Dead Birds*, John Marshall and Adrienne Miesmer's *N!ai* (1980), the various films made for television such as Granada Television's *Disappearing World* series (Leslie Woodhead & David Turton, 1974–2001), *Maasai Women*, and other films relating to language, rituals, religion, gender and so on. Few universities offer in-depth courses on visual anthropology, and even fewer offer master's or doctoral programs. Universities that offer more extensive courses or training in visual anthropology in the United States include San Francisco State University, Temple University, New York University, and University of Southern California. Outside the United States, visual anthropology is offered at the Australian National University, the University of British Columbia, the University of Kent, the University of London (Goldsmith's College), the University of Manchester, and the University of Troms.

Conclusion

While historically the field of anthropology has been dominated by the use of words, the visual world has always played an important role within ethnography and the representation of people and culture. In the early years, anthropologists brought exotic “others” to museums, world fairs, and colonial expositions, putting them on show “as curiosities at circuses and other entertainments” (MacDougall, 1997, p. 276). Anthropologists then realized that this approach was problematic, because unless the indigenous people were filmed or photographed in their home environments, they were stripped from their cultural context, and the people themselves couldn't be incorporated into the written word. Enter the role of visual anthropology as a mechanism to bring the real people front and center. Visual anthropology has a robust history using photography and ethnographic film in the production of knowledge about various people throughout the world, particularly in a cross-cultural context. Visual anthropology continues to be an emerging subfield of anthropology, constantly finding new ways to produce meaningful visual accounts, films, and research.

While visual anthropology has often been equated to the production and use of ethnographic films, the scope is much broader and includes photography, art and material culture, research on the body and movement, and more. Throughout history, many anthropologists have probably been doing a version of visual anthropology without knowing it (Jacknis, 1988). New avenues, such as interdisciplinary approaches of visual research, participatory photography projects, and interactive multimedia Web projects are adding to the complexity and richness of visual anthropology as it continues to grow and define itself as a subfield of anthropology. Advances in technology, globalization, and a greater emphasis on collaborative approaches to research not only within academia but also in partnership with community members and indigenous populations offer many exciting possibilities for the future of visual anthropology.

COMPUTERS AND ANTHROPOLOGY

STEFAN ARTMANN

Friedrich Schiller University in Jena

Human beings are toolmakers. The history of their civilization is strongly influenced by technological innovations that, to an ever-greater extent, make the use of matter and energy for human purposes possible. From the building of huts and the making of a fire to the construction of skyscrapers and the fusion of nuclei, all cultures have been transforming the resources of nature to reproduce and improve the basis of their own survival. Besides matter and energy, there exists another source of supply that has been exploited technologically since time immemorial—information. Whoever used, for the first time, a sharp edge to leave a durable mark that could express excitement, appeal to demons, or represent a bagged animal, stood at the beginning of a process that led to our modern technologies for storing, transmitting, and processing information. Writing, printing, telegraphy, telephony, radio, and television opened new ways of storing and transmitting information; digital computers also revolutionized the processing of information. Although other innovations of the 20th century, such as the industrial production of artificial fertilizers, might have a greater impact on the biological survival of the human species, the computer is the key technology of today when it comes to the emergence of a globalized information society.

The computer is an artifact that has manifold and far-reaching repercussions on current anthropological research. Apart from being a very useful tool for scientific data management and analysis, the computer serves as a model

of the human mind and shapes the understanding of information society. The individual and culture are interwoven when the future of humankind is discussed in terms of the relation between human beings and the technologies they invent: Does cultural evolution lead to super-intelligent artifacts, or to yet unknown kinds of hybrid systems that will take the place of *Homo sapiens*?

It is necessary for an anthropologist to have at least a basic understanding of the technological history and the conceptual foundations of the computer. In the following, historical landmarks, which are representative of the cultural role of digital calculating technology, are described, and future trends, which are already discernible today, are presented. Then, the fundamental concept of computation is introduced, together with the simplest form of an abstract computing machine. The science called artificial intelligence finally occupies the focus of attention; it builds a bridge between computer science and anthropology so that the field of computational anthropology can be established.

From Abacuses to PCs and Beyond: A Very Short History of Digital Calculating Technology

The desire to create artifacts that have all the abilities human beings possess is documented by testimonials handed down to us from antiquity. The legendary king

Pygmalion of Cyprus, whose story Ovid tells, carved a statue of his ideal woman, because true women did not live up to his expectations. After he had fallen in love with his work of art, Aphrodite breathed life into the statue so that Pygmalion could marry her. Real technologies, however, were largely bound to mimic and enhance the physical capacity of human beings and other organisms. None of the Greek gods gave assistance in creating objects with cognitive skills. The long history of digital devices for calculating with numbers, which led eventually to the development of computers, clearly shows the difficulties human inventors had in order to overcome constructing intelligent artifacts. Digital, from the Latin *digitus*, meaning “finger” (the principal corporeal counting aid), means that these devices are based on counting discrete units as representations of numbers, in contrast to analog instruments based on measuring continuous physical quantities.

Digital Calculators

The Abacus

Although the development of intelligent machines is still a matter of front-line research, digital instruments that help human beings with routine mental activities, such as doing arithmetic, were already used in early but advanced cultures. Most widespread was the *abacus* (the Latin loan word of a Greek expression meaning “slab”), which has been used in various forms, for example, in Mesopotamia, Persia, Greece, Rome, India, China, and Central America. Typically, it consists of a stable structure, such as a tablet inscribed with geometrical markings or a frame holding parallel rods, in which small objects (*calculi*, Latin for “pebbles”), such as stones or beads, are moved as counters.

Strictly speaking, an abacus does not calculate. It is a number-representing mnemonic tool, the functioning of which is completely dependent on manual activity. An abacus assists in a calculation; its stable structure makes its user follow the internal order of a particular numerical system, and the actual positions of its counters store the partial results of an ongoing calculation.

Mechanical Calculators

The next decisive step, beyond number-recording aids, was the invention of mechanical calculators in early modern times, when thinking in terms of mechanisms flourished. These calculators could perform more and more complex arithmetical tasks with less and less human intervention. In 1623, the first one was built for astronomical tasks by the German theologian and scientist, Wilhelm Schickard (1592–1635). It was called a “calculating clock,” could add as well as subtract, and—what is most important—had a decimal carryover mechanism: If the sum of two digits

exceeded nine, a one was carried over to the next column of numbers to the left.

Two famous philosophers, both of whom were also pioneers in mathematics, pushed the development of calculators forward. In the early 1640s, for his father, a tax collector, the young Blaise Pascal (1623–1662) invented a machine that could add and subtract with automatic carryover. Thirty years later, Gottfried Wilhelm Leibniz (1646–1716) formulated, within the context of his Enlightenment project to free mankind from the tiring burden of tedious mental activity, the design principles of calculators that implement all the first rules of arithmetic. Leibniz’s so-called “stepped reckoner mechanism” was used until the 20th century. Great technological progress happened, of course, in respect to the complexity, accuracy, speed, user-friendliness, and durability of such calculators.

What the calculators mentioned so far have in common is that the level of difficulty of the tasks they can perform is quite strictly limited by their mechanical structure. Ideas to overcome those limits evolved during the 19th century. A legendary calculator of that time, the analytical engine, was planned from 1834 onward by the British mathematician Charles Babbage (1791–1871). Although he would never realize it, not least because of the inadequate mechanical engineering of those days, the analytical engine made a great advance by introducing the idea of programming. Babbage wanted to use perforated cards, which had been employed for the control of mechanical looms since the 18th century, in order to instruct the analytical engine to work through a sequence of simple calculations that, altogether, perform a complex mathematical task. In this system, each simple calculation depended on the result of the previous calculation in the sequence. Had Babbage succeeded, a great step toward full mechanization of arithmetic would have been taken. With his failed project, mechanical calculators entered, at least conceptually, the age of automatization.

The First Digital Computers

The rapid development of science and technology, with which the industrial revolution went hand in hand, led to a strong demand for calculating machines and people who could operate them fast and reliably, in order to solve mathematical equations. These people were called computers—a word derived from the Latin *computare*, “to calculate” (originally, to cut numerals into a piece of wood). However, machines were not called “computers” before the end of World War II. General technological prerequisites for their development included the use of electricity (not only as a power source but also as a carrier of information, e.g., in Morse code telegraphy), the development of relays as electromagnetic switches that can control the flow of electricity, and the refinement of punched card and paper tape technology, for example, in tabulating systems that were used for the storage and statistical analysis of huge volumes of data.

The first who began to project digital computers in the 1930s, and build them in the 1940s, were physicists and engineers in Germany, the United States, and Great Britain. Their developments were carried out in parallel and, for the most part, independently from each other. Whereas the literature on the history of early computers is sometimes biased by national and institutional interests, the following selection of four machines shall just show the variety of technology and purpose that characterizes the first generation of computers.

Pioneering Machines: Z3, ASSC, ENIAC, and Colossus

The first functioning general-purpose digital computer, the Z3, was built by the German civil engineer, Konrad Zuse (1910–1995), in 1941. Following an idea of Leibniz, Zuse based his machine on the binary system—in hindsight, this was a natural consequence of using relays (the Z3 contained about 2600). These electromechanical switches can be in two different states, which represent zero and one, respectively. Zuse implemented logical operations (the junctors AND and OR as well as the negation NOT) in electrical circuits and used them to calculate with binary numbers.

Zuse was not encouraged much by the official institutions of Nazi Germany; after the war, he set up the leading computer company of West Germany. In Great Britain and the United States, the situation was completely different. The development of computers, at first particularly for military purposes, had a lot of support from companies, scientific institutions, and governments. Thus, it cannot come as a surprise that the first large-scale computer was built in the United States. In 1937, a Harvard engineer, Howard H. Aiken (1900–1973), proposed to construct an electromechanical computer on the bases of the available technology of decimal-system calculating machines. With the support of IBM, this machine became the automatic sequence controlled calculator (ASSC), or Harvard Mark I, and it was put into operation in 1944. Aiken's calculator—a large-scale machine, indeed: 50 feet long and nearly 10 feet high, made of 750,000 parts and 500 miles of wire—realized Babbage's dream: a special-purpose programmable machine for number crunching in order to numerically solve differential equations. A giant of the preelectronic epoch, the ASSC was in use until 1959.

Only 2 years after Aiken's machine, America's first large-scale electronic computer was completed. The ENIAC, the acronym of electronic numerical integrator and computer, was built by J. Presper Eckert (1919–1995), an electrical engineer, and John W. Mauchly (1907–1980), a physicist, at the University of Pennsylvania between 1943 and 1945. Whereas the ASSC had been the result of an ingenious combination of traditional technology, the ENIAC was based on state-of-the-art electronics: high-speed vacuum tubes that were not as reliable as relays but could switch

1,000 times faster. Its 18,000 tubes made it the incomparably fastest machine built so far, yet to program it took quite a long time; rewiring was necessary for each new problem. The ENIAC was used, like the ASSC, mainly to calculate (in the decimal system) solutions of differential equations for military and civic purposes until 1955.

Only 30 years after the end of World War II, it became known that the ENIAC was not the world's first large-scale electronic computer. Since the 1970s, declassified information of the British intelligence service unveiled step by step the existence and specifications of the Colossus machines, a series of computers the first of which had been completed in 1943. They were special-purpose machines used to discover the settings of the code wheels of German cipher machines, so intercepted encrypted messages could be decrypted. Encoding and decoding is a form of the manipulation of symbols—and even a more general one than calculating; it is not restricted to numerals. Since cryptanalysis must happen as fast as possible, particularly in times of war, the electrical engineer Thomas H. Flowers (1905–1998), who worked at the now-famous Government Communications Headquarters Bletchley Park during World War II, decided to automate it by using computers that were based on vacuum tubes (about 1,500 in the first Colossus, about 2,500 in the later machines) and operated in binary logic.

Triumph of the Computer

After World War II, the computer started its triumphal march and became the key technology of modern developed societies. This success story has been made possible by an impressive series of technological breakthroughs, some of which will be highlighted below.

Technological Progress on the Basis of the von Neumann Architecture

None of the four pioneer machines introduced above had an internal memory that could store programs. The first more-than-experimental computers that incorporated such storage were the electronic discrete variable computer (EDVAC) built by Mauchly and Eckert between 1945 and 1951, a smaller and faster successor to their ENIAC, and the IAS computer, named after the Institute for Advanced Study in Princeton, New Jersey, where its construction was started in 1946 and finished in 1952. What seemed to be just a rather innocuous technological improvement was, in fact, a great conceptual step toward the realization of a truly all-purpose computer. Storing, in an internal memory, the program (or software) that controls the working of the computer made it easier to change instructions—not only for the human programmer, but also for the computer itself—even during its operation. From that time on, programs were considered symbol structures that were data for other programs.

The general design principles of the IAS computer were developed by the Hungarian-born mathematician John von Neumann (1903–1957), one of the greatest scientists of the 20th century. He not only knew the need for fast, reliable, and simply programmable computers very well from his wartime work, for example, on the atomic bomb, but he also had the ability to recognize the formal structures underlying a tremendous variety of scientific and engineering problems very quickly and to find ingenious solutions for them. After Mauchly and Eckert had told von Neumann about their ideas for the EDVAC, he began to tackle the formal problem of conceiving a general architecture for the all-purpose computer. The solution he found—in honor of him, it is now called the von Neumann architecture—is the abstract organization according to which ordinary computers are designed to this day. It distinguishes the five essential material (hardware) components of a computer:

- A memory unit, whose locations store data and programs so that they can be read and rewritten arbitrarily
- A central arithmetic unit, which implements the fundamental rules of arithmetic
- An input unit, which allows the user to feed the computer new data and programs
- An output unit, which transmits the results of computations and other information about the computer to the user
- A central control unit, which manages the sequential execution of programs by coordinating the information flow in the computer

The IAS machine served as the paradigm for a number of influential noncommercial and commercial computers, both inside and outside the United States. The implementation of von Neumann's general architecture has, of course, been benefiting from incredible technological progress, which concerns all components of the computer. The most evident trend is miniaturization. Since the mid-1950s, after the pioneer machines of the 1940s and early 1950s used electromechanical relays and vacuum tubes as switches, the second generation of computers experimented with transistors, a solid-state technology invented in 1947. A few years later, the third generation used integrated circuits, or chips (invented 1957–1958), which combine transistors and other semiconductors in prewired configurations and are fabricated from a single piece of silicon. This process led, in the early 1970s, to implementing the arithmetic and the control unit (plus working memory) on one chip, the microprocessor. According to the so-called Moore's Law, which was postulated by the engineer Gordon E. Moore (b. 1929) in 1965 and has been validated to this day, the number of transistor functions on a chip is doubling every 18 months.

The progress of switching technology led to a spectrum of machines that implemented the von Neumann architecture on different scales. In the 1960s, mainframe computers, such as the IBM System/360, continued the tradition of the

pioneer machines. These room-filling and expensive systems were built for the high-speed processing of very large data sets and were operated by specialists. Minicomputers, such as the DEC PDP-8, appeared in the second half of the 1960s. They were smaller and less expensive machines made possible by transistors. Not only did these machines allow their users to interact directly with them, but also their standard design required them to be individually adapted to particular applications. In the second half of the 1970s, microprocessor-based personal computers, such as the Apple II, began to fascinate hobbyists, and these computers have been welcomed by small businesses and common consumers since the 1980s. These innovations made the use of the computer easier and easier in the office and at home; for example, by implementing graphical user interfaces, the personal computer and its mobile siblings became an integral part of everyday life.

Besides miniaturization and increasing user-friendliness, the spread of computer networks is another very important trend of the last 25 years. Starting in the mid-1980s, personal workstations, as parts of local networks that connect computers of any size, made the idea of distributed systems familiar in many professional contexts. The 1990s and the beginning of the third millennium saw the rise of global networking, via the Internet, and especially the World Wide Web, in all areas of society; the transmission and processing of information, communication, and computation began to fuse together in such a way that a truly global information society is technologically possible now.

SAGE: The System Dynamics of Information Society in a Nutshell

From the perspective of cultural anthropology, the most significant tendency in the history of digital computing, since World War II, is the development of an ever-stronger integration of computers into all fields of human activity. They are used in offices (e.g., for accounting), in factories (e.g., for control of manufacturing machines), in laboratories (e.g., for data analysis), in the armed forces (e.g., for early warning), in the infrastructure (e.g., for traffic-flow control), and at home (e.g., for playing).

What is quite remarkable for computers, compared to other artifacts, is their astonishing capacity to induce, due to their information processing abilities, the emergence of new sociotechnological systems in all contexts of use. Such systems are purposefully ordered sets of equipment and processes on the one hand and ordered sets of institutions and persons who conceive, realize, and use technologies on the other. The task to create and develop those complex organizations, by controlling them through networked computers, forced engineers and scientists to think generally about systems as functional units of the information society.

To show the impact of that thought on modern culture, it is advisable to have a closer look at the prototype of a

computerized sociotechnological system, the Semi-Automatic Ground Environment (SAGE). It served, from the 1950s to the 1980s, as a command, control, and communications system for the continental air defense of the United States. SAGE automated the early warning about, and interception of, attacking aircraft as a complex process that involves radar detection, the computer processing of incoming data, the countrywide communication of analyzed data, and the direction of intercepting aircraft. Ground-based and airborne radar systems, planes, ships, missile sites, command stations, and a hierarchy of military decision makers were to be so connected that a fast flow of reliable information was guaranteed.

A necessary condition for gaining an information advantage in air defense was the availability of computers that could process information in real time, that is, so fast that the results could lead to successful action in the situation that had been depicted by the initial data. The Whirlwind machines, built at the Massachusetts Institute of Technology between 1945 and 1953 under the direction of Jay W. Forrester (b. 1918), were the progenitor of the SAGE computers. They constituted the knots not only of a nationwide network of telephone-line information transmission channels but also of local clusters of cathode-ray terminals that had access to a central computer in time-sharing mode. They outputted radar information graphically and were interactively operated by a light pen. Those innovations implied that programs of a length and complexity unknown so far had to be developed and the definition of new high-level programming languages included. Since human beings were needed to accomplish these feats, scientists, engineers, and operating crews had to be trained. Psychological barriers among academia, the military, and civil companies needed to be overcome. To solve these problems, technological progress required institutional innovation; the nonprofit MITRE Corporation was founded. It was a group of research, development, and implementation organizations that worked only for governmental clients, both military and civil.

SAGE required interacting in real time with a complex technological system that contributed to the stability of deterrence during the cold war. People who were responsible for its development, use, and maintenance had to learn the management of complex systems. Thus, it cannot come as a surprise that many SAGE professionals set up, or became managers in, companies that were pioneers of the computer industry. The best example of how the SAGE experience influenced the emerging information society is Forrester himself, who, as an engineer, invented a new type of storage device—the magnetic core memory, which was faster and more reliable than the vacuum tubes used before. Forrester became a professor of management at MIT, started research on the computer-based modeling of complex social systems, and provided the scientific basis of the famous Club of Rome reports in the 1970s.

SAGE already represented, a few decades ago, those important aspects of the interaction between technology

and culture that characterize the internal dynamics of organizations in today's information society. It could adopt this symbolic quality because it contributed to a most important public good, national security, during an era in which the latter was highly threatened, so technological as well as institutional innovation in this field was strongly supported. Thus, the development of SAGE is a main event in the origin of the information society, and it needs to be intensely contemplated by cultural anthropologists.

Today's Information Society

The social life of organisms is based on communication, the exchange of information by means of the transport of matter and energy. In this sense, any society in the history of life is an "information society." What cultural anthropologists mean when they use this term, which was invented by Japanese journalists in the mid-1960s (*joho shakai*), is essentially two things: First, the velocity and direction of societal change in today's developed countries is to a large degree explainable only by taking into account the central role they allow the development of information technologies to play as sources of material and intellectual wealth; second, the great importance of information technologies is a key element when members of developed countries describe the society they live in, and acknowledge that those technologies are a powerful motor of their productivity. From both points of view, it follows that scientific, economic, political, and juridical decisions about information technology are not only a most important factor in the transformation of all areas of society, but also these decisions are recognized as such. The computer becomes the preferred medium of influencing social and cultural change.

Some Trends Toward Human-Computer Symbiosis

It is difficult to give a fairly sensible forecast of the volume and direction of growth of information technology for even the near future. Twenty years ago, the impact of the Internet on everyday life would generally not have been considered as being as tremendous as it has become. Extrapolating progress from the status quo too conservatively is just one widespread error in prediction, while underestimating the difficulties of technological innovation is another one. However, promising candidates for trends in computing that are likely to become very important in the near future are as follows:

Pervasive and ubiquitous computing: The difference between computers and other artifacts of everyday life, such as kitchen utensils and clothes, will vanish almost completely. What is more, those computer-equipped objects

can be connected with each other so that a continuous flow of information between them will be possible.

Unconventional computers: Beyond the von Neumann architecture, many other design principles of computers are being developed. This involves, for example, the construction of a quantum computer whose processor could, according to the strange laws of quantum physics, work through a program starting simultaneously with a very great number of different input data. Another important research direction experiments on organic matter (e.g., DNA), sometimes even whole organisms (e.g., slime molds), as computational media.

Agent software: Programs are beginning to be conceived as agents that their principals allow to perform simple or complex tasks independently in respect to certain types of behavior. A mobile agent, for example, is sent out to search information in a computer network that might be helpful in solving a problem, and its way through the network is not determined by its user.

Autonomous robots: Computer-controlled automata that process sensory input from their environments, move in real space-time, and autonomously carry out specific functions in complex situations will be mass-produced. Future children will grow up with such robots, and when the behavioral complexity of the latter becomes high enough, intelligence and an ethical status will be ascribed to them.

Altogether, these technological developments will converge on a new quality of technological existence, which might be called “human-computer symbiosis.” This concept was introduced by the American psychologist Joseph C. R. Licklider (1915–1990) as early as 1960. In biology, the Greek *symbiosis* (literally, “living together”) basically means that at least two organisms of different species continuously cooperate in a way that benefits all involved. As regards the interaction of human beings and computers, a symbiosis that enriches the physical and intellectual life of humans, as well as fosters autonomy in computers, is accompanied by astounding phenomena at the intersection of biology, sociology, and engineering, for example, virtualization and hybridization. (Network-based communities of software agents will strongly influence how human individuals form their identities by communicating through their agents, and ontologically new types of entities, hybrid systems that synthesize evolved and engineered components, will emerge). Anthropology has to become anthropotechnology.

Turing’s Universal Machine and the Concept of Computation

The impact of computers on modern society since World War II is obvious, and their future significance can hardly be overestimated. To grasp the influence of the computer on an anthropological understanding of the

human being, a look at the conceptual basis of the von Neumann architecture, the abstract technological scheme according to which nearly all of today’s computers are built, is a prerequisite.

Most generally, computers are machines; thus, it must be asked what is meant by “machine.” Computers constitute a special class of machines, so the difference between them and other such classes has to be described. This involves stating the meaning of “calculation” more precisely, which can be done very elegantly by introducing an abstract automaton, the *Turing machine*, which in turn helps define the concept of a computer as it is understood conventionally. An analysis of this machine shows the fundamental limits of mechanical computations.

Machines: Particular and Universal

A physical object is considered a machine if the explanation of its behavior supposes that a mechanism is working in its inside in order to generate the behavior. Moreover, the mechanism is thought to perform its task neither by chance nor by some mysterious power. Instead, how the internal mechanism generates the system’s external behavior is assumed to be explainable by a process that runs, in time and space, according to laws of nature, which have effects under boundary conditions set by the organization of the system.

More generally, a machine implements, through its mechanism, a rule leading to a certain result (behavior) when given a certain input. A machine not only fulfils a concrete function (a task that it shall perform) but also realizes an abstract function (a formal rule that maps input on output). The behavior of a car, for example, can be explained as a movement in a coordinate system, with time and space axes, that results according to natural law from the interaction of many independent variables: the design of the car, the actions of its driver, and environmental conditions.

Most machines, such as planes, television sets, and refrigerators, perform just one or very few specific tasks; they are particular machines. If machines for many functions are constructed, then the guiding principle is to let the machine utilize a part of its input as a specification of the behavior it shall show next. By extending the set of alternatively possible behaviors more and more, the universal machine results. It can perform an infinite number of formally describable different tasks, given arbitrary input, if the correct mechanism is chosen for processing the input. From the abstract point of view introduced above, the universal machine can realize an infinite class of rules that map input on output. That should sound familiar; it is a reformulation of the idea of the all-purpose calculator, the computer. Thus, it must be possible to give a precise meaning to the idea of calculation by describing the basic architecture of the universal machine, and to define, in terms of

this abstract automaton, what any particular computer does: to calculate an output given an input and a program.

The Turing Machine

John von Neumann has described the basic architecture according to which ordinary computers are designed to this day. Yet, more than 10 years before von Neumann wrote down his ideas, a British mathematical genius, Alan M. Turing (1912–1954), had already invented a most simple abstract automaton that was able to do anything that an all-purpose digital information processor can do. In retrospect, his 1936 paper “On Computable Numbers, With an Application to the Entscheidungsproblem,” which introduced the machine that is named for Turing nowadays, is the birth certificate of theoretical computer science. During World War II, Turing acted as chief scientist for the Bletchley Park cryptanalysts and designed electromechanical devices, which were predecessors of the Colossi machines, for decrypting intercepted German messages. After the war, he was the guiding spirit of the development of the first British all-purpose electronic computer, the automatic computing engine (ACE), whose design was far ahead of that of contemporary machines and shifted priority from complex hardware to complex software.

The Turing machine integrates all components of the von Neumann architecture in an astonishingly simple way:

- The memory unit is an infinitely long tape that consists of linearly ordered discrete squares, each containing a zero or a one.
- The combined input and output unit is a head that can read and overwrite the content of one square of the tape at a time.
- The combined central control and arithmetic unit is a look-up table that contains information on what the read/write head should do next according to the internal state (represented by a row of the look-up table) the machine is in. It reads the symbol in the square on which the head is positioned at any given time, overwrites it with a symbol, and moves one square to the left or the right. The look-up table says what the new state of the machine will be after the head’s action is executed.

The Turing machine works as follows: The machine starts out in its initial state. The input, to be processed by the automaton, is written out in a sequence of binary digits on the tape. The head reads the symbol in the square on which it is positioned. The look-up table says what the head should do, given the initial state of the machine and the symbol read. This is done (e.g., the head writes a zero and moves to the left), and the internal state of the machine is updated according to what, given the read symbol, the look-up table says. Then the operational cycle starts again: The machine reads the symbol in the square on which the head is now positioned, the look-up table says what the head should do, and so on. The machine stops if, given its present

internal state and the symbol just read, the look-up table sends the machine into the halting state after the head has executed its operation. The machine will not do anything further. Then, the sequence of symbols on the tape is the result of the calculation the machine has done, given the initial contents of the tape and the particular look-up table.

The look-up table of Turing’s ingenious automaton is analogous to the program of a digital computer. The Turing machine can, thus, be programmed by an appropriately completed look-up table, in order to make a particular calculation using as input a series of symbols on the tape. What is more, the Turing machine can be programmed to interpret a part of its input as a description of another Turing machine whose program it shall execute. Such a programmable Turing machine is equivalent to a digital computer, even though it takes it comparatively many more steps to do even simple calculations; it is a universal Turing machine that can implement all possible programs any computer based on the von Neumann architecture is able to process. Thus, the universal Turing machine defines abstractly what a computer is.

Turing introduced his universal machine in order to prove that it defines the class of all processes that can be carried out by stepwise going through a sequence of well-defined rules, that is, by an algorithm (from the name of an Arabic mathematician of the 9th century, Al-Khwarizmi, who wrote the oldest known work on algebra). Anything that is calculable by such a process—a mathematician would speak of general recursive functions—is computable by a universal Turing machine. The vague concept of calculation can thus be substituted with Turing’s more precise concept of mechanical computation by means of his universal machine. This proposal is called the Church-Turing hypothesis—Alonzo Church (1903–1995) being an American logician who worked on a clarification of the concept of calculation at the same time as Turing. It is just a hypothesis, since it cannot be proven to be true; it is a well-founded proposal to state a vague concept more precisely. Unconventional computers of the future, for example, both quantum and organic computers, might make it necessary to revise the Church-Turing hypothesis.

Mechanically Undecidable Problems

Turing also showed mathematically that it is possible to confront his universal machine with problems it principally cannot solve in finite time. Such problems are called mechanically undecidable and represent the limits of what can be done by computers.

A famous problem, called the “halting problem,” that has been proven, by the American mathematician Martin Davis (b. 1928), to be unsolvable, is to program a Turing machine so that it decides, in a finite lapse of time, whether any given Turing machine will stop its processing of an arbitrary input. By using proof techniques known from metamathematics, Davis showed that there does not exist a

Turing machine that implements a general decision procedure for solving the halting problem. The simplest solution seems to be to let a tested machine run and see if it stops the processing of a given input. Yet, this would not help in the case of very long computations, since the testing Turing machine does not know whether it has waited long enough; the tested machine might stop just one second after the testing machine has stopped the test run. The general idea of how to prove the undecidability of the halting problem involves the construction of a self-contradictory Turing machine that tests itself as a testing machine and does not halt when it, as a tested machine, does so, and vice versa.

Turing's ideas on abstract universal machines seem far away from anthropological considerations on computers, yet the reverse is true. That there are principal and mathematically provable limits on what computers can do is of utmost importance when it comes to computational models of human thinking and behavior. This is most evident in the science of artificial intelligence, one of whose founding fathers was Turing.

Artificial Intelligence as Computational Anthropology

Anthropologists, like most other scientists, apply the computer as a tool for scientific data management and analysis or just for text processing. Already in the 1950s, the French ethnologist Claude Lévi-Strauss (b. 1908) insisted that, without the intensive use of computers for documentation and analysis, anthropologists could not handle their large volumes of collected data any more. Yet, the computer is also used as an explanatory model of human thinking and behavior, most explicitly in artificial intelligence (AI), a research program that emerged just a few years after the first digital computers had been constructed. Its name was invented by an American computer scientist, John McCarthy (b. 1927), to title a workshop at Dartmouth College in 1956; this event went down in the annals of AI as the foundation event of this discipline.

The research program of AI can be construed in both a narrow and a broad sense. Its aim may expressly be an anthropological one: to understand human intelligence, so that computer scientists are called upon to construct artifacts whose internal mechanisms and external behaviors get closer and closer to the cognitive and behavioral patterns of *Homo sapiens*. AI may, on the other hand, be indifferent to the resemblance of the artifacts computer scientists construct to resemble human beings. Then, AI is considered the general science of all possible intelligent systems that have, neither in their externally observable behavior nor in their internally detectable information processing, to measure up to humans. Yet, even if AI is regarded as an anthropological science, its constructions are possible intelligent systems in a particular sense: After they have been successfully designed and people have accustomed themselves to

interacting with them over a considerable lapse of time, AI artifacts might be accepted as possessing humanlike but, of course, not real human intelligence.

The Turing Test, or How to Make the Concept of Human Intelligence Operational

Whether AI is construed in the narrow or the broad sense, it needs a catalogue of criteria that a system must fulfill if it is to be recognized as being intelligent. In an experimental science, those criteria should take on the form of operationalizable sufficient conditions of ascribing intelligence. This was stated clearly by Turing in his 1950 paper "Computing Machinery and Intelligence," a historic document of AI's beginnings that still is hotly disputed.

Turing proposed a game in which a computer communicates to a human being in order to convince the latter that it is also human. This so-called imitation game can be transformed into a test that nowadays is named for Turing and basically requires the following components: two computer terminals, a connection between them, a human being who operates one of the terminals, a digital computer that operates the other, and a partition wall between the human and the computer so that the former cannot see the latter. The human starts the test by typing a question into the terminal. This question is sent to the other terminal, into which the computer then keys an answer. The human receives the answer, asks another question, and so on. After some time, the conversation is interrupted, and the human must address the question of whether he communicated with another human or with a computer. The computer passes the Turing test when it succeeds in deceiving the human, a feat that, as Turing hoped, will be performed by a digital computer in the near future.

The Turing test suggests that one may ascribe intelligence to a computer when its communicative behavior is not distinguishable from that of an intelligent human in the same situation. This reasoning is based on an analogy that invites one to infer an externally unobservable cognitive competence from an observable behavior known to be shown by humans who are considered intelligent.

The Need for a Full Structural Comparison of Humans With Computers

The criterion of intelligence provided by the Turing test, or similar experimental procedures, does not refer to the internal information processing of possible intelligent systems. This is an important shortcoming, if AI is to be construed as the science of human-like intelligent systems; the comparison of humans with artifacts in respect to their intelligence must then also refer to mechanisms of information processing that are working inside.

On the hardware level of, roughly speaking, the human brain and the microprocessor of the computer, differences prevail, as von Neumann showed in his lectures on

the computer and the brain: The brain is not a purely digital machine, and statistical methods of data analysis are hard-wired in neurophysiology that are not implemented in the integrated circuits of conventional computers. Yet, if human beings and computers are compared on the software level, similarities might be discernible. The conceptual basis of such a comparison is given by Turing's structural definition of computation: It does not need to specify whether a computing system has been evolved by natural selection, educated by cultural interaction, or engineered by scientific construction. Thus, the science of computing might apply to digital computers as well as to human beings, and it is an empirical question whether human cognition can be described by computational models as a form of programmable processing of digital information. If the answer is affirmative, then the concept of computing becomes a most important supportive part of a general framework for anthropology that also includes an engineering part: AI or, as this discipline might then be called more adequately, "computational anthropology."

The Physical Symbol System Hypothesis: A Paradigm of Computational Anthropology

The hypothesis that has been most influential in the history of AI was developed by two American computer scientists, Allen Newell (1927–1992) and Herbert A. Simon (1916–2001), who did research also in psychology, economics, political science, and philosophy. Simon is the only computer scientist so far to become a Nobel laureate; he was awarded the 1978 prize in economics.

The unifying idea of Newell and Simon's work is the physical symbol system hypothesis. It says that, for any system that shows general intelligent action, it is a necessary and sufficient condition to be a physical symbol system. By "general intelligence," Simon and Newell mean that such a system is comparable to a human being as regards the realization of its aims in complex situations and the adaptation of its aims to the environment. Against the backdrop of Turing's structural theory of computation, it is easy to explain what symbol systems are: They are identical to universal machines. Newell and Simon decided to introduce a new name for Turing's abstract automaton, since they realized that the mechanism by which a Turing machine interprets its input is necessarily based on symbol-based designation: A particular symbol on the tape stands, relative to a well-defined internal state of the machine, for a certain operation of its read/write head and a change of its internal state. The same is true for the interpretation of symbols on the tape as representations of other Turing machines—the essential feature of computational universality.

The reason Simon and Newell speak of physical symbol systems is that they are interested, as empirical scientists, in really existing symbol systems. Any symbol system in the physical world, such as a personal computer,

is not an unrestrictedly universal machine; in contrast to the abstract machine of Turing, it cannot possess, for example, an infinitely large memory. Differences between real symbol systems are, thus, due to their respective material constitution that appears as a limitation on information processing if compared to a universal Turing machine. Another way of expressing this idea is to say that the behavior of all physical symbol systems can exhibit general intelligence, because it is generated by a universal machine, but each system does so on a particular material basis that results in its specific form of bounded rationality (e.g., cells in the human brain and integrated circuits in digital computers).

These remarks show that the physical symbol system hypothesis is not to be interpreted as being incompatible with more biologically inspired approaches to intelligent behavior (such as neural net modeling, artificial life research, and evolutionary robotics), most of which have their intellectual origins in cybernetics (from the Greek *kybernetes*, "steersman"), the structural science of communication and control, which was founded by the American mathematician Norbert Wiener (1894–1964). The idea of a computational anthropology based on the physical symbol system hypothesis does not exclude those approaches; it integrates them. Any anthropological model of intelligent behavior and cognitive processes that can be expressed in the form of a program (which is the case in the approaches mentioned above) is principally executable by a symbol system (i.e., a universal Turing machine). Biological research is, in fact, of utmost importance for Newell and Simon's conception of AI; the difference in computational power between a program that simulates the cognitive mechanisms and generates the intelligent behavior of an average human being in everyday situations on the one hand, and the universal Turing machine on the other, is due to the physical constraints of the human body on its internal information processing.

An intensely debated question asks whether human beings have cognitive and behavioral abilities that are not algorithmically formalizable. If there do not exist such skills, then the principal limits of computability are also the anthropological limits of human thought and action. Otherwise, it might be good to advise anthropologists that they should expect the construction of new, unconventional types of computers beyond the von Neumann architecture; these automata might then help the anthropologist to understand what human beings are by analyzing what they can engineer and how they think about the limits of their artifacts.

Conclusion

The enormous impact of computers on modern society urges anthropologists, engineers, and philosophers to discuss today how traditional ideas of the human condition will fare in the technological world of tomorrow. Humanism has

been proposing, since the Renaissance, that the way toward a humane existence leads neither through religious belief nor through ideologies of collective welfare, but through the education of the individual. "Education" here means a process of developing oneself into a spiritually and corporeally refined, ethically autonomous, and socially agreeable being. Traditional humanism, which recommends the study of classical works of art as the best way toward independent individuality, usually spreads the fear of technology, the latter being considered the quintessence of standardization and heteronomy. However, anthropologists may help undermine this misleading confrontation: Humans are toolmakers from the beginnings of their history, and progress in science and engineering makes the individualization of artifacts possible. Information technology is not only a tool adaptable to individual needs and abilities but also a medium for developing them.

Particularly in respect to the computer, it is of great importance for anthropologists to listen to a warning of the Spanish philosopher José Ortega y Gasset (1883–1955): The real danger of our time is that human beings are becoming too lethargic and unimaginative to introduce unusual uses for their tools, machines, and automata or to invent new technologies. One reason for this threatening weakness might be the still widespread attitude of traditional humanism that an eternal essence of humankind must be defended against technology. Instead, anthropology should consider the computer to be not only an adaptable tool of and a developmental medium for humanity but also an existential challenge to humanity, in the sense of a venturesome call to discover the unexplored possibilities of human existence. Since technology has always been powerful in transcending given circumstances, an anthropologically enlightened humanistic perspective on today's information technology might properly be called "transhumanism."

HEALTH AND ILLNESS

STEPHEN D. GLAZIER AND MARY J. HALLIN

University of Nebraska–Lincoln

Medical anthropologists disagree about definitions of the terms *health* and *illness*. A complicating factor is that health and illness are not—and never have been—opposites, since both health and illness can reside within the same individual at the same time. Clearly, health, illness, and disease are related concepts. But how does illness relate to disease? All definitions of health are imbued with moral, ethical, and political implications. Perhaps the broadest definition of health is that proposed by the World Health Organization (WHO), defining health with reference to an “overall sense of well-being.” By WHO’s criteria, only a relatively small percentage of the world’s population could be classified as healthy.

Medical anthropologists find it necessary to distinguish disease from illness (Beyerstein, 1997; Eisenberg, 1977; Helman, 2001). Beyerstein argues that the term *disease* applies mainly to organic, physical conditions that can be traced to viruses and bacterial infections, tissue damage, cancerous growths, and so on, while *illness* refers to how patients perceive the physiological experience of “things not being quite right.” He narrows this distinction even further by contending that disease is primarily organic, while illness is primarily psychological. Not all medical anthropologists would accept his distinction. Beyerstein’s ideas need further refinement, because it is well established that psychological and cultural factors, such as expectations, folk explanatory models, subjective biases, and even self-delusion, may

greatly shape the experience of illness (Green, 2003; Kleinman, 1997). The placebo effect (*placebo* is Latin for “I will please”), for example, has been noted in all medical systems (Moerman, 2001), and 21st-century medical anthropologists have become increasingly concerned with the symbolism of healing and the impact of belief (the patient’s belief and that of the healer) on the healing process itself (Buckser & Glazier, 2003; Lévi-Strauss, 1967).

Anthropologists researching health and illness have focused mainly on the relationships that cultural systems have with organizations, institutional practices, and power structures, as well as the epistemological basis of medical knowledge. In addition, they have explored the cultural dimensions of health and illness from ethnographic, comparative, theoretical, and phenomenological perspectives.

Anthropological approaches to health care differ from those of other social scientists in a number of respects. Sociologists often focus their attention on single institutions, while medical anthropologists study multiple institutions and embrace medical pluralism (Baer, Singer, & Susser, 2003). Anthropologists recognize that all societies possess numerous and sometimes conflicting ideas about illness, curing, and health, ranging from predominantly local health systems (like core-shamanism) to scientific systems (like biomedicine). As anthropologist Murray Last (1996) pointed out, there is a wide range of subcultures represented within all medical systems.

Anthropologists assert that health care specialists can be found in all societies, because sickness, pain, suffering, morbidity, and mortality exist everywhere. The wide variety of beliefs and practices associated with death and diseases; ideas about what constitutes the “good life” and “well being”; connections between morality, illness, and ethics; and the use and abuse of power and social control as mechanisms for dealing with misfortune serve to highlight the universal interconnectedness of culture, health, and illness. Indigenous ideas concerning health differ markedly from biomedicine. The !Kung San of the Kalahari Desert, for example, interpret the ability to sweat as indicative of good health, since sweat is regarded as a “life-giving” substance (R. Katz, 1982). American biomedicine does not share this interpretation of sweat.

Anthropologists are equally concerned with the hows and whys of healing. As noted, all medical systems are grounded in human frailty; that is, all humans must deal with the realities of pain, suffering, and death. But cultures deal with pain in different ways (Morris, 1998). While some societies rely almost exclusively on traditional systems of knowledge (which may seem less effective from a strictly biological point of view), other societies advocate modern, scientific biomedicine. Both traditional and biomedical systems can make claims to efficacy; for example, an estimated 25% to 50% of substances used in traditional nonbiomedical botanicals have been shown to be effective by accepted scientific measures (Singer & Baer, 2007). All societies share common concerns about the quality of life, their valuations of human life, and the alleged adequacy and/or inadequacy of their own medical practices. As a consequence, medical anthropologists have expanded their field to encompass complex social, political, economic, philosophic, religious, and ethical issues like organ transplants (Lock, 2001).

The Scope of Medical Anthropology

As noted, anthropologists look at health and illness from a broad perspective; for example, Ember and Ember's (2004) *Encyclopedia of Medical Anthropology* contains 53 thematic and comparative essays as well as 52 “cultural portraits” of health and illness in specific cultures around the world. Thematic and comparative essays address topics as diverse as bioethics, medical pluralism, shamanism, homelessness, nutrition, social stratification, aging, breastfeeding, immunization, genital mutilation, alcohol use and abuse, cholera, culture-bound syndromes, stress, diabetes, diarrhea, HIV/AIDS research, malaria, mental retardation, sudden infant death syndrome (SIDS), tobacco use and abuse, and tuberculosis. The 52 cultural portraits include case studies from every continent and represent diverse cultural groups ranging from the Amish of Lancaster County, Pennsylvania, to the Hmong in Laos and the United States, to the Yoruba of Nigeria.

Another indication of the broadened scope of medical anthropology is the number of anthropologists contributing to the second edition of *The Gale Encyclopedia of Alternative Medicine* (2005).

Medical anthropologists examine health and illness from a human-centered perspective focusing on individuals and their well-being. Medical anthropologists are also activists. The field of medical anthropology is characterized by its applied focus and its extensive use of ethnography and participant-observation to better understand the complexities of health, illness, and health care. There is a sense of urgency in all medical anthropological research. Translation of anthropological findings is of vital concern—not only to transcend language barriers (translating research findings into local languages) but also to bringing research findings to the attention of those in a position to implement them.

From Periphery to Center

Historically, medical anthropologists have focused on marginalized groups and marginal individuals, but a number of recent studies have examined elites and elite health practices. For example, Rayna Rapp (1999) has shown how social class influences female experiences of the reproductive cycle (pregnancy, infertility, abortion, and child delivery), Myra Blueblood-Langer (1996) demonstrated how middle-class parents and siblings cope with cystic fibrosis and other chronic illnesses, and Pearl Katz (1981, 1998) has examined the interactions of senior surgeons at a Canadian hospital. Surgeons, as Katz pointed out, constitute an elite group among biomedical practitioners.

The field of medical anthropology has become highly nuanced. Few societies make either/or distinctions with respect to health. Anthropologists often focus on subjective ideas about health and illness as negotiated within the context of an increasingly sophisticated understanding of human physiology, as well as increasing disparities in global access to health care (Green, 2003). Paul Farmer (2000) has shown how social forces may alter the distribution of diseases and contribute to the advent of new microbial diseases, which often are confined to the poor. Farmer concludes by noting that in the 21st century, social forces often are—following French sociologist Pierre Bourdieu—“embodied,” or interpreted as biological events. In addition, Farmer emphasizes that many people do not have access to health care technology. A growing percentage of the world's population is becoming medically disenfranchised.

Medical anthropologists frequently cross disciplinary boundaries and draw from the research findings of other disciplines (e.g., epidemiology, demography, paleobiology, and forensics). While anthropologists document the tremendous variation in cultural perceptions of health and illness, demographers and epidemiologists categorize these changes in terms of a worldwide health transition

associated with increased life expectancy, a decline in mortality, and an overall decrease in infectious diseases due to the widespread availability of antibiotics. As noted, not all people have benefited equally from advances in biomedicine. There has been a dramatic increase in the number of chronic and degenerative diseases, as well as new epidemics like HIV/AIDS. Demographers point out that poorer nations struggle mightily with disruptions caused by rapid urbanization and—at the same time—are faced with a dramatic increase in infectious diseases like tuberculosis that have been eradicated elsewhere. As Nancy Scheper-Hughes (1992) contended, developing nations are forced to deal with all the medical problems of the developed world plus additional problems like higher rates of infant mortality, life-threatening dehydration, the lack of potable water, urban violence, and widespread hunger.

Medical anthropologists also examine ways people explain and treat diseases and ways people adapt to changing environments. McElroy and Townsend (2004) convincingly argued that environmental factors are becoming increasingly important in predicting the incidence and prevalence of diseases. Their approach—influenced greatly by the writings of Rene Dubos (1959) and Alexander Alland Jr. (1970)—looks at disease over time and space and posits that a community's health status closely reflects its adaptations to the environment.

Negotiating Disciplinary Boundaries

Over the past 30 years, American medical anthropology has become the largest subfield of anthropology and is now the second largest unit within the American Anthropological Association. Also over the past 30 years, medical anthropologists have expanded their field to encompass everyone, any time, everywhere. They see their field as unbounded.

Some have criticized medical anthropology for its lack of boundaries, but medical anthropologists themselves celebrate the many opportunities presented by loose boundaries (Ember & Ember, 2004; Singer & Baer, 2007). Like the discipline of anthropology itself, there is consensus that medical anthropologists should not be confined to researching strictly medical topics. Medical anthropology, according to its practitioners, is the sum total of “whatever medical anthropologists do.” We have adopted this broad perspective in writing this chapter.

Some have portrayed medical anthropology as yet another subfield within anthropology, while others perceive it as a separate discipline that draws on the findings of other subfields. Some say that medical anthropology constitutes a fifth subfield within anthropology, comparable to the four standard subfields: anthropological linguistics, biological anthropology, cultural anthropology, and archaeology.

Sometimes, medical anthropologists appear inconsistent when they resist delimiting the scope of their field, especially when they argue that biomedicine should be

limited in scope. Following Ember and Ember (2004), they seek to encompass topics like environmental pollution, pesticide use, alcohol and drug abuse, sexual practices, dangerous work environments, and so on within their purview (Singer & Baer, 2007) while at the same time arguing that all problems should not be seen as medical problems. Medical anthropologists frequently criticize what they see as the increasing “medicalization” of social problems like alcoholism, AIDS, and drug abuse and suggest that modern biomedicine may not provide adequate solutions to these far-ranging problems.

Toward an Anthropology of Health and Illness

Foundations of Medical Anthropology

Medical anthropology presents itself as a new discipline, although it is not all that new. It has its own intellectual traditions going back to the 19th century, and some medical anthropologists claim that their field has even earlier roots among the ancient Greeks and Romans; for example, the Roman physician Galen (Claudius Galenus) was among the first to explore comparative medical systems. Galen's most important contribution was establishing empirical observation and scrupulous record keeping as hallmarks of medicine practice. In many respects, the 16th-century Spanish priests charged with documenting Aztec cosmology and medical practices were also pioneers in medical anthropology (Ortiz de Montellano, 1989).

In the United States, medical anthropology emerged as a specialized field of research immediately following World War II, when a number of prominent American anthropologists were brought in as consultants on health care projects in Latin America, Asia, Africa, and the Caribbean. But its origins are clearly in the 19th century. Organizationally, American medical anthropology traces its roots to the formation of the Medical Anthropology Group in 1967 under the leadership of nurse-practitioner Hazel Weidman. In 1972, the Society for Medical Anthropology was formally accepted as a section of the American Anthropological Association.

The Torres Straits Expedition (1898–1899)

Alfred C. Haddon, along with British physicians W. H. R. Rivers and C. G. Seligman, initiated the Cambridge University Torres Straits Expedition of 1898–1899. Haddon, Rivers, and Seligman are considered to be among the first to conduct systematic research in medical anthropology. Rivers (1864–1922) anticipated many of the future directions of medical anthropology. He collected valuable data on traditional healing practices among Australian aborigines (Slobodin, 1997) and reported on these practices and beliefs in *Medicine, Magic, and Religion* (1924/2001).

As a physician, Rivers privileged biomedical models of illness and disease, and he concluded his study of Australian aborigines by noting that while preliterate societies may appear to possess systematic and coherent beliefs concerning the causes and effects of diseases, native beliefs and practices are not equivalent to those offered by Western biomedicine. For Rivers—and the other members of the Torres Straits team—ethnomedicine and biomedicine were seen as separate and unequal domains.

From Clinic to Field (and Back)

Other 19th-century founders of medical anthropology include Rudolf Virchow, who greatly influenced Franz Boas when both were colleagues at the Berlin Ethnological Museum between 1883 and 1886; Forrest E. Clements and Erwin Ackerknecht, who published a number of seminal articles in the 1930s dealing with native understandings of illness and disease; anthropologist Cora Du Bois, who was hired by WHO in the 1950s; Edwin Wellen, who worked for the Rockefeller Foundation; and—perhaps most significant—Benjamin Paul, who was the first anthropologist to have an appointment at the Harvard School of Public Health. Funded research projects included the Navajo-Cornell Field Health Project directed by psychiatrists-anthropologists Alexander and Dorothea Leighton and a number of projects administered by Yale physician William Caudill.

Early medical anthropologists—like many medical anthropologists today—focused on infectious diseases. In many poor nations, infectious diseases were the main cause of illness and death, and in many regions of the world, 50% or more of infants died before reaching 5 years of age. Between 1945 and 1965, antibiotics transformed the treatment of infectious diseases. The use of antibiotics, immunization of children, improved sanitation, and improved nutrition became major concerns of large-scale health programs.

Western-trained physicians who directed health care projects frequently encountered resistance from locals who underutilized their clinics, ignored instructions to boil water, and otherwise refused to comply with professional advice. Project workers suggested that local cultural traditions posed insurmountable barriers to adoption of modern health practices. Anthropologists were brought in who intervened and proposed ways of incorporating native ideas to supplement allopathic health practices. Benjamin D. Paul's *Health, Culture, and Community* (1955), consisting of case studies that were first presented at the Harvard School of Public Health, soon became a basic text for researchers who, encouraged by private foundations and increased availability of funding through the National Institute of Health and the National Institute of Mental Health, began new graduate programs to train medical anthropologists. Today, most anthropology departments and most medical schools

regularly offer classes in medical anthropology, and medical anthropology graduate programs now exist in 34 North American universities:

Brown University	University of Colorado Denver
Case Western Reserve University	University of Connecticut
City University of New York	University of Hawai'i
Emory University	University of Iowa
Harvard University	University of Kansas
McGill University	University of Kentucky
Michigan State University	University of Manitoba
Rensselaer Polytechnic University	University of Massachusetts
Southern Methodist University	University of Memphis
State University of New York at Binghamton	University of Michigan
University of Alabama	University of Missouri
University of Alberta	University of North Carolina at Chapel Hill
University of Arizona	University of South Florida
University of Buffalo	University of Toronto
University of California, San Diego	University of Washington
University of California, San Francisco	Wayne State University
	Yale University
	York University

Prior to the 1960s, training of medical anthropologists varied greatly. A number of prominent 20th-century medical anthropologists had their primary training in medicine, nursing, nutrition, psychology, or psychiatry. Most notable among these are Abram Kardiner, Robert I. Levy, Jean Benoist, Gonzalo Beltrán, Arthur Kleinman, Margaret Lock, Ronald M. Wintrob, George Devereaux, and Roland Littlewood. Conversely, a number of early contributors to medical anthropology were first trained in anthropology, sociology, social work, or psychology. Examples include George M. Foster, Veena Das, Byron J. Good, Tullio Seppilli, Gilles Bibeau, Luis Mallart, András Zemleni, Gilbert Lewis, Alexander Alland Jr., Ronald Frankenberg, Horacio Fabrega, Eduardo Menéndez, Gretel Pelto, Hans Baer, Ida Susser, and Merrill Singer.

In an essay published in the journal *Science*, physician William Caudill adumbrated what would become the main interests and concerns of 21st-century medical anthropology. Caudill reported as follows:

Social anthropologists and other social scientists have been doing unusual things of late: participating with physicians in conferences in social medicine, teaching in medical schools, working with public health services in Peru, studying the social structure of hospitals, interviewing patients about to undergo plastic surgery, and doing psychotherapy with Plains Indians. (1952, p. 3)

Caudill's vision placed medical anthropology squarely in clinical settings. American researchers worked within the culture of medical organizations. In Europe, cooperative relationships between practitioners of anthropology and medicine are long-standing and well documented, especially in Portugal and Spain (Martinez-Hernaez, 2008). In the Americas, cooperative programs between anthropology and medicine developed in the United States, Mexico, Brazil, and Canada (Saillant & Genest, 2007).

Anthropology once occupied a prominent place in the medical sciences corresponding to those subjects commonly referred to as "preclinical." But as medical education began to be confined to clinical settings, European medical practitioners abandoned ethnography. However, as Comelles (2000) noted, the divergence of anthropology and medicine was never complete.

Medical anthropology during the mid-1970s at the University of Connecticut Health Center in Farmington closely followed Caudill's 1952 model for the emerging field. Lectures were given by social scientists and physicians who had appointments at the medical school. They addressed many of the topics that had been outlined by Caudill in 1952. The main textbook was Alexander Alland's *Adaptation in Cultural Evolution: An Approach to Medical Anthropology* (1970). Today, medical anthropology classes at the University of Connecticut are very different. In the 21st century, UConn medical anthropology is informed by critical medical anthropology (CMA) and by the community-based perspectives of Pam Erickson, W. Penn Handwerker, Merrill Singer, Steve Schensul, and Jean Schensul.

Theoretical Approaches

Biomedical Approaches to Illness

As noted, medically trained researchers (Beyerstein, 1997; Eisenberg, 1977) demanded more precise definitions of *illness* and *disease*. For these researchers, the term *disease* is limited to organic, physical conditions, while *illness* refers to how patients perceive the physiological experience of "things not being quite right." But this distinction requires further refinement, because psychological and cultural factors, such as expectations, folk explanatory models, subjective biases, and even self-delusions greatly shape the experience of illness (Kleinman, 1997; Littlewood, 2005). The term *disease* refers to biological causes that can be treated physically, while *illness* refers to the experience of symptoms. Traditional medicine is holistic, while biomedicine is predicated on mind-body dualism with the body separated from mental and social functions (Rhodes, 1996). Paul Farmer (see Kidder, 2003) advocates both a biomedical and cultural approach to illness as he seeks to bring biomedical advances to poor nations of South America, Africa, and the Caribbean.

Ecological Approaches

Medical ecology looks at health implications of interactions between human groups and their physical and biological environments. It provides a useful corrective to the clinical preoccupation with disease and the anthropological focus on ethnomedicine. Following Rene Dubos (1959) and Alexander Alland Jr. (1970), medical ecology's unit of analysis is not the individual or the society, but the total ecosystem. From the perspective of ecological anthropologists (McElroy & Townsend, 2004), health is understood with respect to individual and group adaptations. Health behaviors are behaviors that foster survival within a given environment. Health is determined by the quality of relationships within a group, with neighboring groups, and with plants and animals within the environment. Ecological anthropologists focus on beliefs and behaviors that protect individuals from diseases or injury; for example, McElroy and Townsend (2004) pointed out that use of snow goggles among Arctic dwellers protects them from Arctic glare.

Sociological (Institutional) Approaches to Illness

Still others have examined medical beliefs and practices from institutional perspectives. Medical institutions can be portrayed as monolithic or pluralistic. As Cecil G. Helman (2001) astutely observed, it is difficult to separate a society's health care system from aspects of their religion, politics, or economics. The arbitrary division of health care sectors into popular, folk, and professional is impractical and unsatisfactory. Helman—like other social scientists—outlines a variety of help-seeking behaviors that, he suggests, will inevitably lead to what he terms healthcare pluralism. He correctly argues that while one form of health care may be elevated above all others within a given society (and that form may be upheld exclusively by the legal system), it cannot be divorced from alternative healing techniques or from other societal institutions.

Critical Medical Anthropology

Critical medical anthropology (CMA) emphasizes the structures of power and inequality in health care systems and broadens the scope of medical anthropology to include wider causes and determinants of human decision making and behaviors as they relate to health and illness (see Singer & Baer, 2007, pp. 33–34). A critical understanding of health and illness involves paying closer attention to the vertical links connecting individuals to regional, national, and global forces. The CMA perspective examines dominant cultural constructions of health and illness with respect to structures of power and inequality in health care systems and shows how these dominant systems serve to reinforce social inequalities, for example, how poverty, violence, and the fear of violence relate to disease. CMA

assumes a degree of autonomy, agency, and power in making health decisions, but it also recognizes that people make these decisions in a world that is not of their own making. They have little control over factors such as the lack of health care access, the influence of the media, the lack of productive resources (e.g., land and water), and social status. Advocates of CMA consider the daunting effects of pollution, pesticides, drug laws, and street violence in the making and breaking of health and illness cross-culturally. In addition, advocates of CMA explore the roles medical practitioners play in the creation and perpetuation of illnesses. Following Ivan Illich's *Medical Nemesis* (1975), CMA suggests that many illnesses are iatrogenic; that is, they are caused or exacerbated by biomedical treatment. Unlike Illich, most contemporary advocates of CMA do not blame biomedical practitioners but seek broader explanations for biomedical failures.

As noted, critical medical anthropologists seem inconsistent when defining the scope of their field. They argue that biomedicine should be limited in scope, but at the same time contend that the scope of their own discipline should not be limited. More than any other perspective, CMA emphasizes that the anthropological study of health and illness should be expanded to address global issues. But these anthropologists also protest the increasing medicalization of social problems in the United States and suggest that allopathic medicine cannot provide adequate solutions to many of these far-ranging problems.

Phenomenological Approaches to Illness

Advocates of phenomenological approaches attempt to come to terms with the subjectivity of human illness. They accomplish this by adopting traditional participant-observation methods of listening and discovering and try to provide an insider perspective; for example, Margaret Lock compared differences in women's experiences of menopausal symptoms in Japan and the United States. Patient and healer narratives provide useful insights into cultural ideas concerning illnesses and their respective treatments (Garro & Mattingly, 2000; Good & Delvecchio Good, 2000).

As noted, Myra Blueblood-Langer researched how other family members cope when a family member is diagnosed with cystic fibrosis (CF). Siblings, Blueblood-Langer discovered, are deeply affected by the disease as are their interactions in the larger community (school, church, etc.). Like all medical anthropology, phenomenological studies also have an applied focus. Blueblood-Langer, for example, suggests concrete applications of her findings. By understanding how other family members experience CF, she was able to propose guidelines for physicians and other health care professionals dealing with the families of CF patients.

One of the most revealing phenomenological studies was provided by Columbia University anthropologist Robert

Murphy, who—during the final years of his life—was afflicted with brain cancer and became paralyzed. Professor Murphy—while immobilized—described his struggle with the disease in an evocative book, *The Body Silent* (1987). Murphy's book is a poignant, personal testament of what it means to be treated as disabled. He noted that as he became more and more dependent, he also began to vanish socially. Disability, Murphy contends, is experienced not just in terms of bodily affliction but as a disease that alters one's sense of self and colors all social interactions.

Epistemological Concerns

A number of medical anthropologists have attempted to combine biological and symbolic or meaning-centered approaches to health and illness. Psychiatrists have been at the forefront of this movement because, as Tanya Luhrmann so astutely noted in *Of Two Minds* (2000), they have one foot in each camp.

Arthur Kleinman, an anthropologist and psychiatrist who has researched health and illness in Taiwan, China, and North America since 1968, is one of the most influential "bridge builders" in medical anthropology. He draws on his own multidisciplinary background to propose alternative strategies for thinking about interrelationships between medicine, society, and the modern world.

Kleinman's *Writing at the Margin* (1997) explores the permeable borders between medical and social problems and examines boundaries that separate health from social change. According to Kleinman, "health" is at once an end and a means. Following French sociologist Pierre Bourdieu's ideas about "embodiment," Kleinman conceptualizes the body as a mediator between individual and collective experiences. He suggests that many health problems—like the trauma associated with violence and depression stemming from chronic pain—are not just individual medical problems but interpersonal experiences of suffering as well. Like Margaret Lock (2001), he emphasizes that definitions of health and illness possess wide-scale moral implications and argues for an ethnographic approach to moral practice in medicine that incorporates sociopolitical contexts of illness, responses to illnesses, social institutions relating to illness, and documents how illness is configured within medical ethics.

In the 1970s, social scientists attributed multiple medical shortcomings to the malfesance of doctors. Medical anthropologists no longer subscribe to such negative assessments, but—like Kleinman—continue to explore tacitly held medical assumptions and epistemological concerns.

In *On Knowing and Not Knowing in the Anthropology of Medicine* (2005), Roland Littlewood—himself an MD and an anthropologist—argued that many medical studies have been based on the assumption that medical knowledge is uniform and consistent. Anthropologists reject the notion that cultures are discrete, bounded, rule-driven entities, but medical science has been slow to develop alternative

approaches to understanding diverse, unbounded cultures of “health.” Littlewood considers the theoretical, methodological, and ethnographic implications of the disconcerting fact that most medical knowledge is dynamic, incoherent, and contradictory and that all understandings of medicine are necessarily incomplete and partial. In settings ranging from the homes of indigenous individuals to Western hospitals, it is necessary to consider issues such as how to define the boundaries of “medical” knowledge as opposed to other types of knowledge; how to understand overlapping and shifting medical discourses; how to deal with the medical profession’s need for anthropologists to produce “explanatory models”; how to address the limits of the Western scientific method and its potential for methodological pluralism; and the constraints on fieldwork, including violence and structural factors limiting access, and the subjectivity of researchers.

Practical Applications

Religion, Magic, and Healing

Religion and healing are closely interrelated. When Forrest E. Clements (1932) first proposed a first cross-cultural classification of native causes (etiology) of disease (i.e., sorcery, breach of taboo, intrusion of a foreign object, spirit intrusion, and soul loss), four of five native explanations were essentially religious. Erwin Ackerknecht (1971) reinforced Clements’s understanding when he suggested that all tribal medicine should be viewed as “magic medicine.” Tribal healing, Ackerknecht asserted, lacks an empirical basis. It is grounded in witchcraft and superstition.

E. E. Evans-Pritchard’s classic study *Witchcraft, Oracles and Magic Among the Azande* (1937) concluded that the Azande interpret all illness and misfortune as a direct manifestation of witchcraft. According to Azande beliefs, there is no such thing as a natural sickness, a random accident, or a timely death. Even when a granary that is overfull and in ill repair collapses, or a 99-year-old with a history of heart trouble dies in his sleep, these events are nevertheless attributed to witchcraft.

Edward C. Green (1999) has argued that far from being the province of witchcraft, indigenous understandings of contagious diseases in Africa parallel Western concepts of diseases and are similar to “germ theory.” Green calls this indigenous contagion theory (ICT). Major components of ICT include (1) pollution and/or “mystical” contagion, (2) naturalistic infections, (3) environmental dangers, and (4) violations of taboos. Pollution beliefs, Green suggests, may be a common concern for both biomedicine and traditional healers.

There are, however, important distinctions between superstition and belief.

Traditional healers interpret and manipulate powerful cultural symbols. By introducing complex psychosocial

factors, dramatic symbolic imagery, metaphor, prayers, and enactments, healers activate beliefs and expectation in patients triggering psycho-neuro-immunological responses (Cannon, 1942; Winkelman, 2000). Using theatricality and symbolism, imagery, and metaphor, healers provide a way for patients to situate and comprehend their somatic sensations (Lévi-Strauss, 1967; Romberg, 2009). Daniel Moerman (2001) convincingly postulated substantial pathways linking physiological and cognitive states. These pathways, he suggested, are the stage on which metaphorical concepts of performance may effectively influence biological processes. Just as some native ethnobotanicals have been shown to have strong efficacy, some native healing practices have been shown to have efficacy as well (Turner, 1996). Sidney M. Greenfield’s *Spirits With Scalpels: The Cultural Biology of Religious Healing in Brazil* (2008) addresses the symbolic aspects of psychic surgery. Greenfield neither accepts nor dismisses the bizarre practices he personally has witnessed. Instead, he seeks to reconcile religious-based healing and recent findings from neurobiology. Like Moerman, Greenfield clearly recognizes the place of symbols within the healing process and advances a theoretical model that stresses altered states of consciousness and hypnotic states and moves beyond the limitations imposed by mind/body dualism.

Navajo Healing and Aesthetics

Healing, music, and art are also closely interrelated (see Csordas, 2000). Gary Witherspoon (1977) documented the healing power of Navajo chants, while Nancy J. Parezo (1983) charted a dramatic transformation of Navajo sand paintings from the sacred to the secular. Prior to the 1920s, Navajo sand paintings were used primarily as part of a healing ritual. Sand paintings were produced to “allow the patient to absorb the powers depicted, first by sitting on them, next by application of part of the deity to corresponding parts of the patient—foot to foot, knees to knees, hands to hands, head to head” (Parezo, 1983, p. 14). Today, Navajo sand paintings are commodities. They are bought and sold as tourist art.

Shamanism

Shamans are the prototypical healers in tribal societies. The term *shaman* is derived from the Mongol-Tungusic word *saman* (to know). As Michael J. Harner (1980) correctly asserted, shamanism is “the most widespread and ancient system of mind-body healing” (p. 175).

Shamanic techniques are surprising universal. Joan B. Townsend (1999) has outlined some of the basic components of what has become known as the shamanic complex. These include direct communication with the supernatural, an ability to control spirits, the ability to enter into and exit altered states of consciousness, a focus on problem solving, and soul flight. In practice, shamans

serve as mediums for spirits. At times, they are able to call on the spirits without entering into trance, and they sometimes remember parts of what occurs on their journeys to the spirit (supernatural) realm. (For differing interpretations see Kehoe, 2000, and Winkelmann, 2000.)

Shamanic beliefs and practices have been a major topic of anthropological study since the beginnings of the discipline, but the first systematic studies of the entire repertoire of illness concepts and therapeutic practices did not begin until the 20th century, when anthropologists began to question the efficacy of shamanism (Lévi-Strauss, 1967). As noted, earlier researchers like W. H. R. Rivers had been less ambivalent about traditional healing practices and suggested that traditional healers were frauds. This changed as critics of Western medicine began to challenge the value of Western medicine, faulting it for its positivist separation of mind from body; its dehumanizing focus on body parts, malfunctions, and lesions; and its treatment of pregnancy and birthing as pathological disorders rather than normal biological processes. Shamanic techniques, critics suggested, might be superior to those of allopathic medicine. This opened the way for collaboration between biomedical practitioners and traditional healers.

Collaboration

Collaboration is a key concern for 21st-century anthropologists. As defined by Mattessich, Murray-Close, and Monsey (2001), collaboration is “a mutually beneficial and well-defined relationship entered into by two or more organizations to achieve common goals” (p. 4). Collaboration entails shared decision making and mutual respect (Caluccio & Maguire, 1983, as cited in Henneman, Lee, & Cohen, 1995). In all cases, a major concern is the patient’s well-being. Within medical anthropology, collaborative efforts have been focused in two directions: participatory community research and collaborative projects among health care professionals.

The primary goal of collaboration research is to foster productive relationships (both formal and informal) among all parties concerned (El Ansari & Phillips, 2001). In participatory community research, community members take an active role in the research process itself (Taylor et al., 2004). For example, Noel Chrisman (2008)—an anthropologist who teaches in a school of nursing—conducted primary research with indigenous groups like the Yakima Indians of Washington State and has worked as an evaluator for numerous community-based participatory projects sponsored by the Centers for Disease Control.

Addressing a critical shortage of biomedical personnel in Africa, WHO adopted a number of resolutions to promote collaboration between traditional and biomedical practitioners. In 1978, WHO and UNICEF passed the Declaration of Alma-Ata recommending the use of traditional healers in government-sponsored health care

programs, and in 2007, the ministers of health for the WHO African Region reaffirmed their support for collaborative efforts by adopting the Declaration of Traditional Medicine.

There is considerable debate among public health professionals regarding collaboration between traditional and biomedical practitioners. Those favoring collaboration emphasize that 80% of the African population regularly use traditional medicine and point out that the ratio of traditional healers to biomedical doctors is 100:1 (Green, 2003; UNAIDS, 2000). Those against collaboration point to what they see as irreconcilable differences between the methods and goals of biomedical and traditional practitioners. Some notable examples of organizations conducting successful collaborative initiatives include Traditional and Modern Health Practitioners Together Against Aids (THETA) in Uganda, and Tanga AIDS Working Group (TAWG) in Tanzania. Much literature on collaboration has focused on ways to train, educate, and integrate traditional healers into existing biomedical systems rather than fostering collaborative relationships between them and biomedical practitioners. Initiating collaboration with traditional healers is a complicated process (Kayombo et al., 2007), and 21st-century medical anthropologists will need to examine factors that serve to promote and those that impede collaborative efforts.

Comparisons: Global and Topical

Global Comparisons: Clements, Murdock, and Fabrega

In a reassessment of Forrest E. Clements’s 1932 study, anthropologist George Peter Murdock (1980) compared medical beliefs and practices of 186 societies included in the Human Relations Area Files (Murdock, 2004). Murdock divided theories about the causation of illness into two broad categories: theories of natural causation and theories of supernatural causation. Later, Murdock attempted to correlate different types of beliefs about causality with different global regions and different levels of social organization (foragers, horticulturists, pastoralists, and citizens of early states). Regional differences were found to be the most significant. Africa, Murdock found, ranks high in theories stressing mystical retribution, while North America outranked all other regions in theories of sorcery. South America ranks highest in theories emphasizing spirit aggression. A major problem with Murdock’s approach—like that of Clements—is that most societies rely on multiple theories of causation. Few tribal societies (and even fewer modern societies) posit a single cause for any single illness.

Horacio Fabrega (1997) offered a more sophisticated comparison of medical systems that has greatly influenced 21st-century research. Fabrega examined behaviors that he

saw as biological adaptations related to sickness and healing (SH). Chimpanzees, he posited, enact behaviors like dressing wounds with leaves or wiping their feces. Neanderthals posed an even more elaborate SH repertoire. In foraging (hunting and gathering) societies, SH behavior was provided by insightful and socially attuned individuals who possessed a keen knowledge of the biological, cultural, and social environments in which they lived. A primary focus of tribal healers is ritual intended to restore social relationships. Village-level societies are characterized by more specialized healers, more elaborate ceremonies, and a better-defined “sick role,” whereby individuals perceived as “sick” were excused from normal social and economic obligations.

As societies became more complex—as in the development of chiefdoms and early states (e. g., the Greeks and the Aztecs), medical knowledge became systematized and institutionalized to include (1) a standardized, widely accepted corpus of medical knowledge; (2) incipient medical pluralism, and (3) the presence of a wide array of competing healers—herbalists, bonesetters, and midwives who would undergo systematic training and/or apprenticeships. These trends continue.

Medical Pluralism: Looking at Health and Illness in Haiti

The Caribbean nation of Haiti ranks as the poorest country in the Americas and is one of the poorest nations on earth. Health care options range from advanced biomedicine for elites in Port au Prince to floating hospitals like Project Hope to herbalists, religious healers (Pentecostals), and Voodoo practitioners. Access at every level is restricted to those who are able to obtain referrals, contribute bribes, and/or establish political connections.

The Haitian medical system is also among the most pluralistic and convoluted on earth. It consists of five unrelated sectors: (1) the public sector (The Ministry of Public Health and Population and The Ministry of Social Affairs); (2) the private, pay-as-you-go sector (a limited number of health care providers in private practice); (3) the mixed nonprofit sector (Ministry of Health personnel who actually work in private institutions such as nongovernmental organizations [NGOs] or faith-based organizations [FBOs]); (4) the private nonprofit sector (NGOs, foundations, and associations); and (5) traditional healers. A number of overlapping bureaus supervise health programs (except treatments for AIDS and tuberculosis, which are directly under the Office of the Director General). In principle, all health-related organizations are coordinated by the Ministry of Health. In practice, the Ministry of Health has been unable to assume leadership. Allopathic medicine is available to less than 60% of the population. In 1998, there were 2.4 physicians for every 10,000 people, and in 1996, there was 1 nurse per 10,000 people and 3.1 auxiliary professionals per 10,000 people. Haiti has both public and

private medical schools, but of four private Haitian medical schools, only one is accredited.

In the countryside, the most common sources of medical care are traditional healers, NGOs, FBOs (largely American-funded clinics), and aid from other Caribbean nations. In 1999, a bilateral cooperation agreement was signed with Cuba. Under the agreement, 500 Cuban health professionals began working in 62% of the municipalities for a period of five years (or until the return of 120 Haitians selected to study medicine in Cuba). This agreement has been extended.

In Haiti, as in other poor nations, religion, magic, and healing are very much interconnected. In 1987, when Brodwin (1996) began an extensive study of folk ideas concerning illness, healing, and mortality in a small (3,000+ residents) Haitian village he called “Jeanty” (a pseudonym), his primary interest was in health-related activities among villagers. Brodwin’s major concerns were as follows: (1) How does medical pluralism function in Haiti? (2) How do clients select which ethnomedical system to access from among many available options? (3) What factors influence their selections? and (4) What happens when patients and healers interact?

Brodwin observed over 50 consultations between patients and herbalists as well as consultations between patients and *houngouns* (Voodoo practitioners). He concluded that villagers readily consulted *houngouns* for pressing health problems, but—at the same time—they were ambivalent, because a *houngoun* has the ability to send illness as well as to cure it.

In 1987, physician and medical anthropologist Paul Farmer—along with Ophelia Dahl, Jim Young Kim, Thomas J. White, and Todd McCormack—founded the NGO Partners in Health (PIH). The first PIH clinic was established in the central plateau of Haiti. The PIH hospital in Haiti provides free treatment and dispenses drugs to treat tuberculosis and HIV/AIDS. In addition to the clinic in Haiti, PIH oversees medical clinics in Russia, Rwanda, Lesotho, Malawi, and Peru. By and large, Farmer’s clinics follow an allopathic model, with emphasis on ethnographic analysis and real-world practicality. In *Mountains Beyond Mountains: The Quest of Dr. Paul Farmer, a Man Who Would Cure the World* (2003), Tracy Kidder details Farmer’s work in Haiti, Peru, and Russia, as well as Farmer’s efforts to balance clinical, humanitarian, and academic responsibilities. Kidder’s book documents the myriad difficulties Farmer faces as he attempts to secure health care for the poor.

As noted, an estimated 25% to 50% of substances used in traditional nonbiomedical ethnobotany have been demonstrated to be effective by scientific measures (Singer & Baer, 2007). This is also true of Voodoo medicines. In *Passage of Darkness: The Ethnobiology of the Haitian Zombie* (1988), ethnobotanist Wade Davis provided great insight into the Haitian underworld and its relationship to healing through an examination of the secret Bizango society. Equally important, Davis provided incontrovertible evidence

for the existence of zombies (the living dead). Davis points out that hougouns possess extensive knowledge of plant irritants and animal poisons, such as tetrodotoxin, which is produced by puffer fish. Hougouns might administer tetrodotoxin to place their intended victims in a catatonic state (heart rate slows, breathing is imperceptible, and the victims appear dead). The victims are then buried while fully conscious. They are dug up later—often by the same hougoun who administered the tetrodotoxin, and moved to another island location where, under the influence of the botanical *Datura*, they become confused and disoriented. This process, according to Davis, is the process by which Haitian zombies are created.

New Directions

Since its inception, medical anthropology has undergone a number of dramatic transformations. Its applied focus remains, but its methods and goals have expanded from those advocated by W. H. R. Rivers and the Torres Straits Expedition of 1899 (Slobodin, 1997). Twenty-first-century anthropologists pay greater attention to culture and symbolic healing (Moerman, 2001). There is increased reliance on ethnographic methods and a greater emphasis on collaborative research (Chrisman, 2008). Additional research is needed to identify factors that promote collaborative relationships between indigenous and biomedical practitioners.

Conceptions of health and illness are also changing (Beyerstein, 1997). There is greater attention to native ethnobotany (Davis, 1988) and to exploring the possible efficacy of traditional healing techniques (Greenfield, 2008). Epistemological and phenomenological issues have come to the forefront (Kleinman, 1997; Littlewood, 2005). Last, CMA (Singer & Baer, 2007) has had a tremendous impact on the field and has broadened the scope of medical anthropology to include wide-scale international problems like malnutrition, limited access to health care (Farmer, 2000), environmental pollution, alcoholism (Heath, 2003), sexually transmitted diseases and AIDS, smoking, violence, traffic accidents, crime, and drug abuse (Fassin, 2007; Green, 2003). Twenty-first-century medical anthropologists have become less critical of biomedicine and more concerned about worldwide access to health care.

PART XV

ONGOING ISSUES IN ANTHROPOLOGY

SOCIOBIOLOGY

Nature and Nurture

CHRISTIAN SPAHN

Friedrich Schiller University in Jena

Ever since the publication of Charles Darwin's *On the Origin of Species* in 1859, many attempts have been made to apply the insights of evolutionary biology to the study of humans. The first edition of *On the Origin of Species* gives only a small hint at the possible impact that the theory of evolution could have on anthropology:

In the distant future I see open fields for far more important researches. Psychology will be based on a new foundation, that of the necessary acquirement of each mental power and capacity by gradation. Light will be thrown on the origin of man and his history. (Darwin, 1859)

But within about 10 years, Darwin himself had already given a first account of *The Descent of Man, and Selection in Relation to Sex* (Darwin, 1871) and developed an evolutionary explanation of the modes of the *Expressions of the Emotions in Man and Animals* (Darwin, 1872). In the edition of 1876 of his *On the Origin of Species*, Darwin appraised, in the same passage quoted above, H. Spencer's way of founding psychology on the principles of evolutionary biology (Spencer, 1873). From Darwin's time on, the application and extension of evolutionary biology to the study of human nature has gone through changing tides of "biologization" and antibiological demarcations, resulting in the nature-nurture distinction and in the debate of how much in human behavior is innate or inherited—and thereby a possible candidate for a biological explanation,

and how much is influenced by nurture—which can therefore only be explained by reference to cultural and intellectual influences.

From the first trials until today, the application of evolutionary biology in order to explain not only human morphological traits, but also human mind and human behavior, has been under attack from both social scientists and biologists alike, but it has also found enthusiastic support. Dawkins (1976) states in quoting G. G. Simpson (1966) that any effort to grasp human nature and humans' reason for existence that was undertaken before 1859 should be ignored, thereby putting the strongest possible emphasis on a Darwinian understanding of nature in the nature-nurture distinction. Tooby and Cosmides (1992) write that social sciences as they have been studied before without the incorporation of evolutionary biology have been extraordinarily unsuccessful as science just because of the shortfall of ignoring the evolved human nature.

On the other hand, in cultural studies, sociologists but also biologists have always emphasized that it is only nurture that can explain the richness and variety of human culture and behavior and have attacked biocentrism or gene-centrism as an oversimplification that is not sufficiently explanatory and may be even politically dangerous. These scientists include Sahlins (1976); Lewontin, Rose, and Kamin (1984); Gould (1978, 1981, 1997); Jablonka and Lamb (2005); Richerson and Boyd (2005); and Wilson and Wilson (2007).

Since nearly all important realms of human behavior—from gender roles, aggression, love, questions of altruism and egoism, questions of acquiring knowledge, and malleability of character ultimately to the question of freedom, responsibility, and individuality—are affected by the nature-nurture debate, this debate is and will continue to be a controversial issue in biology, social sciences, and even in everyday life and politics.

Nature and Nurture: Darwinism and the Nature of Nature

Darwin's theory of evolution by natural selection (Darwin, 1859) describes the world of organisms as a world of competition for survival and replication. Due to the high fertility rate of most populations, within a few generations the world would be overcrowded by most species, but in fact we observe in most cases an almost steady state of population. From that observation, Darwin infers that there must be strong competition for the resources organisms need; that is, not all individual organisms that are born are in fact able to survive and to reproduce (the *struggle for existence*). The next step is the fact that individuals of the same kind slightly differ in their qualities and that often certain varieties are inherited (Darwin refers to knowledge from the field of breeding). In the struggle for existence, those qualities that lead to better survival chances (natural selection in a narrower sense) and higher chances of reproduction (sexual selection) will thereby necessarily be more often present in the next generation than maladaptive features or disadvantageous traces.

This process is labeled by Darwin, in analogy to humans' selection in breeding, *natural selection*. Natural selection "chooses" from the occurring differences (*mutations*) those features that tend to increase fitness, and Darwin infers that this process leads over a long time of accumulation of small differences to the origin of new species and to the astonishingly complex and highly functional adaptations (designs) that we find everywhere in nature. Darwin was of course not the first scientist to hold the view that species have evolved, but he was the first to discover—independent from but consistent with the ideas of Wallace (Darwin & Wallace, 1858)—the causal mechanism (natural selection) that is responsible for the generation of all the observed adaptations of organisms.

The later combination of Darwin's theory with the discovery of the true mechanism of inheritance and with new insights from population genetics and cell biology led to a new powerful explanatory framework in biology, labeled *synthetic theory* (Huxley, 1942; Mayr, 1942). Within post-Darwinian biology, many features of Darwin's theory have been and are being critically discussed: What is the level or unit of selection? To what degree is, for instance, group selection possible (e.g., Dawkins, 1976, 1982, vs. Richerson & Boyd, 2005; Wilson & Wilson, 2007)? How much

emphasis should we lay on the adaptive side of the process instead of stressing the contingency and internal constraints within the development of organic systems? In the process of evolution, does randomness and contingency prevail, or are there certain trends and specific trajectories of adaptation and evolutionary pressure that make certain "inventions" more likely or even probable (e.g., Gould & Lewontin, 1979, vs. Conway Morris, 2003)? Is it true that there is no way of inheriting individually acquired traces, and is every mutation random, or can we revive some elements of Lamarckism? Is it reasonable to see the genes as the ultimate unit of selection and as a causal power using the individual organisms as their vehicle (Dawkins, 1976, 1982), or must we consider a complex interplay of evolution and environment, of the extraction of genetic information and independent laws and factors of development (e.g., Jablonka & Lamb, 2005)?

All these discussions, however, are discussions *within* the Darwinian framework; they all accept the idea that the combination of blind mutation, inheritance, and competition will lead to differential survival (natural selection). They all agree, therefore, that knowledge about the mechanisms and logic of natural selection is in fact the key to understanding the biological world: As Dobzhansky (1964, 1973) famously put it, "Nothing in biology makes sense except in the light of evolution" (1964, p. 499; 1973). The modern picture of nature in the nature-nurture distinction is thereby profoundly shaped by Darwin's theory of evolution.

Nature Versus Nurture: The Case for Nurture

Before and still after the rise of sociobiology in the 1970s, two ways of dealing with the biological side of human nature in the social sciences and philosophical anthropology can be distinguished.

Humans are either, first, regarded as a very special animal that has been equipped by evolution with a very peculiar nature. Since this peculiar nature has been brought forward by the forces of evolution, biological knowledge can to some degree be fruitfully applied in the enterprise of understanding humans (see Gehlen, 1940/1993; Plessner, 1928, 1940; Scheler, 1925, 1928). Since, however, human nature differs distinctly from animal nature, there are in this view limits for this application, and there is a clear distinction between the realm of animals and the human sphere: Evolution itself has led to a creature that has left the realm of pure biological determination.

Second, against this cautious incorporation of biological knowledge in the humanities, a strong antibiological tendency can be found in the doctrine of the antiuniversalistic character of human cultures and in the idea of the autonomy of cultural processes, an idea originally already put forward by Alfred Kroeber in his theory of the "superorganic" nature of cultural processes (Kroeber, 1917). Cultural processes that shape human behavior are considered to be

not at all biologically determined, and they might even be independent from the individual psychology of human beings (Durkheim, 1895/1982; Geertz, 1973; Kroeber, 1916, 1952; Sahlins, 1976; see also Lewontin, Rose, & Kamin, 1984; Richerson & Boyd, 2005).

The Case for Nurture: Nature Requires Nurture

Scheler, Plessner, and Gehlen all tried to give accounts of the difference between human actions and abilities and animal behavior by looking at the peculiar evolved *nature* of human beings.

Although Scheler praised the new insights in the abilities and capacities of animal intelligence, he insisted that the human mind could not be understood in terms of pure, survival-oriented “strategic rationality.” This capacity is only quantitatively different in humans and their capacity for technical inventions, and it might even be that animals in this realm are much more securely guided by instincts (Scheler, 1925). The new feature that places humans away from and above nature and biology is their ability to grasp objective reasons and values and to contemplate what value might be preferred to others. (Even abstract values might be preferred to the value of personal survival). Thus, humans seem to have freed themselves from the instinct-driven means-end rationality of other animals (Scheler, 1925, 1928).

Plessner (1928) emphasizes the “ex-centric” nature of humans that places them partly outside the realm of biology. He argues in favor of leaving the “body versus mind” or “nature versus human” distinction behind: Humans must place themselves within nature (they are not bodiless rational beings), but without betraying their peculiar position or special nature. Plessner tries in his philosophy of biology to capture the different modes of life in the three realms of plants, animals, and humans. While animals are centric insofar as they are guided by nature through their instincts, humans have the ability to consciously relate to themselves and to distance themselves from their nature. Humans therefore are in an ex-centric position; that is, they have an open, not biologically fixed, relation to the world. Consequently, due to the reduction of instincts, humans must heavily rely on nurture (culture and institutions) in order to survive. Plessner (1928) puts this in the famous phrase of humans’ *natürliche Künstlichkeit* (“natural artificiality”): By their very nature, humans must rely on human-made products, nurture, and culture.

Gehlen (1940/1993) follows the concept of Herder when he interprets a human primarily as an instinct-deprived animal, as a *Mängelwesen* (“deprived creature,” *Homo inermis*) that bears the stamp of an overall retardation.¹ Human infants are born premature, go through what might be called an extra-uterine embryonic year (compared to other primates), and have a very long phase of neoteny. Compared to other animals with their high specializations, humans are

weak in their morphology: They lack natural weapons and seem to be less specialized to cope with specific environments or to fulfill certain tasks. In order to compensate for this reduction of instincts and physical strength, humans must exert their rational capacities and intellect in order to survive. Technological tools can be regarded as “external organs” that help them. Gehlen calls this “the need for institutions,” and his definition of *institution* includes all kinds of nonbiological intelligent survival techniques, from tool use to social institutions. It is exactly humans’ extraordinarily *weak* or *deprived* nature that compels them, more than any other animal, to nurture and culture. Gehlen backs his thesis with contemporary scientific insights (Lorenz, 1943; Tinbergen, 1952), according to which there is a fixed nature of stimulus-response mechanisms in animals that cannot be the predecessors of the flexible, not-content-bounded mind of man. Whereas animal cognition seems to be constrained to certain well-defined stimulus patterns, humans are *weltoffen* (“open to the world”) and can think about all kinds of objects, theories, and even fictional events.

The common assumption of these views is the emphasis on “the *reduction* of nature” (fewer instincts, less physical power) that lead in a situation of Darwinian competition to the urge to compensate for these disadvantages through the further and further development of reasoning and intelligence. Humans must invent tools, invent clever hunting strategies, compensate for the lack of guidance through instincts, and so forth, thereby developing the ability for cognitive problem solving to such a high degree that this capacity itself becomes the basic foundation for nurture, and yes even for the overcoming of nature.

In contrast to old, pre-Darwinian dualistic views, the specialness of human nature (its rationality) is not given by a divine creator, nor is it a sign of human superiority, but is itself a product of a special evolutionary pressure that operates on the basis of the given human weakness and human physical inferiority. Nevertheless, this view emphasizes a distinction between humans and animals, nature and nurture, claiming that through reasoning humans eventually leave nature behind. The process of leaving nature behind may in this view be described in Darwinian terms “through the logic of selection pressure,”² but the result is viewed as a state in which humans have freed themselves from biological nature via “rational nurture.” This view became dominant in the European and Anglo American social sciences and shaped their accentuation of nurture over nature.

The Case for Nurture: The Autonomy and Pluralism of Cultures as a Counterargument Against the Influence of Nature

Modern anthropological and ethnographic researchers have been impressed by the vast variety of and innumerable

differences among human cultures all over the world, and by the human culture, behavior, and society in comparison to animal behavior. Modern ethnography and cultural studies, from the beginning of the 19th century onward, have put forward a strong antiuniversalistic stance, dismissing and heavily criticizing the idea of a single common human nature or common human culture.

In this view, there simply exists no such thing as *one* human culture, there are only human *cultures*. Geertz (1973), following Kroeber, even famously calls the so-called anthropological universals such as religion, marriage, trade, and property “fake universals” (p. 39). Mead (1949) also in her early studies stresses the cultural differences in gender roles; Whorf (Whorf & Carroll, 1964) famously claimed that the Hopi Indians did not possess a concept of time analogous to that of “Western thought”; Darwin’s view of a common human way of expressing emotions seems to be refuted by the richness of human habits and customs. Generally, modern studies along the lines of “postcolonial” approaches try to avoid at all costs the measurement of different cultures and habits with one common universal standard. (For a critical overview, see Brown’s important book on human universals [1991].)

Since a common biological nature of humans cannot, it seems at first sight, account for this pluralism of cultures among humans, the differences must be culturally induced; therefore nurture and cultural learning become in these approaches the most important factors in understanding human behavior. Human nature, it seems, only equips us with flexibility and does not bind us to a specific expression of behavior.

The alternative view, that these differences might be traced back to a different biological or genetic set-up of different groups, was from the time of its origins heavily criticized by Kroeber (1916) and can now be considered to be totally refuted. (See Tooby & Cosmides, 1990, for the Darwinian argument against the view that there could be fundamental biological differences between different human “races.”) Kroeber (1916) argues that, if Weismann’s (1885) neo-Darwinian doctrine is right, different acquired cultural habits, customs, and so forth cannot be inherited, and the idea of a biological basis for the differences in cultures is—according to the biological neo-Darwinian standard—*itself* absurd (Kroeber, 1916; see also Geertz, 1973).

Nevertheless, racist tendencies and ideas of biological determinism that gave rise to social Darwinism and eugenic ideologies were popular in science at the beginning of the 20th century. It is the merit of Boas and his pupils, including Alfred Kroeber and Margaret Mead and also Ruth Benedict (1934), that they emphasized the value of cultural plurality. They insisted from early on that this pseudoscientific thinking could not be rooted in neo-Darwinian evolutionary biology and that the idea of racial determinism of cultural behavior is completely misguided.

If differences in culture cannot be traced back to nature in this way, it is then, as argued above, plausible to consider

them to be a product of nurture. This insight and the misuse of biological views in the age of racism and eugenics have led to a strong disregard of human nature in social sciences. The difference between human capacities and those of an animal mind—conceptualized as being guided by stimuli and responses, narrow behavioral patterns, and content specificity—obviously seems to ask for a strong emphasis on nurture in order to account for human culture. The study of culture alone becomes therefore the main, sometimes the only, focus in social sciences and anthropology. In some of these views, human nature becomes almost completely irrelevant and negligible; human nature is only important insofar that it *enables* flexibility and cultural diversity. In order to do so, it cannot be regarded as fixed or as determining human action.

This line of reasoning has become even more dominant in the school of behaviorism (Skinner, 1938, 1957) that describes the human mind as a black box that can, in an astonishingly flexible way, be adjusted to almost any task simply by learning through reinforcement. While Pavlov developed the idea of classical conditioning (given stimulus-response reactions can be triggered by a different stimulus through association), Skinner expanded this idea to the more universal method of *operant conditioning*: Animal behavior can be influenced in a flexible way through positive or negative reinforcement (punishment or reward), leading to completely new stimulus-response connections. This idea led to the concept of a great flexibility of cognition that is expressed in Watson’s famous words that describe a strong *independence* of nurture (training/conditioning) over nature:

Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I’ll guarantee to take any one at random and train him to become any type of specialist I might select—doctor, lawyer, artist, merchant-chief, and, yes, even beggar-man and thief, regardless of his talents, penchants, tendencies, abilities, vocations, and race of his ancestors. (Watson, 1925, p. 82)

Although this view does not claim that the human mind is a tabula rasa, the general ability to learn seems to make the human mind more similar to a general-purpose computer that can be programmed by nurture for almost any task, from riding bicycles to solving theoretical problems in proto-plasma physics. Only the fact that nurture is much more important than nature could, it seems, give an account that renders justice to the generality, flexibility, and diversity of human actions and capacities.

The Case for Nature: Ethology

In strong opposition to the autonomy thesis of culture, ethologists, sociobiologists, and evolutionary psychologists have stressed the dependence and deep connection between nature and nurture. The insights of Tinbergen and

Lorenz in animal behavior and cognition corrected the view of a simple stimulus-response model. Lorenz's work on the biological function of aggression is a good example of the ethological approach to behavior. Lorenz argues that he cannot accept the dualism of a life-fostering drive (*eros*) and a drive for destruction (*thanatos*) that Freudian psychology postulates. From a biological point of view also, the negative drive of destruction must have a positive or adaptive function for the organisms and cannot be seen as an antibiological drive of (self-)destruction.

Lorenz tries to give an account of how aggressiveness can have evolved and what its adaptive function in the animal realm is (Lorenz, 1963). Thereby he claims that aggression is simply a necessary feature of life, not something that is externally induced by frustration or stimuli: Since, for Lorenz, drives have a certain autonomy, one cannot avoid aggression simply by avoiding frustration or aggression stimuli. Lorenz draws conclusions for humanity: We should not try to overcome aggression but rather deal with it in a productive way. Lorenz hereby challenged the mainstream view of his time—that any education that avoids frustration will lead to nonaggressive personalities.

This inference from biological insights to the realm of human education has, however, met heavy criticism from the social sciences, but the school of ethology has also been criticized by biologist for *internal* Darwinian problems. Lorenz analyzes the positive function that aggression has for the preservation of the species, thereby postulating a drive to do what's good for the species. Such a drive, however, cannot be postulated and can only be assumed by making unreasonable claims about group selection. This problem has led to the rise of the new paradigm of *sociobiology* that replaced the dominant understanding of behavioral adaptation (“do what is good for the group”) in the framework of ethology.

The Case for Nature: Sociobiology—Theory and Application

Interestingly enough, the sociobiological application of evolutionary biology to the realm of humans was in part made possible by a view dominant in the social sciences that was still in the tradition of those views that stress the distance between humans and animals. Human beings are considered to be the *rational* animal. The rational choice theory or theory of games developed in economics (Von Neumann & Morgenstern, 1944) considered human beings to make rational choices: No one wants, for instance, to buy a product for a higher price than necessary; nobody wants to sell it for a lower price than possible. It is clear that the situation in the free market resembles a Darwinian scenario: It is a situation of competition for scarce resources (customers), in which any company that wants to survive will have to improve its products in direct competition or has to find its own ecological (economic) niches.

Looking at rational strategies of market participants therefore intrinsically resembles the task of searching for *evolutionarily stable strategies*, that is, for inheritable or programmed animal behavior that will increase the reproductive fitness of that animal using the strategy. An evolutionarily stable strategy is a strategy that, if the majority of a population uses it, cannot be outcompeted by any other strategy (Maynard Smith, 1982; Smith & Price, 1973). The same mathematical models, the same types of problems and questions (when and why cooperate, when and why “cheat”?) can be asked in both fields. Lewontin (1961), Hamilton (1967), and Maynard Smith (1982) successfully applied the models of game theory to biology.

Interestingly, both views were challenged by empirical facts. From an evolutionary viewpoint, it seems that programs for maximizing egoistic fitness would out-compete more altruistic strategies. But in the realm of biology, it is in fact true that the animal world is full of examples of mutual cooperation, even of acts of self-sacrifice: Parents sacrifice themselves for their offspring, mutual cooperation in groups is not rare, birds give alarm calls, thereby exposing themselves to danger, and so forth. Within the realm of social sciences, evidence was found that people executed “defections” from the ideal egoistic strategies in “dictator games” or “ultimatum games.” People in an ultimatum game are willing to altruistically punish certain behavior of others: They are willing to invest resources in a non-profit-maximizing way just to punish others who deviate from expected moral norms (Fehr & Fischbacher, 2003; Henrich et al., 2004).

How can this contradiction between the expected egoism in a game of competition and the observed cooperation and altruism be reconciled? How, in both Darwinian situations of fitness maximizing and rational (strategic) choice making, can altruism occur?

Darwin noted that there can be a conflict between activities that are good for the group and those that are beneficial for the individual organism. For a group of monkeys, for instance, it might be good to have courageous individuals that are willing to aggressively fight against other groups (for instance, in order to defend territory and resources). Such a group will have an advantage over a defenseless group. For the individual, however, it is better to let others do the violent and potentially dangerous job (see Darwin, 1871, p. 161). Freeloaders always have a higher chance for reproduction, simply because they avoid putting themselves in danger; therefore, this strategy must be much more successful and must over generations replace the strategy to defend the group in an altruistic fashion. If one does not want to impose implausible group-selectionistic theories or evoke the notion of a drive to preserve the species, a theoretical solution must be found to explain the existence of altruistic behavior in the animal realm. More dramatically, this problem is almost a Darwinian paradox. A biological definition of altruism would be the following: An altruistic act is an act by which an organism enhances

the chances of survival and reproduction of another organism by decreasing its own chances of reproduction. Acts of this kind exist, but at first sight *they cannot evolve* in the logic of Darwinism if one assumes that behavioral strategies must be genetically inherited. Altruistic organisms (in this sense) tend (by definition) to leave fewer offspring than egoistic organisms; therefore, they cannot have, it seems, a chance in the course of evolution.

There are three possible answers to this problem. First, you can try to unmask acts of altruism as being in fact egoistic. The gazelle might not jump in a self-sacrificing way to draw the attention of a lion away from a weak conspecific; it may be a selfish act to display her own strength and health, thereby signaling that the other weak conspecific is a much easier target (Dawkins, 1976). Similarly, giving an alarm call might have egoistic advantages: The bird's call might have the effect of asking the other birds to be quiet, thereby increasing its own chances of survival; it might also fly away with them, so that its chances of being caught are fewer than in a solitary attempt to escape (Dawkins, 1976). But there are many cases where it is implausible to find such an individual-egoistic advantage. A parent sacrificing itself for its offspring hardly has any individual egoistic advantages in terms of further reproductive success.

A second solution is to shift the perspective from the individual level to the gene level. This is one of the basic original insights of sociobiology in comparison to the group-level orientation of early ethology: If the level of selection *is not* the group and *not* the individual, but the genes, then altruism toward relatives is likely to occur. Hamilton's rule names the factors that make altruism in the animal realm likely to occur: If the costs of an altruistic act are smaller than the chances of reproduction of the same genes (these chances are dependent on the extent of relatedness between the altruist and the beneficiary), then selection should favor altruistic strategies (Hamilton, 1964). In this view, it is not important that the *individual* organism enhances *his own* fitness and reproductive success but that he increases the overall fitness of his *kin*, for many of his genes are also present in his kin. You can therefore foster the replication of your genes either directly or by helping your kin to reproduce.

The fact that altruism in the animal realm is indeed very often linked to kin and the fact that different social strategies (the astonishing social altruism of worker bees, for example) can be traced back to different mechanisms of inheritance indicates the great success of these theories in evolutionary biology. Insects of the group Hymenoptera, for example, are haplodiploid. This leads of course to different degrees of relatedness than in diploid species; therefore, it might for a worker bee be much more "rational" to invest in the offspring of the mother ($r = 3/4$) than in its own reproduction (Trivers & Hare, 1975).³ By shifting the focus in biology away from the idea that the individual is the unit of selection to the idea that the gene is the unit, many behavioral phenomena can be mathematically explained as a

natural outcome of selection. Altruism on the level of the organism must be traced back to "egoism" on the level of genes in order to solve the Darwinian paradox of altruism. Also, this leads to interesting biological research questions: If it is necessary to limit your altruism to kin, what mechanisms of kin-detection can we find? What different strategies apply to those species that are able to individually recognize conspecifics in comparison to those that can't? What possible counterstrategies can freeloaders find to break a rule of kinship detection? What could be possible refinements to counter the counterstrategy?

Given this view, one can, for example, ask what would be a good strategy of parental investment. Trivers (1972) and Maynard Smith (1977, 1982) regard the relation between the sexes as an "economic" enterprise: Both parties must try to invest as little as possible and try to gain the highest possible rate of replications of their own genes in this process. Because of the anisogamy, there is from the beginning an advantage on the male side; he brings 50% of his genes into the offspring, but he invests less than 50% of his energy in them, especially in those cases where conception takes place within the female. Therefore, in some fish, males are left behind in a cruel bind: The female fish can spawn the eggs some seconds earlier than the male fertilizes them, and can use this advantage to escape raising and protecting the young. The male fish must then decide whether to raise the offspring (defend the eggs) since he already made a parental investment, or whether to start a new investment. When conception takes place within the female, the advantage is at first sight on the male side.

Further interesting strategic questions can be asked: Should males be more cautious when investing in their offspring, because they are more insecure than females as to whether the offspring are in fact their own? Should parents invest more in healthy offspring, neglecting the weak ones? Is it in the interest of a "step parent" to kill his step sons, as we see with lions? Should sexual strategies differ fundamentally between the sexes? Does animal behavior in fact resemble these predictions? All these questions are useful tools and guidance for giving a truly evolutionary account of animal behavior, and the explanatory power—even if sometimes overstressed and even if many examples are still in debate—is impressive.

These two first steps, however, are limited to altruism to *kin*; they cannot explain cooperation or symbiotic relations that expand beyond kin. Altruism beyond kin can be interpreted as a malfunction of the kin-detection mechanism (e.g., in the case of cuckoo birds, who lay their eggs in the nests of other birds), but cooperation, altruism, sociality, and group living expand, in many cases in the animal realm, beyond the realm of close kin. The advantages of group living are obvious (for a discussion, see Lorenz, 1963), but again the freeloader problem emerges: For altruism of this level, the gene view must be left behind, and the focus must be set on insights from general game

theory (the theoretical analysis of successful strategies in different situations of competition).

Therefore, the third step to explain the necessary emergence of altruism in the Darwinian scenario of sociobiology is the idea of reciprocal altruism and the search for evolutionarily stable strategies (Axelrod, 1984; Axelrod & Dion, 1988; Axelrod & Hamilton, 1981; Trivers, 1971). The result of the empirical researches along this line was famously summarized in E. O. Wilson (1974, 1975). Hamilton's mathematical approach can in this way be further generalized if you regard the individual organism as a vehicle for executing selfish gene programs (Dawkins, 1976, 1982); then also other contingent facts in evolution might be explainable as consequences of the struggle of genes to maximize their frequency in the gene pool by finding the most successful strategy in balancing cooperation and defection.

An act of altruism among nonrelated organisms may in fact be likely if there is an act of retaliation. These considerations, however, lead to the well-known problems of strategic behavior that have been discussed for a long time in game theory and to the theory of the rational agent as noted above. Since there usually is a time span between the altruistic act and the act of reciprocity, it is tempting to defect. A betrayer naturally always gets the highest payoff: He receives the benefit from the altruistic act but does not bear the cost of reciprocation. This situation is known as *the prisoner's dilemma* in game theory: Both parties would be better off if they cooperate, both sides would individually profit more from defection (if the other cooperates), each side risks having the highest costs if it cooperates but the other side betrays it. If you assume that your aim is to maximize your profit, you will defect, and so should the other if he is a rational (strategic) agent.

How can cooperation among nonrelatives arise in a Darwinian scenario if there is always a higher possible payoff for betrayers? Trivers, Axelrod, and Hamilton have worked out mathematical models for these situations and searched for strategies that are sustainable, that is, strategies that will be able to evolve and survive in a Darwinian competition of strategies. The most striking example is the extraordinary success of the tit-for-tat strategy. For this mixed strategy, the choice for cooperation or defection depends on the other player. (Obviously, this strategy presupposes the ability to recognize individual players; it can therefore be applied only to certain species.) If the other one has cooperated in the last encounter, then you cooperate; if he has defected, you defect. Tit for tat is in many scenarios an evolutionarily stable strategy (Axelrod, 1984). Surprisingly, strategies that include cooperation might in many scenarios be much better off than pure egoistic strategies.

Due to the mathematical generality of this approach, it can also be used to describe cultural evolution in analogy to the biological situation. The theory of *memes* claims that "cultural units" (songs, ideas, theories, institutions—called

memes in analogy to genes) are also in competition for instantiation. Cultural history thus resembles a Darwinian scenario: Ideas or memes are more or less faithfully copied from generation to generation; better adapted memes out-compete others, and so forth. This extension of Darwinism can be understood in biological or in structural terms. Evolutionary psychology would emphasize the fitness of certain memes by pointing out that they fit with certain evolved biological traces of cognition: Memes that help the individual to gain a fitness advantage will be more likely to succeed. But this extension can also be interpreted in the strict sense of a structural analogy. Even if nonbiological entities such as robots had culture, cultural memes would have to be replicated, thereby being in competition for attention, and the mathematics of game theory and evolutionary biology would still apply. This view could stress the independence of meme evolution; memes are for Dawkins (1976) in a certain sense replicators *sui generis*. A meme might lead to a fitness disadvantage in the individual (the meme for celibacy or self-sacrifice) but can nevertheless be successful. It can, in Dawkins's terms, use the individual just like a vehicle, just like a gene can; it can therefore override or free humans from gene determinism, if only (in this view) to the price of meme-determinism (see also Blackmore, 1999). However, since memes must fit with brains as their environment, Dawkins and Blackmore stress the fact that memes are most likely selected if they increase and do not decrease the inclusive fitness of the individual.⁴

All these examples and considerations highlight the basic tenet of sociobiology: Seeking for egoistic advantages is seen as the natural outcome of evolution; however, since gene replication is the crucial goal, altruistic compromises may be possible or even necessary, but whenever the circumstances allow it, these compromises will be broken. This framework, however, can claim to be truly Darwinian and can give some good explanations both for altruism and egoism on the level of individual organisms, without demanding that altruism and cooperation must evolve *against* the laws and probabilities of natural selection. It is also clear that from this perspective, the interpretation of culture and humans in terms of adaptive, inclusive, fitness-maximizing behavior becomes an important key to understand human beings.

The Case for Nature: The Shift to Evolutionary Psychology

Evolutionary psychology shifts the focus from the sociobiological analysis of fitness-maximizing success of behavioral strategies to an inquiry about underlying evolved psychological mechanisms. Rather than finding out how far certain cultural behavior leads to increased inclusive fitness, the question is whether we can find basic psychological features in the human mind that might have been adaptive during the phase of hominization, especially in

the context of hunter-gather societies, even if they lead to disadvantageous behavior under modern circumstances. Tooby and Cosmides (1992) claim that in fact evolutionary psychology is thereby the missing link (Cosmides & Tooby, 1987) between biology and the social sciences: Society and culture are produced by humans, and humans are a product of biological evolution; thus, psychology links these fields. The program and basic tenets of this approach are summarized in Buss (1995) and Tooby and Cosmides (1992); the necessity of this shift after the dominance of sociobiology is argued in Barkow (1978, 1984).

Two developments in empirical sciences have led to the rise of evolutionary psychology. First, the conception of human cognition as a general-purpose computer has come under attack. Results from the analysis of the visual system, insights from the research on artificial intelligence, and studies on language acquisition suggest that cognition is a content-specific modular process. (For cognition in general, see Fodor, 1983.) Chomsky influentially attacked Skinner's view of learning as a general mechanism, leading to speculations about a special adaptation or an evolved module device for language acquisition (Chomsky, 1959, 1975, 1980; Pinker, 1984, 1994). Research on artificial intelligence stressed the idea that much more innate knowledge is needed for problem solving. To keep the computational possibilities reasonably small, artificial cognitive systems must already have implemented knowledge and biases. (For an overview over these, see Tooby and Cosmides, 1992, pp. 106 ff.)

Experiments with animals have further supported this idea of cognitive preparedness. A monkey raised in captivity can be trained (via a video tape showing a panic reaction to a snake by a conspecific) to show panic reaction to snakes; however, he cannot be trained to show this reaction to flowers (Mineka, Keir, & Price, 1980). Rats can learn avoidance only in a module-specific way: They can associate nausea with food and taste, shock with sounds and lights, but not vice versa (Garcia & Koelling, 1966). The facts that humans also learn certain things more easily than others, that all children are equipped to learn language, that they seem to have an innate physics (expectations about the behavior of objects), and so forth render the idea plausible that human cognition is in fact not all based on a reduction of instincts but relies heavily on instinctive knowledge, which can be recombined and generalized. Gould and Marler (1987) coined the phrase "learning by instinct," and Lorenz (1973) developed a complex account of the steps from animal to human cognition beyond the stimulus-response model, distinguishing between open and closed instinct programs. Not the reduction of innate programs but strongly relying on them makes learning possible. Accordingly, the human mind can no longer be conceptualized as a content free general-purpose computer (see Buller, 2005; Carruthers & Chamberlain, 2000; Carruthers, Laurence, & Stich, 2005).

Second, the idea of "human universals" has become more popular again, following the refutations of the claims

of Mead (see Freeman, 1983, and Gewertz, 1981), Whorf (see Malotki, 1983), and against the claim of the cultural dependence of the expression of emotions (see Ekman, 1973, 1992; Ekman & Friesen, 1986; Ekman, Sorenson, & Friesen, 1969; Ekman et al., 1987). Berlin and Kay (1969) discovered culturally independent ways of color classification. These results and new cross-cultural studies (summarized in Brown, 1991) led to the distinction of "innate evolved universals" with different cultural manifestations, in analogy to the genotype-phenotype distinction (see Cosmides & Tooby, 1989, Tooby & Cosmides, 1989a, 1989b, 1992). If one distinguishes innate universals from their local modes of expressions (their "display rules"), many differences seem to vanish. Culture may shape the *expressions* of certain universals, but the underlying cognitive mechanism might be the same in all humans (Brown, 1991).

These developments strengthened the research program of evolutionary psychology: Just as the study of the human visual system reveals a marvelous and complex computational and highly specific adaptive structure (Marr, 1982), might it not be plausible to search for complex information processing modules or "mental organs" (Chomsky, 1975, 1980) in the human mind that have been selected as solutions to recurring adaptive problems such as finding mates, detecting kin, and so forth? (For an overview, see Tooby & Cosmides, 1992, pp. 101 ff.) The questions that are asked in this approach are the following: What are the adaptive problems that humans faced during the phase of hunter-gather societies? What cognitive information processes could have been implemented by evolution into human cognition? Does human cognition show traces of this kind of adaptation? Symons (1979), Buss (1994), and Miller (2000) asked these questions concerning human sexuality, mating strategies, and gender roles. Pinker (1984, 1994) pursued this inquiry for the evolution of language. Even questions of aesthetic taste and moral judgments, prejudices, and preferences can be addressed in the same fashion. (See the selection of essays and topics in Barkow, Cosmides, & Tooby, 1992, and see Buss, 1999, 2005, and Buller, 2005.)

The difference with the sociobiological approach, again, is that the question is not whether these mental organs or domain-specific cognitive mechanisms are adaptive today but whether they were adaptive during the course of human evolution. The difference between this and the standard social sciences model (Tooby & Cosmides, 1992) is the search for a universal human nature beyond the cultural differences.

Conclusion and Future Directions

The view of nature and nurture in sociobiology and evolutionary psychology is and will remain a controversial issue within science. Since almost all fields of human

activity can be situated in relation to the nature-nurture distinction, it is not possible to even try to give an overview of the state of the art of ongoing discussions in the fields of human intelligence, aggression, emotions, gender roles, life history, evolutionary esthetics, ethics, cognitive sciences, and so forth.

However, while most of the empirical insights of evolutionary psychology and sociobiology in all the named fields cannot be ignored, their importance and fruitfulness for a full-fledged understanding of human nature has to be evaluated on a case by case basis (Kitcher, 1985). There is no clear method to give a precise and general account of what in humans is mere nature and what can be attributed to mere nurture. Furthermore, all the important debates within the framework of Darwinism that have been mentioned affect the relevance and shape of sociobiological insights into human nature. Two important avenues for criticism can, however, be highlighted.

First, after a strong emphasis on the possibilities of biological reductionism, a countertendency can be observed that puts humans again away from a biological or genetic determination (Lewontin, Rose, & Kamin, 1984). “Gene-determinism” has come under attack from both social scientists and biologists. Alternative theories to explain eusociality have been proposed, and it might even be necessary to “rethink the theoretical foundation of sociobiology,” as Edward O. Wilson himself put it (Wilson & Wilson, 2007, p. 327). New theories suggest that it is a complex interplay of environment, development, and selection at the gene level, the individual level, and even at the group or cultural level that shapes evolution (Jablonka & Lamb, 2005; Kerr & Godfrey-Smith, 2002; Okasha, 2006; Wilson & Wilson, 2007). These new multilevel approaches render a monocausal view more and more implausible; thereby, they also try to leave the dualistic nature-nurture divide and gene determinism behind (Lewontin et al., 1984; Oyama, 2000). If some of these theories can be sustained, then it might also be false to view culture as a mere evoked manifestation, because it is then itself a causal factor, as it is expressed in the theories about gene-culture coevolution or dual inheritance (see Boyd & Richerson, 1985; Lumsden & Wilson, 1981; Richerson & Boyd, 2005). Due to the fact that the first cultural exchanges in human history took place a very long time ago, it is further likely to assume that human nature has in part been shaped by human culture and that a causal interdependence or coevolution was in fact crucial in the evolution of mankind (see also Geertz, 1973, Chapters 2 and 3).

Second, we see along these lines the revival of the basic ideas of the nature-requires-nurture theorem: Human nature may not be driven by the reduction of instincts, but it is still a plausible possibility that evolution itself has brought forward peculiar features in human nature, leading to a take-off of cultural evolution. Humans’ ability to frame a complex theory of mind, to engage in an explicit “we-intentionality” (Searle, 1983) of doing things intentionally

and jointly together, might be a special ability that enables cultural evolution, as comparative studies of human and primate cognition seem to suggest (Tomasello, 1999; Tomasello et al., 2005). It is plausible to assume that social cognition and the challenges of group life, along with the extension of the human brain—the neoteny and so forth—gave rise to the peculiar human (growing) dependence on culture. It may well be that in fact a special ultrasociality or special tribal instincts fostered the shift to cultural evolution (see Richerson & Boyd, 2005). These approaches emphasize again the very special *social* or *altruistic* nature of humans, thereby distancing themselves from the selfish gene view (see also Sober & Wilson, 1998).⁵ To identify those uniquely human traits that enable the uniquely human cultural process *and* explain how these peculiar traits might have evolved, given the logic of selection, is one of the most important tasks for future research.

Cultural evolution might then, nevertheless, be spelled out according to a Darwinian logic (analogous or biocentric), but it is clear that cultural evolution resembles what is in fact a much more Lamarckian process: Acquired knowledge of individuals can be faithfully transmitted and become perfected over generations in an accumulative process (a “ratchet effect”), different traditions can be combined, new ideas can be brought forward not by chance of random mutations but through thoughtful guesses and intentional advancement, and human technology might free us more and more from a competition for survival. All of these factors allow a much faster evolution than biological evolution (Tomasello, 1999).

However, it remains true that shifting the power away from genes to a somewhat more autonomous understanding of cultural evolution is not in itself a claim for any autonomy of human behavior. Cultural determinism might be a dubious view just as biological determinism is. Only a theory that incorporates the peculiar ability of humans to follow and question reasons, to live out and to distance themselves from their own drives, preferences, prejudices, influences and predeterminations, might be compatible with the fact that sociobiology, evolutionary psychology, cultural determinism, and so forth are themselves theories—theories that appeal to us because they might be true and convincing, and because we might be able to follow their reasoning.

Notes

1. Gehlen relies on the biological studies of Portmann (1942).
2. Gehlen, however, does not want to attribute the reduction of instincts to natural selection or evolution.
3. New theories are critical toward this explanation, and alternative reasons for this kind of eusociality have been proposed, see especially Wilson and Hölldobler (2005) and Wilson and Wilson (2007).
4. For an overview of the meme debate, see Aunger (2000). A recent critical assessment of common assumptions in relation

to the meme approach and cultural evolution in general can be found in Henrich, Boyd, and Richerson (2008).

5. Eldakar and Wilson (2008) give an account of cases where selfishness can be understood as second-order altruism, thereby reversing Dawkins's view. Against Dawkins's view, it can in general be stressed that the metaphor of selfishness is misleading: Genes are self-replicating entities; if they "care for themselves," they do in fact (have to) care for *other instances* of themselves. If like egoists, they only "cared for" their own instantiations in one specific vehicle, they would disappear. Therefore, they are, metaphorically speaking, not egoists but more like "coterie altruists": They have to care for others of their kind, just like a decent altruist should in fact care more for other altruists than for egoists (see Hösle, 2004).

PSYCHOLOGY AND ANTHROPOLOGY

JACOB R. HICKMAN

University of Chicago

Researchers doing work at the intersection of anthropological and psychological phenomena often bemoan the fact that anthropology and psychology are by and large considered separate and distinct disciplines. There are certainly distinct theoretical and methodological differences between what might be considered the prototypical work that mainstream psychologists and anthropologists do, such as controlled laboratory experiments versus ethnographic participant observation. However, historically this has not always been the case, and some contemporary researchers bridge this divide in several interdisciplinary fields that seek to account for both cultural and psychological influences in the mental worlds of people.

While space does not permit a complete overview of even these interdisciplinary efforts to integrate research on cultural and psychological phenomena, this chapter will discuss a few of the key figures and movements in the historical relationship between psychology and anthropology as disciplines, as well as some work that has transgressed these disciplinary divisions. Further, some key theoretical, methodological, and epistemological tendencies in mainstream psychology and mainstream anthropology will be discussed, with particular attention given to differences that have contributed to fragmentation and mutual critique between the two disciplines. Several interdisciplinary fields in which researchers seek to bridge these differences will then be discussed, followed by a summary of some

examples of the main areas of human life and mental function where researchers who are concerned with both mental and cultural phenomena are doing their work. Finally, some future directions for integrated research in psychology and anthropology will be laid out.

This summary cannot account for all of the variations in either discipline, and there will most certainly be areas of each discipline that contradict the summary characterizations made here. This account is not designed to represent either discipline in its totality or to characterize psychological or anthropological research agendas in their entirety, but more to point to general trends in the mainstreams and interstices of these two disciplines that are clearly observable. The references cited and further readings list at the end of this chapter, including the literatures cited by those sources, should be consulted for further consideration of psychology and anthropology as separate disciplines, as well as the interdisciplinary fields that engage both.

A Brief History of Psychology and Anthropology

Before the canonization of psychology and anthropology into separate disciplines, social theorists in the late 19th and early 20th centuries had all things both psychological and cultural on the table in their work. During the latter

half of the 19th century, for example, unilinear cultural evolution was a primary paradigm among theorists that anthropologists claim as intellectual ancestors, namely Lewis Henry Morgan, Edward Burnett Tylor, and James Frazer. (See the entries on Culture Change and Social Evolution in this volume for a complete summary of this paradigm.) Chief among their theories was the notion of “the psychic unity of mankind,” an idea propagated by Adolf Bastian, a founding figure in German anthropology (Köpping, 1983/2005). The basic premise of psychic unity is that all humans have the same basic psychological structure, makeup, or evolutionary potential. (For a more comprehensive history of the meanings and assumptions underlying psychic unity as it relates to both anthropology and psychology, see Shore, 1996, Chapter 1.)

Importantly, for the cultural evolutionists, this characteristic made all human societies comparable for placing them on an evolutionary scale from primitive to modern. Without psychic unity, cultural evolution as a framework would dissolve into simple biological differences, and no framework beyond Darwinian evolution would be necessary to explain differences between societies. For cultural evolutionists, however, psychic unity did not equate to cultural relativism. On the contrary, it meant that all humans had the same cultural or psychological (one could argue that these were equated in this framework) evolutionary *potential* but that this potential was realized to differing degrees in differing societies. Thus, industrial societies (i.e., the “West”) were more culturally and psychically evolved than hunter-gatherer societies. However, these more “primitive” societies were seen as having the potential to evolve through the same evolutionary phases as more “advanced” societies, in order to realize the same psychic potential that industrialized peoples were said to have under this framework.

The cultural relativist turn among anthropological theorists in the early 20th century disregarded this evolutionary take on psychic unity for a more relativizing perspective. In *The Mind of Primitive Man*, Franz Boas (1911) argued against the scientific racism inherent in cultural evolutionary approaches. Importantly, during this period and even preceding it, there is no firm line drawn between “mind” and “culture” for these theorists. A modern-day reading of *The Mind of Primitive Man*, for example, leaves one wondering where the psychological content is, but one is left to realize that, for Boas, mind and the cultural milieu are not easily extracted from one another and in fact form elements of the same phenomenon. Similarly, for unilinear evolutionists, cultural practice was conceptualized as indicative of the more-or-less evolved underlying psychic conditions of members in a given society.

Thus, up until the late 19th and early 20th centuries, and even afterward, many of the major figures concerned with both culture and psychology did not necessarily separate the two into different domains for research. Certainly, until this point, there existed no institutional

structures to separate them. For example, Franz Boas, who established the first department of anthropology in the United States in 1896 at Columbia University and is widely considered a founding figure of American anthropology, had prior training and taught alongside psychologists. Boas was a student of Wilhelm Wundt, a figure claimed by modern psychologists as a founding figure of their discipline and the developer of the first psychological laboratory. Wundt was also interested in folk psychology (see below), and among his students were both Boas and Bronislaw Malinowski, another important early figure in both American and British anthropology (Mattingly, Lutkehaus, & Throop, 2008). Further, one of Boas’s early academic jobs was in the anthropology division of G. Stanley Hall’s psychology department at Clark University (LeVine, 2007). Hall founded the American Psychological Association and was a key figure in shaping the discipline in America. Briefly, among foundational figures in both psychology and anthropology as modern-day disciplines, there was a significant interchange of ideas, and the institutional and disciplinary boundaries observed in the present day were of little or no issue.

Disciplinary Fragmentation

Shortly after Boas established the first anthropology department in the United States and helped found the American Anthropological Association, the discipline began to take root in its modern institutional form, including the four-field approach (i.e., emphases on the teaching of biological anthropology, archaeology, sociocultural anthropology, and linguistic anthropology). For its part, psychology in the 19th century was not clearly delineated from philosophy or even medicine, but it also began to separate and become a distinct academic discipline in the early 20th century. Originally, this disciplinary fragmentation did not preclude productive research that crossed these disciplinary lines. Some of the founding figures of American anthropology continued to engage psychological theories and research psychological topics within their newly formed discipline (e.g., Benedict, 1934; Malinowski, 1927). Formative figures in psychology also continued to see culture as an essential consideration in their theorizing and empirical work.

However, throughout the course of the 20th century, one could argue that the centers of each discipline drifted away from one another, both theoretically and methodologically, pushing the work that sought to integrate cultural and psychological phenomena further into the peripheries of each discipline. This continued until a recent, reinvigorated interest in the intersection of psychology and anthropology (Cole, 1996; Shweder, 1990) led to increased activity and recognition of the interdisciplinary fields that focus on both culture and psyche in a holistic research agenda. The future looks bright for these interdisciplinary endeavors, but before discussing them, it is important first to outline

some of the different orientations that resulted from the increased factionalization of psychology and anthropology over the course of the 20th century.

Theoretical Orientations and Explanations

In contemporary psychology and anthropology, each discipline's mainstream has come to adopt distinct theoretical orientations for the explanation of human behavior and the human condition, and these divergent orientations have led to mutual critique. Note that the description that follows temporarily sidelines the interdisciplinary efforts that are designed specifically to either overcome or answer these mutual critiques, in an effort to draw out in high relief the different types of scientific and social explanations that tend to be offered in each discipline. These interdisciplinary efforts and their work will be discussed subsequently.

Centrality of Individual Psyches

Brent Slife and his colleagues have written extensively on the taken-for-granted assumptions in contemporary psychology in order to analyze the theoretical approaches in the field and offer alternatives to the normative stances. Their work is useful in understanding how these assumptions vary from those normative assumptions that one might find among anthropologists. Perhaps one of the most relevant analyses in this comparison is what Slife terms *atomism* (Slife, 2004). Atomism can be applied to separate levels of psychological analysis, from individuals to individual constructs, but for present purposes one could say that atomism assumes that individuals are akin to hermetically sealed units, self-functioning and self-contained. In other words, under this assumption, an individual's psyche is perceived to be a self-contained unit that can be studied under a microscope, as it were, by itself, in order to discover its nature. This assumption makes the context in which the psyche develops or operates from day to day less important, since the psyche is perceived to *contain* all of the necessary characteristics or attributes worthy of its investigation. Thus, the individual becomes the primary unit of analysis for mainstream psychology.

This assumption becomes clear in a consideration of prominent Western psychological conceptions of personality. The "big five" personality enterprise (see Goldberg, 1993, for a summary and history of the development of this model of personality), for example, is built around the notion of five salient factors that are said to be descriptive at the highest level of personality traits located in individual psyches. Since the emergence and psychometric validation of this model, much psychological research has been devoted to explaining individual psychological differences in many domains and how these variations relate to these personality traits, including the advocating of job

selection and training according to individual personality profiles (Goldberg, 1993). Importantly, this entire conception rests on the explanatory value of individual psyches and their "content." The way that culture often factors into these explanations is on the order of affecting the personality trait outcomes in individuals. Within such a framework and in mainstream psychology in general, culture is primarily conceived of as an explanatory variable for individual psychological variation. This can be juxtaposed to the conceptions of culture in anthropology, as well as the interdisciplinary efforts to integrate psychological and cultural phenomena in research agendas (see below). Suffice it to say that the assumption of atomism and the resulting conception of individuals as hermetically sealed psychic units to be either explained or used as explanatory variables results in a quite different theoretical enterprise than when culture is taken as the primary object of study.

A second important aspect of theoretical work in psychology regards the importance of psychological constructs. A construct is an unobservable entity that is presumed to exist within an individual psyche and that gives rise to observable phenomena, such as behavior. An example would be depression. One cannot directly observe depression, but one can observe the behavioral outcomes of this theoretical construct (e.g., crying, sad facial expressions, etc.). Given the theoretical centrality of individual psyches, different subdisciplines of psychology have built up research enterprises around studying the theoretical constructs in the psyche. The five factors of the big five model are examples. Great effort is devoted to developing psychometric instruments that use information from the supposed observable effects of these constructs in order to test for their salience, nature, or even theoretical existence. Measures of these constructs are often used to predict behaviors or the strength of other constructs.

Centrality of Culture as an Explanatory Framework

Anthropologists have historically been much less concerned with individual variation but instead have focused on collective differences at the level of a society, group, or subculture. Ever since the time of Boas, fighting scientific as well as banal racism and propagating cultural relativism have been central projects of the anthropological discipline. When translated to theoretical work, this project has often been directed toward taking the findings of other social scientists, or even everyday common sense in Western society, and delivering rich ethnographic detail to show how groups vary (or occasionally how they are similar) on different dimensions, given their cultural milieus. Some prominent examples include Margaret Mead's argument that the social dimensions of the sexual tension and upheaval of adolescents perceived to be universal in the West are not necessarily the case among Samoan adolescents (Mead, 1928/1964). While the ethnographic validity

of this project (her first significant fieldwork) has been questioned, the argument was influential and contributed significantly to this anthropological project of relativizing scientific universalizations derived from Western cultural contexts. Importantly, as compared to normative research among psychologists, the unit of analysis here becomes a group; it is larger than one individual.

Clifford Geertz remarked that psychologism, or psychological reductionism, is one of two “great saboteur[s] of cultural analysis,” along with logicism (Geertz, 1973, p. 405). By this, he means to argue that the reduction of all human phenomena to some addition of individual psychological processes misses a fundamental point. Geertz makes the case that psychologism overlooks the entire world of meaning that predates such individuals and that shapes and gives interpretive tools for the psychological experience of individuals. Thus, Geertz’s realm of analysis is meta-individualistic and is particularly critical of the universalizing explanations offered by psychologists that place an individual psyche at the center of explanatory or predictive models. Geertz seeks to replace the prospect of psychological reductionism with what he terms the “scientific phenomenology of culture.” While Geertz’s analytic material and observations certainly contain what psychologists might label as psychological content, his emphasis is on the process of meaning-making at a level that extends what goes on in individual minds.

Specifically, in his essay “Person, Time, and Conduct in Bali” (1973), Geertz argues that thought is inherently social. In other words, a system of meaning-making must presuppose the interpretation that is engaged by individuals. It is this system of meaning-making—the culture that resides outside of individual minds and in the social interstices of human life (Shore, 1996)—that Geertz took as his object of study. In this essay, he goes on to delineate the rules of naming and keeping time in Bali. Using these ethnographic data, he argues that Balinese conceptions of the person and, indeed, time itself are fundamentally distinct from the corollary Western concepts, which are often held as universal by philosophers and psychologists. The psychological worlds of the Balinese are thus affected, as they see time, for instance, in more qualitative than quantitative terms (i.e., “what kind of time it is” as opposed to “what time it is,” respectively). Compared to the aforementioned psychological emphasis on how individual psychological constructs drive behavioral outcomes, the tension in theoretical orientations between mainstream psychology and anthropology becomes clearer.

Positivism and Antipositivism

Again, these comparisons certainly cannot account for the variation in approaches and dispositions of variegated theorists in either psychology or anthropology but are designed to point the reader to some trends among prototypical work in each field and some significant differences

between these disciplines. Another significant difference that merits pointing out regards orientations toward positivism. Without consciously doing so, many psychologists tend to see their discipline in more positivistic terms. Importantly, the term would rarely be used among researchers of similar orientations in the nature of science. When referring to *positivism* in this context, one might say that psychological research is generally considered to contribute to additive knowledge toward the supposed end of a complete understanding of the individual psyche, thus conceiving the psychological discipline(s) as a positive science working toward an end of some final or complete truth of their object of study.

While there is certainly wide disagreement among anthropologists on this point, many recent theoretical strains in the discipline have come to use the terms *positivism* and *positivists* in degrading terms, understood by these postmodern critiques to be indicative of some sort of modernist naïveté. This mode of critique is particularly typical of postmodern or poststructural camps in anthropology, and generally it might favor a more socially or culturally constructed view of scientific truth, in which science itself is seen as a cultural endeavor in the most extreme sense. This point is important because of the extent to which interdisciplinary critiques between psychologists and anthropologists focus on the scientific value of each other’s work or question that category in the first place. As a natural response, psychologists, who tend to see their discipline more as an additive or positive science, argue that these modes of analysis are rather unscientific and do not contribute to the greater understanding of human life. This point leads to the next important comparison between these disciplines: epistemological approaches.

Differing Epistemologies and Methodological Approaches

Generalizability Versus Deep Understanding

The normative epistemological approaches between anthropologists and psychologists during the 20th century have led to the development of vastly different sets of methods for each discipline. At least to some extent, the differing objects of inquiry in theoretical underpinnings, as outlined above, have driven these epistemological differences, but certainly do not account for the entirety of their divergence.

Most university psychology departments offer methodological training to students in the form of statistical techniques and psychometric measurements. Anthropology departments, on the other hand, tend to stress the importance of in-depth fieldwork, which typically consists of extensive interviewing, observation, linguistic analysis, or archival research. At the heart of this divergence is the

question of how one can “know” one’s subject, be it a cultural system or the nature of the human psyche. Anthropologists tend to argue that depth is the important factor in figuring out the important aspects of one’s research context. This depth tends to be qualitative in nature (see below) and is generally focused on tracking the phenomenon that is of interest instead of taking more superficial observations that might be generalized to some sampled population. This is certainly not the case for all anthropologists and has varied widely throughout the history of the discipline. Indeed, many prominent anthropologists in the 20th century were primarily concerned with quantitative techniques and sampling issues, but the trend at the moment favors other forms of knowing.

Geertz’s oft-quoted term *thick description* (Geertz, 1973) is commonly mobilized to describe the dominant methodological field among anthropologists. By thick description, Geertz meant the extensive documentation of cultural milieus themselves and coming to understand local symbols and phenomena on their own terms and in their own contexts. The object of this form of cultural analysis is to come as close as possible to seeing these symbols through the eyes of members of the community that deal in them, thus enabling the ethnographer to comment comparatively (given one’s native worldview) on them and their significance. Embedded fieldwork has become a hallmark of anthropology. Indeed, it is often seen as essential to anthropology’s identity as an academic discipline. Cultural relativism, as a principle, is partially responsible for this, as early anthropologists sought to refute or at least overcome supposedly superficial observations of armchair anthropologists of the late 19th century, whose accounts were largely based on the reports of missionaries who encountered various peoples around the world. Cultural relativism became important for refuting evolutionary or simply ethnocentric claims about universal humanity, and embedded fieldwork provided the deep perspectives and data to engage in that effort. Briefly, given assumptions of cultural specificity, in order to truly understand local variations in all their idiosyncrasies and permutations, one must become immersed in the cultural contexts in order to be a subject of one’s own analysis.

Psychologists, for their part, have historically largely assumed that, despite cultural superficialities, the psychological structures and processes of all humanity are universal (Shweder, 1990). This assumption, coupled with that of naturalism (Slife, 2004), has led to an epistemology quite distinct from anthropology’s hallmark of qualitative fieldwork. Instead, psychologists have historically favored the testing of psychological phenomena across populations in order to derive generalizations about psychological processes that are assumed to permeate those populations. Methods developed toward this end have been largely quantitative in nature, such that assertions made about samples could theoretically be generalized to embrace entire populations from which samples are drawn.

With regard to psychological constructs, population distributions of constructs and developing quantitative techniques of measuring the existence and correlation of constructs with other phenomena have been central. Ideally, sampling is an essential consideration in this epistemology, but practical concerns sometimes outweigh this importance. Those outside the subdiscipline often levy the criticism that social psychological theories tend to overproject the psychodynamics of undergraduate psychology students to the entire population, as this is certainly the most studied group in this line of research, given their availability for research participation in academe. Even considering sampling limitations, however, the important distinction with regard to epistemological comparison regards the anthropologist’s ethnographic emphasis on deep local knowledge, in contrast to the typical psychologist’s interest in quantitatively deriving the nature of a psychological construct or its relationship to a behavior or characteristic of personality.

Conceptions of Culture

Interpenetrating both the epistemological and theoretical differences outlined here are the varying conceptions of culture in each discipline. It is certainly not the case that all or even most anthropologists have arrived at a consensus on the nature of culture. In fact, the culture concept has been at the center of the discipline’s most intense debates. (See the “Concept of Culture” entry in this reference handbook.) Psychologists, for their part, have not historically engaged in the philosophical arguments surrounding the nature of culture to any comparable extent. However, this is not to say that one cannot point to systematic differences in the ways that psychologists and anthropologists have treated culture in their work, whether or not the assumptions about the nature of culture are explicit in such work.

As outlined above, prominent anthropologists such as Geertz have strongly advocated that culture is not something that resides in the heads of people but rather in the interstitial social spaces where people live and interact. He famously remarked,

The concept of culture I espouse . . . is essentially a semiotic one. Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning. (Geertz, 1973, p. 5)

One might well say that the “experimental science in search of law” refers to, among other things, the psychological sciences that tend to operate under the assumptions of naturalism (Slife, 2004).

Not all psychologists are concerned with cultural phenomena or testing their theories in various cultural milieus.

However, for those that do take culture into account, such as the subdiscipline of cross-cultural psychology (see below), the assumption of psychic unity writ large reigns (Shweder, 1990). In other words, it is largely assumed that humans are all basically the same type of psychological beings, but that cross-cultural work should be dedicated to uncovering or revealing the cultural variation in certain constructs. The deep psychological structure, however, is perceived to remain universal across all peoples (Shweder, 1984). In much of the psychological research where culture factors into the models, it is often seen (or at least treated) as one of many variables in a person's psychological profile, much like gender or age. Thus, it can be codified and worked into a regression or correlation model of the psychological construct or phenomena of interest. In this way, as many anthropologists tend to argue, culture is reduced to near insignificance, and the entire point is missed. For Geertzian anthropologists, the webs of meaning that constitute a cultural context are the very phenomena of interest, and they cannot be simply reduced to a variable in a statistical model. Instead, such a context must be treated as the very means through which psychological worlds are enabled to exist. Thus, anthropologists tend to have a much deeper and richer sense of culture per se, or at least a more substantive debate on the topic, and these different disciplinary orientations certainly drive the different epistemological approaches outlined above.

It is also important to note that a similar debate wages around the topic of individual psychological variation. On this topic, psychologists certainly have a more rigorous and developed methodology for dealing with population distributions and individual deviations from the norm. However, these methods are largely quantitative, except perhaps in certain domains of clinical psychology. Thus, psychologists might criticize anthropologists for overemphasizing norms and not paying significant attention to variations.

Interdisciplinary Fields of Relevance

Despite the above outlined mainstream trends and comparisons of psychological and anthropological approaches to understanding human life, several important interdisciplinary fields have emerged at the intersection of psychological and anthropological research. Each of these various subfields has a slightly different focus, but they share the effort to integrate cultural explanation and meaning with the psychological dynamics of individuals. What follows is a brief description of each field and how they relate to one another. It is important to note that many of the mutual critiques and incompatibilities outlined above are the precise obstacles that researchers in the following fields often strive to overcome in order to develop a more holistic model of both mind and culture. While this description seeks to classify some of

the interdisciplinary approaches into different areas of emphasis, these divisions are not hard and fast, and much research might extend beyond the boundaries of categories laid out below. Indeed, the point here is not to draw boundaries around the different subfields, but rather to signal some of the important trends at the nexus of psychological and anthropological research.

Cultural Psychology

In an essay designed to clear the field and set an agenda for the (re-)emerging discipline of *cultural psychology*, Richard Shweder describes his take on the historical development of the field as well as many of its distinctions from other, related fields (Shweder, 1990). In this essay, Shweder argues specifically for a model of people and culture that inextricably links them together, so that it is impossible to ferret out the person and the cultural context into separate, distinct, independent, and dependent variables. Instead, Shweder argues that cultural psychology takes an integrated, holistic view of culture and mind where, in fact, these two categories are impossible in the absence of the other. In this view, culture penetrates mind, and vice versa, to the extent that, in Shweder's terms, "You can't take the stuff out of the psyche, and you can't take the psyche out of the stuff" (Shweder, 1990, p. 22). In other words, this approach to the person and his or her cultural context must take account of the dynamics of both in order to understand either.

This theoretical model has led to some methodological preferences in the field as well. But, as in many interdisciplinary fields, the range of methods spans the gamut of quantitative and qualitative, psychometric and ethnographic methods. Ethnography and a deep understanding of ethnographic context are essential in this approach, which has certainly been influenced by Geertz and his conception of culture. Some cultural psychologists, on the other hand, use more traditional psychological techniques, informed by ethnography. (See, for example, Markus & Kitayama, 1991, including many of the cultural psychological studies they cite.)

In addition to utilizing methods from general psychology and anthropology, many working in this discipline have also developed new techniques designed to investigate the interpenetrating nature of culture and psyche, such as person-centered ethnography and interviewing (Hollan, 2001; Levy & Hollan, 1998). Epistemologically, cultural psychologists tend to be less dedicated to particular methods in an a priori basis but tend to value the approach of any method, qualitative or quantitative, that allows the researcher to investigate psychological and cultural dynamics without the types of reductionism (both cultural and psychological) outlined above. Given this conception of the psyche's coconstitution with the cultural world it inhabits, this orientation would include both sides of the theoretical and epistemological critiques outlined in the sections above, leveled

at both mainstream psychology and anthropology. An overemphasis of the individual psyche at the expense of cultural context, as well as a focus on the context itself without significant regard to the mentalities of those inhabiting the context, are equally seen as partial and inadequate from this point of view. To be clear, it is not the case that all researchers working in the field of cultural psychology have derived an epistemological or methodological consensus. In fact, Shweder points out that this is an important arena for future debate in the field (Shweder, 1990).

Psychological Anthropology

One caveat to these descriptions is that much of the contemporary work being done under the umbrella of *psychological anthropology* would actually fit Shweder's classification of cultural psychology (Schweder, 1990), and not all or even most scholars have taken to his classification of the field as such. This cultural psychology–psychological anthropology distinction is one particular area where these classifications of subdisciplines are rather nebulous. In Shweder's description, "classical" psychological anthropology is constituted by the work of people such as Ruth Benedict (Benedict, 1934, 1946) and others of the "culture and personality" school. He points to developments in cultural psychology as an important break with this classical school, particularly with regard to the assumption of psychic unity. However, many contemporary researchers at the nexus of anthropology and psychology use the term *psychological anthropology* to classify their own work, even if it meets the criteria laid out above. Further, the term *psychological anthropology* tends to be more inclusive than Shweder's and others' delineation of cultural psychology. Indeed, one of the more significant professional organizations for this type of multidisciplinary work is the Society for Psychological Anthropology, a section of the American Anthropological Association. As a result, this classificatory title may be said to encompass the work in anthropology that has psychological ramifications, but perhaps it does not fit under the banner of cultural psychology. As such, ethnography tends to be more central and indispensable for psychological anthropologists than it is for cultural psychologists, particularly in comparison to those who might solely claim cultural psychology but not also psychological anthropology as their discipline.

Beyond what overlap psychological anthropology has with the previously outlined cultural psychology, this field tends to be considered inclusive of several subfields in anthropology, such as cognitive anthropology, psychoanalytic anthropology, and ethnopsychology.

Cognitive Anthropology

Roy D'Andrade defines *cognitive anthropology* in its simplest terms as "the study of the relation between

human society and human thought," particularly with regard to "the objects and events which make up their world, including everything from physical objects like wild plants to abstract events like social justice" (D'Andrade, 1995, p. 1). While on the surface this may seem to coincide with the general emphasis of psychological anthropology or cultural psychology, the emphasis here is on thought. Similar to the emphasis in cognitive psychology on thought processes such as memory or learning, the emphasis in cognitive anthropology is on the thought content in various cultural contexts and on understanding how culture shapes these thought processes. The domain of cognitive anthropology can thus be seen as a subset of psychological anthropology.

A central concept in cognitive anthropology is the notion of a *cultural model*, sometimes also referred to in psychological terms as a *schema*. The basic idea behind a cultural model is the collection of knowledge about a topic in a form that is intersubjectively shared among a group of people, although the group need not be explicitly recognized as such (D'Andrade, 1990). These models organize cultural information, such as what constitutes a goal in soccer, a good person, or a shamanic ritual. Bradd Shore argues that this concept is useful for anthropologists in overcoming some of the debates surrounding the nature of culture and the recent poststructural relegations of culture to the ambiguity of "power" and "discourse" (Shore, 1996). Shore presents a more extensive theorization of cultural models toward this end.

Psychoanalytic Anthropology

Psychoanalysis influenced early anthropologists, particularly those identified with the history of *psychological anthropology*, although the modern field of psychoanalytic anthropology did not solidify as such until the 1960s (LeVine, 2001). Some prominent earlier works did engage psychoanalytic theories in fieldwork, however. A notable example is Bronislaw Malinowski's *Sex and Repression in Savage Society* (1927). As psychoanalytic theory was gaining ground in society, Malinowski challenged the presumed universal nature of the Oedipus complex, using his ethnographic account of family life in the Trobriand Islands. Importantly, Malinowski did not completely reject psychoanalytic theory on this point, but instead proposed a culturally specific, parallel nuclear complex with similar psychodynamics as the Oedipal complex proposed by Sigmund Freud and his colleagues.

More recently, Anne Parsons carried out a similar effort in proposing a "Madonna complex" in southern Italy as another, culturally specific alternative nuclear family complex (Parsons, 1964). Melford Spiro, an ardent critic of cultural relativism, argues against both Malinowski and Parsons in favor of the universal Oedipal model (Spiro, 1982). Spiro has extended psychoanalytic theory

to functional analyses of his ethnographic data in Burma as well, arguing that the special place of monks in Burmese society provides an acceptable outlet for what might otherwise be dysfunctional psychodynamic problems of the people that fill those roles (Spiro, 1965). These few examples illustrate but a few of the many inroads that anthropologists have found for integrating, critiquing, or adapting psychoanalytic theory and ethnographic accounts.

Ethnopsychology and Folk Psychology

Two related fields, *ethnopsychology* and *folk psychology*, constitute efforts to derive emic theories about psychological function or how people operate in different societies. These are to be contrasted with the etic theories developed by outsiders to the cultural group of interest. Linguistic data are commonly used in order to gain insight into the (often latent) models of psychological function within a given group, such as moral development, emotional socialization, interpersonal interaction, and so forth. As a brief example, Catherine Lutz used linguistic and ethnographic insight to reveal the Ifaluk model of both the everyday function and the development of emotion (Lutz, 1983). This emic model is important for Lutz's work; if the ethnopsychological model is made apparent, then one can gain deeper insights into the process of socialization among those who ascribe to the model. Notice the affinity of this approach to the emphasis on cultural models by cognitive anthropologists.

Psychiatric and Medical Anthropology

One large area of research with psychological import, which has gained a lot of ground and grown recently, regards comparative cultural research on mental health. Researchers working on this and related topics find themselves straddling medical and psychological anthropology, and some refer to their field as *psychiatric anthropology*. The important distinction between this vast research agenda and other areas of psychological anthropology regards its focus on the cultural construction, labeling, and means of dealing with mental illness. However, it is construed in different contexts. Some researchers in this domain also integrate psychoanalytic perspectives and many even gain training as mental health care providers as a gateway to understanding the process of mental health treatment ethnographically (Luhmann, 2000).

Cross-Cultural Psychology

The previously delineated category of cultural psychology is designed to be inclusive of research being conducted from a psychological frame of reference that also ascribes to a notion of the person and culture as interpenetrating

one another and to a need for ethnographically informed research in order to gain an understanding of both the context and the happenings of the mind. However, there is certainly much work being done in psychology that deals explicitly with cultural variation (or lack thereof) in the various phenomena of study, without necessarily ascribing to this particular model of the person-in-context/context-in-person. Much of this would be considered *cross-cultural psychology*. The essential distinction that Shweder makes between cultural and cross-cultural psychology regards the tendency of both to assume psychic unity, albeit at varying levels. Examples of this work abound and often take the form of developing a psychometric technique, such as the big five personality inventory mentioned above, performing a translation of the inventory into another language, and conducting the necessary psychometric techniques (e.g., factor analysis) to validate the measure in the target culture. The objective is to develop psychometric measures that are presumed to measure the same constructs in different linguistic and cultural communities, in order to study the geographic distribution of these constructs, be it personality factors or depression or self-esteem. Cultural psychologists are quick to offer critiques of this enterprise on the basis of the lack of ethnographic grounding of these measures in target cultures in order to derive their cultural relevance in the first place. Thus, cultural psychologists and psychological anthropologists have been quick to criticize such endeavors as scientific imperialism at worst, or preemptive universalizing at best (Triandis & Suh, 2002).

Theoretical and Philosophical Psychology

It is worth noting briefly that an emergent subfield of psychology is dedicated to dealing with the taken-for-granted assumptions of various subdisciplines of psychology and proposing alternatives to the status quo when it comes to conventional methods and theoretical approaches (see, for example, Slife, Reber, & Richardson, 2005). While the field of *theoretical and philosophical psychology* is not dedicated to psychological matters with cultural import per se, the theoretical work and philosophical critiques leveled in this vein of psychology have great potential to open doors for a more serious consideration of cultural issues in general psychology. These critiques often directly engage many of the assumptions that preclude a more serious and in-depth consideration of the fundamental importance of cultural considerations in psychological research. They address these assumptions in ways that prevent culture from being reduced to a mere independent variable in a person's psychological profile. As but one example of these potential inroads, challenging the assumption of atomism lends itself to a more thorough consideration of the model of person and culture laid out by Shweder as a hallmark for cultural psychology (Shweder, 1990).

Future Directions

One of the hot forefronts of psychology concerns the major advances in neuroscience that have the potential for technologies, such as neuroimaging, to reveal new findings on the workings of the brain and correlate these with observed behavior and psychological trends. An interesting nascent subfield of anthropology is emerging to take such findings and relate them to cultural data and analysis as well. While some scholars may be cautious about such advancements, particularly with regard to the potentials for biological reductionism, this new field—sometimes termed *neuroanthropology*—shows promise for integrating new findings on the substrates of the brain with anthropology's historical expertise—cultural analysis. (For an example of what these analyses may look like, see Quinn, 2006.) It will be interesting to see the directions in which this field develops.

In conclusion, even given the current directions in which academe and its institutions are proclaiming an increased valuation of interdisciplinary research, institutional structures and practices still remain that hamper genuine interdisciplinary exchange, including theoretical and methodological exchanges between psychologists and anthropologists. Overcoming these challenges and engaging in deeper interchanges will be an important task for those working on psychological issues from an anthropological approach. Those working on issues of anthropological import from a psychological perspective will no doubt contribute to increasing interdisciplinary values at academic institutions. That is not to say that this is not happening on the fringes of each discipline, or that there are not people who genuinely straddle both disciplines, such as many of the authors cited here and the work of other scholars engaged in some of the interdisciplinary fields of study outlined above. These interdisciplinary efforts have certainly gained more traction recently, but varying levels of disciplinary marginalization still remain, and they often revolve around the lack of adherence to methodological orthodoxy of each field. Overcoming these methodological and theoretical tensions between psychology and anthropology will be an important continuing task for researchers cutting across these two disciplines. A related task will be to outline and further develop the methodological foundations of interdisciplinary fields themselves (Mattingly, Lutkehaus, & Throop, 2008), which may indeed help them gain further traction as well as further the research agenda that seeks to genuinely engage phenomena both psychological and anthropological.

IQ

Viewpoints and Controversies

CYNTHIA CROSSER

University of Maine

All cultures value intelligence; however, definitions of what constitutes intelligence vary across cultures. The term *intelligence quotient* (IQ) was coined by German psychologist William Stern (1871–1938) in 1912. IQ tests measure specific skills and specific knowledge that have been used to represent overall intelligence. The exporting and translation of Western measurements of intelligence through IQ testing has influenced views of intelligence globally. In the West, IQ testing has generated controversy as beliefs and assumptions have been challenged. There are three major issues for IQ testing: the question of whether there is a single general intelligence or multiple intelligences, the nature-nurture debate, and the use of IQ tests in policy and legal decisions.

Western psychometric IQ testing is based on the assumption that humans have a general intelligence that can be measured quantitatively. However, this assumption is not universally accepted. Opposing theorists such as American psychologists Louis Thurstone (1887–1955) and Howard Gardner (b. 1943) claim that intelligence is really composed of discrete abilities and cannot be viewed as a single cognitive entity.

The nature-nurture debate has generated a great deal of controversy. While many researchers accept an interaction between genetics and heredity, others have taken more extreme positions. British psychologist Cyril Burt (1883–1971) used twin studies in the 1950s to claim that

genetics play the only important role, while Canadian cultural psychologist John Berry (b. 1939) argued in 1974 that intelligence can be viewed only as a cultural construct.

The use of IQ tests for policy and legal decisions has been and continues to be highly controversial. IQ testing has been involved in the areas of education, employment, immigration, and law, this last with respect to sterilization. IQ testing continues to play a role in screening for special needs students and as a gatekeeper for programs for gifted students in the United States. Related standardized aptitude and achievement tests are used for admissions in higher education and for job placement in the military.

The General Intelligence Controversy

Views of intelligence are dependent on the metaphors and assumptions of a culture. The Western concept of a generalized measure of intelligence can be traced back to the ancient Greek philosopher Plato (427–347 BCE), who compared people's intelligence to blocks of wax differing in size, hardness, moistness, and purity. The view of multiple intelligences can be traced back to the 18th-century German philosopher Immanuel Kant's (1724–1804) portrayal of intelligence as a multifaceted structure. More recently, the emergence of psychology as an academic field has driven Western concepts of intelligence and the emergence of IQ testing.

IQ testing has two main branches of development, with one branch following the assumption of a general intelligence and the other advocating the view of multiple intelligences. The first branch has become accepted in educational psychology, and its assumptions are those that are widely used in screening students for special programs. The multiple intelligences view had been incorporated into educational curricula and is used in cross-cultural research.

Development of General Intelligence Testing

British biologist Francis Galton (1822–1911) was a 19th-century pioneer of mental testing research. Galton was influenced by the work of his cousin, Charles Darwin, and the philosophy of Wilhelm Wundt (1832–1920). Wundt's psychological laboratory in Leipzig, Germany, studied the general principles of sensation, perception, and other mental processes using laboratory techniques that were state of the art for that time period. Galton believed that intelligence was a general inherited characteristic composed of an individual's perceptual sensitivity and the capacity to exert effort. Galton assumed that this general mental ability could be objectively measured using tests for sensory discrimination and reaction times. Galton devised and ran tests to measure differences in the ability to discriminate differences in weight, tone, color, and other perceptual differences. His book *Hereditary Genius: An Inquiry Into Its Laws and Consequences*, which was published in 1869, influenced the thinking of subsequent researchers. Galton was the first researcher to use a normal distribution curve to map out differences in intelligence. This was an important contribution that is still utilized today.

Some of Galton's beliefs have generated controversy, especially his assumptions that intelligence is biologically based and varies by race and social class. Galton believed that members of higher social classes should perform better on sensory-based intelligence tests. He coined the term *eugenics*, the practice of selective reproduction, as a way to improve mankind as a species.

In 1890, American psychologist James Cattell (1860–1944) proposed 50 tests, including tests for physical strength, movement speed, reaction time, and memory, which he believed would correlate with intelligence. He conducted large-scale testing of college students in an attempt to correlate his tests with each other and with measures of intelligence, such as college grades. The research did not produce the desired results. However, British psychologist Charles Spearman (1863–1945) believed that poor methodology was responsible for Cattell's failure to show correlations among tests associated with intelligence.

Spearman was attracted to Galton's concept of a general mental ability with a strong biological basis. In 1904, Spearman used factor analysis to postulate the existence of

general intelligence as the correlation among all complex mental tests. He developed a two-factor theory of general (*g*) and specific (*s*) intelligence, with *g* describing the variance attributed to general intelligence and *s* describing the variance that is unique for each individual test. Because he was able to connect a theoretical construct with a mathematical correlation, Spearman's work helped to establish a school of thought that assumes intelligence as a single mental reality with an inherited biological basis. This has given rise to the continued practice of measuring overall intelligence using tests believed to measure components of general intelligence. In addition to his impact on the field of intelligence, Spearman made important contributions to the field of statistics. Statistics continues to be used as an important tool in intellectual assessment.

Alfred Binet (1857–1911) and Theodore Simon (1863–1961) published the first modern intelligence test in *L'année psychologique* in 1905. The goal of their assessment scales was to identify children who would benefit from special education classes. Binet and Simon believed in a general intelligence based on higher-level judgment skills. The original Binet-Simon test was an untimed test administered individually by a trained examiner. The test consisted of a series of tasks of increasing difficulty. Binet and Simon believed that each task represented the normal level of performance for a given age. The highest level that a child successfully performed was designated as his or her mental age. The Binet-Simon test laid the foundation for all individually given IQ tests today.

American psychologist Henry Goddard (1866–1957) was the first to translate the Binet-Simon test into English, distributing thousands of copies throughout the United States for testing students in public schools. Goddard's work was influential in advocating a strong heritability of intelligence. His book *The Kallikak Family: A Study in the Heredity of Feeble-Mindedness*, first published in 1912, argues for a strict genetic view of feeble-mindedness (very low intelligence). Goddard also proposed the controversial solution of involuntary sterilization of the feeble-minded to improve the intelligence of the American people.

Goddard was invited to test immigrants at Ellis Island in 1913. Using his version of the Binet-Simon intelligence test, Goddard concluded that the intelligence of the average steerage passenger was very low. Because the immigrants tested came from Southern and Eastern Europe, public perception of the people from these regions was negative. This negative view of the intelligence of immigrants from these countries influenced the establishment of immigration quotas.

American psychologist Lewis Terman (1877–1956) translated and adapted the revised Binet-Simon Intelligence Test Scales for use in the United States in 1916. Terman also incorporated the intelligence quotient that had been introduced by William Stern in 1912. Stern defined the intelligence quotient (IQ) as the ratio of the mental age and the chronological age multiplied by

100 (e.g., 10 years/8 years \times 100 = 125). Terman called his new version the Stanford-Binet Intelligence Test Scales (SBITS). The SBITS is in its fifth revision and is still used today as a measure of general intelligence. It is not without controversy and has been criticized as culturally biased.

The United States entered World War I in 1917. During this critical time the military worked with psychologists to adapt the Stanford-Binet for group testing. In 1917, Robert Yerkes (1876–1956), head of the American Psychological Association, lobbied and received permission from the National Research Council to create a Committee on Psychology. As chair of this committee, Yerkes was responsible for bringing together psychologists (including Henry Goddard and Lewis Terman) to modify the SBITS for use by the U.S. Army. The army was interested in classifying recruits according to their mental abilities for job placement.

Yerkes's group designed two multiple choice tests that could be administered to groups. The alpha test was given to literate recruits, and the beta test was given to recruits who could not read and write in English, if at all. The army tests are significant for two reasons. First, the change in format provided a model for group testing, and second, the results were interpreted to indicate that recent immigrants from Southern and Eastern Europe were of lower intelligence than immigrants from Western Europe, who tended to have been in the country longer. Although the results showed a strong correlation between years living in the United States and scores on the Army Beta test, this explanation was rejected by Yerkes in favor of a biological explanation.

David Wechsler (1896–1981), who had been involved with Army intelligence testing during World War I, published the Wechsler-Bellevue Intelligence Scales in 1939. Wechsler was influenced by Spearman's work on generalized intelligence. His intelligence scales comprised the verbal and nonverbal factors believed to compose general intelligence. The Wechsler scales are performance tests that measure a person's ability to complete a drawing or provide verbal definitions of orally presented words. Because Wechsler worked initially with adults, he rejected the concept of a mental age. He developed a point system that could be used effectively for both children and adults. Each subtest reflected an ability that expressed general intelligence. A major innovation came in 1949 with the introduction of the deviation IQ score. Wechsler scales yield IQ scores with a mean (or average) score of 100 and a standard deviation of 1.5. Individuals are compared to others their own age when computing the IQ score. The deviation score has replaced the mental age score as the standard way for measuring IQ. Tests derived from the original Wechsler intelligence tests are still used today.

Wechsler's biggest contributions to the field of intelligence testing were his use of standardization sampling and normalizing procedures. However, despite these procedures, the Wechsler tests generated criticisms of cultural bias. Researchers looked for ways to get beyond the limitations of

language problems and culture-specific knowledge. In 1936, John C. Raven (1902–1970) developed Raven's Progressive Matrices Test, an untimed nonverbal assessment of abstract reasoning. To answer test questions, participants identify the missing segment necessary to complete a larger pattern. In 1940, Raymond Cattell (1905–1998) introduced the concept of the Culture-Fair Test. The purpose of this test is to avoid test bias based on linguistic skills and general knowledge. This was the first test designed to distinguish between genetic and environmental factors in intelligence. Both tests are still in use today in the United States and internationally. They have both generated criticisms that they are not free of cultural bias.

In the mid-1950s, English psychologist Cyril Burt (1883–1971) published a series of studies on monozygotic twins. Burt claimed that monozygotic twins reared together had an almost perfect correlation on tests of intellectual ability. He went on to claim that monozygotic twins reared apart showed only slightly less similarity on intellectual tests. Burt used his data to argue that the environment played no role in differences in intelligence and to argue for biological differences between social classes in Great Britain. Subsequent research has shown that Burt was careless or dishonest in reporting his data and that the correlations were lower than he reported. However, Burt's work formed the basis of subsequent research by Arthur Jensen (b. 1923), who claimed in a 1969 article in the *Harvard Educational Review* that biological differences between individuals of different races are responsible for differences in IQ between white and African American students. Jensen's article incited sharp reactions from the American Anthropological Society and the Society for the Psychological Study of Social Issues, a division of the American Psychological Association.

John L. Horn (1928–2006) and Raymond Cattell published several important articles on the theory of fluid and crystallized intelligence in 1966. This theory assumes the existence of a general entity of intelligence and divides it into a fluid general intelligence (*fg*) and crystallized general intelligence (*cg*). The former refers to the ability to draw inferences and understand relationships in new situations, while the latter refers to abilities dependent on knowledge and experience. In its simplest version, crystallized intelligence is said to increase over time, while fluid intelligence declines with age. This theory generated controversy because of test results indicating racial group differences in fluid intelligence.

American psychologist Richard Herrnstein (1930–1994) and political scientist Charles Murray (b. 1943) published *The Bell Curve* in 1994. This book claims that intelligence is one of the most important factors in socioeconomic success in the United States. It also claims that IQ plays a role in socioeconomic differences among races. Both the American Anthropological Association and the American Psychological Association responded to the controversy surrounding publication of *The Bell Curve*. In December 1994,

the American Anthropological Association issued an official statement in response, disputing the existence of biological racial categories as a concept with any value for explaining human variation in intelligence or other traits. In 1996, the American Psychological Association published “Intelligence: Known and Unknowns” (Neisser et al., 1996). This paper acknowledges group differences between whites and African Americans, but claims that the reasons for these differences are unknown.

Development of Multiple Intelligences Testing

Although many researchers in the early 20th century believed that intelligence was a single biological entity, others challenged this view. American psychologist Louis Thurston (1887–1955) disputed the results of Spearman’s factor analysis. Thurston’s 1938 book *Primary Mental Abilities* proposed that intelligence is not a single factor. Thurston claimed that intelligence is composed of seven primary abilities or factors: word fluency, verbal comprehension, spatial processing, ability to perform numeric calculations, memory, induction, and perceptual speed. Thurston’s work in statistics has been disputed; however, it laid a foundation for the view that does not accept the concept of a general intelligence.

Canadian psychologist George A. Ferguson (b. 1914) published “On Transfer and the Abilities of Man” in 1956. Ferguson argued that culture plays a critical role in learning. Ferguson admitted that biology fixes limits for learning but disputed the idea that intelligence is biologically determined. He argued that society has an obligation to provide educational processes to improve outcomes for its people. Ferguson influenced the work of John Berry.

Canadian cultural psychologist John Berry (b. 1939) published the controversial book chapter “Radical Cultural Relativism and the Concept of Intelligence” in 1974. Berry rejected assumed universals across cultural systems, claiming that intelligence can only be understood as an indigenous construct within a cultural context. This work challenged the practice of using Western intelligence testing cross-culturally. In subsequent publications, Berry accepted biologically universal concepts such as memory but posited ecological influences as the most important factors in determining intelligence.

In 1974, American psychologist Leon Kamin (b. 1928) published *The Science and Politics of IQ*, in which he claimed that there was no evidence that IQ was heritable. Kamin’s book was instrumental in discrediting Cyril Burt’s research on identical twins reared apart. German-born psychologist Hans Eysenck (1916–1997), who had studied under Burt in London, challenged Kamin’s attack on Burt. However, Kamin’s criticism of Burt was followed by further examination, resulting in a

general disbelief in Burt’s results. Kamin’s claim that there is no evidence for the genetic basis of intelligence remains controversial. However, his work has been influential on educational practices, such as tracking students by ability.

In 1977, two issues of the journal *Principal* were brought out in the book *The Myth of Measurability*. This book, edited by Paul L. Houts (b. 1937), the journal’s director of publications and editor, contains 29 papers that are highly critical of general tests for intelligence. The book includes articles dealing with issues of cultural bias and articles claiming that general intelligence does not exist. This controversial book encouraged the development of theories of multiple intelligences.

American paleontologist, evolutionary biologist, and historian of science Stephen J. Gould (1941–2002) published *The Mismeasure of Man* in 1981. Gould argued against the concepts of generalized intelligence, the heritability of intelligence, and the ranking of individuals by IQ. This book generated a great deal of controversy and there were claims that the book contained inaccuracies.

In 1983, American psychologist Howard Gardner (b. 1943) published *Frames of Mind*. Gardner reviewed the data in studies of intelligence using eight criteria for indicators of intelligence:

1. Potential isolation by brain damage
2. The existence of idiots savants, prodigies, and other exceptional individuals
3. An identifiable core operation or set of operations
4. A distinctive development history, along with a definable set of “end-state” performances
5. An evolutionary history and evolutionary plausibility
6. Support from experimental psychological tasks
7. Support from psychometric findings
8. Susceptibility to encoding in a symbol system

Gardner suggested the existence of seven separate intelligences: linguistic, logical-mathematical, musical, bodily-kinesthetic, spatial, interpersonal, and intrapersonal. This work played an important role in setting criteria that could be used to evaluate separate intelligences and has been incorporated into teaching methods. However, a way of assessing the individual intelligences has not been published or endorsed by Gardner.

Robert Sternberg (b. 1949) published *Beyond IQ: A Triarchic Theory of Human Intelligence* in 1985. Sternberg believes intelligence comprises three components: the analytical, the creative, and the practical. Sternberg believes intelligence must be translated into real-life success and is dependent on motivation, perseverance, and self-control. In 1991 he proposed the Sternberg Triarchic Abilities Test (STAT) to measure his theory of intelligence. Because the triarchic theory includes an assessment tool, it provides a possible alternative to IQ testing that assumes an overall general intelligence. This test is used in cross-cultural research.

Cultural Bias in Modern General Intelligence Tests

The existence of a general intelligence that drives the ability to reason, plan, problem solve, and think abstractly remains theoretically controversial. The main criticism of these tests has been that they are culturally biased. Cultural bias can be a problem for use internationally and for use with minority ethnic groups in the country that developed the test. An example of a culturally biased test item would be an analogy question involving snow given to young children in Hawai'i, who may have never experienced snow.

The Stanford-Binet V of 2003 is an IQ test that is used to assess individuals between the ages of 2 and 90. Some important characteristics of the original test have remained. The test is still untimed and given individually by a trained examiner. However, it has been altered so that verbal and nonverbal skills are weighted equally. Also, it is no longer based on mental age. Instead the deviation IQ measures a person's performance relative to others of the same chronological age. The test has been statistically renormalized against a large population so that the results of individual assessments can be statistically compared with those of a large up-to-date base population. However, there is still some controversy as to the accuracy and cultural bias of the test.

The Wechsler Intelligence Scales include the Wechsler Adult Intelligence Scale (WAIS), Wechsler Intelligence Test for Children (WISC), and the Wechsler Preschool and Primary Scale of Intelligence (WPPSI). The WAIS IV of 2008 and the WISC IV of 2003 include a composite general intelligence score and subtests measuring verbal comprehension, perceptual reasoning, working memory, and processing speed. The WPPSI III of 2003 provides subtest scores in verbal and performance cognitive domains, and includes a composite general intelligence score. Although the tests have been modified and updated, there are still claims of cultural bias in the Wechsler Intelligence Scales.

Raven's Progressive Matrices Test is an untimed nonverbal assessment of abstract reasoning. The test questions require the participant to identify the missing segment necessary to complete a larger pattern. Three versions of the test exist: Standard Progressive Matrices (all ages), Colored Progressive Matrices (children only), and Advanced Progressive Matrices (all ages with above-average intelligence). This test can be used for assessing individuals with language deficits. Because the test does not require competence in any language, it is useful internationally. This test has generated some controversy over its use in some third world countries, such as South Africa. It is claimed that cultural differences render the test inappropriate to some groups.

The theory of fluid and crystallized intelligence put forward by John Horn and Raymond Cattell was incorporated into the Kaufman Adolescent and Adult Intelligence Test (KAIT), first published in 1993. The fluid portion of the

KAIT tests for the ability to decode picture-words and to solve logic problems. The crystallized portion tests comprehension of oral stories, words with double meanings, and definitions. The KAIT has been criticized for its lack of multicultural consideration.

Cultural Bias and Achievement Tests/Aptitude Tests

While intelligence tests are designed to measure general thinking abilities, achievement/aptitude tests are designed to test specific knowledge acquisition. However, standardized achievement/aptitude tests are highly correlated with IQ scores and are frequently included in the controversy of cultural bias. Examples include the Armed Services Vocational Aptitude Battery (ASVAB), the SAT (formerly Scholastic Aptitude Test or Scholastic Assessment Test), the Graduate Record Examination (GRE), and the Law School Admission test (LSAT).

The SAT, originally known as the Scholastic Aptitude Test, was first used in 1926 as a measurement of a student's level of preparation for college work. The SAT was most recently updated in 2005, with the introduction of a writing section. The current version assesses critical reading, mathematics, and writing. Use of the test as an assessment of college preparedness is controversial because of charges that it is culturally biased. A 2006 *USA Today* article (Bruno, 2006) reported that many liberal arts colleges, including Bowdoin, Middlebury, Hamilton, and Bates, have made the SAT optional. The National Collegiate Athletic Association 2008 eligibility requirements for incoming Division I freshmen do not have a minimum SAT requirement. Instead, freshman eligibility is judged on a sliding scale incorporating both grade point average (GPA) and combined scores of the reading and mathematics sections of the SAT. A Division I incoming freshman with a GPA of 3.5 or over requires a combined mathematics and reading score of 400; a student with a GPA of 2.0 must have a combined score of 1010.

The ASVAB was introduced as an assessment tool in 1968 and was most recently updated in 2002. Although the official ASVAB site claims that the test is not an intelligence test, the test is used to sort individuals for military placement and as a tool for career placement in high schools. The ASVAB is controversial both because of charges that it is culturally biased and because the military uses it to recruit high school seniors who are given the test for occupational testing. The ASVAB tests knowledge in eight areas: general science, arithmetic reasoning, word knowledge, paragraph comprehension, mathematics knowledge, electronics information, auto and shop information, and mechanical comprehension.

A group called FairTest, first formed in 1985, monitors standardized tests for evidence of bias. This group tries to

ensure that tests are reliable, valid, and used appropriately. FairTest has also been active in lobbying for more access to test data and the establishment of alternative testing procedures.

The Nature-Nurture Controversy

Most researchers accept that intelligence is based on both genetic and environmental factors. Some researchers have taken extreme positions, such as those mentioned above of British psychologist Cyril Burt and Canadian cultural psychologist John Berry.

Genetic Factors and Intelligence

Heritability of Intelligence

Heritability refers to the proportion of a characteristic that is attributable to genetic variance. It is a population concept that ranges from a proportion of 0.0 to 1.0. A heritability of .50 would indicate, on average, 50% of the individual differences that we observe in a trait or behavior are attributable to genetic individual differences in the population. It does not mean that 50% of any person's trait or behavior is due to genes and the other 50% is due to environment. Heritability depends on the range of typical environments in the population that is studied. If the environment of the population is fairly uniform, then heritability can be high, but if the range of environmental differences is large, then heritability can be low.

According to a 1996 review of the literature on intelligence published by the American Psychological Association, the heritability of intelligence varies with age. Research indicates that in children it is estimated to be about .45, while in adults it is estimated to be .75. This means that as children grow up, intelligence test scores tend to increasingly reflect their specific genes and individual experiences rather than differences among the families in which they were raised. The reasons for the shift are unknown. It should be noted that most of the available studies included in the review dealt with white Americans and that the lack of subjects from other cultural backgrounds in the study is a known limitation.

Twin Studies

Although Francis Galton did not originate the use of twin studies, he was the first researcher to make use of the genetic similarity between twins to study the nature-nurture question. The results of his study were published in an 1876 article, "The History of Twins as a Criterion of the Relative Powers of Nature and Nurture." Unfortunately, the difference between monozygotic (identical) and dizygotic (fraternal) twins was not understood at that time, which limits the usefulness of his research.

Monozygotic twins have 100% genetic similarity, while dizygotic twins have approximately 50% genetic similarity. The most powerful type of twin study involves comparing adopted monozygotic twins reared separately with monozygotic twins reared in the same home. These studies assume that twins reared in the same home will experience the same environment, while twins reared apart will have different environments. Since ethics prevents twins being deliberately placed in extreme environments, the effects of environments that are radically different cannot really be tested.

The first well-known modern twin studies were performed by British psychologist Cyril Burt in the 1950s. Burt reported in several studies that monozygotic twins reared together had almost perfect correlations in intelligence tests and that monozygotic twins reared apart had only slightly less strong correlations. He used his test results to claim that biology is the only important factor in intelligence, as noted earlier. American psychologist Leon Kamin discredited Burt's work in 1974. It is now believed that Burt was either extremely careless or dishonest in reporting his results. A literature review published in 1997 by Thomas Bouchard (b. 1937), director of the Minnesota Center for Twin and Adoption Research at the University of Minnesota, gives the average correlation of intelligence tests between identical twins reared apart as 75%.

Intelligence as a Cultural Construct

The strong view that John Berry posited in 1974 claims that intelligence can only be viewed as a cultural construct. In later publications with other researchers, Berry proposed the law of cultural differentiation or Ferguson's law based on the following quote from Ferguson's 1956 paper on cognitive transfer: "Cultural factors prescribe what shall be learned and at what age; consequently different cultural environments lead to the development of different patterns of ability." This view of intelligence is controversial.

Researchers such as Hans Eysenck and Arthur Jensen, who believe that intelligence is the same cross-culturally, contest this view and believe that properly translated tools can be successfully used internationally. American psychologist Robert Sternberg has argued for a middle position, claiming that intelligence is the same across cultures but that the instruments of measurement are not. Sternberg believes that the components of intelligence are universal but that the types and items of knowledge vary across cultures.

A literature review by Sternberg in 2007 provides examples of modern views of intelligence in China and Africa. A 1994 study conducted in Taiwan argues that the Chinese conception of intelligence involves three factors: nonverbal reasoning ability, verbal reasoning ability, and rote memory. A 1997 study also conducted in Taiwan argues that the

Chinese view of intelligence involves five factors: a general cognitive factor, interpersonal intelligence, intrapersonal intelligence, intellectual self-assertion, and intellectual self-effacement. A 1996 study of Chewa adults in Zambia claims that this group considers intelligence to consist of performance in three areas: social responsibilities, obedience, and cooperativeness. Sternberg's review of the literature makes clear the need for more cross-cultural research on intelligence.

Intelligence and Gender

Before educational opportunities for women were equal to those for men, it was frequently assumed that males had intelligence that was superior to that of females. Modern research has not found significant gender effects for intelligence. Most research has found differences in patterns of mental abilities rather than differences in overall intelligence. Visual-spatial and mathematical abilities are generally superior for males, while verbal and memory abilities are generally higher for females.

However, some researchers are still pursuing this line of research. Canadian psychologist Phillippe Rushton (b. 1943) and other researchers used biological measures, such as head size, and academic achievement tests, such as the SAT, to claim that males have superior intelligence (Jackson & Rushton, 2006). The addition of the writing section to the SAT may address this issue, since females generally outperform males in language abilities.

Intelligence and Race

General intelligence tests in the United States consistently find group differences for race. Some researchers, such as Arthur Jensen and Phillippe Rushton, continue to argue that biological differences between races are responsible for group differences in intelligence test results. Other researchers, such as Leon Kamin, argue that environmental factors are responsible for group differences. The American Psychological Association acknowledges differences in group results but claims that the reasons are unknown. The American Anthropological Association claims that race is not a valid category.

The Bell Curve

American psychologists Richard Herrnstein (1930–1994) and political scientist Charles Murray (b. 1943) published *The Bell Curve* in 1994. This book claims that intelligence is one of the most important factors in socioeconomic success in the United States. It also claims that IQ plays a role in socioeconomic differences between races. Both the American Anthropological Association and the American Psychological Association responded to the controversy surrounding publication of *The Bell Curve*.

Official Statement of the American Anthropological Association

The American Anthropological Association released the following statement in December 1994 in response to the controversy surrounding the publication of *The Bell Curve* earlier that year:

The American Anthropological Association (AAA) is deeply concerned by recent public discussions which imply that intelligence is biologically determined by race. Repeatedly challenged by scientists, nevertheless these ideas continue to be advanced. Such discussions distract public and scholarly attention from and diminish support for the collective challenge to ensure equal opportunities for all people, regardless of ethnicity or phenotypic variation . . . ,

WHEREAS all human beings are members of one species, *Homo sapiens*, and

WHEREAS, differentiating species into biologically defined "races" has proven meaningless and unscientific as a way of explaining variation (whether in intelligence or other traits),

THEREFORE, the American Anthropological Association urges the academy, our political leaders and our communities to affirm, without distraction by mistaken claims of racially determined intelligence, the common stake in assuring equal opportunity, in respecting diversity and in securing a harmonious quality of life for all people.

Literature Review From the American Psychological Association

The following quote is taken from a paper published by the American Psychological Association in 1995. Prompted by the public controversy surrounding the publication of *The Bell Curve* in 1994, this paper reviews the relevant literature on intelligence and summarizes important findings:

Differences in genetic endowment contribute substantially to individual differences in (psychometric) intelligence, but the pathway by which genes produce their effects is still unknown. The impact of genetic differences appears to increase with age, but we do not know why.

Environmental factors also contribute substantially to the development of intelligence, but we do not clearly understand what those factors are or how they work. Attendance at school is certainly important, for example, but we do not know what aspects of schooling are critical. . . .

The differential between the mean intelligence test scores of Blacks and Whites (about one standard deviation, although it may be diminishing) does not result from any obvious biases in test construction and administration, nor does it simply reflect differences in socioeconomic status. Explanations based on factors of caste and culture may be appropriate, but so far have little direct empirical support. There is certainly no such support for a genetic interpretation. At present, no one knows what causes this differential.

Controversies in Group Results

Controversies in education, immigration, hiring practices, and reproductive freedom have all been affected by group results in general IQ tests. The manner in which the results affect society is influenced by views of the nature-nurture debate.

Policy and Legal Controversies in Education

Head Start

American educational researcher Benjamin Bloom (1913–1999) published *Stability and Change in Human Characteristics* in 1964. Bloom's book rejects the view of biological determinism for intelligence and advocates the mastery of educational goals for all children. Bloom's work was influential in the establishment of the Head Start program in 1964.

In 1969, Arthur Jensen, an educational psychologist at the University of California, Berkeley published the highly controversial article mentioned previously, "How Much Can We Boost IQ and Scholastic Achievement?" In this article, Jensen argues that programs such as Head Start, which were designed to promote school readiness by enhancing the social and cognitive development of children, could never succeed because of the heritability of IQ. Jensen claims that the lower IQ scores of African Americans are caused primarily by racial differences. The article led to protests outside his office in Berkeley and numerous publications disputing his claims. The Society for the Psychological Study of Social Issues, a division of the American Psychological Society, issued a five-page statement to news agencies outlining their disagreement with Jensen's conclusions. The 1969 convention of the American Anthropological Society passed a resolution condemning him. The controversy surrounding Jensen brought to light the polarized views of the nature-nurture controversy and the way in which they impact views of educational policy.

In 2005, a review of the intelligence literature by Rushton and Jensen was published in *Psychology, Public Policy, and Law*. The authors defend Jensen's original position on Head Start and argue for the abolishment of affirmative action. A reply by Robert Sternberg challenging this view was printed in the same journal issue (Sternberg, 2005).

Tracking and Special Education

The federal suit *Hobson v. Hansen* in 1967 had a huge impact on the use of group-administered IQ tests for school tracking. The Hobson case claimed that the tracking program then in place in the Washington, D.C., public schools violated Title VI of the Civil Rights act of 1964. The evidence in the case was based on the disproportionate number of African American children in the lower-ability

tracks. Judge Skelly Wright ruled that the tests were racially biased. This ruling eliminated the tracking system in the D.C. public schools.

One of the most important legal cases involving education policy is *Larry P. v. Wilson Riles*. The parents of seven African American children brought suit against the State of California in November 1971, claiming that their children had been incorrectly placed in classes for the educable mentally retarded (EMR), based on the children's scores on an IQ test. This suit claimed that the individually administered IQ test was culturally biased. During the course of the trial, Judge Robert Peckham granted a temporary injunction halting any future placement of African American children into EMR classes on the basis of intelligence tests. In 1979, Judge Peckham ruled that the tests were culturally biased. The verdict was upheld by the U.S. Court of Appeals for the Ninth Circuit in 1984. In 1992, a federal judge ruled that African American students could be given intelligence tests at the request of their parents.

Employment and IQ Testing

U.S. employers' use of intelligence testing in hiring practices increased from 26% in 1940 to 63% in 1957. The federal government played a role in increasing employer testing by making intelligence tests available free of charge through the U.S. Employment Service, which was founded by the Wagner-Peyser Act of 1933. However, controversy over the use of intelligence testing in the workplace led to lawsuits.

The case of *Griggs v. Duke Power Company* set important precedent for the use of intelligence testing by employers. A group of African American employees brought suit against the power company, claiming that their rights were being violated under the Civil Rights Act of 1964. The company had a policy of requiring a high school diploma and a satisfactory intelligence score for certain jobs. The effect of the policy was to maintain the practice of segregation that had been in place prior to the passage of the Civil Rights Act. The U.S. Supreme Court ruled on March 8, 1971, that employers could use general intelligence test scores only in special circumstances. The ruling specified that high school diplomas and minimum scores on general intelligence tests could be used as job requirements only if they could be shown to significantly relate to job performance.

In 1989, the Committee on the General Aptitude Test Battery published *Fairness in Employment Testing*. This report deals with a proposal by the U.S. Department of Labor to promote use of the General Aptitude Test Battery throughout the U.S. Employment Service. The report concludes that test score adjustments are necessary for African Americans and Hispanics because of test bias.

The Law and Sterilization Based on IQ

The eugenics movement in the United States advocated for the use of compulsory sterilization of individuals with

low intelligence or mental illness. Indiana became the first state to pass a compulsory sterilization law in 1907. California and Washington passed similar laws in 1909. In *Buck v. Bell*, the U.S. Supreme Court upheld the 1924 Virginia law requiring sterilization of the mentally retarded. The ruling on this case encouraged other states, and eventually 33 states passed compulsory sterilization laws. The Virginia law was repealed in 1974, following a national trend to discontinue the practice.

In Canada, the province of Alberta passed the Sexual Sterilization Act in 1928 (Grekul, Krahn, & Odynak, 2004). A four-member Alberta Eugenics Board was created to oversee approval of procedures. The Sterilization Act was used as a basis for compulsory sterilization of over 2,800 people between 1929 and 1972, when the act was repealed. Aboriginals were particularly targeted by the Alberta Eugenics Board. In 1995, Leilani Muir successfully sued the Alberta government for performing a wrongful sterilization on her in 1959, and she was awarded \$740,000 in damages and \$230,000 in legal costs. After Muir's case was decided, a class action lawsuit on behalf of other sterilized individuals reached an out-of-court settlement with the government of Alberta. Approximately 700 people were awarded damages for wrongful sterilization.

After taking power in Germany, the Nazi government introduced the 1933 Law for the Prevention of Offspring with Hereditary Diseases. This law required all physicians to register every case of hereditary illness, including low IQ. Only women over the age of 45 were exempt, since they were considered too old to produce children. The law was used as a basis for the forced sterilization of over 400,000 people between 1934 and 1937.

IQ Testing and Immigration Policy

The public perception of immigrants from certain countries was influenced by Henry Goddard's work on Ellis Island in 1913 and Robert Yerkes's work on U.S. Army testing during World War I. Belief in the intellectual inferiority of certain peoples led to passage of the Immigration Restriction Act of 1924. This law introduced quotas for countries in Southern and Eastern Europe and eliminated immigration from Asia. This law remained in effect until passage of the Immigration and Nationality Act of 1965.

Conclusion

All cultures value intelligence. Western culture developed IQ testing that reflected the cultural values and scientific beliefs that were held at the time the tests were developed. Divergent beliefs and values are reflected in the controversies surrounding IQ testing. There are three major issues for IQ: the question of whether there is a single general intelligence or multiple intelligences, the nature-nurture debate, and the use of IQ tests in policy and legal decisions.

The first of these three questions has not been answered. Instead the two views are reflected in different usages. General intelligence tests are used to screen for special education and as a gatekeeper for gifted programs in public schools. The theory of multiple intelligences has been incorporated into curriculum theory for teaching purposes and is used for cross-cultural research. Although most researchers accept that the interaction of genetics and environment determines intelligence, the topic still excites controversy. The use of group results for policy and legal decisions remains an important controversy. As recently as 2005, Rushton and Jensen advocated changing public policies, such as affirmative action, because African Americans' scores on intelligence tests were lower than those of other groups.

Recent research has provided new insights about the views of intelligence in other cultures. Further cross-cultural research is needed to help answer the controversial issues in intelligence testing.

HUMAN LONGEVITY AND WORLD POPULATION

SANG-HEE LEE

University of California, Riverside

The link between human longevity and world population seems direct and obvious: The world population is increasing, and the proportion of elderly is increasing as well, as more humans are living longer. Will human life span increase infinitely? Why is there an aging process? How does human longevity compare to that of other primates? How did longevity change over human evolutionary history? What follows is a review of research examining these questions and other aspects of human longevity and a discussion of world population growth.

Definitions of Longevity

Longevity, or life span, is the period of time between the birth and death of an organism. This definition is misleadingly straightforward, because the point when life begins and ends is a matter of some arbitrariness. Although most definitions of life would begin with birth, arguments have been made that life begins at various points before birth—for example, fertilization, implantation, beginning of the third trimester in humans, or after birth, as can be seen in the effective age calculations for prematurely born babies. The point of birth that is culturally acknowledged adds further variation in the concept of birth.

Most definitions of death include cessation of breath and heartbeats, but arguments have been made for different kinds of deaths, as not all organs in a body cease to function at the same time—for example, brain death. As in the case of life, the point of death that is culturally acknowledged

can vary from biological point of death. However, the range of variation in the beginning and ending points is small compared to the total length of life span.

It is thought that maximum life span is biologically determined and not variable. The maximum life span can be empirically noted by observing the longest survival of an individual member of a species, which provides the minimum threshold of the maximum life span. This is a difficult challenge for studying long-lived organisms such as humans, since researchers do not outlive the subjects and cannot record births and deaths. Researchers have to rely on records and age estimations. Living to the age of 100 is unlikely for humans, but not rare: About 7 in 1,000 people are estimated to reach the centenarian milestone. Beyond 100, surviving each additional year is subject to a 50% probability. The maximum human life span is estimated to be between 115 and 150 years, with the longest-lived human on record having lived 122 years (died in 1997). The majority of centenarians are women, and most of the oldest old are women. Reasons for sex differences in longevity are not clear, although many have attributed it to greater testosterone-driven mortality in males.

As a group, primates show a strong tendency for increased longevity as a result of long gestation, long maturation, and long adulthood. Cross-species comparisons of life spans that are explained by biological variables such as brain size, body size, metabolic rate, and body temperature have yielded statistically significant relationships (Cutler, 1975; Sacher, 1978), which suggest that life span is an evolutionary variable that contributes to the fitness of a species. The maximum life spans of most mammalian species form a straight line when

they are plotted against various biological variables. Human life span is not noteworthy, given that there are many other mammals, such as whales and elephants, with life spans as long as or longer than those of humans. While human life span falls within the expected range based on brain size, it is extraordinarily long for body size (Hill, 1993). However, the statistical nature of such studies should be kept in mind. Human life span easily exceeds 90 when looking at the species as a whole, after sampling millions of people; however, a random sample of a village population would more likely yield 60 or 70 years of average life span. In contrast, life span data for nonhumans are based on a very small sample. It is unknown how much of the life span differences are attributable to the extreme discrepancy in sample sizes.

The maximum potential life span of humans is longer than that of other great apes. Among hunter-gatherers, life spans in the 70s and 80s are well-known, while chimpanzees in the wild rarely reach 45 years of age, and orangutans in the wild, 50 years. Even in captivity, maximum life span on record is about 60 years for apes, in contrast to the markedly longer life span of the oldest human on record.

Making a uniformitarian assumption that the relationships between body size, brain size, and maximum life span that are observed in the present are as valid for species in the past, maximum life span can be estimated for various fossil human ancestors (hominids; Weiss, 1981). The maximum life span for hominids that existed before the genus *Homo* came into being (*Australopithecus africanus*, *A. robustus*, and *A. boisei*) is around 50. The value increases with *Homo habilis* at 61, *Homo erectus* at 69 and 78, archaic *Homo* at 89, and more than 90 years of life span is predicted for Neanderthals as well as modern humans (Weiss, 1981). There is an increase in the estimated maximum life span through the years. This acceleration of the increase in maximum life span plateaus with the modern humans. However, it should be remembered that the estimation of maximum life span of fossil hominids was based on estimated brain size and body size. Therefore, the observed increase pattern in maximum life span is actually the increase pattern in brain size and body size over time.

While maximum life span implies a biological limit to how long an individual lives, average life span is estimated from the mortality data. Although maximum life span for humans is more than 100 years, the average life span is over 70 years. This is a substantial increase from less than 30 years, which was the average life span for humans from the time of ancient Greece until the 18th century. The life expectancy at birth in North America and northwestern Europe is thought to have been 35 to 40 years until the end of the 18th century. Despite the increase in average life span, there is no evidence of increase in the maximum life span. There is no evidence that mortality of centenarians decreased: The increase in the number of centenarians is a result of the decrease in mortality for people under 100 years of age. It seems to be the case that the trend is for more people to reach the maximum life span rather than for the maximum life span to increase. Few studies show that maximum life span has changed much over time (Wilmoth & Robine, 2003).

In contrast, if human longevity is defined as average life expectancy, it has increased over time. Life span is related to, but different from, life expectancy, which is a hypothetical number derived from mortality tables. Life expectancy is the number of years that a cohort is expected to live. Life expectancy at a specific age is the average number of years the cohort (those born into a population at the same time) will live to be.

Estimated life expectancy through human evolution has increased. Since it is impossible to get an accurate measurement of life expectancy, it is estimated by using demographic models. Assuming a stationary population (zero growth), life expectancy at birth is the inverse of the crude birth rate. Based on the life tables collected for anthropological societies, the crude birth rate for hunter-gatherers is around 0.045, which yields life expectancy at birth to be 22 years (Weiss, 1973). In contrast, life expectancy at birth in some developed countries is more than 75. When life expectancies at different points in life (birth, puberty, old age) are compared, it can be seen that life expectancy at birth is the one that changes the most, followed by life expectancy at puberty; life expectancy at old age has not changed much over time.

Humans have a distinctively long average adult life span. While great ape females in the wild who survive to age 15 can be expected to live 15 to 20 more years (Hill et al., 2001; Wich et al., 2004), humans of forager populations who survive to age 15 can be expected to live at least 30 more years (Blurton Jones, Hawkes, & O'Connell, 2002; Hill & Hurtado, 1996; Howell, 1979). The average adult life span beyond maturity for Ache hunter-gatherers is about 42 years (Goodall, 1986; Hill & Hurtado, 1996).

Fossil data show that adult survivorship increased quite recently in human evolution. Adult survivorship has been very low for much of human evolution, increasing dramatically with the modern humans of the Upper Paleolithic age (Caspari & Lee, 2004). Further work has shown that this increase in adult survivorship is not a direct consequence of the emergence of modern humans as a taxon (Caspari & Lee, 2006).

Although the adoption of agriculture is believed to have led to population growth, it is not clear that it was accompanied by an increase in longevity: In other words, although more people were born, they were not living longer. A substantial increase in longevity took place only after the Industrial Revolution, probably due to better nutrition and public hygiene measures that reduced infectious diseases, which decreased adult mortality. Advances in biomedicine started to play a big role in longevity only in the 20th century.

Considering the plasticity of longevity, it can be concluded that the differences in life expectancy between different populations are due to external mortality differences originating from physical and cultural environments. Across populations, mortality causes are the same, but in different order of importance. Extensive study of populations shows that there is a strong relationship between different causes of death and life expectancy (Preston, Keyfitz, & Schoen, 1972): Extrinsic causes of mortality, such as infectious diseases, are correlated with a higher crude death rate (the number of deaths each year in a population), while chronic degenerative diseases, such as

cancer and cardiovascular diseases, are correlated with a lower crude death rate. Considering that infectious diseases affect a younger demography, while chronic degenerative diseases are more likely to affect an older demography, a higher incidence of chronic degenerative diseases in a population implies that more people have survived longer to be subject to chronic degenerative diseases. In other words, the increase in life expectancy that has been seen since the Industrial Revolution is likely due to a decrease in the number of deaths due to infectious diseases.

Aging and Longevity in Humans

Humans are distinctive in having a long life span, a slow aging process, and a long postreproductive life span. Chimpanzees in the wild start a visible aging process characterized by external appearance of frailty and senescence in their 30s (Goodall, 1986), and once they reach this age, they seem to age rapidly, dying by age 40. In comparison, humans show a slow aging process, with muscular strength declining over several decades. However, a lot more research on the aging process of nonhuman primates would be necessary to arrive at a sound conclusion with comparative data on performance.

Longer adult life spans can be explained by lower adult mortality rates. Typically, mortality rate is highest for infants, decreases during childhood to reach a minimum at puberty, and increases after adulthood. Case studies of supercentenarians suggest that mortality plateaus after a certain point. Humans have low adult mortality rates compared to nonhuman primates and other mammals of similar body size. The adult mortality rate for humans doubles every 8 years, while for mice it doubles every 120 days (Hill, 1993). The decrease in adult mortality rates can be explained by a lower extrinsic mortality rate, which is determined by predation and environmental hazards (Harvey & Nee, 1991). With a lower extrinsic mortality rate, adults will live long enough to die from age-specific frailty (Robson, van Schaik, & Hawkes, 2006); therefore, senescence rates are directly related to the extrinsic mortality rate. A slower rate of aging among humans would lead to greater differences in maximum life spans between humans and great apes (Hawkes, 2003).

One unique aspect of human longevity is the long postreproductive phase, especially for women. In mammals, females are born with a store of oocytes that then go through the final stage of oogenesis and ovulation (release of egg) during the reproductive phase of life. Once the number of remaining oocytes nears zero, reproductive senescence begins, and reproduction ceases. Cessation of the menstrual cycle is called menopause. A mammalian female will experience menopause, if she lives long enough. Likewise in human females, ovulatory cycling stops when there are not enough oocytes to stimulate ovulation. However, in nonhuman species, there is more or less a correspondence of reproductive and somatic senescence; humans, in particular women, are unique in that reproductive senescence occurs far before somatic senescence. In fact, women can be expected to live 25 years or more after menopause; a woman

undergoing menopause does not experience a corresponding aging process in other parts of her body.

Although not enough research has been done to document age-specific changes in fertility and fecundity in older female nonhuman primates, the few studies of captive female primates show that the age at which fertility declines for these females, about 45, is similar to that of human females. This suggests that the timing of menopause is consistent through different taxa; women undergo menopause in accordance with other primate species. What is unusual in humans is the slow rate of aging beyond menopause resulting in a long postreproductive period.

The long postreproductive phase for humans, specifically human females, is a rare phenomenon in biology and therefore warrants attention. Menopause is unique in the sense that women cease to be reproductive while survival probability is still quite high and will remain so for many years. This phenomenon is found only in humans; it is not observed in nonhuman primate females, who do not live for an extended period beyond the cessation of ovulation (Pavelka & Fedigan, 1991). The grandmother hypothesis proposes to explain the extended postreproductive period by positing that human females maximized reproductive fitness by helping their daughters take care of their own offspring (Hawkes, O'Connell, Blurton Jones, Alvarez, & Charnov, 1998). The hypothesis received much attention, but it still needs strong empirical support (Hill & Hurtado, 1991).

Theories on the Evolution of Longevity and Aging

The idea of an innate biological limit of life span is supported by the observation that maximum life span does not seem to change over time. In addition, there seems to be a limited number of cell divisions *in vitro* even when the medium is kept fresh. It is not clear that the same limit applies to cells *in vivo*. However, some consider it evidential for programmed death.

Although some have argued for a nonevolutionary explanation of life span and aging, an emerging consensus is that life span and aging are processes that are possibly subject to natural selection. In this view, life span is extended or shortened as a result of selection. One explanation for aging lies in pleiotropy or antagonistic pleiotropy: That is, the same gene responsible for benefits early in life is also responsible for aging and deterioration late in life (Williams, 1957). Since increasingly fewer individuals survive to older age, there will be fewer in the age cohort, and consequently deleterious effects will not be under strong selection; likewise, a gene that confers a slight advantage early in life, when there is stronger selection due to larger population size, would be selected for even if it causes a major deleterious effect later in life. A version of the antagonistic pleiotropy theory is the disposable soma theory, which explains senescence (Kirkwood & Rose, 1991). The proponents of the disposable soma theory argue that energy needs to be used for somatic maintenance and repair. Reproductive efforts divert the

energy away from such somatic repair and maintenance, resulting in a tradeoff between survival and reproduction. Natural selection will favor energy allocation to reproduction at the expense of somatic maintenance, and therefore infinite survival is not achieved.

The decrease of mortality results in the increase in average life expectancy, as more people survive to later age. There are two components of death (mortality): external mortality, due to environment, and internal mortality, referring to the presumably innate biological limit of life span. In theory at least, there is a distinct difference between extrinsic and intrinsic mortality: Extrinsic mortality refers to mortality sources that are not results of reproductive and other life history decisions; intrinsic mortality refers to mortality that is not influenced by extrinsic sources and is, therefore, implicitly innate. Accordingly, aging can be defined as an increase in the intrinsic mortality with age. It is often assumed that internal mortality is specific to a species, while external mortality can be variable due to environmental factors including food supply, diseases, and accidents. In modern days, external factors also include medicine and public health measures. However, it is not easy to distinguish between intrinsic and extrinsic effects using empirical data. Once an individual survives all external mortality factors, senescence starts the process in which the individual's likelihood of survival declines. The aging process is not well studied among organisms in the natural habitat, because few survive to be old.

A useful theory to explain life span comes from the evolutionary perspective, which views life span as a balance between external and internal forces (Stearns, 1992). External forces lengthen life span by changing the relative value of adults versus offspring. If adult mortality is low and not variable compared to juvenile mortality, allotting resources for repair and maintenance of adult soma retains value; hence, there is selective advantage on extending adult life span. However, if adult mortality is high and variable compared to juvenile mortality, selection for adult life span becomes weak; as a result, aging effects accumulate and life span shortens.

The contribution of genetics to life span is not clear, nor is the effect of environment. Although genetics have been shown to influence life span in organisms such as nematodes and fruit flies, even nematode longevity seems to be plastic, with great variation in aging and life span. Although it is often said that long life runs in families, this does not directly point to a high heritability of longevity as a trait. This is because human families share more than genetics; they share lifestyle, wealth, education, socioeconomic status, and so forth. Therefore, even if a strong familial connection is shown, it does not lead to a clear conclusion about the genetics of human longevity. Studies on monozygotic twins also support plasticity of longevity.

The idea that aging is programmed for the fitness of the species (Weismann, 1889) has not received much support, because most organisms in the wild do not live long enough for the aging trait to be effective, and because group selection in general is not supported. The programmed aging hypothesis has not been supported by empirical evidence, either. Although several genes have been discovered to extend

longevity in their mutant form, no gene has been discovered that completely eliminates aging altogether in its mutant form.

Current evolutionary thinking on aging takes a combination of the mutation accumulation model and the antagonistic pleiotropy model. The mutation accumulation model posits that late-acting mutations will remain in the genome, even if they are detrimental to survival and reproduction, if not many individuals live long for these mutations to be exhibited due to high extrinsic mortality. Because of weak selective force, such mutations accumulate over generations, and the accumulative effect will result in aging for those individuals who survive long enough (Medawar, 1952). The antagonistic pleiotropy model provides a case for why late-acting mutations would be selected: If a pleiotropic gene provides a selective advantage during an individual's life when selection is strong, while providing a selective disadvantage during the time when selection is weak, such a gene would be selected for (Williams, 1957). Genes associated with the aging process would be such an example. Antagonistic pleiotropy and mutation accumulation are not mutually exclusive; both mechanisms are a result of weakening selective forces later in life. Physiological and biochemical expressions of aging are thought to be a result of reduced investment in repair and maintenance from the two mechanisms. However, research efforts to find antagonistic pleiotropic genes involved in aging have so far yielded unconvincing results, except life-extending genes that have been shown to have detrimental effects during early life.

There is some evidential support in physiology research that shows a trade-off. The disposable soma model argues that a lifetime of trade-offs (decision to allocate resources to some and not to others among growth and development, somatic maintenance and repair, and reproduction) evolved to maximize fitness (Kirkwood, 1977). Resources are used for somatic maintenance only if there is a good chance of survival in terms of extrinsic mortality: Under high extrinsic mortality, resources are diverted toward reproduction, away from somatic maintenance. The cost of accumulation of wear and tear (somatic damage) that is not repaired is the aging process. Indirect support for this model can be found in the match between intrinsic longevity (maximum life potential) and extrinsic mortality (Ricklefs, 1998). If these two are associated, a decrease in extrinsic mortality should result in the increase of longevity. This connection has been used to explain human longevity.

The aging process is intimately associated with the accumulation of damage on the molecular or the cellular level. Organisms with longevity invest more on repair and maintenance than those with short lives do, resulting in slower accumulation of damage over life. Thus, slow aging and longevity are connected.

Although a substantial proportion of research concentrates on discovering a specific single gene that is directly responsible for aging, there is increasing awareness that aging is a phenomenon contributed to by multiple factors and genes. This is predicted by evolutionary theory, given the variation and plasticity of the aging process. However, it is also true that mutation in a single gene can have a major effect on life span in

some organisms, such as *C. elegans*. There seems to be a central regulator of aging that regulates the multiple genes involved in aging (Cutler, 1975) by responding to environmental signals: When environment is hostile and nutritional access becomes difficult, organisms will change allocation of resources, diverting energy away from reproduction and into somatic maintenance. Findings that calorie restriction leads to life span extension can be explained by this hypothesis.

An evolutionary analysis of human longevity often applies life history theory. Life history theory aims to explain the variation in timing of fertility, growth, developmental rates, and death of living organisms according to trade-off mechanisms between mortality, fertility, and reproductive success. Life history variables include age-specific mortality and fertility as well as traits that are associated with age-specific mortality and fertility, such as life span, age at which an individual first gives birth (for females), and growth and development. First developed in the 1950s, life history research saw an increase in attention in the 1990s (Charnov, 1993; Roff, 1992; Stearns, 1992). The basic principle of life history theory relies on trade-offs; that is, due to limited resources, decisions have to be made in terms of resource allocation in such a way that allocation to one purpose deprives allocation to another, competing purpose. Assuming an optimal allocation strategy, one could posit a pattern of life history of organisms. Natural selection shapes life histories that lead to fitness advantage while also leading to evolution of the ability to change life history variables in different environments.

The human life history pattern differs from that observed in the great apes in its slow maturation, slower growth, higher fertility, and increased longevity, which is associated with menopause in women (Hawkes et al., 1998; Kaplan, Hill, Lancaster, & Hurtado, 2000; Robson et al., 2006). Within the framework of life history study, human longevity becomes a part of a configuration of life history variables that can be summarized as *slow life*: slow growth, late onset of reproduction, and slow mortality (Charnov & Berrigan, 1993). Primates in general are slow, and humans are particularly slow, although there are some parts of human life that are fast, such as increased fertility (Charnov, 1993; Harvey & Clutton-Brock, 1985; Harvey & Nee, 1991; Prothero & Jurgens, 1987).

Although it is often argued that humans have only recently started to live long lives, some argue that increased longevity and decreased mortality may have a long history in human evolution (Paine & Boldsen, 2006). According to Charnov, it is the slow growth that is driving the evolution of slow life history (Charnov & Berrigan, 1993). As such, longevity is an associated, correlated phenomenon (or an epiphenomenon) resulting from slow growth, and it is slow growth that needs to be explained. On the contrary, longevity itself may be selected for, and this needs to be explained. Examining the changes in longevity through time may shed light on this issue.

Longevity in the Human Fossil Record

Changes in longevity itself have not been empirically assessed. This lack of focus on longevity is at least partially

due to constraints inherent in paleodemography that impede the reconstruction of life tables for fossil populations. Longevity is difficult to assess for prehistoric populations because of a number of well-known problems that affect paleodemography. First, fossils are almost always available only in small sample sizes, which limits application of conventional statistical methods. There is always a question of whether specimens adequately represent the populations to which they belonged.

Second, different age groups are differentially preserved. This is particularly problematic for juveniles, since their fragile skeletons are less likely to be preserved than those of older individuals. This has far-reaching implications, because most of the parameters of interest in demography, those that are present in life tables, are dependent on information about juveniles. Understanding of longevity is likewise affected by juvenile data, because life span is strongly influenced by juvenile mortality rates.

Finally, there is the problem of assessing age at death. Even for modern humans, adult ages at death can be difficult to estimate with precision, especially for older individuals. Virtually all aging methods become less accurate with increasing age, and are most effective with multifactorial approaches, which utilize many different criteria for aging a single skeleton. Because most fossils are fragmentary, multifactorial approaches are usually impossible, and because so much is unknown about maturation rates and other life history factors, estimation of age at death is daunting. In addition, uncertainties about maturation rates, which may have varied over the course of human evolution, make numerical assessments of age at death problematic.

These three problems—sample size and associated statistical limitations, the absence of representative juvenile data that impede the construction of demographic profiles, and the lack of resolution possible when determining ages at death for fossilized remains—have caused impediments to the empirical study of human longevity in the fossil record.

Because it is so hard to study directly, prehistoric longevity has been discussed through its correlation with other variables, such as body size, brain size, and growth and development patterns. The actual pattern of change in adult survivorship critical to testing the relevance of correlations between brain size and longevity for human evolution, and any of the other questions surrounding the evolution of human longevity, have yet to be empirically established.

Population Growth and World Population

Humans live everywhere in the world, in both northern and southern hemispheres. However, this was not always the case. At the beginning of the ancestral human lineage, after the divergence between humans and their closest related species, ancestral fossil humans (hominids) lived only in Africa, in small numbers. It is with the appearance of the genus *Homo* in the terminal Pliocene and Pleistocene epochs that ancestral humans spread out of Africa into the world. Presuming that population density was maintained

during the worldwide spread of humans, the overall population size would have increased accordingly. As of January 1, 2009, world population was estimated at 6.75 billion.

While ancestral humans subsisted on foraged foods, population size increase was kept at a relatively modest rate. With food production through agriculture and animal domestication, population size and density increased substantially. With the Industrial Revolution, world population saw an increase in the increase rate, leading to an exponential increase in population that led to many alarmist concerns about a population explosion. World population has seen acceleration in its growth rate since the mid-18th century.

Population growth is a result of an accumulated surplus over time, a surplus generated from an imbalance between members coming in (births) and members going out (deaths). Regional population sizes are determined by migrations (emigrations and immigrations) in addition to births and deaths, but the effects cancel out when viewed from a world perspective.

For population to grow, fertility has to be higher than mortality. When the number of people reaching adulthood and reproducing equals the number of people dying, the population size is at equilibrium, and there is no growth. Such a population is said to be stationary. For most of human history, it is assumed that there has been a balance between fertility and mortality, that both fertility and mortality have been kept high. With recent advances in medical care and nutrition, mortality has decreased, while fertility has not changed much. The resulting increase in population size has subsequently met with another change, a decrease in fertility. Eventually, population size will reach a plateau with both fertility and mortality kept low. The demographic transitions model argues that human populations undergo a series of changes, first a decrease in mortality, then a decrease in fertility.

The actual birth rate, or the fertility rate, is lower than the maximum possible birth rate; biological events such as miscarriages, abortions, and stillbirths as well as sociocultural conditions such as contraception, delayed reproduction, late marriage, and celibacy contribute to the difference between possible birth rate and actual birth rate. Human populations differ in fertility rates, from more than 10 children per woman to 2 children per woman.

In the 1970s, there was quite an interest in the total number of humans that have lived throughout history, and some scholars gave estimates based on an exponential growth model for human populations. Based on the distribution pattern and density of archaeological sites, it seems that human species lived in small populations with low population density during most of human evolutionary history. Weiss used hunter-gatherer population density of 0.28 per square kilometer to estimate population size from areas of habitation during the Pleistocene: His calculations indicate that there were 0.5 million people between half a million and a million years ago, and that this number increased to 1.3 million in the Middle Paleolithic (Weiss, 1984), although such estimates are far from accurate and associated with large error.

With the appearance of the genus *Homo* in the early Pleistocene, hominid populations expanded throughout the

world, continuing to grow in size. The world population now is well over 6 billion. For most of human history, humans lived in small, mobile groups. Consequently, population size was small. It is only in the last 10,000 years, with the adoption of food production through agriculture, that world population has seen an explosion in its growth rate. Considering that only 6 million people may have inhabited the world around the beginning of the Holocene (and agriculture), there is a 1,000-fold increase in world population in the last 12,000 years (Weiss, 1984). Such exponential population growth has continued since the start of agriculture in the early Holocene (Pennington, 1996) and possibly started before that during the late Pleistocene (Hawks, Hunley, Lee, & Wolpoff, 2000).

The proportions of people at different ages are often represented by a population pyramid, which shows the percentage of population by age and sex. The shape of a population pyramid reflects the mortality and growth rate of that population. A population pyramid with a wide base and narrow top (approximating a triangle) represents a high mortality or high fertility rate. If fertility rate increases, the base will expand, as there will be a higher proportion of younger people in the population. If fertility rate decreases, the base will narrow, and the population becomes older. The recent global trend of fertility decrease is producing a top-heavy population pyramid with a higher proportion of older people in many countries. Such countries have met this prospect with much concern about the economic support of the elderly, their healthcare, and their quality of life. It should be noted that the demographic shift has occurred with changes in fertility and few changes in mortality or adult life expectancy. In a forager population, only about 10% in a cohort will survive beyond age 60, and they will make up 3% of the population; in contrast, modern industrialized countries can easily see 75% to 85% in a cohort surviving to age 65 (Weiss, 1981).

Conclusion

There are several aspects of longevity. Maximum life span is thought to be biologically determined, while average life span or life expectancy is subject to extrinsic mortality rates. Several models have been proposed to explain the biology of longevity and aging. The hypothesis of programmed death does not have a strong support. Current research supports the combination of the mutation accumulation model and the antagonistic pleiotropy model.

Using the correlation between longevity and brain size or body size, life span of ancestral humans can be estimated. Increased longevity over time is one of the distinguishing features of the human species. Documenting the pattern of changes in longevity through time is critical in understanding the evolutionary origin of human longevity and its relationship with other human life history variables. However, empirical examination of past human longevity faces methodological difficulties due to the nature of fossil data. While there is a trend of increase in longevity over the course of human evolution, the increase is most dramatic in

the modern age since the Industrial Revolution. Increased longevity is a result of decreased adult mortality and is one of the factors contributing to increase in population size. As in the case of longevity, human population size increased over time, with the most dramatic increase coming after the Industrial Revolution.

ENVIRONMENTAL ISSUES

ERIN E. ROBINSON

Canisius College

Environmental issues can be discussed within a number of different contexts. For anthropology and sociology, culture and society become important factors in understanding environmental issues. By incorporating a perspective that includes environmental history, aspects of environmental change, dialogue and culture, and future concerns, a more complete understanding of the relationship between sociocultural actions and the natural environment can be developed. In an effort to understand the nature of environmental problems, one must develop an understanding of the cultural paradigms that guide human behavior and interaction with the natural environment. Many perspectives seek to explain this relationship. Social scientists look toward dialogue and cultural perspectives to trace the history of environmental concern.

Historically, humans have understood their role to be one of dominion over nature. This is explained in numerous classic works and referenced in many religious and spiritual texts as well (Bell, 2008; Dunlap & Mertig, 1992). Cultural paradigms exist that serve to guide our interactions with the environment. Most stem from the anthropocentric belief that the world is centered around people and that human society has the right to maintain dominion over nature. Structural beliefs provide the foundation of these understandings.

Cultural Beliefs and the Environment

The belief that a free market system provides the greatest good for the greatest number of people leads us to

place economic decision-making processes in private hands. Frequently, private decisions have public consequences, but these public consequences are not accounted for in production costs or covered by market costs. Instead, the costs are passed on to consumers in the form of taxes and higher base prices for goods and services. Esteemed environmentalists Al Gore Jr. and Robert Kennedy Jr. have argued that if the external costs of production were assumed by manufacturers, then the ultimate benefit would be a system that accounted for waste created in the production process. This is evident in their research on global warming. Coal-fired power plants are promoted as one of the cheapest forms of creating energy. This is misleading, because the health effects of pollution caused by coal are not included in the costs of production. Others argue that those costs would have to be passed on to the consumer. However, they are passed on now in the way of pollution and medical expenses for illnesses associated with environmental contaminants. Coal is one of the biggest contributors to greenhouse gases, thus leading to the overall societal costs of global warming.

Another cultural belief is that the natural world is inexhaustible. Extraction of natural resources happens at an incredible rate without a consideration to limits. Society's constant dependence on nonrenewable energy forces mining and the refining of coal and oil to keep up with these demands. Consumer goods are deliberately planned to become obsolete within a relatively short time, and consumers are pressured to buy replacements. This process

has been conceptualized in research focused on the treadmill of production. Production and utility processes, using natural resources, dominate the modes of production. The reliance on the treadmill model provides perpetual extraction and production, increasing the fragility of the natural environment.

Another cultural value resides in a lasting faith in technology. Culturally, we believe that technology can meet any challenge. Humans are seen as ingenious creatures able to devise solutions for any problem. However, technology itself is not sufficiently controlled and can create more problems that contribute to environmental degradation. This can lead to a situation known as *culture lag*, used here to describe a situation in which technology has outpaced the cultural ability to respond to the consequences of using a given technology.

The philosophy of the growth ethic argues that growth equals progress. Successful cultures are often defined by their levels of progress. Urban sprawl exemplifies the connection between progress and environmental destruction. Urban ecologists argue urban sprawl follows the concentric circle urban planning mode of the early 20th century. Residents were encouraged to develop space for residential purposes further away from city centers. This was culturally promoted as prime real estate, and individuals continued to purchase land as a showing of class standing. Urban sprawl results in the loss of green and open space, increased use of natural resources, and more vehicle miles traveled as commuting distance continues to increase.

Materialism is a cultural value that also contributes to how environmental problems emerge. Americans tend to measure success in terms of the consumption of material things. Globally, the most valued nation is one that can command and use the largest fraction of the world's resources. Currently, the United States supports 5% of the world's population and uses 25% of the world's natural resources. This is evidence that the cultural emphasis on the consumption of material goods is in direct correlation with natural resource use.

Two final cultural values that impact environmental practices are individualism and an anthropocentric worldview. Cultures that emphasize individual rights and personal achievements tend to have a greater environmental impact. We place benefits to the self over what is best for the collective. Subsequently, the anthropocentric worldview is centered around human beings, thus inferring that human beings are superior to other beings and have natural rights to use the environment to ensure the progress of human beings as a species.

Subsequently, these cultural beliefs form the principles that overwhelmingly guide cultural interactions with nature. Theoretically, they serve as paradigms that explain the emergence of environmental issues. The following section provides specific theoretical underpinnings of environmental issues.

Theory and the Environment

Theory addressing environmental issues has been situated in the social constructionist and political economy approaches. Within these approaches, attention has been paid to developments of subfields in social science research, such as social movements and the environment, environmental health, and environmental justice.

Social Construction and the Environment

Social constructionists focus on the construction of social problems and how this allows individuals to assign meaning and give importance to the social world. Sarbin and Kitsuse argued that "things are not given in the world, but constructed and negotiated by humans to make sense of the world" (1994, p. 3). When interests are at stake, claims are made around an activity in order to define the interests as problems. The process of claims making is more important than the task of assessing whether the claims are true (Hannigan, 1995).

Hannigan provides a three-step process for the construction of environmental problems: assembling, presenting, and contesting. He argues that each step develops the claims-making activities of environmental activists and antagonists. Environmental problems are different from other social problems, because claims are often based on physical, chemical, or biological scientific evidence (Hannigan, 1995). In nearly all cases of environmental problems, even though such problems are based on scientific evidence, the burden of proof falls on the claims-makers, the environmental actors.

When a claim about an environmental problem is presented, state and corporate actors emerge most often to challenge the validity of these problems. Although these actors are willing to construct the issue as a "problem," support to alleviate the problem is often lacking. If it supports the alleviation of the problem, most probably through funding remedial efforts or research, the state or corporation is seen as taking responsibility for the problem. If the state is seen as responsible, its perceived legitimacy decreases, which may lead to decreased trust. On the other hand, if a problem is not acknowledged, then trust in government may also decrease, because the perception arises that the interests of the state are not the best for the people.

The power of individuals in roles and positions to define these claims is ultimately what allows problems to be defined as problems. Claims may be made by others not in a position of power, but they are often not seen as valid because of the lack of power associated with the role. Different claims of environmental problems then lead to different definitions of the problems.

Definitions of problems are framed to illustrate specific viewpoints of what the problem is. Goffman used

the term *frame* in order to explain interpretations of occurrences. Frames can serve as explanations or guideposts to individual or collective action (Snow & Benford, 1988). Snow and Benford describe framing as an activity performed by social movements to express their viewpoints and “to assign meaning to and interpret relevant events and conditions in ways that are intended to mobilize potential adherents and constituents—to garner bystander support and demobilize antagonists” (p. 198).

By framing events in certain ways that assign meaning to them, actors can attempt to mobilize support and delegitimize opposing viewpoints. Because different frames may emerge surrounding the same problem, individuals may choose to adopt one or the other on the basis of the reliability of the frames. One factor in determining reliability is trust in the actors who present the frame. Constituents may mobilize around one frame because trust in that explanation and the organization that presents it is high (Robinson, 2009). This impacts how individuals interpret the seriousness of environmental problems and subsequently whether issues will be acted on and in what manner.

Social Construction and Social Movements

The framing process can serve to mobilize constituents for or against a particular cause. Mobilization against frames that are presented by actors emerges when the audience of the frame has low trust in the source of the frame. Social movement literature has acknowledged the emergence of mobilization over environmental issues where lack of trust is present. Examples include institutional recreancy, lack of trust in government agencies and officials, and the combination of the two (Brown & Mikkelsen, 1990; Cable & Cable, 1997; Freudenburg, 1993; Gaventa, 1980; Gibbs, 1982).

Charles Tilly provides a model for mobilization that bridges some of the ideological views of frame analysis with collective action and resource mobilization theory. Tilly’s (1978) definition of mobilization is “a process by which a group goes from a passive collection of individuals to an active participant in public life” (p. 69). A further extreme of this model is resource mobilization theory, which gives even less importance to ideological factors and, instead, emphasizes the need for available resources. The combination of ideologies, resources, and the power of frame presentation contribute to mobilization. Using this analytical framework, the emergence of environmental problems and mobilization around these problems can be better understood.

Environmental problems in communities provide a setting to further explore this connection. Community organizing around local problems has a long history in the United States. Many forms of community organizing exist. These have included writing and literacy circle

newsletters in the late 19th and early 20th centuries, Saul Alinsky’s model of radical politics to create mass organizations to seize power and give it to the people (1971), and neighborhood block clubs. The goals to spread awareness, ensure social justice, and understand that city hall can be fought vary in scope and magnitude but have often proved to be effective models for organizing.

Citizen action in response to toxic waste at Love Canal has emerged as the premier example of community organizing over environmental issues. The story of neighborhood organizing and the quest for a clean, healthy environment is acknowledged in most major studies on environmental issues. The specifics of this case follow in a later section where the application of environmental issues is discussed.

Political Economy and the Environment

Theories of political economy of environmental issues focus on the development of political and economic practices and policies that contribute to environmental problems. Primarily, the focus has been on the creation of the capitalist mode of production that leads to overwhelming environmental destruction. Furthermore, the development of capitalism promotes a political environment that is friendly to more profitable, but less environmentally friendly, practices.

In addition to physical environmental realities that production processes cause, issues of health and economic injustice exist. Bryant and Mohai (1992) asked whether a safe environment is a civil right. They argue that people of color see environmental degradation interrelated with economic and political justice. This is the fundamental idea behind environmental justice in both action and theory. Another issue in environmental justice arises because people of color and lower income are less likely to have access to health insurance; thus, they become more ill if exposed to environmental hazards without means of treatment. Therefore, these populations share more of the negative environmental burden and have fewer resources to resolve the given problems.

The connection between health and economic justice is not a new relationship. Since World War II, there has been an increase in the development of the petrochemical industry. Coinciding with an increased demand for synthetic chemicals was an increased demand for disposal sites for waste byproducts of these chemicals. Many disposal sites were created in vacant plots of land, without the regulated disposal standards in place today. Expensive land used for the disposal sites of the 1940s and 1950s became the residential suburban developments of the 1960s, 1970s, and 1980s. With the post-World War II increase in population, many families were moving into suburban neighborhoods. Families felt safe from the problems of the cities, but they were not aware that many

residential properties were built near the abandoned chemical waste sites of prior decades.

The problems of environmental contamination were first addressed publicly in Rachel Carson's *Silent Spring* (1962). Her warning of chemical contaminants silencing biological life was not heeded at the time her book was published. These issues were not addressed until the 1970s with the first Earth Day in 1970, followed by the passing of numerous pieces of environmental protection legislation and the creation of the Environmental Protection Agency (EPA). Through this period of uncertainty, unclear scientific findings overwhelmed policymakers and the public, leading to confusion about how to develop environmental policies and actions.

Environmental Issues: Method and Application

Environmental problems have manifested most directly in the form of pollution. Evidence of environmental destruction is seen in the form of air, water, and land pollution that has a direct impact on the health of the human population. One of the most direct links between pollution and negative health effects has been identified since the creation of the petrochemical industry in the 1940s. Since this time, we have seen more cases of cancer and respiratory illness in the human population. The rate remains high even when controlling for mitigating factors, such as the effects of advanced medical technology in treating these illnesses, and lifestyle factors, such as diet and smoking. This case was made with the infamous discovery of toxic waste at Love Canal, New York, in 1978.

Literature in this area addresses the possible effects of exposure to toxins on one's health. However, few studies have provided irrefutable evidence supporting the research hypothesis (association exists) or the null hypothesis (no association exists). Scientists know that chemicals can have adverse effects on the human condition when ingested, but they argue that some indirect exposures through air, soil, water, or residential habitation in proximity to such toxins have not provided similar consequences. The basic disagreement emerges in how one views risk, either through the precautionary principle or through risk assessment and evaluation. Proponents of the precautionary principle argue that if the chance of danger is present, then precaution should be used to avoid exposure. Risk assessment would argue the opposite—that the risk must be known before action is taken to avoid exposure. The difficulty is that science has not provided irrefutable evidence on the dangers of many chemical substances; therefore action for their removal from products and the environment has been slow. Recently, Devra Davis took on this phenomenon in *The Secret History of the War on Cancer* (2008). She outlined the lack of scientific responsibility in reporting findings connecting cancer and chemical exposure.

Most reports have not described exposures accurately, or they have failed to completely identify a causal factor (National Research Council, 1991). The Committee on Environmental Epidemiology was formed to assess the progress on hazardous waste assessment since the creation of Superfund and the Agency for Toxic Substance and Disease Registry. The committee concluded that no conclusive reports could be used to base policy on, because there are no measures in place to accurately depict exposure assessments. Their conclusions continue: There exists no comprehensive inventory of waste sites, no site discovery program, no minimum data set on human exposures, and no policy for immediate action if exposure exists (National Research Council, 1991). The report indicates that “the nation is not adequately identifying, assessing, or ranking hazardous-waste site exposures and their potential effects on human health” (p. 21).

Environmental toxins have long been thought to be causally related to the incidence of disease. Air pollution, specifically with carbon dioxide and sulfur dioxide, has been studied in association with asthma and pulmonary disorders (Carnow, Lepper, Shekelle, & Stamler, 1969). Water pollution, particularly with trichloroethylene and tetrachloroethylene, sparked a concern about childhood and adult leukemia in Woburn, Massachusetts (Brown & Mikkelsen, 1990). Similarly, numerous studies have been conducted that investigate the exposure-ailment connection (Landrigan, 1990; Neutra, Lipscomb, Satin, & Shusterman, 1991; Paigen, Goldman, Mougant, Highland, & Steegman, 1987). These studies use descriptive and case-control methods and field investigations consisting of surveys and physical examinations, resulting in quantitative analyses in order to test hypotheses.

Descriptive studies portray disease patterns in populations according to person, place, and time, and they include time-series analyses (National Research Council, 1991). For example, a study performed by the National Cancer Institute used maps of cancer incidences and toxic waste sites, concluding that the high incidence of bladder cancer in northwestern Illinois counties was significant and leading to the implementation of an incidence study using survey methods (National Research Council, 1991).

A cohort study was employed with North Carolina residents who consumed raw polluted river water contaminated by an industrial site from 1947 to 1976. Residents' rates of all forms of cancer were more than twice those expected in the general population (National Research Council, 1991). Once exposure ceased, rates returned to the expected level, adjusting for latency.

The epidemiologic case-control study carried out in Woburn, Massachusetts, yielded an association between leukemia and drinking from contaminated wells. The EPA could not pinpoint the source of contamination; therefore, it could not infer conclusively that the cases of leukemia were due to the proximity of a hazardous waste site (Lagakos, Wessen, & Lelen, 1986).

Griffith, Duncan, Riggan, and Pellom (1989) analyzed EPA and cancer mortality data from 13 U.S. sites where there were major incidences of cancer between 1970 and 1979. They found evidence that contaminated ground water was used for human consumption at 593 waste sites in 339 U.S. counties in 49 states. Significant associations were found between several cancers and exposure to contaminated water in white males; these included cancers of the lung, bladder, esophagus, stomach, large intestine, and rectum (Griffith et al., 1989). Higher incidences of cancers of the lung, bladder, breast, stomach, large intestine, and rectum were found in white females in these counties (Griffith et al., 1989), when compared with females in counties that did not have hazardous waste sites. However, this study has been criticized based on its use of population-based incidences of cancer rather than individual-level estimates. Researchers inferred that proximity to hazardous waste sites caused cancer.

Wong, Morgan, Whorton, Gordon, and Kheifets (1989) performed an ecologic and case-control analysis to evaluate whether there was an association between groundwater contamination with dibromochloropropane (DBCP) and mortality from gastric cancer and leukemia. The only positive association that was found was in farm workers. No relationship was found for gastric cancer or leukemia with DBCP contamination of drinking water.

Neutra et al. (1991) found that individuals living near toxic waste sites had one or more bothersome symptoms that those living in control areas did not have. However, rates of cancer and birth defects were not found to be statistically significantly different for these individuals than for those in the control neighborhoods. Symptoms such as worrying, depression, and nervousness were more likely to be the result of knowledge of the site and its contaminants than the result of chemical exposure. Although some practitioners argue that residents near these sites do show higher incidences of asthma and psychological disturbances than individuals in control groups, the findings remain highly controversial (Neutra et al., 1991).

For the most part, these studies consist of survey and field investigation methodologies, relying on self-report methods. One problem with explaining associations that rely on self-report methods is that if residents want to be relocated or have other agendas, then the degree to which symptoms are reported may increase. Many residents felt that this was what some homeowners were hoping for at Love Canal. This remains one of the most critical problems with state and federal agency studies that seek to provide evidence of community risk.

With the increase in studies in this area, the public has been partially reassured by having the knowledge that at least concerns are being recognized. Specifically, cancer rates are still high, but the fear of human-made chemicals has largely been dispelled. Most recently, the organic food movement has been gaining legitimacy. Yet, many still doubt the health benefits behind this movement. Studies

concerning environmental racism have been more prevalent, focusing on the incidence of lower-income, nonwhite families living near toxic waste sites. This focus has taken attention away from specific health problems. Instead, the focus has been on issues of political economy and equity. This is not a criticism of environmental justice but rather a call for the convergence of natural science and sociology in order to address both issues. Other variables to be considered in these studies may include racial composition of counties, social class of counties, concentration of low-income occupations in counties, new housing starts in counties, and the percentage of welfare recipients per county.

Risk Perception and Environmental Health

The uncertainty of science had created cross-discipline dialogue. Social scientists have addressed environmental issues in studies of risk assessment, disaster relief (both natural and technological), toxic exposure, and other data-driven areas. Because of the risk of chemical exposure due to toxic waste, landfills emerged as one of the most imminent public health threats with the discovery of Love Canal. However, even in cases where studies to show an association between illness and exposure to toxic chemicals have been inconclusive, the message has been that these chemicals cause cancer and needed to be eradicated.

An important role of science is to inform the public of findings, usually through the media. Epidemiologic studies deal with human populations and are often questioned based on the legitimacy of the data and the willingness of the agency or corporation funding the research to share findings with the public. These studies are also usually based on relatively small populations and a small number of events; this results in a lack of significant findings, because sample sizes are too small to generate statistically reliable conclusions. Researchers are asked to report conclusions to various interest groups that may have a stake in the research problem. The pressure of the public arena and media, with emerging concerns and consequences for public health and the environment, has led to a decrease in the willingness to share data and be criticized if the data do not fit the public agenda. Politics and public perception surpass what science is able to provide. Science's inability to prove negatives has led to public policy that tries to control what cannot be established. This uncertainty shapes policy to err on the side of protection; yet in many communities the risks are endured regardless.

Findings often snowball into hard line conclusions and the perception of a problem when one may not exist, or vice versa. Risk perception and the realization of risks are two different things. Risk perception may encompass what one believes might occur or an understanding based on secondary information. Risk realization occurs when one is physically affected by the agent or situation and a decision to act is based on that encounter. The problem arises

in this discrepancy. Perception is what people perceive to be happening. With different information from different scientific experts, the public is left to decide on their own who or what is right, based on the health and well-being of themselves and their families.

Freudentburg (1993) discussed the concept of risk and recreancy in public decision making. He argues that an increase in institutional responsibility for risk management has created a system where responsibilities are often overlooked. This concept proposes increased frequency in institutional decision making in risk analysis. Freudentburg (1993) coined the term *recreancy* to identify the institutional failure to follow through on a duty or responsibility or broadly expected obligations to the collective. Questions are now raised by individuals deciphering scientific studies for themselves, but they now question the role of institutional actors. Without correlational data from an alternative institutional source that they trust, citizens do not know where to turn for clear answers about data regarding environmental toxins.

Community-based studies by community organizers have emerged in an attempt to address the failure of institutions to provide real, understandable answers regarding human health and exposure rates. Specifically, recent literature calls for more involvement of the scientific community in the decision-making process. A resurgence of popular epidemiology, since Lois Gibbs's attempt in 1978–1979, has found individuals using lay methods to determine association. Even if they don't result in strong, scientific evidence, community-based studies at least provide the groundwork and show a need for more in-depth studies. Brown and Mikkelsen's 1990 study is a strong example of this method. The question of whether there was a connection between childhood leukemia and known contaminated well water divided the community, but it forced epidemiologic studies.

Coinciding with these revelations, other studies were being conducted that attempted to link other contaminated sites with adverse health effects. As Gots (1993) stated, most were laboratory studies in simulated environments. Examples of human studies existed only in the sociological and epidemiological literature (Brown & Mikkelsen, 1990; Gibbs, 1982; Landrigan, 1990; Neutra et al., 1991). Incidences of chemical scares were also prevalent. Headlines concerning the dioxin scare at Times Beach, Missouri; contamination of apple crops with the synthetic growth regulator Alar; and use of Agent Orange created the fear that human-made chemicals cause disease. Evidence existed that these specific chemicals may cause health problems in humans, but data on the incidence of illness relative to exposure and on synergistic effects of these chemicals were missing. Furthermore, there was even less information available about other potential threats to health, such as airborne and waterborne contaminants, environmental sensitivity disorders, and living in proximity to hazardous waste sites. To establish a causal relationship

between exposure and chemicals, obtaining valid measures and estimates for exposure is essential.

Environmental Movements

Contaminated Communities; The Challenge of Social Control; Environmental Problems as Conflicts of Interests; Disasters, Collective Behavior, and Social Organization; Love Canal: Science, Politics, People, and Power; and Powerlessness are just a few of the book titles that describe the scope and emergence of the mobilization surrounding environmental problems. Since the publication of *Silent Spring*, the struggle to define, understand, and resolve environmental problems has inundated environmental literature as well as the agendas of environmental organizations at both the national and local levels.

The environmental movement in the United States can be traced back to the early conservationists at the turn of the 20th century, whose focus was on control of natural resources for technological and societal use. Accompanying this was a movement toward the preservation of the natural environment simply for nature's sake and separate from any use and/or value that human society had placed upon it.

The contemporary environmental movement embraced both of these traditions while focusing on building a political alliance to ensure the passage of legislation that would protect both nature and human health. As evidenced by the multitude of legislative victories the environmental movement claimed during the 1970s, the environmental movement was gaining prominence as one of the most successful efforts of social movement organizers.

Politically, momentum began to shift back toward the wise-use movement throughout the 1980s. Environmental problems were framed in opposition to capitalist goals. Politicians took an either/or stance: jobs or the environment. With one's economic livelihood seemingly at stake, it is no wonder that concern for the environment was diminished in the public agenda. The environmental health movement is arguably one area that continued to keep environmental issues in the public's consciousness. One of the classic and influential cases in environmental organizing, Love Canal, illustrates the interconnectedness of politics, science, and the environment.

Mobilization Around Toxic Waste Sites: Love Canal

To understand the factors contributing to the emergence, awareness, and mobilization around environmental problems, the scope and focus of the problem must be considered. This analysis focuses on the emergence of and mobilization around toxic waste sites found in residential communities. Literature addressing toxic waste sites in communities place Love Canal, New York, as the first community to encounter such a problem that received

national media attention. Although community protests were occurring around the toxics issue as early as 1970, no other site received the same degree of national media attention (Szasz, 1994).

In 1978, Love Canal was declared a federal disaster area, but the final homeowner evacuation was voluntary, not mandatory, even though the state had said a health emergency may exist. Given the possibility of ill-health effects, residents were given the choice about whether to stay or move. Because of the lack of strong correlational evidence, public health officials were not able to substantiate a link between exposure to chemicals and disease (Robinson, 2002).

The questionable contaminated area was evacuated and became known as the Emergency Declaration Area (EDA). It was divided into seven sampling areas. Two studies were performed to assess the habitability and safety of the area. The first study was completed in 1982 by the New York State Department of Health (DOH), the EPA, and the U.S. Department of Health and Human Services. Problems arose about the study's conclusion, which was that the EDA was as habitable as comparable control areas. The Congressional Office of Technology Assessment found that the study lacked information to determine whether unsafe levels of contamination existed and that it did not make clear what next steps should be taken. Thereafter, DOH and EPA conducted a second study on habitability; it was released in 1988. Habitability and safety have been studied in regard to numerous hazardous waste sites, but actual rates of illness have not been linked to exposure to toxic substances from nearby chemical waste sites.

The Superfund Act, passed in 1980, was written specifically in response to the known hazardous waste site at Love Canal. Policymakers recognized that industry used land-based disposal methods, that industrial sites were contaminated, and that an increase in clean air and water standards led to a decrease in land-based regulated disposal (Barnett, 1994). The problem was that there was neither an informed way of counting or tracking these sites, nor evidence of an adverse ecosystem and human effects (Barnett, 1994).

Since Love Canal, no other neighborhood has received the same degree of attention, although many have encountered toxic waste contaminants in their communities (Brown & Mikkelsen, 1990; Bryant & Mohai, 1992; Cable, Walsh, & Warland, 1988). No conclusive, significant correlation between chemicals and cancer has been found at Love Canal or at the other identified exposure sites. Nor has any truly verifiable evidence been found that exposure to, and living near, any other toxic waste site causes disease, though disorders have been loosely associated with chemical exposure, such as asthma, respiratory disease, nerve damage, miscarriages, and cancer.

People living near these sites must often decide on how much they want to expose themselves to risk. Once the presence of a waste site is known, they must decide, without data to guide their decisions, whether to stay in

their homes or leave. This has historically interfered with the availability and collection of valid data. When a study is conducted, residents request to be informed of the results and progress of the study. Because most epidemiological studies require longitudinal or cohort analysis in order to be reliable and valid, it is advantageous to have a stable, nonmobile population. This begs ethical questions, on behalf of the researchers, to disclose data relating to exposure before the study is completed. Researchers cannot both verify exposure findings and expect residents to remain so that they can carry out the remainder of the study. Thus, individuals, families, and communities are asked to base their decisions on claims that cannot be substantiated one way or the other.

Toxic waste sites continue to be discovered in communities. In many cases, the resulting community struggles are extended battles. The operative phrase in many cases is "once a site is discovered." The chemicals in Love Canal were buried 30 years before it was known to the community that their houses, school, and playground were built on top of and surrounding a chemical site containing 22,000 tons of waste. This is not to say that the problem didn't exist before its discovery by residents; it just wasn't defined as a problem. From the time the chemicals were buried to the discovery of the site by residents 30 years later, residents noticed dogs with burned noses, children with skin rashes, and increased rates of miscarriages, leukemia, and nerve and respiratory disorders. But they were not aware that these rates were out of the ordinary. The effects of the problem did not change, but the way the problem was represented did. The shift was in an awareness of the existence of the problem.

In addition to the chemical disaster at Love Canal, other environmental issues have been the subject of various social movement activities, as well as political legislation. In each instance, public perception influences how and whether the problem is acted on by those with the power to make a difference.

Conclusion

Culturally and socially, environmental problems represent problems of social organization, communication, and socialization. Social scientists can look toward the phenomenon, visible in the reaction to environmental problems, to begin making sense of culture and society at large. Our understanding of environmental issues as primarily social constructions offers insight into how these issues are created, maintained, and resolved.

For example, in many cases where chemical contamination is the focal issue of community groups, the level of risk is perceived by affected individuals rather than established by science. It is the social processes in a community that lead to risk determination, not the natural science interpretations of an issue. Individuals have been socialized

to trust science for valid information. When the determination of risk is uncertain, individuals are left to determine the level of risk for themselves by other means. In most cases, this determination is made through contact with state or federal government officials, through collaboration with other community members, or through other sources of information, such as the media. This framework helps to explain disagreements over the seriousness of most environmental issues, from global climate change to mountain-top coal removal.

The subjective reality of environmental problems becomes visible in terms of how the issue is circulated in cultural discourse. Each stakeholder constructs different means of projecting information for public consumption. When presented in the media, the perception is that information is true and accurate. Most often the determination of risk takes place in the form of a public meeting. In this situation, public officials are in control of the meeting, drawing on public anticipation surrounding the specific issue and information to be released. At Love Canal, for example, officials kept the information to be discussed at the meeting private until the meeting in order to build anticipation and increase their power over the dissemination of information.

At both the cultural and social level, power is maintained through these exercises. Often, the state controls the dissemination of information that individuals perceive to be true and accurate. However, different modes of collaboration among community members can create a different means of risk determination. The sharing of common experiences among community residents can lead to a broader sense of mobilization. Once commonalities are recognized, residents begin to determine their own level of risk. Risk perception is based on the potential danger of a problem. The sources that individuals base their information and understanding on are numerous. Each source has developed a frame of events and information on which they base their version of reality. Whether from the media, science, the state, or local knowledge, such frames serve as a means to display a problem in terms of a specific group. Social movement development, in relation to the environment, offers a powerful tool for individuals looking to construct the frame of a given environmental reality.

The ways in which environmental realities have been constructed influences how they will be acted on socially, culturally, and politically. Cultural discourse then circulates in the public sphere and becomes normative. Environmental issues become part of the public dialogue. This dialogue serves to help develop an understanding about the factors that coalesce to create, maintain, and resolve social processes that influence environmental problems.

Community-level interaction is an interesting social space from which to witness environmental understanding. Community-based, environmental problems affect individuals in many ways. Some communities mobilize and form environmental organizations to address a specific problem. Others, with existing community organizations, add

environmental problems to their agenda. Environmental problems can vary in scope, size, and duration.

Mobilization in these communities may occur due to individuals' fear that nothing is being done to ensure the safety of their children and families. It may also occur on the basis of frustration and an inability to understand what and why this is happening in their community. In addition, community groups often mobilize as a result of a lack of trust in government. The mobilization of individuals to resist the state's discourse challenges the power of the state. The level of trust in government is a key factor in determining the level of power the state can maintain during the presentation of its frame. For example, if trust in government is low, then a stronger frame needs to be developed to legitimize the government's position. Government often emerges as the key stakeholder, as the actor that will have the power to create change.

Previous research addresses the state's desire to maintain legitimacy at the same time that community groups seek to resist state discourse. Admitting that there is a problem shows that the state is capable of mistakes, and thus, the state's legitimacy can be questioned and it is vulnerable. The goal in the rhetoric of the state is not to raise questions, thereby maintaining legitimacy.

Most environmental problems are categorized by place: global, local, or national. These categories are not mutually exclusive. For example, ozone depletion is a global problem because of the total atmospheric effects the ozone layer has on the biosphere from ultraviolet rays. Yet the problem can be seen as being local in an area where heavy smog is causing ozone depletion and high surface area ozone levels, such as in a highly urban area like Los Angeles.

Similarly, the discovery of toxic waste sites across the United States can be seen as a national problem. But in the specific communities where these sites are discovered, it is a local problem affecting individuals directly. The problem is no longer seen as away from them; it is now part of their community. This developing framework of environmental issues has helped individuals become aware of the multitude of impacts that these problems have. Social scientists have been able to develop an understanding of the environment that moves away from the depiction of the earth as something separate from human society, but, instead, the earth is a system with interrelated consequences and realities. One of the most vivid paradigm shifts has been the movement away from an anthropocentric worldview and toward an environmental worldview. This shift can be represented in the movement from the human environmental paradigm (HEP) to the new environmental paradigm (NEP).

Social scientists focus on this shift as a way to explain a cultural movement that has embraced a way of understanding the impact that society has on the environment. Arguably, once the NEP is part of the natural discourse of environmental issues, they become more easily recognized as problems that have risen from a system out of balance. This approach focuses on sustainable development and other modes of

development that provide environmentally sensitive growth models. These efforts move toward a culture that is sensitive to a responsibility that ensures less devastating environmental impact in the future. As environmental sociologists and other environmental researchers seek answers for a sustainable society, we must consider the devastating impacts of our current modes of production. New modes of production that take into consideration innovative, green energy solutions will provide a stronger sustainable economy and environment for culture and society.

HUMAN ECOLOGY

LUCAS BOWMAN

Appalachian State University

While researching for this entry on human ecology, the author perused books and articles about ecology, biology, geography, and anthropology; human ecology uses all these disciplines, and more, toward its own end. Human ecology refuses to condense its focus into one approach; it investigates many approaches to a problem. This investigation method involves all the above mentioned disciplines. However, because its focus is so broad, no one agrees on a concrete definition of human ecology. In an attempt to reveal its definition, this article describes theories, research, and case studies in this field.

Theory

What happens when the two words composing *human ecology* are defined separately and then combined? A common definition for *human* is “a bipedal primate mammal (*Homo sapiens*): man” (Mish, 2004). Such a definition is easy to understand in nearly any context, but defining *ecology* may prove more difficult. Levine et al. collect various definitions in the introduction to their book, *Human Ecology* (1975). For example, German biologist Ernest Haeckel defines ecology as “the body of knowledge concerning the economy of nature—the investigation of the total relation of the animal both to its organic and inorganic environment” (Levine et al., 1975, p. 1). American ecologist Eugene Odum defines ecology as “the study of

the structure and function of nature” (p. 1). These definitions are great abstractions of the word *ecology*; but what is the simple dictionary definition? Ecology is “a branch of science concerned with the interrelationship of organisms and their environments” (Mish, 2004). If human ecology is interpreted as literally the ecology of humans, then, logically, it is the study of relationships between humans and their environments.

Is this definition too base for science? Sargent defines human ecology as “man’s relationship to all systems of life” (1983, p. 3). Strickland and Ulijaszek, authors of *Seasonality and Human Ecology* (1993), define human ecology simply as “the study of interrelations that exist between individuals, populations and the ecosystems of which they are a part” (p. 1). Sociologist Robert E. Park felt human ecology was the study of processes or systems that develop to upset or align the biotic balance of equilibrium (1961, p. 29). There is a common theme among these mentioned definitions: relationships. Relationships are a large aspect of human ecology, but they do not constitute its entire scope of study.

In his article, “Human Ecology and Interactional Ecology,” James Quinn (1940) examines four views of human ecology. The first is J. W. Bews’s vision of human ecology as an all inclusive science composed of sociology, psychology, geography, biology, and anthropology; the second is H. H. Barrows’s view of human ecology as synonymous with human geography; while the third sees

human ecology as solely sociological (Quinn, 1940, p. 714). Quinn rejects each of these proposals and declares his own theory as the fourth viewpoint: Human ecology borrows from sociology, biology, and geography to form separate branches of science beneath each discipline. These branches are under the name human ecology; the branch from sociology is called interactional ecology, the branch from biology is called general ecology applied to man (Quinn had not proposed a working definition for this branch), and the branch from geography is called human geography. Quinn's theory is represented by three circles (one each for sociology, biology, and geography) situated as a triangle with each being cut in half by a fourth circle (human ecology) in the middle. The author of this entry agrees with Quinn's diagram because it represents human ecology as its own science, borrowing some, but not all, of its principles from other sciences. However, the author feels human ecology is an opportunistic science that can borrow from all sciences (not just sociology, biology, or geography) to understand a given problem. With this additive, human ecology becomes the holistic view it is.

Indeed, human ecology uses all sciences as a working foundation to solve problems between humans and the environment; however, there is much disagreement about its origin. Hawley (1986) attributes human ecology's beginning to sociologists. These sociologists looked to contemporary ecologists' work on the role of floral communities within an ecosystem as being comparable to the role of groups and individual humans within a human ecosystem. Sociologists such as Park (1936, 1961) and McKenzie (1934) established the idea of "an association of species joined in a division of labor and thereby forming a distinguishable adaptive unit" (Hawley, 1934, p. 2). In Hawley's view, the most central idea to human ecology is the adaptation process. As different flower species share labor to create their similar spatial environment, so do different human groups interact when adapting to their shared spatial environment. A common theme in all studies under the name "human ecology" is a focus on what people have done, are doing, and will do within their environment and whether these actions affect their success or failure at preserving the environment. Basically, human ecology studies the relationships between environmental and human systems.

Even though human ecology borrows from sociologists' theory, human ecologists ask questions that span many disciplines. A human ecologist asks a series of questions any one scientist would not, such as how do people's interactions with each other affect land use practices? In researching this question, one could find that human interrelations are influenced by success or failure of crops. Researchers would then investigate why a harvest was sufficient or insufficient. If it was insufficient, did erosion cause a strain on crop yields? What caused the erosion? If it was sufficient, did land use practices cause success? And so on. A human ecologist does not stop after the first question is

answered. Casey and Schwartzberg provide an exemplary definition of human ecology as a holistic science when they describe its scope as covering relationships between human populations, the environment, technology, human organizations, and social psychology (1969, p. 3). Being holistic, human ecology absorbs sociological ideas, as well as ideas from many other disciplines, to answer questions.

In contrast to Hawley's (1986) placement of human ecology as a category of sociology, Sutton and Anderson argue that it falls under anthropology and adheres to the scientific method (2004, p. 7). In the 1940s, anthropologist Julian Steward proposed the theory of multilineal evolution and labeled it *cultural ecology*. This theory placed subsistence practices at the center of cultural development but allowed cultural evolution variations within each subsistence practice. Leslie White (1949), also an anthropologist, wrote that cultural evolution was directly related to how efficient a culture was at harnessing energy. His ideas of evolution spurred further study of relations between humans and their environments and how these interactions are played out (McGee & Warms, 2004). Although human ecology has sociological and anthropological roots, its development has transcended the bounds of either field.

Moran suggests human ecology is an enveloping discipline that includes at least "anthropology, geography and sociology" (2000, p. 4). Indeed, because it is holistic, human ecology utilizes these disciplines, among others, to solve its questions. When using a holistic view, it is important to remember that parts are not greater than the whole, nor the whole greater than its parts. Steiner echoes this with his own statement about holism: "The whole would not exist without the parts; the parts would not be without the whole" (2002, p. 36). Following this quote, human ecology acts as a connection between the parts of science but does not completely adhere to a single discipline. Just as connective tissues in the body are part of neither the bones nor the muscles they connect, so human ecology is not wholly a part of any science it chooses to incorporate.

Using this myriad of definitions, human ecology materializes as the study of relationships between human adaptive systems and the adaptive systems of the environments humans inhabit.

Adaptation

All organisms must choose their method of survival; their choice is based on getting as much energy from the environment as possible while expending the least amount of energy possible. The Canadian ecologist Pierre Dansereau explains how these choices are made using his law of inoptimum, which reads as follows: "No species will encounter a given habitat and find the optimal conditions for its functions" (as quoted in Sargent, 1983, p. 55). This principle explains why humans change environments to suit their needs, or even why certain trees alter chemicals in the soil

in their favor. However, to make these survival choices, an organism needs access to an environment. Without an environment, an organism could not exist.

Also imperative for an organism's survival is other organisms of its own kind (Hawley, 1986, p. 5). This principle is true mainly for reproductive and ecological reasons, but in humans, it is also true sociologically. Choices are made by individuals based upon relationships with other individuals and the environment. Environments also change along with organisms they sustain, because environments and organisms act upon one another and grow together (Sargent, 1983, p. 3). Now, more than ever, humans have the ability to inflict change upon all environments across the globe through their survival choices (Hawley, 1986, p. 6).

Human survival choices have been honed over thousands of years through culture. Culture is conveyed through a system of learned symbols—intentional abstractions of an idea or an action. Using culture, humans have shifted their place within ecological communities and attained dominance over available energy in any given community or ecosystem. They achieved this dominance through learned behaviors, which enabled humans to expand upon existing knowledge. This foundation of knowledge affords humans a great advantage in survival. Each human need not rediscover concepts such as the use of fire, stone tools, or the wheel; humans are simply instructed how to use these tools and survival techniques through culture (Watson & Watson, 1972; White, 1949). Culture is simultaneously an adapter of environments and an element of the environment.

Hawley names two kinds of environmental elements: biophysical elements, including “land features, climate, soil characteristics, plant and animal life, mineral and other naturally occurring materials”; and ecumenical elements, including “ecosystems or cultures possessed by peoples in adjacent areas and beyond, to which access is provided by the existing facilities for transportation and communication” (1986, p. 14). (Note: Hawley uses *ecumenic* to avoid the confusion that might be created by the connotations of the words *economic* and *social*. But the author feels that *ecumenic* actually creates more confusion due to its modern religious connotation. As Hawley's use of *ecumenic* is intended to combine *social* and *economic*, the term *socioeconomic* will replace Hawley's *ecumenic* in this entry.) For an example of biophysical and socioeconomic elements working together, Hawley (1986) cites Spencer's research with inland Alaskan Eskimo depopulation. Traditionally, inland Eskimos traded caribou hides with coastal Eskimos for whale blubber and other supplies that were unattainable inland. When Europeans arrived, coastal Eskimos ceased most trade with inland Eskimos, because Europeans had more attractive trade goods than inland Eskimos. This change in Eskimo life forced inland Eskimos to move toward coastal areas, because they could no longer support themselves without coastal trade. This

move is an example of how socioeconomic elements forced inland Eskimos to modify their adaptation systems to biophysical elements.

Both classes of environmental elements have constant and variable conditions. Constant conditions comprise the initial adaptive challenge such as mountains, rivers, flora, and fauna of an environment, but even these constant conditions can be changed by humans. Variable conditions occur after initial adaptation; they deal with time or duration. Unpredictable or irregular events, such as natural disasters, swarms of insects, appearances of new human groups, invasive warfare, and other cultural diffusions are examples of variable conditions existing over time.

To recapitulate, there can be constant biophysical conditions, such as a nearby mineral deposit, and there can be variable biophysical conditions, such as natural disasters. There can also be constant socioeconomic conditions, such as permanent settlements, and variable socioeconomic conditions, such as warfare. The combination of these two elements and their present conditions form a culture's environment and shape its adaptive strategies.

Case Study

Parts of North America's environment have been shaped by the people who lived there. Native Americans lived for thousands of years in North America before European contact. Black, Abrams, and Ruffner (2006) conducted a study in northern Pennsylvania, examining exactly which kinds of trees composed forests, a constant biophysical condition, in different areas. They found that forests in areas of low Native American activity were populated mostly with beech, hemlock, and maple, whereas forests in areas of high Native American activity mostly consisted of oak, beech, hemlock, chestnut, pine, and maple. Their study showed Native American activity paralleled the growth of stands of oak, hickory, and chestnut. Black walnut occurred only near village sites, and its presence had the highest correlation with Native American influence. As several Native American land practices could have transformed northern hardwood forests to oak-hickory-chestnut forests, the group believes Native Americans shaped tree composition within forests through their land practices.

By clearing forests near villages for agriculture, Native Americans encouraged early-succession edge species. Oak and hickory thrive in open fields and clearings, because they are less shade tolerant than other species. Also, Native Americans' collection of firewood and building material would have increased the chance that oak and hickory would survive, because the Native Americans thinned the forest near villages. They may have been girdling trees competing with the desired species of oak, hickory, and chestnut. These desired species are adapted to survive fire. These fire adaptations include “thick corky bark, a tenacious ability to resprout following top kills due to high root/shoot

ratio . . . and resistance to rot” (Black, Abrams, & Ruffner, 2006, p. 1272). Native American fire practices encouraged “primary forest efficiency” by reducing forest litter to allow easier mobility, increased acorn quality and quantity for winter and spring subsistence, and increased deer herd sizes in certain managed areas. Dendrochronology suggests tree disturbances sharply declined after European contact. During the Late Woodland period and the Historic period, Native Americans were an important source of disturbance for forests.

This case study is an example of constant socioeconomic elements shaping constant biophysical elements. Without Native American land practices, oak and hickory would not have been as populous in the forest as they were. Native Americans certainly influenced where these species grew using constant socioeconomic tactics.

The Earth in Space

Earth’s biophysical environment begins with its mass in space. The earth’s mass determines its gravitational attraction, while the tilt and revolution of earth determines how it receives radiation from the sun. The distance to the sun determines the intensity of radiation received from the sun. Radiation levels are controlled by the solar constant as well as the angle at which the radiation is received. Gravity limits the weight of organisms, because energy is used against the force of gravity; accordingly, gravity limits an organism’s size, because it must support its weight against gravity. Gravity also limits circulatory systems and, in effect, limits organism height. Earth’s gravity retains gases that compose its atmosphere, although lighter gases such as hydrogen and helium can escape (Levine et al., 1975).

Our present atmosphere was created from volcanic eruptions expelling gases from inside the earth’s mantle. These gases consisted mostly of water vapor and nitrogen with lesser amounts of other gases. Water vapors were trapped by gravity, condensed, and fell back to the earth, forming the oceans. The first plants were aquatic and grew near volcanoes in warm pools. Protected from the sun’s radiation by the oceans, aquatic plants received light filtered through water. As oxygen released by plants entered the atmosphere, it oxidized iron and other minerals. When there were no more minerals to use the newly released oxygen, it filled the atmosphere. Due to the sun’s radiation, the initial oxygen transformed into ozone, which absorbed the sun’s deadly rays. As the atmosphere continued to fill with oxygen, less of the ocean was pounded by radiation, and life could expand its borders. About this time, free oxygen respiration systems developed. Oxygen continued to fill the atmosphere, displacing more and more radiation from the surface of the earth, and allowed life to move onto land around 420 million years ago. Such movement onto land was not by animals, but by plants. Plants moved from the waters onto the shores and then further inland (Levine et al., 1975).

Earth has the temperature and climate it has because our atmosphere selectively absorbs radiation of specific wavelengths. Weather is created through air and water molecule movement powered by the sun’s radiation. Weather is a real-time experience, whereas climate is an abstraction that represents a region’s average weather over time. Topography and distribution of land and water can affect climate in various ways (Levine et al., 1975). By creating rain shadows, topography can form areas of lower precipitation. Rain shadows occur when water-laden clouds lose their moisture before rising over mountains. On the mountains’ leeward side, it is dry, because little moisture can travel over the mountains. Large water bodies heat and cool more slowly than land bodies, and this can affect where and how quickly moisture is absorbed into the atmosphere. Vegetation can also have an impact on weather, such as cooling the air, causing precipitation.

Without soil, there could be no vegetation. Soils are formed by water, chemicals, wind, and living organisms on bedrock (parent rock). Bedrock controls basic soil composition (Levine et al., 1975). For example, sandy soils usually occur over sandstone; chalky soils occur over chalk; clay soils over shale; and rich organic soils over peat. Soils of the same character can spread across different rock types, and so, when forming soils, climate and vegetation can be just as important as rock type. Soil is a mixture of organic and inorganic components (sand, silt, and clay). The mixtures of these inorganic materials control soil texture and its ability to retain moisture and nutrients. Organic matter changes the physiochemical properties of inorganic materials and is food for microorganisms as well as plants. Molecular space between solid soil particles is filled with either gas or liquid. Liquid is a complex solution and is the medium by which nutrients move to microorganisms and plants. Gas in soil is essentially air. Air is normally saturated with water vapor and can contain much larger amounts of carbon dioxide than air in the atmosphere. When soil is waterlogged, it can no longer exchange gases with the atmosphere or aerobic life forms (Levine et al., 1975).

All of these above factors govern the earth’s dimension and environment, and they form the land humans live on. Land is not all the same due to topography and climate. Humans prefer land with good soil, a water source, and an agreeable climate. Not all the land on earth is suitable for human habitation under these specifications. Estimates report almost 30% of the land surface is potentially arable; 20% is nonarable mountains; 20% is desert or steppe; 20% is under snow, ice, or permafrost; and 10% lies on soils or regions inadequate for cultivation (Ehrlich, Ehrlich, & Holden, 1973). From the favorable environments of Africa where the human species was born, humans spread to inhabit nearly all the arable lands (Liu, Prugnolle, Manica, & Balloux, 2006). Culture enables humans to adapt to these biophysical elements within the environment and ensures human survival.

Systems

Besides being able to bring change and adapt, humans create. Just as we have created the tangible idea of culture, we create other things we cannot see. Steiner (2002) quotes the Chinese American geographer Yi-Fu Tuan as follows:

Humans not only submit and adapt [to change]; they transform in accordance with a preconceived plan. That is, before transforming, they do something extraordinary, namely, “see” what is not there. Seeing what is not there lies at the foundation for all human culture. (p. 35)

The preconceived plan Tuan remarks about is a system. Botkin and Keller define a system “as any part of the universe that can be isolated for purposes of observation and study” (as quoted in Steiner, 2002, p. 21). Ecosystems, then, are systems of ecology. Humans are part of ecosystems, because they interact with and within ecology. Culture is a system, and it is the method humans use to transmit ideas and adapt to environments. Culture directs adaptation to any given environment. For example, this explains why, in the same type of environment, humans will utilize different housing styles.

Just as humans will use different housing types for the same environment, there are different ideas of adaptive systems. Unfortunately, some popular ideas of systems conceptualize them as linear, going from point A to point B. Environmentalist Paul Hawken suggests “[changing] linear systems into cyclic systems,” because this “is the way of the world around us” (as quoted in Steiner, 2002, p. 35). Certainly, most systems in nature are cyclic (e.g., water, carbon, and nitrogen cycles); however, not all human systems are cyclic. The sheer abundance of the American frontier shaped American culture toward consuming resources with the belief they were inexhaustible. Cities grew at unprecedented rates while resources were consumed wastefully, and soon foreign resources were sought to continue the trend (Chen, Coa, & Liu, 2007). The American frontier idea is a linear system that provides end results quickly but in an unsustainable way; that is, linear systems have a beginning and an end; they will end when they have used up all available resources. Energy is expended in linear systems. An easy example of a linear system is the path of most Western products.

Products are manufactured, used, then dumped into the ground and never used again; there is a beginning and an end. In cyclic systems, there is no beginning or end, and nearly the same amount of energy sustains the cycle, as long as conditions permit. When Western products are used in a cyclic system, they are recycled instead of being dumped. Now the product is manufactured, used, and then recycled into the beginnings of another product, which will be manufactured, used, and recycled into the beginnings of another product. In the linear system, energy spent burying discarded products could have been

channeled into converting discarded products into raw materials to make new products; instead, energy is used to bury old products, and more energy is needed to produce raw materials for new products. So, a linear system requires fresh input to start it each time; cyclic systems harness initial inputs to continue indefinitely. Cultures exhibit these same system characteristics.

There are many types of systems within a culture. These systems are manifested within a culture’s technology, sociology, and ideology. Technology is usually a physical system, meaning it is a tangible system. Forts, weapons, irrigators, shovels, and the wheel are all manifestations of a technological system. Sociological systems are also tangible and mainly affect social organization at individual and collective levels. Individual, family, and political organization are displays of sociological systems. Ideological systems are intangible systems that affect both technological and sociological systems. These ideologies are contained within myths, beliefs, and knowledge (White, 1949).

In other words, technological and sociological systems are physical representations of the ideological systems held by any particular culture. Each system has influence over the other two systems, and the interaction of these three systems allows cultures to evolve. These systems are very interesting, because they shape tangible representations of people. Kinship organization displays a system’s tangibility and intangibility best. Due to certain ideals held by particular cultures, kinships are arranged differently. Indeed, kinship relationships to mothers and fathers are arranged differently across the world, because people live and think differently. Therefore, intangible ideas shape tangible kinship ties (and vice versa for that matter). But before any system—human or not—can begin, it needs a push; a source of energy.

Energy

All energy originates from the sun; consequently, all organisms are governed by thermodynamics. Thermodynamics is the study of how energy converts from heat to mechanical motion. The first law of thermodynamics states energy is neither created nor destroyed; it only passes through different entities (Ehrlich et al., 1973). At the same time, earth’s forces are always moving toward equilibrium by way of depleting all energy, or radiation, from its matter (Watson & Watson, 1972). The second law of thermodynamics states that in each energy transfer there is a loss of usable energy. This law is true for our consumption of foods as well as plants’ conversion of sunlight into energy. During photosynthesis, only 1% or less of sunlight is transferred into usable energy by plants (Ehrlich et al., 1973). The *trophic pyramid* reflects this energy loss during transfers; its bottom is larger than its top. If energy was not lost during transfers, the trophic pyramid would instead be a trophic square; all initial

energy entered into the bottom would be passed to the upper trophic levels. Indeed, energy is always in motion and moving toward being released or dissipated. Humans are one of many organisms trying to capture energy.

Anthropologist Leslie White succinctly states, “All life is a struggle for free energy” (1949, p. 367). Indeed, life contradicts the rest of the cosmos, because it seeks to collect escaping energy. Life attempts to retain as much energy in each transfer as possible. As time passes, humans have become more adept at collecting free energy. White argues human culture evolves with its increasing efficiency to collect energy. He outlines a formula devising this rate of cultural evolution. This formula is based on the amount of harnessed energy per capita or the increase of efficiency in capturing this energy. Indeed, cultural achievements were greatest near periods of markedly increased energy yields, such as during the Agricultural and Industrial Revolutions (White, 1949). Cultures evolved by harvesting energy from their environments, but to do this, humans also derive energy from outside the trophic pyramid.

Energy for human technology comes from natural resources, but its extraction and use is related to time, economics, and scale of demand (Levine et al., 1975). For example, coal mining was scarce before the 19th century because there was little demand for coal. As the Industrial Revolution gained momentum, the demand for coal rose and became an influential part of the economy. During the initial period of increased demand, coal mining technology was crude, and so, extraction and transportation was slow. As the demand for coal grew, it became an even bigger driving force of the economy. As advances in technology increased over time, more coal was made available faster. As time continued and technology gave access to cheaper and more efficient fuels, coal became less and less in demand. Nowadays, some coal is extracted by mountaintop removal, which is more efficient than coal mining was: It employs fewer workers, requires less time, and gains access to smaller coal seams. This example exemplifies how time, economics, and demand influence the extraction of natural resources. However, this extraction technique comes at an environmental cost. Erosion, flooding, and loss of wildlife habitat occur from these extraction techniques. Pollution is another environmental cost.

Pollution is everywhere in the environment. Some of it occurs naturally, such as air pollution from lightning-caused forest fires and volcanic eruptions, while some of it is produced by humans, such as noise pollution from human activities and air pollution from automobiles. There are two types of pollutants: qualitative and quantitative. Qualitative pollutants are synthetic substances introduced by humans, such as DDT, PCBs, industrial chemicals, and herbicides. These substances are usually not biodegradable, and they remain in the environment for decades. Qualitative pollutants do not lose potency during energy transfers and grow more concentrated within organisms as

they travel up the trophic pyramid. For example, there are 10,000 aquatic plants supporting 1,000 salmon and 100 eagles in a trophic pyramid. If each aquatic plant has 1 part DDT and each salmon eats 10 aquatic plants, then each salmon has 10 parts of DDT in it. When eagles eat 10 salmon each, each eagle has 100 parts of DDT in it. So, 10,000 parts of DDT become concentrated in 100 eagles.

Quantitative pollutants occur naturally, but they become pollutants as their amounts within the environment are increased by humans. Nitrogen in fertilizers and carbon emitted from combustible engines are quantitative pollutants, because they add to natural levels of nitrogen and carbon already in the environment (Ehrlich et al., 1973). Heat is a quantitative pollutant that humans have drastically increased within the environment. It is the main pollutant from every extraction, conversion, and use of human energy sources (Ehrlich et al., 1973). However, the effect of some pollution is diluted throughout an ecosystem by species diversity.

Diversity

Ecosystems stay healthy through organism diversity. The more species in an ecosystem, the better, because these inhabitants help disperse energy throughout the ecosystem. If an ecosystem loses one species, another species will fill the resulting empty niche and continue the flow of energy (Ehrlich et al., 1973). This energy flow allows food webs to evolve, and food webs allow environmental change, because energy and nutrients can follow diverse courses before returning back to the environment; subsequently, the course of energy can be different each time (Sargent, 1983). A stable ecosystem grows through complex species diversity, which allows energy different avenues through which to flow. When energy cannot follow different paths, it has the possibility to be cut off. Humans drastically change ecosystems' species composition, replacing complex stable ecosystems with simple unstable ecosystems through modern agriculture (Ehrlich et al., 1973). However, Meso-American maize agriculture is seen as a stable ecological system, because farmers plant a wide range of maize, such as modern hybrid maize and traditional strains; their focus on maintaining a healthy environment is evident in their culture.

Case Study

Brush and Perales (2007) conducted a study about what maize type certain ethnic groups chose to plant, where they planted it, and why they planted it. Their research was collected within the state of Chiapas in southern Mexico across different environments and social groups. Brush and Perales found maize diversity was not randomly distributed but rather was a function of biophysical factors,

such as altitude and maize species, and socioeconomic factors, such as whether the farmers were mestizo or indigenous and what the economics of their community were. Because mestizo and indigenous people are different in language, ethnolinguistic communities shape the maize landscape, and altitude shapes where ethnolinguistic groups reside. Most indigenous people choose to live at altitudes higher than 1,400 meters above sea level, while mestizos favor lower altitudes, because they evolved from European and indigenous people. Europeans interested in better crop yields favored the lower, flatter areas for cultivation, leaving indigenous groups to higher and more mountainous fields.

But even with these cultural preferences, both ethnicities are found at all elevations. This dispersion affects where particular maize species are grown. Higher than 1,400 meters, maize is grown in a very natural way in small patches among other crops using little commercial input; this method yields less than 1,500 kilograms per hectare of maize. This high-altitude strategy is mostly for subsistence. Conversely, in altitudes below 1,400 meters, and increasingly below 900 meters, maize is grown commercially using large single-crop fields with commercial inputs; this method yields more than 2,000 kilograms per hectare.

At all altitudes, mestizo farmers are geared more toward commercial agriculture than indigenous farmers. At lower altitudes, there is more maize diversity, because farmers must grow nontraditional crops for commercial export while also growing traditional crops. White grain maize is favored by low-altitude farmers for its commercial value. Traditional maize strains are found at all altitudes, while modern strains are only at lower altitudes. Both mestizo and indigenous people plant a variety of maize throughout all altitude levels, although mestizo farmers will try to change their maize seeds and promote gene flow between traditional and modern maize strains.

Maize color is the utmost classifying factor for all farmers. White maize appears only in lower altitudes, while yellow maize is dominant for both mestizo and indigenous farmers. Indigenous farmers favor other maize colors rather than white and yellow, possibly because minor maize colors are associated with indigenous rituals throughout Mexico. Since most commercial growers are mestizo and farm at lower altitudes, they plant white maize, because their buyers prefer white maize. Farmers at lower elevations import modern seed from outside sources, while farmers at higher elevations restock seed banks from the community. Mestizo growers employ a more linear system of energy (it cannot support itself), whereas indigenous farmers obtain their seed directly from their last crop (a circular system).

Between the two farmer groups, Brush and Perales (2007) found three possible differences in maize management: environmental factors, socioeconomic factors, and cultural knowledge. They found mestizo and indigenous farmers live in different ecological niches across each

altitude range, and their management choices are inspired by the environment, but not determined by it. Because similar strains of maize are found across all elevations on both mestizo and indigenous farms, the environments in which the two types of farmers farm cannot be very different from one another. This argument suggests environmental differences are minor within a particular altitude range and not the main reason influencing different avenues of maize production within a particular elevation.

Socioeconomic factors such as education, farm size, and access to credit may restrict indigenous farmers from entering the commercial market in areas where both ethnic groups live in lower altitudes. But, this does not explain why farmers at higher altitudes grow maize only for subsistence. Cultural differences are not very significant either, but they provide the best explanation for the contrast in maize management: Indigenous people acquire seeds from within the community, which supports local knowledge and social networks, whereas mestizo farmers do not. Indigenous culture is geared toward crop diversity and a more stable ecosystem, while lower-elevation mestizos are geared toward homogenous commercial crops. These planting practices are mostly a result of cultural attitudes and choices simultaneously affecting and being affected by socioeconomic as well as environmental factors. Indeed, this study aims to clarify relationships between humans and their environment.

All these explanations influence one another. Environmental constraints influence socioeconomic, which, in turn, influence cultural attitudes. These cultural attitudes represent adaptive strategies toward the environment, which is in turn being shaped by cultural attitudes. Understanding these relationships is a key step in human ecology.

Overpopulation

Whether humans realize it or not, they affect the earth with nearly every action they perform. Human action can either be directed toward preserving earth's systems or destroying them. As much as humans want to believe it, "a long history of growth does not imply a long future" (Ehrlich et al., 1973, p. 10). There are several factors that will ultimately affect whether the earth collapses or continues as an appropriate environment for humans. A major factor is overpopulation.

Momentum is the gathering speed behind population growth. Momentum is propelled by the number of females in a population at child-bearing age combined with the number of females who have yet to reach child-bearing age, because both female groups have the potential to increase population growth for another generation. Momentum fosters economic growth and technological advancements, intensifying production of natural resources; this exerts more pressure upon resources.

The delay between cause and effect adds pressure to environments too. Time between an occurrence and its effects may mislead some into believing there was no injury or the problem was solved, postponing necessary action needed to correct problems (Ehrlich et al., 1973). When dealing with population growth, understanding momentum and time lag are crucial.

However, the world's overpopulation problem is not just one problem; therefore, it requires more than one solution. Humans need to reduce consumption, reduce and improve technological impacts on the environment, and slow or stop population growth (Ehrlich et al., 1973). Just as population can grow exponentially, so can population problems. The larger a population, the more quickly it will grow and develop more problems. Following this trend, humans' ability to address increasing problems diminishes, because there are more people to be governed by less responsive governors. The most feasible options are lost to humans the longer they wait. Time lag can delay notice of a problem, and the time it takes to fix a problem grows longer with increased population growth (Ehrlich et al., 1973).

Population growth is mostly controlled by birth and death rates. Birth rates are expressed as babies born per 1,000 people per year. To calculate birth rate, the total number of births for the year is divided by the estimated population at the midpoint of that year. For example, the birth rate for Argentina in 2007 was 19 births per 1,000 people. Death rates are calculated the same way as birth rates except without midpoint growth estimation. In 2007, Argentina's death rate was 8 deaths per 1,000 people (Population Reference Bureau, 2009). Natural population growth is calculated using the difference between birth and death rates divided by the total population and recorded as per hundred (Ehrlich et al., 1973). Therefore, Argentina's natural growth rate was 1.1% for 2007. The actual population growth rate accounts for immigration and emigration.

Before modern times, population growth was mainly controlled by death rates. Where population increases occurred throughout history, it is because of lower death rates, not increased birth rates. The first big drop in death rates was during the Agricultural Revolution, and this was also the first demographic transition. During this time, people turned their attention from food gathering toward food cultivation, and this made more food available to everyone year round. This change in food production freed people from gathering food, because enough food to feed an entire village could be grown by fewer people. The newly acquired leisure time was directed toward bettering every aspect of human life, which further lowered death rates (Ehrlich et al., 1973). As technology bettered life through industry, agriculture, medicine, sanitation, and transportation, the death rate dropped even further and allowed populations to grow. As long as the environment would allow it, most people on earth had high birth rates and low death rates; however, during the Industrial Revolution, birth and death rates in Western Europe began

to decline. This decline was caused by a production shift from agriculture to industry and caused another demographic transition.

In agrarian societies, families encouraged high birth rates, because more children meant more people to help with necessary chores. Hence, children in an agrarian culture are seen as an economic benefit and asset. As industry shifted focus away from agriculture, the need and want for larger families declined, because children in an industrial society are an economic liability. They must be fed, clothed, educated, and kept healthy; these necessities demand large incomes. Children are also consumers and decrease family mobility, which is valued in an industrial society. Children make it harder to gain capital, because they do not usually contribute to income but take away from it. Further hindering birth rates in industrial societies, women and men marry later in life; accordingly, women lose many of their prime reproductive years before marriage, and this further decreases birth rates (Ehrlich et al., 1973).

A third major demographic change occurred after World War II, when major decreases of death rates appeared in underdeveloped countries (UDCs). Death rate decrease in UDCs was caused primarily by better health measures; medicine, drugs, and education about sanitation moved from developed to underdeveloped countries. With better medical knowledge and supplies, UDCs' death rate decline is in large part due to control of infectious diseases such as malaria, yellow fever, smallpox, and cholera. The death rate decreased most for small children and young adults. Although these health benefits produced a major change in UDCs, this change did not occur within UDCs; it was a function of outside factors, and socioeconomics did not encourage lower birth rates at the same time the death rate dropped. Indeed, these UDCs were not industrialized, so they did not have the same cultural or economic pressures to drop their birth rates. Due to the last major demographic trend, UDCs have a larger base of dependents to support, and this fosters more growth, which further undermines their economic situation (Ehrlich et al., 1973). Zambia is an example of a UDC trying to modernize its socioeconomics using industrial tactics across a large population.

Case Study

In the late 1950s, the colonial government of Zambia, with the help of the World Bank, built the Kariba Dam on the Middle Zambezi River, and relocated entire Gwembe Tonga villages from their traditional areas. Cliggett, Colson, Hay, Scudder, and Unruh (2007) utilized ethnographic data collected over a span of 50 years with modern satellite imagery to formulate opinions about land cover and the Gwembe people's land use patterns. Over time, the Gwembe people utilized the environment in the most opportunistic way possible.

In southern Zambia, where the dam is located, farmers are no longer willing to invest in seed or fertilizers, because they know there is high risk of losing their crops. The dam produced this uncertainty. In the 1980s and early 1990s, drought reduced water levels in the reservoir behind the dam, and irrigation became unfeasible, leaving some farmers without water for crops. Conversely, when the lake shrank, fertile land was exposed along the shores for farming. Switching their focus to these newly exposed shore fields, farmers were able to let other fields lie fallow that had been worked constantly since the dam was built.

In the late 1990s and early 2000s, rainfall brought floods and quickly raised the water level of the reservoir. Farmers lost crops, cattle, and farm equipment. Below the dam, fields along the river banks were flooded when floodgates were opened on short notice or no notice at all. These shore fields provide a great resource, but uncertainty makes farming them a high risk operation. Because humans have cleared land for fields, firewood, and building materials, vegetation cover has decreased, allowing flash floods to cause erosion.

War has also brought misery to farmers indirectly. In the 1950s, new roads were built, and credit facilities set up soon after for “seeds, fertilizers and agricultural equipment” (Cliggett et al., 2007, p. 23). The roads allowed farmers to transport their crops to market and receive foreign inputs in the form of fertilizers and pesticides, which produced more crops. However, war in Rhodesia spilled into Zambia and created problems for rural communities. Landmines were strewn across the land, roads were destroyed, and a new structural adjustment curtailed rural economies. Buyers no longer found picking up crops from farms profitable due to deteriorated roads. The poor road conditions also meant inputs were delivered late, if at all. Prices of crops swelled or dropped because of competition with foreign relief grain, and government policies for credit vanished. Some farmers have switched to growing marijuana, because it is profitable, drought resistant, transportable, and requires few inputs. Otherwise, due to production and market uncertainties, farmers invest as minimally as possible in agriculture.

As birth rates are high in the Gwembe region, the arable land available per person is dwindling. People resort to other ventures to generate more income, such as mining, fishing, producing tourist knickknacks, or resettling their entire village where they can farm more profitably. Population pressures increase when prime arable land is given to Europeans or non-Zambians for plantations, crocodile farms, and game ranches for tourists. Whenever there is available land, people will try to make it work until the next opportunity comes along. Fundamentalist Christian churches could bring livelihood changes, because the old Gwembe cult of witchcraft is beginning to be seen as a source of misfortune. These spiritual shifts may alter how people “identify family, mobilize labor, and choose to make a living” (Cliggett et al., 2007, p. 26).

The latest subsistence trend has been to uproot completely, and move to where land is available. Most Gwembe people move to lands near the Kafue National Park because there are benefits of “higher rainfall, better fields, better crops, abundant wood and lots of wild game” (Cliggett et al., 2007, p. 26). These rewards offset the costs imposed by lack of infrastructure, isolation, inadequate water supplies, and threats from wild animals. Overall, mobility has been a primary Gwembe strategy to deal with “environment change, population growth and socio-political dynamics” (Cliggett et al., 2007, p. 27). The only certainty Gwembe people have is uncertainty.

Zambia’s Gwembe Tonga encountered changes in their environmental elements. As the Kariba Dam was not an initial adaptation challenge, the dam is a variable biophysical condition caused by a variable socioeconomic condition: Politics changed to allow the dam. Change in these two environmental conditions initiated changes in other conditions. The dam affected constant biophysical conditions, such as land availability and field access, while also affecting constant socioeconomic conditions of the Gwembe, such as their traditional method of subsistence and social integration.

Future Directions

As seen in Zambia’s example, humans must adapt new sustainable resource management strategies or face collapse. To achieve sustainability, there must be agreement with respect to major goals and how these goals are defined (Sargent, 1983). Developing new technology, easing population pressures, and changing antiquated ideas about humankind’s relationship to the earth are essential goals. However, the balance of sustainability mostly deals with population numbers; if the population gets too large, something must change to accommodate the increase.

Along with increasing their populations, humans have given increased mobility, through advanced technology, to nearly every other organism on the earth: plant, animal, insect, and disease. These organisms hitch a ride on human means of transportation (Park, 1961). As humans continue to impact ecological systems, the connection between these systems and their own well-being is apparent.

An easy step toward achieving sustainability is implementing global recycling. On average, recycling consumes less energy than processing raw materials and saves energy while emitting less pollution; yet, few countries have moved toward encouraging recycling in their economies. Earth’s natural systems sometimes mirror effects produced by humans. For example, the earth’s climate has periodic temperature shifts, making it hard to assess humans’ impact on global temperatures through greenhouse gases. Rapid climatic shifts experienced in modern times are not unlike shifts that occurred naturally between glacial periods, and such shifts make data on human impacts hard to

identify (Chen et al., 2007). Even with continued research, only time may reveal humans' impact with respect to warming the earth.

Human ecology is a science aimed toward the future. Not only does it aim to solve current problems, it seeks to implement new sustainable strategies to balance human systems within environmental systems. If human adaptive strategies continue to lack an emphasis on sustainability, humans may allow looming crises to swell into a global catastrophe. The most pressing of these crises for humans is overpopulation. Due to time lag and momentum, humans will not know they have exceeded the earth's carrying capacity until it is too late. Humans must address overpopulation immediately to quell growing numbers.

Ehrlich et al. (1973) ask some significant questions about humanity's future on earth: How long will it take the earth to return to equilibrium after humans exert their final pressure on the carrying capacity? And how many of these pressures on the earth can be alleviated through technology? Indeed, technology paved the way for human comforts and expansion. Will technology continue to alleviate population pressure, allowing the idea of business as usual to continue? Or will change occur within the human mind to stimulate action toward sustainability?

The answers lie in utilizing both approaches, not just one or the other; this tactic has worked splendidly when it has been employed by humans. With it, humans have expanded their environment so much there are no more environments on earth to conquer. Clearly, the human future depends on answering these pressing ecological questions. Human ecology will help ask and answer questions for the future and facilitate strategies to solve ecological problems between humans and their environment, and it will do so through its holistic nature. Human ecology, along with other sciences, can solve life-threatening problems by providing sustainable solutions; only then will humans be an enduring presence on the earth.

FEMINIST ANTHROPOLOGY

CHRISTINA TAYLOR BEARD-MOOSE

Suffolk County Community College

This chapter critically reviews and discusses the emergence and maturation of feminist anthropological thought over the past three decades. The chapter also examines the ways in which feminist anthropology has critiqued, rebuked, and theorized the metadiscipline of anthropology. Feminist anthropology has, from its academic beginnings, sought to subvert a number of difficulties that came to define the metadiscipline in the 20th century.

Even while coming from multiple ideological viewpoints, feminist anthropologists have had several common themes through which to discuss and theorize the metadiscipline. These themes include, but are not restricted to, (1) correcting academic male bias in the ethnographic record, (2) developing an anthropology of women, (3) seriously discussing the oppression of women, (4) rediscovering women anthropologists of the 20th century, and (5) theorizing about gender relationships and their social meanings. In order to discuss the broad swath of feminist anthropology, it is necessary to move freely through the literature from the 1970s to the early 2000s; however, it is not the intention of the author to create a teleological survey of the literature. Instead, here is an overview of an ever-changing, ever-growing division of anthropology.

Subverting Dominant Paradigms

To accomplish the five above-stated goals, feminist anthropologists are influential in turning long-held notions

of women's lives and daily lived experience on their heads. Sociocultural dichotomies are among the many restrictive models used by the metadiscipline over the last 100 plus years. These dichotomies are those pairs that have been identified by anthropologists in the course of conducting fieldwork and reviewing and studying ethnology, and/or these pairs may have been conceived and applied as a result of personal experience. Under this category, I would include such pairs as female: male, nature: culture, domestic: public, raw: cooked, self: other, and so forth. In most cases, these pairs began their academic tenure as so-called intrinsic, universally constant, essential elements of all human beings.

Upon "discovering" and defining these dichotomies, anthropologists began the process of commenting on the possible meanings. Of particular importance to feminist anthropology are the central, idealized subjects, "woman" and "man." After reading and pondering over a wide variety of theoretical and ethnographic materials, this writer comes up with the same conclusion over and over again. That is, the only universally, biologically essential characteristic that is applied over and over again to human beings everywhere is that of woman: nature, or childbearing and the functions of women's bodies. What is important in multiple cultural contexts, and how that specific definition is manipulated through both theoretical statements and "concrete facts," is perhaps the major concern of feminist anthropological thought. Whether we are discussing foraging societies and household arrangements or the meaning

of family in postmodern societies such as the United States, this characteristic and its ensuing influences and problematics resurfaces over and over again.

The modern feminist movement, as a whole, was and is a reaction to Western society's attempt to pigeonhole women into a single role, that of child-bearer and servant to men, devoid of an autonomous personhood. This fact alone has been a primary factor in the still emerging thought of feminist anthropology. One of the ways that emergent thought is expressed is in the attempt to critique and subvert dominant Western stereotypes. Feminist anthropology is most concerned with the oppression of women and essentialized explanations of gender, social relationships, kinship systems, sexuality, and division of labor perpetuated by a male-dominated, European American, professional population since the 19th century (Moore, 1988).

Feminist anthropologists have been on the leading edge of subverting and redefining these stereotypes. In the beginning, feminist anthropological theory was an attempt to answer the seemingly obvious questions, "Are women universally oppressed?" and "Where did the oppression of women begin?" (Rosaldo & Lamphere, 1974). However, these questions were challenged even as they were being asked from within the feminist anthropological community and so began to subvert the very assumptions upon which they were based (Leacock, 1978; Moore, 1994; Rapp Reiter, 1975; Rosaldo & Lamphere, 1974). In this process, feminist anthropologists identified, and began grappling with, centuries-old assumptions about women and women's lives. Because of this, feminist anthropology is intertwined with some of the most recent developments in general anthropological theory, most notably postmodern and poststructural interpretative paradigms. To their credit, feminist anthropologists have managed to employ elements of postmodern and poststructural thought without, necessarily, continuing to a continually deconstructing—and ultimately unusable—theme. Feminist anthropology, unlike some poststructural critiques, provides the ability to create both new models and a "simultaneous move towards plurality and specificity" (Moore, 1994, p. 11).

Universalizing or Particular Knowledge

In the following discussion, we will explore what feminist anthropologists have theorized and subverted toward the ends of answering not only the initial questions of the universality and origins of the oppression of women, but more recently and more provocatively, "How does the oppression of women continue so effectively and in so many places?" and "How do specific groups of women and men work against gendered and other oppressions in their everyday lived experience?"

In the initial exploratory texts of feminist anthropology, *Woman, Culture, and Society* (Rosaldo & Lamphere, 1974) and *Toward an Anthropology of Women* (Rapp Reiter,

1975), there was an assumption by the majority of emerging feminist anthropologists that the universal oppression and subordination of women was and is a given. Rosaldo and Lamphere stated in the introduction to *Woman, Culture, and Society* that women have always, everywhere, been socially and politically inferior to men. Ruth Behar describes this tenet as an "effort to understand the [world-wide] social and political ramifications of women as the second sex" (Behar, 1995, p. 14). This in itself is a Western, deBeauvoirian tenet. This universalizing tenet led early feminist anthropologists to attempt to discover the "*origins* [italics added] of women's subjugation" (Nicholson, 1990). Rayna Rapp Reiter stated that the "subjugation of women is a fact of our daily existence . . . we find that sexual inequality appears widespread and that the institutions in which it is embedded have a long and complex history" (1975, p. 11). However, the major difference, and a division, between *Woman, Culture, and Society* and *Toward an Anthropology of Women* in the exploration of these questions was the historical specificity of the oppression of women in Rapp Reiter's volume.

From the outset, feminist anthropology tackled the internal theoretical debates by transforming the major dichotomies from an "or" to an "and" equation. This reformulation of the structuralist binary equation began the immediate subversion of the structuralist stance from which it came (Lévi-Strauss, 1973; Moore, 1994; Rapp Reiter, 1978; Rosaldo, 1980; Strathern, 1984). In this way, feminist anthropology subverted the tension between universalism and specific knowledge and forced a complimentary "freeplay" on them (Derrida, 1978). Jacques Derrida describes freeplay as

the disruption of presence. The presence of an element is always a signifying and substitutive reference inscribed in a system of differences and the movement of a chain. Freeplay is always an interplay of absence and presence, but if it is to be radically conceived, freeplay must be conceived of before the alternative of presence and absence; being must be conceived of as presence or absence beginning with the possibility of freeplay and not the other way around. (1978, p. 294)

This interplay between what is present or "universal" (woman as subordinate and man as dominant) and what is absent or "specificity of knowledge" (women and men in equity) is a long-standing anthropological view.

Michelle Rosaldo complicated this discussion by adding another dichotomy, domestic:private. In her *ovular*¹ article of 1974, "Women, Culture, and Society: A Theoretical Overview," Rosaldo established a "public domain:domestic domain" split as a universal characteristic of the oppression of women. By 1980, however, she had reassessed her position and noted that the very language of the criteria on which the public:domestic split was based was problematic. That is, the assumption of oppression was a purely generic Western, capitalist, middle-class definition that gives primacy to the domestic:public sphere split that

became prominent in the 19th-century Industrial Revolution (Landsman, 1995; Rosaldo, 1980).

The so-called public sphere is male and assumed to be of the greatest cultural value in all societies that have evolved in the West. This leaves women in the less valued so-called domestic sphere. For Western feminist anthropologists concerned with authorial power and the wielding of that power, the domestic sphere is an inferior and devalued sector. Thus, by framing arguments in a simplistic and dichotomous way, the opposite of the original intention is achieved. That was to discover and undermine the “original” cases of the oppression of women. Instead, by overlaying the domestic:public dichotomy as universal, European-American-patriarchal-monotheistic-unilineal-essentialist schemas of women’s and men’s roles became reinscribed in the literature over and over again (Leacock, 1978; Yanagisako & Collier, 1987). Rosaldo’s eloquent critique called for simultaneously retaining and rejecting this split.

However, far from suggesting that the domestic:public pair is an outmoded and unusable category, this structural apparatus is indeed still a useful theoretical tool in many situations. Before mapping both our Western categories and ideology onto the social relationships of another group, we must redefine what domestic:public may mean. Granted, wherever the juggernaut of industrialization and capitalism has changed the economic landscape, these categories are relevant (Leacock, 1978; Moore, 1994; Rosaldo, 1980). In many other cases, however, this domestic:public apparatus does NOT work, and there have been many advocates of making an attempt at revisualizing gendered social and societal relationships through a non-Western lens (Rapp Reiter, 1979; Yanagisako & Collier, 1987). Catherine Lutz clearly states that Western academics falsely universalize *our own* dichotomies everywhere in the world, regardless of the on-the-ground situation. This “constrains both our research on gender and our efforts to bring about social change” (quoted in di Leonardo, 1991, p. 19). The freeplay, and the reformulation of the structuralist binary equation from *or to and*, still allows for practical applications in critiquing and theorizing the subjugation of women.

To accomplish the task of revisualization, a return to the early work of Karen Brodtkin Sacks and Eleanor Leacock is in order. Both women, as Marxist feminist anthropologists, concentrated their analytical efforts toward the political economies of specific Native North American nations. Brodtkin Sacks, in the essay “Social Bases for Sexual Equality: A Comparative View” (1970), pointed to the Iroquois as an alternative to static Western notions of the public:domestic spheres. She stated, “In Iroquois society, women [had] an enormous amount of decision making power in the domestic, political, and religious spheres of life” (Brodtkin Sacks, 1970, p. 457). Leacock, too, after working with other matrilineal populations of Native North Americans—specifically the Montagnais-Naskapi—found evidence of a different way of conceptualizing the daily lived experience of the division of labor (Leacock, 1978).

Leacock (1972) also points out that what was significant for women’s status is that the household was communal. A gendered division of labor existed but was reciprocal, and the economy did not involve a dependence of the wife and the children on the husband. Household management was not construed as it has been for Western society. “In primitive communal society,² the distinction did not exist between a public world of men’s work and a private world of women’s household service. The large collective household *was* the community, and within it both sexes worked too produce the goods necessary for livelihood” (Leacock, 1972, p. 33). Therefore, the domestic:public dichotomy did not exist.

While there are certainly role sets and division of labor, in these ethnohistorical cases, the people did not perceive themselves in “power over”—or authorial power—relationships per se. Instead, Brodtkin Sacks, Leacock, and other researchers have found evidence of social relations based on a nonhierarchical web (Ackerman, 1995; Ashcraft & Mumby, 2003; Bacigalupo, 2007; Bilharz, 1995; Dossa, 2004; Duggan, 2005; Goodwin, 2006; Gunewardena & Kingsolver, 2007; Perdue, 1995; Regis, 2002; Shoemaker, 1995; Sparks, 1995; Watson-Franke, 1992), one that weights women’s work and men’s work equally in the social and societal workings of the community. Brodtkin Sacks admonished in 1970 that at the end of exploitation “looking at Iroquois and Mbuti societies suggest that we need a complete reorganization of ‘work,’ a radically different kind of division of labor. If they can do it, so can we” (p. 455). This statement implies that indigenous women “overthrew” an exploitative situation similar to our deBeauvoirian one. There is no evidence of that. Brodtkin Sacks’s research can be well utilized to see around our assumptions.

Even as we discuss, describe, and cite numerous instances in which feminist anthropologists of various ideologies have given ethnographic, empirical evidence to subvert the notion of the *universal* oppression of women, in most of the literature there are some of the same complaints that began in the 1970s. The term *ovular* was coined at that time as a woman-centered alternative to *seminal*. This was experimented with in order to bring up that important academic work was, all too often, “manly.” Whether implicitly stated by feminist anthropologists of color or reiterated by quoting ovular work within a new attempt at inclusion, there is a sense of frustration with the movement—or lack of it—away from a universalizing stance (Okely, 1975, as quoted in Lutz, 1995; Zavella, 1997). The metadiscipline of anthropology has yet to fully utilize and incorporate the knowledge that feminist anthropologists have gained and written in our efforts to refocus attention toward specificity and “situated knowledges” (Haraway, 1991).

Despite the rethinking and revision of numerous feminist anthropologists on subjects as diverse as Malinowski’s ethnographic snapshot of Trobrianders (Weiner, 1988) to power and prestige among American Indian women (Klein & Ackerman, 1995), the metadiscipline reiterates and

reinforces an older definition of universal oppression. In the 1997 text by Burton Pasternak and Carol and Melvin Ember, *Sex, Gender, and Kinship: A Cross-Cultural Perspective*, the authors state that “comparative research tells us that women have very low status in a considerable number of societies, and we know of none in which women clearly have more status than men” (1997, p. 65). One can only assume that many academic departments adopted this text—written by respected and established anthropologists—as a teaching tool when it was first published, and it is still being used over a decade later. This leaves yet another generation of young anthropology students out of the feminist anthropology loop.³

Even though it is still dealing with some vestiges of the “universal oppression of women,” feminist anthropology has thrown off the shackles of continually asking why as an attempt to find the “origins” of women’s subordination in favor of asking much more sophisticated and complex questions about women’s relationships to each other and to the worlds of their daily lived experience (di Leonardo, 1991). Some of these include the following: (1) How do women act as agents in their daily lived experience (Lamphere, Ragoné, & Zavella, 1997)? (2) How do women subvert local social rules to gain agency in their lives (Lopez, 1997)? (3) What does a woman’s position as producer and controller of goods lend to her overall position—status—in her community (Babb, 1989)? (4) How does the continued encroachment of a global capitalist system affect women and their choices at a local level (Harrison, 1997)? So, while the definition and face of universalism may have been radically altered by and within feminist anthropology, we still must address the question within the metadiscipline.

Biological Essentialism or Social Construction

In the same way that the universalizing tenet was subverted through the use of specific knowledge and the reformulation of the structuralist equation, so too does social construction subvert biological essentialism. Feminist anthropologists, by necessity, recognize sex (as represented by the XX and XY pairs of chromosomes) in order to be able to talk about the categories “women” and “men.” In Henrietta Moore’s words, “Bodies. It all has something to do with bodies” (Moore, 1994, p. 17). In practice, the words *woman*, *femme*, *mujer*, *bean*, *a ge yv* represent not only a valid concept, but also a distant one. She—*elle*, *ella*, *si*—is, in fact, globally embodied in daily lived experience. It is not *being* “woman” that causes problems for those who are—or embody—it. It is, instead, the constructed role sets within which “woman” is cast that continue to subject *her* to oppression (Lamphere et al., 1997). In her 1990 article, “Can There Be a Feminist Anthropology,” Abu-Lughod commented that the great “importance of the fact that the women we encounter in the field often recognize us as women, however different, has not received much attention” (1990, p. 26).

Biological essentialism, sociobiology, and bioculturalism have a tendency to set the women’s movement and women’s status back into a Victorian/post-World War II “Angel in the House” or “Donna Reed” realm (Moore, 1994; Ortner, 1984; Stocking, 1987). In the same way that the metadiscipline has persisted in retaining ideas about the universalism of women’s oppression in its primary form, so too has this kind of essentialism held on. Relegated a century ago to the role of mother and dependent partner of “man the hunter,” “woman” was, and is, essentialized and universalized in the Victorian European American ideal (Dahlberg, 1981; Lee & DeVore, 1968). Stocking found proof that the early metadiscipline largely ignored women and women’s lives, noting that Herbert Spencer

later justified the limitation of women’s political rights on evolutionary grounds: because the vital needs of reproduction arrested their individual mental evolution at an earlier age, and their [feeble] characteristic mental traits . . . were those adapted to “dealing with infantine life” and relating to the stronger male, their present hereditary makeup would incline them to support authoritarian government and incautious (i.e. maternal) social policy. (Stocking, 1987, p. 205)

Frances Dahlberg’s work, in fact, predated Stocking’s findings; she summed up the metadiscipline’s read on that oft-told story, “Man the Hunter”:

Hunters [read: men] must be intelligent—to remember where they have gone and successfully return with meat to their *waiting* [italics added] wives and children, to find food and water for themselves on the hunt, to anticipate their prey’s actions, to make weapons, and to plan with other men for a successful hunt. (1981, pp. 1–2)

Clearly, this form of biological essentialism plays into the universalizing tendencies that feminist anthropology has always striven to subvert, that is, that “woman” is essentially tied to her role as child bearer in near exclusion of any other. Rosi Braidotti expresses it best when she says that women’s bodies are “not an essence nor indeed a form of anatomical destiny, but rather it is ‘one’s primary location in the world, one’s primary situation in reality’” (as quoted in Moore, 1994, pp. 18–19). Here I turn to the free play between essentialism and social construction in the feminist anthropology literature.

In the same way that feminist anthropology utilized specific knowledge to analyze the universal oppression of women, so too did these researchers utilize the idea of social construction to analyze the ways in which the essential nature, for example, the reproductive capabilities, of human bodies are socially manipulated (Ginsburg & Rapp, 1991). Feminist anthropologists generally agree that gender, gender relationships, sexuality, kinship systems, and divisions of labor are not a given based on these essential physical, biological attributes. Instead these social organizations are constructed from era to era, place to place, and society to society

(Lamphere et al., 1997; Moore, 1994; Rapp Reiter, 1975; Rosaldo & Lamphere, 1974). As di Leonardo (1991) states, “Social constructionism clearly implies a respect for historical difference and change, but it also entails an understanding of the human use of history—of *constructions* [italics added] of the past—to legitimize or to contest the status quo” (p. 29).

From *Woman, Culture, and Society* (Rosaldo & Lamphere, 1974) and *Toward an Anthropology of Women* (Rapp Reiter, 1975) to the mid-1990s volume *Situated Lives: Gender and Culture in Everyday Life* (Lamphere et al., 1997) to the most recent additions, *The Gender of Globalization: Women Navigating Cultural and Economic Marginalities* (Gunewardena & Kingsolver, 2007) and *Making Miss India Miss World: Constructing Gender, Power, and the Nation in Postliberalization India* (Dewey, 2008), study after study points to the fact that the construction of gender, gender relationships, sexuality, kinship systems, and divisions of labor not only differs from country to country and region to region but also is enacted heterogeneously within populations. Because the evidence for this is clearly obtainable in the ethnographic record, feminist anthropologists once again subvert a universalizing tenet that would essentialize all women into a single role set and all men into another.

Sherry Ortner’s ovular work of 1974, “Is Female to Male as Nature Is to Culture?” reconceptualized and attempted to problematize a dichotomous pair in much the same way Rosaldo did the public:domestic pair. In a 1996 essay designed “partly in the spirit of defining [her]self, but largely . . . in the spirit of learning something from all this” (Ortner, 1996, p. 177), Ortner deconstructs her own structural pairs—female:male as nature:culture—by calling on some of the critiques of the original essay (Collier & Rosaldo, 1981; Leacock, 1981; MacCormack & Strathern, 1980; Yanagisako & Collier, 1987). While some scholars critiqued Ortner’s universalizing (MacCormack, 1980; Yanagisako & Collier, 1987), others discriminated between universalism and essentialism and leveled their criticisms at Ortner’s implementation of the dichotomies cross-culturally, as an essentializing position (Collier & Rosaldo, 1981).⁴ Judith Okely’s rereading of Simone de Beauvoir’s *The Second Sex* suggests that Ortner’s early reliance on that work (Ortner, 1974, 1996) places essentialized biologism “squarely on woman,” since “de Beauvoir systematically outlines a dominant European tradition which, since the 18th century Enlightenment, sees nature as inferior to culture. . . . She [Ortner] is implying it is ‘natural’ to look at ‘nature’ in a specific way” (Okely, 1996, pp. 179–180).

Ortner, like Rosaldo before her, reassessed her original argument to reconfigure what both female:male and nature:culture may mean as socially constructed terms. Her reassessment also includes a turn toward practice theory (Ortner 1983, 1996).⁵ With this turn, she places herself in a position to critique her early work by employing notions of social construction to subvert her earlier essentialized, universalizing position. About her own paper “Is Female to Male as Nature Is to Culture?” Ortner writes,

I also think that the *linkage* between such structures and any set of social categories—like female:male—is a culturally and politically constructed phenomenon. . . . My interests lay much more in understanding the politics of the construction of such linkages, than in the static parallelism of the categories. (Ortner, 1996, p. 180)

Ortner’s *linkage* corresponds to what I have defined as a reformulation of the structuralist binary equation, a clearly common theoretical tool of feminist anthropology.

I would go so far as to suggest that in some field situations—those similar to what is described as appropriate through the domestic:public lens—female:male as nature:culture is a valid frame. However, we must constantly be mindful of the tendency toward oversimplification, universalizing, and essentializing in the metadiscipline. There is still room for feminist anthropologists to rewrite the equation and allow for “universal particularity” (MacKinnon, 1993, as quoted in Moore, 1994, p. 17).

Interpretive or Cultural Materialism

Interpretive anthropology was heavily affected by Geertz’s 1973 work on symbolic anthropology, *The Interpretation of Cultures*. He defined culture as a “historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic forms by means of which [people] communicate, perpetuate, and develop their knowledge about and attitudes toward life” (Geertz, 1973, p. 89). Lamphere et al. (1997) invoke this general definition of culture for use in their anthology, *Situated Lives*, over the Boasian “culture history” definition of “complex patterns of elements, traits, and configurations that constituted the lifeways in separate but equal ‘cultures’” (p. 2). To complete their definition of “culture” in an interpretive context, it is necessary to include the work of linguistic anthropology. Di Leonardo (1991) states, “Envisioning language and political economy as mutually constitutive exemplifies the larger ‘culture and political economy’ tendency within the metadiscipline” (p. 27).

The cultural materialism school in the metadiscipline, by contrast, emphasized the “impact of external forces, and . . . the ways in which societies change or evolve largely in adaptation to such impact” (Ortner, 1984, p. 135). Ortner goes on to say that most anthropologists “ignore[d] the fact that peasants are part of states, and that even ‘primitive’ societies and communities are invariably involved in wider systems of exchanges” (Ortner, 1984, p. 141). Because of the polarity of this pair within the metadiscipline (hence the specializations), this has been a difficult subversion to attempt.

In the 1990s, as a result of a decade of ground-breaking work in the 1980s, the subversion of this dichotomy became more commonplace (Babb, 1989; Gal, 1989; Strathern, 1987). Feminist anthropologists revisualized the universalizing and essentializing stance taken by many cultural

materialist anthropologists, and the sometimes extreme cultural relativistic stance of symbolic anthropologists, to transform them through the aforementioned use of the conjunction *and* instead of *or*. In 1991, di Leonardo borrowed the term “culture and political economy” (Schneider & Schneider, 1976, as quoted in di Leonardo, 1991, p. 27)⁶ to describe the tone of many of the articles in her edited volume, *Gender at the Crossroads of Knowledge* (di Leonardo, 1991).

So, too, do Lamphere et al. (1997) invoke this stance for the articles included in their volume. Even more calculated use of dichotomous pairs as an *and* equation instead of an *or* equation exemplifies how feminist anthropology can move the metadiscipline in positive and exciting ways (Harp, 1991; Weedon, 1987). By utilizing both culture and political economy—while also acknowledging that even this stance will produce a partial knowledge—feminist anthropologists again strike a blow at structurally dichotomous pairings as theoretical tools.

The basic frame for culture and political economic feminist anthropology has been succinctly summarized by di Leonardo (1991, pp. 28–31) in five key points. These are as follows:

1. Social evolution is radically rejected. The critiques of Shostak's work *Nisa: The Life and Words of a !Kung Woman* (1981) are used as an example.
2. Those patterns of behavior conceived as “innately human or at least as well-established are neither.” Terms that label a myriad of socially constructed forms, for example, *homo-* and *heterosexual*, *race*, and *ethnicity*, do not have the same meanings across space and time.
3. As a “material and social institution and as a set of ideologies,” gender has an embedded nature in human society.” Recognizing this embedded nature of gender also means that women “must be seen not only in relation to men but to one another as well.”
4. “All forms of patterned inequality merit analysis. . . . Thus the hoary anthropological shorthand, ‘the X say’ must be replaced with genuine attention to what varying populations among the X say.”
5. Feminist anthropologists, and all anthropologists, must “attend to and investigate actively the multiple layers of . . . social location . . . through which we perceive particular cultural realities.” First and foremost, di Leonardo includes here the relationship of “researcher and researched,” a reflexive turn for the metadiscipline.

Di Leonardo continued her critique in her 2000 volume, *Exotics at Home: Anthropologies, Others, and American Modernity*, by bringing “the X” to the American doorstep to be recognized as ourselves (di Leonardo, 2000).

Culture and Political Economy or Experimental Ethnography

Di Leonardo's final point allows me to move to a final subversion in this discussion, culture and political economy

(as discussed above) or literary (experimental) ethnography (as discussed below). Di Leonardo's plea for attention to social location and perceptions of social reality are a direct response to the *Writing Culture: The Poetics and Politics of Ethnography* (Clifford & Marcus, 1986), which summarily passed over some 15 years of feminist anthropology with hardly a “by your leave” (Behar, 1995; di Leonardo, 1991). However, di Leonardo's answering text, *Gender at the Crossroads of Knowledge: Feminist Anthropology in the Postmodern Era* (1991), strikes a decidedly different tone from that of another feminist anthropological text that also purports to be an answer to *Writing Culture*, that is, *Women Writing Culture* (Behar & Gordon, 1995). The advent of both culture and political economy and literary (experimental) ethnography were deeply affected by the feminist and postmodern turn in anthropology of the 1980s and into the 2000s. These paradigms called into question the ways in which anthropologists approached the slippery term *culture* and the representations of societies and their cultural systems. As was the case with feminism and poststructuralism, in critiquing and subverting structural dichotomies, feminism and postmodernism made some of the same demands on the metadiscipline of anthropology and its traditional views of “culture” and its representations of the “other” (Boddy, 1991; di Leonardo, 1991, 2000; Moore, 1994; Wolf, 1992). Postmodern analysts critiqued traditional ethnography for claiming a homogenizing approach that placed “the X,” or the other, in a static, racist, and untenable “ethnographic present” (Clifford, 1986; Cole, 1995; Silverstein & Urban, 1996). These critics claimed—and rightly so—that knowledge, even within a relatively isolated and genetically homogenous group, is an always partial, ever-shifting set of circumstances (Clifford, 1986).

Of course, feminist anthropology had pointed out the inherent partiality within the metadiscipline of anthropology by pointing to the absence therein of both representations of women in society and of women anthropologists (Leacock, 1978; Rapp Reiter, 1975; Rosaldo & Lamphere, 1974). That was more than a decade prior to *Writing Culture*. The static, ethnographic present of “the X,” feminist anthropologists concluded, was also a static androcentric viewpoint. If and when women were included, it was to shore up the very dichotomies that I have previously discussed—essentialized and universalized notions of the public:domestic spheres and the question of whether female:male was equivalent to nature:culture (Ardener, 1975; Behar, 1995; Buckley, 1989; di Leonardo, 1991, 2000; Mascia-Lees, Sharpe, & Cohen, 1988; Moore, 1988; Rosaldo & Lamphere, 1974).

The more complex and sophisticated feminist anthropological theory becomes, the more our different ideological stances crash into one another without specifically relating. To wrap up the previous section, culture and political economy can be characterized as grounded in empirical evidence. Not, as in Geertz's words, as “empiricism, magpie amassment of cultural detail, produc[ing] an ethnographical

telephone book” (Geertz, 1995, p. 23), but as best exemplified in this statement by di Leonardo (1991):

In the end, the careful attempt to discern the meanings of gender in other cultural worlds and the bringing together of ethnographic, historical and political-economic knowledge of particular populations can be seen as the most fruitful modes of feminist anthropological practice. (p. 17)

Literary (experimental) ethnography, the supposed opposite of culture and political economy, is a complex mix of “textual experimentation” that can include “autobiography, ethnography, and memoir to reflect on Western feminist desire, location, and knowledge” (Gordon, 1995, p. 432). It is important to note that this work is grounded in empirical evidence used in the same spirit as di Leonardo’s above definition. Yet, there are some striking differences as well. To further clarify literary (experimental) ethnography, the modifiers *self-reflexive* and *personal* are added.

Self-reflexivity—in and of itself—is, in the 21st century, a fairly common occurrence in anthropological literature. I daresay that most graduate students have come to expect a certain level of self-reflexivity to add contextualization—that is, social location—to the anthropological text. Further, it is practically impossible to include that self-reflexivity without some personal information becoming evident. Again, this is expected, as it lends an air of reality to both the writing and the writer, and perhaps more importantly, to the ethnographic material. However, the degree of personal self-reflexivity⁷ in works that are identified by the authors as being in the field of culture and political economy is less than is evident in a great deal of the literary (experimental) ethnography (Abu-Lughod, 1993; Behar, 1993; Gottlieb & Graham, 1993; Visweswaran, 1994).

In the 1990s, feminist culture and political economy and feminist experimental literature have been an answer to postmodernist critiques, each going its own way toward complex and holistic anthropological work. Whether the literature is based in the more familiar ethnographic form and concentrates on using its empirical base to describe and theorize “the play between speech and economy, power and agency” for a group of aboriginal women (Povinelli, 1991, p. 249) or whether it takes a more experimental form that incorporates women’s poetry (and its effect on men) and representation of women’s oral narratives (Abu-Lughod, 1993), the feminist anthropological project ends up critiquing and theorizing the metadiscipline (Ferrari, 2008).

Upon reading much of this literature, it becomes apparent that many of the same scholars are writing very different kinds of articles for volumes that fall within the purview of each of these genres. An unfortunate phenomenon is that despite that fact, there is very little cross-citation. It is as if they stand in near complete isolation relative to one another (Behar & Gordon, 1995; di Leonardo, 1991; Lamphere et al., 1997). To begin to subvert this most recent dichotomy that has arisen within feminist anthropology itself, the conclusion

will identify an inclusive stance that, while it is no means new (Brodin Sacks, 1989; Rothfield, 1991; Yanagisako & Collier, 1987), has yet to be fully embraced.

Conclusion

Feminist anthropology has long advocated a methodological stance that Rosaldo and Lamphere called for in *Woman, Culture, and Society* in 1974, that is, to be proactive and inclusive. Gordon (1995) also called for this proactive stance in 1995 when she said,

We need feminist fieldwork in the U.S. that participates in political activist and advocacy-oriented research. Interdisciplinary dialogue with oral historians who work within a disciplinary tradition of public advocacy might pull feminist anthropology at home toward grittier intellectual alliances such as with community educators and activists and with each other. (p. 375)

Faye Harrison’s work cuts across these boundaries. In her latest volume, *Outsider Within: Reworking Anthropology in the Global Age*, Harrison invokes the concept of “weaving” to achieve the goals of being both proactive and inclusive (Harrison, 2008).

This is especially important in U.S. society, where cultural interpretations crash into each other at an astounding rate. For example, feminist anthropologists need to theorize and offer solutions where the new world order reorganizes so-called debtor countries’ economic systems to match our own, with military buildups paid for by social program extinction; or where multinational corporations in search of cheap labor strip adults and children from subsistence activities and thereby create situations in which people who were relatively self-sufficient become exclusively dependent upon a cash economy (Davison, 1989; Harrison, 1997, 2008; Lamphere et al., 1997).

Humans have the cognitive ability to see beyond their milieus of familiarity. As proof, as feminist anthropologists, we must take ourselves. Our experiences, writing, fieldwork, and teaching pedagogies have extracted a great many of us from our consanguine relationships and make it difficult, if not impossible, to “go home again” (Abu-Lughod, 1991; Behar, 1993; Visweswaran, 1994). Feminist anthropologists are collectively writing toward a theoretical stance with a breadth, width, and flexibility to articulate concerns of multiple groups of women—for example, feminist anthropologists with various ideological backgrounds, and those myriad groups of women with whom we work—that continues to *weave* itself and be woven by its thinkers (Harrison, 2008). Feminist anthropology also continues to move toward a theoretical stance that is not a reaction to some earlier adaptation but is inclusive, an inclusion that is not only rhetorical but practical as well. This means that *all* of the work we undertake as feminist anthropologists is validated: (1) historiography—both theoretical and auto- and biographical, (2) ethnography—from empirical data

collection to experimental text, (3) social relations—from culture and political economy to linguistics, and (4) women's lives—to include oral narrative and individual story (Behar & Gordon, 1995; di Leonardo, 1991; Gunewardena & Kingsolver, 2007; Lamphere et al., 1997; Silverblatt, 1991).

There is also a need to develop a way to critique an argument without resorting to the accusatory polemic that ends up rejecting many women and most men from the conversation. A web, not a hierarchical frame or yet another binary dichotomy, must be more widely acknowledged to elucidate the complex and continually shifting set of relationships that all individually effect the whole (Ackerman, 1995; Bilharz, 1995; Harrison, 2008; Medicine, 2001; Perdue, 1995; Shoemaker, 1995; Sparks, 1995; Watson-Franke, 1992).

Structural dichotomies serve to constrict the scholarly work of feminist anthropologists to a continual recapitulation of and with Western academic norms. Feminist anthropological theory generally insists upon “greys”—polarizing to nether black nor white—and, as we have seen in the discussion of the subversion of the structuralist equation, can rarely give a sole good/bad definition to its tenets. Dichotomous thinking serves racist, colonialist, and imperialist ends by continuing to exclude the very voices of those caught in the midst of them. A. Lynn Bolles admonished feminist anthropologists in 1995 at the American Anthropological Association meetings by asking, “Where are the African American women anthropologists?” Seldom cited (except for the rare exceptions of Brackette Williams, Patricia Hill Collins, Faye V. Harrison, and now, after decades of invisibility, Zora Neale Hurston), the thoughts and voices of these women—and of Latina, Native American, Asian and Asian American, African, and other women anthropologists—are still largely lost between the polar reaches within the metadiscipline. In the continuing debate and lack of mutual citation and inclusion of each other's work over the best way to theorize and discuss the ever-widening rage of gendered relationships and women's roles in societies globally, we, feminist anthropologists, are denying ourselves the solidarity that could become a factor in effecting positive change in the actual lived experiences of women.

The continued marginalization of women's cultural knowledge and experience, feminist anthropological writing, and feminist anthropologists themselves in the coursework of anthropology graduate students keeps producing—or reproducing—the knee-jerk reaction of astounded discovery that initiated the 1970s explosion in feminist anthropological literature. This is the reason that feminists, women and men, continually need to “discover” that literature over and over again. Until some primacy is given to a feminist anthropological viewpoint, and until and unless there is an effort made on the part of the metadiscipline of anthropology to be more inclusive within the discipline, graduate and undergraduate students will be “discovering” Ruth Bunzel, Elsie Clews

Parson, Ella Deloria, and Zora Neale Hurston all over again decade after decade.

Notes

1. Collier and Yanagisako (1987).
2. It should be noted here that Leacock did indeed fall into the universalizing trap that probably caused much of her work to be overlooked in recent feminist anthropological literature. However, looking past that tenet, her point is well taken and can be used as a tool for rethinking the public:domestic dichotomy.
3. A look at the bibliography of this book corroborates the critique. Few works of feminist anthropologists are cited, and those that are are from the 1970s, when the question of universal oppression was first addressed (Pasternak, Ember, & Ember, 1997).
4. These feminist anthropologists also critiqued Rosaldo's domestic:public dichotomy as essentializing (Collier & Yanagisako, 1987; MacCormack, 1980).
5. Practice theory is defined as “anything people do . . . the study of all forms of human action” (Ortner, 1984, p. 149).
6. While Schneider and Schneider (1976) are not generally described as “feminist,” per se, the corpus of Jane Schneider's work (in collaboration with self-described feminists, e.g., Rayna Rapp Reiter and Annette Weiner) may be loosely seen as such. Thus, this very specific reformulation of the structuralist equation was developed in conjunction with an anthropology by and of women. Also note that in 1984, Ortner did not use the reformulation but instead criticized the work as “studying the effects of capitalist penetration upon . . . communities” (Ortner, 1984, p. 141).
7. That may seem redundant, but the aim here is to separate positionality (self-reflexivity) from consciousness-raising-style “gut spilling” (personal). While there is still a place for consciousness raising, it has not been included in much academic literature.

TERRORISM

JAMES F. MISKEL

Long Island University, U.S. Naval War College, and Norwich University

The September 11, 2001, terrorist attacks on the World Trade Center in New York City and the Pentagon were the first in a series of dramatic and destructive terrorist attacks in which Islamist extremists sought to coerce Western and pro-Western governments into changing at least some of their policies. Subsequently, there were major attacks in the United Kingdom, Spain, Algeria, Egypt, and Jordan by Islamist radicals. Thousands of people perished in the September 11 attacks alone, and hundreds died after trains were bombed in London and Madrid.

These attacks made terrorism a front-and-center issue in the United States and Western Europe, but terrorism has been a major concern for many decades in many different parts of the world. Israel, Sri Lanka, India, Pakistan, Indonesia, the Philippines, and Japan, for example, have also experienced serious terrorist incidents since the mid-1990s. Indeed, terrorism in various forms has existed for centuries. Perhaps the earliest organized terrorist movement was by the Zealots in the first century. The Zealots used public assassinations as a tactic for frightening Jewish residents into refusing to cooperate with the Roman occupiers of the Holy Lands.

Terrorism was particularly widespread in 19th-century Europe. Anarchist and nationalist groups all resorted to violence against government officials and/or average citizens suspected of collaborating with the authorities. Anarchists sought to topple governments by killing key

leaders—hoping that this would usher in an era of self-governance by the people themselves. Nationalists as far apart as Armenia (in the Ottoman Empire), Bosnia (in Austria-Hungary), and Ireland (in the British Empire) used violence against nonmilitary targets, including civilian infrastructure like the London subway, to do what the Zealots had attempted to do centuries earlier: compel an imperial power to withdraw and grant their territories independence.

Definition of Terrorism

It is ironic that despite the international concern over terrorism, the states of the world have been unable to agree on a single definition of the term. The primary reason is political. Some states believe that certain forms of violence should not be categorized as terrorism, merely because it suits their foreign policy interests, or because they believe that “Western” definitions of terrorism are hypocritical. This is particularly the case with the violence perpetrated by Palestinian groups against targets in Israel. Often these attacks consist of suicide bombings on Israeli streets or the firing of small rockets into Israeli villages from the Gaza strip. Arab states believe that these actions should be considered a legitimate form of resistance against an occupying power. (Israel occupied Gaza until recently and still occupies much of the West Bank.) Often this view is associated with the perception that Israel is not a legitimate

state in the first place—despite the fact that it was recognized by the United Nations 60 years ago and that some Arab states and the Palestinian Authority have acknowledged Israel's legitimacy.

Arab and Muslim states, in general, also believe that the United States and other Western powers should recognize that the actions taken by the Palestinians are not so different from the violent acts performed by American and European revolutionaries in the 18th and 19th centuries or by the anti-Nazi resistance in World War II. They maintain that it is hypocritical to label Palestinian violence as terrorism but attacks on nonmilitary targets during the American or French Revolutions as acts of heroism. Of course, it is equally hypocritical for these same Arab states to deny—as they do in statements by the League of Arab States—that antiregime violence directed at them by domestic revolutionaries is terrorism, not a legitimate form of resistance.

The differences about whether Palestinian violence should or should not be classified as terrorism will persist for the foreseeable future—so there may not ever be a common, international definition. There has, nevertheless, been a consensus among scholars and statesmen in most of the world that terrorism is

violence against nonmilitary or civilian targets that is designed to create fear outside the immediate circle of victims, in order to promote a political objective.

This definition provides important criteria for distinguishing among “ordinary” crime, psychotic behavior, and terrorism. The definition also allows us to distinguish between terrorism and insurgency or guerrilla warfare, although in practice there is overlap, as insurgents often use terror tactics. For our purposes, though, an insurgency is an organized attempt by a group of people to confront the military forces of a state and to secure control over a specified territory. Insurgents usually are also organized in an overt and military-like manner. Terrorists typically avoid direct confrontation with military forces and are organized more like criminal gangs—secretive and smaller in number—and rarely chose to directly confront military forces. Terrorists also ordinarily do not seek to directly control and administer territory.

The purpose of most violent crime is, obviously, financial gain for the perpetrator. Other violent crime may be intended to satisfy some personal agenda or emotional need—for example, revenge against someone for a real or perceived slight. Clearly, such forms of criminal violence can instill fear in the victims, their families, and perhaps entire neighborhoods, but unlike the case with terrorism, this fear is not created in order to serve a political purpose. Violence by a mentally unbalanced individual ordinarily can also create fear, but it is not designed to achieve a rational political goal.

Another form of politically motivated violence against civilian targets is terror practiced by the state against its

own population or the population of an occupied territory. One of the most infamous examples is the violence of Nazi Germany against German Jews and others as well as against civilian populations in much of Europe during World War II. An equally infamous example was the Great Terror in the Soviet Union, notably under Joseph Stalin, where millions of average citizens were killed or sent to labor camps and even government and military functionaries were jailed or executed, even though they were innocent of any crimes against the state. In both cases, the purpose of the violence was political: to eliminate opposition to the regime and its policies. Thus, the practice of state terror differs from terrorism in important respects. It is conducted by the state itself and is designed to prevent policy or regime changes, whereas terrorism is conducted by non-state actors (individuals or groups that are not employed by a state and are thus free to act independently of any state) who are seeking change.

Because of their nonstate status and the fact that their violence is illegal, terrorists ordinarily organize into conspiratorial groups with internal discipline necessary to evade the authorities in the states where they commit their acts of violence. As noted below, there are exceptions, as some groups have become so large and so entrenched that they have essentially two wings: a political or social services wing that operates in public and another wing that undertakes terrorist operations.

Some important distinctions need to be made when discussing state terror and terrorism. One is that states occasionally use violence to further their national interests. When the violence is conducted by the military against the armed forces of another state, it is war—not state terror or terrorism. When the violence is covert (as in the assassination of a foreign leader), it is technically an act of war—not state terror or terrorism. When states in effect use terrorist groups (nonstate actors) to engage in acts of violence against civilian targets in another country, that is state-sponsored terrorism.

State-Sponsored Terrorism

Sponsorship can take various forms, but usually it consists of a state providing financial support, equipment, or technical assistance to a client terrorist group or groups. The support can be passive, as would be the case when a state allows a terrorist group or groups to operate headquarters and perhaps even run its own training camps inside the state's borders. Or, the support can be active, as would be the case when a state actually trains the terrorists and/or provides them with weapons, money, and travel documents. In some cases, a state may even pay the terrorists to conduct specific operations in another country.

Some states sponsor terrorist groups because it enables them to commit acts of violence against a rival state without having to go to war. Typically, a state would do this in

order to weaken the other state or create political discord inside it. States may also sponsor terrorist groups because they are in ideological agreement with the group's objectives. For example, during the Cold War, communist East Germany supported leftist terrorists in West Germany to help further the spread of communism and weaken West Germany's attachment to NATO. Domestic political pressures may also be factor. For example, after losing the 1948 war against Israel, Egypt supported the *fedayeen* (Arabic for self-sacrificers or freedom fighters), who infiltrated and attacked Israel. Egypt was too weak to directly attack Israel, but its support of the fedayeen allowed it to demonstrate to the Egyptian people that it was still standing up to Israel. Syria is another example. The Syrian government in Damascus allows Islamist terrorist groups to maintain headquarters in the country, in part so that the regime can tout its Islamic credentials (the regime of President Assad is dominated by Alawites, a sect that many Muslims regard as heretical) and claim that it too is standing up to Israel despite having been defeated on the battlefield.

The bottom line is that states sponsor terrorism because they are unwilling or too weak to confront another state militarily. In effect, the states use the terrorist groups for the purposes of the state—a fact that is amply demonstrated by Syria's efforts to divide the Palestinian movement by playing one group off against another and by its use of violence against Palestinian groups that did not adhere to Syrian foreign policy in the 1980s. In 1988, Syria helped the Amal militia in Lebanon attack the strongholds of the Palestine Liberation Organization (PLO) because the PLO had become too powerful and too independent. Thus, accepting state sponsorship can be something of a Faustian bargain for a terrorist group, as the sponsor can restrain the group from pursuing its own goals or can even take action against a group it once sponsored.

The U.S. government has formally designated four states as state sponsors of terrorism: Syria, Iran, Sudan, and Cuba. Until 2006 and 2008, Libya and North Korea, respectively, were also on the list. A state that has been designated is subject to a variety of economic sanctions by the United States, the most important of which are restrictions on foreign assistance, a ban on defense-related sales, and controls over exports of "dual use" items (systems that can be used in both commercial and military applications, such as advanced computers). There is some controversy about the efficacy of these sanctions—some of the designated states have been on the list for more than 20 years; the duration obviously suggests that the sanctions have not caused those states to change their policies. This certainly seems to have been the case with respect to Iran, which continues to provide training and financial support to Hezbollah, a terrorist group that has effectively taken over southern Lebanon. A primary reason for the apparent ineffectiveness of the sanctions is that they are not universal. For a variety of reasons, few other states apply economic pressure on the states that the United States has designated as state sponsors.

During the 1970s and 1980s, Libya adopted the unusual policy of openly supporting a wide variety of terrorist groups. (Most state sponsors officially deny that they support terrorist groups or claim that the groups they support do not engage in terrorism.) Libya supported groups as disparate in their ideology as the politically conservative Irish Republican Army, the leftist Japanese Red Army, and assorted Palestinian factions by them providing with training camps, technical assistance, and financing. The Libyan leader, Muammar Qaddafi's apparent intention was to destabilize the status quo, which favored the United States and Europe, and in so doing increase Libya's influence at least in North Africa. Ultimately, Qaddafi's support for terrorism and his erratic foreign policy alienated neighboring states and made Libya a pariah even in the region.

Libya's role in a terrorist attack on a Berlin night club frequented by American servicemen led to a retaliatory attack by the United States in 1986. This attack consisted of bombing runs by U.S. warplanes over some Libyan government facilities and terrorist camps. The attacks did not cause Libya to reduce its support to terrorists (there actually was an increase in Libya-supported terrorism immediately after the attacks), but it did help convince European states that they should cooperate with the United States in tightening economic sanctions against Libya's only important industry, energy.

By the late 1980s and 1990s, oil prices had fallen sharply and the sanctions prevented Libya from getting the drilling and refining equipment it needed to expand production and offset its loss of revenue from lower oil prices. The result was the gradual erosion of the Libyan economy and an increase in dissatisfaction with the status quo among the Libyan people. Eventually, these developments caused Libya to take the steps it needed to convince the West that it no longer supported terrorism. North Korea was also driven by a combination of economic distress and diplomatic pressure to abandon its sponsorship of terrorism and, more important, its nuclear weapons programs in 2008.

The oil markets in the 21st century are quite different than they were in the 1990s. Prices are high and supplies tight. Thus, it seems unlikely that economic sanctions can have similar effects on Iran, which has both the world's third-largest oil reserves and an ideological commitment to the Islamist groups it has been supporting. Indeed, Iran has officially stated that it shares the objectives of these groups, that is, the destruction of Israel and the return of the territory occupied by the Jewish state to Islam in general and to the Palestinians in particular. As long as Iran shares these objectives and is able to support its economy through oil exports, it will likely continue to sponsor Hezbollah and Hamas, two groups that have been designated by the United States and most European states as terrorist organizations. Iran rejects that designation, claiming instead that both groups are engaged in legitimate resistance against an occupying power.

There is, as well, controversy about the “stickiness” of the “state-sponsored” designations. What this means is that it is sometimes politically difficult to remove a state from the list of designated states. Cuba, for example, has remained on the list, even though the U.S. government concedes that in recent years its biggest offenses have been that it failed to take a strong stand on counterterrorism and that it has maintained relations with Iran and North Korea. The reason that Cuba has remained on the list is concern about the political symbolism of taking it off the list as long as the Castro regime (Fidel Castro’s brother assumed the presidency in 2006) is still in power in Havana.

Nonstate Actors: Their History, Goals, and Strategies

The major terrorist threat in the early 21st century is not from the states that sponsor terrorism, but rather from nonstate terrorist groups—organizations operating as independent actors even though they may occasionally accept support from states. Al Qaeda is the most notorious example of a nonstate terrorist group, but there are many others, and nonstate terrorist groups have been a serious law enforcement and foreign policy issue for at least the past two centuries.

Al Qaeda (Arabic for “the base”) is the perpetrator of perhaps the most infamous terrorist attack of all times: the September 11, 2001, destruction of the World Trade Center in New York City and the extensive damage at the Pentagon, the headquarters building of the U.S. Department of Defense. The September 11 attacks were remarkable for the number of casualties they caused, the high profile of the targets, and the sophistication of the terrorists’ methods. They hijacked four airliners roughly simultaneously and crashed them into the two World Trade Center towers and the Pentagon. The fourth hijacked plane did not reach its target, apparently because the passengers realized what was happening and fought with the hijackers. This plane crashed in a rural area of Pennsylvania, killing all aboard. Overall, more than 3,000 people were killed in these incidents, excluding the hijackers themselves who, of course, also perished. By way of comparison, 2,400 people were killed in the Japanese attacks on Pearl Harbor that propelled the United States into World War II.

Headed by Osama Bin Laden, Al Qaeda was established at the end of the Soviet-Afghan war in 1988. This war was fought by so-called *mujahedin* (Arabic for strugglers or warriors)—groups of Afghan refugees infiltrated back into the country from Pakistan, tribal groups inside Afghanistan, and foreign fighters from other Muslim countries—who were supplied with weapons and equipment by the United States and Saudi Arabia. The weapons were distributed through the Pakistanis, thus the myth that the *mujahedin* defeated the Soviets without help from the West was allowed to grow.

After the Soviets withdrew from Afghanistan, most of the foreign fighters (also known locally as Afghan Arabs) returned to their homelands, but some chose to continue fighting those whom they perceived to be the enemies of Islam. Bin Laden and his closest allies were prominent among this group, and they built Al Qaeda both as a terrorist organization and as supporter of other terrorist organizations.

Among Bin Laden’s inner circle were a number of Egyptian radicals who wanted to return to Egypt to fight against the secular regime in Cairo; others chose to follow Bin Laden’s strategy of fighting the “far enemy”—the United States, the nation that was supporting many of the regimes in the Middle East that Al Qaeda and other Islamic radicals regarded as the “near enemy” for their failure to adhere closely enough to fundamental Islam, corruption, and the repression of domestic opposition.

Bin Laden and his group left Afghanistan and settled in Sudan, where they operated training camps for Al Qaeda recruits and planned various terrorist operations. Pressure on the Sudanese government by the United States and others caused Sudan to expel Al Qaeda, so Bin Laden and company relocated back to Afghanistan, where they helped the Taliban win the civil war that had broken out after the Soviet withdrawal. Once the Taliban was in power, they allowed Al Qaeda to set up bases and operate extensive training camps in the country. It was from the Al Qaeda bases in Afghanistan that the September 11 attacks were orchestrated, and thousands of young men were trained in terrorist tactics and weapons handling.

The Taliban and Al Qaeda are often referred to as Islamist or Salafist, and they are not the only groups to which these labels have been applied. Hamas, Hezbollah, and the Palestinian Islamic Jihad have also been labeled this way. *Islamist* refers to the ideology (Islamism) that the tenets of Islam should control all aspects of human behavior. *Salafist* is a reference to the early followers of the prophet Muhammed, who are collectively known as the “Salafi,” and they represent a supposed golden era of adherence to the tenets of Islam. Salafists want to get modern society to similarly adhere to the religion—thus their objectives are basically the same as those of Islamists.

What this means in practice is that Islamists and Salafists agree that there should be no division of church and state, and that Islamic holy law or *sharia* should become the law of the land. They also agree that governments that do not adhere to sharia, or are corrupt, must be replaced, although only a minority believes that they should be replaced by force. Many Islamists and Salafists also believe that all Muslim states should be consolidated into a single community of believers known as the Caliphate, essentially a resurrection of the Ottoman Empire or one of its predecessor empires in the Middle East and North Africa. Bin Laden has said that the Caliphate should include not only Israel, but also Spain and Portugal, because those lands were once controlled by Muslims.

Al Qaeda and other Islamist terror groups justify their use of violence in a couple of ways. One is denying that their victims are truly innocent, because the victims are somehow complicit in the supposed mistreatment of Muslims. Indeed, these groups tend to see Western policy in the Middle East as part of a grand conspiracy to undermine Islam that started with the Crusades 1,000 years ago. They also see the state of Israel as the embodiment of the conspiracy, because it occupies land in the heart of the Muslim world and because it was able to defeat Arab armies only because of assistance given to it by the United States, which now is the leading state in the West.

Islamist terror groups also attempt to justify their use of violence through the concept of *jihad*. Jihad is also used to justify other forms of violence, such as insurgency and interstate war—for example, the Ottoman Empire declared jihad when it entered World War I.

There are five pillars of Islam: profession of faith in one god, Allah; daily prayers; alms giving; ritual fasting during Ramadan, a month in the Muslim calendar; and pilgrimage to Mecca, Islam's holiest city. Jihad is considered a sixth pillar by some Sunnis, and it is one of the ten required practices by many Shi'ites. (Sunnis and Shi'ites are the two main sects in Islam—more than 80% of all Muslims are Sunni.) All Muslims recognize jihad as a requirement, but there are different interpretations of jihad among Muslims.

Technically, the word *jihad* means struggle. The term is interpreted to mean both the struggle to live a good life consistent with the faith (the so-called greater jihad) and a struggle against the enemies of Islam (the lesser jihad), in effect a holy war. Holy war can be offensive, for the purposes of spreading the faith or expanding a Muslim state. It can also be defensive—defending the believers and their state against invaders, as during the Crusades. The most common usage is defensive holy war, but terrorists have creatively interpreted the concept in ways that attempt to justify violence against nonmilitary, civilian targets.

The traditional consensus has been that jihad can only be declared with the approval of religious authorities, but Islam does not have a unified hierarchy like the Roman Catholic Church, which can issue rulings that are generally recognized as authoritative by all Catholics. Islam has instead a variety of religious scholars and leaders, some of whom are recognized as the most important scholar in a particular country; others can be self-proclaimed experts in religious law. As a result, jihad has been authorized by a wide variety of religious leaders and for a wide variety of causes. For example, Osama Bin Laden declared jihad on the West using the status he cultivated as a religious scholar, even though most Muslims do not regard him as having the necessary credentials. Indeed, many other Muslim scholars have specifically rejected Bin Laden and his declaration of jihad.

Islamic law articulates rules of war that should be followed whenever holy war is declared. Among those

rules is the proscription against killing or hurting women and children—a rule to which Muslim terrorists obviously do not adhere. Again, extremists sometimes try to justify these violations of the holy law by claiming that when women, children, and the elderly are victimized, it is either inadvertent—even though that is obviously not the case when a terrorist explodes a bomb on a crowded bus or in a restaurant—or unavoidable collateral damage. Extremists sometimes also assert that holy law does not apply when the women and children are part of a militarized society. This last argument has often been used in reference to attacks in Israel, where there is universal conscription and many people work for the Israeli government or a defense-related industry.

Hamas is a Sunni group based in the Gaza Strip and Hezbollah is a Shi'ite group based in southern Lebanon. Each combines nationalist and religious ideologies. That is to say, both believe that the state of Israel should be eliminated and that the lands occupied by Israel must be returned to the Palestinian people. They also believe that the Palestinian state that would replace Israel should be governed by Islamic law. Both of these two groups are more entrenched in their communities than the typical terrorist organization. Indeed, both operate nonviolent branches that provide social services (schooling and medical care) to their constituents, and both also function as political parties. In branching off into legitimate social and political pursuits, these two groups are following in the footsteps of the Muslim Brotherhood in Egypt (indeed, Hamas is an offshoot of the Brotherhood). The Muslim Brotherhood also offers social services and stands candidates for parliamentary elections. Unlike Hamas and Hezbollah, the Brotherhood in Egypt recently renounced violence.

In the 2005 election, Hezbollah won 14 seats in the 128-seat Lebanese parliament; Hamas actually won a majority of the seats in the Palestinian Authority's parliament in the 2006 elections. Since the 2006 elections, Hamas fought a mini-civil war with the other leading party, Fatah, with the result that Hamas took over Gaza entirely and administers it separately from the West Bank. Hamas and Hezbollah even operate their own satellite television stations through which anti-Israeli propaganda is routinely broadcast.

Of the two, Hezbollah has been the greater international threat. Its operatives are suspected of bombing Israeli and Jewish facilities in Europe and as far away as Argentina. Hamas, on the other hand, has concentrated its violence on Israel and other Palestinian factions. One of Hamas's preferred methods is firing rockets into Israel—the rockets are handmade, small, and lack guidance mechanisms. Another is the employment of suicide bombers. Other Palestinian groups use the same tactics—for example, the Palestinian Islamic Jihad group also has an arsenal of improvised rockets that it fires into Israel. Literally hundreds of such rockets are fired into the Jewish state every year.

In a sense, the rockets and suicide bombers are the quintessential terrorist weapons. The rockets are plainly designed to do little more than create fear among Israeli civilians. They are too small and too unreliable (many land without exploding, or explode in unpopulated desert) to have any material effect on Israel's ability to defend itself, but they obviously frighten residents in Israel's southern municipalities. Similarly, suicide bombings on a bus or train or of a restaurant have no effect on the Israel military. Instead, such attacks are intended by the terrorist leaders to frighten the Israeli people and to convince them that the Palestinians are so implacable that reconciliation is impossible. The theory is that this will cause the Israeli people to leave Israel or compel their government to make major concessions—concessions that many Israelis argue would never really satisfy Hamas or Hezbollah, whose stated objectives are to destroy Israel.

Not all terrorism in the Middle East or in Muslim lands has been related to Islamism. Indeed, until the mid-1990s, most of the terrorism in the Middle East was conducted by nonstate groups that espoused secular, nonreligious ideologies. During the Cold War, many Palestinian groups espoused Marxist ideologies. The Popular Front for the Liberation of Palestine and the Democratic Front for the Liberation of Palestine, for example, espoused socialist revolution and the liberation of Palestinian lands from Israel but not the imposition of Islamic Holy Law. Yassir Arafat's Fatah movement, which became the centerpiece of the umbrella Palestine Liberation Organization, also demanded the liberation of Palestinian lands without the imposition of sharia.

During the 1960s, 1970s, and 1980s, most of the terrorist groups outside the Middle East were similarly motivated by nationalism or Marxism. Typical of the nationalist groups are the Irish Republican Army (IRA) and the Euskadi Ta Askatasuna (ETA). The IRA was committed to the end of British rule in Northern Ireland and of the systematic discrimination against Irish Catholics by the Protestant power structure there. The ETA sought independence for the Basque region of Spain. Leftist groups included the Red Army Faction in West Germany, the Red Brigades in Italy, the Japanese Red Army, the Tupamaros in Uruguay, and in Colombia the Ejército de Liberación Nacional (ELN) and the Fuerzas Armadas Revolucionarias de Colombia (FARC). Each of these groups resorted to bombings, kidnappings, and murders in order to disrupt capitalist enterprises, frighten the citizenry, and lead their respective countries down the path to socialism.

The FARC and ELN are still in existence, although they seem to be much less ideologically motivated than in their early years. Indeed, FARC is generally thought to be a prime example of the phenomenon of convergence, wherein terrorist groups and criminal organizations collaborate and eventually become more and more like each other. That is to say, the FARC started out earning money by taxing cocaine producers and protecting them from the Colombian government, other producers, and private

militias. Over time, FARC became less interested in socialist revolution and more interested in maximizing profits from drug operations. Roughly the same can be said for Abu Sayyaf and the Abu Nidal Organization (ANO). Abu Sayyaf is a Philippine-based terrorist group that nominally espouses an Islamist ideology but in fact spends most of its energies in criminal activities that are designed only to increase the funds available to the group and its members. The ANO originally conducted assassinations in order to help eradicate the state of Israel, but over time it devolved into a murder-for-hire criminal gang. Other terrorist groups work with criminal organizations to obtain weapons, bomb-making materials, and forged travel documents and identification cards without losing their ideological fervor.

The Liberation Tigers of Tamil Eelam are another important terrorist group. Based in Sri Lanka, the Tamil Tigers are similar to nationalist groups, such as the ETA and IRA, in that they want an independent homeland for a minority population (the Tamils). But in some respects, the Tamil Tigers have been more ruthless and innovative. They were the first to adopt the technique of suicide bombing, and they developed an all-woman elite unit of dedicated fighters. The Tamil Tigers also pioneered terrorist operations at sea—using small boats laden with explosives to crash into commercial or military ships. They have also been adept at fund-raising from overseas Tamils, particularly in Canada and the United Kingdom.

Other terrorist groups worthy of note for the severity of their violence include the following:

- Aum Shinrikyo, a millenarian group in Japan, attempted several chemical attacks on U.S. military and civilian targets. Only the last attempt, a 1995 chemical release during rush hour in the Tokyo subway system, was successful. Although only a small number died, thousands sought medical treatment, and there was widespread panic in the city.
- Chechen nationalists have undertaken a number of high-profile terrorist operations in Russia. In 2004, they took more than 1,000 school children hostage in the town of Beslan. Almost 200 of the children died when security forces took the school buildings from the terrorists. Two years earlier, Chechen terrorists had taken over a Moscow theater, holding 850 people hostage. All of the terrorists and 130 of the hostages were killed when security forces retook the theater.
- In 2002, Jemaah Islamiya bombed a resort in Bali, Indonesia, killing more than 200 people. In 2005, it set off bombs in a town square and a shopping mall in Bali, killing 20. It is also suspected of bombing a Western hotel in Jakarta in 2003, killing 12.

One of the points of this discussion of nonstate terrorist actors is that this phenomenon is neither new nor confined to a particular part of the globe. Another important point to note is that nonstate actors have created mass casualty incidents on every continent. Given the trends in technology and the economy, it seems likely that terrorist groups will not only increase their capacity for causing damage but

also continue to be able to conduct operations at great distance from their home bases.

Technology and Globalization

Terrorist groups have long been suspected of attempting to acquire weapons of mass destruction (WMD). However, only Aum Shinrikyo has actually employed such a weapon—in its poison gas attack in Tokyo. The technological information and some of the materials needed to build a nuclear, chemical, or biological weapon have been available for a price through illegal sales by governments (e.g., in Pakistan) and criminal smuggling. Aum Shinrikyo actually hired scientists to work on developing chemical weapons, and there are fears that Al Qaeda and some other groups are also actively seeking to develop their own WMD capabilities. That is one of the reasons why the United States and many other governments are working to improve controls over nuclear and other sensitive materials and to crack down on the smuggling of sensitive materials and equipment.

However, as most of the incidents described here demonstrate, substantial numbers of casualties and property damage can be caused by conventional, even simple, weapons. For example, there was nothing sophisticated about the bombs that blew up the Oklahoma City federal building in 1995 or that destroyed a Madrid commuter train in 2004. Even suicide bombers employ what is essentially rudimentary technology, and the September 11 hijackers used no technology of their own—they commandeered commercial airliners and crashed them into buildings. The point is that restrictions on WMD proliferation, as important as they are, will still leave terrorists with most of their preferred tools. Bombs, bomb-making materials, radios to trigger explosions, and a limitless variety of small arms are widely available in the global marketplace.

Further, globalization of the marketplace affects terrorism in a variety of other ways. First, it creates rich targets. Terrorists know that they can create both fear and serious economic disruption by attacking the seaports, airports, and rail terminals upon which international commerce depends. Second, international transportation of goods and people has become much easier and relatively inexpensive. This means that terrorists can readily travel from country to country or continent to continent to avoid capture, get training, or conduct a violent act. The thousands who traveled to remote, isolated Afghanistan for Al Qaeda training and then returned to Western Europe or North Africa are prime examples of the role of modern transportation in the spread of terrorism. Third, international migration for economic and other reasons has created pools of expatriates, particularly in Europe, that have been used by terrorists not only as sources of funding but also as communities into which they can blend and try to escape detection by law enforcement. Expatriate communities have also often been sources of recruitment by terrorist organizations. Finally, some analysts believe that globalization itself has increased terrorism

by creating a sense of grievance in traditionalist communities whose values and beliefs are challenged by the influx of Western media and Western values—such as secularism and gender equality. Certainly, Islamist terrorists view many Western values as deeply subversive and immoral.

Terrorist Financing and Counterterrorism

Terrorists raise the funds they need to maintain their organizations and conduct operations in a variety of ways. One source is donations from people sympathetic to their cause. For example, extremely wealthy individuals in the Persian Gulf have contributed to Islamist groups because they shared their religious ideology, or to Palestinian groups because they believed that the Palestinian people were being oppressed by Israel and deserved a homeland. Another example is donations by Irish Americans to the IRA, or overseas Tamils to the Tamil Tigers. Sometimes, however, such donations are supplemented by extortion and threats of violence by terrorist operatives—this was the case, for example, in South America, where Hezbollah operatives have strong-armed Lebanese expatriate merchants into making donations. It also occurred in Toronto, Ontario, where Tamil Tiger organizers coerced Tamil expatriates to contribute in order to avoid violence or damage to their places of business. Donations can also be supplemented by what amounts to embezzlement from legitimate charities. This has been a particular problem in the Middle East, where charities have only recently come under state regulation and where large sums of money are donated to charities due to Islam's requirement that believers donate 2.5% of their income as alms for worthy causes.

In addition to donations, embezzlement from charities, and extortion in expatriate communities, some terrorists raise funds by accepting support from a state and/or by participating in criminal activities. As noted above, some terrorist groups are so immersed in criminal activity that they have essentially been transformed into criminal organizations that no longer seriously seek political change, even though they may still claim that their goals are socialist or Islamist revolution. Other groups, however, treat crimes such as drug and weapon smuggling, robberies, and kidnappings for ransom (even smuggling tobacco products from a low-tax state to a high-tax state in the United States) only as a means to the end of political change.

One of the major elements of counterterrorism is an international effort to restrict terrorist financing. There is, indeed, a United Nations convention that commits signatory states to develop the legal authorities and systems they need to prosecute individuals who help finance terrorist groups. The U.S. government has also been working quite closely with other governments on restricting *money laundering*—financial transactions whose purpose is to prevent the authorities from knowing where the funds came from (e.g., a criminal activity) or where they are ultimately being sent. The vehicle for this effort is the Financial Action Task Force (FATF).

FATF was initially established to deal with organized crime, but it has since evolved to include terrorist financing. There are 33 member states and several regional task force members, including the Middle East and North Africa FATF that was created in November, 2004, which includes all the states in this region except Iran.

Another major element in counterterrorism is government surveillance of citizens and residents. Analysis of surveillance data about how citizens spend their time and money is used to identify and interdict terror plots. Although increased surveillance has been politically controversial in the United States, where it has been seen by many as an infringement on traditional civil liberties, similar measures have been in place in other countries for many years. Related to this is citizen awareness and alertness—that is to say, much valuable intelligence about nascent terror plots has come from citizens who observe unusual behavior and report it to the local police. This is something that Israel, in particular, emphasizes in its counterterrorism program.

There has also been considerable international cooperation among intelligence and police agencies, although little of this can be described due to its sensitive nature. There have, as well, been international partnerships between the United States and many of its trading partners in order to improve the screening of cargo shipments so as to prevent terrorists from exploding conventional or mass destruction weapons in a port or en route on a cargo ship or aircraft.

Finally, there is an important military aspect to counterterrorism. Military force has been used by the United States, Israel, Pakistan, the Philippines, and many other countries to capture or kill suspected terrorists.

Future Directions

Terrorism is a phenomenon that will never be completely eradicated, but it can be minimized, not only by counterterrorism strategies, but also by economic and political reforms in societies where grievances create pools of discontent or where terrorist leaders and criminal organizations troll for recruits.

This is not to suggest that poverty or some other social ill actually causes people to become terrorists—the record is quite clear that many terrorists are from well-off families and that hardly any poor people are terrorists. Yet, discontent surely seems to be a contributory factor, and people are often more discontent with their economic situation than anything else. Thus, the indirect relationship between economic factors and terrorism is an area in which more research should be done.

Other important areas for future research involve the question of metrics. The specific questions are how progress should be measured in the “war on terrorism” and how much is enough in terms of spending on counterterrorism measures. These are not easy questions to answer,

and even though the answers are necessarily going to be strongly influenced by politics, objective criteria should inform the political debate. For example, it seems plain that the number of terrorists killed or captured is as telling a standard as the amount of drugs seized at the border—both measure the success of a tactic and neither measures the success of the strategy. The number of terrorists killed and captured says nothing about the number of terrorists still at large, just as drug seizures say nothing about the volume of drugs that were actually smuggled into the country. Similarly, a reduction in the number of terrorism incidents over time may indicate nothing more than that the terrorists are regrouping or that they are keeping their powder dry while planning an unusually violent attack.

Answering the second question about how much spending is enough is equally vexing. The question should not be answered without first evaluating the effectiveness of previous spending—yet, there are no standards for such an evaluation. Assessing national preparedness for future crises is something that the military has learned to approximate reasonably well through war games, readiness evaluations of units, and inspections of platforms and equipment, but there is no systemic evaluation of the many parts of government that have roles to play in counterterrorism and homeland security.

HUMAN RIGHTS AND DIGNITY

STEFAN LORENZ SORGNER

University of Erfurt

Human rights and dignity are central normative notions of contemporary politics as well as political and ethical theories. However, they have not had this role for a long period of time, as the main development of these concepts began only during the Age of Enlightenment. During the previous 60 years, their influence can be said to be of global importance. On December 10, 1948, the Universal Declaration of Human Rights was adopted and proclaimed by the General Assembly of the United Nations. Yet, there are traces of both notions in ancient and medieval thought, and this chapter will trace their roots and historical development and make inferences concerning potential future challenges concerning them.

Concepts of Rights

Article I of the United Nations Universal Declaration of Human Rights states, “All human beings are born free and equal in dignity and rights. They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood.”

Human rights are subjective rights of individual human beings. Subjective rights are different from objective rights. Objective rights refer to the completeness of regulations within a legal system. Objective rights grant subjective ones. Subjective rights imply that individual human beings have the authority to do certain things within the

system. The concept of human rights implies that all human beings, because of their being human, have certain rights and freedoms that are universal, inalienable, and indivisible. According to a stricter sense of the concept of human rights, they can be contrasted with civil rights. Civil rights are held by all citizens of a state and include rights that are not human rights, like the right to vote. Human rights are held by all human beings. However, civil rights are included in the United Nations’ *Universal Declaration of Human Rights*.

According to the Czech jurist Karel Vasak (as he originally proposed in 1979), there are three generations of human rights. The first generation deals with liberty, and the rights in this generation are particularly civil in nature. Human rights in the second generation are related to equality, and their nature is primarily social, whereas the third generation rights go beyond the civil and the social and are mostly expressed in soft law declarations of international law. Libertarians are usually skeptical concerning human rights of the second and third generation, as they presume that these rights contain concealed paternalistic political goals.

The term *human rights* came into existence at the beginning of the 19th century. However, as mentioned above, it was not until 1948 that human rights were generally proclaimed, by what was then a newly formed United Nations. The declaration was primarily motivated by the cruelties of World War II. Article I of this declaration

states a close connection between the concept of dignity and that of rights. As a result of this declaration, both concepts, that of human rights and that of human dignity, became highly significant for many countries' constitutions and the post-1945 world.

Relationship Between Rights and Dignity

Both rights and dignity can be justified naturally or solely legally. Natural rights are valid at all times in all places. Solely legal rights are grounded in an actually existing legal system founded by decisions made by human beings. To enforce natural human rights, they also need to be integrated into a legal system, but they are regarded as valid even if they have not been acknowledged by anyone.

Analogously, one can talk about necessary and contingent human dignity. Necessary dignity is a quality that belongs to all human beings at all times and in all places, whereas contingent human dignity is dependent upon an institution that declares that human beings are bearers of dignity. The concepts of *right* and *dignity* imply a normative aspect. The concept of *dignity* often has also an ontological aspect, whereas the concept of *right* can, but does not have to have, an ontological aspect.

In the above case of the United Nations *Declaration*, both concepts have an ontological aspect, as Article I states that all human beings who are the bearers of dignity and rights "are endowed with reason and conscience." Hence, the normative aspect of both concepts is based upon an ontological one. However, the relationship between the two concepts in question can be different than that shown in the last example; for example, in the case of the German basic law, some experts claim that the concept of human dignity is the foundation for all human rights. In this case, it can be seen that only the concept of human dignity has an ontological and normative aspect, whereas that of a human right merely includes normative implications.

Concepts of Dignity

The concept of dignity must not be mixed up with the word *dignity*. The word implies several concepts that can be divided into a sense and a reference. Dignity is a quality that a bearer can have necessarily or contingently. To distinguish between these two types of dignity, it would be best always to clarify which type one is referring to. For pragmatic reasons, the author will use the expressions *necessary dignity* and *contingent dignity* from now on.

Necessary dignity can either be inherent or dependent. Given that human beings necessarily have free will, and free will is the foundation for dignity, it is the case that all human beings have necessary, inherent human dignity. If it were the case that God attributed dignity to all human beings necessarily, then all human beings would have

necessary, dependent dignity. However, both instances would be examples of necessary dignity.

Contingent dignity can also be connected to various qualities. Given that human beings reciprocally attribute dignity to one another, then we would have contingent, dependent dignity. If human beings, on the other hand, were bearers of dignity, because they have the quality to make logical inferences, and this capacity is a bodily capacity, then human beings would have contingent, inherent dignity, as the capacity here is not a necessary one. Both examples represent types of contingent dignity.

The terms *necessary dignity* and *contingent dignity* can be specified further. They can imply equality or inequality concerning the bearers of dignity. In our context, only the concept of dignity that implies equality among its bearers is relevant. This does not mean that the other concept is socially unimportant; for example, bishops and judges have dignity; however, their dignity is a hierarchical one that is irrelevant here.

The concept of dignity that is relevant here is a non-gradual one that implies equality among its bearers and is connected to six characteristic features:

1. Dignity cannot exist independently, but is always connected to a bearing entity.
2. A bearer has the quality *dignity* if he possesses a nongradual quality X, wherein dignity is founded.
3. The relationship between the bearers of dignity is that of equality; that is, all bearers of dignity have a nongradual quality X, because of which their relationship can be specified as descriptive equality.
4. The descriptive equality of the bearers implies a normative one, whereby the norm is related to an ideal of the good and not to that of an evil; for example, dignity is only given if all its bearers are supposed to be treated equally well and not if they are supposed to be treated equally badly.
5. Bearers of dignity have a special status within the world; that is, they are categorically different from all other beings in the world and have a quality that cannot be verified empirically.
6. The concept of dignity will be named "dignity" or named with an equivalent word in a foreign language. (If this trait was not included, then the concept of dignity would refer to too many concepts; for example, most concepts of rights would then also count as concepts of dignity, which would be a questionable position.)

Each entity to which the six features just stated apply is a bearer of the quality *dignity*. Hence, the reference of the concept *dignity* is dependent upon the meaning. However, thereby we have not yet clarified the concept of *human dignity*, but only that of *dignity*. The concept *human dignity* is the result of the intersection of the set of references of the concepts of dignity and of being human. A being belongs to the set of bearers of dignity if it is the case that he has all the features demanded of a bearer of dignity. A being belongs to the set of human entities if it belongs to

the human species, that is, if it potentially belongs to the human reproductive community. It is important to distinguish between human beings and human entities. Both human beings and human entities belong to the human species. However, it does not have to be the case that all human entities are human beings. It is clear that a fertilized egg belongs to the human species, but it is unclear whether a fertilized egg can be called a human being. However, it clearly is a human entity, as it belongs to the human species. There are five possibilities of how the set of bearers of dignity and that of human entities can intersect:

1. The set of human entities can be a subset of that of the bearers of dignity. In this case, someone who is a human entity necessarily is a bearer of dignity. However, it is not the case that all bearers of dignity are human entities. Here, it is the case that someone who belongs to the human species also has to bear dignity, as it would be according to Kant, if we read him as follows: The ability to have reason is actual within the human soul, which is unified with the human body from the moment egg and sperm get together. Dignity here is founded in a feature that can necessarily be found in all human entities. According to Kant, the actual ability for reason can be found in all human beings. However, not all human beings can express this ability, as the capacity to express it is connected to a bodily capacity that one needs to develop.

2. The sets of the bearers of dignity and that of human entities can be identical. If someone is a human entity, then he is a bearer of dignity. Each bearer of dignity necessarily is a human being. In this case, the quality on which dignity is founded is a quality that is being held only by human beings. As here the identity of the set human entities and that of bearers of dignity is a given, it is also the case that the quality on which dignity is founded is the same as the one on which it depends whether one belongs to the human species.

3. The sets of bearers of dignity and that of human entities can overlap. There are human entities that are bearers of dignity, and there are human entities that are not bearers of dignity in the same way as there are bearers of dignity that are human entities, and there are bearers of dignity that are not human entities. In this case, dignity is founded upon a quality that some but not all human entities have, and that some but not all nonhuman entities have. One can read Kant in such a way that his concept of dignity belongs to this group, but only if one assumes that actual reason is not a capacity of the soul but is only present when someone can speak. There are human entities that can talk and who therefore also have dignity. However, there are other human entities that are currently unable to talk and who henceforth do not have dignity. It cannot be excluded, and Kant definitely does not exclude the possibility that there are nonhuman beings that have reason together with this dignity.

4. The set of the bearers of dignity can be a subset of human entities. All bearers of dignity are necessarily human entities. However, there are human entities that are not bearers of dignity. A position which claims that, for a human entity to have dignity, the human needs to be born would be one that belongs to this group. It can be the case that, as in this case, the feature on which dignity is founded is also the feature that turns a human entity into a human being.

5. The set of bearers of human dignity and that of human entities do not overlap. The fifth and last option is not relevant for us, as with it we do not have bearers of human dignity.

Values of Rights and Dignity

Both human dignity and human rights are the foundation of many constitutions and can be found at a prominent place in the charter of the United Nations. There is no moral dilemma or moral challenge for which these concepts are irrelevant. As an example, for the relevance of human dignity, one is referred to a discussion in the field of medical ethics.

The notion of human dignity is a complex one that is not being used in a unified manner. In addition, it is often abused in order to stop an argument or to claim that the opposite opinion can only be held by a scoundrel or a protofascist. Hence, it is important always to reference facts and to clarify the concepts one deals with. In the field of medical ethics, arguments that deal with the beginning of human life are of particular importance. From which moment on can one claim that a human entity has human dignity or the right to live?

1. From the moment of fertilization
2. From the moment of fusion of the precells
3. From the moment at which the nidation in the uterus takes place
4. From 14 days after the fusion, as from that moment on, it is impossible that twins can come about (conjoined twins can still come into existence, however)
5. From the moment at which the embryo becomes a fetus (i.e., after 3 months, when the developmental process of all organs is finished)
6. From the moment of birth

It depends upon a governmental decision which of these various stages is regarded as decisive for a human being to have dignity or the right to live. Legal regulations concerning stem cell research, preimplantation genetic diagnosis (PGD), and abortion are based upon this decision. A particularly striking example can be given in the case of PGD. In contrast to the UK, PGD is forbidden in Germany. One reason for it being forbidden is that in the process of PGD, one or two totipotent cells are taken away from

the fertilized cells and genetically analyzed, and they are destroyed in this process. As it is possible for a totipotent cell to develop into an independent human being, some regard totipotent cells as bearers of dignity, which therefore must not be destroyed.

History of Rights

Even though human rights, as we understand them today, were established only fairly recently, one can trace aspects of the concept back to antiquity. In ancient Athens, in the 6th century BCE, many government posts were given away by drawing lots, and thereby, any citizen could acquire the office in question. However, women or slaves did not have the right of citizenship. An important step in the development of human rights was the upcoming of Stoic philosophy and its concept of the *humanitas*, which implied that all humans, because of their being human, ought to be considered ethically. Yet, this duty was a lower-rank duty.

The proper beginning of the concept of human rights goes along with the beginning of the Age of Enlightenment. In the following paragraphs, the focus will be on the concepts of the most influential philosophers of rights: Thomas Hobbes, John Locke, Jean Jacques Rousseau, and Immanuel Kant.

The first philosopher who was significant for the development of the concept of human rights was Hobbes. Fundamental to his understanding of rights is the fictional state of nature he presents, in which there is a war of all against all, and each person is the potential enemy of every other person—*Homo homini lupus* (“Man is a wolf to [his fellow] man”). Each person is fighting for his own survival and power. Then, each person is supposed to have the right to everything else in order to preserve himself. There is danger lurking in this state, as even the strongest can be killed during the night or by a group of weaker men who cooperate. No one is so much stronger than all the others to actually make sure that his safety can be guaranteed over a long period of time. Hence, there is a certain kind of equality among human beings, as we are all more or less equally strong, or to put it in a different manner: There is no one who is so much stronger than all the others over a long period of time that he could guarantee his own safety in a stable manner. Due to the given equality, this can come to a fictional contract between all human beings, in which all human beings agree to give their natural rights to the Leviathan, who from then on has the absolute power over his citizens. The individual citizens give away their sovereignty, and the political leader receives it.

A slightly less grim picture of human nature was presented by Locke. His ethics is closely connected with Christianity, as he makes clear that without afterworldly sanctions, there would be no reason for not living solely according to the pleasure principle. In the end, morality is based upon a God-given law. In a similar manner, he

approaches his political ethics. He limits the power of the sovereign by putting forward that there are natural rights that are God given and valid universally. According to Locke, the natural law and the natural rights exist also in the state of nature. According to Hobbes, in that state everyone has a right to everything. According to Locke, on the other hand, the rights of a human being are limited by the rights of the others. And the most basic rights can be described as the right to the inviolability of a person and his property, which can be specified further by making a distinction between the right to life, health, liberty, and possession. As there are people in the state of nature who do not accept the natural law, there is a need to move from the natural state to a political system.

In contrast to Locke and Hobbes, Rousseau presents a more optimistic understanding of human behavior in the hypothetical state of nature. According to him, there are enough goods available for all human beings, they live separate from one another, and they are peaceful. Then human beings exist in a state of healthy self-love, which includes sympathy, which stops them from acting egoistically. The positively evaluated state of nature ends when someone develops the category of private property due to egoistic desires. Such an action leads to inequality and promotes further egoistic desires, so that one ends up in a system with richer and poorer people. The richer people force the poorer ones to accept a social contract whereby the poorer ones do not realize that they were being forced into the contract. Even though they claim that the social contract serves the common interest, it is supposed to be solely in the interest of the rich. However, there is also the possibility of an ideal social contract, which would be one in which all citizens realize that they are the general will. In that case, the political and moral freedom consists in sticking to the law that one has given oneself. Here, the general will would correspond with the individual one.

Autonomy, in a different sense from Rousseau's, is central for Kant's understanding of rights. Rights, according to Kant, are supposed to help individuals to live together so that they do not get into conflict with one another. Anyone is supposed to live such that his arbitrary will can coexist with the wishes of others. Kant also holds that a social contract is the basis of a state. He agrees with Locke that there are inviolable natural rights, with Rousseau that the highest norm concerning law giving ought to be the general will, and with Hobbes that in the state of nature there is the war of all against all. By transforming the particular individual wills into a general will, the state of nature changes into a constitutional state.

History of Dignity

Early Greek philosophers did not hold a concept of dignity that can be compared to the one we have. In their case, dignity was always connected to a hierarchy. According to

Aristotle, there are natural slaves, who of course have less dignity than citizens. Dignity today, however, implies the equality of its bearers. As said before, the concept of equality of all human beings is developed and becomes particularly influential in Stoic thought. As an outgrowth of Stoic philosophy, the first important concept of human dignity is put forward by Cicero. His thinking is reflected particularly in Renaissance philosophy. Pico della Mirandola and Manetti are two Renaissance philosophers who put forward paradigmatic theories of dignity. Another reader of the philosophy of Cicero was Kant, whose concept of dignity became particularly influential. In this section, first the paradigmatically most important theories of human dignity in historical order (Cicero, Manetti, Pico della Mirandola, and Kant) are presented, and these are followed specifically by the vehement criticism of the concept by Nietzsche, who provides us with a useful basis for reflections concerning the future of human dignity.

Cicero was the first great philosopher who put forward a concept of human dignity. He holds that all human beings, which implies all beings with *ratio*, have dignity. Concerning Cicero, the sets “members of the species human beings” and “beings with ratio” are identical concerning the extension, which means that if someone is a member of the one set, he also has to be a member of the other set, and it is impossible for a being to be a member of the one set without being a member of the other one. However, dignity is not the central concept within his ethics, as it often is today. The focus of his ethics lies on the highest good, which again is connected with the honorable, the *honestum*. Anyone who possesses the four cardinal virtues—justice, wisdom, bravery, and moderation—is honorable. Hence, the highest good is solely identified with the virtues. External goods are irrelevant concerning the highest good, which implies, however, a hierarchy of duties. The highest duties are the duties against the gods, followed by the duties against one’s political community and then the duties against one’s parents. We also have duties against other human beings who are bearers of dignity like us. However, these duties are of lower rank. This does not mean that they are irrelevant. These duties are of direct importance concerning our interaction with slaves and foreigners, who are also supposed to be treated in a just and dignified manner. Due to the high relevance of the duties against the political community, Cicero holds that the *vita activa* is more important than the *vita contemplativa*, even though the latter corresponds to our human nature.

Another paradigmatically important concept of dignity was put forward by the Renaissance humanist Manetti, whose views were ultimately founded in his faith in the Christian God. Faith is supposed to lead to appropriate actions and right thinking and also to the knowledge of God, human dignity, and the highest good. As in Cicero’s ethics, the concept of dignity is not the central one, which is the concept of the highest good. The highest good lies in a state of afterworldly bliss. To be able to reach this state, one has to be virtuous according to Manetti. The virtues piety, justice, and

wisdom are of particular importance, according to him. Anyone who possesses these virtues reaches the highest good. Even though one reaches the correct understanding of these concepts only by means of contemplation, the main focus in life ought to be in the *vita activa*; with such a focus, one can fulfill one’s duties against God and the other human beings in an appropriate manner. Due to the duty of justice, one ought to love all human beings as one’s brother and consider that love in one’s deeds. However, the possession of human dignity is independent of one’s deeds, as it is connected to the *imago dei*, the image of god, which we possess within our immortal souls. To act in accord with our dignity, we ought to stick to the duties that God has given all men and that are connected with the highest good. One of the duties is the duty of charity. Herein the consideration of other human beings, bearers of dignity, becomes directly relevant.

Another paradigmatically central foundation of human dignity was put forward by Pico della Mirandola. His concept is cited in many contemporary debates, even though current thinkers tend to receive his concept in a biased manner. According to him, human dignity lies in our free will, which lets human beings become a likeness of God and represents the signature of the creator upon his special creations. Human beings, according to Pico, participate in all layers of being, but, in contrast to other creations, they are not connected to one specific layer of being exclusively. Because of our free will, we have the chance to become who we wish to become. Of course, this does not mean that we can turn into fish or pigeons. However, it implies that we can choose our lifestyle according to our own fantasies, desires, or thoughts. It is this aspect which modern interpreters usually focus upon.

Yet, there is another side that can also be found in Pico’s philosophy. Even though we can choose to become who we apparently wish to become, there is supposed to be a real wish within all of us. We all wish to return to our origin, our creator, God, even though not all of us are conscious of this wish. The only way by which human beings are supposed to reach the highest good, which is the center also of Pico’s ethics, is by means of the *unio mystica* with God. This goal cannot be reached by conscious decisions. We depend upon the mercy of God to reach this state. However, we must first be prepared in order to be eligible for mercy. We must possess the political virtues within our character, which means that we ought to make peace, be just, have the virtue of love, and act in accord with it. On that fundamental level, the dignity of other human beings is considered, as here our duty to consider other human beings, bearers of duty, comes in, and we have the obligation to consider it in an appropriate manner. Our main duty concerning the highest good, however, is to go beyond our connection with the sensual world, to purify ourselves, and in the end God might grant us the chance to return to him and become one with him. The *vita contemplativa*, according to Pico, is much more relevant than the *vita activa*. If a human being does not consider the duties just stated, he does not lose his

dignity, because his dignity is connected to his free will, which he cannot lose.

The most influential conception of human dignity was put forward by Kant. However, even according to him, the focal point of his ethics lies in the highest good. In contrast to the previous positions mentioned, the highest good, according to Kant in his *Grundlegung zur Metaphysik der Sitten* (“Groundwork of the Metaphysics of Morals”), does not enclose happiness, but it lies in the good will, which any being has who has will and reason and who acts out of respect for the moral law in accord with the moral law. Anyone who acts on maxims out of respect for the moral law, fulfils the moral law. This implies that his actions are based on maxims. To check whether a statement can be a maxim is to try to universalize the statement and check the reflections. If the reflections lead to contradictions, the statement cannot be a maxim. If the procedure does not lead to any challenges, the statement can serve as a maxim. The categorical imperative, which can be described in various ways, is a way of paraphrasing the moral law. One formulation of the categorical imperative includes the concept of human dignity, which is founded upon autonomy. The highest good and the moral law are valid for all beings with dignity, and dignity applies to autonomous beings only. One implication of the practical formulation of the categorical is that one must never treat humanity, neither in oneself nor in any other person, solely as a means. Any being with dignity must never be treated solely as a means. Hereby, it becomes clear that dignity is of some relevance in Kant’s philosophy; however, even according to him, the highest good is the central focus within his ethics. A further indication that human dignity does not have a foundational role within his ethics is that it turns up mainly within only one formulation of the categorical imperative.

The foundation of dignity, according to Kant, is the capacity of being autonomous, which is a necessary condition for acting in accord with the moral law. Autonomy must not be misunderstood as representing arbitrariness as freedom. Beings with dignity have the necessary duty to act in accord with duty. All acts that are in accord with the categorical imperative are in accord with duty.

In his *Kritik der praktischen Vernunft* (“Critique of Practical Reason”), Kant holds a similar position. Only his concept of the highest good changes slightly. It still encloses the moral law, but the person who acts out of duty in accord with duty not only deserves to become happy, according to Kant, but he can actually hope to receive happiness in proportional means to his acting morally. However, to act morally implies that one must not act in accord with the moral law while hoping to receive happiness in proportional means to his acting morally, even though one can hope that this will be the case. Only someone who acts morally out of respect for the moral law, without being motivated by his hope that he will be rewarded with happiness, acts morally. He can expect to be rewarded with happiness in an after-world but not with a happy this-worldly life.

The most vehement criticism of human dignity was put forward by Nietzsche. Explicitly, he attacks solely necessary concepts of dignity, and all the concepts mentioned above have been necessary ones. Implicitly, however, his philosophy also goes against contingent concepts of human dignity. His argument against necessary human dignity goes as follows: The concept of necessary human dignity is founded upon four mistakes. Hence, it ought to be abandoned. The four mistakes he refers to are the following:

1. Human beings have an incomplete understanding of themselves.
2. Human beings attribute to themselves invented qualities.
3. Human beings regard themselves to be in the wrong relationship concerning animals and nature.
4. Human beings invent hierarchies of good, which they falsely regard as eternal and unconditional.

Concerning human dignity, these mistakes can be explained further by merely selecting some specific examples in order to support his argument:

1. Human beings correctly understand that they have reason. However, they have an incomplete understanding of themselves, as they do not realize that reason is not eternal and that it does not provide us with knowledge concerning the world but was developed in order to help us survive. Reason, according to Cicero, is the foundation of human dignity, but his concept is based on the wrong understanding of reason. Hence, it is not valid.
2. Human beings invented the concept of free will, which cannot even be thought of in a non-self-contradictory manner. Free will is the foundation of human dignity according to Pico. However, as free will does not exist, his concept of human dignity is invalid.
3. Human beings think that they were created in God’s image and that they have a special status in relation to animals and nature. According to Nietzsche, neither of these claims is correct. Human beings do not have a special status in nature, and they differ merely in degree from other animals. As the concept of God was merely invented, human beings also cannot be created in God’s image. According to Manetti, human dignity is founded on humans being created in the image of God, which is not correct. Hence, his concept of human dignity is invalid.
4. According to Nietzsche, all systems of morals, as well as all values and norms, were invented by a certain group that has common interests. There are no eternal values and norms. According to Kant, human dignity represents an eternal norm. Hence, his concept of dignity is invalid.

Against the concept of contingent human dignity, Nietzsche implicitly puts forward at least three separate arguments:

1. Nietzsche holds that human beings do not have special status in the world. However, such a special status is demanded by all concepts of human dignity, both necessary and contingent ones.

2. Nietzsche holds that there are no universally valid norms. However, necessary and contingent concepts imply that human dignity is a universally valid norm.
3. Nietzsche holds that all human beings are not equal, and that there are two groups of people that have to be evaluated differently. However, necessary and contingent concepts imply that human dignity demands the equality of all human beings.

Given these three last points, it is clear that Nietzsche attacks not only necessary concepts of human dignity but also contingent ones.

Contemporary Concepts of Rights

All concepts of human rights that will be presented in the following paragraphs stem from the Anglo-American tradition: Nozick, Rawls, Nussbaum, Taylor. All four political philosophers defend human rights, but they represent four diverse basic positions within the spectrum of possible communitarian and liberal attitudes. Liberal positions can be characterized as positions in which the right has priority over the good, whereas in communitarian positions, the good comes first and provides the basis for deriving a concept of the right. Nozick is a libertarian thinker and therefore the most liberal of them all. His work is a reaction to the theory of justice that was put forward by his colleague in the department of philosophy at Harvard University, John Rawls. Rawls's position represents a classical liberal one. Taylor and Nussbaum represent two left-wing interpretations of communitarianism; Taylor puts forward a communist communitarianism and Nussbaum a social-democratic version of it.

Nozick's political philosophy builds on a version of Locke's natural rights position. The right to one's own body and one's property are fundamental, according to him. The best state is supposed to be a night watchman state, whereby the state secures the basic human rights but does not interfere with the free exchange among, and contracts between, consenting adults. Many philosophers criticized him for this system, as they regard the social consequences as not appealing.

According to Rawls, international human rights specify a limit to the internal autonomy of a regime, and any country that provides human rights to its citizens is entitled to tolerance. Hence, a desire to provide human rights entitles countries that see gravely unjust behavior in the internal practice of other countries to promote interventions in the countries in question. In contrast to the dominant lists of human rights, Rawls's suggestion is more limited; he particularly stresses the rights to life, liberty, property, and equality. His suggestion takes into consideration that promulgation of human rights does not imply the risk of getting rejected as being too liberal or too closely related to the Western tradition. However, Rawls

agrees with most human rights theorists by holding that the rights are universal, international, have a high priority, set minimal standards that should save people from the severest forms of unjust treatment, and are relevant primarily for governments.

In contrast to the liberal theories previously discussed, the political philosophies of the following two thinkers are based on a concept of the good that is supposed to be the basis for a concept of the right. Nussbaum's concept of the good includes two separate lists, based on her intuition, which are supposed to describe (1) the *conditio humana*, which is relevant for all human beings, and (2) goods and capacities, which are supposed to be important within all human lives. The first list includes mortality, the human body, perception, early childhood development, practical reason, community with other human beings, relationship to animals and nature, humor and play, and individuality. In the second list, she mentions that it is good to live through all stages of life, to be healthy, to fulfill one's sexual desires, to avoid pain, to have a concept of the good, and to live in a community in which solidarity exists. Hence, she puts forward a strong, but vague, concept of the good. It is strong, as it says something about all aspects of life, but it is vague, as it does not state in detail what ought to be done. Both lists serve as a basis for deriving rights.

Taylor's concept of the good from which he derives the right, on the other hand, can be described as weak but detailed. It is weak, as it does not put forward anything about all the various aspects of life. Hence, he favors a pluralist ethics. On the other hand, he holds a detailed position concerning religion, as he interprets the world from a Roman Catholic perspective.

Contemporary Concepts of Dignity

In contrast to the human rights tradition, the most prominent concepts of human dignity come from various traditions worldwide. This section will deal with those of Gewirth, Margalit, and Spaemann. The first two thinkers hold a contingent concept of dignity and the last one holds a necessary concept of dignity.

Gewirth holds that all human beings are "actual or prospective purposive agents." If all beings who are able to actually or potentially act on purpose are bearers of dignity, and all human beings are such beings, then all human beings are bearers of dignity. He connects the rights to freedom and well-being with the concept of dignity. Hence, all bearers of dignity hold the rights to freedom and well-being. According to Gewirth, it is necessary for any agent to have these rights, as these rights are supposed to be necessary for any action, and an agent would be self-contradictory if he denied having these rights. As morality is concerned with human action and being a human agent, Gewirth claims that human beings have dignity and the

two human rights mentioned. The line of thought which he proposes implies some tacit assumptions:

- Morality is concerned with action.
- Human beings are “actual or prospective purposive agents.”
- Person X is a human being.
- Person X wishes to do action A.
- In order for X to be an agent who seeks to fulfill his purpose A, it is necessary for X to assume having the right to act thus, and it would be self-contradictory not to do so, as he would reject what he needs as a purposive agent.
- All human beings, all actual or future purposive actors, need to assume that they have the right to action.
- Rights need to be granted by others.
- Hence, there is a contract between all actual or future purposive actors that need the rights necessary for action.
- All actual or future purposive actors grant the rights necessary for action, which are the rights to freedom and well-being, to all other actual or future purposive actors, so that the others grant oneself the same rights.
- The rights to freedom and well-being are connected with dignity.
- As all actual or future purposive actors grant one another the rights to freedom and well-being that are connected with dignity, and it is necessary for all actors to do so, it is also the case that all actual or future purposive actors grant one another dignity, and granting one another dignity is necessary.

With this line of thought, which, of course, is open to many criticisms, Gewirth argues for human dignity based on a theory of action combined with a contract theory.

Margalit's argument in favor of dignity is a negative justification of the concept, as he does not state what dignity is but rather what one must not do to others, so that their dignity is recognized. His method can be described as appellative rather than a logical inference that shows the necessity of dignity. His negative justification is supposed to show that human dignity is attacked whenever a person is humiliated. He puts forward examples and reasons that are supposed to show that humiliation is bad, and avoiding humiliation is all that is needed for a decent society. A society that is nonhumiliating is a society that respects human dignity. This position implies that human beings are hurt not only by physical attacks but also by means of symbolic actions.

In contrast to these two this-worldly concepts of dignity, Spaemann's position is metaphysical. According to him, the concept of human dignity refers to something sacred, the preciousness of human beings themselves, which, however, cannot be thought of without God. Dignity is a religious-metaphysical notion, and human beings have dignity just because they represent the Absolute. It is impossible, according to him, that any human being can be without a certain minimum of dignity. This does not imply that dignity is a gradual notion. The human dignity that is important for contemporary discussions and that does not

have any gradations refers to the minimum amount of dignity that all human beings have to have and that they can never lose, according to Spaemann. On the basis of some transcendental-pragmatic reflections, he links dignity to a nonempirical substance, which again is connected with a personal soul. When egg and sperm come together, this soul is united with the body, as the soul is not part of nature. In addition, the dignity connected to the personal soul is not identical with human rights but represents the foundation of human rights.

Future Directions

Given the most recent scientific innovations and artistic creations, it is not a daring prophecy to claim that transhumanism and posthumanism are and will continue to be significant movements. They share the basic attitude that the special status of human beings has dissolved, which means that human beings do not have a special factor that separates them categorically from other forms of life: Human beings are merely gradually different from other forms of life. This conception can already be found in the reflections of Darwin and Nietzsche.

However, transhumanism and posthumanism must not be identified with one another. Their values differ significantly. Whereas transhumanism upholds humanist values, posthumanism sticks to antihumanist values. Humanist values are such that the Renaissance type counts as an ideal that is to be aspired to. Antihumanist values, on the other hand, are such that there is no absolute set of values—values depend upon perspectival interpretations, and it is up to the interpreter in question which values he sticks to. As the concepts of human rights and dignity are connected with humanist concepts like the affirmation of the special status of human beings, which both transhumanism and posthumanism reject, the future development of these movements is directly connected to the evolution of the concepts of rights and dignity. Concerning rights, the next battle will be one between animal and human rights, whereas concerning dignity, human dignity might have to evolve into a trans- or posthuman dignity.

Future: Animal Rights Versus Human Rights

One of the current and future developments concerning rights is related to the dissolution of the special status of human beings. Human rights apply only to human beings, and only humans ought to be considered in the moral realm, because they have a special ontological and normative status in the world. Given the dissolution of the special status of human beings, this position no longer holds. The most prominent defender of animal rights is Tom Regan. He argues that the fact of being a “subject-of-a-life” is a necessary and contingent condition for having rights. As there are nonhuman animals that also possess this quality,

they also ought to possess rights, and one ought to alter the concept of human rights into one that includes humans and some nonhumans.

Another attack concerning our current attitude toward animals was put forward by Peter Singer. He compares the discrimination against animals just because they do not belong to the human species with sexism and racism. As an alternative, he proposes an ethics that considers an equal consideration of interests. Hence, two beings that have similar preferences ought to be morally considered equally, too. Both Regan and Singer take the dissolution of the special status of human beings seriously. Thereby, they show that the current concept of human rights ought to be revised, as it does not adequately represent the relationship between human beings and nonhuman beings.

Future: Human Dignity Versus Transhuman and Posthuman Dignity

The current and future developments concerning the concept of dignity are also related to the dissolution of the special status of human beings in the world. One of the qualities necessarily connected with human dignity is the special status of human beings in the world. Human beings are categorically different from nonhuman animals, according to this view. It can imply, as it does according to German law, that only a human being is a person and all other beings are things. To hurt an animal is to commit a damage to a property, a thing. Given the dissolution of the special status of human beings, this estimation becomes implausible, and as such, the categorical difference between human beings and animals vanishes. Hence, there is a need to revise the concept of human dignity to integrate the altered attitude concerning the status of human beings in the world. In that case, we might already be able to talk of a posthuman instead of a human dignity. Another option would be to completely get rid of the concept of human dignity, as the qualities related to it are no longer plausible, and given the origin of the concept, it has religious implications, which are also no longer held by a majority of people.

In addition, a further development has to be noted. Genetic engineering enables us to alter the genetic setup of humans significantly, and it can be expected that many further developments will take place in this respect. These developments are significant also for the concept of dignity. Two attitudes concerning human alteration have been developed within two movements. First, there is the transhumanist movement, and second, the posthumanist movement. Both accept the dissolution of the special status of human beings in the world and the integration of human beings in nature so that they are different only in degree from other animals. However, their views concerning the genetic alterations of human beings differ. In contrast to the transhumanists who uphold a humanist—a Renaissance—ideal of human beings, posthumanists uphold antihumanist values.

However, the transhumanist movement is not a unified one. Esfandiary distinguishes between the transhuman and the posthuman. A *transhuman* is a transitional human who represents the link to the posthumans but still belongs to the human species. A *posthuman* is a member of the posthuman species, which represents a further step in evolution. Bostrom, on the other hand, has a different notion of the posthuman. He regards a posthuman to be a member of the human species but with capacities that greatly exceed “the maximum attainable by any current human being without recourse to new technological means.” Both uphold a humanist ideal that implies that not all alterations count as enhancements. Only if the alterations stick to a certain ideal of the good, which is similar to the Renaissance ideal of human beings, do they count as enhancements.

The posthumanist movement, on the other hand, is more open concerning what counts as an enhancement. It does not uphold that there is only one moral ideal or that there is only one set of values and norms valid for everyone. There are various ideals that are valid for certain types of human beings. There is a group that upholds the Renaissance ideal, but there are other groups, too. There is also the group of the blind, which regards being blind as an ideal. Posthumanism, in contrast to transhumanism, does not claim that one group holds a mistaken ideal, as transhumanists would claim with respect to the group of the blind for example. Posthumanists have greater respect for the value of negative freedom, which this author regards as a cultural achievement that cannot be underestimated and that one must not sacrifice lightly. The genetically altered, from the perspective of posthumanism, can also be referred to as posthumans. However, there are also concepts of the posthuman within posthumanism that are not directly concerned with questions of genetic enhancement, like Hayles’s concept of the posthuman or Haraway’s concept of the cyborg, which put forward a new anthropology. Hence, posthumanism from their perspective is the attempt of putting forward a radically new picture of what the *anthropos* is.

There are various ways to understand and affirm genetically altered human beings. If one refers to members of the human species as bearers of human dignity, which one can continue to do, and if one revises the traditional concept by integrating the dissolution of the special status of human beings, then one should seriously consider what type of dignity applies to trans- and posthumans. Given the differences between them and current human beings, this ought to have an effect upon their moral status. Maybe they can be regarded as bearers of transhuman and posthuman dignity, respectively.
